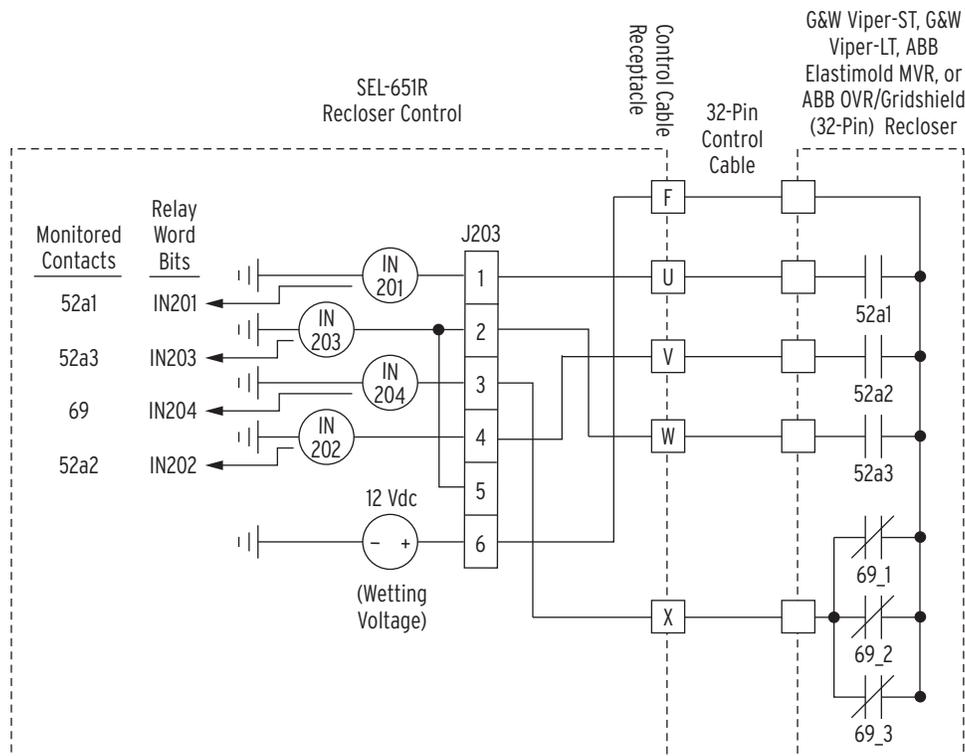
Figure 2.60 shows the SEL-651R-2 factory wiring for trip/close/recloser status for Control-Powered Eaton NOVA or G&W Control Power Viper-S reclosers; 53 Vdc power goes out Pins R, S, T to the recloser and then returns through the trip circuit and close circuit paths.

Pin C is monitored by input IN201. The 52a recloser status is derived from this input.

If the Control-Powered Eaton NOVA or G&W Control Power Viper-S reclosers are not VTC-equipped, then the signals to Pin F and IN206 can be ignored—they will not affect normal recloser operation. VTC-equipped reclosers cannot trip/close without the 24 Vdc signal to Pin F.

IN205 monitors the 53 Vdc trip/close voltage output from J204-1. When this voltage is present, IN205 is asserted. IN206 monitors the 12/24 Vdc converter. If the 12/24 Vdc converter is operating correctly, then IN206 is asserted. Use IN205 or IN206 as an alarm, routing it to an LED, front-panel display point, SCADA output, or an output contact (e.g., make the following settings: ESV := 2, SV02PU := 600 cycles, SV02DO := 600, SV02 := NOT [IN206], and OUT202 := SV02T. OUT202 asserts, providing an alarm, if the 12/24 Vdc converter fails).

RELAY WORD BIT TCCAP
Relay Word bit TCCAP indicates that the 53 Vdc voltage in Figure 2.60 is present for recloser operations (TCCAP = logical 1). The 53 Vdc voltage comes into the relay module via connector J205 (CAPACITORS), from the trip/close capacitors in the power module (see Figure 2.2, Figure 2.5, Figure 2.7, and Figure 2.9). If there is a problem with this connection or otherwise in the power module, then Relay Word bit TCCAP = logical 0. Relay Word bit TCCAP is used in factory-default close logic settings (see Figure 6.4 and Figure 6.5) and reclose supervision settings (see Table 6.8). Relay Word bit TCCAP does not detect an operation of fuse F203 in Figure 2.60.


① See Figure 7.25.

Recloser Interface Connection Details (Control Cable Interface)

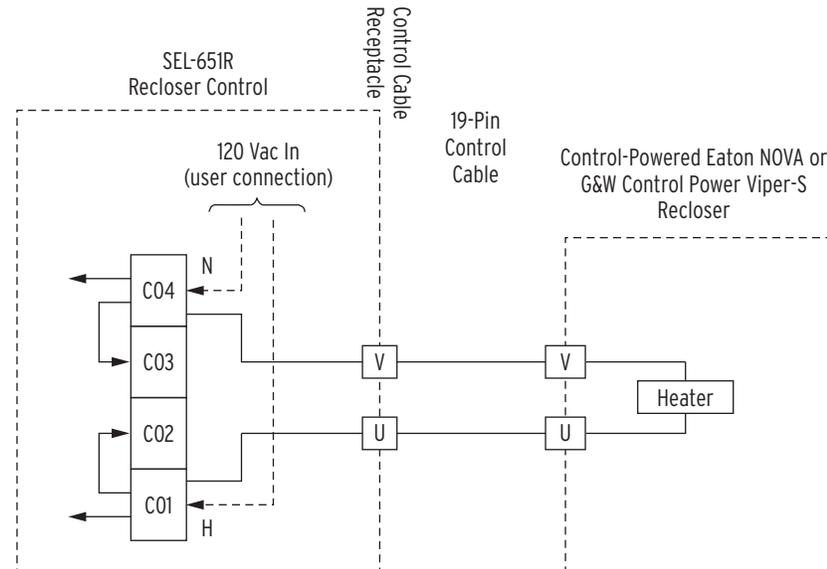
Figure 2.61 shows the routing of 120 Vac power through the 19-pin control cable to heaters in the Control-Powered Eaton NOVA or G&W Control Power Viper-S reclosers.


Figure 2.61   120 Vac Power Circuit Connections Between SEL-651R-2 Recloser Control and Control-Powered Eaton NOVA or G&W Control Power Viper-S Recloser

ABB Joslyn TriMod 600R Reclosers

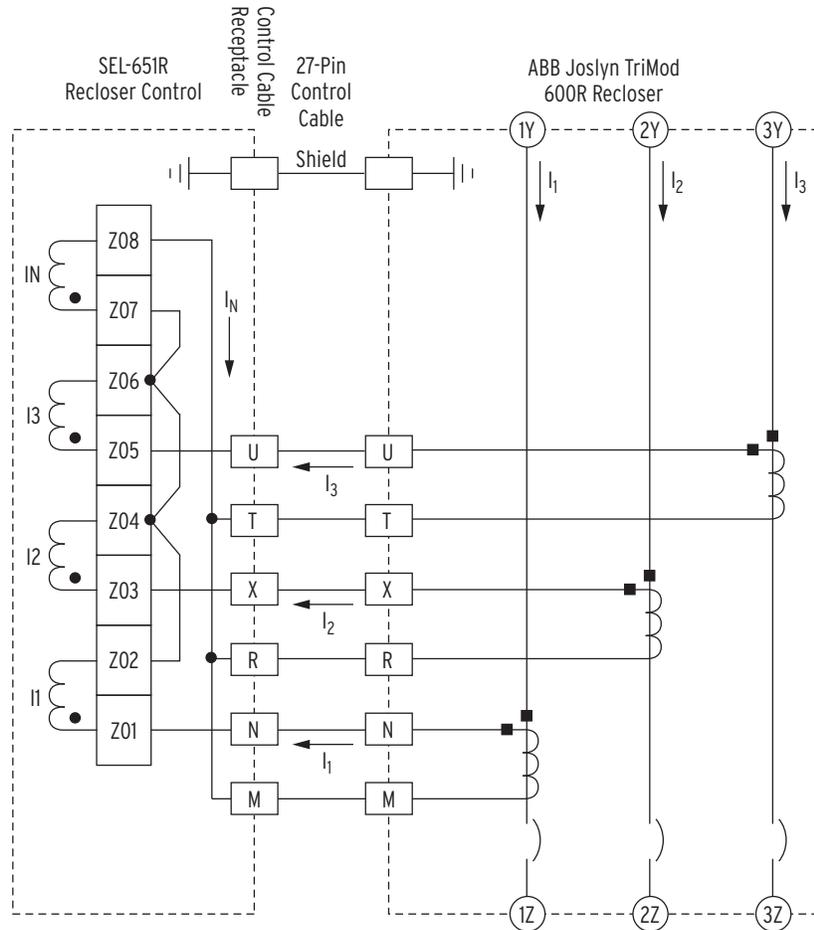
Figure 2.62 shows the SEL-651R-2 factory wiring for current connections for ABB Joslyn TriMod 600R reclosers. The current transformers in the recloser are wired like a circuit breaker in that the residual path through control cable pins is on the nonpolarity side of the current transformer secondaries. This contrasts with the Traditional Retrofit recloser in *Figure 2.49*. Either wiring is easily accommodated by the wiring on the Z01–Z08 terminals of the SEL-651R-2 relay module.


Figure 2.62   Current Connections and Polarity From ABB Joslyn TriMod 600R Recloser Primary to SEL-651R-2 Recloser Control Current Inputs

Notice also that the phase current terminals are labeled I1, I2, I3 (not IA, IB, IC). A-B-C designations are given to the current channels with Global setting IPCONN. Current transformer polarity can effectively be changed with the global CTPOL setting, which is helpful for designating forward or reverse power flow and similar things.

Figure 2.63 shows the SEL-651R-2 factory wiring for trip/close for ABB Joslyn TriMod 600R reclosers. Each pole of the recloser has its own trip and close coils. This facilitates single-phase tripping/reclosing, although the SEL-651R-2 factory settings have the recloser operating in a three-phase trip/close mode.

RELAY WORD BIT TCCAP
Relay Word bit TCCAP indicates that the 155 Vdc voltage in Figure 2.63 is present for recloser operations (TCCAP = logical 1). The 155 Vdc voltage comes into the relay module via connector J205 (CAPACITORS), from the trip/close capacitors in the power module (see Figure 2.2, Figure 2.5, Figure 2.7, and Figure 2.9). If there is a problem with this connection or otherwise in the power module, then Relay Word bit TCCAP = logical 0. Relay Word bit TCCAP is used in factory-default close logic settings (see Figure 6.4 and Figure 6.5) and reclose supervision settings (see Table 6.8).

Trace the trip path for Coil 1 in *Figure 2.63*:

Relay Word Bit RCTR1X (Trip 1; see *Figure 7.26*) turns on the FET (155 Vdc) connected to terminal J206-9. This wiring goes through control cable Pins H and I to Trip Coil 1. The 155 Vdc across Trip Coil 1 causes the current to flow through the coil.

Trace the close path for Coil 1 in *Figure 2.63*:

Relay Word Bit RCCL1X (Close 1; see *Figure 7.26*) turns on the FET (155 Vdc) connected to terminal J206-3. This wiring goes through control cable Pins A and C to Coil 1. The 155 Vdc across Close Coil 1 causes the current to flow through the coil.

Tripping and closing for phases 2 and 3 operate similarly.

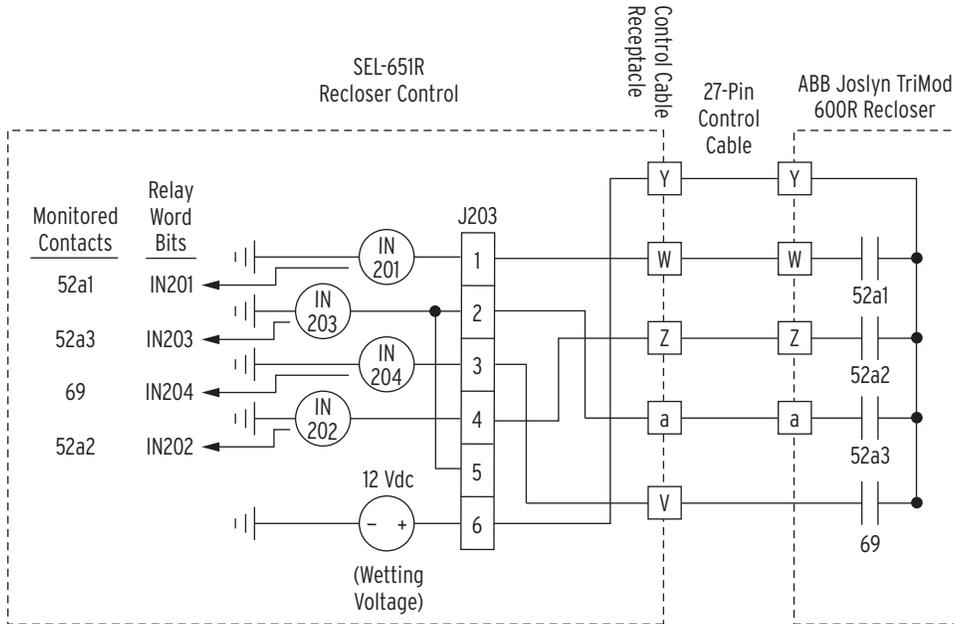
Figure 2.64 shows inputs IN201–IN203 monitoring individual 52a recloser pole status. Input IN204 monitors the status of the yellow operating handle. The yellow operating handle mechanically trips all three phases, and the 69 contact opens for the yellow operating handle going to the lock-open position.


Figure 2.64 Recloser Pole Status Circuit Connections Between ABB Joslyn TriMod 600R Recloser and SEL-651R-2 Recloser Control

Eaton NOVA-TS or NOVA-STS Triple-Single Reclosers

RESISTIVE VOLTAGE SENSORS

To make use of the optional resistive voltage sensors in Figure 2.65, the SEL-651R-2 needs to be ordered with Eaton NOVA LEA voltage inputs for the three-phase VY voltage inputs. See Table 9.11 for voltage phase angle correction settings for such voltage inputs.

Other voltage input options are available, though not using the control cable shown in Figure 2.65 (see SEL-651R-2 Model Option Table).

Figure 2.65 shows the SEL-651R-2 factory wiring for current connections for Eaton NOVA-TS or NOVA-STS Triple-Single reclosers. Notice that the current transformers in the recloser are wired such that the residual path (through Pin Y) is on the polarity side of the current transformer secondaries. This is nonstandard as far as traditional circuit breakers are concerned, but is easily accommodated by the wiring on the Z01–Z08 terminals of the relay module of the SEL-651R-2.

Notice also that the phase current terminals are labeled I1, I2, I3 (not IA, IB, IC). A-B-C designations are given to the current channels with Global setting IPCONN. Current transformer polarity can effectively be changed with the global CTPOL setting, which is helpful for designating forward or reverse power flow and similar things.

Figure 2.65   Current Connections and Polarity From Eaton NOVA-TS or NOVA-STS Triple-Single Recloser Primary to SEL-651R-2 Recloser Control Current Inputs (Voltage Connections Also Shown)

Figure 2.66 shows the SEL-651R-2 factory wiring for trip/close for Eaton NOVA-TS or NOVA-STS Triple-Single reclosers. Each pole of the recloser has its own trip/close coils. This facilitates single-phase tripping/reclosing, although the SEL-651R-2 factory settings have the recloser operating in a three-phase trip/close mode.

Trace the trip path for Trip Coil 1 in *Figure 2.66*:

Relay Word Bit RCTR1X (Trip 1; see *Figure 7.25*) turns on the FET (ground) connected to terminal J206-3. This wiring goes through control cable Pin E and on to contact 52a_1 and Trip Circuitry 1.

Installation 2.79
Recloser Interface Connection Details (Control Cable Interface)

RELAY WORD BIT TCCAP
Relay Word bit TCCAP indicates that the 53 Vdc voltage in Figure 2.66 is present for recloser operations (TCCAP = logical 1). The 53 Vdc voltage comes into the relay module via connector J205 (CAPACITORS), from the trip/close capacitors in the power module (see Figure 2.2, Figure 2.5, Figure 2.7, and Figure 2.9). If there is a problem with this connection or otherwise in the power module, then Relay Word bit TCCAP = logical 0. Relay Word bit TCCAP is used in factory-default close logic settings (see Figure 6.4 and Figure 6.5) and reclose supervision settings (see Table 6.8). Relay Word bit TCCAP does not detect an operation of fuse F203 in Figure 2.66.

Trace the close path for Close Coil 1 in *Figure 2.66*:

Relay Word bit RCCL1X (Close 1; see *Figure 7.25*) turns on the FET (ground) connected to terminal J206-9. This wiring goes through control cable Pin H and on to contact 52b_1 and Close Circuitry 1.

Tripping and closing for phases 2 and 3 operate similarly.

See *Figure 2.67*. The operation of any individual yellow lockout handle on the Eaton NOVA-TS or NOVA-STS Triple-Single recloser results in the opening/lockout of that phase (if not already open) and the opening of the corresponding "69" contact (69_1, 69_2, or 69_3) and the subsequent assertion of the corresponding input (IN204, IN205, or IN206) in the SEL-651R-2. Inputs IN204, IN205, and IN206 are effectively used in default SELOGIC control equation trip setting TR3X to trip the other two phases when the yellow lockout handle of one phase is operated (see *Figure 5.2*).

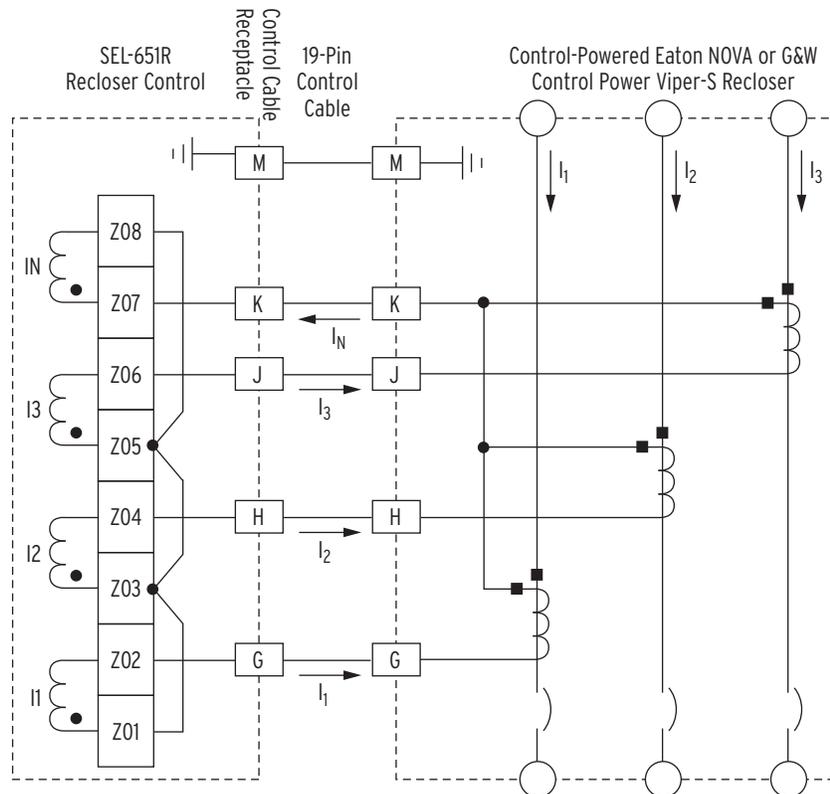
Tavrida OSM Al_2 Recloser

Figure 2.68 shows the SEL-651R-2 factory wiring for current and voltage connections for the Tavrida OSM Al_2 recloser. The current transformers in the recloser are wired like a circuit breaker in that the residual path through control cable Pin 14 is on the nonpolarity side of the current transformer secondaries. This contrasts with the Traditional Retrofit recloser in *Figure 2.49*. Either wiring is easily accommodated by the wiring on the Z01–Z08 terminals of the SEL-651R-2 relay module.

Notice also that the phase current terminals are labeled I1, I2, I3 (not IA, IB, IC) in *Figure 2.68*. A-B-C designations are given to the current channels with Global setting IPCONN. Current transformer polarity can effectively be changed with the global CTPOL setting, which is helpful for designating forward or reverse power flow and similar things.


The Tavrida OSM Al_2 recloser has built-in capacitive voltage sensors (signified with capacitance C_1 in *Figure 2.68*) that are connected to the 8 Vac LEA voltage inputs of the SEL-651R-2 via capacitance C_2 (capacitances C_1 and C_2 making an effective voltage divider). See *Factory-Default Settings on page 9.61* for the required potential transformer ratio settings PTRY (for VY-terminal voltage inputs) and PTRZ (for VZ-terminal voltage inputs) that allow the SEL-651R-2 to meter correctly with the capacitive voltage sensors of the Tavrida OSM Al_2 recloser.

RELAY WORD BIT TCCAP
Relay Word bit TCCAP indicates that the 155 Vdc voltage in Figure 2.69 is present for recloser operations (TCCAP = logical 1). The 155 Vdc voltage comes into the relay module via connector J205 (CAPACITORS), from the trip/close capacitors in the power module (see Figure 2.2, Figure 2.5, Figure 2.7, and Figure 2.9). If there is a problem with this connection or otherwise in the power module, then Relay Word bit TCCAP = logical 0. Relay Word bit TCCAP is used in factory-default close logic settings (see Figure 6.4 and Figure 6.5) and reclose supervision settings (see Table 6.8).

The parallel connections shown between terminals 2, 4, 6, 8, 10, 12, 13, and 14 on the left-hand side of the intermediate terminal block in *Figure 2.68* are realized with hidden busing inside the intermediate terminal block itself. Terminal 14 of the intermediate terminal block is then taken to cabinet ground.

The Tavrida OSM Al_2 recloser operates as a three-phase trip/three-phase close device—it does not have single-phase tripping/closing capability. There is only one trip/close coil (referenced as SC/coil in *Figure 2.69*) for the Tavrida OSM Al_2 recloser: trip for current flow in one direction, close for current flow in the other direction.

In *Figure 2.69*, note that the trip and close FETs in the SEL-651R-2 are stacked on top of one another, between 155 Vdc power and ground, with a tap in the middle. For a given FET stack, both FETs can never be on at the same time or else there would be a direct short between the 155 Vdc power and ground. Interlocking logic prevents both FETs from being on at the same time.

Also, note that there are redundant trip/close circuits connected to SC/coil:

➤ Three FET stacks (top trip FET/bottom close FET) paralleled to terminals 19 and 20 of the intermediate terminal block in *Figure 2.69*

➤ Three FET stacks (top close FET/bottom trip FET) paralleled to terminals 17 and 18 of the intermediate terminal block in *Figure 2.69*

Trace one of the trip paths in *Figure 2.69*:

Relay Word Bit RCTR1X (Trip 1; see *Figure 7.26*) turns on the bottom trip FET (ground) connected to terminal J206-3 (then terminal 18 of the intermediate terminal block) and the top trip FET (155 Vdc) connected to terminal J206-9 (then terminal 20 of the intermediate terminal block). This wiring continues through control cable Pin 3 and Pin 1 to SC/coil in the Tavrida OSM Al_2 recloser. The 155 Vdc across SC/coil (top to bottom) causes the current to flow in the indicated trip direction.

Trace one of the close paths in *Figure 2.69*:

Relay Word Bit RCCL1X (Close 1; see *Figure 7.26*) turns on the top close FET (155 Vdc connected to terminal J206-3 (then terminal 18 of the intermediate terminal block) and the bottom close FET (ground) connected to terminal J206-9 (then terminal 20 of the intermediate terminal block). This wiring continues through control cable Pin 3 and Pin 1 to SC/coil in the Tavrida OSM Al_2 recloser. The 155 Vdc across SC/coil (bottom to top) causes the current to flow in the indicated close direction.

The other paralleled trip/close circuits in *Figure 2.69* operate similarly. Relay Word bits RCTR1X, RCTR2X, and RCTR3X all operate the same—their controlling SELOGIC settings (see *Figure 7.26*) are set the same in default settings. Likewise, Relay Word bits RCCL1X, RCCL2X, and RCCL3X all operate the same—their controlling SELOGIC settings (see *Figure 7.26*) are set the same in default settings.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 131 of 1080
Wolfe

Installation 2.85
Recloser Interface Connection Details (Voltage Cable Interface)

A single 52b contact (AS1) is connected in parallel to inputs IN201, IN202, and IN203 as shown in *Figure 2.69* for recloser status. With the following *Factory-Default Settings on page 9.61* for the Tavrida OSM Al_2 recloser:

Global setting BKTYP := **1**

Group setting ESPB := **N**

Group settings 52A_A := **NOT IN201**, 52A_B := **NOT IN202**, 52A_C := **NOT IN203**

these three paralleled inputs only provide a three-phase open/three-phase closed status, not a per-pole recloser status (see resultant 52A3P Relay Word bit in *Figure 6.2*). It is irrelevant that IN201 is apparently assigned to an A-phase designation (52A_A := NOT IN201) and likewise IN202 with B-phase (52A_B := NOT IN202) and IN203 with C-phase (52A_C := NOT IN203). Resultant Relay Word bit 52A3P only conveys three-phase open/three-phase closed status, not any single-phase status.

Contacts AS2, AS3, and AS4 are brought to the intermediate terminal block in *Figure 2.69*, but are not connected to the SEL-651R-2.

When the external yellow operating handle on the Tavrida OSM Al_2 recloser is pulled to the lock-open position, the following occurs:

➤ The Tavrida OSM Al_2 recloser trips open (if not already open).

➤ The 69 contact in the trip/close circuit (*Figure 2.69*) opens and stays open.

With contact 69 open, there is no way to close the Tavrida recloser until the yellow operating handle is reset again. With the yellow operating handle reset, contact 69 in the trip/close circuit is closed again and the Tavrida recloser can then be closed by the SEL-651R-2.

Yellow Operating Handle Status

Input IN105 in *Figure 2.69* indicates yellow operating handle status:

➤ IN105 asserted (yellow operating handle in reset position and contact 69 closed in trip/close circuit)

➤ IN105 deasserted (yellow operating handle in lock-open position and contact 69 open in trip/close circuit)

The OSM Detection Module senses contact 69 position (open or closed) in the trip/close circuit, via the continuity source and detect connections. The OSM Detection Module then controls the assertion/deassertion of input IN105.

The following factory-default settings for the Tavrida OSM Al_2 recloser provide a front-panel display indication of the yellow operating handle status (reset or lock-open), qualified for 150 cycles.

SHO L Command

ESV := **3**

SV02PU := **150.00**

SV02DO := **150.00**

SV02 := **IN105 # QUALIFY YELLOW HANDLE OPERATION**

SHO F Command

EDP := **4**

DP03 := **SV02T,"YELLOW HANDLE",RESET,LOCK-OPEN**

Disconnected Control Cable Alarm

Input IN105, from *Figure 2.69*, combined with recloser status (Relay Word bit 52A3P) provides a disconnected control cable alarm. If the control cable is disconnected in *Figure 2.69*, then inputs IN105, IN201, IN202, and IN203 are all deasserted, thus indicating the following contradictory condition.

➤ yellow operating handle in lock-open position (input IN105 deasserted)

➤ recloser closed (52b inputs IN201, IN202, and IN203 are all deasserted)

If "recloser closed," then the yellow operating handle must be reset. Pulling the yellow operating handle to lock-open causes the recloser to open and remain open. Thus, the condition "recloser closed" and yellow operating handle "lock-open" is an abnormal/alarm condition and is indicative of a disconnected control cable.

The following factory-default settings for the Tavrida OSM Al_2 recloser provide a front-panel display indication of a disconnected control cable, qualified for 150 cycles.

SHO L Command

ESV := **3**

SV03PU := **150.00**

SV03DO := **150.00**

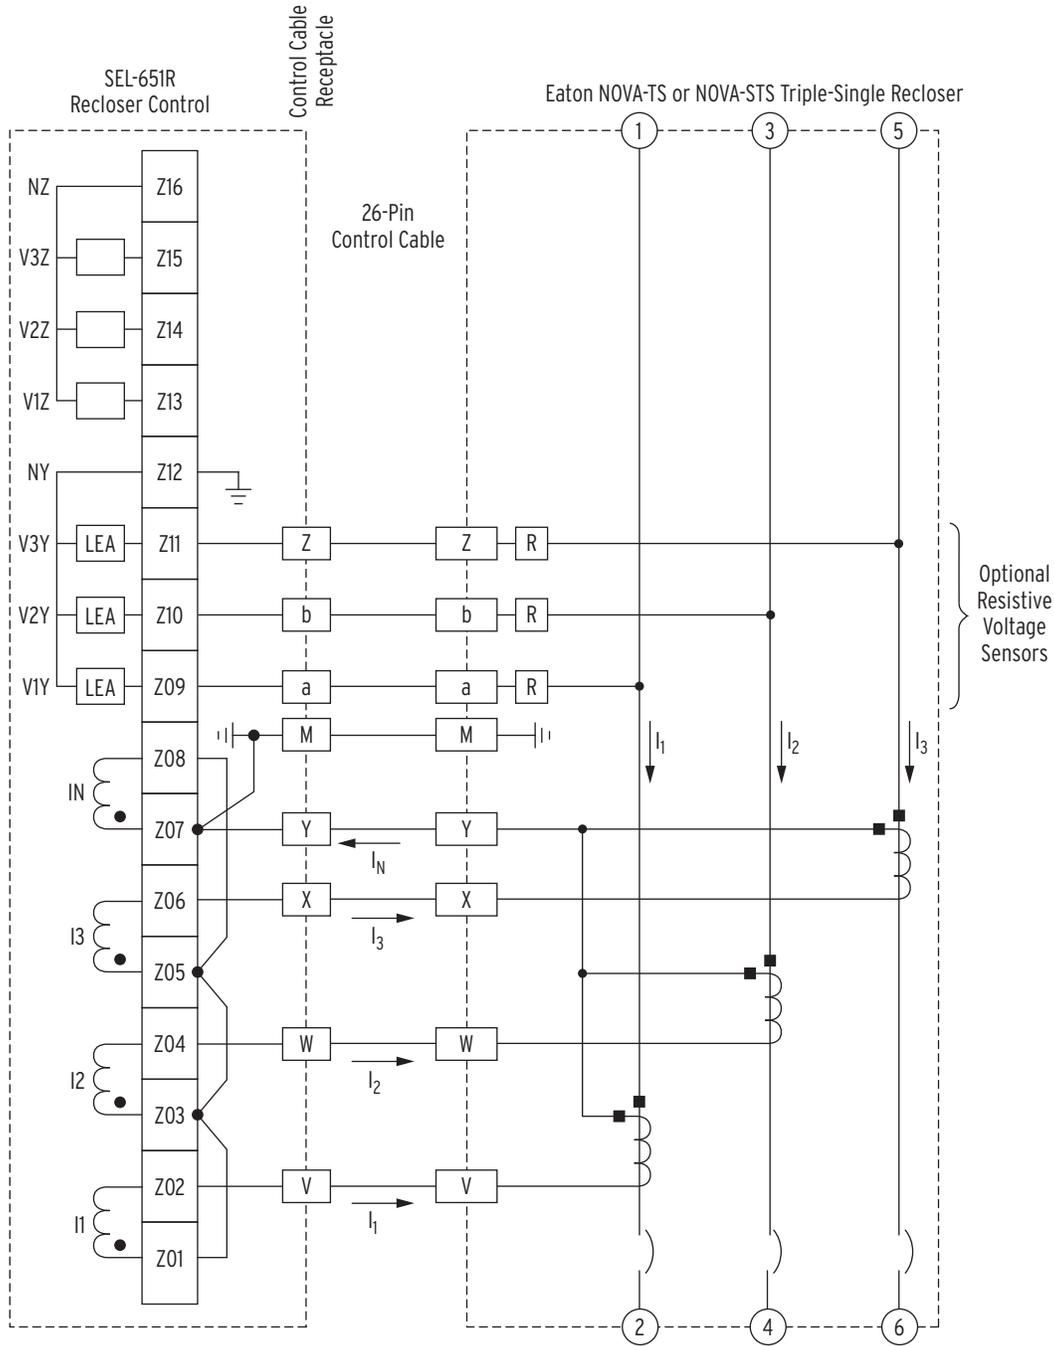
SV03 := **NOT(IN105) AND 52A3P # QUALIFY DISCONNECTED CABLE**

SHO F Command

EDP := **4**

DP04 := **SV03T,,"CABLE DISCONNECTED"**

Siemens SDR Reclosers

Figure 2.70 and *Figure 2.71* show the SEL-651R-2 factory wiring for current connections for Siemens SDR Triple-Single and Siemens SDR Three-Phase reclosers, respectively. Note that the phase current terminals are labeled I1, I2, I3 (not IA, IB, IC) in *Figure 2.70* and *Figure 2.71*. A-B-C designations are given to the current channels with Global setting IPCONN. Current transformer polarity can effectively be changed with the global CTPOL setting, which is helpful for designating forward or reverse power flow and similar things.


The Siemens SDR reclosers have optional built-in resistive voltage sensors (signified with resistance R in the recloser tanks in *Figure 2.70* and *Figure 2.71*) that are connected to the VZ-terminal Siemens LEA voltage inputs of the SEL-651R-2 (resistance R in the recloser tank and resistance in the Siemens LEA voltage inputs making an effective voltage divider). See *Table 9.14* and *Figure 9.24* for the required phase angle correction settings and potential transformer ratio settings, respectively, that allow the SEL-651R-2 to meter primary voltage correctly with the resistive voltage sensors of the Siemens SDR reclosers.

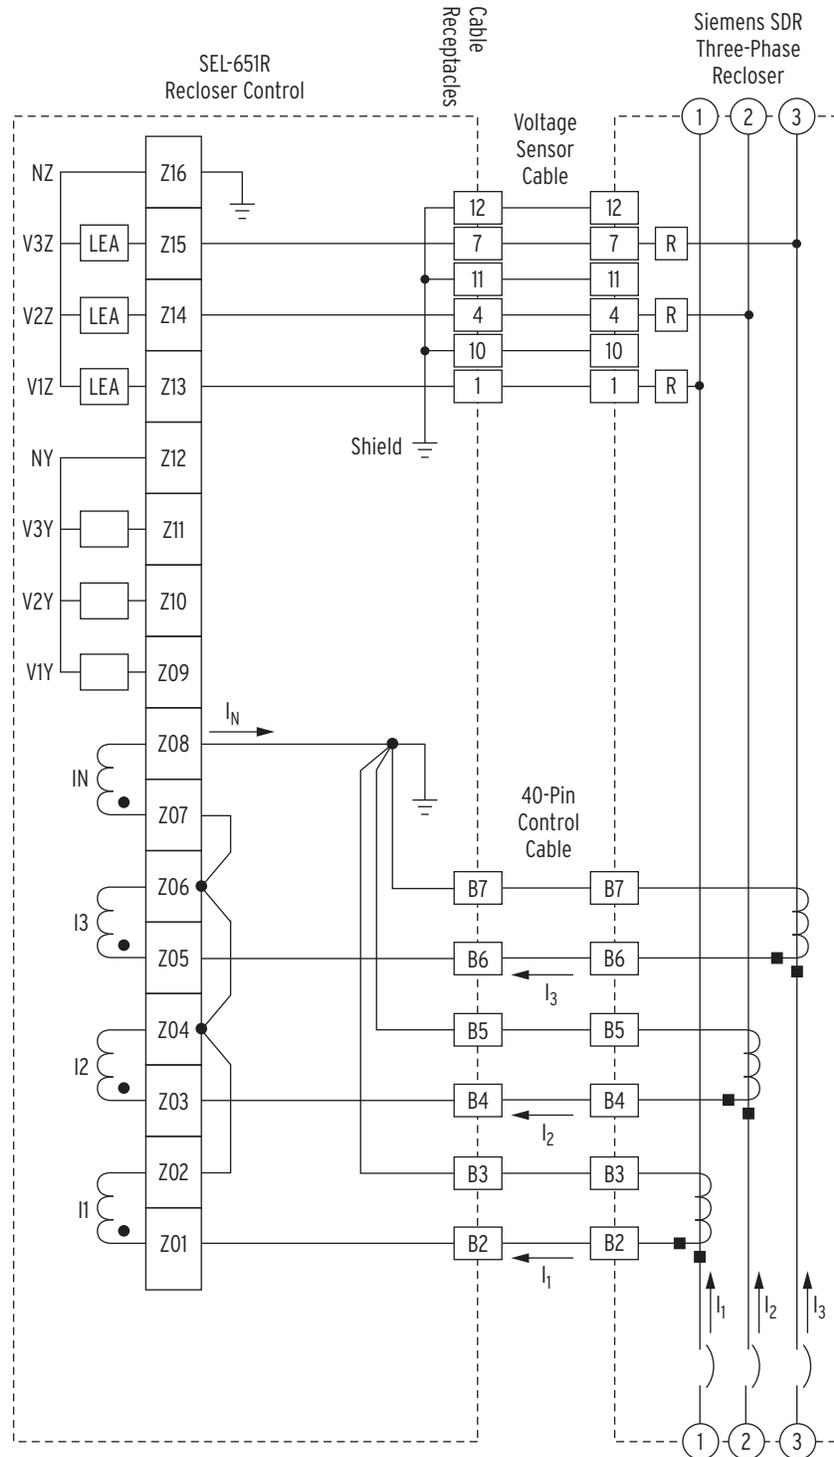

Figure 2.71   Current Connections and Polarity From Siemens SDR Three-Phase Recloser Primary to SEL-651R-2 Recloser Control Current Inputs

The Siemens SDR Triple-Single recloser in *Figure 2.72* has single-phase tripping/closing capability, while the Siemens SDR Three-Phase recloser in *Figure 2.73* does not. Thus, the Siemens SDR Triple-Single recloser in *Figure 2.72* has the additional complexity of per-phase tripping/closing and per-phase recloser status via the "CLOSE, S2 (52a)" contacts. The "OPEN, S1 (52b)" contacts in *Figure 2.72* are not used by the SEL-651R-2.

RELAY WORD BIT TCCAP
Relay Word bit TCCAP indicates that the 155 Vdc voltage in Figure 2.72 and Figure 2.73 is present for recloser operations (TCCAP = logical 1). The 155 Vdc voltage comes into the relay module via connector J205 (CAPACITORS), from the trip/close capacitors in the power module (see Figure 2.2, Figure 2.5, Figure 2.7, and Figure 2.9). If there is a problem with this connection or otherwise in the power module, then Relay Word bit TCCAP = logical 0. Relay Word bit TCCAP is used in factory-default close logic settings (see Figure 6.4 and Figure 6.5) and reclose supervision settings (see Table 6.8).

The operation of any individual lockout handle on the Siemens SDR Triple-Single recloser results in the opening/lockout of that phase (if not already open) and the assertion of the corresponding "LOCKOUT, S3 (69)" contact in *Figure 2.72* and the subsequent assertion of input IN204 in the SEL-651R-2.

The operation of the yellow lockout handle on the Siemens SDR Three-Phase recloser results in the opening/lockout of all three phases (if not already open) and the assertion of the "LOCKOUT, S3 (69)" contact in *Figure 2.73* and the subsequent assertion of input IN204 in the SEL-651R-2.

Input IN204 can be used in SELOGIC control equation settings to functionally keep the SEL-651R-2 in lockout (settings 79DTL__), block the issuing of a close (settings ULCL__), or (in the case of the Siemens SDR Triple-Single recloser) trip the other phases (settings TR__; see *Figure 5.2*).

In *Figure 2.72* and *Figure 2.73*, note that the trip and close FETs in the SEL-651R-2 are stacked on top of one another, between 155 Vdc power and ground, with a tap in the middle. For a given FET stack, both FETs can never be on at the same time or else there would be a direct short between the 155 Vdc power and ground. Interlocking logic prevents both FETs from being on at the same time.

Trace one of the trip paths in *Figure 2.72*:

Relay Word Bit RCTR1X (Trip 1; see *Figure 7.26*) turns on the bottom trip FET (ground) connected to terminal J206-3 and the top trip FET (155 Vdc) connected to terminal J206-9. This wiring continues through control cable pins A10/(1)C9 and A9/(1)A9 to Coil 1 in the Siemens SDR Triple-Single recloser. The 155 Vdc across Coil 1 (bottom to top) causes the current to flow in the indicated trip direction.

Trace one of the close paths in *Figure 2.72*:

Relay Word Bit RCCL1X (Close 1; see *Figure 7.26*) turns on the top close FET (155 Vdc) connected to terminal J206-3 and the bottom close FET (ground) connected to terminal J206-9. This wiring continues

through control cable pins A10/(1)C9 and A9/(1)A9 to Coil 1 in the Siemens SDR Triple-Single recloser. The 155 Vdc across Coil 1 (top to bottom) causes the current to flow in the indicated close direction.

The other trip/close circuits in *Figure 2.72* and *Figure 2.73* operate similarly.

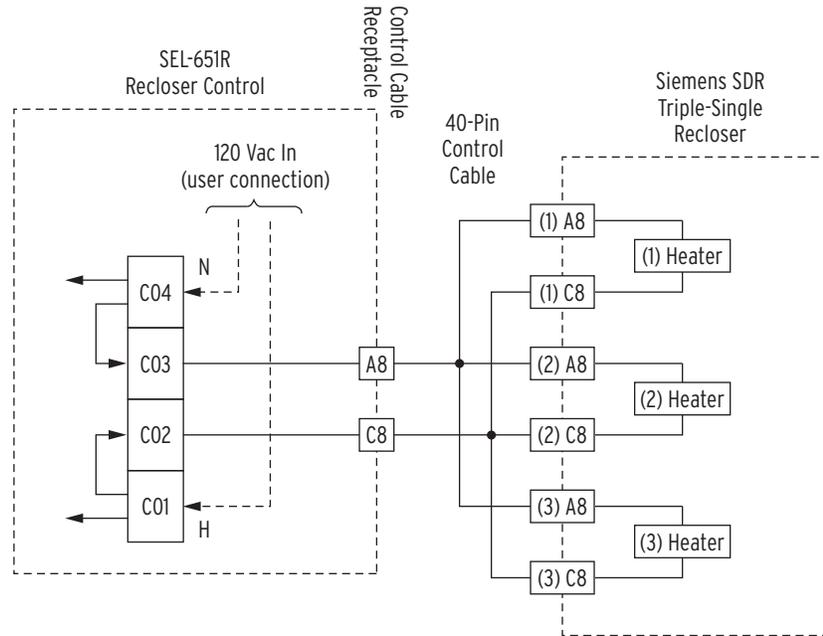
Figure 2.74 and *Figure 2.75* show the routing of 120 Vac power through the 40-pin control cable to heaters in the Siemens SDR reclosers.


Figure 2.74   120 Vac Power Circuit Connections Between SEL-651R-2 Recloser Control and Siemens SDR Triple-Single Recloser
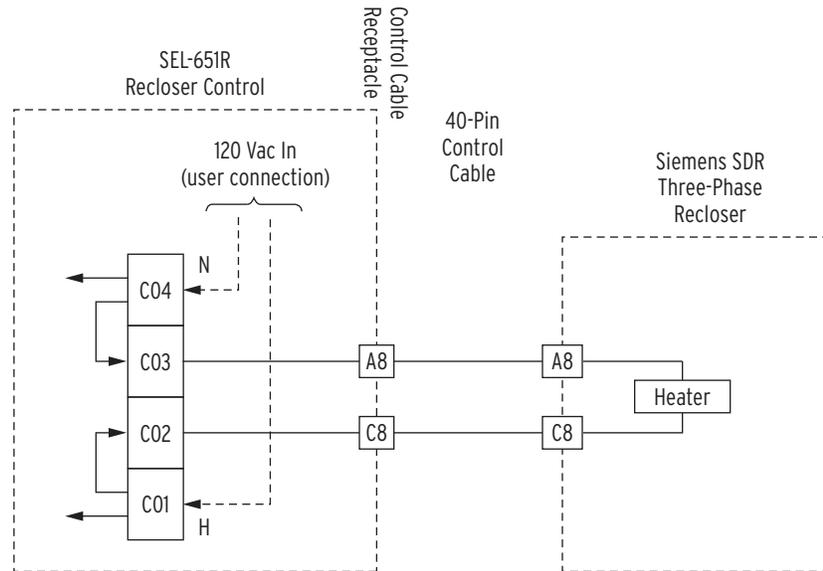

Figure 2.75   120 Vac Power Circuit Connections Between SEL-651R-2 Recloser Control and Siemens SDR Three-Phase Recloser

Multi-Recloser Interface

An SEL-651R-2 Recloser Control ordered with the Multi-Recloser Interface is compatible with the following single-phase trip/close capable reclosers:

➤ G&W Viper-ST, 32-pin and 42-pin

➤ G&W Viper-LT, 32-pin and 42-pin

➤ ABB Elastimold MVR

➤ Tavrida OSM Al_4

➤ ABB OVR/Gridshield, 32-pin and 42-pin

➤ Eaton NOVA NX-T

The interface uses a 42-pin control cable receptacle (see *Figure 2.16*, *Figure 2.25*, and *Figure 2.34*).

GLOBAL SETTING RECL_CFG
Global setting RECL_CFG is only available if the SEL-651R-2 Recloser Control is configured with a Multi-Recloser Interface. Otherwise, it is hidden.

The Multi-Recloser Interface makes the following settings and Relay Word bit additions:

➤ Introduces new, required Global setting RECL_CFG and associated Relay Word bits A1_CFG, A2_CFG, and A3_CFG (see *Table 2.4*)

➤ Automatically sets Global setting BKTYP:=1 [and hides the setting; see *Breaker/Recloser Type Setting (BKTYP) and Enable Single-Phase Breaker Setting (ESPB) on page 9.30*]

➤ Introduces new Relay Word bit 69_YH for 69 contacts operated by the yellow operating handles (see *Table 2.6*, *Figure 2.80*, and *69_YH Relay Word Bit for Multi-Recloser Interface on page 5.5*)

The Multi-Recloser Interface automatically sets the following SELOGIC settings (and hides them) according to Global setting IPCONN, as detailed in the corresponding tables:

➤ Breaker monitor initiate Global settings: BKMONA, BKMONB, and BKMONC (*Table 9.15*)

➤ Breaker/pole status (52a) settings: 52A_A, 52A_B, and 52A_C (*Table 2.7*)

➤ Trip output settings: RCTR1, RCTR2, and RCTR3 (*Table 9.19*; see also *Figure 7.26*)

➤ Close output settings: RCCL1, RCCL2, and RCCL3 (*Table 9.20*; see also *Figure 7.26*)

Table 2.4   Required Global Setting RECL_CFG and Corresponding Relay Word Bits and Recloser Configurations for the Multi-Recloser Interface (Sheet 1 of 2)

Recloser	Set Global Setting RECL_CFG :=	Resultant Relay Word Bit Logic State[a]	Source-Side Voltage Inputs[b]	Load-Side Voltage Inputs[b]	Adapter Cable Required?
G&W Viper-ST, 32-pin and Viper-LT, 32-pin	A1	A1_CFG= 1	V1Z, V2Z, V3Z	V1Y, V2Y, V3Y	yes [32-pin to 42-pin]
G&W Viper-ST, 42-pin and Viper-LT, 42-pin	A1	A1_CFG= 1	V1Z, V2Z, V3Z	V1Y, V2Y, V3Y	no
ABB Elastimold MVR	A1	A1_CFG= 1	V1Z, V2Z, V3Z	V1Y, V2Y, V3Y	yes [32-pin to 42-pin]
ABB OVR/Gridshield, 32-pin	A1	A1_CFG= 1	V1Z, V2Z, V3Z	V1Y, V2Y, V3Y	yes [32-pin to 42-pin]
ABB OVR/Gridshield, 42-pin	A1	A1_CFG= 1	V1Z, V2Z, V3Z	V1Y, V2Y, V3Y	no

Table 2.4   Required Global Setting RECL_CFG and Corresponding Relay Word Bits and Recloser Configurations for the Multi-Recloser Interface (Sheet 2 of 2)

Recloser	Set Global Setting RECL_CFG :=	Resultant Relay Word Bit Logic State[a]	Source-Side Voltage Inputs[b]	Load-Side Voltage Inputs[b]	Adapter Cable Required?
Tavrida OSM Al_4	A2	A2_CFG= 1	V1Y, V2Y, V3Y	V1Z, V2Z, V3Z	no
Eaton NOVA NX-T	A3	A3_CFG= 1	V1Y, V2Y, V3Y	V1Z, V2Z, V3Z	yes [37-pin to 42-pin]

[a] Relay Word bits An_CFG (where n = 1–3) not shown are equal to 0.
[b] These are the nominal source and load sides, per recloser current transformer polarity convention (see Figure 2.76, Figure 2.77, and Figure 2.78).

Table 2.5   Default Global Setting CTPOL

Global Setting RECL_CFG :=	Default Global Setting CTPOL :=[a]
A1	POS
A2	POS
A3	NEG

[a] See Changing Global Setting RECL_CFG Changes the CTPOL Setting and the PTRY and PTRZ Settings for 8 Vac LEA Voltage Inputs on page 2.95.

Table 2.6   Breaker Auxiliary Contacts, Yellow Operating Handles, and Corresponding 69 Contacts for the Multi-Recloser Interface

Recloser	Set Global Setting RECL_CFG :=	Monitored per-phase breaker auxiliary contacts (Figure 2.80)[a]	Number of yellow operating handles on recloser	Monitored 69 contacts corresponding to yellow operating handles (Figure 2.80)	Yellow operating handle in lock-open position	
					Monitored 69 contacts status (Figure 2.80)	69 contacts status in trip/close circuit (Figure 2.79)[b]
G&W Viper-ST, 32-pin and Viper-LT, 32-pin	A1	52a1, 52a2, 52a3	Three (one per phase)	69_1, 69_2, 69_3	closed	open
G&W Viper-ST, 42-pin and Viper-LT, 42-pin	A1	52a1, 52a2, 52a3, 52b1, 52b2, 52b3	Three (one per phase)	69_1, 69_2, 69_3	closed	open
ABB Elastimold MVR	A1	52a1, 52a2, 52a3	Three (one per phase)	69_1, 69_2, 69_3	closed	open
ABB OVR/Grid-shield, 32-pin	A1	52a1, 52a2, 52a3	One (for all three phases)[c]	69_1, 69_2, 69_3	closed	open
ABB OVR/Grid-shield, 42-pin	A1	52a1, 52a2, 52a3, 52b1, 52b2, 52b3	One (for all three phases)[c]	69_1, 69_2, 69_3	closed	open
Tavrida OSM Al_4	A2	52b1, 52b2, 52b3	One (for all three phases)[d]	69	open	open
Eaton NOVA NX-T	A3	52a1, 52a2, 52a3, 52b1, 52b2, 52b3	Three (one per phase)	69_1, 69_2, 69_3	closed	open

[a] A recloser might have both 52a and 52b breaker auxiliary contacts available – the above listed breaker auxiliary contacts are those monitored for determining recloser pole status (see Table 2.7).
[b] The 69 contacts in the trip/close circuits in each recloser pole (see Figure 2.79) are not directly monitored, but provide the actual safety feature of disabling recloser operation (by open circuiting the trip/close circuit) when the corresponding yellow operating handle is pulled to the lock-open position. See 69_YH Relay Word Bit for Multi-Recloser Interface on page 5.5 for more information.
[c] The ABB Gridshield 3SP has three yellow operating handles (one per phase).
[d] Figure 2.80 shows three separate 69 contacts (69_1, 69_2, and 69_3), corresponding to per-phase yellow operating handles, for reclosers in Table 2.6 with Global setting RECL_CFG := A1 and RECL_CFG := A3. The reclosers in Table 2.6 with Global setting RECL_CFG:= A2 have only one yellow operating handle and a single corresponding 69 contact wired to input IN204 (not the three separate 69 contacts portrayed in Figure 2.80). See 69_YH Relay Word Bit for Multi-Recloser Interface on page 5.5 for more information.

OTHER AUTOMATIC SETTINGS FOR MULTI-RECLOSER INTERFACE
See the settings in Table 9.15, Table 9.19, and Table 9.20.

Notice in *Table 2.7* that breaker/pole status (52A) settings effectively switch between monitoring 52a or 52b contacts (see *Figure 2.80*), depending on the logic state of Relay Word bits A1_CFG, A2_CFG, or A3_CFG, respectively (see *Table 2.4* and *Table 2.6*). In *Table 2.7*, 52b contact logic is inverted (e.g., "… OR NOT IN201 AND A2_CFG") to effective 52a contact logic.

Changing Global Setting RECL_CFG Changes the CTPOL Setting and the PTRY and PTRZ Settings for 8 Vac LEA Voltage Inputs

RE-EVALUATE PROTECTION SETTINGS AFTER CHANGING GLOBAL SETTING RECL_CFG
The adjacent discussion concerns potential transformer ratio settings automatically changing for particular circumstances when Global setting RECL_CFG is changed. But, all other settings are left unchanged. When a "Multi-Recloser Interface" SEL-651R-2 is changed to a different recloser, Global setting RECL_CFG could very well change (see Table 2.4). After such a setting change, protection-related settings (e.g., PT ratios, CT ratios, CT polarity, overcurrent, and voltage element pickups) should especially be re-evaluated.

When a "Multi-Recloser Interface" SEL-651R-2 is changed to a different recloser, Global setting RECL_CFG could very well change (see *Table 2.4*). If Global setting RECL_CFG changes, the following occur:

➤ The CTPOL setting automatically changes (see *Factory-Default Settings on page 9.61* and *Table 2.5*). You can change the CTPOL setting after the automatic change if desired.

➤ If there are 8 Vac LEA voltage inputs on the SEL-651R-2, the corresponding potential transformer ratio settings (PTRY and/or PTRZ) will change automatically. You can change these ratio settings after the automatic change if desired. See *Factory-Default Settings on page 9.61* for the required potential transformer ratio settings PTRY (for VY-terminal voltage inputs) and PTRZ (for Z-terminal voltage inputs) that allow the SEL-651R-2 to meter correctly with connection to these LEA voltage sensors. *Potential Transformer (PT) Ratios (Group Settings) on page 9.42* explains how such settings are derived.

Figure 2.76   Current Connections and Polarity for the Multi-Recloser Interface (Global Setting RECL_CFG := A1;
Optional Voltage Connections Also Shown)

NOTE: LEA sensor voltage dividers in some reclosers may be resistive instead of capacitive as depicted.

SHIELDED CABLES

Shielded cables for LEA voltage inputs (see Figure 2.76 and Figure 2.77) come preinstalled on newer Multi-Recloser installations, with the shields effectively connected to ground at the bottom of the enclosure.

RELAY WORD BIT TCCAP

Relay Word bit TCCAP indicates that the 155 Vdc voltage in Figure 2.79 is present for recloser operations (TCCAP = logical 1). The 155 Vdc voltage comes into the relay module via connector J205 (CAPACITORS), from the trip/close capacitors in the power module (see Figure 2.2, Figure 2.5, Figure 2.7, and Figure 2.9). If there is a problem with this connection or otherwise in the power module, then Relay Word bit TCCAP = logical 0. Relay Word bit TCCAP is used in factory-default close logic settings (see Figure 6.4 and Figure 6.5) and reclose supervision settings (see Table 6.8).

In *Figure 2.76*, *Figure 2.77*, and *Figure 2.78*, notice that the phase current terminals are labeled I1, I2, and I3 (not IA, IB, and IC). A-B-C designations are given to the current channels with Global setting IPCONN. Current transformer polarity can effectively be changed with the Global CTPOL setting, which is helpful for designating such characteristics as forward or reverse power flow.

Figure 2.79 shows the SEL-651R-2 factory wiring for trip/close for the Multi-Recloser Interface. Each pole of the recloser has its own trip/close coil, trip for current flow in one direction, close for current flow in the other direction. This facilitates single-phase tripping/reclosing, although the SEL-651R-2 factory settings have the recloser operating in a three-phase trip/close mode setting (ESPB := N).

Note that the trip and close FETs in the SEL-651R-2 are stacked one atop another, between 155 Vdc power and ground, with a tap in the middle. For a given FET stack, both FETs can never be on at the same time or else there would be a direct short between the 155 Vdc power and ground. Interlocking logic prevents both FETs from being on at the same time.

Trace the trip path for Coil 1 in *Figure 2.79*:

Relay Word Bit RCTR1X (Trip 1; see *Figure 7.26*) turns on the bottom FET (ground) connected to terminal J206-3 and the top FET (155 Vdc) connected to terminal J206-9. This wiring goes through control cable Pins 2 and 3 to Coil 1. The 155 Vdc across Coil 1 (bottom to top) causes the current to flow in the indicated direction (Trip 1).

Trace the close path for Coil 1 in *Figure 2.79*:

Relay Word Bit RCCL1X (Close 1; see *Figure 7.26*) turns on the top FET (155 Vdc) connected to terminal J206-3 and the bottom FET (ground) connected to terminal J206-9. This wiring goes through control cable Pins 2 and 3 to Coil 1. The 155 Vdc across Coil 1 (top to bottom) causes the current to flow in the indicated direction (Close 1).

The other trip/close circuits in *Figure 2.79* operate similarly.

SHO F Command

EDP := **4**

DP03 := **SV02T,"YELLOW HANDLE","LOCK-OPEN","RESET"**

Disconnected Control Cable Alarm for the Multi-Recloser Interface

The disconnect control cable alarm for the Multi-Recloser Interface enables the front-panel display message. To be valid, the recloser is required to include both 52a and 52b breaker auxiliary contacts or the active Recloser Configuration setting is required to be A2. Review footnote "a" accompanying *Table 2.6*.

For Recloser Configuration A1 or A3, if both per-phase 52a and 52b breaker auxiliary contacts are connected in *Figure 2.80*, then a disconnected control cable can be detected. For a given phase, the 52a and 52b breaker auxiliary contacts should normally be of the opposite state. If they are both of the same state, then the control cable is disconnected or something is otherwise wrong with the connections in *Figure 2.80*.

For a recloser with Global setting RECL_CFG := A2, a de-energized input IN204 in *Figure 2.80* indicates that the yellow operating handle is in the lock-open position. Such yellow operating handle action (pulled from the reset to the lock-open position) causes all three recloser phases to open and remain open (see *69_YH Relay Word Bit for Multi-Recloser Interface on page 5.5*). The standard per-phase 52b breaker auxiliary contacts all go closed, energizing corresponding inputs IN201, IN202, and IN203. This is all normal, expected operation.

If the control cable is disconnected, then inputs IN201–IN204 in *Figure 2.80* are all de-energized. This indicates the following contradictory conditions for a recloser with Global setting RECL_CFG := A2:

➤ Recloser closed (52b inputs IN201, IN202, and IN203 all de-energized; see *Table 2.7*)

➤ Yellow operating handle in lock-open position (input IN204 de-energized)

Thus, the condition "recloser closed" and yellow operating handle "lock-open" is an abnormal/alarm condition and is indicative of a disconnected control cable or that something is otherwise wrong with the connections in *Figure 2.80* for a recloser with Global setting RECL_CFG := A2.

The following factory-default settings for the Multi-Recloser Interface provide a front-panel display indication of a disconnected control cable, qualified for 5 cycles.

PC Software

Overview

This section contains the following subsections:

➤ *QuickSet Setup on page 3.3*

➤ *QuickSet Terminal on page 3.5*

➤ *QuickSet HMI on page 3.6*

➤ *QuickSet Settings on page 3.8*

➤ *QuickSet Event Analysis on page 3.18*

➤ *QuickSet Settings Database Management on page 3.21*

➤ *QuickSet Help on page 3.23*

SEL provides many PC software solutions (applications) that support SEL devices. These software solutions are listed in *Table 3.1*.

Table 3.1   SEL Software Solutions

Product Name	Description
SEL Compass	This application provides an interface for web-based notification of product updates and automatic software updating.
ACSELERATOR QuickSet SEL-5030 Software	QuickSet is a powerful setting, event analysis, and measurement tool that aids in applying and using the relay. See *Table 3.2* for information about the various QuickSet applications.
	This application allows you to customize relay settings to particular applications, instead of dealing with all settings in the device. These custom settings are stored in QuickSet Design Templates. You can lock settings to match your standards or lock and hide settings that are not used. This makes installation of a new device simple and helps ensure that new devices are applied according to your organization's standards.
ACSELERATOR Architect SEL-5032 Software	Use this application to design and commission SEL IEDs in IEC 61850 substations, create and map GOOSE messages, generate predefined reports, create and edit datasets, and read in SCD, ICD, and CID files.
ACSELERATOR TEAM SEL-5045 Software	The TEAM system provides custom data collection and movement of a wide variety of device information. The system provides tools for device communication, automatic collection of data, and creation of reports, warnings and alarms.
ACSELERATOR Analytic Assistant SEL-5601 Software	Converts SEL Compressed ASCII and COMTRADE event reports files to oscillography.
Cable Selector SEL-5801 Software	Selects the proper SEL cables for your application.

QuickSet is a powerful setting, event analysis, and measurement tool that aids in applying and using the relay. *Table 3.2* shows the suite of QuickSet applications. This section describes how to get started with QuickSet.

Table 3.2   QuickSet Applications

Application	Description
Terminal	Provides a direct connection to the SEL device. Use this feature to ensure proper communications and directly interface with the device.
HMI	Provides a summary view of device operation. Use this feature to simplify commissioning testing.
Rules Based Settings Editor	Provides online or offline device settings that include interdependency checks. Use this feature to create and manage settings for multiple devices in a database.
Event Analysis	Provides oscillography and other event analysis tools.
Settings Database Management	QuickSet uses a database to manage the settings of multiple devices.
Help	Provides general QuickSet and device-specific QuickSet context-sensitive help.

Obtaining QuickSet

QuickSet can be obtained from the Software Solutions area of the SEL website. To have the software automatically update as new relay drivers are released, download and install SEL Compass Software, then use Compass to download and install QuickSet. When you download QuickSet within Compass, you will be asked to select which relay drivers you want to include. Select drivers for all SEL relays that you may be required to set. If you need additional drivers at a later time, QuickSet provides an easy method to request new drivers and updates. See *Updating QuickSet on page 3.17*.

QuickSet is also available on CD upon request.

QuickSet Main Menu

The main menu provides the following options and submenu options. Selected submenu options are explained in detail in *Table 3.3*.

Table 3.3   QuickSet Submenu Options (Sheet 1 of 2)

File	➤ New—Create new settings for a connected device or offline ➤ Open—Open existing settings stored in a Relay Database (RDB) file ➤ Close—Close settings instance that is open in the QuickSet window ➤ Save/Save As—Save settings instance that is open in the QuickSet window to the active Relay Database (RDB) file ➤ Print Design—Print Design Template settings ➤ Print Device Settings—Print standard or custom settings reports ➤ Read—Read settings from a connected device and display the settings in the QuickSet window ➤ Send—Send settings instance that is open in the QuickSet window to a connected device ➤ Active Database—Change which Relay Database (RDB) file is used for the Open and Save/Save As commands. ➤ Database Manager—Open Database Manager to create a new Relay Database (RDB) file, copy settings within the active Relay Database (RDB) file, add descriptions to settings within the database, and copy and move settings between different databases. ➤ Exit—Quit the QuickSet software
Edit	➤ Copy—Copy settings from one Settings Group to another ➤ Search—Search for a text string within the settings instance ➤ Compare—Compare the settings instance that is open in the QuickSet window to another settings instance in the Relay Database file ➤ Merge—Merge the settings instance that is open in the QuickSet window with another settings instance in the Relay Database file ➤ Part Number—Change the current part number for the settings instance that is open in the QuickSet window

Table 3.3 QuickSet Submenu Options (Sheet 2 of 2)

Communications	➤ Connect—Request QuickSet to attempt to connect to a device by using the current Connection Parameters ➤ Parameters—Modify the Communications Parameters, including connection type (Serial, Network, or Modem), PC port numbers, speed, and settings, device passwords, IP addresses, ports, and file transfer options, and modem phone numbers and speeds. ➤ Network Address Book—Select from a list of Ethernet-connected devices. Add or modify devices by specifying the Connection Name, IP Address, Telnet Port Number, User ID, and Password. ➤ Terminal—Open terminal window to issue ASCII commands directly to a connected relay. ➤ Logging—Initiate terminal logging to record terminal communications. View and clear the connection log.
Tools	➤ Settings—Convert settings between settings versions. Import and export settings from and to text files. ➤ HMI—Open HMI for connected device and manage custom HMI Device Overviews. ➤ Events—Collect event and view reports from connected devices. ➤ Options—Control QuickSet options, including Settings Prompt and Layout Options, Event Viewer, Terminal Options, and Advanced Communications Settings. ➤ Firmware Loader—Upgrade relay firmware. ➤ Commissioning Assistant, Motor Start Viewer, Chart Viewer—Plug-in applications that support commissioning and data analysis for specific relays.
Windows	➤ Cascade, Tile Horizontally, Tile Vertically—Arrange multiple QuickSet windows for easy viewing.
Help	➤ Access program and settings help ➤ Check for software updates.

QuickSet Setup

Follow the steps outlined in *Section 2: Installation* to prepare the relay for use. Perform the following steps to initiate communications:

Step 1. Connect the appropriate communications cable between the relay and the PC.

Step 2. Apply power to the relay.

Step 3. Start QuickSet.

When QuickSet starts, the initial screen presents the following icons:

New—Create new settings for a connected or unconnected device

Read—Read settings from a connected device

Open—Open previously saved settings

Communications Parameters—Configure serial and network connections

Manage Databases—Manage offline settings and databases

Update—Install and update QuickSet software and drivers

The functions represented by these six icons are also included in the menu items. See the discussions of the individual menu items in this section for a description of these functions.

Communications Parameters

QuickSet can communicate with a relay via any relay serial port set to SEL protocol, via the front-panel USB port, or via Ethernet. Perform the following steps to configure QuickSet to communicate with the relay.

Step 1. Select **Communications > Parameters** from the QuickSet main menu bar to open the **Communication Parameters** dialog box, or select **Communications Parameters** from the startup screen.

Step 2. Select the type of connection to be used: Serial, Network, or Modem. To use the relay front-panel USB port, select Serial. Communications parameters can be defined simultaneously for Serial, Network, and Modem connections. The connection to be used is selected in the **Active Connection Type** drop-down menu.

Step 3. Configure the PC port.

If **Serial** is selected as the connection type:

a. Select the port number of the PC from the Device drop-down box.

b. Select the Data Speed for the relay serial port, or select Auto detect to allow the software to automatically determine the Data Speed. The default Data Speed for the relay is 9600.

c. Select appropriate settings for Data Bits, Stop Bits, Parity, and RTS/CTS (Hardware Handshaking) according to the settings of relay serial port. Default settings are Data Bits = 8, Stop Bits = 1, Parity = N, and RTS/CTS = OFF.

d. Enter the relay Access Level One and Access Level Two passwords in the respective text boxes.

If **Network** is selected as the connection type:

a. Enter the IP address of the relay Ethernet port as the Host IP Address

b. Enter the Telnet port number

c. Select **Telnet** as the File Transfer Option.

d. Enter the relay Access Level One and Access Level Two passwords in the respective text boxes.

e. Use the **Save to Address Book** button to save the entered information with a Connection Name for later use.

f. Relay Ethernet port setting ETELNET must be set to Y.

If **Modem** is selected as the connection type:

a. Select the port number of the PC modem from the **Device** drop-down box.

b. Enter the phone number of the remote modem.

c. Select the data speed for the modem, or select Auto detect to allow the software to automatically determine the data speed.

d. Enter the relay Access Level One and Access Level Two passwords in the respective text boxes.

Step 4. Click **OK** when finished.

PC Software 3.5
Page 155 of 1080
QuickSet Terminal
Wolfe

QuickSet Terminal

Terminal Window

The terminal window is an ASCII interface with the relay. This is a basic terminal emulation with no file transfer capabilities. Many third-party terminal emulation programs are available with file transfer encoding schemes.

Open the terminal window by either clicking **Communication > Terminal**, clicking on the Terminal icon on the toolbar, or by pressing **<Ctrl+T>**.

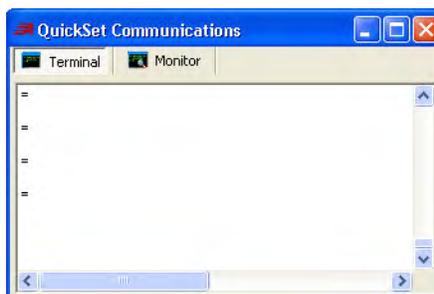
Verify proper communications with the relay by opening a terminal window, pressing **<Enter>** a few times, and verifying that an = (equal) prompt is received, as shown in *Figure 3.1*. If a prompt is not received, verify proper setup.


Figure 3.1   Terminal Prompt

Terminal Logging

If the **Terminal Logging** item in the **Communication** menu is selected, QuickSet records all communications between the relay and the PC in a log file.

Drivers

Enter Access Level 1 and issue the **STA** command to view the Firmware Identification (FID) string.

Locate and record the Z-number in the FID string. It will look similar to *Figure 3.2*. The first portion of the Z-number (Z001xxx, for example) determines the QuickSet relay settings driver version when you are creating or editing relay settings files. The later portion of the Z number (Zxxx001, for example) determines the HMI version number. These numbers are used by the applications to ensure proper interaction between the relay and QuickSet. The use of the driver version will be discussed in more detail later in this section.

Relay Settings Version Number

FID = SEL-651R-2-Rxxx-Vx-Z001001-Dxxxxxxxx

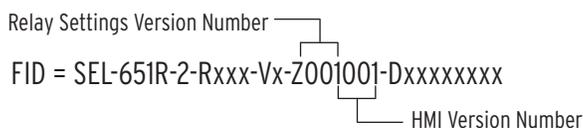
HMI Version Number


Figure 3.2   QuickSet Driver Information in the FID String

QuickSet reads the latter portion of the Z-number to determine the correct HMI to display when you select the menu. See *Open the QuickSet HMI on page 3.6* for instructions.

PC Software 3.7
QuickSet HMI
Wolfe

Table 3.4   QuickSet HMI Tree View Functions

Function	Description
Device Overview	View general metering, selected targets, control input, control outputs, and the virtual front panel.
Phasors	A graphical and textual representation of phase and sequence voltages and currents.
Instantaneous	A table of instantaneous voltages, currents, powers, and frequency.
Synchrophasor	A table of synchrophasor data.
Demand/Peak	A table showing demand and peak demand values. This display also allows demand and peak demand values to be reset.
Min/Max	A table showing maximum/minimum metering quantities. This display also allows maximum/minimum metering quantities to be reset.
Energy	A table showing energy import/export. This display also allows energy values to be reset.
Targets	View Relay Word bits in a row/column format.
Status	A list of relay status conditions.
LDP	View load profile data.
SER	Sequential Events Recorder data listed oldest to newest, top to bottom. Set the range of SER records with the dialog boxes at the bottom of the display.
SSI	View voltage Sag, Swell, and Interruption data.
Breaker Monitor Data	A table showing the latest circuit breaker monitor data.
Control Window	Metering and records reset buttons, trip and close control, output pulsing, target reset, time and date set, group switch, and remote bit control.

The flashing LED representation in the lower left of the QuickSet window indicates an active data update via the communications channel (see *Figure 3.3*). Click **Disable Update** to suspend HMI use of the communications channel.

HMI Device Overview

Select the **Device Overview** branch to display an overview of the relay operation. This view includes a summary of information from many of the other HMI branches, including fundamental metering, contact input/output status, and front-panel LED status.

The **Device Overview** colors and text can be customized. White LED symbols indicate a deasserted condition and LED symbols with any other color indicate an asserted condition. Click an LED symbol to change its assert color. Double-click the LED label to change the label.

Double-click an operator control pushbutton label to change the label.

HMI Control Window

Select the **Control Window** branch to reset metering values, clear event records, trip and close reclosers/breakers, pulse output contacts, and set and clear remote bits (see *Figure 3.4*).

3.8 | PC Software

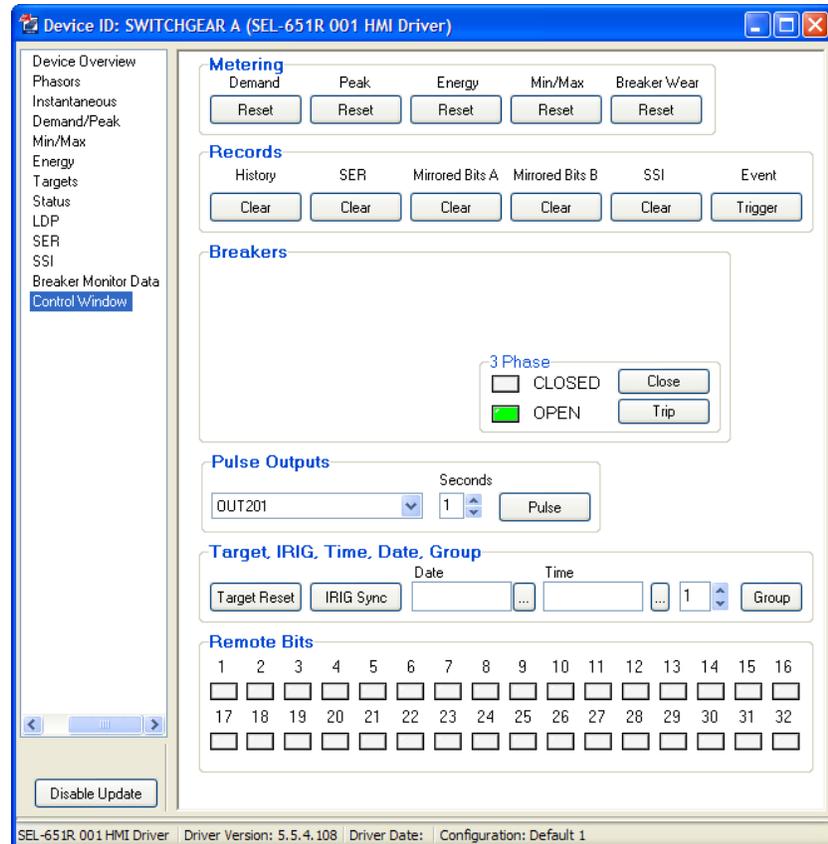
Attachment to Response to AG-2 Question No. 68(g)
Page 158 of 1080
Wolfe


Figure 3.4   Control Window

Other HMI Branches

The remaining HMI branches display metering, targets, status, reporting, and monitoring information.

HMI Configurations

Customized **Device Overviews** can be saved as HMI Configurations. To save the current configuration, select **Tools > HMI > Save Configuration** to save the configuration under the current name, or **Tools > HMI > Save Configuration As** to specify a configuration name.

HMI configurations are identified by relay type and a configuration name. To use an existing configuration, select **Tools > HMI > Select Configuration**. To view available configurations, select **Tools > HMI > Manage Configurations**. To make an existing configuration the default configuration for a given relay type, select the configuration in the **Manage Configurations** window, select **Edit**, and select the **Default** check box.

QuickSet Settings

QuickSet provides the ability to create settings for many relays, or download and store settings from existing relays (see *Database Manager on page 3.22*). You can then modify and upload these settings from the settings library to a relay.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 159 of 1080
Wolfe

PC Software 3.9
QuickSet Settings

SEL provides QuickSet for easier, more efficient configuration of relay settings. However, you do not have to use QuickSet to configure relays; you can use an ASCII terminal or a computer running terminal emulation software. QuickSet provides the advantages of rules-based settings checks, SELOGIC Control Equation Expression Builder, event analysis, and help.

Design Templates

A Design Template is a customized user interface for manipulating the settings of any SEL product supported by QuickSet. Design Templates are created with a licensed copy of QuickSet and are stored as relay files in a QuickSet relay database file (*.rdb). Various Design Templates are available from SEL. Contact SEL to inquire about licensing QuickSet to begin building your own custom templates.

The Design Template makes available only the settings that might need to be modified for a specific device application. These user-defined settings are referred to as design settings. They are the settings that are accessible through the Design Template view in QuickSet. The actual relay settings are calculated by rules inside the Design Template and are not visible in the Design Template view.

The SEL-651R-2 can store a QuickSet relay database (*.rdb) containing a Design Template. The Design Template is stored as a SWCFG.ZIP file separate from the relay settings (see *File > Read*). Although QuickSet automatically handles all communications necessary to manage Design Template storage, if the relay settings are modified using the SEL ASCII **SET** command or the relay front panel, it is possible for the current relay settings to be different from the settings stored within the Design Template file. *File > Read on page 3.11* discusses how QuickSet helps reconcile these differences.

The following discussion identifies two types of settings:

➤ Design Template settings are calculated and stored within a Design Template and can be stored as a file within the relay. The relay stores this file, but cannot read or change its content.

➤ Device settings are used for protection and control. These settings can be modified using QuickSet, SEL ASCII **SET** command, or the relay front panel.

File Menu

QuickSet uses a database to store and manage SEL device settings. Each unique device has its own record of settings. Use the **Settings** menu to create **New** settings, **Open** an existing record, or **Read** device settings.

File > New

To get started creating relay settings, select **File > New** from the main menu. QuickSet will display the **Settings Editor Section** window as shown in *Figure 3.5*. Select SEL-651 from the **Device Family** menu and the appropriate model (for example, SEL-651R-2) from the **Device Model** menu. Finally, select the Z number from the **Versions** menu. Click **OK**.

If the device family, device model, or version for the relay are not present, select **Install Devices** and follow the on-screen instructions to add the appropriate drivers.

3.10 | PC Software
QuickSet Settings

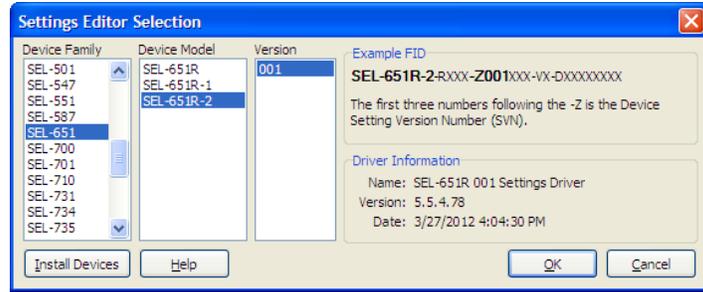
Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 160 of 1080
Wolfe


Figure 3.5   Settings Editor Selection

After the relay model and settings driver are selected, QuickSet presents the **Device Part Number** dialog box (shown in *Figure 3.6*). Use the drop-down menus within the **Device Part Number** dialog box to select the part number of the relay. Click **OK**.

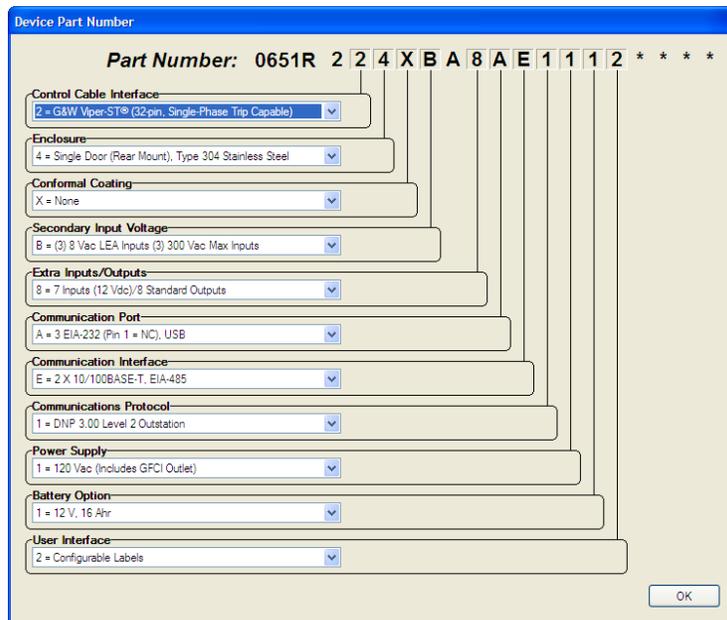
View the bottom of the **Settings Editor** window to check the **Settings Driver** number (see *Figure 3.7*). Compare the QuickSet driver number and the first portion of the Z-number in the FID string. These numbers must match. QuickSet uses this first portion of the Z-number to determine the correct **Settings Editor** to display.


Figure 3.6   Setting the Part Number

Case No. 2018-00295

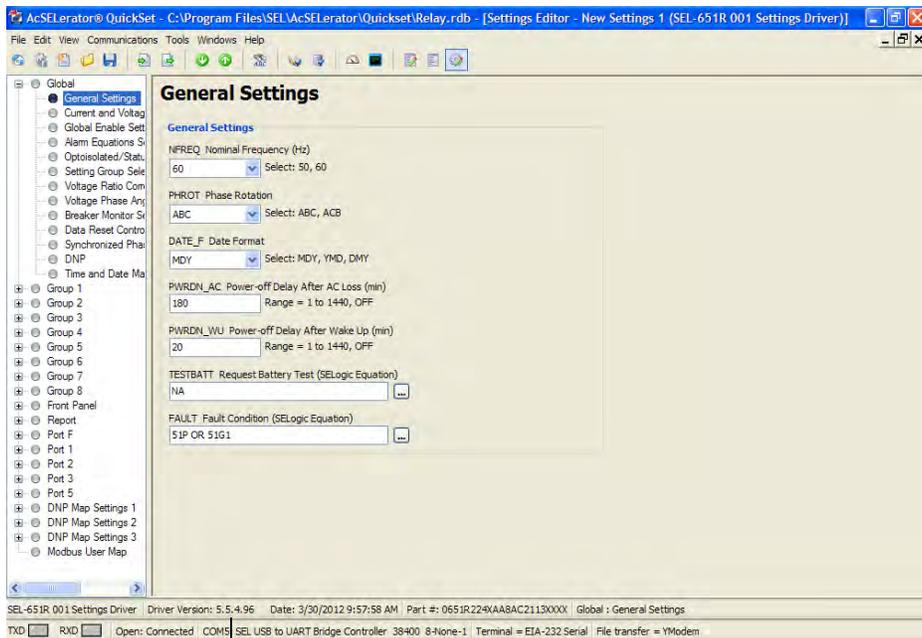
Page 161 of 1080
Wolfe
PC Software 3.11
QuickSet Settings


Relay Settings Driver Version Number

Figure 3.7   Settings Driver

File > Open

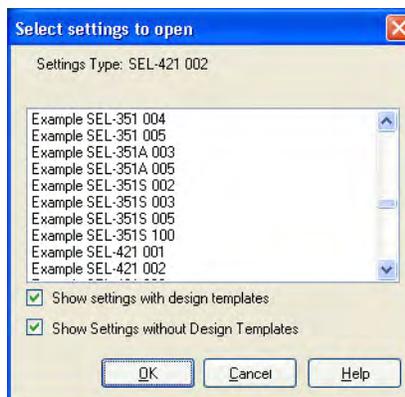
The **Open** menu item opens existing relay settings from the active database folder (see *Figure 3.8*). QuickSet displays the **Select Settings to Open** window and prompts for a device to load into the **Settings Editor**. The **Show settings with design templates** and **Show settings without design templates** check boxes allow settings with or without design templates to be included in or excluded from the **Select Settings to Open** window.


Figure 3.8   Opening Settings

Highlight the relay settings to be opened and click **OK**.

File > Read

When the **Read** menu item is selected, QuickSet displays the **Settings Group/Class Select** window (see *Figure 3.9*). Select the check boxes to specify which settings groups or classes are to be read from the connected device. Click **OK**. Note that settings not read from the device will be populated with the default settings. As QuickSet reads the device, a **Transfer Status** window appears.

3.12 PC Software
QuickSet Settings

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 162 of 1080
Wolfe

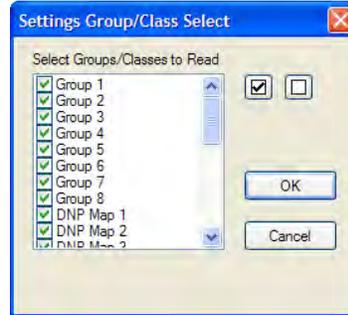
If the Settings Group/Class Select window is not displayed, select
Tools > Options and navigate to the **Settings** tab. When the **Specify Groups on Settings Read** check box is selected, the **Settings Group/Class Select** window is displayed for **File > Read**. When the **Specify Groups on Settings Read** check box is cleared (not selected), the **Settings Group/Class Select** window is not displayed, and the software reads all of the settings. Select whichever option you prefer.


Figure 3.9 Reading Settings

If the software detects a Design Template stored as a SWCFG.ZIP file inside the relay, the **Settings Group/Class Select** window includes the option to Read Designer Template from Device.

Figure 3.10 Read Designer Template From Device

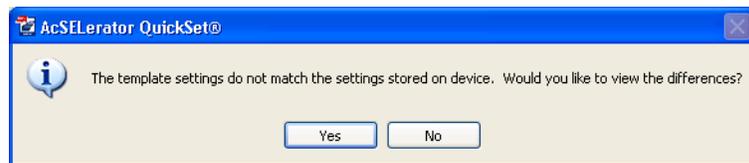
Selecting the **Read Designer Template from Device** check box instructs the software to read all the device settings and the Design Template. The software compares the device settings to the settings within the Design Template and offers to display the differences, if any. See *Figure 3.11*.


Figure 3.11 View Settings Differences

Clicking **Yes** causes the software to display a settings comparison, allowing you to verify the settings that may have changed since the Design Template was installed. In *Figure 3.12*, MAIN BREAKER 1 is the Relay Identifier (RID) from the Design Template, and TEST BREAKER 1 is the Relay Identifier read from the relay settings.

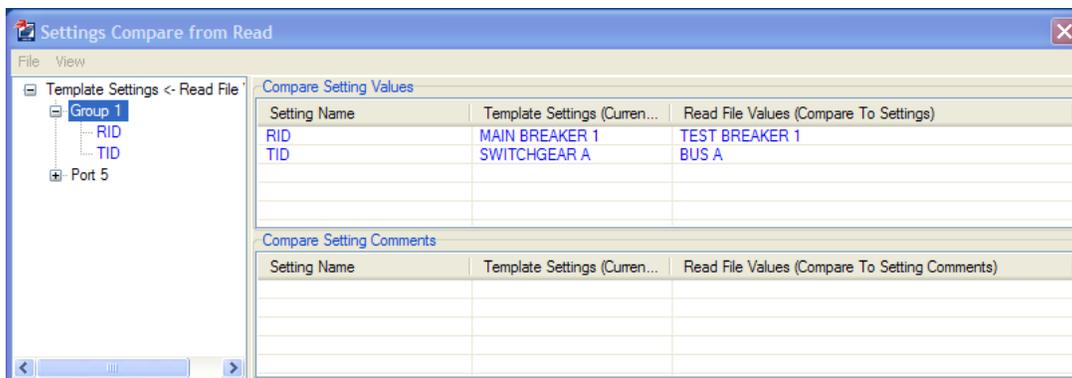
Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 1163 of 2102
PC Software 3.13
Quickset Settings
Wolfe


Figure 3.12   Settings Compare

In the Settings Compare view, select **File** to save the comparison to use later.

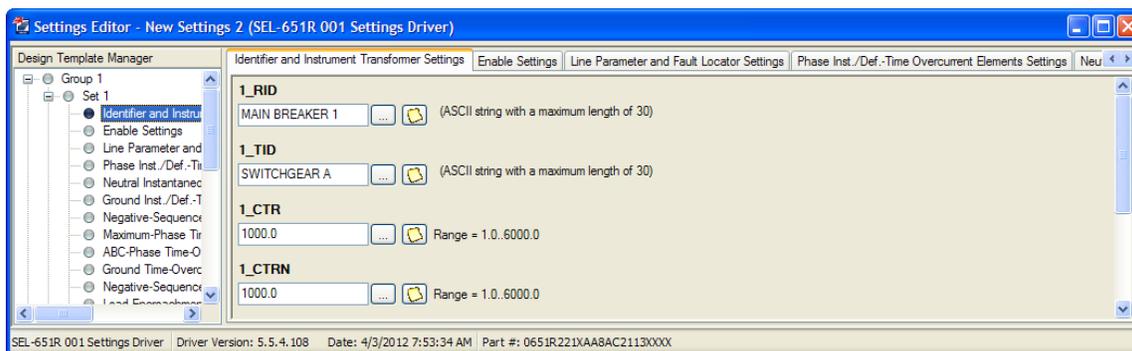
When you have evaluated all of the differences, close the settings comparison to view the Design Template. The relay settings are not displayed. Note in *Figure 3.13* that the Relay Identifier has the setting value MAIN BREAKER 1 from the Design Template, not TEST BREAKER 1 from the relay settings.


Figure 3.13   Design Template Settings Editor: New Settings

If you want to view the relay settings rather than the Device Template, leave the **Read Designer Template from Device** option unchecked.

Device Editor

The SEL-651R-2 settings structure makes setting the relay easy and efficient. Settings are grouped logically and relay elements that are not used in the selected protection scheme are not visible. For example, if settings are entered through use of the **SET** command and only three levels of a particular type of overcurrent protection are enabled, the Level 4, Level 5, and Level 6 overcurrent element settings do not appear on the communications terminal screen. Hiding unused elements and settings that are not enabled greatly simplifies the task of setting the relay.

QuickSet uses a similar method to focus attention on the active settings. Unused relay elements and inactive settings are dimmed (grayed) in the QuickSet menus.

QuickSet shows all of the settings categories in the settings tree view. The settings tree view does not change when settings categories are enabled or disabled. However, any disabled settings are dimmed. *Figure 3.14* illustrates this feature of QuickSet.

3.14 PC Software
QuickSet Settings

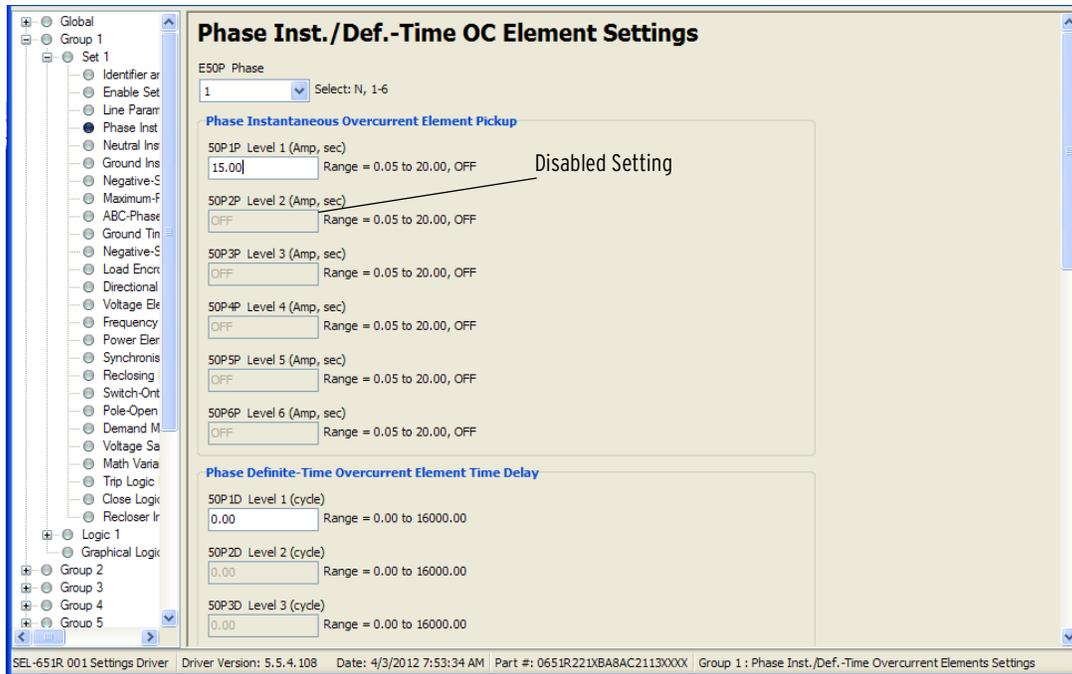
Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 164 of 1080
Wolfe


Figure 3.14   Settings Editor

Entering Settings

Click the arrows and the buttons in the Settings Tree View to expand and select the settings you want to change. Use the **Tab** key to navigate through the settings, or click on a setting.

To restore the previous value for a setting, right-click the setting and select **Previous Value**. To restore the factory-default setting value, right-click in the setting dialog box and select **Default Value**.

If you enter a setting that is out of range or has an error, QuickSet shows the error at the bottom of the **Settings Editor**. Double-click the error listing to go to the setting to enter a valid input.

Expression Builder

SELOGIC control equations are a powerful means for customizing relay operation. QuickSet simplifies this process with the Expression Builder, a rules-based editor for programming SELOGIC control equations. The Expression Builder organizes relay elements and SELOGIC control equation variables and focuses equation decision-making.

Access the Expression Builder

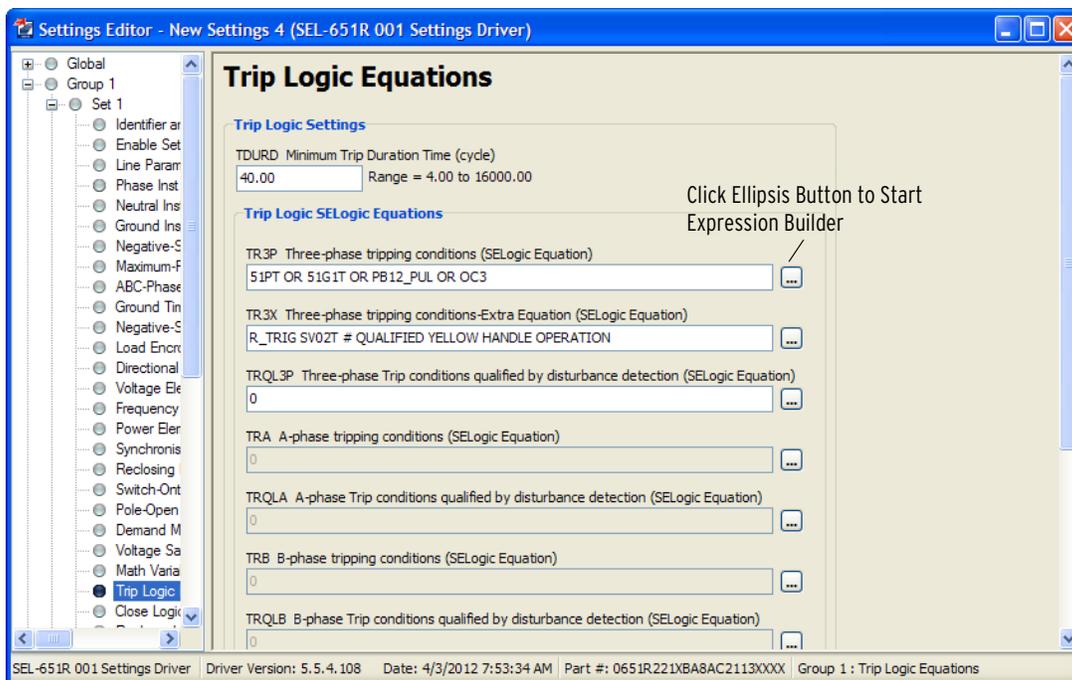
Click the ellipsis button to the right of each Logic setting in the Settings Editor window to start the Expression Builder (see *Figure 3.15*).


Figure 3.15   Settings Editor Window
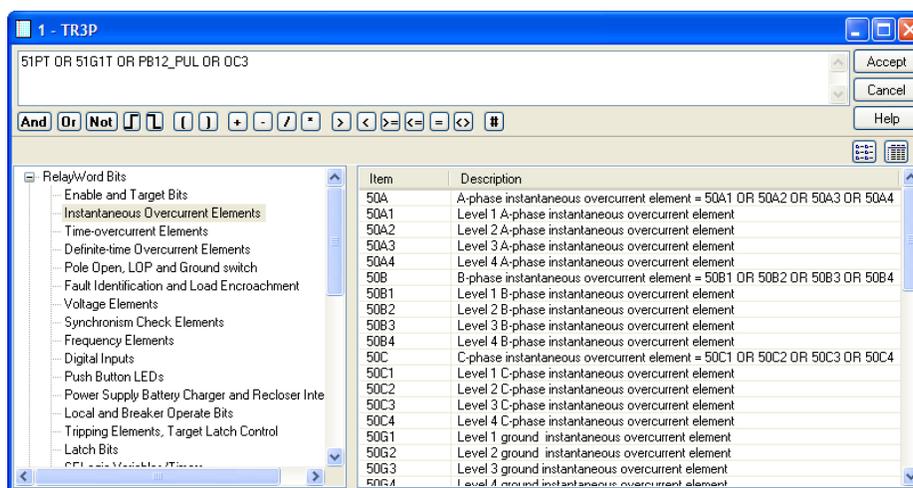

Figure 3.16   Expression Builder

Using the Expression Builder

SEL<small>OGIC</small> control equations can be built from a list of Relay Word bits. Select the + for Relay Word bits in the lower left box of the Expression Builder to expand the Relay Word bit tree. Relay Word bits are arranged in categories. Select the individual categories to view the associated Relay Word bits within the lower right box of the Expression Builder. Double-click a Relay Word bit to place it in the equation box at the top of the Expression Builder. Single-click the SEL<small>OGIC</small> operators below the equation box to add operators to the equation. Equations may also be typed directly in the equation box. Click **Accept** to exit the Expression Builder and save the equation, or **Cancel** to exit without saving.

For more information on programming SEL<small>OGIC</small> control equations, see *Section 7: SEL<small>OGIC</small> Control Equation Programming*.

QuickSet Settings

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 166 of 1080
Wolfe

File > Save

Select **Save** or **Save As** from the **File** menu once settings are entered into QuickSet. This will help ensure the settings are not lost.

File > Send

Select the **Send** menu item from the **File** menu to send the settings to a connected device. Select which settings group you want to send and click **OK**.

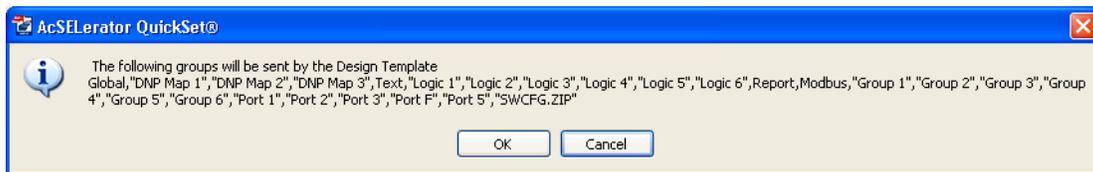
If you are editing settings inside a Design Template, it is not necessary to select which settings groups to send. The creator of the Design Template specifies which groups to send and whether the Design Template itself is stored in the SWCFG.ZIP file. All settings groups are sent to the relay along with the Design Template. See *Figure 3.17*.


Figure 3.17   Settings Groups Sent by Design Template

Edit Menu

The Edit menu includes selections that aid in the creation and viewing of settings.

Edit > Copy

Use this menu item to copy group (set and logic) settings.

Edit > Search

Use this menu item to search for a particular setting or Relay Word bit.

Edit > Compare

Use this menu item to compare the open record with another record.

Edit > Merge

Use this menu item to merge the open record with another record.

Edit > Part Number

Use this menu item to change the part number if it was entered incorrectly during an earlier step.

Tools Menu

The **Tools** menu provides access to the HMI menus (see *QuickSet HMI on page 3.6*), event analysis tools (see *QuickSet Event Analysis on page 3.18*), and Settings Conversion and Options menus.

PC Software 3.17
QuickSet Settings

Tools > Settings > Convert

Use the **Tools > Settings > Convert** menu item to convert from one settings version to another. Typically this utility is used to upgrade an existing settings file to a newer version when installed relays have a newer setting version number. In all settings conversions, settings that are new in the latest settings version are populated with the default settings unless otherwise indicated in this section. QuickSet provides a **Convert Settings** report that shows missed, changed, and invalid settings created as a result of the conversion. Review this report to determine whether changes are required.

Managing Relays Set With Design Templates

Design Templates allow you to create a custom view that shows only the settings necessary for a particular application. The relay settings are derived using rules inside the Design Template and may depend on other relay settings and design template settings. Because it is not possible to recalculate the design template settings from derived relay settings, SEL recommends the following process when setting relays through use of Design Templates:

1. When creating the Design Template, use the **Tools > Groups to Send** menu to configure the Design Template to Send Designer Template to Device. Select the **Tools > Design Template Options** menu and select the option **Allow switching to Settings Editor from Design**. In this way, settings which are not under the control of the Design Template equations can be revised within QuickSet.

2. Always use QuickSet to read settings from the relay and make settings changes.

    a. Always select the **Read Designer Template from Device** option when reading settings from the relay.

    b. Make settings changes within the Design Template read from the relay. Revise design template settings from within the Design Template view and select **View > Settings Editor** if it is necessary to revise settings which are not under the control of the Design Template equations.

    c. Use **File > Send** to send the settings and Design Template back to the relay.

    d. Save the Design Template as the record of the relay settings.

3. Avoid changing settings with the SEL ASCII **SET** command, relay front panel, or other software.

Updating QuickSet

The QuickSet software consists of a core application plus driver files for individual devices. As new device firmware versions are released, you may need to update QuickSet to add new driver files. This may be accomplished several ways:

➤ When **Enable Update Notifications** is checked in the **Tools > Options** menu of SEL Compass, the Compass software will automatically check for updates on a specified schedule and facilitate the update process.

➤ The **Update** icon on the QuickSet startup screen starts SEL Compass and checks for updates.

3.18 | PC Software
QuickSet Event Analysis

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 168 of 1080
Wolfe

➤ The **Install Devices** button on the Settings Editor Selection window starts SEL Compass and presents a menu of available drivers.

➤ **Check for updates** in the **Help** menu starts SEL Compass and checks for updates.

An Internet connection is required to add new drivers and to receive update notifications.

QuickSet Event Analysis

QuickSet has integrated analysis tools that help you retrieve information about protection system operations quickly and easily. Use the protection system event information that relays store to evaluate the performance of a protection system.

Event Waveforms

Relays record power system events for all trip situations and for other operating conditions programmed with SELOGIC control equations (see *Section 12: Analyzing Events*).

The relays provide three types of event data captures:

➤ event report oscillography that uses filtered sample per cycle data

➤ unfiltered (raw) data (compressed and COMTRADE format)

➤ high-impedance event report data

See *Section 12: Analyzing Events* for information on recording events. Use QuickSet to view event report oscillograms, phasor diagrams, harmonic analysis, and settings.

Read History

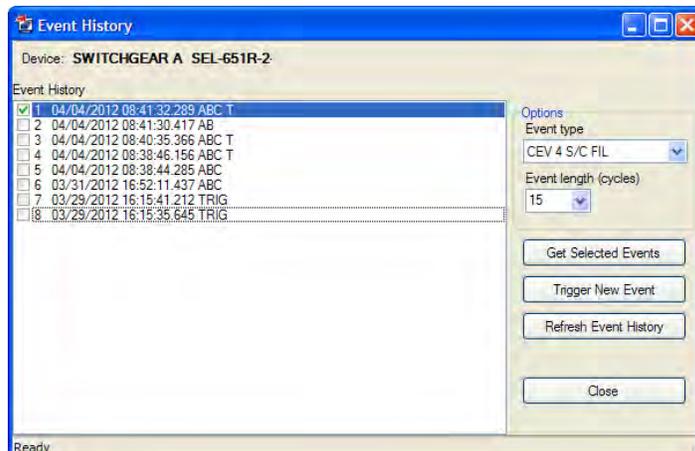
You can retrieve event files stored in the relay and transfer these files to a computer. To download event files from the relay, open the QuickSet **Tools > Events** menu on the QuickSet toolbar and click **Get Event Files**. The **Event History** dialog box will appear (similar to *Figure 3.18*).


Figure 3.18   Retrieving an Event History

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 169 of 1080
Wolfe

PC Software 3.19
Quickset Event Analysis

Get Event

Highlight the event you want to view and click the **Get Selected Event** button. The **Event Options** dialog box allows selection of Event Type and Event Length. When downloading is complete, QuickSet asks for a location to save the file on your computer. Select **Tools > Events> View Event Files** and select an event file to view events saved on your computer. QuickSet displays the Analytic Assistant dialog box and the event oscillogram (see *Figure 3.19* and *Figure 3.20*).

When viewing the event oscillogram, use keyboard function keys to measure the time of oscillogram occurrences. These function keys and related functions help in event analysis.

> ➤ **<F2>**: go to trigger

> ➤ **<F3>**: Cursor 1

> ➤ **<F4>**: Cursor 2

The display shows the time difference between Cursor 1 and Cursor 2.

To see high-accuracy time-stamp information on the event oscillogram, click the **Pref** button at the bottom of the oscillogram and select **Time** (under **Time Units, Starting/Ending Row**); click **OK**. Click on any point in a graph to observe the **Event Time** in microseconds of that point at the bottom of the oscillogram.

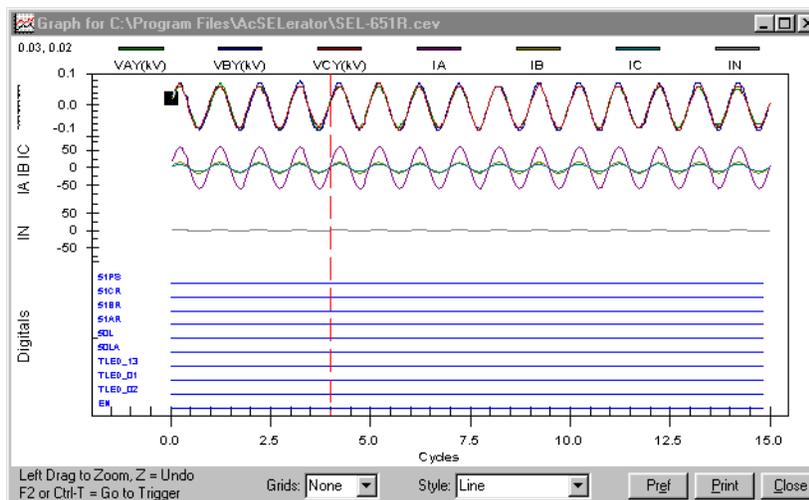
Figure 3.19   Event Waveform Window


Figure 3.20   Sample Event Oscillogram

Other event displays are available through the **AcSELerator Analytic Assistant** dialog box. Select the **View** menu and click **Phasors**, as shown in *Figure 3.21*, to view a sample-by-sample phasor display. The phasor display should be similar to *Figure 3.22*.

QuickSet Settings Database Management

QuickSet uses a database to save device settings. QuickSet contains sets of all settings files for each device specified in the **Database Manager**. Choose appropriate storage backup methods and a secure location for storing database files.

3.22 | PC Software
QuickSet Settings Database Management

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 172 of 1080
Wolfe

Active Database

Change the active database to the one that needs to be modified by selecting **File > Active Database** on the main menu bar.

Database Manager

Select **File > Database Manager** on the main menu bar to create new databases and manage records within existing databases.

Settings Database

Open the **Database Manager** to access the database by clicking **File > Database Manager**. A dialog box similar to *Figure 3.26* appears.

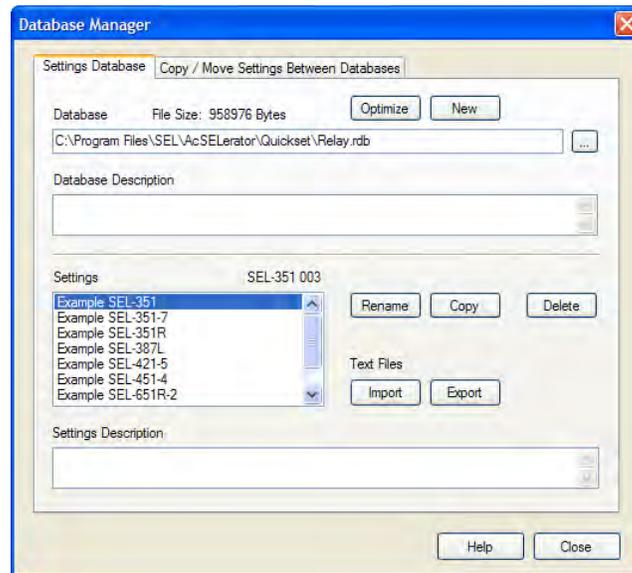
The default database file already configured in QuickSet is **Relay.rdb**. Enter descriptions for the database and for the settings in the database in the **Database Description** and **Settings Description** dialog boxes.


Figure 3.26   Database Manager

Highlight one of the devices listed in **Settings** and select the **Copy** button to create a new collection of settings. QuickSet prompts for a new name. Be sure to enter a new description in **Settings Description**.

Copy/Move Relays Between Databases

Select the **Copy/Move Settings Between Databases** tab to create multiple databases with the **Database Manager**; these databases are useful for grouping similar protection schemes or geographic areas. The dialog box is shown in *Figure 3.27*. Click the ellipsis button next to the **Database B** file extension window to open a database. Type a file name and click **Open**; for example, Relay2.rdb is the **B** database in *Figure 3.27*.

Highlight a setting in the **A** database, select **Copy** or **Move**, and click the ">" button to create a new setting in the **B** database. Reverse this process to take settings from the **B** database to the **A** database. **Copy** creates identical settings that appear in both databases. **Move** removes the settings from one database and places the settings in another database.

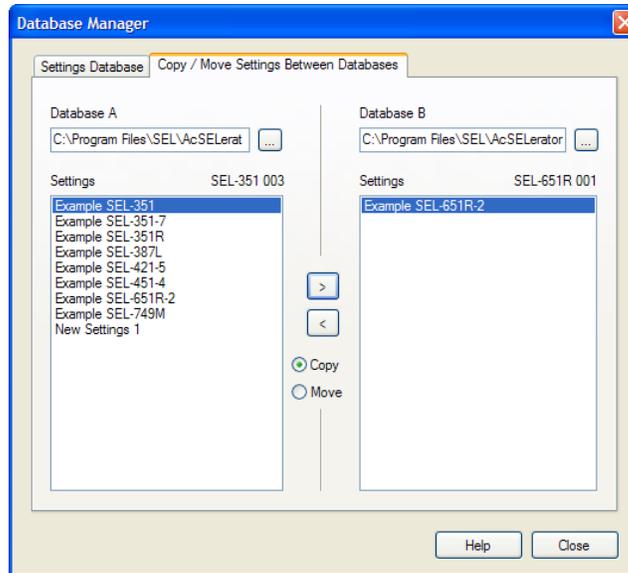
QuickSet Help
Wolfe


Figure 3.27   Database Manager Copy/Move

Create a New Database

To create and copy an existing database of settings to a new database, click **File > Database Manager** and select the **Copy / Move Relays Between Databases** tab on the **Database Manager** dialog box. QuickSet opens the last active database and assigns it as **Database A** (as shown in *Figure 3.27*).

Click the ellipsis button next to the **Database B** file extension window; QuickSet prompts you for a file location. Type a new database name, click the **Open** button, and answer **Yes**; the program creates a new empty database. Load settings into the new database as in **Copy / Move Relays Between Databases**.

QuickSet Help

Various forms of QuickSet help are available as shown in *Table 3.5*. Press **<F1>** to open a context-sensitive help file with the appropriate topic as the default. Other ways to access help are shown in *Table 3.5*.

Table 3.5   Help

Protection Functions

Instantaneous/Definite-Time Overcurrent Elements

Phase Instantaneous/ Definite-Time Overcurrent Elements

Four levels of phase instantaneous/definite-time overcurrent elements are available. Two additional levels of phase instantaneous overcurrent elements (Levels 5 and 6) are also available. The different levels are enabled with the E50P enable setting, as shown in *Figure 4.1–Figure 4.7*.

Single-phase (50A, 50B, 50C) and maximum-phase (50P) elements are available. The single-phase elements operate on the individual phase currents, subject to assignment by setting IPCONN (see *Table 9.8*).

The single-phase and maximum-phase elements operate from the same pickup and time-delay settings. For example, if 50P1P is set to 6.00 A, both 50P1 and 50A1 will assert when the A-phase current exceeds 6.00 A, secondary.

These single-phase and maximum-phase elements are collectively referred to as Phase Instantaneous/Definite-Time Overcurrent Elements.

The single-phase and maximum-phase definite-time elements feature separate torque-control settings, as shown in *Figure 4.3–Figure 4.6*.

Settings Ranges

Setting range for pickup settings 50P1P–50P6P:

0.05–20.00 A secondary

Setting range for definite-time settings 50P1D–50P4D:

0.00–16000.00 cycles, in 0.25-cycle steps

Accuracy

See *Specifications on page 1.9*.

Pickup Operation

The phase instantaneous/definite-time overcurrent element logic begins with *Figure 4.1* and *Figure 4.2*. The pickup settings for each level (50P1P–50P6P) are compared to the magnitudes of the individual phase currents I_A, I_B, and I_C. The logic outputs in *Figure 4.1* and *Figure 4.2* are Relay Word bits and operate as follows (Level 1 example shown):

50A1 =	1 (logical 1)	if I_A > pickup setting 50P1P
	0 (logical 0)	if I_A ≤ pickup setting 50P1P
50B1 =	1 (logical 1)	if I_B > pickup setting 50P1P
	0 (logical 0)	if I_B ≤ pickup setting 50P1P
50C1 =	1 (logical 1)	if I_C > pickup setting 50P1P
	0 (logical 0)	if I_C ≤ pickup setting 50P1P
50P1 =	1 (logical 1)	if at least one of the Relay Word bits 50A1, 50B1, or 50C1 is asserted (e.g., 50B1 = 1)
	0 (logical 0)	if all three Relay Word bits 50A1, 50B1, and 50C1 are deasserted (50A1 = 0, 50B1 = 0, and 50C1 = 0)

Note that single-phase overcurrent elements are not available in Levels 5 and 6 (see *Figure 4.2*).

Ideally, set 50P1P > 50P2P > 50P3P > 50P4P so that definite-time overcurrent elements 50P1T–50P4T will display in an organized fashion in event reports (see *Figure 4.1* and *Table 12.5*).

NOTE: Do not use these elements for load current detection if the fault locator is enabled (setting EFLOC := Y). Set these elements above load current levels so that the fault locator will work correctly. Use the 5OL element instead for load current detection (see Figure 5.6).

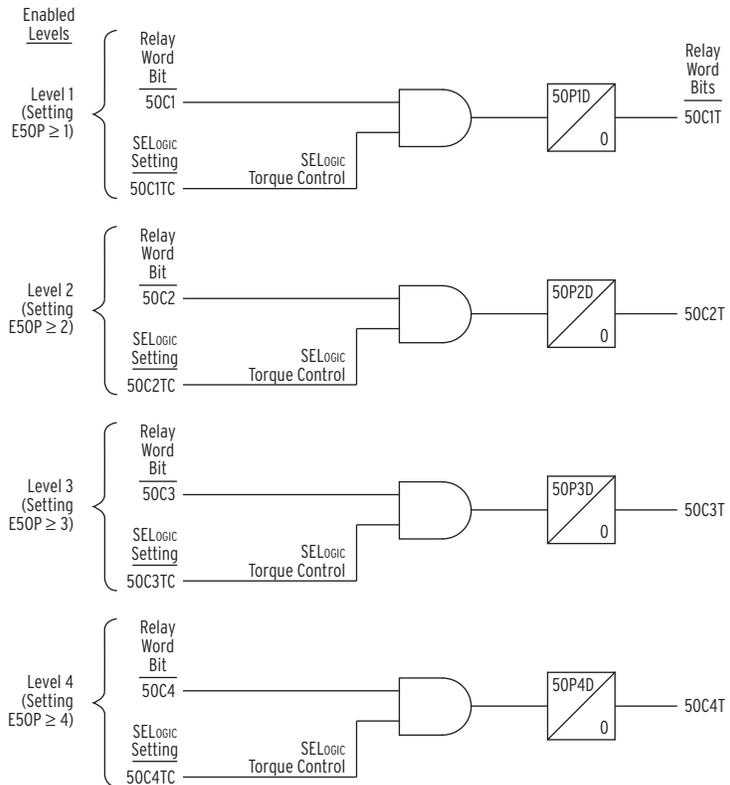

Figure 4.6   Levels 1–4 C-Phase Definite-Time Overcurrent Elements

Torque Control

Levels 1–4 have corresponding SELOGIC control equation torque-control settings:

➤ 50P1TC–50P4TC—Maximum-phase (*Figure 4.3*)

➤ 50A1TC–50A4TC—A-phase (*Figure 4.4*)

➤ 50B1TC–50B4TC—B-phase (*Figure 4.5*)

➤ 50C1TC–50C4TC—C-phase (*Figure 4.6*)

SELOGIC control equation torque-control settings cannot be set directly to logical 0. The following are torque-control setting examples for Level 1 phase definite-time overcurrent elements 50P1T and 50B1T.

50P1TC := **1**   Setting 50P1TC set directly to logical 1:

Phase definite-time overcurrent element 50P1T is enabled.

Note: In the SEL-651R-2 factory-default settings, the instantaneous/definite-time overcurrent element torque-control settings are set to logical 1. See *Factory-Default Settings on page 9.61*.

50B1TC := **IN105**   Input IN105 deasserted (50B1TC := IN105 = logical 0):

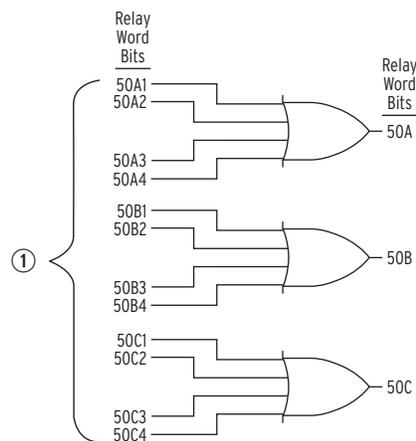
> Then B-phase definite-time overcurrent element 50B1T is defeated and nonoperational, regardless of any other setting.

Input IN105 asserted (50B1TC := IN105 = logical 1):

> B-phase definite-time overcurrent element 50B1T is enabled.

Combined Single-Phase Instantaneous Overcurrent Elements

The single-phase instantaneous overcurrent element Relay Word bit outputs in *Figure 4.1* are combined together in *Figure 4.7* on a per-phase basis, producing Relay Word bit outputs 50A, 50B, and 50C.

Relay Word bits 50A, 50B, and 50C can be used to indicate the presence or absence of current in a particular phase.


① From Figure 4.1.

Figure 4.7   Combined Single-Phase Instantaneous Overcurrent Elements

Pickup and Reset Time Curves

NOTE: The pickup time curve in Figure 4.8 is not valid for conditions with a saturated CT, where the resultant current to the relay is nonsinusoidal.

Figure 4.8 and *Figure 4.9* show pickup and reset time curves applicable to all instantaneous overcurrent elements in the SEL-651R-2 (60 Hz or 50 Hz systems). These times do not include output operating time and, thus, are accurate for determining element operation time for use in internal SELOGIC control equations.

Neutral Instantaneous/ Definite-Time Overcurrent Elements

GLOBAL SETTING EGNDSW
See Ground Switch Logic on page 4.76.

When Global setting EGNDSW := N, four levels of neutral instantaneous/definite-time overcurrent elements are available. Two additional levels of neutral instantaneous overcurrent elements (Levels 5 and 6) are also available. The different levels are enabled with the E50N enable setting, as shown in *Figure 4.10* and *Figure 4.11*.

When Global setting EGNDSW := Y (factory default), the E50N enable setting is forced to N and the neutral instantaneous/definite-time overcurrent elements are not available. In this application, use the Ground instantaneous/definite-time overcurrent elements (50G1–50G6 and 50G1T–50G4T) described in the next subsection.

To understand the operation of *Figure 4.10* and *Figure 4.11*, follow the explanation given for *Figure 4.1*, *Figure 4.2*, and *Figure 4.3* in the preceding subsection *Phase Instantaneous/ Definite-Time Overcurrent Elements on page 4.1*, substituting current I_N (channel IN current) for phase currents and substituting like settings and Relay Word bits.

Instantaneous/Definite-Time Overcurrent Elements

Wolfe

Ground Instantaneous/ Definite-Time Overcurrent Elements

Four levels of ground instantaneous/definite-time overcurrent elements are available. Two additional levels of ground instantaneous overcurrent elements (Levels 5 and 6) are also available. They operate on ground current I_G that comes from one of two sources:

➤ channel IN current

➤ calculated residual-ground current $3I_0 = I_A + I_B + I_C$ (vector summation)

EGNDSW, CTR, AND CTRN SETTINGS CONFIGURATIONS
See Table 4.23.

CHANNEL IN WIRING CONFIGURATIONS
See Table 4.23.

PHASE CURRENT CHANNEL ASSIGNMENTS
Made with Global setting IPCONN (see Table 9.8).

RESIDUALLY CONNECTED CHANNEL IN
The following figures show the factory-default wiring for channel IN wired residually with the phase current channels for the various recloser applications: Figure 2.49, Figure 2.52, Figure 2.55, Figure 2.59, Figure 2.62, Figure 2.65, Figure 2.68, Figure 2.70, Figure 2.71, Figure 2.76, and Figure 2.77.

The different levels are enabled with the E50G enable setting, as shown in *Figure 4.12* and *Figure 4.13*.

When Global setting EGNDSW := Y, ground current I_G is automatically switched between the following:

➤ channel IN current (for low ground current values)

➤ calculated residual-ground current $3I_0 = I_A + I_B + I_C$ (for higher ground current values)

This gives the ground instantaneous/definite-time overcurrent elements the widest range for pickup settings and operating current. It especially provides for increased sensitivity at lower ground current values. In this application, the pickup settings 50G1P–50G6P must be made on the channel IN current base.

Factory defaults (see Scenario 1 in *Table 4.23*):

➤ Global setting EGNDSW := Y

➤ Channel IN wired residually with the phase current channels

Therefore, the phase channel current base is the same as the channel IN current base and the respective current transformer ratio settings should be set the same (CTR = CTRN).

If uncommon Scenario 2 in *Table 4.23* is true for an SEL-651R-2 installation, then refer to *50G1P Setting Example When EGNDSW := Y and CTR ≠ CTRN on page 4.10* for guidelines on making pickup settings 50G1P–50G6P on the channel IN current base.

When Global setting EGNDSW := N (see Scenarios 3 and 4 in *Table 4.23*), ground current I_G is fixed on the calculated residual-ground current $3I_0 = I_A + I_B + I_C$ (vector summation). In this application, the pickup settings 50G1P–50G6P must be made on the phase current channel base.

To understand the operation of *Figure 4.12* and *Figure 4.13*, follow the explanation given for *Figure 4.1*, *Figure 4.2*, and *Figure 4.3* in the preceding subsection *Phase Instantaneous/ Definite-Time Overcurrent Elements on page 4.1*, substituting ground current I_G (see *Ground Switch Logic on page 4.76*) for phase currents and substituting like settings and Relay Word bits.

Settings Ranges

POSSIBLE EXTRA 2-CYCLE DELAY
For 50G1P–50G6P elements with settings less than 0.050 A secondary (on the phase current base), or when Relay Word bit GNDSW is asserted, there is an additional 2-cycle time delay on the ground instantaneous (50G1–50G6) and definite-time (50G1T–50G4T) element(s). Any time delay provided by definite-time settings 50G1D–50G4D is in addition to this 2-cycle time delay.

Setting range for pickup settings 50G1P–50G6P:

0.005–20.000 A secondary in 0.001-A steps

(on channel IN base*, when Global setting EGNDSW := Y and Group setting CTR = CTRN)

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 184 of 1080
Wolfe

4.10 | Protection Functions
Instantaneous/Definite-Time Overcurrent Elements

0.005–[20 • (CTR/CTRN)] A secondary in 0.001-A steps

(on channel IN base, when Global setting EGNDSW := Y and Group setting CTR ≠ CTRN)

0.010–20.000 A secondary in 0.001-A steps

(on IA, IB, IC base, when Global setting EGNDSW := N)

* **Note**: in the case where EGNDSW := Y and CTR = CTRN, there is no difference between the IN current base and the IA, IB, IC current base. This is the standard configuration for the SEL-651R-2.

Setting range for definite-time settings 50G1D–50G4D:

0.00–16000.00 cycles, in 0.25-cycle steps

Accuracy

See *Specifications on page 1.9*.

Pickup and Reset Time Curves

See *Figure 4.8* and *Figure 4.9*.

50G1P Setting Example When EGNDSW := Y and CTR ≠ CTRN

In applications where a separate CT is connected to the neutral channel of the SEL-651R-2, the CT ratio is often different than the phase CTs (connected to recloser control terminals I1, I2, I3). If the neutral CT is measuring zero-sequence current from the same line or bus location as the phase CTs, make Global setting EGNDSW := Y and enter the proper CTR and CTRN values in the *Group Settings on page SET.7*.

The SEL-651R-2 ground overcurrent pickup settings must be made on the channel IN base. In this example, the system has 1000:1 phase CTs, a 100:1 neutral CT, and a desired pickup level for a ground element of 75 A primary $(3I_0)$.

Make Global setting EGNDSW := Y and Group settings CTR := 1000.0 and CTRN := 100.0. To determine the proper setting for 50G1P, the primary pickup value (75 A) must be converted to secondary units on the channel IN base.

$$\text{Pickup in secondary}_{(\text{IN base})} = (\text{pickup in primary}) / \text{CTRN}$$

Equation 4.1

Example pickup = 75.0 / 100 = 0.750 A secondary

Make settings

E50G := **1**

50G1P := **0.750 A**

With the calculation method shown in *Equation 4.1*, the phase CT ratio is not used. If the SEL-651R-2 is being installed at a location that already had the ground instantaneous overcurrent setting value calculated on the phase current base, the pickup value must be converted to the IN current base.

Continuing with the example, if the secondary ground trip value was provided on the phase CT base, (use *Equation 4.2* to obtain = 75.0 / 1000 = 0.075 A), the secondary value must be converted to the IN base prior to entry in the SEL-651R-2 (using *Equation 4.3*).

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 185 of 1080
Protection Functions 4.11
Instantaneous/Definite-Time Overcurrent Elements
Wolfe

$$\text{Pickup in secondary}_{(\text{Phase CT base})} = (\text{pickup in primary}) / \text{CTR}$$

Equation 4.2

(Where CTR is the SEL-651R-2 Group setting.)

$$\text{Pickup in secondary}_{(\text{IN base})} = \text{Pickup (IA, IB, IC base)} \cdot (\text{CTR} / \text{CTRN})$$

Equation 4.3

(Where CTR and CTRN are the SEL-651R-2 Group settings.)

Example pickup = Pickup (Phase CT base) • (CTR/CTRN) = 0.075 A • 1000/100 = 0.750 A. The two calculation methods yield the same result.

NOTE: Do not use elements 50G1—50G4 for load unbalance current detection if the fault locator is enabled (setting EFLOC := Y). Set elements 50G1—50G4 above load unbalance current levels so that the fault locator will work correctly. Elements 50G5 and 50G6 may be used for load unbalance current detection.

Negative-Sequence Instantaneous/ Definite-Time Overcurrent Elements

Important: See *Setting Negative-Sequence Overcurrent Elements on page 4.105* for information on setting negative-sequence overcurrent elements.

Four levels of negative-sequence instantaneous/definite-time overcurrent elements are available. Two additional levels of negative-sequence instantaneous overcurrent elements (Levels 5 and 6) are also available. The different levels are enabled with the E50Q enable setting, as shown in *Figure 4.14* and *Figure 4.15*.

To understand the operation of *Figure 4.14* and *Figure 4.15*, follow the explanation given for *Figure 4.1*, *Figure 4.2*, and *Figure 4.3* in the preceding subsection *Phase Instantaneous/ Definite-Time Overcurrent Elements on page 4.1*, substituting negative-sequence current $3I_2$ [$3I_2 = I_A + a^2 \cdot I_B + a \cdot I_C$ (ABC rotation), $3I_2 = I_A + a^2 \cdot I_C + a \cdot I_B$ (ACB rotation), where $a = 1 \angle 120°$ and $a^2 = 1 \angle -120°$] for phase currents and substituting like settings and Relay Word bits.

Settings Ranges

Setting range for pickup settings 50Q1P–50Q6P:

  0.05–20.00 A secondary

Setting range for definite-time settings 50Q1D–50Q4D:

  0.00–16000.00 cycles in 0.25-cycle steps

NOTE: Do not use elements 50Q1–50Q4 for load unbalance current detection if the fault locator is enabled (setting EFLOC := Y). Set elements 50Q1–50Q4 above load unbalance current levels so that the fault locator works correctly. Elements 50Q5 and 50Q6 may be used for load unbalance current detection.

Neutral #1	*Figure 4.20*	51N1, 51N1T, 51N1R, 51N1S	E51N1	51N1TC, 51N1SW
Neutral #2	*Figure 4.21*	51N2, 51N2T, 51N2R, 51N2S	E51N2	51N2TC, 51N2SW
Ground #1	*Figure 4.22*	51G1, 51G1T, 51G1R, 51G1S	E51G1	51G1TC, 51G1SW
Ground #2	*Figure 4.23*	51G2, 51G2T, 51G2R, 51G2S	E51G2	51G2TC, 51G2SW
Negative-Sequence	*Figure 4.24*	51Q, 51QT, 51QR, 51QS	E51Q	51QTC, 51QSW

The time-overcurrent elements in *Table 4.1* are run in alternating processing intervals:

➤ The phase time-overcurrent elements in one processing interval

➤ The neutral-, ground-, and negative-sequence time-overcurrent elements in the following processing interval

Each time-overcurrent element is run twice per power system cycle. If the SELOGIC control equations in *Table 4.1* are set with rising or falling edge trigger operators (see *Table 7.1*), then there is the possibility that the logical 0 to logical 1 (or 1 to 0) transition of some logic will be missed because of the time-overcurrent elements not being run every processing interval.

See the figures referenced in *Table 4.1* for a block diagram of each element.

Page 188 of 1080
Wolfe

Enable Settings

The dual-characteristic feature allows one of two setting characteristics, labeled J and K, to be used in each time-overcurrent element under SELOGIC control. The dual-characteristic feature is only active for a particular element when the enable setting is set to 2. See *Table 4.1* for the enable setting names.

If the enable setting for a time-overcurrent element is set to 1, the time-overcurrent element only operates from the J characteristic.

If the enable setting for a time-overcurrent element is set to 2, the time-overcurrent element operates from the J or the K characteristic, depending on a Relay Word bit controlled by a SELOGIC control equation, as shown in *Table 4.2*.

Table 4.2   Effect of Enable and Characteristic Switch Settings on 51__ᵃ Elements

Enable Setting	Characteristic Switch Setting	Controlling Relay Word Bit	J Characteristic	K Characteristic
E51__ := N	None	N/A	Disabled	Disabled
E51__ := 1	None	N/A	Active	Disabled
E51__ := 2	51__SW	51__S	Active when 51__S = logical 0	Active when 51__S = logical 1

ᵃ The "__" represents P, A, B, C, N1, N2, G1, G2, or Q.

Characteristic Switch Setting

Refer to the figures referenced in *Table 4.1*. Any one of these figures helps in understanding characteristic switching.

The characteristic switch setting, 51__SW, acts as a request to change the active characteristic. The Relay Word bit 51__S will normally mimic the state of the characteristic switch setting 51__SW. To prevent a change in characteristic during a power system fault, the 51__SW setting is ignored if the time-overcurrent element is picked up (Relay Word bit 51__ is asserted). In this case, the 51__S Relay Word bit will remain at its previous state (just before 51__ asserted) as long as the element remains picked up. After the time-overcurrent element drops out (Relay Word bit 51__ deasserts), the 51__S Relay Word bit again follows the 51__SW setting.

Make the characteristic switch setting, 51__SW, only when the enable setting E51__ := 2. When E51__ := 1, the 51__SW setting is not presented in the **SHO** or **SET** commands (see *Section 10: Communications*) and it is internally set to logical 0.

Relay Word Bits

The time-overcurrent elements each use four Relay Word bits, as shown in *Table 4.1*. The J and the K characteristics share the same Relay Word bits, because only one of J or K characteristics can be active at any time.

The standard event reports indicate which characteristic is in effect for each time-overcurrent element by the use of uppercase or lowercase letters in the digital status columns—see *Table 12.5*.

Torque Control

Each of the dual-characteristic time-overcurrent elements are supervised by a torque-control SELOGIC equation setting (see *Table 4.1*). The torque-control equation controls the entire element, regardless of which characteristic, J or K, is in use.

Protection Functions 4.15
Time-Overcurrent Elements
Wolfe

Maximum-Phase Time-Overcurrent Elements

The maximum-phase time-overcurrent element is a dual-characteristic element that operates on the maximum phase current (maximum of I_A, I_B, or I_C). See *Table 4.1* for figure references, enable settings, Relay Word bits, and controlling SELOGIC equation names.

Settings Ranges

The 51PT maximum-phase time-overcurrent element settings are shown in *Table 4.3*.

Table 4.3   Maximum-Phase Time-Overcurrent Element Settings

Setting[a]	Definition	Range
51PJP 51PKP	pickup	0.05–3.20 A secondary
51PJC 51PKC	curve type	U1–U5 (U.S. curves; see *Table 9.5*), C1–C5 (IEC curves; see *Table 9.6*), recloser curves (see *Table 9.7*)
51PJTD 51PKTD	time dial (has no multiplying effect on constant time adder or minimum response time)	0.50–15.00 (U.S. curves), 0.05–1.00 (IEC curves), 0.10–2.00 (recloser curves)
51PJRS[b] 51PKRS	electromechanical reset timing	Y, N
51PJCT 51PKCT	constant time adder—adds additional time to curve	0.00–60.00 cycles (no effect if set = 0.00)
51PJMR 51PKMR	minimum response time—flattens curve at set time; curve can operate no faster than this set time	0.00–60.00 cycles (no effect if set = 0.00)
51PTC[c]	SELOGIC control equation torque-control setting	Relay Word bits referenced in *Table F.1* or set directly to logical 1 (=1)
51PSW[d]	SELOGIC characteristic switch setting	Relay Word bits referenced in *Table F.1*

[a] Dual-Characteristic Time-Overcurrent element settings: the letters J and K in the setting names represent the two characteristics.

[b] The electromechanical reset setting (51PJRS) is not available when the curve selection setting (51PJC) is set to a recloser curve. In this situation, 51PJRS is effectively set to N internally. Similarly, setting 51PKRS is not available when setting 51PKC is set to a recloser curve.

[c] SELOGIC control equation torque-control setting (e.g., 51PTC) cannot be set directly to logical 0 or NA.

[d] SELOGIC Characteristic Switch Setting (51PSW) is available only when E51P := 2. 51PSW cannot be set to NA.

See *Time-Overcurrent Curves on page 9.4* for curve selection details.

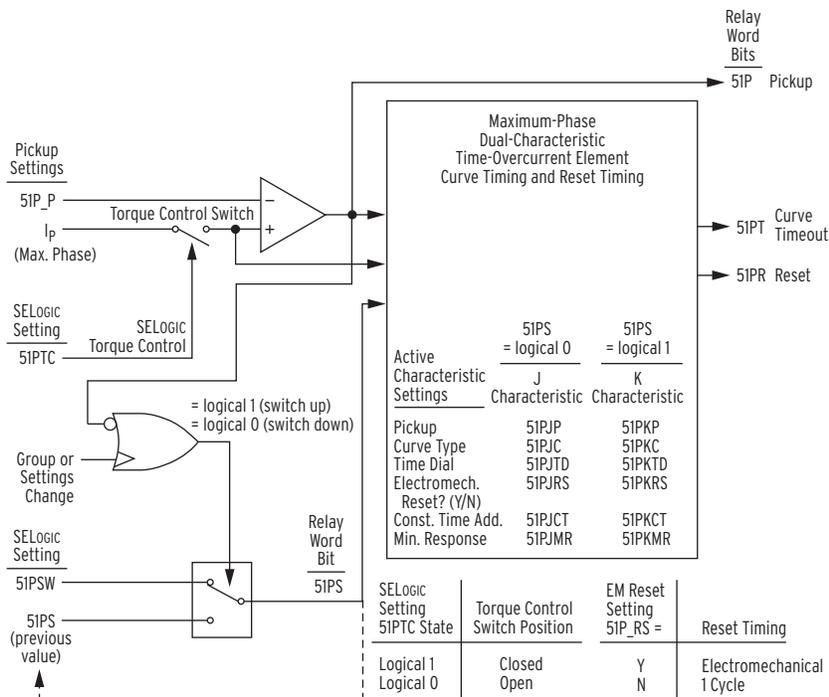
NOTE: Do not use these elements for load current detection if the fault locator is enabled (setting EFLOC := Y). Set these elements above load current levels so that the fault locator will work correctly. Use the 50L element instead for load current detection (see Figure 5.6).


Figure 4.16   Maximum-Phase Dual-Characteristic Time-Overcurrent Element 51PT

Accuracy

See *Specifications on page 1.9*.

Logic Outputs (51PT Element Example)

The resultant logic outputs in *Figure 4.16* are shown in *Table 4.4*.

Table 4.4   Maximum-Phase Time-Overcurrent Element Logic Outputs

Relay Word Bit	Definition/Indication	Application
51P	Maximum phase current, I_P, is greater than phase time-overcurrent element pickup setting 51PJP or 51PKP (depending on 51PS status).	Element pickup testing/indication or fault indication (see FAULT in *Table 5.2* and ABOVE MIN TRIP in *Table 5.3*
51PT	Phase time-overcurrent element is timed out on its curve.	Tripping and other control applications (see *Trip Logic on page 5.1*)
51PR	Phase time-overcurrent element is fully reset.	Element reset testing or other control applications
51PS	Maximum-phase time-overcurrent element is operating on the K characteristic.	Indication, targeting, and event reporting

Torque-Control Switch Operation (51PT Element Example)

The maximum-phase time-overcurrent element J characteristic settings are used in this example, which corresponds to the case where E51P := 1, or where E51P := 2 and the characteristic switch setting 51PSW = logical 0. The

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 191 of 1080
Protection Functions 4.17
Time-Overcurrent Elements
Wolfe

same torque-control behavior applies to the K characteristic (when 51PSW = logical 1), with the J replaced with K in the settings listed throughout the example.

Torque-Control Switch Closed

The pickup comparator in *Figure 4.16* compares the pickup setting (51PJP) to the maximum phase current, I_P, if the Torque-Control Switch is closed. I_P is also routed to the curve timing/reset timing functions. The Relay Word bit logic outputs operate as follows with the Torque-Control Switch closed:

51P =	1 (logical 1)	if I_P > pickup setting 51PJP and the phase time-overcurrent element is timing or is timed out on its curve
	0 (logical 0)	if $I_P \leq$ pickup setting 51PJP
51PT =	1 (logical 1)	if I_P > pickup setting 51PJP and the phase time-overcurrent element is timed out on its curve
	0 (logical 0)	if I_P > pickup setting 51PJP and the phase time-overcurrent element is timing, but not yet timed out on its curve
	0 (logical 0)	if $I_P \leq$ pickup setting 51PJP
51PR =	1 (logical 1)	if $I_P \leq$ pickup setting 51PJP and the phase time-overcurrent element is fully reset
	0 (logical 0)	if $I_P \leq$ pickup setting 51PJP and the phase time-overcurrent element is timing to reset (not yet fully reset)
	0 (logical 0)	if I_P > pickup setting 51PJP and the phase time-overcurrent element is timing or is timed out on its curve

Torque-Control Switch Open

If the Torque-Control Switch in *Figure 4.16* is open, maximum phase current, I_P, cannot get through to the pickup comparator (setting 51PJP) and the curve timing/reset timing functions. For example, suppose that the Torque-Control Switch is closed, I_P is:

I_P > pickup setting 51PJP

and the phase time-overcurrent element is timing or is timed out on its curve. If the Torque-Control Switch is then opened, I_P effectively appears as a magnitude of zero (0) to the pickup comparator:

I_P = 0 A (effective) < pickup setting 51PJP

resulting in Relay Word bit 51P deasserting to logical 0. I_P also effectively appears as a magnitude of zero (0) to the curve timing/reset timing functions, resulting in Relay Word bit 51PT also deasserting to logical 0. The phase time-overcurrent element then starts to time to reset. Relay Word bit 51PR asserts to logical 1 when the phase time-overcurrent element is fully reset.

Torque-Control Setting

Refer to *Figure 4.16*.

4.18 | Protection Functions
Time-Overcurrent Elements

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 192 of 1080
Wolfe

SEL<small>OGIC</small> control equation torque-control settings (e.g., 51PTC) cannot be set directly to logical 0 or NA. The following are setting examples of SEL<small>OGIC</small> control equation torque-control setting 51PTC for phase time-overcurrent element 51PT.

51PTC := **1**   Setting 51PTC set directly to logical 1: Torque-Control Switch is closed and maximum-phase time-overcurrent element 51PT is enabled.
Note: Some of the overcurrent element SEL<small>OGIC</small> control equation torque-control settings are set directly to logical 1 (e.g., 51PTC := 1) for the factory-default settings. See *Factory-Default Settings on page 9.61* for a list of the factory-default settings.

51PTC := **IN105**   Input IN105 deasserted (51PTC := IN105 = logical 0): The Torque-Control Switch opens and maximum-phase time-overcurrent element 51PT is defeated and nonoperational, regardless of any other setting. Input IN105 asserted (51PTC := IN105 = logical 1): The Torque-Control Switch closes and maximum-phase time-overcurrent element 51PT is enabled.

Reset Timing Details (51PT Element Example)

The maximum-phase time-overcurrent element J characteristic settings are used in this example, which corresponds to the case where E51P := 1, or where E51P := 2, and the characteristic switch setting 51PSW := logical 0. The same reset timing behavior applies to the K characteristic (when 51PSW := logical 1), with the "J" replaced with "K" in the settings listed throughout the example. The J and K characteristics may have different reset settings, for example: 51PJRS := Y and 51PKRS := N. If the characteristic is switched while the element is performing reset timing, the new characteristic will start in the fully reset position.

Refer to *Figure 4.16*.

Any time current I_P goes above pickup setting 51PJP and the phase time-overcurrent element starts timing, Relay Word bit 51PR (reset indication) = logical 0. If the phase time-overcurrent element times out on its curve, Relay Word bit 51PT (curve time-out indication) = logical 1.

Setting 51PJRS := Y

If electromechanical reset timing setting 51PJRS := Y, the maximum-phase time-overcurrent element reset timing emulates electromechanical reset timing (see *Table 9.5* and *Table 9.6*). If maximum phase current, I_P, goes above pickup setting 51PJP (element is timing or already timed out) and then current I_P goes below 51PJP, the element starts to time to reset, emulating electromechanical reset timing. Relay Word bit 51PR (resetting indication) = logical 1 when the element is fully reset.

Setting 51PRS := N

If reset timing setting 51PJRS := N, element 51PT reset timing has a 1-cycle dropout. If current I_P goes above pickup setting 51PJP (element is timing or already timed out) and then current I_P goes below pickup setting 51PJP, there is a 1-cycle delay before the element fully resets. Relay word bit 51PR (reset indication) = logical 1 when the element is fully reset.

Protection Functions 4.19
Time-Overcurrent Elements

Wolfe

Single-Phase Time-Overcurrent Elements

The single-phase time-overcurrent elements 51AT, 51BT, and 51CT are dual-characteristic elements that operate on phase currents I_A, I_B, and I_C, respectively. See *Table 4.1* for figure references, enable setting, Relay Word bits, and controlling SELOGIC equation names.

The single-phase elements operate on the individual phase currents, subject to assignment by setting IPCONN—see *Table 9.8*.

The 51AT, 51BT, and 51CT elements are controlled by the enable setting E51ABC. There are separate torque-control and characteristic switch SELOGIC control equation settings for each of the single-phase time-overcurrent elements.

To understand the operation of *Figure 4.17–Figure 4.19*, follow the explanation given for *Figure 4.16* in the preceding subsection *Maximum-Phase Time-Overcurrent Elements on page 4.15*, substituting current I_A, I_B, or I_C (A-phase, B-phase, or C-phase current) for maximum phase current I_P and substituting like settings and Relay Word bits.

Settings Ranges

The single-phase time-overcurrent element settings are shown in *Table 4.5*:

Table 4.5   A-, B-, or C-Phase Time-Overcurrent Element Settings

Setting[a,b]	Definition	Range
51*n*JP 51*n*KP	pickup	0.05–3.20 A secondary

Accuracy

See *Specifications on page 1.9*.

Neutral Time-Overcurrent Elements

GLOBAL SETTING EGNDSW
See Ground Switch Logic on page 4.76.

When Global setting EGNDSW := N, two dual-characteristic neutral time-overcurrent elements 51N1T and 51N2T are available. They operate on channel IN current. See *Table 4.1* for figure references, enable settings, Relay Word bits, and controlling SELOGIC equation names.

The neutral time-overcurrent elements 51N1T and 51N2T are controlled by enable settings E51N1 and E51N2, respectively. The neutral time-overcurrent elements are independent, with separate torque-control and characteristic switch SELOGIC control equation settings.

When Global setting EGNDSW := Y (factory default), the E51N1 and E51N2 enable settings are forced to N, disabling the neutral time-overcurrent elements. The ground time-overcurrent elements described in *Ground Time-Overcurrent Elements on page 4.23* are still available.

To understand the operation of *Figure 4.20* and *Figure 4.21*, follow the explanation given for *Figure 4.16* in *Maximum-Phase Time-Overcurrent Elements on page 4.15*, substituting channel IN current for maximum phase current IP and substituting like settings and Relay Word bits.

[a] Dual-Characteristic Time-Overcurrent element settings: the letters J and K in the setting names represent the two characteristics.

[b] n = 1 or 2.

[c] The electromechanical reset setting (51NnJRS) is not available when the curve selection setting (51NnJC) is set to a recloser curve. In this situation, 51NnJRS is effectively set to N internally. Similarly, setting 51NnKRS is not available when setting 51NnKC is set to a recloser curve.

[d] SELOGIC control equation torque-control setting (e.g., 51NnTC) cannot be set directly to logical 0 or NA.

[e] SELOGIC Characteristic Switch Setting (51NnSW) is only available when E51Nn := 2. 51NnSW cannot be set to NA.

See *Time-Overcurrent Curves on page 9.4* for curve selection details.

Accuracy

See *Specifications on page 1.9*.

Ground Time-Overcurrent Elements

Two dual-characteristic ground time-overcurrent elements 51G1T and 51G2T are always available. They operate on ground current I_G that comes from one of two sources:

➤ channel IN current

➤ calculated residual-ground current $3I_0 = I_A + I_B + I_C$ (vector summation)

EGNDSW, CTR, AND CTRN SETTINGS CONFIGURATIONS
See Table 4.23.

CHANNEL IN WIRING CONFIGURATIONS
See Table 4.23.

PHASE CURRENT CHANNEL ASSIGNMENTS
Made with Global setting IPCONN (see Table 9.8)

See *Table 4.1* for figure references, enable settings, Relay Word bits, and controlling SELOGIC equation names.

The ground overcurrent elements 51G1T and 51G2T are controlled by enable settings E51G1 and E51G2, respectively. The ground time-overcurrent elements are independent, with separate torque-control and characteristic switch SELOGIC control equation settings.

4.24 | Protection Functions
Time-Overcurrent Elements

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 198 of 1080
Wolfe

When Global setting EGNDSW := Y, ground current I_G is automatically switched between the following:

➤ channel IN current (for low ground current values)

➤ calculated residual-ground current $3I_0 = I_A + I_B + I_C$
(for higher ground current values)

This gives the ground time-overcurrent elements the widest range for pickup settings and operating current. It especially provides for increased sensitivity at lower ground current values. In this application, the pickup settings 51G1JP, 51G1KP, 51G2JP, and 51G2KP must be made on the channel IN current base.

Factory defaults (see Scenario 1 in *Table 4.23*):

➤ Global setting EGNDSW := Y

➤ Channel IN wired residually with the phase current channels

Therefore, the phase channel current base is the same as the channel IN current base and the respective current transformer ratio settings should be set the same (CTR = CTRN).

If uncommon Scenario 2 in *Table 4.23* is true for an SEL-651R-2 installation, then refer to *50G1P Setting Example When EGNDSW := Y and CTR ≠ CTRN on page 4.10* for guidelines on making like pickup settings 51G1JP, 51G1KP, 51G2JP, and 51G2KP on the channel IN current base.

When Global setting EGNDSW := N (see Scenarios 3 and 4 in *Table 4.23*), ground current IG is fixed on the calculated residual-ground current $3I_0 = I_A + I_B + I_C$ (vector summation). In this application, the pickup settings 51G1JP, 51G1KP, 51G2JP, and 51G2KP must be made on the phase current channel base.

To understand the operation of *Figure 4.22* and *Figure 4.23*, follow the explanation given for *Figure 4.16* in the preceding subsection *Maximum-Phase Time-Overcurrent Elements on page 4.15*, substituting ground current I_G for maximum phase current I_P and substituting like settings and Relay Word bits.

RESIDUALLY CONNECTED CHANNEL IN
The following figures show the factory-default wiring for channel IN wired residually with the phase current channels for the various recloser applications: Figure 2.49, Figure 2.52, Figure 2.55, Figure 2.59, Figure 2.62, Figure 2.65, Figure 2.68, Figure 2.70, Figure 2.71, Figure 2.76, and Figure 2.77.

Negative-Sequence Time-Overcurrent Element

The negative-sequence time-overcurrent element 51QT is a dual-characteristic element that operates from the calculated negative-sequence currents $3I_2$. See *Table 4.1* for figure references, enable settings, Relay Word bits, and controlling SELOGIC equation names.

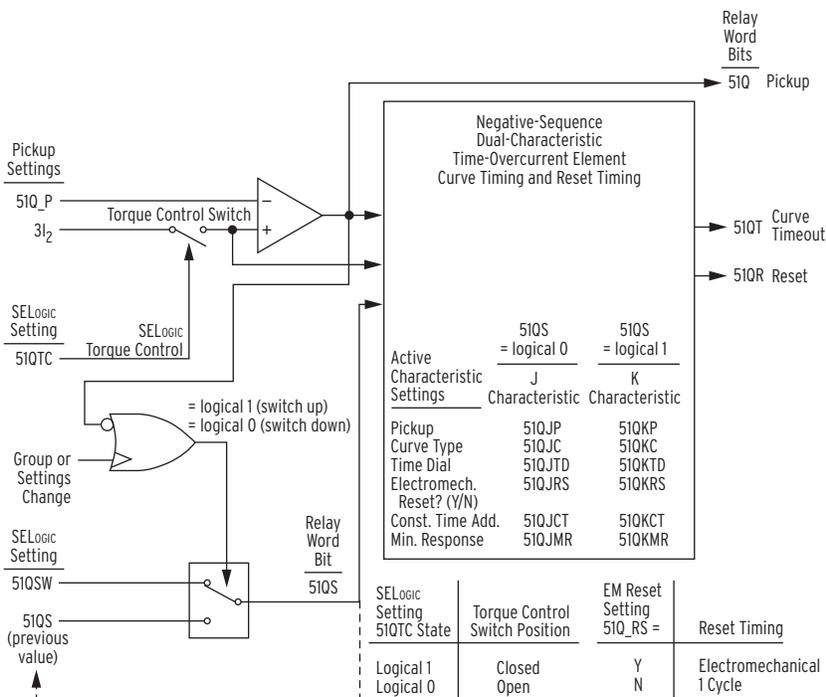
The 51QT element is controlled by the enable setting E51Q.


Figure 4.24   Negative-Sequence Time-Overcurrent Element 51QT

IMPORTANT: See Setting Negative-Sequence Time-Overcurrent Elements on page 4.105 for information on setting negative-sequence overcurrent elements.

To understand the operation of *Figure 4.24*, follow the explanation given for *Figure 4.16* in the preceding subsection *Maximum-Phase Time-Overcurrent Elements on page 4.15*, substituting negative-sequence current $3I_2$ [$3I_2 = I_A + a^2 \cdot I_B + a \cdot I_C$ (ABC rotation), $3I_2 = I_A + a^2 \cdot I_C + a \cdot I_B$ (ACB rotation), where $a = 1 \angle 120°$ and $a^2 = 1 \angle -120°$] for maximum phase current I_P and substituting like settings and Relay Word bits.

Settings Ranges

The negative-sequence time-overcurrent element settings are shown in *Table 4.8*.

Table 4.8   Negative-Sequence Time-Overcurrent Element Settings (Sheet 1 of 2)

Setting[a]	Definition	Range
51QJP 51QKP	pickup	0.05–3.20 A secondary
51QJC 51QKC	curve type	U1–U5 (U.S. curves; see *Table 9.5*), C1–C5 (IEC curves; see *Table 9.6*), recloser curves (see *Table 9.7*)
51QJTD 51QKTD	time dial (has no multiplying effect on constant time adder or minimum response time)	0.50–15.00 (U.S. curves), 0.05–1.00 (IEC curves), 0.10–2.00 (recloser curves)
51QJRS[b] 51QKRS	electromechanical reset timing	Y, N

Table 4.8 Negative-Sequence Time-Overcurrent Element Settings (Sheet 2 of 2)

Setting[a]	Definition	Range
51QJCT 51QKCT	constant time adder— adds additional time to curve	0.00–60.00 cycles (no effect if set = 0.00)
51QJMR 51QKMR	minimum response time—flattens curve at set time; curve can operate no faster than this set time	0.00–60.00 cycles (no effect if set = 0.00)
51QTC[c]	SELOGIC control equation torque-control setting	Relay Word bits referenced in *Table F.1* or set directly to logical 1 (=1)
51QSW[d]	SELOGIC characteristic switch setting	Relay Word bits referenced in *Table F.1*

[a] Dual-Characteristic Time-Overcurrent element settings: the letters J and K in the setting names represent the two characteristics.

[b] The electromechanical reset setting (51QJRS) is not available when the curve selection setting (51QJC) is set to a recloser curve. In this situation, 51QJRS is effectively set to "N" internally. Similarly, setting 51QKRS is not available when setting 51QKC is set to a recloser curve.

[c] SELOGIC control equation torque-control setting (e.g., 51QTC) cannot be set directly to logical 0 or NA.

[d] SELOGIC Characteristic Switch Setting (51QSW) is available only when E51Q := 2. 51QSW cannot be set to NA.

See *Time-Overcurrent Curves on page 9.4* for curve selection details.

Accuracy

See *Specifications on page 1.9*.

Second-Harmonic Blocking Logic

When a distribution feeder supplies many transformers, magnetizing inrush currents may cause sensitive overcurrent elements to operate when the line is energized. The second-harmonic blocking logic can prevent this by blocking such elements until inrush currents have subsided. As shown in *Figure 4.25*, this logic uses the ratio of the second-harmonic content of each phase to the fundamental current of the same phase to calculate the percent second-harmonic content.

When SELOGIC torque-control equation HBL2TC = logical 1, and if the second-harmonic content exceeds the adjustable pickup threshold (HBL2P) for the pickup time delay (HBL2PU), the blocking Relay Word bit for that phase asserts. Once asserted, if the second-harmonic content falls below the threshold for the dropout time delay (HBL2DO), the output deasserts. If any of the phase outputs assert, Relay Word bit HBL2T also asserts.

Page 1203 of 2102
Protection Functions 4.29
Second-Harmonic Blocking Logic
Wolfe

Table 4.9   Second-Harmonic Blocking Settings

Setting	Definition	Range
EHBL2	Enable Second-Harmonic Blocking	Y, N
HBL2P	Second-Harmonic Pickup Threshold	5–100%
HBL2PU	Second-Harmonic Blocking Timer Pickup	0.00–16,000.00 cycles
HBL2DO	Second-Harmonic Blocking Timer Dropout	0.00–16,000.00 cycles
HBL2TC	Second-Harmonic Blocking Torque Control	Relay Word bits referenced in *Table F.1* or set directly to logical 1 (= 1)[a]

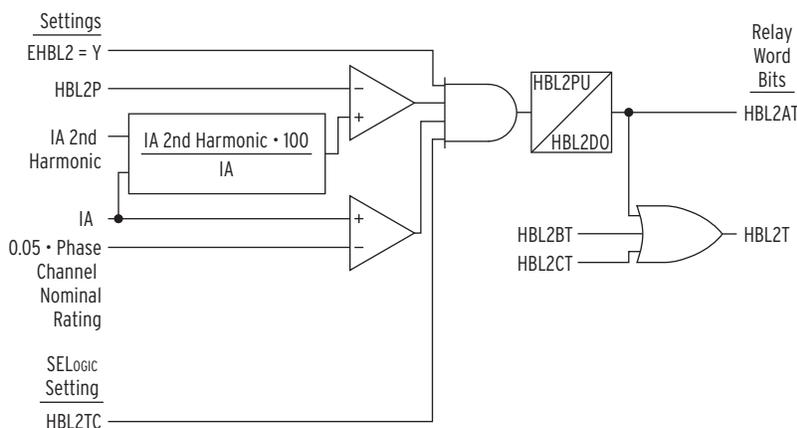
[a] SELOGIC control equation torque-control settings (e.g., HBL2TC) cannot be set directly to logical 0.


Figure 4.25   Second-Harmonic Blocking Logic

Table 4.10   Second-Harmonic Blocking Logic Outputs

Relay Word Bit	Definition	Application
HBL2AT	A-phase second-harmonic element timed out	Overcurrent element control
HBL2BT	B-phase second-harmonic element timed out	Overcurrent element control
HBL2CT	C-phase second-harmonic element timed out	Overcurrent element control
HBL2T	One or more phases second-harmonic element timed out	Overcurrent element control

Second-harmonic blocking elements are typically used to supervise sensitive overcurrent elements. CT saturation during faults can cause the relay to measure second-harmonic current. The second-harmonic blocking element may also assert briefly when the fundamental frequency current changes. Either condition might delay the supervised element. Set an unsupervised element above the expected inrush current to provide fast protection during large faults. Set the second-harmonic blocking timer pickup for more than one cycle in applications that cannot tolerate the element operating because of current changes.

Settings Examples

Instantaneous Overcurrent Element Blocking

In this example, including second-harmonic blocking element HBL2T in the torque-control equation for Level 1 Phase Overcurrent element 50P1 helps prevent operation because of transformer inrush.

50P1P = **2.00 A**

50P2P = **4.00 A**

50P1D = **2.00 cycles**

50P1TC = **NOT HBL2T**

50P2TC = **1**

TR3P = **...OR 50P1T OR 50P2T OR...**

The Level 1 time delay 50P1D allows time for the blocking element to assert. Level 2 Phase Overcurrent element setting 50P2P is high enough that the element will not operate when the line is energized but low enough to operate for high-current faults when current transformer saturation or fundamental frequency current change might briefly block the Level 1 element.

Time-Overcurrent Element Blocking

For time-overcurrent elements, it may be desirable for the element to continue timing when transformer inrush is detected, yet trip the breaker if the time-overcurrent element remains asserted after the inrush conditions have subsided.

51PJP = **1.2 A**

HBL2DO = **2.00 cycles**

51PTC = **1**

TR3P = **...OR 51PT AND NOT HBL2T OR...**

ER = **...OR R_TRIG 51P OR R_TRIG 51PT OR...**

In this example, 51PT is allowed to assert regardless of the state of the second-harmonic blocking element. However, 51PT cannot cause a trip if HBL2T is asserted. Dropout timer HBL2DO ensures that the blocking condition is maintained until 51PT deasserts. If electromechanical reset is disabled (51PR = N), 51PT remains asserted for 1 cycle after the phase current falls below pickup setting 51PJP. HBL2DO may be increased to provide additional security should the second-harmonic current fall below the pickup threshold before the fundamental frequency current falls below the overcurrent element pickup. Because the relay may not trip when 51PT asserts, the ER Event Report Trigger SELOGIC control equation is modified to trigger an event report. This event report can be used to evaluate the effectiveness of the harmonic blocking and determine if setting adjustments are necessary.

Changing the Pickup of a Time-Overcurrent Element

Use the second-harmonic blocking elements to increase the pickup current of a time-overcurrent element during inrush conditions without changing the time delay characteristics. For example,

51PJP = **1.2 A**

50P3P = **2.5 A**

51PTC = **NOT HBL2T OR 50P3**

TR3P = **...OR 51PT OR...**

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 205 of 1080
Wolfe

Protection Functions
Voltage Elements   4.31

In this example, the 51P time-overcurrent element operates if the second-harmonic blocking element is deasserted or the phase current exceeds the Level 3 Phase Instantaneous Overcurrent setting. If second-harmonic blocking is asserted and the phase current is below the Level 3 Phase Instantaneous Overcurrent setting, the time-overcurrent element 51P does not operate. Thus the pickup of the 51P element is increased from 1.2 A secondary to 2.5 A secondary during inrush. Once the maximum phase current exceeds 50P3P, the timing of the 51P element does not change, so coordination is maintained for large faults.

As shown in *Figure 4.16*, if torque-control equation 51PTC deasserts, the Level 1 phase time-overcurrent element may fully or partially reset. When second-harmonic blocking elements are included in torque-control equations for time-overcurrent elements, the element will need to time from reset after the blocking element deasserts. Consider this when evaluating time-overcurrent coordination and when reviewing event reports in which harmonic blocking has operated.

Voltage Elements

Enable numerous voltage elements by making the Enable setting:

EVOLT := **N (None), VY, VZ, or BOTH**

The VY-terminal voltage elements are enabled when EVOLT := VY or BOTH. The VZ-terminal voltage elements are enabled if EVOLT := VZ or BOTH.

Voltage Values

The VY-terminal voltage elements operate off of Y-terminal voltage values shown in *Table 4.11* (Z-terminal is similar—see terminals in *Figure 2.42*).

Table 4.11   Voltage Values Used by VY-Terminal Voltage Elements (VZ-Terminal Similar)

Voltage	Description
$V_{A(Y)}$	A-phase voltage[a]
$V_{B(Y)}$	B-phase voltage[a]
$V_{C(Y)}$	C-phase voltage[a]
$V_{AB(Y)}$	Phase-to-phase voltage
$V_{BC(Y)}$	Phase-to-phase voltage
$V_{CA(Y)}$	Phase-to-phase voltage
$3V_{0(Y)}$	Zero-sequence voltage
$V_{2(Y)}$	Negative-sequence voltage
$V_{1(Y)}$	Positive-sequence voltage

[a] Global setting VYCONN determines the assignment of VY-terminal voltage inputs V1Y, V2Y, and V3Y to phases A, B, and C, thus allowing voltages $V_{A(Y)}$, $V_{B(Y)}$, and $V_{C(Y)}$ to be derived (see Table 9.9).

Voltage Element Settings

Table 4.12 lists available voltage elements and the corresponding voltage inputs and settings ranges for SEL-651R-2 recloser controls.

Voltage Element Operation

Note that the voltage elements in *Table 4.12* and *Figure 4.26–Figure 4.29* are a combination of "undervoltage" (Device 27) and "overvoltage" (Device 59) type elements. Undervoltage elements (Device 27) assert when the operating voltage goes below the corresponding pickup setting. Overvoltage elements (Device 59) assert when the operating voltage goes above the corresponding pickup setting.

Undervoltage Element Operation Example

Refer to *Figure 4.26* (top of the figure).

Attachment to Response to AG-2 Question No. 68(g)
Page 1211 of 1080
Protection Functions 4.37
Voltage Elements
Wolfe

Pickup setting 27YP1P is compared to the magnitudes of the individual phase voltages $V_{A(Y)}$, $V_{B(Y)}$, and $V_{C(Y)}$. The logic outputs in *Figure 4.26* are the following Relay Word bits:

27YA1 =	1 (logical 1)	if $V_{A(Y)}$ < pickup setting 27YP1P
	0 (logical 0)	if $V_{A(Y)}$ ≥ pickup setting 27YP1P
27YB1 =	1 (logical 1)	if $V_{B(Y)}$ < pickup setting 27YP1P
	0 (logical 0)	if $V_{B(Y)}$ ≥ pickup setting 27YP1P
27YC1 =	1 (logical 1)	if $V_{C(Y)}$ < pickup setting 27YP1P
	0 (logical 0)	if $V_{C(Y)}$ ≥ pickup setting 27YP1P
3P27Y =	1 (logical 1)	if all three Relay Word bits 27YA1, 27YB1, and 27YC1 are asserted (27YA1 = 1, 27YB1 = 1, and 27YC1 = 1)
	0 (logical 0)	if at least one of the Relay Word bits 27YA1, 27YB1, or 27YC1 is deasserted (e.g., 27YA1 = 0)

Overvoltage Element Operation Example

Refer to *Figure 4.26* (bottom of the figure).

Pickup setting 59YP1P is compared to the magnitudes of the individual phase voltages $V_{A(Y)}$, $V_{B(Y)}$, and $V_{C(Y)}$. The logic outputs in *Figure 4.26* are the following Relay Word bits:

59YA1 =	1 (logical 1)	if $V_{A(Y)}$ > pickup setting 59YP1P
	0 (logical 0)	if $V_{A(Y)}$ ≤ pickup setting 59YP1P
59YB1 =	1 (logical 1)	if $V_{B(Y)}$ > pickup setting 59YP1P
	0 (logical 0)	if $V_{B(Y)}$ ≤ pickup setting 59YP1P
59YC1 =	1 (logical 1)	if $V_{C(Y)}$ > pickup setting 59YP1P
	0 (logical 0)	if $V_{C(Y)}$ ≤ pickup setting 59YP1P
3P59Y =	1 (logical 1)	if all three Relay Word bits 59YA1, 59YB1, and 59YC1 are asserted (59YA1 = 1, 59YB1 = 1, and 59YC1 = 1)
	0 (logical 0)	if at least one of the Relay Word bits 59YA1, 59YB1, or 59YC1 is deasserted (e.g., 59YA1 = 0)

Detecting Absence of Voltage with Various LEA Voltage Inputs

Refer to *PT Ratio Setting Adjustments on page 9.42* and *Voltage-Related Settings and LEA Inputs (Group Settings) on page 9.47* for voltage divider information and background for connecting to various LEA voltage inputs. Using 8 Vac LEA voltage inputs as an example, convert low-end pickup setting 27YP1P = 1.00 V (300 V base) to the 8 V base:

1.00 V • 8/300 = 0.0267 V (8 V base)

The accuracy variation for the effective 0.0267 V (8 V base) pickup setting (from *Specifications on page 1.9*) is:

0.01 V + 0.0267 V • (0.01) = 0.01 V (8 V base)

So, the effective 0.0267 V (8 V base) pickup could vary from:

0.0167 V (= 0.0267 V – 0.01 V)
  to
0.0367 V (= 0.0267 V + 0.01 V)

4.38 | Protection Functions
Synchronism-Check Elements

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 212 of 1080
Wolfe

Converting the effective pickup (with "positive" variation) 0.0367 V (8 V base) to the primary voltage level (via the 10,000 ratio voltage divider for 8 V LEA applications) results in:

0.0367 V • 10,000 = 367 V primary

Apply this resultant primary value to a 4.16 kV primary system (2.4 kV phase-to-neutral):

(367 V/2400 V) • 100% = 15.3%

An adequate voltage measurement to determine absence of voltage on a 4.16 kV primary system is 15.3% of nominal voltage (which includes the above stated "positive" accuracy variation). Again, this is achieved with the previously mentioned example pickup setting 27YP1P = 1.00 V (300 V base).

Alternatively, for a 12.47 kV primary system (7.2 kV phase-neutral), 15% of nominal voltage would extrapolate to the following voltage on the the 8 V LEA input:

(15%/100%) • (7200 V/10,000) = 0.108 V (8 V base)

Factoring in accuracy variation, the effective 0.108 V (8 V base) pickup could vary from:

0.098 V (= 0.108 V – 0.01 V)
    to
0.118 V (= 0.108 V + 0.01 V)

This is a much tighter variation than the preceding 4.16 kV primary system example, because a 12.47 kV primary system provides more signal to the 10,000 ratio voltage divider than does a 4.16 kV primary system. The 27YP1P pickup setting (300 V base) for this 12.47 kV primary system example (15% of nominal voltage) would be:

0.108 V • 300/8 = 4.05 V (300 V base)

Synchronism-Check Elements

Enable the two single-phase synchronism-check elements by making the enable setting:

E25 := **Y**

Synchronism check is performed with the voltages connected to voltage terminals V1Y and NY, and V1Z and NZ (see *Figure 2.5*, *Figure 2.9*, *Figure 2.42*, and *Table 9.9*). In this synchronism-check subsection, these voltages are referred to as the following:

V_P and V_S

Global setting FSELECT selects which voltage functions as V_P (and by default, which functions as V_S), as shown in *Table 4.13*.

Table 4.13   Voltages V_P and V_S for Synchronism Check

Global Setting FSELECT :=	VP = Voltage connected to voltage terminals:	VS = Voltage connected to voltage terminals:
VY	V1Y, NY	V1Z, NZ
VZ	V1Z, NZ	V1Y, NY

Page 213 of 1080
Protection Functions 4.39
Synchronism-Check Elements
Wolfe

The two synchronism-check elements use the same voltage window (to ensure healthy voltage) and slip frequency settings (see *Figure 4.30*). They have separate angle settings (see *Figure 4.31*).

If voltages V_P and V_S are static (not slipping with respect to one another) or the breaker close time setting TCLOSD := 0.00, the two synchronism-check elements operate as shown in the top of *Figure 4.31*. The angle settings are checked for synchronism-check closing.

If voltages V_P and V_S are not static (slipping with respect to one another) the two synchronism-check elements operate as shown in the bottom of *Figure 4.31*. The angle difference is compensated by breaker close time, and the breaker is ideally closed at a zero degree phase angle difference to minimize system shock.

These synchronism-check elements are explained in detail in the following text.

Setting SYNCP

Sometimes synchronism-check voltage V_S cannot be in phase with voltage V_P. This happens in applications where any of the following are true:

➤ Phase-to-phase voltage is connected to one voltage input and phase-to-neutral voltage is connected to the other voltage input.

➤ The voltage inputs are connected to different phases.

➤ One of the voltage inputs is connected beyond a delta-wye transformer.

For such applications requiring V_S to be at a constant phase angle difference from V_P, an angle setting is made with the SYNCP setting (see *Table 4.14*). The angle setting choices (0, 30, …, 300, or 330 degrees) for setting SYNCP are referenced to V_P, and they indicate how many degrees V_S constantly lags V_P.

System Rotation Can Affect Setting SYNCP

If system rotation is ABC and V_P is connected to Phase A and V_S is connected to Phase B, then SYNCP := 120 (V_S lags V_P by 120 degrees). If voltage input connections are the same, but system rotation is ACB, then setting SYNCP := 240 degrees (V_S constantly lags V_P by 240°). See the SEL Application Guide *AG2002-02, Compensate for Constant Phase Angle Difference in Synchronism Check with the SEL-351 Relay Family* for more information on setting SYNCP with an angle setting. This guide is still generally applicable to the SEL-651R-2.

Other Uses for Voltage Window Elements

If voltage limits 25VPLO/25VPHI and 25VSLO/25VSHI are applicable to other control schemes, Relay Word bits 59VP and 59VS can be used in other logic at the same time they are used in the synchronism-check logic.

If synchronism check is not being used, Relay Word bits 59VP and 59VS can still be used in other logic, with the voltage limit settings set as desired. Enable the synchronism-check logic (setting E25 := Y) and make settings 25VPLO/25VPHI and 25VSLO/25VSHI. Apply Relay Word bits 59VP and 59VS in the desired logic scheme, using SELOGIC control equations. Even though synchronism-check logic is enabled, the synchronism-check logic outputs (Relay Word bits SF, 25A1, and 25A2) do not need to be used.

Block Synchronism-Check Conditions

Refer to *Figure 4.30.*

The synchronism-check element slip frequency calculator runs if both voltages V_P and V_S are healthy (59VP and 59VS asserted to logical 1) and the SELOGIC control equation setting BSYNCH (Block Synchronism Check) is deasserted (= logical 0). Setting BSYNCH is most commonly set to block synchronism-check operation when the circuit breaker is closed (synchronism check is only needed when the circuit breaker is open):

> BSYNCH := **52A3P** see *Figure 6.2*

In addition, synchronism-check operation can be blocked when the relay is tripping:

> BSYNCH := **... OR TRIP3P**

Slip Frequency Calculator

Refer to *Figure 4.30.*

The synchronism-check element Slip Frequency Calculator in *Figure 4.30* runs if voltages V_P and V_S are healthy (59VP and 59VS asserted to logical 1) and the SELOGIC control equation setting BSYNCH (Block Synchronism Check) is deasserted (= logical 0). The Slip Frequency Calculator output is:

> Slip Frequency = $f_P - f_S$ (in units of Hz = slip cycles/second)
>
> f_P = frequency of voltage V_P (in units of Hz = cycles/second)
>
> f_S = frequency of voltage V_S (in units of Hz = cycles/second)

A complete slip cycle is one single 360-degree revolution of one voltage (e.g., V_S) by another voltage (e.g., V_P). Both voltages are thought of as revolving phasor-wise, so the "slipping" of V_S past V_P is the relative revolving of V_S past V_P.

For example, in *Figure 4.30*, if voltage V_P has a frequency of 59.95 Hz and voltage V_S has a frequency of 60.05 Hz, the difference between them is the slip frequency:

> Slip Frequency = 59.95 Hz – 60.05 Hz = –0.10 Hz = –0.10 slip cycles/second

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 217 of 1080
Protection Functions 4.43
Synchronism-Check Elements
Wolfe

The slip frequency in this example is negative, indicating that voltage V_S is not "slipping" behind voltage V_P, but is in fact "slipping" ahead of voltage V_P. In a time period of one second, the angular distance between voltage V_P and voltage V_S changes by 0.10 slip cycles, which translates into:

0.10 slip cycles/second • (360°/slip cycle) • 1 second = 36°

Thus, in a time period of one second, the angular distance between voltage V_P and voltage V_S changes by 36 degrees.

The absolute value of the Slip Frequency output is run through a comparator and if the slip frequency is less than the maximum slip frequency setting, 25SF, Relay Word bit SF asserts to logical 1.

The SF Relay Word bit may not operate if the VP frequency is changing too quickly. This will not be an issue when the synchronism-check elements are being used to verify phase alignment across breakers in transmission systems with multiple paths. However, if one side of the circuit breaker is expected to vary in frequency (perhaps it is connected to a generator bus), the best configuration for using the synchronism-check element is to connect the VP terminals to the more stable system (e.g., the power grid) while the VS terminals are connected to the machine.

Generator Application for SSLOW and SFAST

Relay Word bits SSLOW and SFAST in *Figure 4.30* indicate the relative slip of voltages V_P and V_S.

The SFAST, SSLOW, and SF operation over various slip frequencies is summarized in *Table 4.15* and *Figure 4.32*.

Table 4.15   SSLOW and SFAST Relay Word Bit Operating Range

Slip Frequency Range	Relay Word Bit SSLOW	Relay Word Bit SFAST
$(f_P–f_S) < –0.005$ Hz	logical 1	logical 0
$–0.005 < (f_P–f_S) < 0.005$	logical 0	logical 0
$(f_P–f_S) > 0.005$ Hz	logical 0	logical 1

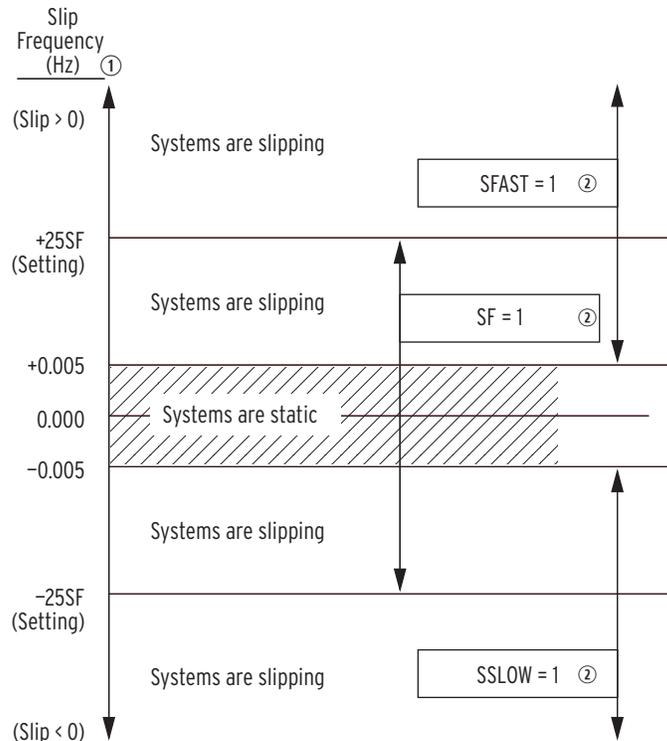
Synchronism-Check Elements

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 218 of 1080
Wolfe


① Slip Frequency = Frequency of **VP** signal−Frequency of **VS** signal; ② from Figure 4.30.

Figure 4.32   Graphical Depiction of SFAST, SSLOW, and SF Operation Range

An application idea for SSLOW and SFAST is a small generator installation.

> With some logic (perhaps to create pulsing signals), SSLOW and SFAST might be used as signals (via output contacts) to the generator governor. SSLOW indicates that the V_P frequency is lower than the V_S frequency, while SFAST indicates that the V_P frequency is higher than the V_S frequency. If the enable into the slip frequency calculator in *Figure 4.30* is disabled (e.g., SELOGIC setting BSYNCH asserts because the breaker closes; BSYNCH = 52A3P OR …), then both SSLOW = logical 0 and SFAST = logical 0, regardless of slip frequency.

The SEL-651R-2 SSLOW and SFAST outputs are available over a larger slip frequency range than the synchronism-check element and are independent of the SF Relay Word bit. If the slip frequency is greater than the 25SF setting, Relay Word bit SF will be deasserted (logical 0) and one of the SSLOW or SFAST Relay Word bits may operate to indicate the polarity of the slip frequency.

The SSLOW and SFAST Relay Word bits may not operate reliably if the V_P frequency is changing too quickly. The best configuration for using the SSLOW and SFAST outputs is when the voltage terminal selected by Global setting FSELECT (and thus V_P) is connected to the most stable system (e.g., the power grid), while the other terminal (V_S) is connected to the "machine" side of the circuit breaker.

Angle Difference Calculator

The synchronism-check element Angle Difference Calculator in *Figure 4.31* runs if the absolute value of slip frequency is less than the maximum slip frequency setting 25SF (Relay Word bit SF is asserted).

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Protection Functions 4.45
Page 219 of 1080
Synchronism-Check Elements
Wolfe

Voltages V_P and V_S are "Static"

Refer to the top of *Figure 4.31*.

If the absolute value of slip frequency is less than or equal to 0.005 Hz, the Angle Difference Calculator does not take into account breaker close time—it presumes voltages V_P and V_S are "static" (not "slipping" with respect to one another). This would usually be the case for an open breaker with voltages V_P and V_S that are paralleled via some other electric path in the power system. The Angle Difference Calculator calculates the angle difference between voltages V_P and V_S:

$$\text{Angle Difference} = \left| (\angle V_P - \angle V_S) \right|$$

For example, if SYNCP := 90 (indicating V_S constantly lags $V_P = V_A$ by 90 degrees), but V_S actually lags V_A by 100 angular degrees on the power system at a given instant, the Angle Difference Calculator automatically accounts for the 90 degrees and:

$$\text{Angle Difference} = \left| (\angle V_P - \angle V_S) \right| = 10°$$

Also, if breaker close time setting TCLOSD := 0.00, the Angle Difference Calculator does not take into account breaker close time, even if the voltages V_P and V_S are "slipping" with respect to one another. Thus, synchronism-check elements 25A1 or 25A2 assert to logical 1 if the Angle Difference is less than corresponding maximum angle setting 25ANG1 or 25ANG2.

Voltages V_P and V_S are "Slipping"

Refer to bottom of *Figure 4.31*.

If the absolute value of slip frequency is greater than 0.005 Hz and breaker close time setting TCLOSD ≠ 0.00, the Angle Difference Calculator takes the breaker close time into account with breaker close time setting TCLOSD (set in cycles; see *Figure 4.33*). The Angle Difference Calculator calculates the Angle Difference between voltages V_P and V_S, compensated with the breaker close time:

$$\text{Angle Difference} = \left| (\angle V_P - \angle V_S) + \left[(f_P - f_S) \bullet \text{ TCLOSD} \bullet \left(\frac{1 \text{ second}}{\text{NFREQ}} \right) \bullet \left(\frac{360°}{\text{slip cycle}} \right) \right] \right|$$

Equation 4.4

NFREQ is the Global setting that defines the nominal system frequency as 50 or 60 Hz.

Angle Difference Example (Voltages V_p and V_S are "Slipping")

Refer to bottom of *Figure 4.31*.

For example, for a 60 Hz nominal system, if the breaker close time is 10 cycles, set TCLOSD = 10 and NFREQ = 60. Presume the slip frequency is the example slip frequency calculated previously. The Angle Difference Calculator calculates the angle difference between voltages V_P and V_S, compensated with the breaker close time as shown in *Equation 4.4*.

4.46 Protection Functions
Synchronism-Check Elements

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 220 of 1080
Wolfe

Intermediate calculations:

$(f_P - f_S) = (59.95 \text{ Hz} - 60.05 \text{ Hz}) = -0.10 \text{ Hz} = -0.10 \text{ slip cycles/second}$

TCLOSD • (1 second/60 cycles) = 10 cycles • (1 second/60 cycles)
= 0.167 second

Resulting in (using *Equation 4.4*):

$$= \left| (\angle V_P - \angle V_S) + [-0.10 \bullet \ 0.167 \bullet \ 360°] \right|$$
$$= \left| (\angle V_P - \angle V_S) - 6° \right|$$

NOTE: The angle compensation in Figure 4.33 appears much greater than six degrees. Figure 4.33 is for general illustrative purposes only.

During the breaker close time (TCLOSD), the voltage angle difference between voltages V_P and V_S changes by six degrees. This six degree angle compensation is applied to voltage V_S, resulting in derived voltage V_S*, as shown in *Figure 4.33*.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 22 of 1080

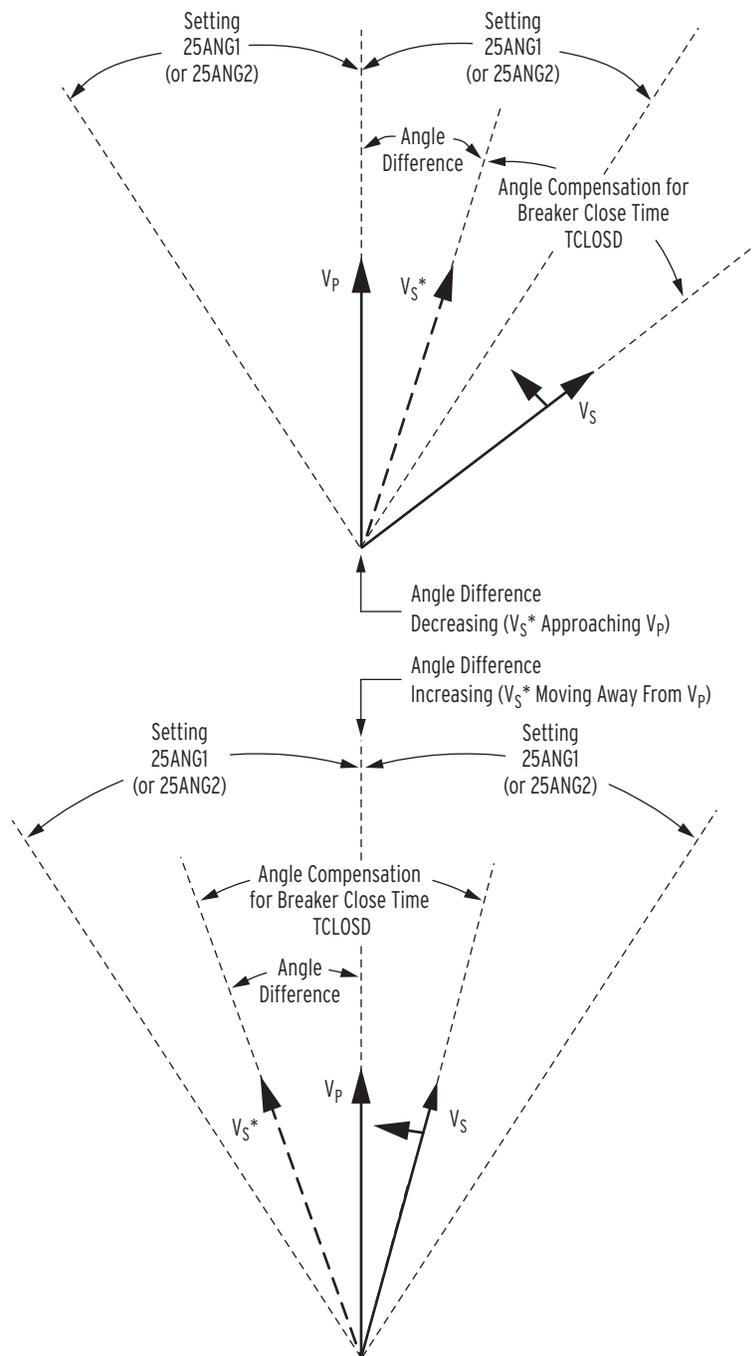
Protection Functions 4.47
Synchronism Check Elements


Figure 4.33   Angle Difference Between V_P and V_S Compensated by Breaker Close Time ($f_P < f_S$ and V_P Shown as Reference in This Example)

The top of *Figure 4.33* shows the Angle Difference *decreasing*—V_S^* is approaching V_P. Ideally, circuit breaker closing is initiated when V_S^* is in phase with V_P (Angle Difference = 0 degrees). Then when the circuit breaker main contacts finally close, V_S is in phase with V_P, minimizing system shock.

The bottom of *Figure 4.33* shows the Angle Difference *increasing*—V_S^* is moving away from V_P. Ideally, circuit breaker closing is initiated when V_S^* is in phase with V_P (Angle Difference = 0 degrees). Then when the circuit breaker main contacts finally close, V_S is in phase with V_P. But in this case,

4.48 | Protection Functions
Synchronism-Check Elements

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 222 of 1080
Wolfe

V_S* has already moved past V_P. To initiate circuit breaker closing when V_S* is in phase with V_P (Angle Difference = 0 degrees), V_S* has to slip around another revolution, relative to V_P.

Synchronism-Check Element Outputs

Synchronism-check element outputs (Relay Word bits 25A1 and 25A2 in *Figure 4.31*) assert to logical 1 for the conditions explained in the following text.

Voltages V_P and V_S are "Static" or Setting TCLOSD := 0.00

Refer to top of *Figure 4.31*.

If V_P and V_S are "static" (not "slipping" with respect to one another), the Angle Difference between them remains constant—it is not possible to close the circuit breaker at an ideal zero degree phase angle difference. Thus, synchronism-check elements 25A1 or 25A2 assert to logical 1 if the Angle Difference is less than corresponding maximum angle setting 25ANG1 or 25ANG2.

Also, if breaker close time setting (TCLOSD := 0.00), the Angle Difference Calculator does not take into account breaker close time, even if the voltages V_P and V_S are "slipping" with respect to one another. Thus, synchronism-check elements 25A1 or 25A2 assert to logical 1 if the Angle Difference is less than corresponding maximum angle setting 25ANG1 or 25ANG2.

Voltages V_P and V_S are "Slipping" and Setting TCLOSD $\neq$ 0.00

Refer to bottom of *Figure 4.31*. If V_P and V_S are "slipping" with respect to one another and breaker close time setting TCLOSD $\neq$ 0.00, the Angle Difference (compensated by breaker close time TCLOSD) changes through time. Synchronism-check element 25A1 or 25A2 asserts to logical 1 for any one of the following three scenarios.

1. The top of *Figure 4.33* shows the Angle Difference *decreasing*—V_S* is approaching V_P. When V_S* is in phase with V_P (Angle Difference = 0 degrees), synchronism-check elements 25A1 and 25A2 assert to logical 1.

2. The bottom of *Figure 4.33* shows the Angle Difference *increasing*—V_S* is moving away from V_P. V_S* was in phase with V_P (Angle Difference = 0 degrees), but has now moved past V_P. If the Angle Difference is *increasing*, but the Angle Difference is still less than maximum angle settings 25ANG1 or 25ANG2, then corresponding synchronism-check elements 25A1 or 25A2 assert to logical 1.

   In this scenario of the Angle Difference increasing, but still being less than maximum angle settings 25ANG1 or 25ANG2, the operation of corresponding synchronism-check elements 25A1 and 25A2 becomes *less restrictive*. Synchronism-check breaker closing does not have to wait for voltage V_S* to slip around again in phase with V_P (Angle Difference = 0 degrees). There might not be enough time to wait for this to happen. Thus, the "Angle Difference = 0 degrees" restriction is eased for this scenario.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 223 of 1080
Wolfe

Protection Functions 4.49
Synchronism-Check Elements

NOTE: In scenario 3, concerning reclose supervision, SELOGIC control equation setting 79CLS3P (reclose supervision for three-phase reclosing) is used. The logic discussed in scenario 3 is equally applicable to reclose supervision settings 79CLSA, 79CLSB, and 79CLSC if single-pole reclosing is enabled (Group setting ESPB := Y).

3. Refer to *Reclose Supervision Logic on page 6.10*.

Refer to the bottom of *Figure 6.6*. If timer 79CLSD is set greater than zero (e.g., 79CLSD := 60.00 cycles) and it times out without SELOGIC control equation setting 79CLS3P (Reclose Supervision) asserting to logical 1, the relay goes to the Lockout State (see top of *Figure 6.7*).

Refer to the top of *Figure 6.6*. If timer 79CLSD is set to zero (79CLSD := 0.00), SELOGIC control equation setting 79CLS3P (Reclose Supervision) is checked only once to see if it is asserted to logical 1. If it is not asserted to logical 1, the relay goes to the Lockout State.

Refer to the top of *Figure 4.33*. Ideally, circuit breaker closing is initiated when V_S^* is in phase with V_P (Angle Difference = 0 degrees). Then when the circuit breaker main contacts finally close, V_S is in-phase with V_P, minimizing system shock. But with time limitations imposed by timer 79CLSD, this may not be possible. To try to avoid going to the Lockout State, the following logic is employed:

If 79CLS3P has not asserted to logical 1 while timer 79CLSD is timing (or timer 79CLSD is set to zero and only one check of 79CLS3P is made), the synchronism-check logic at the bottom of *Figure 4.31* becomes *less restrictive* at the "instant" timer 79CLSD is going to time out (or make the single check). It drops the requirement of waiting until the *decreasing* Angle Difference (V_S^* approaching V_P) brings V_S^* in phase with V_P (Angle Difference = 0 degrees). Instead, it just checks to see that the Angle Difference is less than angle settings 25ANG1 or 25ANG2.

If the Angle Difference is less than angle setting 25ANG1 or 25ANG2, then the corresponding Relay Word bit, 25A1 or 25A2, asserts to logical 1 for that "instant" (asserts for 1/4 cycle).

For example, if SELOGIC control equation setting 79CLS3P (Reclose Supervision) is set as follows:

79CLS3P := **(25A1 OR ...) AND ...**

and the angle difference is less than angle setting 25ANG1 at that "instant," setting 79CLS3P asserts to logical 1 for 1/4 cycle, allowing the sealed-in open interval time-out to propagate to the close logic in *Figure 6.3*. Element 25A2 operates similarly. The AND is used in the example to include hardware requirements for reclosing. For example, AND TCCAP can be included to indicate sufficient stored energy for trips/reclosures.

Synchronism-Check Applications for Automatic Reclosing and Manual Closing

Refer to *Close Logic on page 6.5* and *Reclose Supervision Logic on page 6.10*.

For example, set 25ANG1 := 15 degrees and use the resultant synchronism-check element in the reclosing relay logic to supervise automatic reclosing:

79CLS3P := **(25A1 OR ...) AND ...** see *Figure 6.6*

4.50 | Protection Functions
Frequency Elements

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 224 of 1080
Wolfe

Set 25ANG2 := 25 degrees and use the resultant synchronism-check element in manual close logic to supervise manual closing (e.g., assert IN106 to initiate manual close):

> SV01 := **(R_TRIG IN106 or CC3) AND NOT TRIP3P OR SV01 AND NOT SV01T AND NOT TRIP3P AND NOT CLOSE3P**

> CL3P := **SV01 AND (25A2 OR ...)** see *Figure 6.3*

Set SV01PU := *n* cycles and SV01DO := 0.00 cycles. Choose *n* to represent the maximum period that a manual close may be attempted. A typical setting for *n* might be 50 to 600 cycles (approximately 1 to 10 seconds).

The timer effectively stretches the one processing interval CC3 pulse (asserted by the **CLOSE** command or via DNP3, Modbus, or SEL Fast Operate protocols—see *Section 10: Communications*) to improve the chances of closing if the synchronism-check element is not asserted at the instant the command is received. Other possible inputs to initiate manual closing include using a local bit (R_TRIG LB*n*), remote bit (R_TRIG RB*n*), or programmable operator control bit (PB*n*).

The rising edge operator "R_TRIG" on IN106 prevents a maintained assertion to logical 1 from creating a standing close condition. The NOT TRIP3P term defeats the manual close window if a relay trip is detected. The NOT CLOSE3P term cancels the timing once the close logic is activated. Other conditions could be added to defeat the manual close.

In this example, the angular difference across the circuit breaker can be greater for a manual close (25 degrees) than for an automatic reclose (15 degrees).

A single output contact (e.g., OUT102 := CLOSE3P) can provide the close function for both automatic reclosing and manual closing (see *Figure 6.1* logic output).

Frequency Elements

Six frequency elements are available. Enable the desired number of frequency elements with the E81 enable setting:

> E81 := **N (none), 1–6**

The enable setting is shown in *Figure 4.38*. Frequency is determined from the voltage applied to the recloser control voltage terminals V1Y and NY or V1Z and NZ, as shown in *Table 4.16*.

Table 4.16   Voltage Source for Frequency Elements

Global Setting FSELECT :=	Frequency for 81 elements measured on voltage terminals:
OFF	N/A[a]
VY	V1Y, NY
VZ	V1Z, NZ

[a] When Global setting FSELECT := OFF, the SEL-651R-2 will measure the frequency for frequency tracking and metering. See Frequency Source Selection Setting (FSELECT) on page 9.33 for more information on frequency tracking. When Global setting FSELECT := OFF, the enable setting E81 is forced to N and cannot be changed.

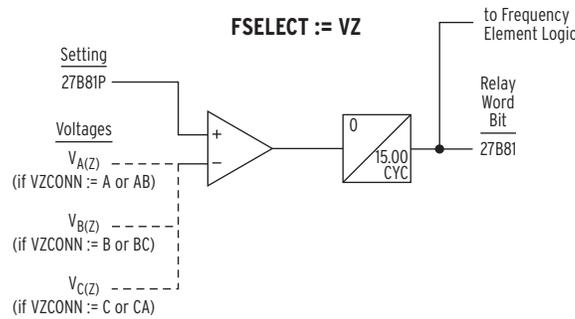

Figure 4.37 Undervoltage Block for Frequency Elements When FSELECT := VZ and Single-Phase Voltage Connected

Frequency Element Settings

Table 4.17 Frequency Elements Settings and Settings Ranges

Setting	Definition	Range
27B81P	undervoltage frequency element block (see *Figure 4.34–Figure 4.37*)	12.50–300.00 V secondary
81D1P	frequency element 1 pickup	40.00–65.00 Hz
81D1D	frequency element 1 time delay	2.00–16000.00 cycles, in 0.25-cycle steps
81D2P	frequency element 2 pickup	40.00–65.00 Hz
81D2D	frequency element 2 time delay	2.00–16000.00 cycles, in 0.25-cycle steps
81D3P	frequency element 3 pickup	40.00–65.00 Hz
81D3D	frequency element 3 time delay	2.00–16000.00 cycles, in 0.25-cycle steps
81D4P	frequency element 4 pickup	40.00–65.00 Hz
81D4D	frequency element 4 time delay	2.00–16000.00 cycles, in 0.25-cycle steps
81D5P	frequency element 5 pickup	40.00–65.00 Hz
81D5D	frequency element 5 time delay	2.00–16000.00 cycles, in 0.25-cycle steps
81D6P	frequency element 6 pickup	40.00–65.00 Hz
81D6D	frequency element 6 time delay	2.00–16000.00 cycles, in 0.25-cycle steps

Frequency element time delays are best set to no less than five cycles. Frequency is determined by a zero-crossing technique on voltage terminal VnY and NY or VnZ and NZ (where n = 1, 2, or 3). If voltage waveform offset occurs (e.g., because of a fault), then frequency may be off for a few cycles. A 5-cycle or greater time delay (e.g., 81D1D := 6.00 cycles) overrides this occurrence.

Create Over- and Underfrequency Elements

Refer to *Figure 4.38*.

Note that pickup settings 81D1P–81D6P are compared to setting NFREQ. NFREQ is the nominal frequency setting (a global setting), set to 50 or 60 Hz.

Overfrequency Element

For example, make the following settings:

NFREQ := **60 Hz** nominal system frequency is 60 Hz

E81 ≥ **1** enable frequency element 1

81D1P := **61.25 Hz** frequency element 1 pickup

With these settings (81D1P ≥ NFREQ), the overfrequency part of frequency element 1 logic is enabled. 81D1 and 81D1T operate as overfrequency elements. 81D1 is used in testing only.

Underfrequency Element

For example, make the following settings:

NFREQ := **60 Hz** nominal system frequency is 60 Hz

E81 ≥ **2** enable frequency element 2

81D2P := **59.65 Hz** frequency element 2 pickup

With these settings (81D2P < NFREQ) the underfrequency part of frequency element 2 logic is enabled. Elements 81D2 and 81D2T operate as underfrequency elements. Setting 81D2 is used in testing only.

Frequency Element Operation

Refer to *Figure 4.38*.

Overfrequency Element Operation

With the previous overfrequency element example settings, if system frequency is less than or equal to 61.25 Hz (81D1P := 61.25 Hz), frequency element 1 outputs:

81D1 := **logical 0** instantaneous element

81D1T := **logical 0** time delayed element

If system frequency is greater than 61.25 Hz (81D1P := 61.25 Hz), frequency element 1 outputs:

81D1 := **logical 1** instantaneous element

81D2T := **logical 1** time delayed element

Relay Word bit 81D1T asserts to logical 1 only after time delay 81D1D.

Underfrequency Element Operation

With the previous underfrequency element example settings, if system frequency is less than or equal to 59.65 Hz (81D2P := 59.65 Hz), frequency element 2 outputs:

81D2 := **logical 1** instantaneous element

81D2T := **logical 1** time delayed element

Relay Word bit 81D2T asserts to logical 1 only after time delay 81D2D.

If system frequency is greater than 59.65 Hz (81D2P := 59.65 Hz), frequency element 2 outputs:

81D2 := **logical 0** instantaneous element

81D2T := **logical 0** time delayed element

Instantaneous Frequency Element Response Time

The SEL-651R-2 uses a zero-crossing period measurement technique on the voltage applied to the V1Y and NY or V1Z and NZ terminals (see *Table 4.16*) to determine the power system frequency. There is an intrinsic delay in the instantaneous frequency elements 81D1–81D6 that depends on the pickup setting, the applied signal, and the conditions prior to the change in signal.

The 81D1–81D6 response time to a valid frequency change is typically 1 to 3 cycles, but could be as long as 4.5 cycles. This detail is usually of little consequence when longer time delay settings 81D1D–81D6D are used. However, understanding this built-in delay may help during testing and in certain applications.

System disturbances that do not cause the undervoltage block element 27B81 to assert can affect the voltage signals and cause the instantaneous frequency elements to briefly assert when there is no actual frequency deviation. For this reason, time-delayed elements 81D1T–81D6T are the only Relay Word bits intended for use in protection, and the recommended minimum time-delay setting is 5 cycles.

Frequency Element Time Delay Considerations

The SEL-651R-2 frequency element time delay settings are specified in cycles, as shown in *Table 4.17*. When determining the time delay settings appropriate for an application, keep in mind that the power system frequency will not be at the nominal value (50 Hz or 60 Hz) when an overfrequency or underfrequency element times out. The relay adjusts the processing algorithms to track the system frequency, and this can make the time delay seem shorter or longer than anticipated.

For pickup settings that are close to the nominal frequency, or with short duration delays, the nominal frequency may be used to convert the desired time delay from seconds into cycles with negligible error.

However, for elements that have pickup settings (81DnP) set further from the nominal frequency, or elements set with long time delays (81DnD), the over- or underfrequency pickup setting may be used for the time-base conversion instead.

The observed time delay will depend on the frequency of the power system or test set during the excursion and whether the frequency change is applied as step-change, a ramp, or some other function.

Overfrequency Element Settings Example

On a 60 Hz nominal system, the planner requires an overfrequency trip to occur if the frequency exceeds 60.60 Hz for 30 seconds.

Convert the time delay from seconds to cycles by using the pickup setting.

$$
\begin{aligned}
\text{Delay} &= 30 \text{ s} \cdot 60.60 \text{ Hz} \\
&= 30 \text{ s} \cdot 60.60 \text{ cycles/s} \\
&= 1818 \text{ cycles}
\end{aligned}
$$

Required settings.

> 81D1P = **60.60 Hz**
>
> 81D1D = **1818.00 cycles**

Using the example settings, if a 60.80 Hz signal is applied for testing, the SEL-651R-2 would be expected to assert 81D1T approximately

> 1818 cycles / 60.80 cycles/s = 29.90 s

after the instantaneous element (81D1) pickup.

If the nominal frequency 60 Hz conversion factor had been used instead, the time delay setting would have been 1800 cycles and the same 60.80 Hz test signal would be expected to assert 81D1T approximately 1800 cycles / 60.80 cycles/s = 29.61 s after the instantaneous element (81D1) pickup.

In this test example, the time delay settings adjustment improves the timing accuracy by about 1 percent.

Frequency Element Voltage Control

Refer to *Figure 4.34–Figure 4.38*.

Note that all six frequency elements are controlled by the same undervoltage element (Relay Word bit 27B81). For example, when Global setting FSELECT := VY and Global setting VYCONN := BAC, Relay Word bit 27B81 asserts to logical 1 and blocks the frequency element operation if any voltage ($V_{A(Y)}$, $V_{B(Y)}$, or $V_{C(Y)}$) goes below voltage pickup 27B81P. This control prevents erroneous frequency element operation following fault inception.

However, if Global setting FSELECT := VY and Global setting VYCONN := B, Relay Word bit 27B81 is affected only by the voltage applied to the V1Y and NY terminals (which is the quantity $V_{B(Y)}$; see *Figure 9.21*). This is useful in applications where there is only single-phase voltage available to the relay.

Other Uses for Undervoltage Element 27B81

If voltage pickup setting 27B81P is applicable to other control schemes, Relay Word bit 27B81 can be used in other logic at the same time it is used in the frequency element logic.

For example, in the SEL-651R-2 default settings, the torque-control equation 81RTC uses the logical inverse of 27B81, as described in *Rate-of-Change-of-Frequency (81R) Protection on page 4.57*.

If frequency elements are not being used, Relay Word bit 27B81 can still be used in other logic, with voltage setting 27B81P set as desired. Enable the frequency elements (setting E81 ≥1) and set 27B81P as desired. Apply Relay Word bit 27B81 in the desired logic scheme by using SELOGIC control equations. Even though frequency elements are enabled, the frequency element outputs (Relay Word bits 81D1T–81D6T) do not have to be used.

Frequency Element Uses

The instantaneous frequency elements (81D1–81D6) are used in testing only.

The time-delayed frequency elements (81D1T–81D6T) are used for underfrequency load shedding, frequency restoration, and other schemes.

Rate-of-Change-of-Frequency (81R) Protection
Wolfe

Underfrequency Load Shedding

For example, to implement underfrequency load shedding with time-delayed frequency element 81D1T, make the SELOGIC control equations trip setting:

TR3P := **... OR 81D1T**

Also make the following settings:

79DTL3P := **... OR 81D1T** drive-to-lockout—see *Figure 6.11* and following explanation

T11_LED := **81D1T** over- and underfrequency target LED—see *Figure 11.13* and *Table 5.3*

See the note at the end of the *Table 5.2* for background on making these two settings when making trip settings changes/modifications.

Rate-of-Change-of-Frequency (81R) Protection

Frequency changes occur in power systems when there is an unbalance between load and active power generated. Typically, generator control action adjusts the generated active power and restores the frequency to nominal value. Failure of such control action can lead to system instability unless remedial action, such as load shedding, is taken. You can use the rate-of-change-of-frequency element to detect and initiate a remedial action. The SEL-651R-2 provides four rate-of-change-of-frequency elements. *Table 4.18* shows the settings available for the elements.

Table 4.18 Rate-of-Change-of-Frequency Settings

Setting	Definition	Setting Range
E81R	Enable Rate-of-Change-of-Frequency Elements	N, 1–4
81RTC	Rate-of-Change-of-Frequency Elements Torque Control	Relay Word bits referenced in *Table F.1* or set directly to logical 1 (= 1)
81R1P	Element 1 Pickup	OFF, 0.10–15.00 Hz/sec
81R1TRND	Element 1 Trend	INC, DEC, ABS
81R1PU	Element 1 Timer Pickup	0.10–60.00 sec
81R1DO	Element 1 Timer Dropout	0.00–60.00 sec
81R2P	Element 2 Pickup	OFF, 0.10–15.00 Hz/sec
81R2TRND	Element 2 Trend	INC, DEC, ABS
81R2PU	Element 2 Timer Pickup	0.10–60.00 sec
81R2DO	Element 2 Timer Dropout	0.00–60.00 sec
81R3P	Element 3 Pickup	OFF, 0.10–15.00 Hz/sec
81R3TRND	Element 3 Trend	INC, DEC, ABS
81R3PU	Element 3 Timer Pickup	0.10–60.00 sec
81R3DO	Element 3 Timer Dropout	0.00–60.00 sec
81R4P	Element 4 Pickup	OFF, 0.10–15.00 Hz/sec
81R4TRND	Element 4 Trend	INC, DEC, ABS
81R4PU	Element 4 Timer Pickup	0.10–60.00 sec
81R4DO	Element 4 Timer Dropout	0.00–60.00 sec

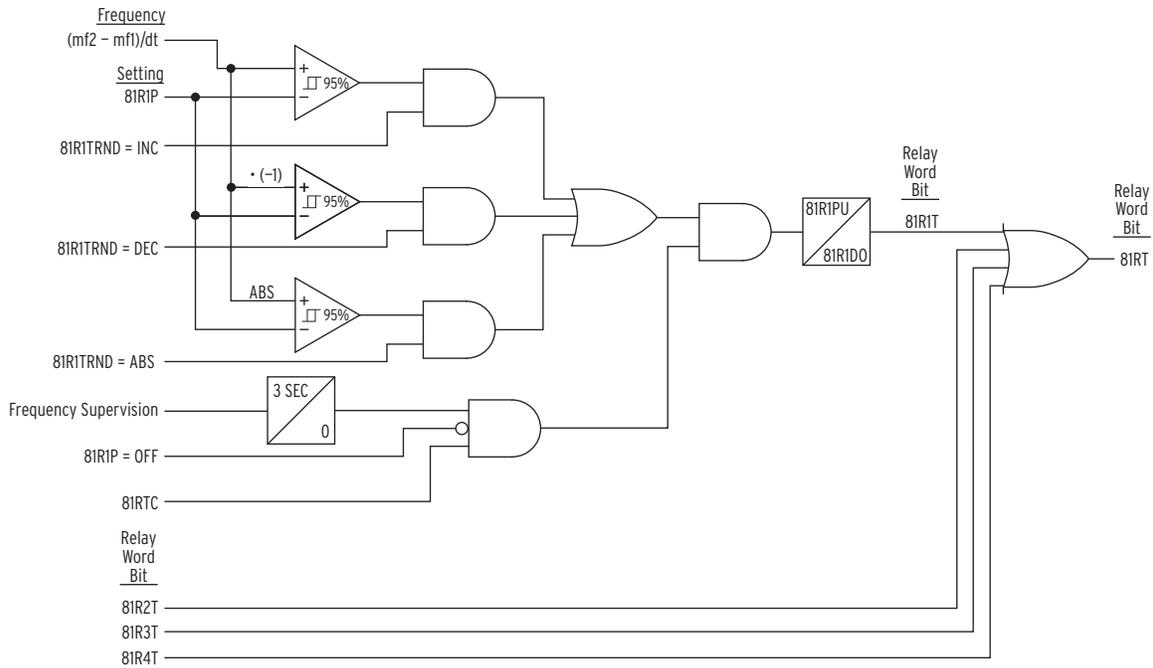
Attachment to Response to AG-2 Question No. 68(g)
Page 232 of 1080
Wolfe

NOTE: The SEL-651R-2 measures the system frequency from the voltage input defined by the FSELECT setting. See Table 4.16 for related details.

Use E81R setting to enable the desired number of the elements. *Figure 4.39* shows the element logic. The SEL-651R-2 measures frequency (mf1), and then measures a second frequency (mf2) after a time window (dt) determined by the Trip Level setting (81RnP). The element has hysteresis, such that pickup is 100 percent of the 81RnP setting and dropout is 95 percent. *Table 4.19* shows the time windows for different trip level settings. The Relay Word bit 81RT = 81R1T OR 81R2T OR 81R3T OR 81R4T.

The SEL-651R-2 does not track the system frequency when the frequency changes faster than 20 Hz/second, and the 81R elements will not respond.


Logic shown for 81R1T. Logic for 81R2T–81R4T is similar.

Figure 4.39   81R Frequency Rate-of-Change Scheme Logic

Table 4.19   Time Window Versus 81RnP Setting

81RnP Setting (Hz/s)	Time Window (ms)
0.10–0.14	1000
0.15–0.19	666
0.20–0.29	500
0.30–0.39	333
0.40–0.59	250
0.60–1.19	166
1.20–2.39	83
2.40–15.00	41

For testing purposes, the expected pickup time can be calculated by using *Equation 4.5*, the 81RnP pickup setting, the corresponding time window from *Table 4.19*, and the rate-of-change-of-frequency of the applied signal. For a given 81RnP pickup setting, the pickup time of the element decreases as the rate of frequency change increases. Use *Equation 4.5* to select the time delay setting 81RnPU so that the element responds as desired.

Protection Functions 4.59
Voltage Sag, Swell, and Interruption Elements
Wolfe

$$81\mathrm{R}n\mathrm{T}\ \text{Minimum Pickup Time}\ =\ \frac{81\mathrm{R}n\mathrm{P} \bullet\ \text{Time Window}}{\text{Rate of Frequency Change}} + 81\mathrm{R}n\mathrm{PU}$$

Equation 4.5

Set 81R*n* Trend to INC or DEC to limit operation of the element to increasing or decreasing frequency respectively. Set the trend to ABS if you want the element to disregard the frequency trend.

Frequency supervision ensures that the frequency measurement is valid, is between 40 and 70 Hz, and is being measured from the voltage V1Y or V1Z channel, according to the FSELECT setting.

Set 81RTC to limit when the 81R elements are active. The default setting is shown below:

81RTC := **NOT 27B81**

Relay Word bit 27B81 asserts when any of the phase voltages fall below the 27B81P threshold. By default, 27B81P is set to 80.00 V. As a result, when configured with default settings, the 81RTC SELOGIC control equation operates as an undervoltage supervision check for the 81R elements. This supervision is important because it prevents the elements from operating during a fault condition where the system frequency may not be measured accurately. The 27B81P pickup setting should be set so that it asserts for fault conditions. Frequency elements must be enabled to modify 27B81P; if no frequency elements are enabled, then 27B81P is set to its default value of 80.00 V.

Use the Relay Word bit 81R*n*T or 81RT in the SELOGIC trip equations to open appropriate breaker(s) as required by your load shedding scheme.

Voltage Sag, Swell, and Interruption Elements

The SEL-651R-2 has three types of elements to detect voltage disturbances. These elements detect voltage sags, swells, and interruptions (abbreviated as VSSI or SSI). These elements are enabled by Group setting ESSI := Y and controlled by the VINT, VSWELL, and VSAG settings.

The SEL-651R-2 VSSI elements monitor and respond to the three-phase voltages connected to either the VY- or VZ-voltage terminals, as designated by Global setting VSELECT := VY or VZ. If Global setting VSELECT := OFF, enable setting ESSI is forced to N and cannot be changed.

Enter the VSSI element threshold settings VSAG, VSWELL, and VINT in percentage units, which relate to the Positive-Sequence Reference Voltage: Vbase. The use of percentage settings instead of absolute voltage limits allows the SSI elements to perform better in systems that have a range of nominal voltages, with no need to adjust settings for seasonal loading or to set them far apart to accommodate the action of a tap-changing transformer. The SSI elements respond to phase-to-neutral voltages.

The Positive-Sequence Reference Voltage is discussed in its own subsection.

The Voltage Sag, Swell, Interruption Recorder automatically uses the SSI elements. These elements are also available as Relay Word bits, so they can be used in any SELOGIC control equation (see *Sag/Swell/Interruption (SSI) Report on page 12.42*).

Voltage Sag Elements

As shown in *Figure 4.40*, if the magnitude of a voltage drops below the voltage sag pickup threshold for one cycle, the corresponding SAG Relay Word bit for that phase asserts (SAGA, SAGB, or SAGC). If all three SAG*p* elements assert, an additional Relay Word bit asserts—SAG3P. The SAG*p* elements remain asserted until the magnitude of the corresponding voltage rises and remains above the sag dropout threshold for one cycle.

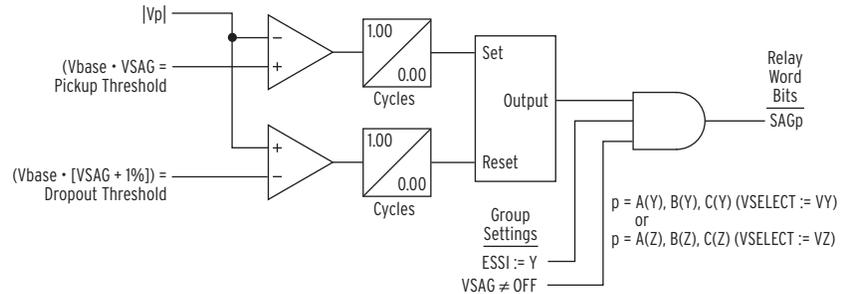
The sag pickup and dropout thresholds depend on Vbase and the VSAG setting.


Figure 4.40   Voltage Sag Elements

Voltage Swell Elements

As shown in *Figure 4.41*, if the magnitude of a voltage rises above the voltage swell pickup threshold for one cycle, the corresponding SW Relay Word bit for that phase asserts (SWA, SWB, or SWC). If all three SW*p* elements assert, an additional Relay Word bit asserts—SW3P. The SW*p* elements remain asserted until the magnitude of the corresponding voltage drops and remains below the swell dropout threshold for one cycle.

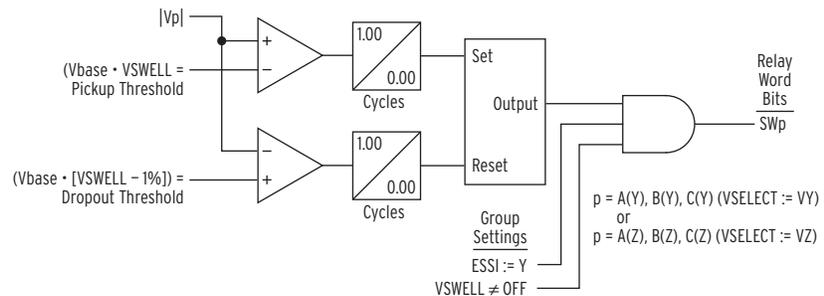
The swell pickup and dropout thresholds depend on Vbase and the VSWELL setting.


Figure 4.41   Voltage Swell Elements

Voltage Interruption Elements

As shown in *Figure 4.42*, if the magnitude of a voltage drops below the voltage interruption pickup threshold for one cycle, the corresponding INT Relay Word bit for that phase asserts (INTA, INTB, or INTC). If all three INT*p* elements assert, an additional Relay Word bit asserts—INT3P. The INT*p* elements remain asserted until the magnitude of the corresponding voltage rises and remains above the interruption dropout threshold for one cycle.

The interruption pickup and dropout thresholds depend on Vbase and the VINT setting.

Protection Functions 4.61
Voltage Sag, Swell, and Interruption Elements

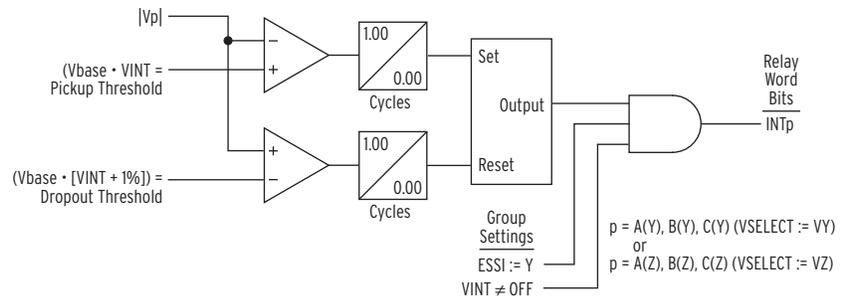
Wolfe


Figure 4.42   Voltage Interruption Elements

Voltage Sag, Swell, and Interruption Elements Settings

The settings ranges for the SSI thresholds are shown in *Table 4.20*.

The factory-default settings match the Interruption, Sag, and Swell definitions in IEEE Std 1159-1995, Classifications of RMS Variations.

**Table 4.20   Sag/Swell/Interruption Elements Settings
(Must First Set ESSI := Y)**

Settings	Definition	Range	Default
VINT[a]	Percentage of memory voltage compared to phase-to-neutral voltage to assert INT elements	OFF, 5 to 95 percent of reference voltage, Vbase	10.00%
VSAG	Percentage of memory voltage compared to phase-to-neutral voltage to assert SAG elements	OFF, 10 to 95 percent of reference voltage, Vbase	90.00%
VSWELL	Percentage of memory voltage compared to phase-to-neutral voltage to assert SW elements	OFF, 105 to 180 percent of reference voltage, Vbase (300 V secondary maximum upper limit)	110.00%

[a] VINT cannot be set higher than VSAG

Positive-Sequence Reference Voltage, Vbase

The relay converts the positive-sequence voltage quantity, $|V1|$, to a reference voltage, Vbase, which has a thermal demand characteristic with a time constant of 100 seconds. This allows the Vbase quantity to slowly track normal system voltage variations (tap changer operations and load effects), but not follow fast system voltage changes (unless the change is held for several seconds).

The $|V1|$ quantity for Vbase is obtained from the voltage terminals selected by the Global setting VSELECT := VY or VZ.

In a balanced three-phase system, $|V1|$ is the average of the three phase-to-neutral voltages.

Vbase tracks $|V1|$, and represents the average phase-to-neutral voltage.

The present value of Vbase can be viewed by issuing the **MET** command (see *MET Command (Metering Data) on page 10.57*).

Vbase Thermal Element Block

To prevent the Vbase quantity from tracking during transient voltage conditions, the calculation of the Vbase thermal element is blocked during the assertion of any of the SAG*p*, SW*p*, or INT*p* Relay Word bits or the SSI_TRIG or FAULT SELOGIC control equation settings. When blocked, the Vbase quantity will not change. This allows the SAG, SWELL, and INT

4.62 | Protection Functions

Attachment to Response to AG-2 Question No. 68(g)
Page 236 of 1080
Wolfe

elements voltage comparisons to be made with the reference Vbase locked at a "healthy" system voltage level. Once the disturbance is over and all of the SAG*p*, SW*p*, and INT*p* Relay Word bits and the FAULT SELOGIC control equation setting deassert, the thermal element for Vbase is unblocked.

Figure 4.43 shows an example of how Vbase tracking is suspended during a voltage disturbance. The example voltage disturbance is the result of an overload condition (three-phase sag), followed by a source-side breaker operation (three-phase interruption). To illustrate the dynamic nature of the VSSI thresholds, the Interrupt, Sag, and Swell pickup levels are also plotted with the factory-default settings for VINT, VSAG, and VSWELL. For this hypothetical three-phase disturbance, V1 has the same magnitude as V_A, V_B, and V_C (as shown). Single-phase disturbances are handled in a similar fashion, except that the phases and V1 will have different voltage magnitudes.

The use of a VSAG setting higher than 90 percent, at the same time as a VSWELL setting lower than 110 percent, should be carefully considered. Moving these thresholds too close together increases the probability that an end of disturbance condition is missed. This could create a false sag or swell condition that may not clear itself until the next disturbance, thus causing the Vbase thermal element to remain blocked.

The SSI_TRIG SELOGIC is described in *SSI Triggering and Recording on page 12.42*.

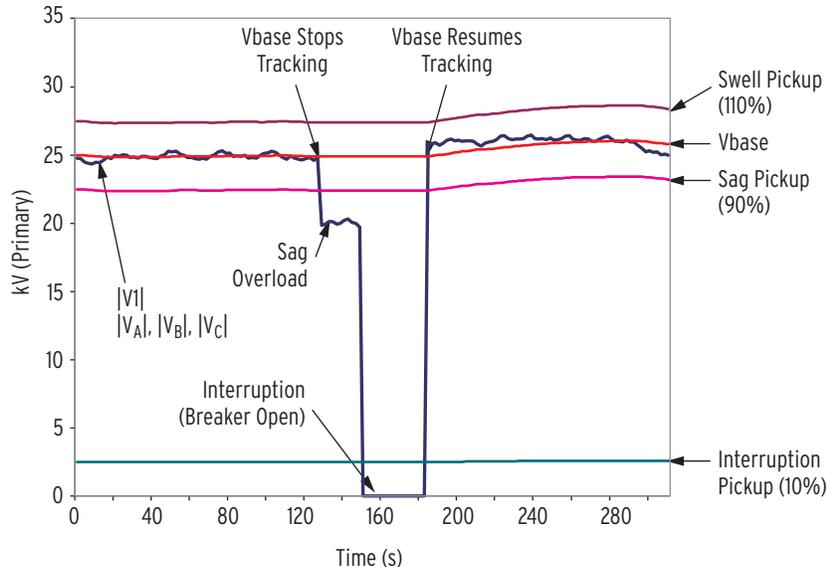
Vbase thermal element blocking by the FAULT Relay Word bit is programmable via SELOGIC setting FAULT. The FAULT Relay Word bit also controls other relay functions; see subsection *SELOGIC Control Equation Setting FAULT on page 5.18*.


Figure 4.43   Vbase Tracking Example (Three-Phase Disturbance)

Vbase Initialization

The Vbase thermal element is automatically initialized when the relay is powered up, and also after a settings change or group change that results in a new ESSI := Y condition.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 237 of 1080
Protection Functions 4.63
Voltage Sag, Swell, and Interruption Elements
Wolfe

You can also force Vbase to initialize by issuing the **SSI R** command (Access Level 1—see *SSI Command (Voltage Sag/Swell/Interruption Report) on page 10.69*).

During initialization, the SSI elements are deasserted and the SSI Recorder is disabled until all of the following conditions are met (for Y-terminal voltages when Global setting VSELECT := VY, or Z-terminal voltages when VSELECT := VZ):

➤ $|V1| > |3V2|$ (correct phase rotation check)

➤ $|V1| > |3V0|$ (correct phase connection check)

➤ V_A, V_B, V_C are all greater than 25 V secondary

➤ SELOGIC control equation setting FAULT is deasserted

➤ $|V1|$ is within three percent of the calculated Vbase value

➤ At least twelve seconds have elapsed

As soon as the above Vbase initialization conditions are satisfied, the SSI Relay Word bits will be allowed to change state according to their settings and the present voltage conditions, and the SSI Recorder will be enabled.

Vbase Tracking Range

The Vbase quantity will track the positive-sequence voltage over a large range of system voltages. The tracking limits are explained below. In normal relay use, these limits are not likely to be reached, because one of the Sag, Swell, or Interruption Relay Word bits would most likely assert for a large voltage deviation, thus blocking the Vbase thermal element from tracking to one of the range limits.

The minimum value that Vbase can achieve is equivalent to a positive-sequence (V1) value of 25 volts secondary. In primary units, the lowest value is the following:

When VSELECT := VY, minimum Vbase $= \dfrac{25V \cdot PTRY}{1000}$ kV.

Equation 4.6

> **NOTE:** If the SEL-651R-2 is ordered with LEA ac inputs on the VY terminals, Equation 4.6 still applies, provided that the PTRY setting is properly scaled—see PT Ratio Setting Adjustments on page 9.42.

When VSELECT := VZ, minimum Vbase $= \dfrac{25V \cdot PTRZ}{1000}$ kV.

Equation 4.7

The maximum value that Vbase can achieve is equivalent to 300 volts secondary divided by VSWELL; therefore, when VSELECT := VY the maximum Vbase in primary kV is the following:

$$\dfrac{300V \cdot PTRY \cdot 100}{VSWELL \cdot 1000} = \dfrac{30V \cdot PTRY}{VSWELL}$$

Equation 4.8

When VSELECT := VZ, the maximum Vbase in primary kV is the following:

$$\dfrac{300V \cdot PTRZ \cdot 100}{VSWELL \cdot 1000} = \dfrac{30V \cdot PTRZ}{VSWELL}$$

Equation 4.9

If the expected higher end of the "normal" system voltage range is close to 300 V secondary, then the VSWELL setting may need to be reduced or turned "OFF" to allow Vbase to track the actual system voltage and not run into the maximum value limit. For example, if connecting to an industrial service rated

4.64 | Protection Functions
Power Elements

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 238 of 1080
Wolfe

at 277 V_{LN} / 480 V_{LL} using the wye-connection (with no PTs), and the normal operating range goes as high as 285 V_{LN}, then the maximum VSWELL setting that will allow for proper Vbase tracking is 105 percent.

SSI Reset Command

After commissioning tests or other maintenance activities that have applied test voltages to the SEL-651R-2, the Vbase element may have locked onto a test voltage. Use the **SSI R** (reset) command once normal system voltages are restored on the voltage terminals. Powering up the relay automatically performs this reset.

See *Commissioning Testing on page 12.46* for more details.

Power Elements

Four independent three-phase power elements are available. Group setting EPWR determines how many (and what type of) power elements are enabled:

EPWR := **N, 3P1, 3P2, 3P3, 3P4**

where

N	None
3P1	Enable one (1) three-phase power element
3P2	Enable two (1, 2) three-phase power elements
3P3	Enable three (1, 2, 3) three-phase power elements
3P4	Enable four (1, 2, 3, 4) three-phase power elements

Each enabled power element can be set to detect real power or reactive power, with the settings in *Table 4.21*. With SELOGIC control equations, the power elements provide a wide variety of protection and control applications. Typical applications are:

➤ Overpower and/or underpower protection/control

➤ Reverse power protection/control

➤ VAR control for capacitor banks

Power Elements Settings

Table 4.21 Three-Phase Power Element Settings and Setting Ranges (EPWR := 3P1, 3P2, 3P3, or 3P4)

Settings	Definition	Range
3PWR1P, 3PWR2P, 3PWR3P, 3PWR4P	Power element pickup	OFF, 1.20–7800.00 VA secondary, three-phase
PWR1T, PWR2T, PWR3T, PWR4T	Power element type	+WATTS, –WATTS, +VARS, –VARS
PWR1D, PWR2D, PWR3D, PWR4D	Power element time delay	0.00–16000 cycles, in 0.25-cycle steps

NOTE: The CT Polarity Setting (CTPOL) on page 9.29 affects the sign of the calculated power quantities.

The power element type settings are made in reference to the load convention:

+WATTS: positive or forward real power
–WATTS: negative or reverse real power
+VARS: positive or forward reactive power (lagging)
–VARS: negative or reverse reactive power (leading)

Power Elements
Wolfe

Power Element Time Delay Setting Considerations

The four power element time delay settings (PWR1D–PWR4D) can be set to have no intentional delay for testing purposes. For protection applications involving the power element Relay Word bits, SEL recommends a minimum time delay setting of 5.00 cycles for general applications. The classical power calculation is a product of voltage and current, to determine the real and reactive power quantities. During a system disturbance, because of the high sensitivity of the power elements, the changing system phase angles and/or frequency shifts may cause transient errors in the power calculation.

Using Power Elements in the Relay Trip Equation

The power elements are not supervised by any relay elements other than the minimum voltage and current level checks shown in *Figure 4.44*. If the protection application requires overcurrent protection in addition to the power elements, there may be a race condition, during a fault, between the overcurrent element(s) and the power element(s) if the power element(s) are still receiving sufficient operating quantities. In some protection schemes this may jeopardize coordination. One method of accommodating this is to increase the power element time delay settings.

Another method is to supervise the power element Relay Word bit(s) with the overcurrent element pickup (the overcurrent element has effective priority over the power element). For example, if the application requires that the relay trip the attached circuit breaker when a forward power flow threshold is exceeded and a phase definite-time overcurrent element is also in the relay trip equation, extra security can be achieved with these SELOGIC control equation settings:

SV01 := **3PWR1 AND NOT 50P1**

SV01PU := **1.50 cycle**

SV01DO := **0.00 cycles**

And Group settings:

50P1P := **5.00 A**

50P1D := **10.00 cycles**

3PWR1P := **360.00 VA**

PWR1T := **+WATTS**

PWR1D := **5.00 cycles**

TR3P := **... OR ... OR SV01T OR 50P1T**

During a fault that exceeds the pickup values of both the power element and the overcurrent element, these settings ensure that the definite-time overcurrent element (50P1T) trips the relay for the fault, even if the PWR1D setting is set to a smaller time delay than the 50P1D setting. Relay Word bit 3PWR1 is ANDed with Relay Word bit NOT(50P1), which effectively blocks 3PWR1 when 50P1 is asserted. The SELOGIC variable timer SV01 is employed in this example to avoid another race condition that could occur if the fault was cleared by another device before the definite-time element time-out, which could potentially deassert 50P1 a few quarter-cycles before 3PWR1 deasserts. Without this timer, an incorrect trip operation may occur.

Accuracy

See *Specifications on page 1.9*.

Three-Phase Power Element Calculations

The numeric method used in the three-phase power elements uses line-to-line voltage and phase current quantities, corrected with zero-sequence voltage and current when unbalanced. The resulting power quantities are subject to the minimum voltage and current tests shown in the lower half of *Figure 4.44*.

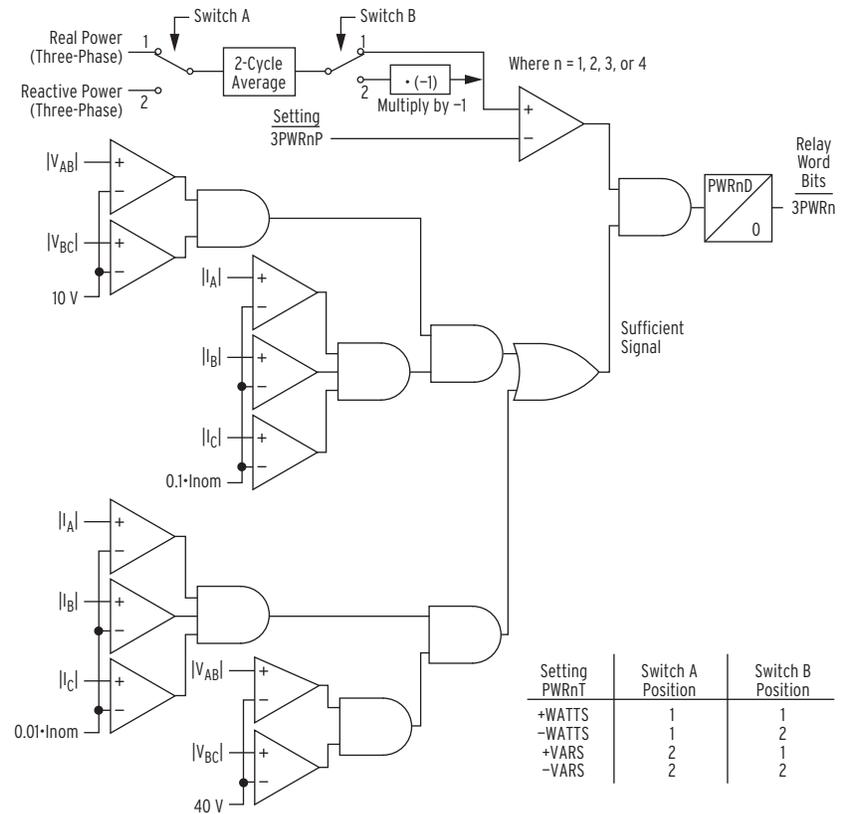
Power Elements Logic Operation


Figure 4.44   Three-Phase Power Elements Logic

Case No. 2018-00295

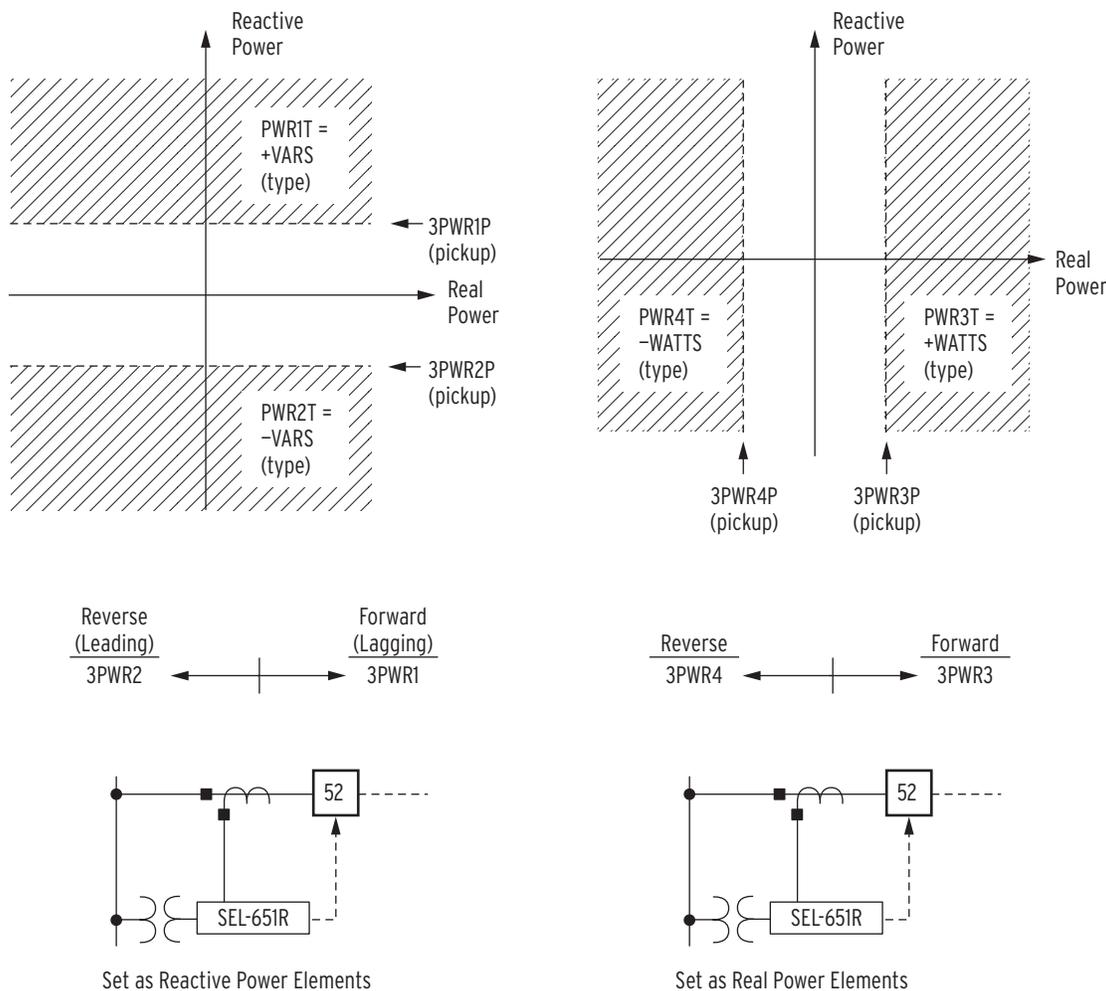
Page 241 of 1080
Protection Functions 4.67
Power Elements
Wolfe


Figure 4.45   Power Elements Operation in the Real/Reactive Power Plane

In *Figure 4.45*, if the three-phase reactive power level is above pickup setting 3PWR*n*P, Relay Word bit 3PWR*n* asserts (3PWR*n* = logical 1) after time delay setting PWR*n*D (*n* = 1–4), subject to the "sufficient signal" conditions.

The "sufficient signal" conditions in *Figure 4.45* require at least 1 percent nominal current if the corresponding phase voltage is greater than 40 V secondary. If the voltage is between 10 and 40 V secondary, at least 10 percent nominal current is required.

Pickup setting 3PWR*n*P is always a positive number value (see *Table 4.21*). Thus, if –WATTS or –VARS are chosen with setting PWR*n*T, the corresponding real or reactive power values have to effectively be multiplied by –1 so that element PWR*n* asserts for negative real or reactive power.

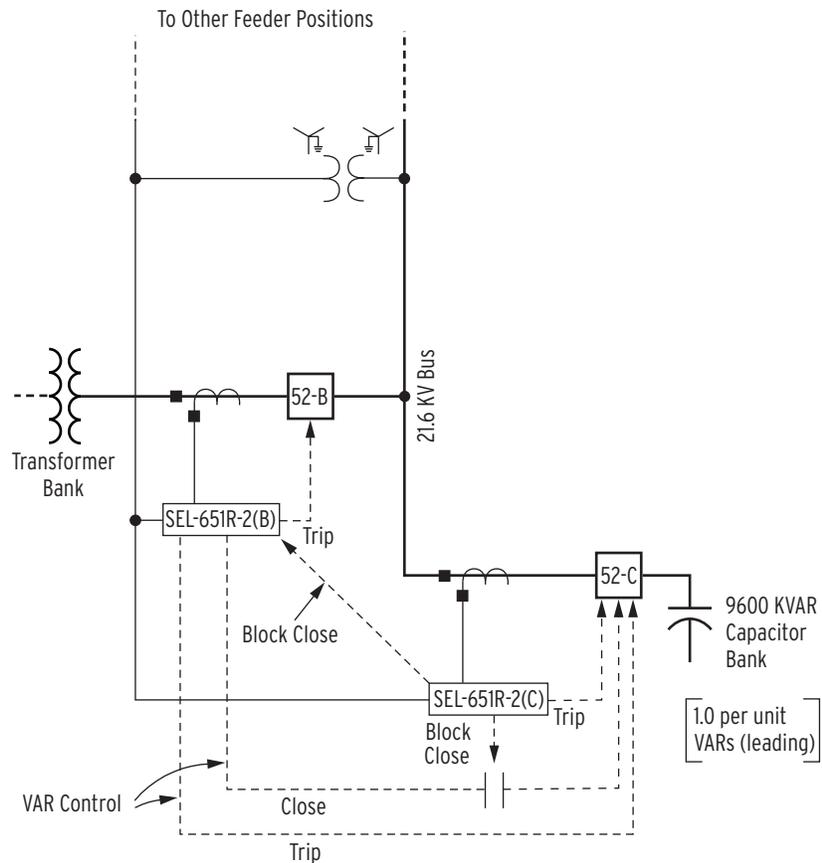
Power Elements Application—VAR Control for a Capacitor Bank


Figure 4.46   SEL-651R-2(B) Provides VAR Control for 9600 kVAR Capacitor Bank

The 9600 kVAR capacitor bank in *Figure 4.46* is put online and taken offline according to the VAR loading on the transformer bank feeding the 21.6 kV bus. The VAR loading is measured with the SEL-651R-2(B) located at bus circuit breaker 52-B.

Two SEL-651R-2 recloser controls operate the capacitor bank—both recloser controls are connected to capacitor bank circuit breaker 52-C. The SEL-651R-2(C) provides capacitor overcurrent protection and trips circuit breaker 52-C for a fault in the capacitor bank. The SEL-651R-2(B) provides VAR control and automatically puts the capacitor bank online (closes circuit breaker 52-C) or takes it offline (trips circuit breaker 52-C) according to the measured VAR level. The SEL-651R-2(B) also provides bus overcurrent protection and trips circuit breaker 52-B for a fault on the 21.6 kV bus.

In *Figure 4.46*, if the SEL-651R-2(C) trips circuit breaker 52-C for a fault in the capacitor bank, then a block close signal is sent from the SEL-651R-2(C) to the SEL-651R-2(B). This prevents the SEL-651R-2(B) from issuing an automatic close to circuit breaker 52-C.

For additional security, the close circuit from the SEL-651R-2(B) to circuit breaker 52-C is supervised by a block close output contact from the SEL-651R-2(C). This block close output contact opens if the SEL-651R-2(C) trips circuit breaker 52-C for a fault in the capacitor bank—no automatic closing can then take place.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 243 of 1080

Protection Functions | 4.69
Power Elements

Wolfe

These block close signals seal in when the SEL-651R-2(C) trips circuit breaker 52-C for a fault in the capacitor bank. Automatic closing of circuit breaker 52-C with the SEL-651R-2(B) can then take place only after the block close signals are reset. The exact implementation of this block close logic requires an application note beyond the scope of this discussion.

The rest of this discussion focuses on the determination of VAR levels (and corresponding power element settings) for automatic tripping and closing of circuit breaker 52-C with the SEL-651R-2(B).

Convert three-phase 9600 kVAR (kVA) to three-phase VA (volt-amperes) secondary, assuming a 1000:1 current transformer ratio and 100:1 potential transformer ratio:

$$9600 \text{ kVA pri} \cdot \frac{1000 \text{ V}}{1 \text{ kV}} \cdot \frac{1}{1000} \cdot \frac{1}{100} = 96 \text{ VA secondary}$$

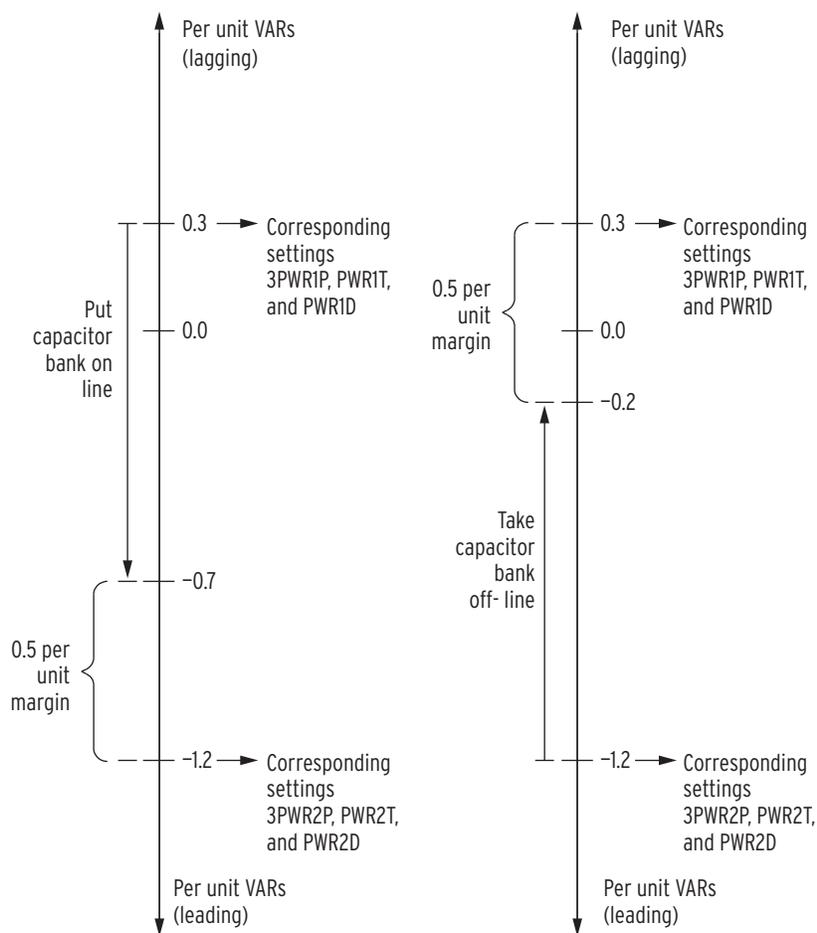
The three-phase 9600 kVAR capacitor is converted to 1.0 per unit VARs (leading) for demonstration convenience in *Figure 4.46*. *Figure 4.47* shows the per unit VAR levels for putting online (closing circuit breaker 52-C) or taking offline (tripping circuit breaker 52-C) the capacitor bank.


Figure 4.47   Per Unit Setting Limits for Switching 9600 kVAR Capacitor Bank Online and Offline

4.70 | Protection Functions
Load-Encroachment Logic

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 244 of 1080
Wolfe

The capacitor bank is put online at the 0.3 per unit VAR level (lagging) on the bus. The per unit VAR level immediately changes to the –0.7 per unit VAR level (leading) when the capacitor bank is put online (0.3 – 1.0 = –0.7). There is a margin of 0.5 per unit VARs until the capacitor bank is then taken offline (–0.7 – 0.5 = –1.2).

The capacitor bank is taken offline at the –1.2 per unit VAR level (leading) on the bus. The per unit VAR level immediately changes to –0.2 per unit VAR level (leading) when the capacitor bank is taken offline (–1.2 + 1.0 = –0.2). There is a margin of 0.5 per unit VARs until the capacitor bank is put online again (–0.2 + 0.5 = 0.3).

Settings for Three-Phase Power Elements

From preceding calculations and figures:

9600 kVAR ≈ 1.0 per unit VARs ≈ 96.0 VA secondary (three-phase)

Convert the per unit VAR levels 0.3 and –1.2 to VA (volt-amperes) secondary:

0.3 • 96.0 VA secondary = 28.8 VA secondary

–1.2 • 96.0 VA secondary = –115.2 VA secondary

Make the following power element settings for the SEL-651R-2(B):

EPWR := **2** (enable two power elements)

3PWR1P := **28.8** (power element pickup; VA secondary)

PWR1T := **+VARS** (power element type; lagging VARs)

PWR1D := **____** (power element time delay; cycles; see following discussion for setting idea)

3PWR2P := **115.2** (power element pickup; VA secondary)

PWR2T := **–VARS** (power element type; leading VARs)

PWR2D := **____** (power element time delay; cycles; see following discussion for setting idea)

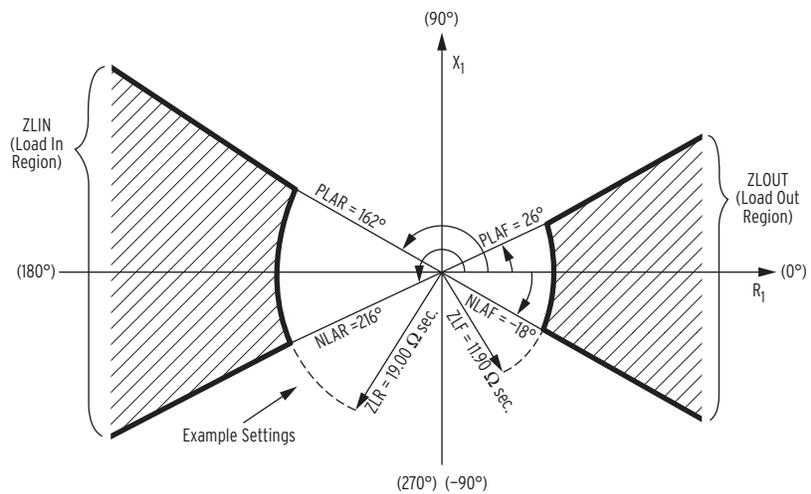
To override transient reactive power conditions, set the above power element time delay settings equivalent to several seconds (or perhaps minutes).

Resulting three-phase power element 3PWR1 asserts when the lagging VAR level exceeds the 0.3 per unit VAR level (lagging) (See *Figure 4.47* and left-hand side of *Figure 4.45*.) This element is used in close logic in the SEL-651R-2(B) to automatically put the 9600 kVAR capacitor bank online.

Resulting three-phase power element 3PWR2 asserts when the leading VAR level exceeds the –1.2 per unit VAR level (leading) (see *Figure 4.47* and the left-hand side of *Figure 4.45*). This element is used in trip logic in the SEL-651R-2(B) to automatically take the 9600 kVAR capacitor bank offline.

Load-Encroachment Logic

The load-encroachment logic (see *Figure 4.48*) and settings are enabled/disabled with setting ELOAD (:= Y or N). (If Global setting VSELECT := OFF, then ELOAD can be set only to N. See *Voltage Source Selection Setting (VSELECT) on page 9.33* for more details on the VSELECT setting.)

The load-encroachment feature allows phase overcurrent elements to be set without regard for load levels. This is especially helpful in bus overcurrent applications. A bus relay sees the cumulative currents of all the feeders but still has to provide overcurrent backup protection for all these feeders. If the phase elements in the bus relay are set to provide adequate backup, they often are set close to maximum bus load current levels. This runs the risk of tripping on bus load current. The load-encroachment feature prevents this from happening as shown in the example that follows in this subsection.


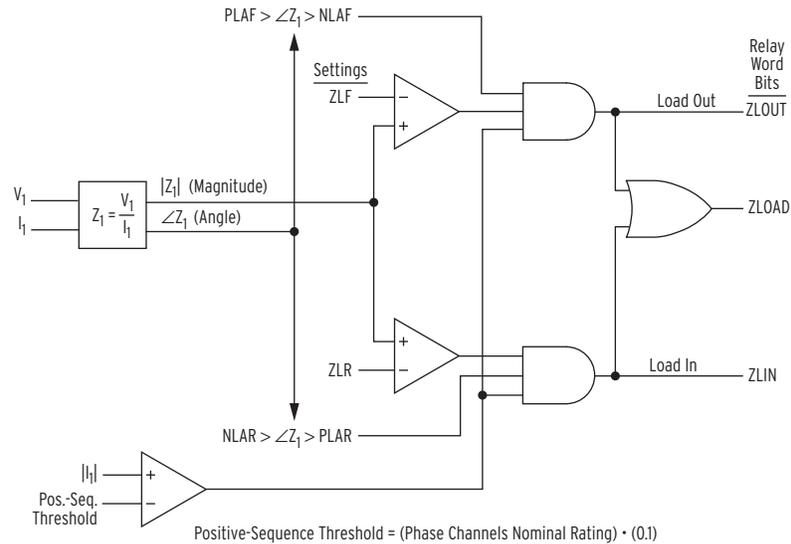


Figure 4.48   Load-Encroachment Logic

Note that a positive-sequence impedance calculation (Z_1) is made in the load-encroachment logic in *Figure 4.48*. Load is largely a balanced condition, so apparent positive-sequence impedance is a good load measure. The load-encroachment logic operates only if the positive-sequence current (I_1) is greater than the Positive-Sequence Threshold defined in *Figure 4.48*. For a balanced load condition, I_1 = phase current magnitude.

Forward load (load flowing out) lies within the hatched region labeled ZLOUT. Relay Word bit ZLOUT asserts to logical 1 when the load lies within this hatched region.

4.72 Protection Functions
Load-Encroachment Logic

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 246 of 1080
Wolfe

NOTE: The CT Polarity Setting (CTPOL) on page 9.29 affects the sign of the positive-sequence impedance calculation.

Reverse load (load flowing in) lies within the hatched region labeled ZLIN. Relay Word bit ZLIN asserts to logical 1 when the load lies within this hatched region.

Relay Word bit ZLOAD is the OR-combination of ZLOUT and ZLIN:

ZLOAD := **ZLOUT OR ZLIN**

Settings Ranges

Refer to *Table 4.22*.

Table 4.22   Load-Encroachment Settings Ranges

Setting[a]	Description and Range
ZLF	Forward Minimum Load Impedance-corresponding to maximum load flowing out 0.50-640.00 ohms secondary
ZLR	Reverse Minimum Load Impedance-corresponding to maximum load flowing in 0.50-640.00 ohms secondary
PLAF	Maximum Positive Load Angle Forward ($-90°$ to $+90°$)
NLAF	Maximum Negative Load Angle Forward ($-90°$ to $+90°$)
PLAR	Maximum Positive Load Angle Reverse ($+90°$ to $+270°$)
NLAR	Maximum Negative Load Angle Reverse ($+90°$ to $+270°$)

[a] If Global setting VSELECT := VY and LEA ac inputs are ordered, the impedance values for ZLF and ZLR must be scaled (see Line Impedance Conversions (Group Settings) on page 9.50).

Load-Encroachment Setting Example

Example system conditions:

Nominal Line-Line Voltage:	230 kV
Maximum Forward Load:	800 MVA
Maximum Reverse Load:	500 MVA
Power Factor (Forward Load):	0.90 lag to 0.95 lead
Power Factor (Reverse Load):	0.80 lag to 0.95 lead
CT ratio:	400/1 = 400
PT ratio:	134000/67 = 2000

The PTs are connected line-to-neutral.

Convert Maximum Loads to Equivalent Secondary Impedances

Start with maximum forward load:

$$800 \text{ MVA} \cdot (1/3) = 267 \text{ MVA per phase}$$

$$230 \text{ kV} / (\sqrt{3}) = 132.8 \text{ kV line-to-neutral}$$

$$267 \text{ MVA} \cdot (1/132.8 \text{ kV}) \cdot (1000\text{kV/MV}) = 2010 \text{ A primary}$$

$$2010 \text{ A primary} \cdot (1/\text{CT ratio}) = 2010 \text{ A primary} \cdot (1 \text{ A secondary}/400 \text{ A primary})$$
$$= 5.03 \text{ A secondary}$$

$$132.8 \text{ kV} \cdot (1000 \text{ V/kV}) = 132800 \text{ V primary}$$

$$132800 \text{ V primary} \cdot (1/\text{PT ratio}) = 132800 \text{ V primary} \cdot (1 \text{ V secondary}/2000 \text{ V primary})$$
$$= 66.4 \text{ V secondary}$$

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Protection Functions 4.73
Page 247 of 1080
Load Encroachment Logic
Wolfe

Now, calculate the equivalent secondary impedance:

66.4 V secondary/5.03 A secondary = 13.2 Ω secondary

This Ω secondary value can be calculated more expediently with the following equation:

[(line-line voltage in kV)^2 • (CT ratio)]/[(three-phase load in MVA) • (PT ratio)]

Again, for the maximum forward load:

[(230)^2 • (400)]/[(800) • (2000)] = 13.2 Ω secondary

To provide a margin for setting ZLF, multiply by a factor of 0.9:

ZLF := **13.2 Ω secondary • 0.9 = 11.90 Ω secondary**

For the maximum reverse load:

[(230)^2 • (400)]/[(500) • (2000)] = 21.1 Ω secondary

Again, to provide a margin for setting ZLR:

ZLR := **21.1 Ω secondary • 0.9 = 19.00 Ω secondary**

Convert Power Factors to Equivalent Load Angles

The power factor (forward load) can vary from 0.90 lag to 0.95 lead.

PLAF := **cos^{-1} (0.90) = 26°**

NLAF := **cos^{-1} (0.95) = −18°**

The power factor (reverse load) can vary from 0.80 lag to 0.95 lead.

PLAR := **180° − cos^{-1} (0.95) = 180° − 18° = 162°**

NLAR := **180° + cos^{-1} (0.80) = 180° + 37° = 217°**

Apply Load-Encroachment Logic to a Phase Time-Overcurrent Element

Again, from *Figure 4.48*:

ZLOAD := **ZLOUT OR ZLIN**

4.74 | Protection Functions
| **Load-Encroachment Logic**

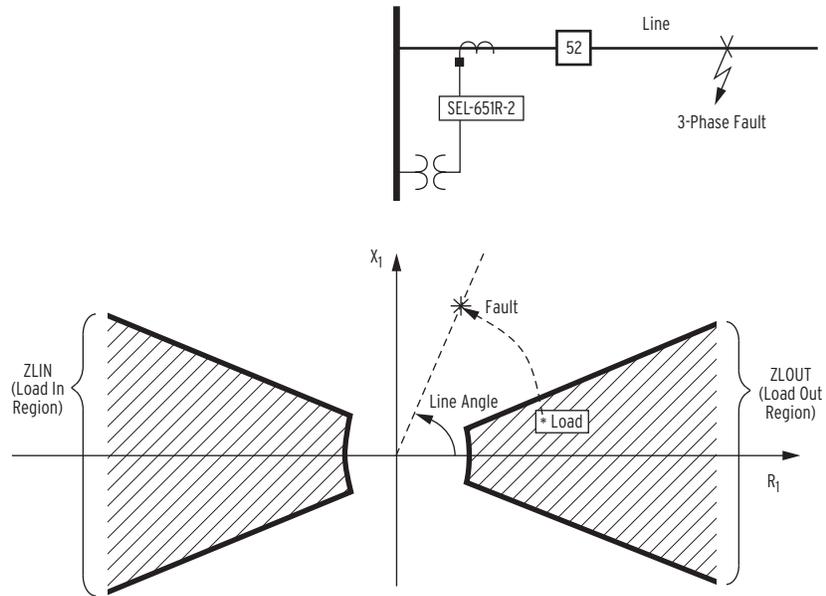
Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 248 of 1080
Wolfe


Figure 4.49   Migration of Apparent Positive-Sequence Impedance for a Fault Condition

Refer to *Figure 4.49*. In a load condition, the apparent positive-sequence impedance is within the ZLOUT area, resulting in:

ZLOAD := **ZLOUT OR ZLIN = logical 1 OR ZLIN = logical 1**

If a fault occurs, the apparent positive-sequence impedance moves outside the ZLOUT area (and stays outside the ZLIN area, too), resulting in:

ZLOAD := **ZLOUT OR ZLIN = logical 0 OR logical 0 = logical 0**

Load Encroachment for Directionally Controlled Elements

Directional elements can be used in torque-control settings for directional control of phase time overcurrent elements, as shown in *Table 4.25*. Directional control elements come from *Figure 4.61*, which refers back to *Figure 4.60*. In *Figure 4.60*, notice that the "NOT ZLOAD" condition is embedded in the positive-sequence voltage-polarized directional element logic. This logic prevents a phase overcurrent element that is being torque controlled by a directional element from operating when the measured positive sequence impedance is within the Load In or Load Out regions.

Load Encroachment for Nondirectional Elements

It is possible to use SELOGIC control equation torque-control settings to apply load encroachment supervision for nondirectional overcurrent elements. However, keep in mind that load encroachment is not a valid representation of the positive-sequence impedance during unbalanced faults, and ZLOAD may assert during certain unbalanced faults. This means that a torque-control equation intended to prevent operation of a phase overcurrent element for load conditions may also prevent operation of the element for unbalanced faults. Therefore, when using load encroachment to control phase overcurrent elements, residual or neutral-ground overcurrent elements must be used to detect phase-ground faults. Similarly negative-sequence overcurrent elements must be used to detect phase-to-phase faults (see *Setting Negative-Sequence Overcurrent Elements on page 4.105*). These phase-to-ground and phase-to-phase elements must be at least as sensitive as the phase overcurrent elements.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Protection Functions 4.75
Page 249 of 1080
Load-Encroachment Logic
Wolfe

Example 1

If it is acceptable for the phase overcurrent element to operate for some unbalanced fault conditions, refer to *Figure 4.16* and make the following SELOGIC control equation torque-control setting:

> 51PTC := **NOT(ZLOAD) AND NOT(LOP) OR 50P6**

As shown in *Figure 4.48*, load-encroachment logic is a positive-sequence calculation. During LOP conditions (loss-of-potential; see *Figure 4.50*), positive-sequence voltage (V_1) can be substantially depressed in magnitude or changed in angle. This change in V_1 can possibly cause ZLOAD to deassert (= logical 0), erroneously indicating that a "fault condition" exists. Thus, NOT (ZLOAD) should be supervised by NOT (LOP) in a torque-control setting. This also effectively happens in the directional element in *Figure 4.60*, where ZLOAD and LOP are part of the logic.

In the above setting example, phase instantaneous overcurrent element 50P6 is set above any maximum load current level—if 50P6 picks up, there is assuredly a fault. For faults below the pickup level of 50P6, but above the pickup of phase time-overcurrent element 51PT, the NOT(ZLOAD) AND NOT(LOP) logic discriminates between high load and fault current. If an LOP condition occurs (LOP = logical 1), the pickup level of 50P6 becomes the effective pickup of phase time-overcurrent element 51PT (51PT loses its sensitivity when an LOP condition occurs):

> 51PTC := **NOT(ZLOAD) AND NOT(LOP) OR 50P6**
>
> := **NOT(ZLOAD) AND NOT(logical 1) OR 50P6**
>
> := **50P6**

Example 2

If it is *not* acceptable for the phase overcurrent element to operate for any unbalanced fault current less than 50P6P or for load conditions, enable load encroachment, refer to *Figure 4.16*, and make the following SELOGIC control equation torque-control setting:

> 51PTC = **F32P OR R32P OR 50P6**

This uses the directional control logic (*Figure 4.60*) to cause the phase overcurrent element to be sensitive only to three-phase fault conditions. Residual or neutral ground-overcurrent elements must be used to detect phase-to-ground faults, and negative-sequence overcurrent elements must be used to detect phase-to-phase faults (see *Setting Negative-Sequence Overcurrent Elements on page 4.105*). These phase-to-ground and phase-to-phase elements must be at least as sensitive as the phase overcurrent elements.

Because the directional control logic is defeated when a loss-of-potential occurs, phase instantaneous overcurrent element 50P6 is set above any maximum load current level—if 50P6 picks up, there is assuredly a fault. If an LOP condition occurs (LOP = logical 1), the pickup level of 50P6 becomes the effective pickup of phase time-overcurrent element 51PT. In other words, 51PT loses its sensitivity when an LOP condition occurs.

The directional elements must be enabled by setting E32 to Y or AUTO. See *Directional Control Settings on page 4.89* for a discussion of other settings that may be necessary for directional control to function properly.

See SEL Application Guide *AG2005-07, Guidelines for Applying Load-Encroachment Element for Overcurrent Supervision*, available on the SEL website, for more information.

Use SEL-321 Relay Application Guide for the SEL-651R-2

The load-encroachment logic and settings in the SEL-651R-2 are similar to those in the SEL-321. Refer to SEL Application Guide *AG93-10, SEL-321 Relay Load-Encroachment Function Setting Guidelines* for applying the load-encroachment logic in the SEL-651R-2. Note that *Application Guide AG93-10* discusses applying the load-encroachment feature to phase distance elements in the SEL-321. The SEL-651R-2 does not have phase distance elements, but the principles and settings example are still generally applicable to the SEL-651R-2.

Ground Switch Logic

PHASE CURRENT CHANNEL ASSIGNMENTS
Made with Global setting IPCONN (see Table 9.8).

Global setting EGNDSW is the primary control for the ground switch logic. The operation of the ground switch logic is summarized in *Table 4.23* and its outputs are listed below:

➤ Ground current I_G

➤ Relay Word bit GNDSW (indicating the I_G current source)

RESIDUALLY CONNECTED CHANNEL IN
The following figures show the factory-default wiring for channel IN wired residually with the phase current channels for the various recloser applications: Figure 2.49, Figure 2.52, Figure 2.55, Figure 2.59, Figure 2.62, Figure 2.65, Figure 2.68, Figure 2.70, Figure 2.71, Figure 2.76, and Figure 2.77.

Ground current I_G is used in the following:

➤ Ground instantaneous/definite-time overcurrent elements (see *Ground Instantaneous/ Definite-Time Overcurrent Elements on page 4.9*)

➤ Ground time-overcurrent elements (see *Ground Time-Overcurrent Elements on page 4.23*)

➤ Directional control (see *Ground Current I_G on page 4.80*)

➤ Metering (see *Ground Switch Option on page 8.3*)

Table 4.23 Ground Switch Logic

Scenario	Channel IN Wiring Configuration	Global Setting EGNDSW :=	Current Transformer Ratio Settings	Source of Ground Current I_G	
				When $|IN| < 4.7$ A, Relay Word bit GNDSW = logical 1	When $|IN| \geq 4.7$ A, Relay Word bit GNDSW = logical 0
1 (factory default)	Residually connected with phase current channels	Y	CTR = CTRN	IN	$3I_0$
2	Separate core-balance CT, encompassing all three phases, on same line section as phase CTs	Y	CTR ≥ CTRN	IN	$3I_0 \bullet \left(\dfrac{CTR}{CTRN} \right)$
				At all times Relay Word bit GNDSW = logical 0	
3	Separate current source (unrelated to phase currents)	N	CTR and CTRN set independently	$3I_0$	
4	Not connected	N	Make CTR; CTRN "don't care"	$3I_0$

Loss-of-Potential Logic
Wolfe

EXTRA ELEMENTS ENABLED WHEN EGNDSW := N
See Neutral Instantaneous/ Definite-Time Overcurrent Elements on page 4.7 and Neutral Time-Overcurrent Elements on page 4.21.

When Global setting EGNDSW := Y (Scenarios 1 and 2 in *Table 4.23*), ground current I_G is automatically switched between the following (depending on the magnitude of channel IN current):

➤ channel IN current

➤ calculated residual-ground current $3I_0 = I_A + I_B + I_C$ (vector summation)

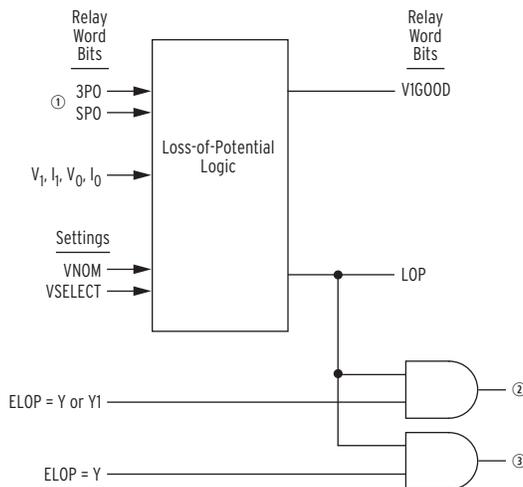
The switching point of 4.7 A secondary (channel IN current) in *Table 4.23* has some intentional hysteresis to prevent rapid I_G current source changes. EGNDSW:= Y gives the aforementioned ground overcurrent elements the widest range for pickup settings and operating current. It especially provides for increased sensitivity at lower ground current values.

Notice that for uncommon Scenario 2 in *Table 4.23*, the $3I_0$ current is adjusted by the current transformer ratio settings CTR and CTRN. This is because the secondary current $3I_0$ needs to be adjusted to the channel IN current base because the ground overcurrent elements (that operate off of ground current I_G) are set on the channel IN current base when EGNDSW:= Y.

If current transformer ratio settings are set the same (CTR = CTRN), then the phase channel current base is the same as the channel IN current base.

When Global setting EGNDSW := N (Scenarios 3 and 4 in *Table 4.23*), ground current I_G is fixed on the calculated residual-ground current $3I_0 = I_A + I_B + I_C$ (vector summation).

Loss-of-Potential Logic

The loss-of-potential (LOP) logic operates as shown in *Figure 4.50*.


① From Figure 5.5; ② to Figure 4.52 and Figure 4.53; ③ to Figure 4.57 and Figure 4.61.

Figure 4.50   Loss-of-Potential Logic

Inputs into the LOP logic are described in *Table 4.24*.

Page 252 of 1080
Wolfe

Table 4.24 LOP Logic Inputs

Input	Description
3PO	Three-pole open condition (indicates circuit breaker open condition).
SPO	Single-pole open condition (indicates one or two phases are open, of a single-pole trip capable recloser)
V_1	Positive-sequence voltage (V secondary).
I_1	Positive-sequence current (A secondary).
I_0	Zero-sequence current (A secondary).
V_0	Zero-sequence voltage (V secondary).
VNOM	PT nominal voltage setting (line-to-neutral secondary).
VSELECT	Voltage source selection (global) setting—selects three-phase source (VY or VZ) for LOP, directional logic, etc.
ELOP	Loss-of-potential enable setting.

The circuit breaker has to be closed (Relay Word bit 3PO = logical 0 and SPO = logical 0) for the LOP logic to operate.

A loss of potential is declared (Relay Word bit LOP = logical 1) when a 10 percent or larger drop in V_1 is detected, with no corresponding change in I_1 or I_0. If the LOP condition persists for 15 cycles, it latches in.

LOP resets (Relay Word bit LOP = logical 0) when V_1 returns above 85 percent of setting VNOM (Relay Word bit V1GOOD also asserts) and V_0 is less than 7.8 percent of setting VNOM.

The loss-of-potential enable setting, ELOP, does not enable or disable the LOP logic. It just routes the LOP Relay Word bit to different logic, as shown in *Figure 4.50* and explained in the remainder of this subsection.

Setting VSELECT := OFF

If setting VSELECT := OFF, the loss-of-potential logic is disabled (Relay Word bits LOP and V1GOOD are forced to logical 0) and setting ELOP can only be set to "N."

Setting ELOP := Y or Y1

If setting ELOP := Y or Y1 and a loss-of-potential condition occurs (Relay Word bit LOP asserts to logical 1), all directional element enables are disabled (see *Figure 4.52*, *Figure 4.53*, and *Figure 4.60*). The loss-of-potential condition makes the voltage-polarized directional elements (which are controlled by these internal enables) unreliable. Thus, they are disabled. The overcurrent elements controlled by these voltage-polarized directional elements are disabled also (unless overridden by conditions explained in the following Setting ELOP := Y discussion).

Setting ELOP := Y

Additionally, if setting ELOP := Y and a loss-of-potential condition occurs (Relay Word bit LOP asserts to logical 1), overcurrent elements set direction forward are enabled (see *Figure 4.57* and *Figure 4.61*). These direction forward overcurrent elements effectively become nondirectional and provide overcurrent protection during a loss-of-potential condition.

As detailed previously, voltage-based directional elements are disabled during a loss-of-potential condition. Thus, the overcurrent elements controlled by these voltage-based directional elements are also disabled. However, this disable condition is overridden for the overcurrent elements set direction forward if setting ELOP := Y.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 253 of 1080
Protection Functions 4.79
Directional Control for Ground Overcurrent Logic
Wolfe

Setting ELOP := N

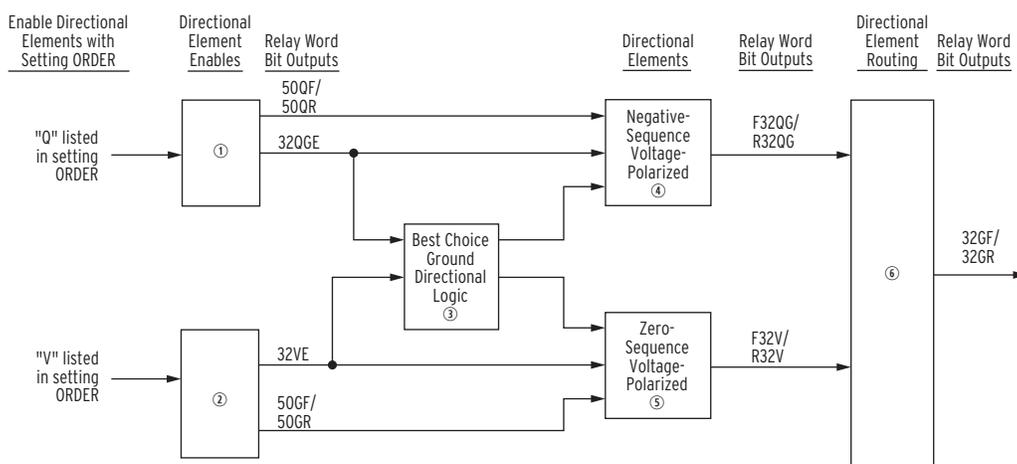
If setting ELOP := N, the loss-of-potential logic still operates (Relay Word bit LOP asserts to logical 1 for a loss-of-potential condition) but does not disable any voltage-based directional elements (as occurs with ELOP := Y or Y1) or enable overcurrent elements set direction forward (as occurs with ELOP := Y).

Directional Control for Ground Overcurrent Logic

Setting E32 enables directional control for overcurrent elements. Setting E32 and other directional control settings are described in *Directional Control Settings on page 4.89*.

Two elements are available to control the ground overcurrent elements. These two directional elements are:

➤ Negative-sequence voltage-polarized directional element

➤ Zero-sequence voltage-polarized directional element


① Figure 4.52; ② Figure 4.53; ③ Figure 4.54; ④ Figure 4.55; ⑤ Figure 4.56; ⑥ Figure 4.57.

Figure 4.51 General Logic Flow of Directional Control for Ground Overcurrent Elements

Figure 4.51 gives an overview of how these directional elements are enabled and routed for control of the ground overcurrent elements.

Note in *Figure 4.51* that setting ORDER enables the directional elements. Set ORDER with any combination of Q and V. They have the following correspondence to the directional elements:

➤ Q (Negative-sequence voltage-polarized directional element)

➤ V (Zero-sequence voltage-polarized directional element)

The order in which these directional elements are listed in setting ORDER determines the priority in which they operate to provide Best Choice Ground Directional Element logic control. See discussion on setting ORDER in *Directional Control Settings on page 4.89*.

Directional Element Enables

Refer to *Figure 4.51*, *Figure 4.52*, and *Figure 4.53*.

The directional element enables, Relay Word bits 32QGE and 32VE, have the following correspondence to the directional elements:

➤ 32QGE (Negative-sequence voltage-polarized directional element)

➤ 32VE (Zero-sequence voltage-polarized directional element)

Note in *Figure 4.52* and *Figure 4.53* that if:

➤ enable setting ELOP = Y or Y1 and a loss-of-potential condition occurs (Relay Word bit LOP asserts; see *Table 4.50*)

➤ or a single-pole open condition occurs (Relay Word bit SPO asserts; see *Table 5.5*)

then both directional element enables are disabled. The directional element enables also have current signal thresholds that must be met (settings 50QFP/50QRP and 50GFP/50GRP, respectively).

Figure 4.52 has extra directional element enable 32QE, which is used in the logic that controls the negative-sequence and phase overcurrent elements (see *Figure 4.58* and *Figure 4.59*).

The settings involved with 32QGE and 32VE in *Figure 4.52* and *Figure 4.53* (e.g., settings a2, k2, a0G, E32IV) are explained in *Directional Control Settings on page 4.89*.

Ground Current I_G

Ground current I_G in *Figure 4.52*, *Figure 4.53*, and *Figure 4.56* can possibly switch between sources, depending on Global setting EGNDSW (see *Table 4.23* and accompanying text).

Best Choice Ground Directional Element Logic

Refer to *Figure 4.51* and *Figure 4.54*.

Relay Word bits 32QGE and 32VE and setting ORDER are used in the Best Choice Ground Directional Element logic in *Figure 4.54*. The Best Choice Ground Directional Element logic determines the order in which the directional element should be enabled to operate. The ground overcurrent elements set for directional control are then controlled by this directional element.

Directional Elements

Refer to *Figure 4.51*, *Figure 4.55*, and *Figure 4.56*.

The enable output of Best Choice Ground Directional Element logic in *Figure 4.54* determines which directional element will run.

Presuming sufficient current signal is present (Relay Word bit 50GF, 50GR, 50QF, or 50QR asserted), an impedance-based directional calculation is then made. Technical paper *Negative-Sequence Impedance Directional Element* by Bill Fleming goes into more detail on this impedance-based calculation for the negative-sequence voltage-polarized directional element (paper available at selinc.com/literature/technical-papers/). The principles discussed in this paper also generally apply to the zero-sequence voltage-polarized directional element.

Directional Element Routing

Refer to *Figure 4.51* and *Figure 4.57*.

The directional element outputs are routed to the forward (Relay Word bit 32GF) and reverse (Relay Word bit 32GR) logic points, for use in controlling ground overcurrent elements.

Protection Functions 4.81
Directional Control for Ground Overcurrent Logic

Wolfe

Table 4.25 and accompanying text give examples of directional control implementation (i.e., by using the outputs of *Figure 4.57* and *Figure 4.61* in overcurrent element torque-control settings and other SELOGIC settings to realize desired directional control).

Loss-of-Potential

Note in *Figure 4.57* that if *both* the following are true:

➤ enable setting ELOP = Y

➤ a loss-of-potential condition occurs (Relay Word bit LOP asserts; see *Figure 4.50*)

then the forward logic point (Relay Word bit 32GF) asserts to logical 1, thus enabling the ground overcurrent elements that are set direction forward. These direction forward overcurrent elements effectively become nondirectional and provide overcurrent protection during a loss-of-potential condition.

As detailed in *Figure 4.52* and *Figure 4.53*, voltage-based directional elements are disabled during a loss-of-potential condition. Thus, the overcurrent elements that are directionally controlled by these voltage-based directional elements are disabled also. But this disable condition is overridden if setting ELOP := Y, as explained above.

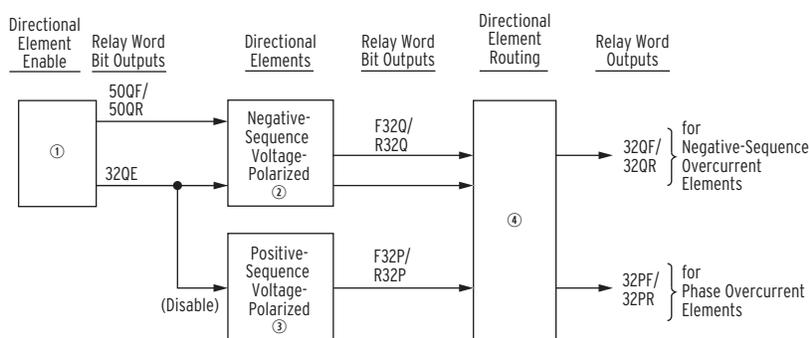
Directional Control for Negative-Sequence and Phase Overcurrent Elements
Wolfe

Directional Control for Negative-Sequence and Phase Overcurrent Elements

Setting E32 enables directional control for overcurrent elements. Setting E32 and other directional control settings are described in *Directional Control Settings on page 4.89*.

The negative-sequence voltage-polarized directional element controls the negative-sequence overcurrent elements. Negative-sequence voltage-polarized and positive-sequence voltage-polarized directional elements control the phase overcurrent elements. *Figure 4.58* gives an overview of how the negative-sequence voltage-polarized and positive-sequence voltage-polarized directional elements are enabled and routed to control the negative-sequence and phase overcurrent elements.


① Figure 4.52; ② Figure 4.59; ③ Figure 4.60; ④ Figure 4.61.

Figure 4.58   General Logic Flow of Directional Control for Negative-Sequence Overcurrent and Phase Overcurrent Elements

Directional Element Enable

Refer to *Figure 4.52* and *Figure 4.58*.

The Relay Word bit 32QE enables the negative-sequence voltage-polarized directional element and disables the positive-sequence voltage-polarized directional element. The positive-sequence voltage-polarized directional element is only operative for three-phase faults, where negative-sequence current (I_2) is minimal or nonexistent, compared to positive-sequence current (I_1; see the a2 setting factor in *Figure 4.52*).

Note in *Figure 4.52* that if:

➤ enable setting ELOP := Y or Y1 and a loss-of-potential condition occurs (Relay Word bit LOP asserts; see *Figure 4.50*)

➤ or a single-pole open condition occurs (Relay Word bit SPO asserts; see *Figure 5.5*)

then the 32QE directional element enable is disabled. The loss-of-potential condition (Relay Word bit LOP) also applies to the positive-sequence voltage-polarized directional element (*Figure 4.60*) and a single-pole open condition (or lack thereof) is effectively checked for in *Figure 4.60* with three-phase overcurrent element 50P32. The 32QE directional element enable also has current signal thresholds that must be met (settings 50QFP/50QRP).

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 260 of 1080
Wolfe

4.86 | Protection Functions
Directional Control for Negative-Sequence and Phase Overcurrent Elements

Figure 4.52 has extra directional element enable 32QGE, which is used in the directional element logic that controls the ground overcurrent elements (see *Figure 4.55*).

The settings involved with 32QE in *Figure 4.52* (e.g., setting a2) are explained in *Directional Control Settings on page 4.89*.

Directional Elements

Refer to *Figure 4.58*, *Figure 4.59*, and *Figure 4.60*.

For an unbalanced fault, presuming sufficient negative-sequence current signal is present (Relay Word bit 50QF or 50QR asserted), an impedance-based directional calculation is then made in *Figure 4.59*. The technical paper *Negative-Sequence Impedance Directional Element* by Bill Fleming goes into more detail on this impedance-based calculation for the negative-sequence voltage-polarized directional element (paper available from website: selinc.com/literature/technical-papers/).

The negative-sequence voltage-polarized directional element operates for unbalanced faults while the positive-sequence voltage-polarized directional element operates for three-phase faults.

VPOLV in *Figure 4.60* indicates that there is sufficient positive-sequence voltage for the positive-sequence voltage-polarized directional element to operate. If there is a three-phase fault close-in to the SEL-651R-2, all three phase voltages depress to zero magnitude. In such a scenario, the SEL-651R-2 then internally generates a positive-sequence memory voltage for a time period of about 30 cycles or more after the voltage depression. This memory voltage is used in the internal phase-to-phase distance-type elements indicated in *Figure 4.60* to keep directional decisions going for several more cycles in the face of such a voltage depression. VPOLV remains asserted until this memory voltage expires.

Note in *Figure 4.60* that the assertion of ZLOAD disables the positive-sequence voltage-polarized directional element. ZLOAD asserts when the relay is operating in a user-defined load region (see *Figure 4.48*).

Directional Element Routing

Refer to *Figure 4.58* and *Figure 4.61*.

The directional element outputs are routed to the forward (Relay Word bits 32QF and 32PF) and reverse (Relay Word bits 32QR and 32PR) logic points, for use in controlling negative-sequence and phase overcurrent elements.

Table 4.25 and accompanying text give examples of directional control implementation (i.e., by using the outputs of *Figure 4.57* and *Figure 4.61* in overcurrent element torque-control settings and other SELOGIC settings to realize desired directional control).

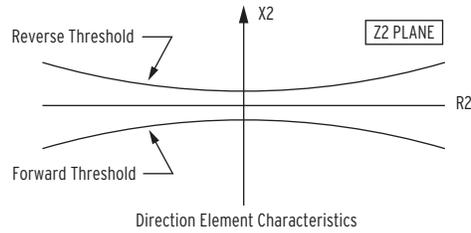
Loss of Potential

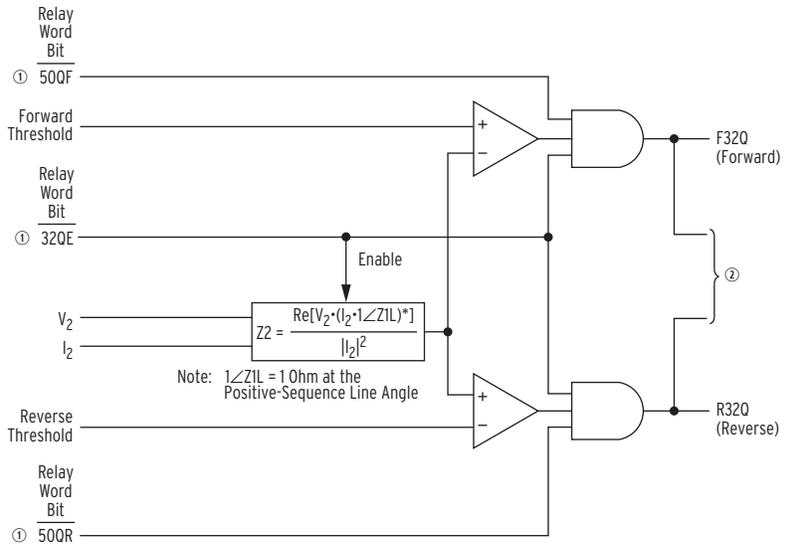
Note in *Figure 4.61* that if *both* the following are true:

➤ enable setting ELOP := Y

➤ a loss-of-potential condition occurs (Relay Word bit LOP asserts)

then the forward logic points (Relay Word bits 32QF and 32PF) assert to logical 1, thus enabling elements that are set direction forward. These direction forward elements effectively become nondirectional and provide protection during a loss-of-potential condition.

As detailed previously (in *Figure 4.52* and *Figure 4.60*), voltage-based directional elements are disabled during a loss-of-potential condition. Thus, the overcurrent elements controlled by these voltage-based directional elements are also disabled. But this disable condition is overridden for the overcurrent elements set direction forward if setting ELOP := Y, as explained above.




Forward Threshold:

If Z2F Setting ≤ 0, Forward Threshold $= 0.75 \cdot Z2F - 0.25 \cdot \left| \dfrac{V_2}{I_2} \right|$

If Z2F Setting > 0, Forward Threshold $= 1.25 \cdot Z2F - 0.25 \cdot \left| \dfrac{V_2}{I_2} \right|$

Reverse Threshold:

If Z2R Setting ≥ 0, Reverse Threshold $= 0.75 \cdot Z2R + 0.25 \cdot \left| \dfrac{V_2}{I_2} \right|$

If Z2R Setting < 0, Reverse Threshold $= 1.25 \cdot Z2R + 0.25 \cdot \left| \dfrac{V_2}{I_2} \right|$

Figure 4.61   Routing of Directional Elements to Negative-Sequence and Phase Overcurrent Elements

Directional Control Settings

The directional control for overcurrent elements is configured by making directional control enable setting E32. Setting E32 has setting choices:

➤ Y (All directional control settings made manually)

➤ N (Disable directional control)

➤ AUTO or AUTO2 (Sets most of the directional control settings automatically)

The directional elements require that three-phase voltages be connected to either the VY- or VZ-voltage terminals, as designated by Global setting VSELECT := VY or VZ. If VSELECT := OFF, enable setting E32 is forced to N and cannot be changed.

Settings Made Automatically

If the directional control enable setting E32 is set:

E32 := **AUTO** or **AUTO2**

then the following directional control settings are calculated and set automatically:

Z2F, Z2R, 50QFP, 50QRP, a2, k2, 50GFP, 50GRP, a0G, Z0F, Z0R, and Z0MTA

AUTO VS. AUTO2
The only difference between E32 := AUTO and E32 := AUTO2 is how settings Z2F, Z2R, Z0F, and Z0R are calculated and set automatically. E32 := AUTO2 is preferred for making automatic settings. See Z2F and Z2R Set Automatically and Z0F and Z0R Set Automatically for details.

Once these settings are calculated automatically, they can only be modified if the user goes back and changes the directional control enable setting to E32 := Y. The remaining directional control settings are not set automatically if setting E32 := AUTO or AUTO2. They have to be set by the user, whether setting E32 := AUTO, AUTO2, or Y. These settings are:

ORDER, 50P32P, and E32IV (E32IV is a SELOGIC setting)

All these settings are explained in detail in the remainder of this subsection.

4.90 | Protection Functions
Directional Control Settings

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 264 of 1080
Wolfe

Not all these directional control settings (set automatically or by the user) are used in every application. The following are particular directional control settings that are hidden/not made for particular conditions:

Settings Hidden/Not Made:	For Condition:
50P32P	setting ELOAD := Y
50GFP, 50GRP, a0G, Z0F, Z0R, Z0MTA, E32IV	setting ORDER does not contain V

Settings

ORDER–Ground Directional Element Priority Setting

Setting Range:

Q (Negative-sequence voltage-polarized directional element)

V (Zero-sequence voltage-polarized directional element)

OFF (Disable ground directional control)

Setting ORDER can be set with any combination of Q and V. The order in which these directional elements are listed determines the priority in which they operate to provide Best Choice Ground Directional logic control. See *Figure 4.54*.

For example, if setting:

ORDER := **QV**

then the first listed directional element (Q = negative-sequence voltage-polarized directional element; see *Figure 4.55*) is the first priority directional element to provide directional control for the ground overcurrent elements.

If the negative-sequence voltage-polarized directional element is not operable (i.e., it does not have sufficient operating quantity as indicated by its internal enable, 32QGE, not being asserted), then the second listed directional element (V = zero-sequence voltage-polarized directional element; see *Figure 4.56*) provides directional control for the ground overcurrent elements.

Another example, if setting:

ORDER := **V**

then the zero-sequence voltage-polarized directional element (V = zero-sequence voltage-polarized directional element; see *Figure 4.56*) provides directional control for the ground overcurrent elements all the time.

Setting ORDER can be set with any element combination (i.e., ORDER := QV, ORDER := VQ, ORDER := V, ORDER := Q, or ORDER := OFF).

50P32P-Phase Directional Element Three-Phase Current Pickup

Setting Range:

0.10–2.00 A secondary

The 50P32P setting is set to pick up for all three-phase faults that need to be covered by the phase overcurrent elements. It supervises the positive-sequence voltage-polarized directional elements F32P and R32P (see *Figure 4.60*).

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 265 of 1080
Wolfe

Protection Functions 4.91
Directional Control Settings

If the load-encroachment logic is enabled (enable setting ELOAD := Y), then setting 50P32P is not made or displayed, but is fixed internally at:

0.1 A secondary

Z2F–Forward Directional Z2 Threshold
Z2R–Reverse Directional Z2 Threshold

Setting Range:

–640.00 to 640.00 Ω secondary

Z2F and Z2R are used to calculate the Forward and Reverse Thresholds, respectively, for the negative-sequence voltage-polarized directional elements (see *Figure 4.55* and *Figure 4.59*).

If configuration setting E32 := Y, settings Z2F and Z2R (negative-sequence impedance values) are calculated by the user and entered by the user, but setting Z2R must be greater in value than setting Z2F by 0.10 Ω secondary.

Figure 4.62 and *Figure 4.63* and supporting text concern the zero-sequence impedance network, relay polarity, and the derivation of settings Z0F and Z0R. The same general approach outlined for deriving settings Z0F and Z0R can also be applied to deriving settings Z2F and Z2R in the negative-sequence impedance network. If the basis for Z2F and Z2R values (Ω secondary) is primary impedance values (Ω primary), convert these primary impedance values to secondary impedance values by using *Equation 9.16* (Global setting VSELECT := VY) or *Equation 9.17* (Global setting VSELECT := VZ).

Z2F and Z2R Set Automatically

If configuration setting E32 := AUTO, settings Z2F and Z2R (negative-sequence impedance values) are calculated automatically, using the positive-sequence line impedance magnitude setting Z1MAG as follows:

Z2F := **Z1MAG/2** (Ω secondary)

Z2R := **Z1MAG/2 + 1.00** (Ω secondary)

If configuration setting E32 := AUTO2, the settings are then set as follows:

Z2F := **–1.5** (Ω secondary; preferred setting for most scenarios)

Z2R := **1.5** (Ω secondary; preferred setting for most scenarios)

These automatic settings for Z2F and Z2R (when E32 := AUTO2) are the preferred settings. For controls with older firmware that does not include the E32 := AUTO2 option, these settings can be set directly as such (Z2F := –1.5 and Z2R := 1.5) when setting E32 := Y.

For more information on these preferred Z2F and Z2R settings, see the following technical paper (available at selinc.com):

Fundamentals and Improvements for Directional Relays by Karl Zimmerman and David Costello (Schweitzer Engineering Laboratories, Inc.)

In particular, see the following pertinent discussions in Section III. FIELD CASE STUDIES:

➤ Subsection A. Low V2 Magnitude Challenges Automatic Thresholds

➤ Subsection D. New Automatic Settings Recommendation

4.92 | Protection Functions
Directional Control Settings

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 266 of 1080
Wolfe

These subsections assume 5 A nominal secondary current inputs, while the SEL-651R-2 has 1 A nominal secondary current inputs. Thus, *Figure 15* and *Figure 20* in these particular subsections show forward and reverse settings that differ from the preferred settings for the SEL-651R-2 (Z2F := –1.5 and Z2R := 1.5) by a factor of five.

One of the only exceptions to using these preferred settings (Z2F := –1.5 and Z2R := 1.5) is if there is an extremely strong source behind the SEL-651R-2. If the absolute value of the equivalent negative-sequence source impedance behind the SEL-651R-2 is less than 2.5 Ω secondary (again, the reference paper shows a factor of five difference for this value), this is indicative of a strong source, and settings Z2F and Z2R should both be set as positive values with Z2F < Z2R. This is similar to the automatic setting of Z2F and Z2R when E32 := AUTO.

50QFP-Forward Directional Negative-Sequence Current Pickup
50QRP-Reverse Directional Negative-Sequence Current Pickup

Setting Range:

0.05–1.00 A secondary

The 50QFP setting ($3I_2$ current value) is the pickup for the forward fault detector 50QF of the negative-sequence voltage-polarized directional elements (see *Figure 4.52*). Ideally, the setting is above normal load unbalance and below the lowest expected negative-sequence current magnitude for unbalanced forward faults.

The 50QRP setting ($3I_2$ current value) is the pickup for the reverse fault detector 50QR of the negative-sequence voltage-polarized directional elements (see *Figure 4.52*). Ideally, the setting is above normal load unbalance and below the lowest expected negative-sequence current magnitude for unbalanced reverse faults.

50QFP and 50QRP Set Automatically

If configuration setting E32 := AUTO or AUTO2, settings 50QFP and 50QRP are set automatically at:

50QFP := **0.10 A secondary**

50QRP := **0.05 A secondary**

a2−Positive-Sequence Current Restraint Factor, $|I_2|/|I_1|$

Setting Range:

0.02–0.50 (unitless)

Refer to *Figure 4.52*.

The a2 factor increases the security of the negative-sequence voltage-polarized directional elements. It prevents the elements from operating for negative-sequence current (i.e., system unbalance), which can circulate as a result of line asymmetries, CT saturation during three-phase faults, or other events.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 267 of 1080
Wolfe

Protection Functions 4.93
Directional Control Settings

a2 Set Automatically

If configuration setting E32 := AUTO or AUTO2, setting a2 is set
automatically at:

a2 := **0.1**

For setting a2 := 0.1, the negative-sequence current (I_2) magnitude has to be
greater than 1/10 of the positive-sequence current (I_1) magnitude in order for
the negative-sequence voltage-polarized directional elements to be enabled
($|I_2| > 0.1 \cdot |I_1|$).

k2–Zero-Sequence Current Restraint Factor, $|I_2|/|I_0|$

Setting Range:

0.10–1.20 (unitless)

Note the directional enable logic outputs in *Figure 4.52*:

➤ 32QE (enable for the negative-sequence voltage-polarized
directional element that controls the negative-sequence and
phase overcurrent elements)

➤ 32QGE (enable for the negative-sequence voltage-polarized
directional element that controls the ground overcurrent
elements)

Factor k2 is an additional threshold to be met by directional element enable
32QGE if the zero-sequence voltage-polarized directional element enable
32VE is already asserted. The negative-sequence current (I_2) magnitude has to
be greater than the zero-sequence current (I_0) magnitude multiplied by k2 in
order for the 32QGE enable (and following negative-sequence voltage-
polarized directional element in *Figure 4.55*) to be enabled:

$$\left|I_2\right| > k2 \cdot \left|I_0\right|$$

Equation 4.10

This check ensures that the relay uses the most robust analog quantities in
making directional decisions for the ground overcurrent elements.

If directional element enable 32VE is deasserted, then factor k2 (and its
effective threshold) is not a requirement for directional element enable
32QGE operation.

Setting k2 is often derived by using zero-sequence current (I_0) values and
negative-sequence current (I_2) values from system studies, load profiles, or
metering. Make sure these current values are on the same base. The easiest
way to ensure the same base is to use primary values.

The zero-sequence current ($I_0 = I_G/3$; I_G is the ground current) source can
switch between residual ground ($I_G = 3I_0 = I_A + I_B + I_C$) and neutral ground
($I_G = I_N$; channel IN) for some scenarios (see *Table 4.23*). This apparent
switching of zero-sequence current base (if CTR ≠ CTRN) is handled
internally for setting k2 applied in *Figure 4.52*.

k2 Set Automatically

If configuration setting E32 := AUTO or AUTO2, setting k2 is set
automatically at:

k2 := **0.2**

4.94 | Protection Functions
Directional Control Settings

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 268 of 1080
Wolfe

For setting k2 := 0.2, the negative-sequence current (I_2) magnitude has to be greater than 1/5 of the zero-sequence current (I_0) magnitude in order for the negative-sequence voltage-polarized directional elements to be enabled ($|I_2| >$ 0.2 • $|I_0|$). Again, this further threshold requirement presumes enable 32VE is asserted, as described previously.

50GFP-Forward Directional Ground Current Pickup
50GRP-Reverse Directional Ground Current Pickup

Setting Range:

NOTE: In the case where EGNDSW := Y and CTR = CTRN, there is no difference between the IN current base and the IA, IB, IC current base. This is the standard configuration for the SEL-651R-2, because the factory-default wiring includes a wired residual connection to the IN channel.

    0.005–1.00 A secondary
        on channel IN base (see Note), when Global setting EGNDSW := Y and Group setting CTR = CTRN

    0.005–[1.00 • (CTR/CTRN)] A secondary
        on channel IN base, when Global setting EGNDSW := Y and Group setting CTR ≠ CTRN

    0.010–1.00 A secondary
        on IA, IB, IC base, when Global setting EGNDSW := N

If preceding setting ORDER does not contain V (the zero-sequence voltage-polarized directional element is not enabled), then settings 50GFP and 50GRP are not made or displayed.

The 50GFP setting (I_G ground current value) is the pickup for the forward fault detector 50GF of the zero-sequence voltage-polarized directional element (see *Figure 4.53*). Ideally, the setting is above normal load unbalance and below the lowest expected zero-sequence current magnitude for unbalanced forward faults.

The 50GRP setting (I_G ground current value) is the pickup for the reverse fault detector 50GR of the zero-sequence voltage-polarized directional element (see *Figure 4.53*). Ideally, the setting is above normal load unbalance and below the lowest expected zero-sequence current magnitude for unbalanced reverse faults.

50GFP and 50GRP Set Automatically

If configuration setting E32 := AUTO or AUTO2, settings 50GFP and 50GRP are set automatically at:

    50GFP := **0.100 A secondary**
    50GRP := **0.050 A secondary**

a0G–Positive-Sequence Current Restraint Factor, $|I_0|/|I_1|$

Setting Range:

    0.001–0.500 (unitless)

If preceding setting ORDER does not contain V (the zero-sequence voltage-polarized directional element is not enabled), then setting a0G is not made or displayed.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 269 of 1080
Protection Functions
Directional Control Settings
4.95
Wolfe

Refer to *Figure 4.53*.

The a0G factor increases the security of the zero-sequence voltage-polarized directional element. It prevents the elements from operating for zero-sequence current (i.e., system unbalance), which can circulate as a result of line asymmetries, CT saturation during three-phase faults, or other events.

Setting a0G is often derived by using zero-sequence current (I_0) values and positive-sequence current (I_1) values from system studies, load profiles, or metering. Make sure these current values are on the same base. The easiest way to ensure the same base is to use primary values.

The zero-sequence current ($I_0 = I_G/3$; I_G is the ground current) source can switch between residual ground ($I_G = 3I_0 = I_A + I_B + I_C$) and neutral ground ($I_G = I_N$; channel IN) for some scenarios (see *Table 4.23*). This apparent switching of zero-sequence current base (if CTR ≠ CTRN) is handled internally for setting a0G applied in *Figure 4.53*.

a0G Set Automatically

If configuration setting E32 := AUTO or AUTO2, setting a0G is set automatically at:

a0G := **0.1**

For setting a0G := 0.1, the zero-sequence current (I_0) magnitude has to be greater than 1/10 of the positive-sequence current (I_1) magnitude in order for the zero-sequence voltage-polarized directional element to be enabled ($|I_0| > 0.1 \cdot |I_1|$).

Z0F-Forward Directional Z0 Threshold
Z0R-Reverse Directional Z0 Threshold

Setting Range:

–640.00 to 640.00 Ω secondary

If preceding setting ORDER does not contain V (the zero-sequence voltage-polarized directional element is not enabled), then settings Z0F and Z0R are not made or displayed.

Z0F and Z0R are used to calculate the Forward and Reverse Thresholds, respectively, for the zero-sequence voltage-polarized directional element (see *Figure 4.56*).

If configuration setting E32 := Y, settings Z0F and Z0R (zero-sequence impedance values) are calculated by the user and entered by the user, but setting Z0R must be greater in value than setting Z0F by 0.1 Ω secondary.

If the basis for Z0F and Z0R values (Ω secondary) is primary impedance values (Ω primary), convert these primary impedance values to secondary impedance values, by using *Equation 9.16* (Global setting VSELECT := VY) or *Equation 9.17* (Global setting VSELECT := VZ).

The zero-sequence current ($I_0 = I_G/3$; I_G is the ground current) source can switch between residual ground ($I_G = 3I_0 = I_A + I_B + I_C$) and neutral ground ($I_G = I_N$; channel IN) for some scenarios (see *Table 4.23*). This apparent switching of zero-sequence current base (if CTR ≠ CTRN) is handled internally for settings Z0F and Z0R applied in the bottom equations in *Figure 4.56*.

4.96 | Protection Functions
Directional Control Settings

ZOF and ZOR Set Automatically

If configuration setting E32 := AUTO, settings Z0F and Z0R (zero-sequence impedance values) are calculated automatically, using the zero-sequence line impedance magnitude setting Z0MAG as follows:

Z0F := **Z0MAG/2** (Ω secondary)

Z0R := **Z0MAG/2 + 1.00** (Ω secondary)

If configuration setting E32 := AUTO2, the settings are then set as follows:

Z0F := **-1.5** (Ω secondary; preferred setting for most scenarios)

Z0R := **1.5** (Ω secondary; preferred setting for most scenarios)

These automatic settings for Z0F and Z0R (when E32 := AUTO2) are the preferred settings. For controls with older firmware that does not include the E32 := AUTO2 option, these settings can be set directly as such (Z0F := –1.5 and Z0R := 1.5) when setting E32 := Y.

Refer to the technical paper reference and discussion that follows in the preceding *Z2F and Z2R Set Automatically* subsection. Though discussing negative-sequence impedance networks, this information is still generally applicable to zero-sequence impedance networks and settings Z0F and Z0R.

Deriving ZOF and ZOR Settings

Figure 4.62 shows the voltage and current polarity for an SEL-651R-2 in a zero-sequence impedance network (the same approach can also be instructive for negative-sequence impedance analysis using settings Z2F and Z2R). For a forward fault, the SEL-651R-2 effectively sees the sequence impedance behind it as:

$Z_M = V_0/(-I_0) = -(V_0/I_0)$ $V_0/I_0 = -Z_M$ (what the relay sees for a forward fault)

For a reverse fault, the SEL-651R-2 effectively sees the sequence impedance in front of it:

$Z_N = V_0/I_0$ $V_0/I_0 = Z_N$ (what the relay sees for a reverse fault)

If the system in *Figure 4.62* is a solidly grounded system (mostly inductive; presume uniform system angle), the impedance plot (in the R + jX plane) would appear as in *Figure 4.63a*, with resultant Z0F and Z0R settings as in *Figure 4.63b*. The zero-sequence line angle noted in *Figure 4.63a* ($\angle$Z0MTA) is the same angle found in *Figure 4.56* (in the equation box with the Enable line).

The preceding method of automatically making settings Z0F and Z0R (where both Z0F and Z0R are positive values; still Z0R > Z0F) usually suffices for mostly inductive systems—*Figure 4.62* and *Figure 4.63* just provide a theoretic background.

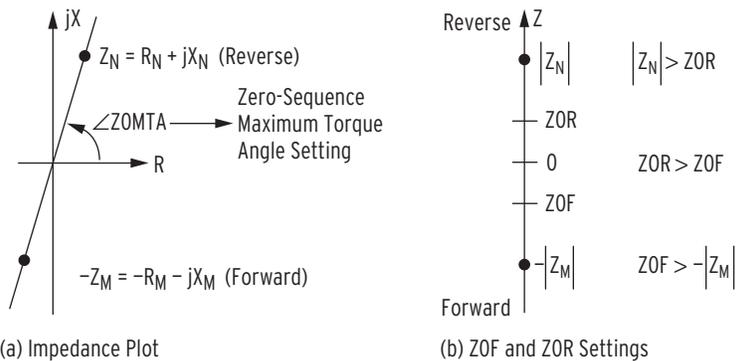
(b) ZOF and ZOR Settings


Figure 4.63   Zero-Sequence Impedance Plot for Solidly Grounded, Mostly Inductive System

Z0MTA–Zero-Sequence Maximum Torque Angle

Setting Range:

–90.00 to –5.00 degrees and 5.00 to 90.00 degrees

The Z0MTA setting is at the heart of the zero-sequence voltage-polarized directional element of *Figure 4.56*. Z0MTA is only available if both of the following conditions are true:

➤ enable setting E32 := Y, AUTO, or AUTO2

➤ setting ORDER contains the value "V"

Otherwise, Z0MTA is hidden and of no consequence. Z0MTA can be set one of two ways:

STILL MAKE SETTING Z0ANG WHEN E32 := Y
Even though setting Z0MTA is not automatically set equal to the value of setting Z0ANG when enable setting E32 := Y, setting Z0ANG should still be made for fault location purposes.

➤ If enable setting E32 := AUTO or AUTO2, then Z0MTA is automatically set to the value of setting Z0ANG (the setting range of Z0MTA encompasses that of setting Z0ANG).

As long as E32 := AUTO or AUTO2, Z0MTA can be seen, but not changed. This automatic setting mode is primarily for traditional applications, where the angle of the zero-sequence system impedance behind the control is deemed to be essentially the same as the angle of the zero-sequence line impedance in front of it (see *Figure 4.62* and *Figure 4.63(a)*).

4.98 | Protection Functions
Directional Control Settings

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 272 of 1080
Wolfe

➤ If enable setting E32 := Y, then Z0MTA is set independently within its setting range.

This option is primarily used for such applications as low-impedance grounded systems, which are discussed in the balance of this subsection.

The distribution system in *Figure 4.64* is low-impedance grounded at the substation by either of the following methods:

➤ a resistance in the transformer bank neutral

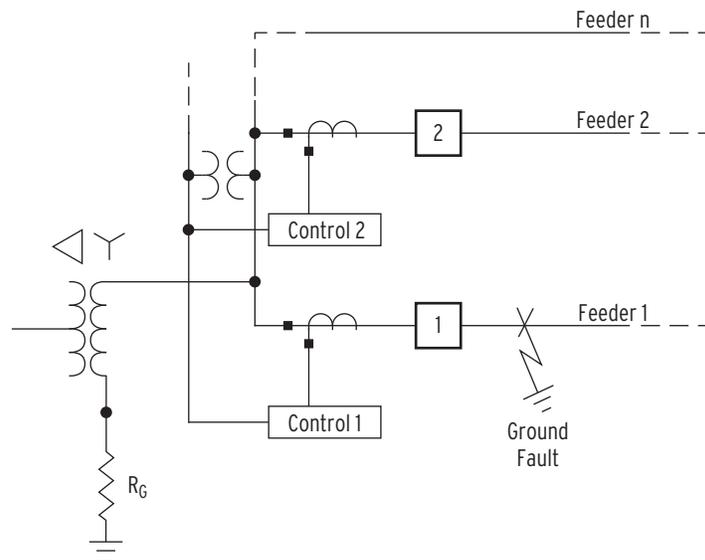
➤ a grounding bank with a resistance in its broken-delta secondary (effectively making it a neutral resistance)


Figure 4.64   Low-Impedance Grounded Distribution System With a Ground Fault on Feeder 1

A grounding bank is installed if low-impedance grounding is desired at a substation and the transformer bank is to remain ungrounded. *Figure 4.64* also shows a ground fault out on Feeder 1 (a forward fault from the perspective of Control 1). This example assumes that SEL-651R-2 recloser controls (Control 1, Control 2, etc.) are installed at feeder positions in a distribution substation.

Figure 4.65 shows the resultant zero-sequence impedance network for the ground fault on Feeder 1 in *Figure 4.64*. V_0 in *Figure 4.65* is the zero-sequence voltage seen by all the controls connected to the distribution substation bus three-phase voltage.

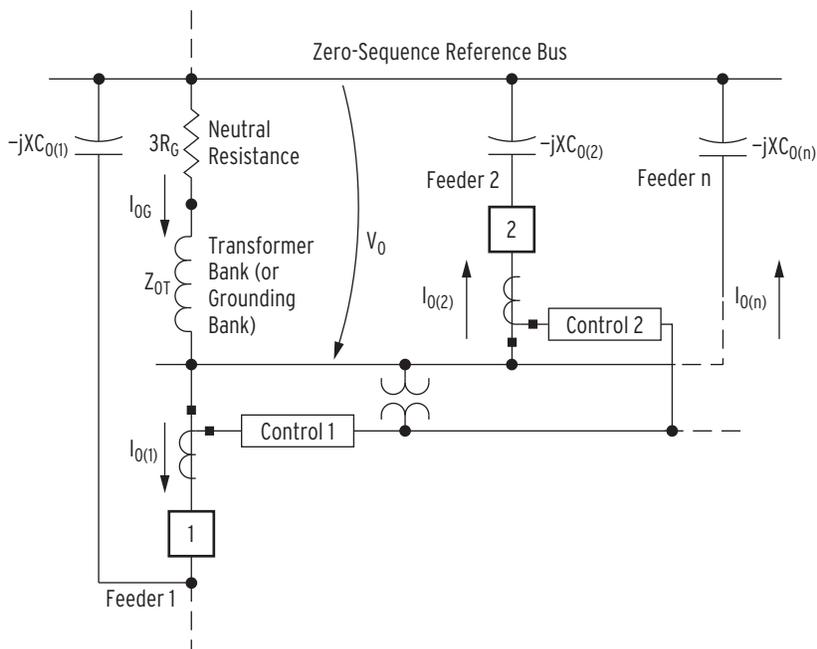
Protection Functions 4.99
Page 273 of 1080
Directional Control Settings
Wolfe


Figure 4.65   Zero-Sequence Impedance Network for Low-Impedance Grounded Distribution System With a Ground Fault on Feeder 1

Impedance definitions for *Figure 4.65*:

➤ $-jXC_{0(1)}$ = zero-sequence capacitive reactance for Feeder 1 (the faulted feeder)

➤ $-jXC_{0(2)}$ = zero-sequence capacitive reactance for Feeder 2

➤ $-jXC_{0(n)}$ = zero-sequence capacitive reactance for the cumulative other feeders

➤ Z_{0T} = transformer bank (or grounding bank) zero-sequence impedance

➤ R_G = neutral resistance, connected to transformer bank (or grounding bank)

The zero-sequence capacitive reactance values of the feeders are much larger than the zero-sequence feeder line impedances, so the zero-sequence feeder line impedances are ignored in this fault analysis.

Current definitions for *Figure 4.65*:

➤ $I_{0(1)}$ = zero-sequence current flow for Feeder 1 (forward direction for Control 1)

➤ $I_{0(2)}$ = zero-sequence current flow for Feeder 2 (forward direction for Control 2)

➤ $I_{0(n)}$ = zero-sequence current flow for cumulative other feeders (forward direction for controls on other feeders)

➤ I_{0G} = zero-sequence current flow through neutral resistance R_G and transformer bank (or grounding bank)

Presume there is a substantial capacitance-creating network (e.g., underground cable) on the individual feeders. As cable capacitance increases, capacitive reactance decreases, allowing for increased capacitive current flow. For the ground fault in *Figure 4.64* (a reverse fault from the perspective of

Directional Control Settings

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 274 of 1080
Wolfe

Control 2), Control 2 sees zero-sequence current $I_{0(2)}$ flow toward the zero-sequence capacitive reactance $-jXC_{0(2)}$. If this current flow is high enough, a false trip may occur, unless otherwise prevented (e.g., by directional control).

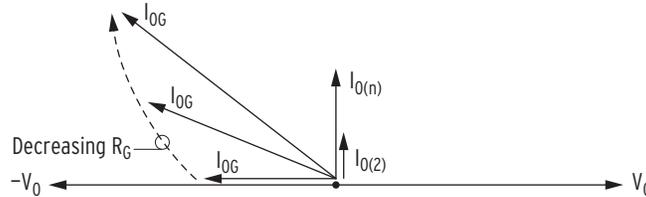
Figure 4.66 plots the increase in zero-sequence current I_{0G} resulting from decreasing neutral resistance R_G.


Figure 4.66   Decreasing Neutral Resistance R_G Results in Increasing Zero-Sequence Current I_{0G}

Vectorially add currents $I_{0(2)}$ and $I_{0(n)}$ to I_{0G} (per direction in *Figure 4.65*):

$$I_{0(1)} = I_{0G} - I_{0(2)} - I_{0(n)}$$

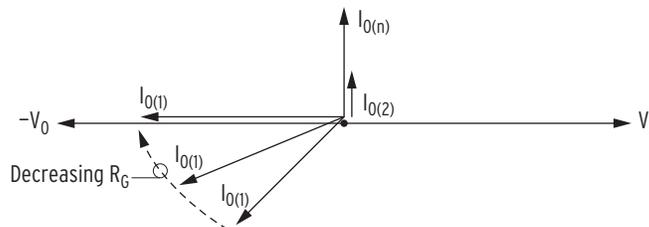
Figure 4.67 plots the increase in zero-sequence current $I_{0(1)}$ (seen by Control 1) resulting from decreasing neutral resistance R_G.


Figure 4.67   Decreasing Neutral Resistance R_G Results in Increasing Zero-Sequence Current $I_{0(1)}$ (Seen by Control 1)

In *Figure 4.67*, the lowest magnitude of zero-sequence current $I_{0(1)}$ (at 225 degrees from zero-sequence voltage V_0) represents a high-resistance grounded system. The following (absolute value) comparisons are typically true for a high-resistance grounded system:

➤ $3R_G \gg Z_{0T}$ (ignore transformer bank [or grounding bank] impedance Z_{0T})

➤ $3R_G$ = resultant impedance from the parallel combination of zero-sequence capacitive reactance values $-jXC_{0(2)}$ and $-jXC_{0(n)}$ (the total capacitive reactance behind Control 1)

As neutral resistance R_G decreases, zero-sequence current $I_{0(1)}$ increases in *Figure 4.67*. The system is moving away from being a high-resistance grounded system toward being a low-resistance grounded system.

APPLY ZOMTA TO HIGH-RESISTANCE GROUNDED SYSTEM?
This example for the ZOMTA setting discussion addresses low-impedance grounded systems. A high-resistance grounded system (with its lower zero-sequence current values for ground fault conditions) requires that channel IN be connected to a separate current transformer, instead of in a factory-default residual connection with the phase current channels.

Such a separate current transformer would have the three primary phase wires running through its core, eliminating any false residual current (see Scenario 2 in Table 4.23). Such current transformer applications are often referred to by one of the following names: flux-summing, core-balance, zero-sequence, ground fault, or window current transformers.

Other settings (see Figure 4.53 and Figure 4.56) also have to be considered to make sure they are sensitive enough for a high-resistance grounded system application.

The technical paper referenced at the end of this subsection also discusses directional element applications for high-resistance grounded systems.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 275 of 1080
Protection Functions 4.101
Directional Control Settings
Wolfe

The zero-sequence voltage/current vector values of *Figure 4.67* are converted (by using polarity and impedances in *Figure 4.65*) to the apparent zero-sequence impedances that the respective controls see, as plotted in *Figure 4.68*:

➤ Ground fault on Feeder 1 is in the forward direction for Control 1:

$V_0/(-I_{0(1)}) =$ parallel combination of zero-sequence impedance values $-jXC_{0(2)}$, $-jXC_{0(n)}$, and $3R_G + Z_{0T}$

$V_0/I_{0(1)} =$ $-$(parallel combination of zero-sequence impedance values $-jXC_{0(2)}$, $-jXC_{0(n)}$, and $3R_G + Z_{0T}$)

$V_0/I_{0(1)} =$ the negative value of the aggregate zero-sequence impedance behind Control 1

➤ Ground fault on Feeder 1 is in the reverse direction for Control 2:

$V_0/I_{0(2)} =$ $-jXC_{0(2)}$

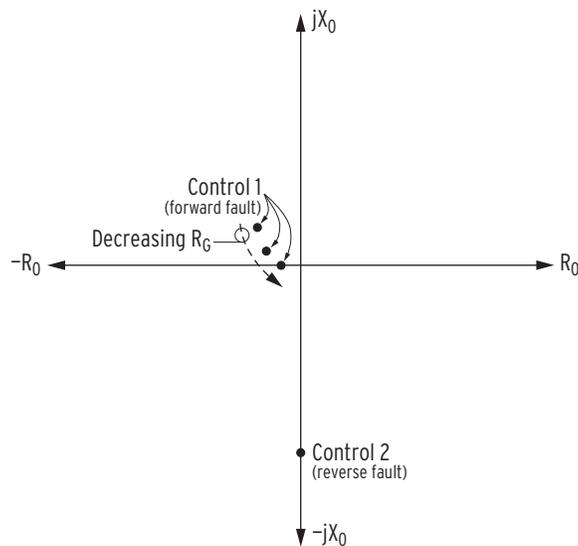
$V_0/I_{0(2)} =$ the zero-sequence capacitive reactance for Feeder 2 in front of Control 2


Figure 4.68 Zero-Sequence Impedance Plots for Ground Fault on Low-Impedance Grounded Distribution System

Assuming that all of the feeders in this distribution substation example have roughly the same amount of capacitance-creating network (e.g., underground cable), the following will apply:

➤ The Control 1 apparent zero-sequence impedance plot in *Figure 4.68* is representative of a ground fault in front of any control in the substation (forward fault).

➤ The Control 2 apparent zero-sequence impedance plot in *Figure 4.68* is representative of a ground fault behind any control in the substation (e.g., a ground fault on another parallel feeder; reverse fault).

Directional Control Settings

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 276 of 1080
Wolfe

The forward/reverse impedance plots in *Figure 4.68* appear asymmetric, especially when compared to *Figure 4.63*(a) for a solidly grounded system with sources at each end. The Z0MTA setting in *Figure 4.63(a)* would (by inspection) be approximately 75 degrees.

Contrastingly, the Z0MTA setting for *Figure 4.68* has to allow the forward/reverse characteristic to fit in between the forward/reverse impedance plots. The forward impedance plot is the most critical to accommodate—one definitely wants to operate for a forward fault. This necessitates a Z0MTA setting of approximately -40 degrees (for the lowest value of neutral resistance R_G), as shown in *Figure 4.69* for this example. Necessary settings are as follows:

Global Settings

EGNDSW:= **Y**

Group Settings

E32:= **Y**

Z0F:= **−0.05**

Z0R:= **0.05**

Z0MTA:= **−40.00**

Other directional settings also have to be made (see *Figure 4.53* and *Figure 4.56*).

All these settings, zero-sequence voltage, and zero-sequence current converge on the zero-sequence voltage-polarized directional element in *Figure 4.56* (and its preceding enable logic in *Figure 4.53*) to produce the directional characteristic in *Figure 4.69*.

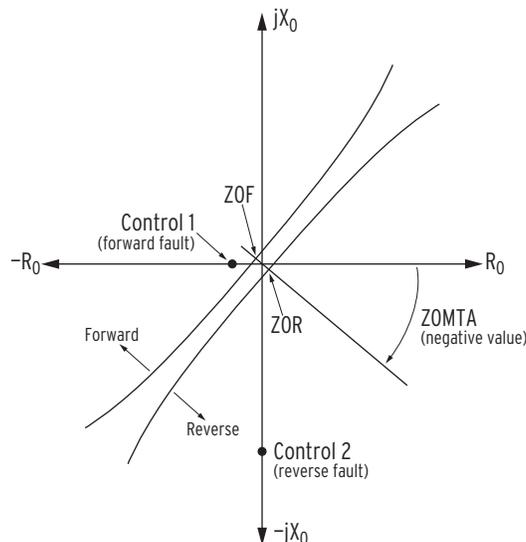
THE PATH FROM I_0 TO I_G
The I_G current value in Figure 4.53 and Figure 4.56 comes from the logic in Table 4.23. With Global setting EGNDSW := Y and channel IN wired in the factory-default residual connection with the phase current channels, I_G is always 3x the zero-sequence current I_0 of the feeders in the Figure 4.65 example. For a forward fault, $I_G = 3xI_{0(1)}$. For a reverse fault, $I_G = 3xI_{0(2)}$.


Figure 4.69   Z0MTA Setting Provides Forward/Reverse Ground Fault Discrimination in a Low-Impedance Grounded Distribution System

For more details on applying the Z0MTA setting on low-impedance grounded systems, refer to the following technical paper (available at selinc.com):

Protection Functions 4.103
Overcurrent Directional Control Provided by Torque-Control Settings
Wolfe

In this paper, especially see pertinent discussion on modified 32V (zero-sequence voltage-polarized directional) elements in the following subsections:

➤ V. Modified Directional Elements for Low-Impedance-Grounded Systems with High Charging Capacitances

➤ VI. Analysis of a Practical Resistance-Grounded System

This subsection includes setting considerations involving the transformer bank (or grounding bank) zero-sequence impedance Z_{0T} and the neutral resistance R_G.

E32IV—SELOGIC Control Equation Enable

Refer to *Figure 4.53*.

SELOGIC control equation setting E32IV must be asserted to logical 1 to enable the zero-sequence voltage-polarized directional element for directional control of ground overcurrent elements.

Most often, this setting is set directly to logical 1:

E32IV := **1** (numeral 1)

For situations where zero-sequence source isolation can occur (e.g., by the opening of a circuit breaker) and result in possible mutual coupling problems for the zero-sequence voltage-polarized directional element, SELOGIC control equation setting E32IV should be deasserted to logical 0. In this example, this is accomplished by connecting a circuit breaker auxiliary contact from the identified circuit breaker to the SEL-651R-2:

E32IV := **IN106** (52a connected to optoisolated input **IN106**)

Almost any desired control can be set in SELOGIC control equation setting E32IV.

Overcurrent Directional Control Provided by Torque-Control Settings

The Relay Word bit outputs of *Figure 4.57* and *Figure 4.61* are used in the torque-control settings to provide directional control for overcurrent elements. These Relay Word bit outputs are listed in the middle column of *Table 4.25*. Each line in *Table 4.25* (left to right) lists the torque-control setting, the suggested Relay Word bits to provide directional control, and the overcurrent element controlled by the torque-control setting. The torque-control setting (left column) can be found in the same figure reference as the corresponding overcurrent element (right column).

51N2TC		51N2T (*Figure 4.21*)
51G1TC	32GF/32GR (*Figure 4.57*)	51G1T (*Figure 4.22*)
51G2TC	32GF/32GR (*Figure 4.57*)	51G2T (*Figure 4.23*)
51QTC	32QF/32QR (*Figure 4.61*)	51QT (*Figure 4.24*)

For example, to provide forward directional control for time-overcurrent element 51G1T, make the following torque-control setting:

51G1TC := **32GF**

The factory-default for this torque-control setting is as follows:

51G1TC := **LT01**   (see *Figure 9.31*)

Latch output LT01 (see *Figure 7.6*) is set to enable/disable ground overcurrent tripping (see setting SET01 and RST01 in *Figure 9.32*), via the **GROUND ENABLED** operator control pushbutton (see *Table 11.9*). To incorporate this factory-default front-panel operator control capability with forward directional control, make the following combined setting:

51G1TC := **LT01 AND 32GF**

Channel IN Overcurrent Elements

Note that no suggested Relay Word bits for directional control are given in the corresponding middle column in *Table 4.25* for channel IN overcurrent elements 50N1T–50N4T, 51N1T, and 51N2T.

As explained in the text accompanying *Figure 4.10* and *Figure 4.20*, these channel IN overcurrent elements only become available if Global setting EGNDSW := N. *Table 4.23* shows that channel IN current is treated as a totally separate current source for this scenario (separate from internal residually derived ground current $I_G = 3I_0 = I_A + I_B + I_C$). Thus, it is unlikely that these channel IN overcurrent elements would be used in a directional scheme, where ground directionality would come from currents I_G (ground/zero-sequence) and I_2 (negative-sequence) derived from currents I_A, I_B, and I_C (see *Figure 4.55* and *Figure 4.56*).

Instantaneous Overcurrent Elements

The 50_ _TC torque-control settings in *Table 4.25* do not control the corresponding instantaneous elements. For example, at the top of *Figure 4.12*, torque-control setting 50G1TC controls the ground definite-time overcurrent element 50G1T, but not ground instantaneous overcurrent element 50G1. To make an instantaneous overcurrent element directional, supervise it with a directional element in SELOGIC control equations (e.g., 50G1 AND 32GR).

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 279 of 1080

Protection Functions 4.105
Setting Negative-Sequence Overcurrent Elements
Wolfe

Single-Phase Tripping

If a recloser is set for single-phase or three-phase tripping (Group setting ESPB := Y; see *Figure 5.1*), the ground directional elements (*Figure 4.55* and *Figure 4.56*) and negative-sequence directional element (*Figure 4.59*) automatically turn off when one or two phases are tripped. This is because of the single-pole open logic (*Figure 5.5*) and Relay Word bit output SPO that supervises the ground directional element enables 32QGE and 32VE (*Figure 4.52* and *Figure 4.53*) and the negative-sequence directional element enable 32QE (*Figure 4.52*).

The phase directional element (*Figure 4.60*) is not supervised by the Relay Word bit output SPO. But once one or two phases are tripped, the phase directional element effectively shuts down/turns off—it cannot make a three-phase decision (all three phases have to agree for a directional decision).

Setting Negative-Sequence Overcurrent Elements

Setting Negative-Sequence Definite-Time Overcurrent Elements

Negative-sequence instantaneous overcurrent elements 50Q1–50Q6 should not be set to trip directly. This is because negative-sequence current can transiently appear when a circuit breaker is closed and balanced load current suddenly appears.

To avoid tripping for this transient condition, use negative-sequence definite-time overcurrent elements 50Q1T–50Q4T with at least 1.5 cycles of time delay (transient condition lasts less than 1.5 cycles). For example, make the following time delay setting for negative-sequence definite-time overcurrent element 50Q1T:

    50Q1D := **1.50**

Refer to *Figure 4.14* and *Figure 4.15* for more information on negative-sequence instantaneous and definite-time overcurrent elements.

Negative-sequence instantaneous overcurrent elements 50Q5 and 50Q6 do not have associated timers (compare *Figure 4.15* to *Figure 4.14*). If 50Q5 or 50Q6 need to be used for tripping, run them through SELOGIC control equation variable timers (see *Figure 7.3*) and use the outputs of the timers for tripping.

Continue reading in *Coordinating Negative-Sequence Overcurrent Elements on page 4.106* for guidelines on coordinating negative-sequence definite-time overcurrent elements and a following coordination example. The coordination example uses time-overcurrent elements, but the same principles can be applied to definite-time overcurrent elements.

Setting Negative-Sequence Time-Overcurrent Elements

Negative-sequence time-overcurrent element 51QT should not be set to trip directly when it is set with low time-dial settings 51QJTD or 51QKTD, which result in curve times below 3 cycles (see curves in *Figure 9.1–Figure 9.20*). This is because negative-sequence current can transiently appear when a circuit breaker is closed and balanced load current suddenly appears. Refer to *Figure 4.24* for more information on negative-sequence time-overcurrent element 51QT.

To avoid having negative-sequence time-overcurrent element 51QT with such low time-dial settings trip for this transient negative-sequence current condition, make corresponding minimum response time setting:

    51Q_MR := **1.50 cycles** (minimum response time; transient condition lasts less than 1.5 cycles) (replace "_" with J or K).

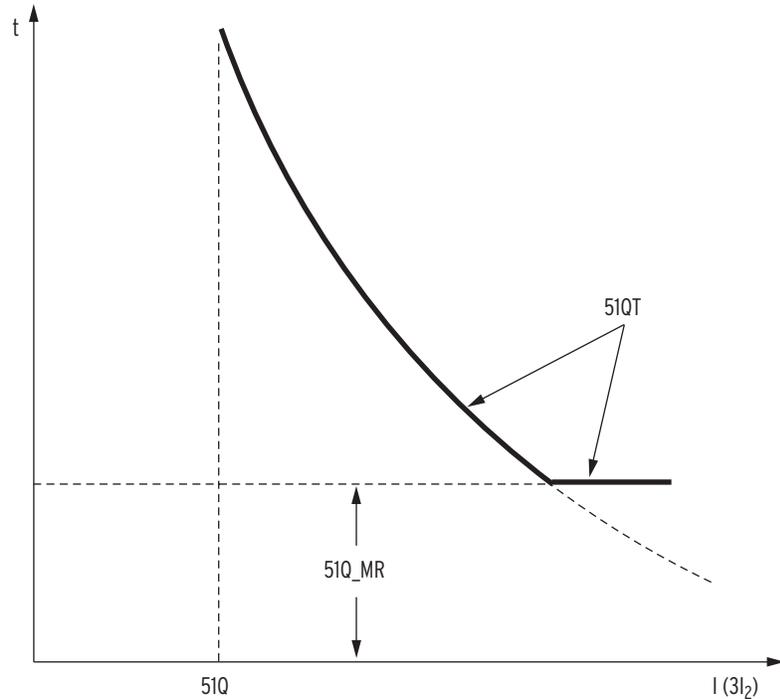

Figure 4.70   Minimum Response Time Added to a Negative-Sequence Time-Overcurrent Element 51QT

Coordinating Negative-Sequence Overcurrent Elements

NOTE: The overcurrent element labels in the example are not the same as the labels of the corresponding SEL-651R-2 overcurrent elements.

The following coordination guidelines and example assume that the negative-sequence overcurrent elements operate on $3I_2$ magnitude negative-sequence current and that the power system is radial. The negative-sequence overcurrent elements in the SEL-651R-2 operate on $3I_2$ magnitude negative-sequence current.

The coordination example is a generic example that can be used with any relay containing negative-sequence overcurrent elements that operate on $3I_2$ magnitude negative-sequence current. The SEL-651R-2 can be inserted as the feeder relay in this example.

Coordination Guidelines

1. Start with the farthest downstream negative-sequence overcurrent element (e.g., distribution feeder relay in a substation).

2. Identify the phase overcurrent device (e.g., line recloser, fuse) downstream from the negative-sequence overcurrent element that is of greatest concern for coordination. This is usually the phase overcurrent device with the longest clearing time.

3. Consider the negative-sequence overcurrent element as an "equivalent" phase overcurrent element. Derive pickup, time dial (lever), curve type, or time-delay settings for this equivalent element to coordinate with the downstream phase overcurrent device, as any phase coordination would be performed. Load considerations can be disregarded when deriving the equivalent phase overcurrent element settings.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Protection Functions 4.107
Setting Negative-Sequence Overcurrent Elements
Page 281 of 1080
Wolfe

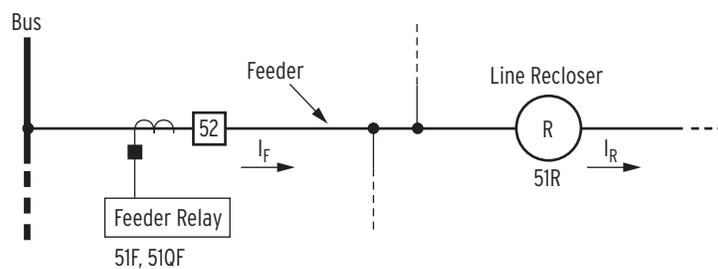
4. Multiply the equivalent phase overcurrent element pickup setting by $\sqrt{3}$ to convert it to the negative-sequence overcurrent element pickup setting in terms of $3I_2$ current.

$$\binom{\text{Negative-sequence overcurrent}}{\text{element pickup}} = \sqrt{3} \cdot \binom{\text{equivalent phase overcurrent}}{\text{element pickup}}$$

Any time dial (lever), curve type, or time delay calculated for the equivalent phase overcurrent element is also used for the negative-sequence overcurrent element with no conversion factor applied.

5. Set the next upstream negative-sequence overcurrent element to coordinate with the first downstream negative-sequence overcurrent element and so on. Again, coordination is not influenced by load considerations.

Coordination Example

In *Figure 4.71*, the phase and negative-sequence overcurrent elements of the feeder relay (51F and 51QF, respectively) must coordinate with the phase overcurrent element of the line recloser (51R).


I_F = Maximum load current through feeder relay = 450 A
I_R = Maximum load current through line recloser = 150 A
51F = Feeder relay phase time-overcurrent element
51QF = Feeder relay negative-sequence time-overcurrent element
51R = Line recloser phase time-overcurrent element (phase "slow curve")

Figure 4.71   Distribution Feeder Protective Devices

4.108 | Protection Functions
Setting Negative-Sequence Overcurrent Elements

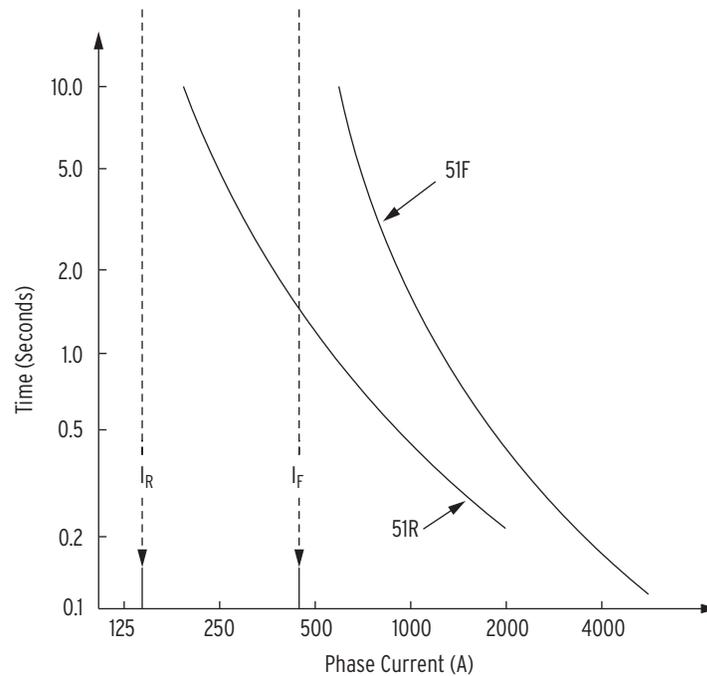
Attachment to Response to AG-2 Question No. 68(g)
Page 282 of 1080
Wolfe

Traditional Phase Coordination


51F: pickup = 600 A (above max. feeder load, I_F)
51R: pickup = 200 A (above max. line recloser load, I_R)

Figure 4.72   Traditional Phase Coordination

Figure 4.72 shows traditional phase overcurrent element coordination between the feeder relay and line recloser phase overcurrent elements. Phase overcurrent elements must accommodate load and cold load pickup current. The 450 A maximum feeder load current limits the sensitivity of the feeder phase overcurrent element, 51F, to a pickup of 600 A. The feeder relay cannot back up the line recloser for phase faults below 600 A.

Apply the Feeder Relay Negative-Sequence Overcurrent Element (Guidelines 1 to 3)

Applying negative-sequence overcurrent element coordination Guidelines 1 to 3 results in the feeder relay equivalent phase overcurrent element (51EP) in *Figure 4.73*. Curve for 51F is shown for comparison only.

Considerable improvement in sensitivity and speed of operation for phase-to-phase faults is achieved with the 51EP element. The 51EP element pickup of 300 A has twice the sensitivity of the 51F element pickup of 600 A. The 51EP element speed of operation for phase-to-phase faults below about 2000 A is faster than that for the 51F element.

Case No. 2018-00295

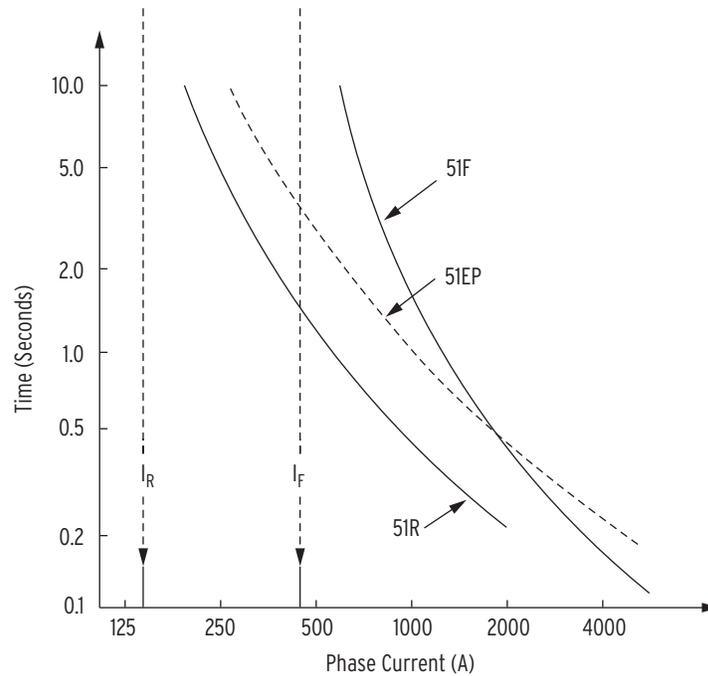
Page 283 of 1080
Protection Functions 4.109
Setting Negative-Sequence Overcurrent Elements
Wolfe


51EP: pickup = 300 A (below max. feeder load, I_F)

Figure 4.73   Phase-to-Phase Fault Coordination

Convert Equivalent Phase Overcurrent Element Settings to Negative-Sequence Overcurrent Element Settings (Guideline 4)

The equivalent phase overcurrent element (51EP element in *Figure 4.73*) converts to true negative-sequence overcurrent element settings (51QF in *Figure 4.74*) by applying the equation given in Guideline 4. The time dial (lever) and curve type of the element remain the same (if the element is a definite-time element, the time delay remains the same).

Having achieved coordination between the feeder relay negative-sequence overcurrent element (51QF) and the downstream line recloser phase overcurrent element (51R) for phase-to-phase faults, coordination between the two devices for other fault types is also achieved.

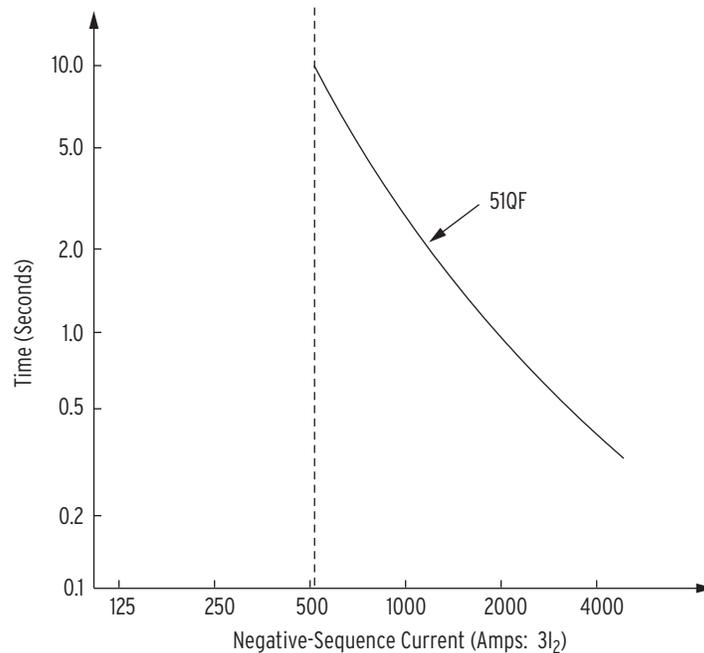

Figure 4.74   Negative-Sequence Overcurrent Element Derived From Equivalent Phase Overcurrent Element 51EP

Negative-Sequence Overcurrent Element Applied at a Distribution Bus (Guideline 5)

The preceding example was for a distribution feeder. A negative-sequence overcurrent element protecting a distribution bus provides an even more dramatic improvement in phase-to-phase fault sensitivity.

The distribution bus phase overcurrent element pickup must be set above the combined load of all the feeders on the bus, plus any emergency load conditions. The bus phase overcurrent element pickup is often set at least four times greater than the pickup of the feeder phase overcurrent element it backs up. Thus, sensitivity to both bus and feeder phase faults is greatly reduced. Feeder relay backup by the bus relay is limited.

Negative-sequence overcurrent elements at the distribution bus can be set significantly below distribution bus load levels and provide dramatically increased sensitivity to phase-to-phase faults. It is coordinated with the distribution feeder phase or negative-sequence overcurrent elements and provides more-sensitive and faster phase-to-phase fault backup.

Ground Coordination Concerns

If the downstream protective device includes ground overcurrent elements, in addition to phase overcurrent elements, there should be no need to check the coordination between the ground overcurrent elements and the upstream negative-sequence overcurrent elements. The downstream phase overcurrent element, whether it operates faster or slower than its complementary ground overcurrent element, will operate faster than the upstream negative-sequence overcurrent element for all faults, including those that involve ground.

Other Negative-Sequence Overcurrent Element References

The following IEEE paper is the source of the coordination guidelines and example given in this appendix. The paper also includes analyses of system unbalances and faults and the negative-sequence current generated by such conditions:

> A. F. Elneweihi, E. O. Schweitzer, M. W. Feltis, *Negative-Sequence Overcurrent Element Application and Coordination in Distribution Protection*, IEEE Transactions on Power Delivery, Volume 8, Number 3, July 1993, pp. 915-924.

The following conference paper gives many good application examples for negative-sequence overcurrent elements. The focus is on the transmission system, where negative-sequence overcurrent elements provide better sensitivity than zero-sequence overcurrent elements in detecting some single-line-to-ground faults:

> A. F. Elneweihi, *Useful Applications for Negative-Sequence Overcurrent Relaying*, 22nd Annual Western Protective Relay Conference, Spokane, Washington, October 24-26, 1995.

High-Impedance Fault Detection (Arc Sense Technology)

NOTE: The SEL-651R-2 uses nonharmonic content in phase currents to detect arcing during high impedance faults. SEL-451 and SEL-751 uses both nonharmonic and odd-harmonic content to detect arcing.

NOTE: Detecting high-impedance faults has challenged utilities and researchers for years, especially in situations where a fault occurs on asphalt or dry sand or generates little or virtually no fault current. As is commonly known, not all HIFs are detectable. Detecting HIFs potentially reduces the risks associated with these faults. The SEL HIF detection method increases the likelihood that an HIF will be detected.

High-impedance fault detection (Arc Sense technology) is available in select SEL-651R-2 models. The part number indicates whether the relay supports high-impedance fault detection.

High-impedance faults (HIF) are short-circuit faults with fault currents smaller than what a traditional overcurrent protective relay can detect. The main causes of HIFs are tree branches touching a phase conductor, failing or dirty insulators that cause flashovers between a phase conductor and the ground or downed conductors. Almost all HIFs involve the ground directly or indirectly.

Staged downed-conductor fault tests in North America indicate that downed-conductor HIFs generate quite small fault currents. The HIF current of multigrounded systems depends highly on the surface types upon which a conductor falls, and the fault current varies from zero to less than 100 A.

The high-impedance fault (HIF) detection method shown in *Figure 4.75* incorporates the following key elements:

> ➤ An informative quantity that reveals HIF signatures as much as possible without being affected by loads and other system operation conditions.

> ➤ A running average of the quantity that provides a stable prefault reference.

> ➤ An adaptive tuning feature that learns and tunes out feeder ambient noise conditions.

> ➤ Decision logic to differentiate an HIF condition from other system conditions such as switching operations and noisy loads.

High-Impedance Fault Detection (Arc Sense Technology)

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 286 of 1080
Wolfe

The HIF detection element derives a Sum of Difference Current (SDI) that represents the total nonharmonic contents of the phase currents to detect a HIF signature. An averaging filter generates a stable reference of SDI and adapts to the ambient conditions of feeder loads. In turn, an adapted detection threshold is established based on the trends of the measured SDI and decision logic is used to separate normal trending from the existence of a HIF on the distribution system. The SEL Technical Paper *Detection of High-Impedance Faults in Power Distribution Systems* by Daqing Hou, details additional information about this HIF detection method.

Protection Functions 4.113
High-Impedance Fault Detection (Arc Sense Technology)
Wolfe

High-impedance fault detection is enabled by Group setting EHIF := Y or T. When EHIF is set to Y and current above the threshold of $0.05 \cdot I_{NOM}$ is applied to the relay, the detection algorithm calculates a running average of the sum of difference current to provide a stable prefault reference. This process is referred to as the initial tuning mode. When the relay is in the initial tuning mode, Relay Word bits ITUNE_A, ITUNE_B, and/or ITUNE_C assert if current is detected on that particular phase. During the initial tuning process, the HIF alarm and fault bits are disabled. The initial tuning process takes 24 hours but is interrupted by a change in the EHIF setting, a change in the NFREQ setting, a change in the VSELECT setting, a loss of load current, or a relay trip condition. Once interrupted, the initial tuning process re-starts when load current is detected.

The initial tuning process can be forced to re-start with either the **INI HIF** command or by asserting the programmable SELOGIC equation HIFITUNE. The **INI HIF** command or HIFITUNE equation are also used to force initial tuning when the line configuration the relay is monitoring changes (see *Example 4.1– Example 4.5* for details). See *INI HIF Command (Only Available In Relays That Support Arc Sense Technology) on page 10.55* for more information on the **INI HIF** command.

After the initial tuning process, the relay enters the normal tuning mode where it continues to tune to the present power system conditions. When the relay is in normal tuning mode, Relay Word bits NTUNE_A, NTUNE_B, and/or NTUNE_C are asserted if current is detected on that particular phase. If the relay does not detect load current while in normal tuning mode, the relay stops tuning and retains the long-term reference value for four hours, this prevents the relay from re-tuning following a short system disturbance. The programmable SELOGIC control equation HIFFRZ can be used to retain the learned reference quantities indefinitely (see *Example 4.1– Example 4.5* for details). If a line is de-energized for more than four hours and the SELOGIC equation HIFFRZ is not asserted, the relay re-starts the initial tuning process upon the re-energization of the line.

When EHIF is set to T (Test), the detection algorithm bypasses the 24-hour tuning process and is immediately available for testing purposes. The relay must be tracking frequency (Relay Word bit FREQOK = 1) in order for the high-impedance fault detection algorithm to work; if the relay is not tracking frequency (Relay Word bit FREQOK = 0) the algorithm is disabled.

The SEL-651R-2 is often applied in systems where reconfiguration occurs. For example, SEL Distribution Network Automation (DNA) solutions use the capabilities of the SEL-651R-2 to reconfigure networks during abnormal power system conditions to limit the number of people that are impacted by system faults. System reconfiguration can impact the effectiveness of the HIF algorithm. The HIF algorithm adapts to minor changes in load, but large changes could potentially cause the long-term reference quantity to not reflect the existing power system conditions. To prevent system reconfiguration from adversely affecting the performance of the HIF algorithm, SEL has introduced the HIFITUNE and HIFFRZ programmable SELOGIC control equations. The following use cases describe examples of using the equations.

EXAMPLE 4.1   Use Case #1 (Loss of load current and line configuration remains the same):

For this example, assume that the following conditions occur:

1.   The HIF algorithm is operating in normal tuning mode.
2.   The energized line goes dead.

4.114 | Protection Functions
High-Impedance Fault Detection (Arc Sense Technology)

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 288 of 1080
Wolfe

3. The line configuration does not change.

4. The line is re-energized.

In this case, the user can assert the SELOGIC control equation, HIFFRZ, which will retain the long-term HIF reference value. When the line is re-energized, HIFFRZ should be deasserted and the HIF algorithm will return to normal tuning mode.

EXAMPLE 4.2   Use Case #2 (Loss of load current for less than 4 hours and line configuration permanently changes):

For this example, assume that the following conditions occur:

1. The HIF algorithm is operating in normal tuning mode.

2. The energized line goes dead.

3. The line configuration permanently changes.

4. The line is re-energized in less than 4 hours.

In this case, the user will more than likely have to take action to ensure the HIF algorithm is not adversely impacted. The line being monitored by the SEL-651R-2 has changed; and therefore, the load characteristics of the system have also changed. The user should consider forcing the HIF algorithm into initial tuning mode by issuing the INI HIF command or asserting the SELOGIC control equation, HIFITUNE. The user can manually assert the HIFITUNE equation or use a distribution automation controller to assert and deassert the HIFITUNE equation. Forcing tuning prevents the algorithm from using the "old" reference value on the "new" line configuration.

EXAMPLE 4.3   Use Case #3 (Loss of load current for more than 4 hours and line configuration permanently changes):

For this example, assume that the following conditions occur:

1. The HIF algorithm is operating in normal tuning mode.

2. The energized line goes dead.

3. The line configuration permanently changes.

4. The line is re-energized more than 4 hours after going dead.

In this case, the user does not have to take any special action to ensure that the HIF algorithm is not impacted by the disturbance. The relay will immediately enter initial tuning mode when the line is re-energized.

EXAMPLE 4.4   Use Case #4 (Load current is not lost and line configuration temporarily changes):

For this example, assume that the following conditions occur:

1. The HIF algorithm is operating in normal tuning mode.

2. The line remains energized.

3. The line configuration the relay is monitoring temporarily changes (e.g., significant load is picked-up or dropped).

In this case, the user should assert the SELOGIC control equation, HIFFRZ, until the original line configuration is restored. Asserting HIFFRZ disables the HIF algorithm. Once the original line configuration is restored, HIFFRZ should be deasserted and the HIF algorithm will return to normal tuning mode.

EXAMPLE 4.5   Use Case #5 (Load current is not lost and line configuration permanently changes):

For this example, assume that the following conditions occur:

1. The HIF algorithm is operating in normal tuning mode.

2. The line remains energized.

3. The line configuration the relay is monitoring permanently changes (e.g., significant load is picked-up or dropped).

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 289 of 1080
Protection Functions 4.115
High-Impedance Fault Detection (Argenta Technology)
Wolfe

In this case, the line configuration being monitored by the SEL-651R-2 has changed; and therefore, the load characteristics of the system have also probably changed. The user should consider forcing the HIF algorithm into initial tuning mode by issuing the INI HIF command or asserting the SELOGIC control equation, HIFITUNE. Forcing tuning prevents the algorithm from using the "old" reference value on the "new" line configuration.

High-impedance fault detection sensitivity is controlled by group SELOGIC control equation setting HIFMODE. Assertion of this logic equation sets Relay Word bit HIFMODE and increases the sensitivity of the detection algorithm.

EXAMPLE 4.6   HIFMODE Programming and Operation

As detailed above, assertion of the HIFMODE SELOGIC control equation controls the sensitivity of the high-impedance fault detection algorithm. Field experience may suggest that downed conductor events that lead to high-impedance faults might occur more frequently during periods of storm activity. Furthermore, conductor configuration could make it likely that a downed conductor might initially create a high-current fault by making temporary contact with another conductor. This fault would be detected and cleared; disappearing upon a successful auto-reclosure. The downed conductor would then be creating a high-impedance fault. It is during this time that it would be desirable to increase the sensitivity of the high-impedance fault detection algorithm. In this example a successful reclosure triggers a timer input. The dropout period of the timer is set to the period of time that is desired for increased detection sensitivity.

Enter the following Group settings:

EHIF := Y

HIFMODE := SV16T AND 52A3P #HIFMODE SELOGIC control equation variable follows the SELOGIC timer output.

Enter the following Logic settings:

SV16PU := 0.0 # Pickup set to 0.0 cycles

SV16DO := 108000.0 # Dropout set to 30.0 minutes on a 60 Hz system

SV16 := R_TRIG 79CY3P # Reclosing relay is in reclose cycle state

When the recloser enters the reclose cycle state, 79CY3P asserts the output for SELOGIC variable 16. The SV16T stays asserted for the duration of the dropout setting, which is 30 minutes in this example. During this 30 minutes, the SV16T assertion maintains the assertion of HIFMODE, assuring a window of time for increased sensitivity of the HIF detection algorithm.

Group SELOGIC control equation setting HIFER allows for the automatic triggering of HIF detection event reports. Assertion of HIFER asserts Relay Word bit HIFREC and triggers an event report.

HIF Detection Logical Outputs

The SEL-651R-2 indicates HIF detection through the Relay Word Bit outputs detailed in *Table 4.27*. Relay word bits can be used in custom logic programming to indicate high-impedance fault detection activity.

HIF Detection Event Reports and Histories

The SEL-651R-2 stores HIF detection information as oscillography in binary COMTRADE format, compressed events, event summaries, and histories. See *HIF Event Summary on page 12.48*, *High-Impedance Fault Compressed Event Report on page 12.52*, *High-Impedance Fault Metering on page 8.23*, *LOG HIF Command (Only Available In Relays That Support Arc Sense Technology) on page 10.55*, and *Viewing the HIF Event History on page 12.51* for more information.

HIF Coordination

Coordination of high-impedance fault detection is possible when multiple SEL-651R-2 recloser controls and/or substation relays that contain high-impedance fault detection, like the SEL-451, are applied on the same line. Coordination can minimize the number of impacted customers and increase efficiency of fault location.

50G High-Impedance (HIZ) Fault Detection

APPLYING 50G HIZ
See 50G HIZ Application Considerations.

50G high-impedance (HIZ) fault detection is available in select SEL-651R-2 models. The part number indicates whether the relay supports high-impedance fault detection.

An additional and wholly separate method of detecting high-impedance fault activity is the ground overcurrent high-impedance (50G HIZ) fault detection method. The 50G HIZ detection method counts the number of times an instantaneous ground overcurrent element (50G) asserts and deasserts at a very low pickup threshold within a settable period of time. This activity could indicate the presence of a small magnitude arcing fault on the system. Some hysteresis is built into the 50G element to minimize element chatter resulting from nonfault activity. The SEL-651R-2 stores 50G HIZ detection information in a report that is obtained with the **HIZ** command. See *Figure 4.76* for a sample HIZ report.

> (on channel IN base*, when Global setting EGNDSW := Y and Group setting CTR = CTRN)

> 0.005–[20 • (CTR/CTRN)] A secondary in 0.001 A steps
> (on channel IN base, when Global setting EGNDSW := Y and Group setting CTR ≠ CTRN)

> 0.010–20.000 A secondary in 0.001 A steps
> (on IA, IB, IC base, when Global setting EGNDSW := N)

> * **Note:** In the case where EGNDSW := Y and CTR = CTRN, there is no difference between the IN current base and the IA, IB, IC current base. This is the standard configuration for the SEL-651R-2.

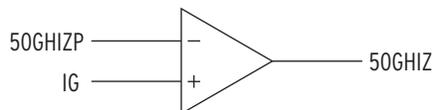
Ground overcurrent high-impedance fault detection is enabled by Group setting 50GHIZP. When 50GHIZP is set to any value other than OFF, ground instantaneous overcurrent element 50GHIZ is enabled to initiate 50G HIZ fault detection. *Figure 4.77* shows the operating logic for element 50GHIZ.


Figure 4.77 Ground Instantaneous Overcurrent Element 50GHIZ

When the 50G HIZ logic is initializing, the Relay Word bit HIZ170 is asserted. Relay Word bit HIZ171 will assert when the 50G HIZ logic begins to process. The assertion of 50GHIZ (HIZ172 asserts) and deassertion of 50GHIZ (HIZ173 asserts) causes counter CPUDO to increment. Group setting NPUDO establishes a threshold that counter CPUDO must meet in order for

4.118 | Protection Functions
50G High-Impedance (HIZ) Fault Detection

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 292 of 1080
Wolfe

50G HIZ fault detection to continue. Group setting TPUDO establishes a time window within which counter CPUDO must meet the NPUDO threshold. If CPUDO reaches NPUDO within TPUDO, counter CHIZ is then incremented (HIZ174 asserts). If it does not, counter CPUDO is reset (HIZ180 asserts) and the logic starts over.

Group setting NHIZ establishes a threshold that counter CHIZ must meet in order for 50G HIZ fault detection to continue. Group setting THIZ establishes a time window within which counter CHIZ must meet the NHIZ threshold. If CHIZ reaches NHIZ within THIZ, Relay Word bit 50GHIZA is asserted (HIZ175 asserts) and latched; group SELOGIC setting HIZRST resets 50GHIZA. Group setting NHIZR establishes a separate threshold at which HIZ report entries are generated. Refer to the following section for an example of how these settings can be utilized to for 50G HIZ fault detection.

NOTE: Use the HIZxxx Relay Word bits during testing to indicate the progression of the 50G HIZ logic. SEL does not recommended using HIZxxx bits in the SER or in SELOGIC during normal operation.

Table 4.29 50G HIZ Relay Word Bits

Relay Word bit	Description of Relay Word bits
HIZ170	50G HIZ logic is in its initialization state, all other 50G HIZ Relay Word bits are deasserted, all counters (CPUDO and CHIZ) are forced to zero, and all timers (TPUDO and THIZ) are forced to zero. The HIZ logic returns to this state if a trip condition is detected.
HIZ171	The HIZ logic is enabled and waiting for 50GHIZ Relay Word bit to assert.
HIZ172	50GHIZ has asserted and the HIZ logic is waiting for 50GHIZ to deassert.
HIZ173	50GHIZ element has deasserted, CPUDO counter increments one count, the TPUDO timer starts (HIZ181), and the HIZ logic is waiting for 50GHIZ to assert again (HIZ171).
HIZ174	The CPUDO count is equal to the NPUDO setting, CPUDO gets reset to zero (HIZ180), CHIZ increments one count, and the HIZ logic returns to waiting for 50GHIZ to assert again (HIZ171).
HIZ175	The CHIZ count is equal to the NHIZ setting, the high-impedance alarm bit, 50GHIZA, latches in, and the HIZ logic enters the initialization state (HIZ170).
HIZ180	CPUDO counter is set to zero (initialization state for CPUDO counter)
HIZ181	The HIZ logic is waiting for CPUDO to equal NPUDO (HIZ174) or for TPUDO to timeout. When one of the conditions is met, CPUDO is reset to zero (HIZ180) and either CHIZ increments (HIZ174) or the HIZ logic re-starts (HIZ171).
HIZ190	CHIZ counter is set to zero (initialization state for CHIZ counter).
HIZ191	The HIZ logic is waiting for CHIZ to equal NHIZ (HIZ175) or for THIZ to timeout. When one of the conditions is met, HIZ192 asserts, CHIZ is reset to zero (HIZ190) and either 50GHIZA (HIZ175) asserts or the HIZ logic re-starts (HIZ171).
HIZ192	Intermediate state before forcing the CHIZ counter back to zero (HIZ190).

50G HIZ Detection Logic Example

Figure 4.78 and *Figure 4.79* show how the example HIZ report entries in *Figure 4.76* are generated. Compared to the settings ranges given in *Table 4.28*, the following example settings NHIZR = 6 and NHIZ = 18 appear especially small and are for illustrative purposes only.

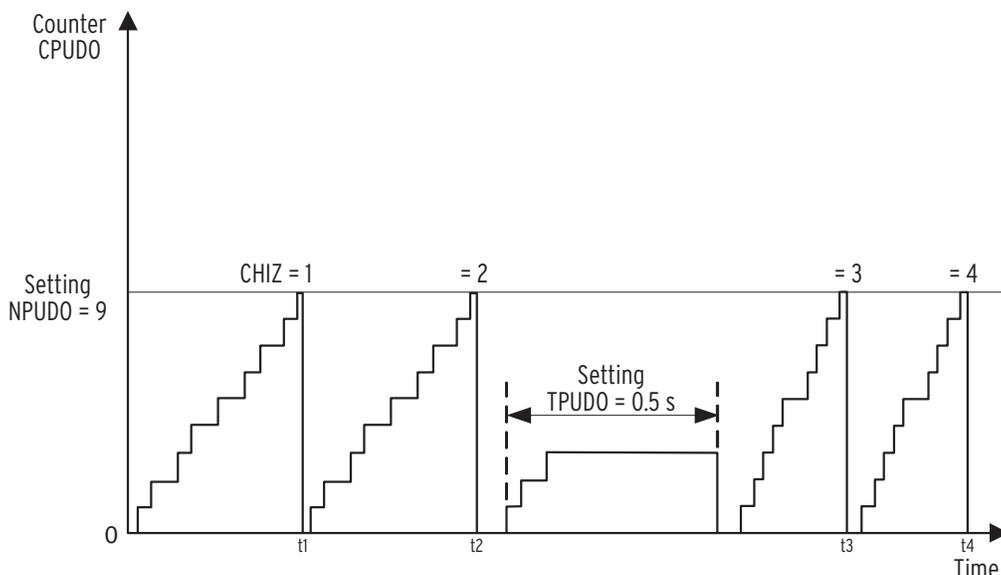
50G High-Impedance (High Fault) Detection


Figure 4.78   Counter CPUDO for Assertion/Deassertion of Ground Fault Overcurrent Element 50GHIZ

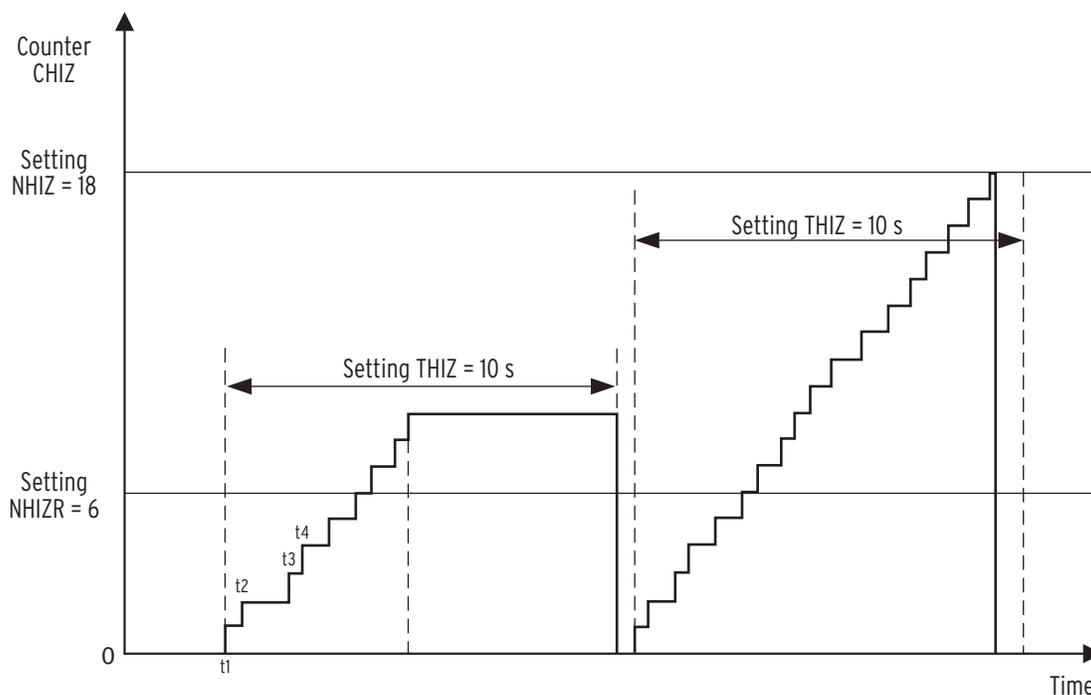
Figure 4.78 shows counter CPUDO incrementing from 0 to NPUDO = 9. This has to be done within time TPUDO (0.5 seconds in this example), or counter CPUDO is reset (HIZ180 asserts). Notice in the middle of *Figure 4.78* that an increment attempt only got as far as counter CPUDO = 3, before time TPUDO = 0.5 seconds expired and counter CPUDO was reset to zero (0). Each time counter CPUDO reaches NPUDO, counter CHIZ is then incremented (HIZ174 asserts) and counter CPUDO resets (HIZ180 asserts). When counter CHIZ first increments to CHIZ = 1, the corresponding date/time is recorded for possible report logging later.


Figure 4.79   Counter CHIZ for High Impedance Ground Fault Detection

Figure 4.79 shows counter CHIZ incrementing, with time stamps t1, t2, t3, and t4 corresponding back to *Figure 4.78*.

If counter CHIZ increments to NHIZ or greater, within THIZ time, then the activity is logged in the HIZ report. Notice in *Figure 4.79* that both incrementing attempts exceed level NHIZR = 6 (CHIZ = Counter HIZ = 9 and CHIZ = Counter HIZ = 18) and thus are displayed in the HIZ report in *Figure 4.76*. Notice that each report entry has a time stamp for Counter HIZ = 1 and a time stamp for the highest Counter HIZ level reached, within time THIZ = 10 seconds. These time stamp differences allow for the determination of the relative activity of ground overcurrent high impedance fault detection. Such analysis may result in modifying settings 50GHIZP, NPUDO, TPUDO, NHIZ, THIZ, or NHIZR.

The first incrementing attempt in *Figure 4.79* only got as far as counter CHIZ = 9, before time THIZ = 10 seconds expired (HIZ192 asserts) and counter CHIZ was reset to zero (0). The second incrementing attempt in *Figure 4.79* reached CHIZ = NHIZ within THIZ time (HIZ175 asserts). Then counter CHIZ was reset to zero (0) (HIZ190 asserts).

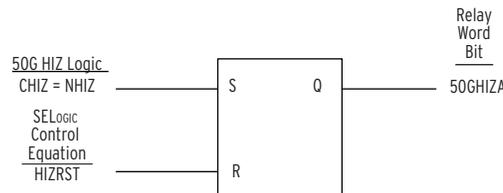
Upon asserting HIZ175, Relay Word bit 50GHIZA is asserted and latched; group SELOGIC setting HIZRST, when asserted, resets 50GHIZA. Relay word bit 50GHIZA can be used in custom logic programming to indicate ground overcurrent high-impedance fault detection activity.


Figure 4.80   50GHIZA Relay Word bit

50G HIZ Application Considerations

Unlike the High-Impedance Fault detection algorithm (see *High-Impedance Fault Detection (Arc Sense Technology) on page 4.111*), the 50G HIZ algorithm does not automatically "tune" to the conditions of the system. Set the algorithm as a high-impedance fault detection alarm until you have determined how the element responds to conditions in your particular application. The following discussion describes how to monitor and adjust the 50G HIZ logic.

Set the 50GHIZP setting equal to the pickup threshold of the 51G element. Arcing faults are intermittent, so the 51G element set the same as the 50GHIZ is not likely to detect the high-impedance fault, but the arcing may cause 50GHIZ activity. Leave the time window settings (TPUDO and THIZ) and threshold settings (NPUDO and NHIZ) at the factory defaults until data are acquired. Make setting NHIZR (report threshold) less than setting NHIZ (fault threshold). This will trigger events that are accessible through the **HIZ** command. The results from the **HIZ** command and conditions reported in the system can then be used to determine if the algorithm should be more or less sensitive.

For example, if there are numerous events logged in the **HIZ** command, but no high-impedance faults are reported in the system, the logic should be made less sensitive. Settings 50GHIZP, NPUDO, NHIZ, and NHIZR can be increased, and time window settings TPUDO and NPUDO can be decreased. On the other hand, if there are no events logged in the **HIZ** command, but high-impedance faults are reported on the system, the logic needs to be made more sensitive. Lower the threshold settings or increase the time window settings. Repeat this process several times until the HIZ results and field data agree.

Section 5

Trip and Target Logic

Trip Logic

The trip logic in *Figure 5.1* provides flexible tripping for single-phase reclosers and three-phase reclosers. Single-phase reclosers can trip/reclose in a single-phase mode (each phase operates independently) or a three-phase mode (all three phases operate in unison). Three-phase reclosers can only trip/reclose in a three-phase mode.

Single-phase reclosers (set for single-phase or three-phase tripping; setting ESPB := Y) can make use of the following logic, also shown in *Figure 5.1*:

➤ Switch-Onto-Fault Trip Logic

➤ Three-Phase Trip Input Logic

➤ Single-Phase Trip Logic

Three-phase reclosers (and single-phase reclosers set for three-phase tripping only; setting ESPB := N) can use the following logic, also shown in *Figure 5.1*:

➤ Switch-Onto-Fault Trip Logic

➤ Three-Phase Trip Input Logic

➤ Three-Phase Trip Output Logic

Table 5.1 includes explanations of the SELOGIC control equation settings in the trip logic in *Figure 5.1*:

Table 5.1 SELOGIC Settings Explanations for Figure 5.1 (Sheet 1 of 2)

SELOGIC Setting	Description
TRSOTF	Switch-Onto-Fault Trip Conditions.
	Setting TRSOTF is supervised by the switch-onto-fault logic output SOTFE (switch-onto-fault logic is described in *Switch-Onto-Fault Logic Output (SOTFE) on page 5.12*). Relay Word bit output SOTFT is provided for testing purposes. Note that the switch-onto-fault tripping routes to both the three-phase trip logic and the single-phase trip logic.
	Switch-onto-fault tripping is a three-phase tripping action, which has its origin in transmission line protection applications. Switch-onto-fault tripping is not used as much in distribution applications.
TRQL3P	Three-Phase Qualified Trip Conditions.
	Setting TRQL3P is supervised by the Disturbance Detector logic output. When the Disturbance Detector bit is not asserted, the qualified trip settings are delayed by two cycles to give the relay self-test time to detect any problem and prevent misoperations. This setting also routes to the single-phase trip logic.

Page 296 of 1080
Wolfe

Table 5.1 SELᴏɢɪᴄ Settings Explanations for Figure 5.1 (Sheet 2 of 2)

SELᴏɢɪᴄ Setting	Description
TR3P, TR3X	Three-Phase Trip Input Conditions.
	Three-phase trip input conditions settings TR3P and TR3X route to both the three-phase trip output logic (ESPB := N) and the single-phase trip logic (ESPB := Y).
	TR3P and TR3X are functionally equivalent. TR3X is for extra three-phase trip logic and is seen as a supplement to TR3P. For the single-phase trip logic, settings TR3P and TR3X provide convenient locations to insert three-phase trip conditions, rather than repetitively inserting them in each single-phase trip setting (TRA, TRB, and TRC).
ULTR3P	Unlatch Three-Phase Trip Conditions.
	Unlatch three-phase trip conditions setting ULTR3P only routes to the three-phase trip output logic (ESPB := N). Note that if setting ULTR3P is set directly to logical 1 (ULTR3P := 1), then the three-phase trip output logic (Relay Word bit TRIP3P) effectively becomes like the individual single-phase trip output logic arrangements (Relay Word bits TRIPA, TRIPB, and TRIPC).
TRQLA, TRQLB, TRQLC	Single-Phase Qualified Trip Conditions.
	The single-phase qualified trip settings are supervised by the Disturbance Detector logic, similar to Trip setting TRQL3P.
TRA, TRB, TRC	Single-Phase Trip Conditions.
	Single-phase trip conditions settings TRA, TRB, and TRC only route to the single-phase trip logic (ESPB := Y).

Factory-Default Trip Settings

AVOID SETTING SCENARIOS THAT CAN CAUSE THE TRIP BITS TO GET SEALED IN.
For example, consider the following settings (refer to Figure 5.1): ESPB := Y, TR3P := TRIPA OR TRIPB OR TRIPC, TRA := 50A1, TRB := 50B1, and TRC := 50C1. In this case, TRIPA asserts if 50A1 asserts. This causes TRIP3P (via setting TR3P) to assert, and this in turn asserts TRIPB and TRIPC. Even if 50A1 then deasserts, TRIPA, TRIPB, and TRIPC will remain asserted (sealed in) because of the preceding setting TR3P. Setting TR3P has to be changed (i.e., not set to trip logic output values) for TRIPA, TRIPB, and TRIPC to deassert.

"YELLOW OPERATING HANDLE" TRIP AND DRIVE-TO-LOCKOUT
The factory-default TR3X trip setting (Figure 5.2) and 79DTL3X drive-to-lockout setting (Figure 6.11) are set the same for G&W Viper-ST, G&W Viper-LT, ABB Elastimold MVR, ABB OVR/Gridshield (32-pin), Siemens SDR Triple-Single, Eaton NOVA-TS or NOVA-STS Triple-Single, and Multi-Recloser Interface reclosers. These settings propagate the pulling of a single yellow operating handle (on a single phase) to trip and lockout all three phases.

The factory-default settings for the trip logic in *Figure 5.1* are the following:

TDURD := **40.00 cycles**

TR3P := **51PT OR 51G1T OR PB12_PUL OR OC3**

TR3X := **R_TRIG SV02T** make setting for G&W Viper-ST, G&W Viper-LT, ABB Elastimold MVR, ABB OVR/Gridshield (32-pin), Siemens SDR Triple-Single, and Eaton NOVA-TS or NOVA-STS Triple-Single recloser applications only

TR3X := **R_TRIG SV02T AND AI_CFG** make setting for Multi-Recloser Interface recloser applications only

TRQL3P := **0**

TRSOTF := **0**

ULTR3P := **1** set directly to logical 1

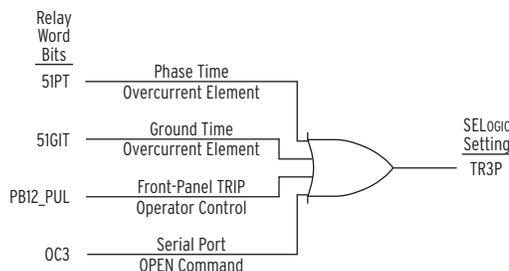
All the other SEL<small>OGIC</small> settings in *Figure 5.1* are set directly to logical 0. See


Figure 5.2   Factory-Default Trip Logic Settings

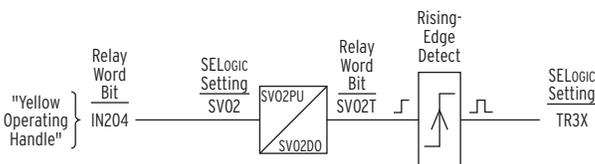
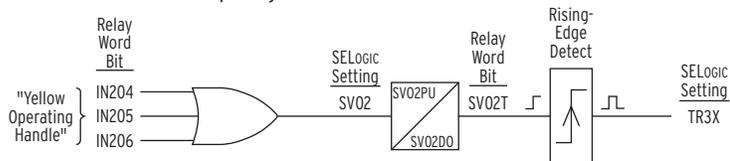
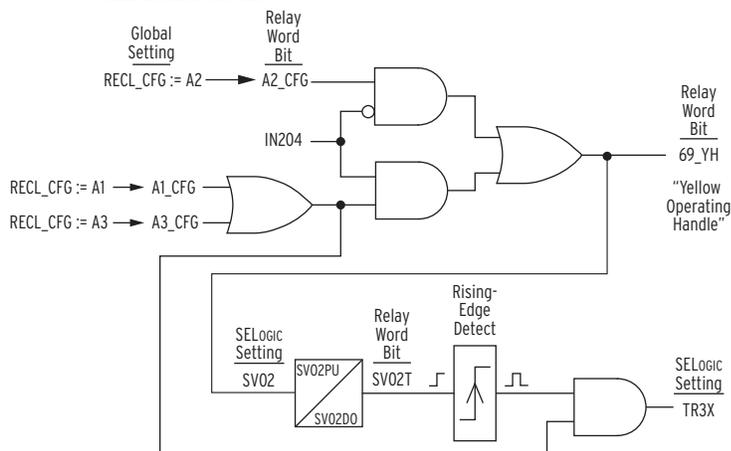
Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 299 of 1080
Trip and Target Logic | 5.5
Trip Logic
Wolfe






As shown in SELOGIC trip setting TR3P in *Figure 5.2*, overcurrent tripping is by either the phase (51PT) or ground time-overcurrent (51G1T) elements. Each of these overcurrent elements can operate in a fast curve or delay curve mode (see *Section 4*). Additional tripping comes from the front-panel **TRIP** pushbutton (PB12_PUL) or the serial port **OPEN** command (**OC3**).

Yellow Operating Handle
(G&W Viper-ST, G&W Viper-LT, ABB Elastimold MVR, ABB OVR/Gridshield (32-Pin), Siemens SDR Triple-Single, Eaton NOVA-TS or NOVA-STS Triple-Single, and Multi-Recloser Interface Reclosers)

EMERGENCY THREE-PHASE TRIP WITH SINGLE-PHASE YELLOW OPERATING HANDLE
This subsection explains how a single-phase yellow operating handle pull (to the lock-open position) is converted into a three-phase trip for certain reclosers (factory-default settings).

For the G&W Viper-ST, G&W Viper-LT, ABB Elastimold MVR, ABB OVR/Gridshield (32-pin), Siemens SDR Triple-Single, and Multi-Recloser Interface reclosers, additional tripping can occur for the time-qualified, rising-edge assertion (SELOGIC operator R_TRIG) of input IN204. Input IN204 detects the operation of any one of the yellow operating handles on the single-phase units of the recloser (see *Figure 2.54*, *Figure 2.72*, and *Figure 2.80*). For the Eaton NOVA-TS or NOVA-STS Triple-Single recloser, inputs IN204, IN205, or IN206 detect the operation of the yellow operating handles on phase 1, 2, or 3, respectively (see *Figure 2.67*). These manual trip conditions are propagated to all three phases, via SELOGIC trip setting TR3X. Each single-phase unit has its own yellow operating handle; operation of this handle manually opens up the single-phase unit and effectively locks it out.

The yellow operating handle could be used in an emergency situation, where tripping of all three phases is necessary. In such a situation, it would take too long to manually operate each individual yellow operating handle on each single-phase recloser unit. Thus, the factory-default TR3X setting propagates the trip operation of one yellow operating handle to the other two single-phase recloser units.

The factory-default settings for timer SV02T in *Figure 5.2* are SV02PU := 5.00 cycles and SV02DO := 60.00 cycles. The 5 cycles setting gives time for the yellow operating handle actuated single-phase unit to lock out its trip/close circuit, before a trip signal is issued to all the units, including the one that is locked out. The 60 cycles setting helps prevent any spurious signal dropout and subsequent apparent rising edge, thus avoiding any unintentional trip.

69_YH Relay Word Bit for Multi-Recloser Interface

Review *Table 2.6* and accompanying footnotes [b] and [d].

For the reclosers in *Table 2.6* with Global setting RECL_CFG := A1 or A3, and which include per-phase handles, pulling a yellow operating handle on a single phase of the recloser to the lock-open position causes the following:

➤ the single phase of the recloser to open, if not already open

➤ the corresponding 69 contact of Trip/Close circuitry in *Figure 2.79* (e.g., contact 69_1) to open, thus open circuiting the trip/close circuit of that phase

➤ the corresponding auxiliary (or status) 69 contact in *Figure 2.80* (e.g., contact 69_1) to close, energizing input IN204. This causes Relay Word bit 69_YH to assert in the Multi-Recloser Interface portion of *Figure 5.2*.

5.6 | Trip and Target Logic
Trip Logic

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 300 of 1080
Wolfe

For the reclosers in *Table 2.6* with Global setting RECL_CFG := A2, pulling the sole yellow operating handle of the recloser to the lock-open position causes:

➤ all three phases of the recloser to open, if not already open

➤ all three 69 contacts in *Figure 2.79* to open, thus open circuiting the trip/close circuits of all three phases

➤ the corresponding 69 contact in *Figure 2.80* to open, de-energizing input IN204. This causes Relay Word bit 69_YH to assert in the Multi-Recloser Interface portion of *Figure 5.2*.

Thus, Relay Word bit 69_YH indicates that a yellow operating handle has been pulled to the lock-open position, for the Multi-Recloser Interface.

The operated phases cannot be closed until their corresponding yellow operating handle is reset again. Resetting the yellow operating handle does not cause the recloser phase(s) to close, but rather returns the corresponding 69 contact(s) to their original state (e.g., contact 69_1 in *Figure 2.79* closes)—then the phase(s) can be closed by the SEL-651R-2.

Qualified Trip Conditions Settings

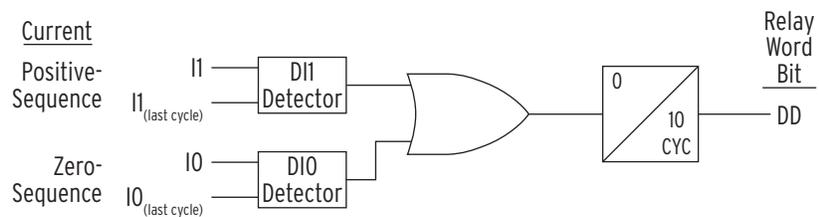
The SEL-651R-2 has self-test functions to detect most hardware problems and prevent misoperation. A small number of transient memory or processor errors may not be detected. The qualified trip conditions settings (TRQL3P, TRQLA, TRQLB and TRQLC) and setting EDDSOTF switch-onto-fault supervision improve security for these transient conditions without increasing relay operating time under most fault conditions. The qualified trip conditions settings are supervised by the disturbance detector logic, as shown in *Figure 5.1*. The disturbance detector (DD) logic detail is shown in *Figure 5.3*. For example, when the SEL-651R-2 evaluates the TRQL3P setting to logical 1, the relay trips immediately if the DD Relay Word bit is already asserted. If DD is not asserted, the relay waits as long as two cycles for DD to assert. If the TRQL3P setting remains asserted the relay trips after the timer expires.


Figure 5.3   Disturbance Detector Logic

The sensitive disturbance detector monitors changes in the magnitude and angle of the positive- and zero-sequence currents and deems a fault condition exists if there is a noticeable change in at least one of these values. The DD element also contains a 10-cycle dropout timer to maintain a logical 1 for a reasonable period after a disturbance is detected. Thus, using the qualified trip conditions settings for instantaneous overcurrent elements will almost never increase tripping time.

Security is improved when a qualified trip conditions setting is asserted momentarily because of a transient memory or processor error, but the disturbance detector does not assert. If the qualified trip conditions setting resets before the two-cycle timer expires, no TRIP is issued.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 301 of 1080
Trip and Target Logic | 5.7
Trip Logic
Wolfe

Use the qualified trip conditions settings with instantaneous elements, such as in the following setting:

TRQL3P := **50P1**

Overcurrent elements that contain an intentional time delay may be used in the qualified trip conditions settings. In certain conditions, such as during bench testing with delays set longer than 10 cycles, the disturbance detector element may deassert before the time-delayed element asserts in the qualified trip conditions settings. This adds two cycles to the overall trip time.

For example, if setting TRQL3P contains a negative-sequence time-overcurrent element

TRQL3P := **... OR 51QT**

the observed trip time may be as many as 2 cycles longer than the expected time-overcurrent characteristic. For backup protection delays lasting several seconds, this extra time is of no consequence. If this extra delay is not desirable, use the time-delayed elements in the unsupervised trip settings TR3P or TR3X instead.

Elements that assert for nonfault conditions, such as a **BREAKER OPEN** command or **OPERATOR CONTROL** pushbutton trip conditions, should not be used in the qualified trip conditions settings because the asserted condition may only exist for one processing interval and the DD bit will often be quiescent. This situation will sometimes result in a nontrip. Use the unsupervised trip settings TR3P or TR3X for automation or control tripping instead.

Setting EDDSOTF := Y enables similar supervision for the switch-onto-fault logic. See *Disturbance Detector Supervision for Switch-Onto-Fault Logic on page 5.13* for more information.

Minimum Trip Duration Timer

The Minimum Trip Duration Timer (with setting TDURD) establishes the minimum time duration for which the TRIP3P, TRIPA, TRIPB, and TRIPC Relay Word bits assert in *Figure 5.1*.

The factory-default setting of TDURD := 40.00 cycles covers the operation requirements of all compatible reclosers. This 40-cycle minimum trip time effectively adds on to any open-interval time for autoreclosing (see *Skip-Shot and Stall Open-Interval Timing Settings (79SKP and 79STL, Respectively) on page 6.29*; setting 79STL3P := TRIP3P). If the recloser is not a motor-operated recloser (see *Motor-Operated Traditional Retrofit Reclosers on page 2.60*) and this 40 cycles is too much additional delay for open-interval timing, then set:

TDURD := **12 cycles**

ULTR3P := **NOT 52A3P** (if recloser is also a Traditional Retrofit standard recloser)

As shown in the time line example in *Figure 5.4*, the Minimum Trip Duration Timer (with setting TDURD) outputs a logical 1 (Signal 2) for a time duration of TDURD cycles any time it sees a rising edge on its input (logical 0 to logical 1 transition on Signal 1), if it is not already timing (timer is reset). If Signal 1 in *Figure 5.4* is logical 1 beyond the TDURD time, Signal 3 remains asserted at logical 1 for as long as Signal 1 remains at logical 1, regardless of other trip logic conditions.

Program Outputs for Tripping the Recloser

See *Trip and Close Mapping and Output Logic on page 7.31* for more information on programming outputs for tripping the recloser. Relay Word bits TRIP3P, TRIPA, TRIPB, and TRIPC from *Figure 5.1* are used to program trip outputs.

Trip Output Logic Used in Other Settings

In addition to operating trip outputs, the TRIP3P, TRIPA, TRIPB, and TRIPC Relay Word bits from *Figure 5.1* are traditionally used in a number of other SELOGIC control equations settings, such as the following (discussed in *Section 6*):

➤ ULCL (unlatch close settings)

➤ 79RI (reclose initiate settings)

➤ 79DTL (drive-to-lockout settings)

➤ 79STL (stall open interval timing settings)

Change the Trip Settings—Check Other Settings

Any time any of the SELOGIC settings in *Figure 5.1* are changed/modified, the following SELOGIC control equations should be checked or considered for modification:

Table 5.2   Settings to Modify When Modifying Trip Logic Settings (Sheet 1 of 2)

Setting	Modification
79DTL3P, 79DTL3X	Drive-to-lockout settings—see *Section 6*
	For example, if frequency element 81D1T is added to the three-phase trip setting (TR3P := … OR 81D1T …), but no autoreclosing should occur after an underfrequency load-shedding trip, then frequency element 81D1T should be added to the three-phase drive-to-lockout setting (79DTL3P := … OR 81D1T …).
50xTC-51xTC	Torque control for overcurrent elements—see *Section 4*
	For example, if ground time-overcurrent element 51G2T is added to the factory-default trip settings (TR3P := … 51G2T …), check its corresponding torque-control setting (51G2TC). Should it be enabled all the time (51G2TC := 1)? Should it be controlled by the **GROUND ENABLED** operator control (51G2TC := LT01; see *Table 11.9*).

Trip and Target Logic 5.9
Pole Open Logic

Table 5.2   Settings to Modify When Modifying Trip Logic Settings (Sheet 2 of 2)

Setting	Modification
T01_LED–T24_LED	Programmable target LEDs *Front-Panel Target LEDs on page 5.13* shows the correlation between tripping elements in factory-default SELOGIC control equation trip settings and the programmable front-panel target LEDs. For example, if ground time-overcurrent element 51G2T is added to the three-phase trip settings (TR3P := … OR 51G2T …), it should perhaps be added to the FAST CURVE or DELAY CURVE trip target LED setting (e.g., T09_LED := … OR 51G2T …) and its pickup indication (51G2) should be added to the GROUND fault type target LED setting (T06_LED := … OR 51G2 …). An additional example, if frequency element 81D1T is added to the factory-default trip setting (TR3P := … OR 81D1T …), then frequency element 81D1T should be assigned to the dedicated FREQUENCY trip target LED setting (T11_LED := 81D1T).
ER	Event report trigger conditions—see *Section 12* For example: if residual ground time-overcurrent element 51G2T is added to the three-phase trip settings (TR3P := … OR 51G2T …), consider adding its pickup indication (51G2) to the event report trigger conditions setting (ER := … OR R_TRIG 51G2 …). A rising edge operator (R_TRIG) is added on the front of the element.
FAULT	Fault indication-used to help determine phases involved in faults and to block certain metering functions during faults For example, if residual ground time-overcurrent element 51G2T is added to the three-phase trip settings (TR3P := … OR 51G2T …), consider adding its pickup indication (51G2) to the fault indication setting (FAULT := … OR 51G2 …).

Pole Open Logic

NOTE: The logic in Figure 5.6 can be used for load current detection, independent of the pole open logic in Figure 5.5.

Combinations of the following items make up the single-pole open and three-pole open logic in *Figure 5.5*.

➤ load current detection

➤ breaker (recloser) pole status (52a auxiliary contacts)

This logic verifies that the poles/phases of the breaker (recloser) are open.

Figure 5.6 shows the load current detection logic, with available single-phase values. Phase pickup setting 50LP is set below minimum load current levels.

In *Figure 5.5*, the breaker (recloser) type setting BKTYP makes the large demarcation for the following recloser types:

➤ BKTYP := 1 (single-phase)

➤ BKTYP := 3 (three-phase)

MULTI-RECLOSER INTERFACE
Global setting BKTYP is automatically set to BKTYP := 1 (and hidden) for the Multi-Recloser Interface on page 2.93.

In general, the following is required to indicate single-pole open (SPO) or three-pole open (3PO) conditions:

➤ an absence of current (Relay Word bit 50Lx deasserted)

➤ a breaker auxiliary contact indication of open recloser poles (Relay Word bit 52Ax deasserted).

5.10 | Trip and Target Logic
Pole Open Logic

Attachment to Response to AG-2 Question No. 68(g)
Page 304 of 1080
Wolfe

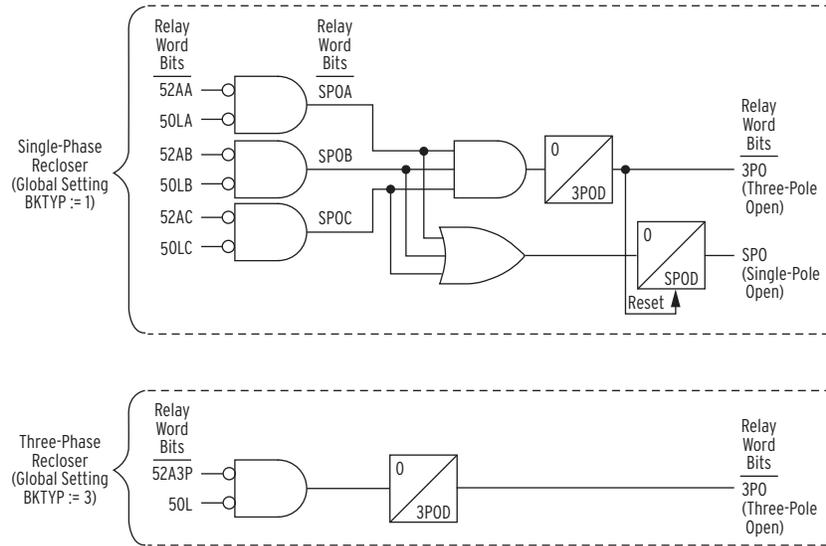
The 3POD and SPOD dropout time settings qualify circuit breaker closure and are usually set around one cycle.


Figure 5.5   Pole Open Logic
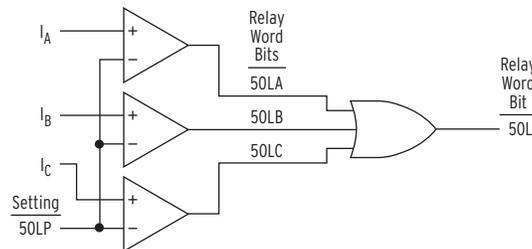

Figure 5.6   Load Current Detection Logic

Overcurrent Element Torque-Control Setting Application

If a single-phase recloser is operating in a single-phase trip/reclose mode, one or two phases can trip open, while at least one phase remains closed, carrying load current. This can result in large unbalance current (zero-sequence and negative-sequence current). To keep zero-sequence (ground) and negative-sequence overcurrent elements from operating for this unbalance situation, the SPO (single-pole open) Relay Word bit is entered in the respective torque-control SELOGIC settings of these overcurrent elements. The SPO Relay Word bit is programmed in the torque-control SELOGIC settings such that when SPO asserts (= logical 1), the torque-control SELOGIC settings effectively deassert (= logical 0). For example, set a ground time-overcurrent element as follows:

    51GITC := **... AND NOT (SPO AND SPE)**

SPE asserts to logical 1 when Group setting ESPB := Y (enabling single-phase settings/operation). This matches the recommended torque-control settings for ground time-overcurrent elements in SEL QuickSet Design Template Guide (LDG002-01), *Single-Phase Operation Setting for the SEL-651R 32-Pin Recloser Control*.

The three-pole open logic output (Relay Word bit 3PO) is used in the following switch-onto-fault logic subsection.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 315 of 1080
Wolfe

Trip and Target Logic 5.11
Switch-Onto-Fault (SOTF) Trip Logic

Switch-Onto-Fault (SOTF) Trip Logic

Switch-onto-fault (SOTF) trip logic is enabled with Group setting
ESOTF := Y and provides a programmable time window for selected elements
to trip right after the circuit breaker/recloser closes. Switch-onto-fault implies
that a recloser is closed into an existing fault condition.

For example, suppose safety grounds are accidentally left attached to a line
after a clearance. If the recloser is closed into such a condition, the resulting
fault needs to be cleared right away and reclosing blocked. An instantaneous
overcurrent element is usually set to trip in the SOTF trip logic.

For added security, the SEL-651R-2 features a selectable disturbance detector
supervision function on the switch-onto-fault trip condition. Enable this logic
by setting EDDSOTF = Y. See *Disturbance Detector Supervision for Switch-
Onto-Fault Logic* for more detail.

Refer to the SOTF trip logic in *Figure 5.1*. This logic permits immediate
tripping if the following are all true:

> ➤ An element asserts in SEL<small>OGIC</small> control equation trip setting
>   TRSOTF
>
> ➤ Relay Word bit SOTFE is asserted to logical 1
>
> ➤ Setting EDDSOTF := N

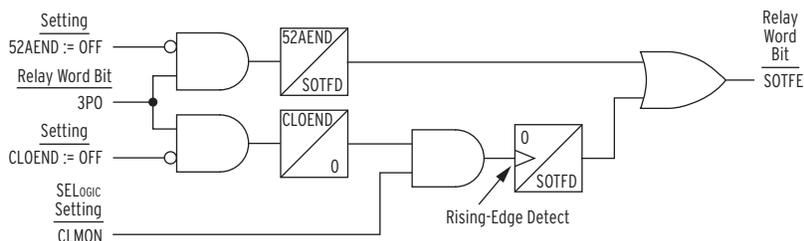
Relay Word bit SOTFE (the output of the SOTF logic) provides the effective
time window for an element in trip setting TRSOTF (e.g., TRSOTF := 50P2)
to trip after the circuit breaker closes. *Figure 5.7* and the following discussion
describe the SOTF logic.


Figure 5.7   Switch-Onto-Fault (SOTF) Logic

Circuit Breaker Operated SOTF Logic

Circuit-breaker operated switch-onto-fault logic is enabled by making time
setting 52AEND (52AEND ≠ OFF). Time setting 52AEND qualifies the three-
pole open (3PO) condition and then asserts Relay Word bit SOTFE:
SOTFE = logical 1.

Note that SOTFE is asserted when the circuit breaker is qualified as open (see
Figure 5.8). This allows elements set in the SEL<small>OGIC</small> control equation trip
setting TRSOTF to operate if a fault occurs when the circuit breaker is open.
In such a scenario (e.g., flashover inside the circuit breaker tank), the tripping
via setting TRSOTF cannot help in tripping the circuit breaker, which is
already open, but can initiate breaker failure protection, if a breaker failure
scheme is implemented in the SEL-651R-2 or externally.

Wolfe

Figure 5.8   SOTF Logic Output (52AEND ≠ OFF)

When the circuit breaker is closed, the 3PO condition deasserts (3PO = logical 0) after the 3POD dropout time (setting 3POD is usually set for no more than a cycle). The SOTF logic output, SOTFE, continues to remain asserted at logical 1 for dropout time SOTFD.

Close Bus Operated SOTF Logic

Close bus operated switch-onto-fault logic is enabled by making time setting CLOEND (CLOEND ≠ OFF). Time setting CLOEND qualifies the three-pole open (3PO) condition, indicating that the circuit breaker is open.

Circuit breaker closure is detected by monitoring the dc close bus. This is accomplished by wiring an optoisolated input on the SEL-651R-2 (e.g., IN101) to the dc close bus. When a manual close or automatic reclosure occurs, optoisolated input IN101 is energized. SELOGIC control equation setting CLMON (close bus monitor) monitors the optoisolated input IN101:

CLMON := **IN101**

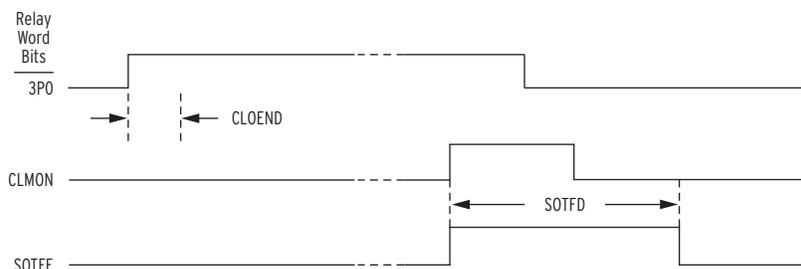
When optoisolated input IN101 is energized, CLMON asserts to logical 1. At the instant that optoisolated input IN101 is energized (close bus is energized), the circuit breaker is still open (3PO = logical 1), so the output of the CLOEND timer continues to be asserted to logical 1. Thus, the ANDed combination of these conditions latches in the SOTFD timer (see *Figure 5.9*). The SOTFD timer outputs a logical 1 for a time duration of SOTFD cycles any time it sees a rising edge on its input (logical 0 to logical 1 transition), if it is not already timing. The SOTF logic output, SOTFE, asserts to logical 1 for SOTFD time, like the edge-triggered timer in *Figure 5.4*.


Figure 5.9   SOTF Logic Output (CLOEND ≠ OFF)

Switch-Onto-Fault Logic Output (SOTFE)

Relay Word bit SOTFE is the output of the circuit-breaker operated SOTF logic or the close bus operated SOTF logic described previously. Time setting SOTFD in each of these logic paths provides the effective time window for the overcurrent elements in SELOGIC control equation trip setting TRSOTF to trip after the circuit breaker closes (see *Figure 5.1*). Time setting SOTFD is usually set around 30 cycles.

Trip and Target Logic 5.13
Front-Panel Target LEDs

Disturbance Detector Supervision for Switch-Onto-Fault Logic

The SEL-651R-2 features a selectable disturbance detector supervision function on the switch-onto-fault trip condition. Enable this logic by setting EDDSOTF = Y (see *Figure 5.1*).

When EDDSOTF = N, the switch-onto-fault logic works with no DD supervision (output of *Figure 5.3*), and the relay immediately asserts SOTFT and issues a TRIP when TRSOTF evaluates to logical 1 with SOTFE asserted.

When EDDSOTF = Y, the relay checks the state of the Disturbance Detector (DD) Relay Word bit when TRSOTF evaluates to logical 1, with SOTFE asserted:

➤ If DD is asserted, the relay immediately asserts the SOTFT output, which causes an immediate trip.

➤ If DD is not asserted and the TRSOTF and SOTFE conditions remain asserted, the relay delays the SOTFT assertion for as many as 2 cycles (until the DD element asserts or until the 2-cycle wait time expires).

➤ If one of the TRSOTF or SOTFE conditions deassert before the 2-cycle timer expires and the DD bit does not assert, no trip is issued. This provides a security improvement in cases where an element in the TRSOTF equation was transient.

The disturbance detector is described in greater detail in *Qualified Trip Conditions Settings on page 5.6*.

The sensitive disturbance detector will almost always be asserted before a high-set overcurrent element asserts for a new fault condition. The DD element also contains a 10-cycle dropout timer to maintain a logical 1 for a reasonable period after a disturbance is detected. In other words, using the EDDSOTF := Y setting while using instantaneous overcurrent elements in the TRSOTF equation will almost never impair tripping speed.

Front-Panel Target LEDs

Refer to *Figure 11.13* for the layout of the front-panel target LEDs. The functions and associated settings for these target LEDs are described in *Table 5.3*.

Not All Front-Panel Target LEDs Are Set and Functional

Even though there is a front-panel inscription for every target LED, not all of these LEDs are programmed from the factory—some are just left set to logical 0. For example, the SELOGIC setting T07_LED for the SEF-labeled (sensitive-earth-fault) LED is programmed T07_LED := 0.

Table 5.3   SEL-651R-2 Front-Panel Target LED Labels and Settings (Factory Defaults) (Sheet 1 of 2)

Trip and Target Logic 5.15
Front-Panel Target LEDs

Front-Panel Target LEDs ENABLED and TRIP

The **ENABLED** and **TRIP** LEDs (top of *Table 5.3*) are not programmable except for choosing the LED illuminated color; they are fixed-function LEDs. The **ENABLED** LED illuminates when the SEL-651R-2 is powered correctly, is functional, and has no self-test failures. The **TRIP** LED illuminates and latches in at the rising-edge of any trip that comes from the trip logic in *Figure 5.1*.

Programmable Front-Panel Target LEDs

Refer to *Table 5.3* and *Figure 5.10*.

The LEDs in *Table 5.3*, labeled by default as SUPPLY through VCZ ON, are programmable via the front-panel settings shown in *Table 5.3*. SELOGIC setting T*xx*_LED is the condition/element being monitored. Setting T*xx*LEDL determines whether the state of the condition/element being monitored is latched in on trip (setting T*xx*LEDL := Y) or not (setting T*xx*LEDL := N).

For an individual LED to be latched in (constantly illuminated) at the occurrence of a trip, the following have to be true:

➤ "latch in on trip?" setting T*xx*LEDL := Y

➤ a new trip has to occur, from the trip logic in *Figure 5.1*

➤ the SELOGIC setting T*xx*_LED (the condition/element being monitored) has to be asserted (effectively, T*xx*_LED = logical 1) sometime during a 1.5 cycle time window. The time window starts at the occurrence of the trip

Latched-in LEDs, including the dedicated **TRIP** LED, remain latched in (constantly illuminated) until one of the following occurs:

➤ a new trip occurs, from the trip logic in *Figure 5.1*

➤ or the reset trip-latched LEDs on close setting RSTLED := Y and the recloser closes (any phase) and no trip is present

➤ or a target reset condition occurs and no trip is present

A target reset condition can be any of the following:

➤ front-panel **TARGET RESET** pushbutton

➤ **TAR R** serial port command

➤ target reset SELOGIC setting RSTTRGT, which is also available as a Relay Word bit

➤ target reset through DNP3 or Modbus protocols

Latched-in LEDs retain their state, even when the relay is powered down, then powered up again.

To program an LED to not be latched in on trip, but to just follow some condition/element, make the following settings for the particular LED:

➤ "latch in on trip?" setting T*xx*LEDL := N

➤ SELOGIC setting T*xx*_LED (the condition/element being monitored)

Then, when T*xx*_LED = logical 1, the LED illuminates (Relay Word bit output TLED_*xx* = logical 1). When T*xx*_LED = logical 0, the LED extinguishes (Relay Word bit output TLED_*xx* = logical 0).

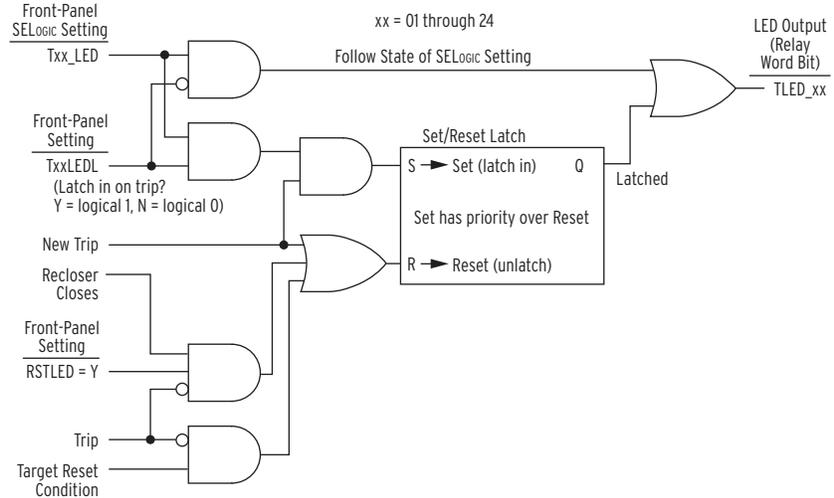
Page 310 of 1080
Wolfe


Figure 5.10   Programmable Front-Panel Target LED Logic

Other Uses for Front-Panel Target LED Relay Word Bits

The LED logic outputs, Relay Word bits TLED*xx*, actually drive the front-panel target LEDs. These Relay Word bits can also be used to drive other things, such as output contacts for a discrete-wired SCADA system. For example, to route phase/ground involvement in a fault to SCADA, set separate output contacts individually to TLED_03, TLED_04, TLED_05, and TLED_06, respectively (e.g., OUT101 := TLED_03, OUT102 := TLED_04, OUT103 := TLED_05, OUT104 := TLED_06; see *Table 5.3*).

Correlation Between Trip Target LEDs and Trip Settings

The SELOGIC control equation factory-default trip settings are shown in *Figure 5.2*. The following LED descriptions discuss how some of the elements that make up the factory-default trip settings are incorporated into LED settings. If trip settings are changed, front-panel target LED settings changes may also be needed. Front-panel target LED relabeling may also be needed, especially for custom schemes (see SEL-651R-2 Configurable Labels instructions).

TRIP LED

As discussed earlier, the **TRIP** LED illuminates and latches in at the rising-edge of any trip, single-phase or three-phase, that comes from the trip logic in *Figure 5.1*.

A Fault, B Fault, and C Fault LEDs

The logic for determining phase involvement for a fault depends on if one of the following conditions are true:

➤ All three phases are initially closed.

➤ Only one or two phases are initially closed (and therefore two or one phases are already open, respectively).

Group setting ESPB enables single-phase operation for reclosers that have such capability. Thus, the condition of "only one or two phases are initially closed" is indicative of Group setting ESPB:= Y. Of course, all three phases can also initially be closed, too, for a recloser with single-phase operation capability.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 311 of 1080
Wolfe

Trip and Target Logic 5.17
Front-Panel Targets

With all three phases initially closed (and Group setting ESPB:= Y or N), when a fault and subsequent trip occur, phase involvement is determined by logic using Relay Word bits FSA, FSB, and FSC. A phase, negative-sequence, or ground-overcurrent element also has to be picked up for this phase involvement logic to work. The output of this embedded logic is the selective assertion of Relay Word bits PHASE_A, PHASE_B, or PHASE_C used in factory-default phase targeting LED settings:

> T03_LED:= **PHASE_A** (A PHASE LED)
>
> T04_LED:= **PHASE_B** (B PHASE LED)
>
> T05_LED:= **PHASE_C** (C PHASE LED)

In addition, the fault must be present for a little longer than 1 cycle (after the control issues a trip) for reliable phase targeting (via this phase involvement logic using Relay Word bits FSA, FSB, and FSC). Inaccurate phase targeting is most noticeable during control testing if currents are immediately turned off when a trip is issued. This results in inaccurate phase targeting because fault currents do not continue to be present as in a normal recloser setup, where fault current would continue until the recloser opens.

With all three phases initially closed, if there is a phase-to-phase or three-phase fault, SELOGIC control equation setting FAULT has to be picked up in order for the appropriate phases to be deemed as being involved (via this phase involvement logic using Relay Word bits FSA, FSB, and FSC). SELOGIC control equation setting FAULT := 51P OR 51G1 in the factory-default settings. Relay Word bits 51P and 51G1 are pickup indicators of the factory-set time-overcurrent elements. Control equation setting FAULT also controls other functions (see *SELOGIC Control Equation Setting FAULT*).

There is not necessarily a one-to-one correspondence between FSA and PHASE_A, etc., for various fault types. Relay Word bits FSA, FSB, and FSC are also used in fault location logic and to help determine event type in event report summaries. Relay Word bits FSA, FSB, and FSC have no direct customer use and should not be used in custom logic.

In contrast to the preceding discussion (determining phase involvement for a fault when all three phases are initially closed), now consider the scenario of Group setting ESPB:= Y and one or two phases are initially closed (and therefore two or one phases are already open, respectively). When a fault and subsequent trip occur in such a scenario, phase involvement is then determined directly by what trip-related Relay Word bits (TRIPA, TRIPB, or TRIPC) assert. Phase involvement logic using Relay Word bits FSA, FSB, and FSC is not used in this scenario—instead Relay Word bits TRIPA, TRIPB, and TRIPC directly assert Relay Word bits PHASE_A, PHASE_B, or PHASE_C, respectively.

Relay Word bits PHASE_A, PHASE_B, and PHASE_C assert only for a processing interval during a trip, when controlled in one of the following ways:

> ➤ By phase involvement logic using Relay Word bits FSA, FSB, and FSC
>
> ➤ Directly by Relay Word bits TRIPA, TRIPB, and TRIPC

as previously discussed. Therefore, **A PHASE**, **B PHASE**, and **C PHASE** LEDs make use of the trip latching logic in *Figure 5.10*.

GROUND LED

Note in *Table 5.3* that the **GROUND** LED directly contains the pickup indicator of the ground time-overcurrent tripping element (TR3X := … OR 51G1T …), indicating ground involvement in the fault:

> T06_LED := **51G1**

FAST CURVE and DELAY CURVE LEDs

The phase and ground time-overcurrent elements (51PT and 51G1T, respectively) each switch between operating as a fast curve and as a delay curve. This switching is indicated by the 51PS and 51G1S Relay Word bits, respectively, for elements 51PT and 51G1T (51xS = logical 0, indicates fast curve operating mode; 51xS = logical 1, indicates delay curve operating mode). See *Time-Overcurrent Elements on page 4.13* for more details.

> T08_LED := **NOT(51G1S) AND 51G1T OR NOT(51PS) AND 51PT**

> T09_LED := **51G1S AND 51G1T OR 51PS AND 51PT**

ABOVE MIN TRIP LED

The monitored minimum trip pickups are for the phase and ground time-overcurrent elements (51PT and 51G1T, respectively). When current is above one of the pickup indicators, the **ABOVE MIN TRIP** LED illuminates.

> T16_LED := **51P OR 51G1**

Note that the **ABOVE MIN TRIP** LED does not latch in on trip.

SELᴏɢɪᴄ Control Equation Setting FAULT

SELOGIC control equation setting FAULT has control over or is used in the following:

➤ Front-panel target LEDs A FAULT, B FAULT, and C FAULT (with factory-default front-panel settings, T03_LED through T05_LED set as shown in *Table 5.3*).

➤ Demand metering—FAULT is used to suspend demand metering peak recording (see *Demand Metering on page 8.6*).

➤ Maximum/Minimum metering—FAULT is used to block Maximum/Minimum metering updating (see *Maximum/ Minimum Metering Update and Storage on page 8.18*).

➤ Voltage sag, swell, and interruption elements—FAULT is used to suspend the calculation of Vbase (see *Voltage Sag, Swell, and Interruption Elements on page 4.59*).

The FAULT setting is located in the Global settings class (see *Global Settings on page SET.1*).

Section 6

Close and Reclose Logic

Introduction

Figure 6.1 provides an overview of the close logic and reclosing relay logic described in this section. This logic is provided for the following:

➤ Three-phase reclosers or single-phase reclosers operating in a three-phase mode (Group setting ESPB := N; one reclosing relay available—one for all three phases)

➤ Single-phase reclosers operating in a single-phase mode (Group setting ESPB := Y; three separate reclosing relays available—one for each phase)

Figure 6.1 shows a logic migration:

➤ From main reclosing relay logic

➤ To reclose supervision logic

➤ To close logic

In this section, these logic subsections are discussed in reverse order, starting with Breaker Status Logic. If you are not using the SEL-651R-2 for automatic reclosing, but using it to close the recloser for other close conditions (such as manual close initiation via serial port or optoisolated outputs), focus on the Breaker Status Logic and Close Logic subsections. Note particularly the description of SELOGIC control equation setting CL in the Close Logic subsection.

Breaker Status Logic. Breaker Status Logic shows how the effective breaker status (Relay Word bit 52Ax; x = 3P, A, B, or C) is derived for the required application, three-phase or single-phase mode.

Close Logic. Close Logic describes the final logic that controls the close output. This output controls the recloser for automatic reclosures and other close conditions.

Reclose Supervision Logic. Reclose Supervision Logic describes the logic that supervises automatic reclosing when an open-interval time times out: a final condition check right before the close logic asserts the close output.

Reclosing Relay Logic. Reclose Logic describes the remaining reclosing relay settings and logic needed for automatic reclosing.

NOTE: Reclose enable setting E79 := N defeats the reclosing relay, but does not defeat the ability of the close logic described in the first subsection (Figure 6.3) to close the circuit breaker for other close conditions via SELOGIC control equation setting CL.

6.2 | Close and Reclose Logic
Introduction

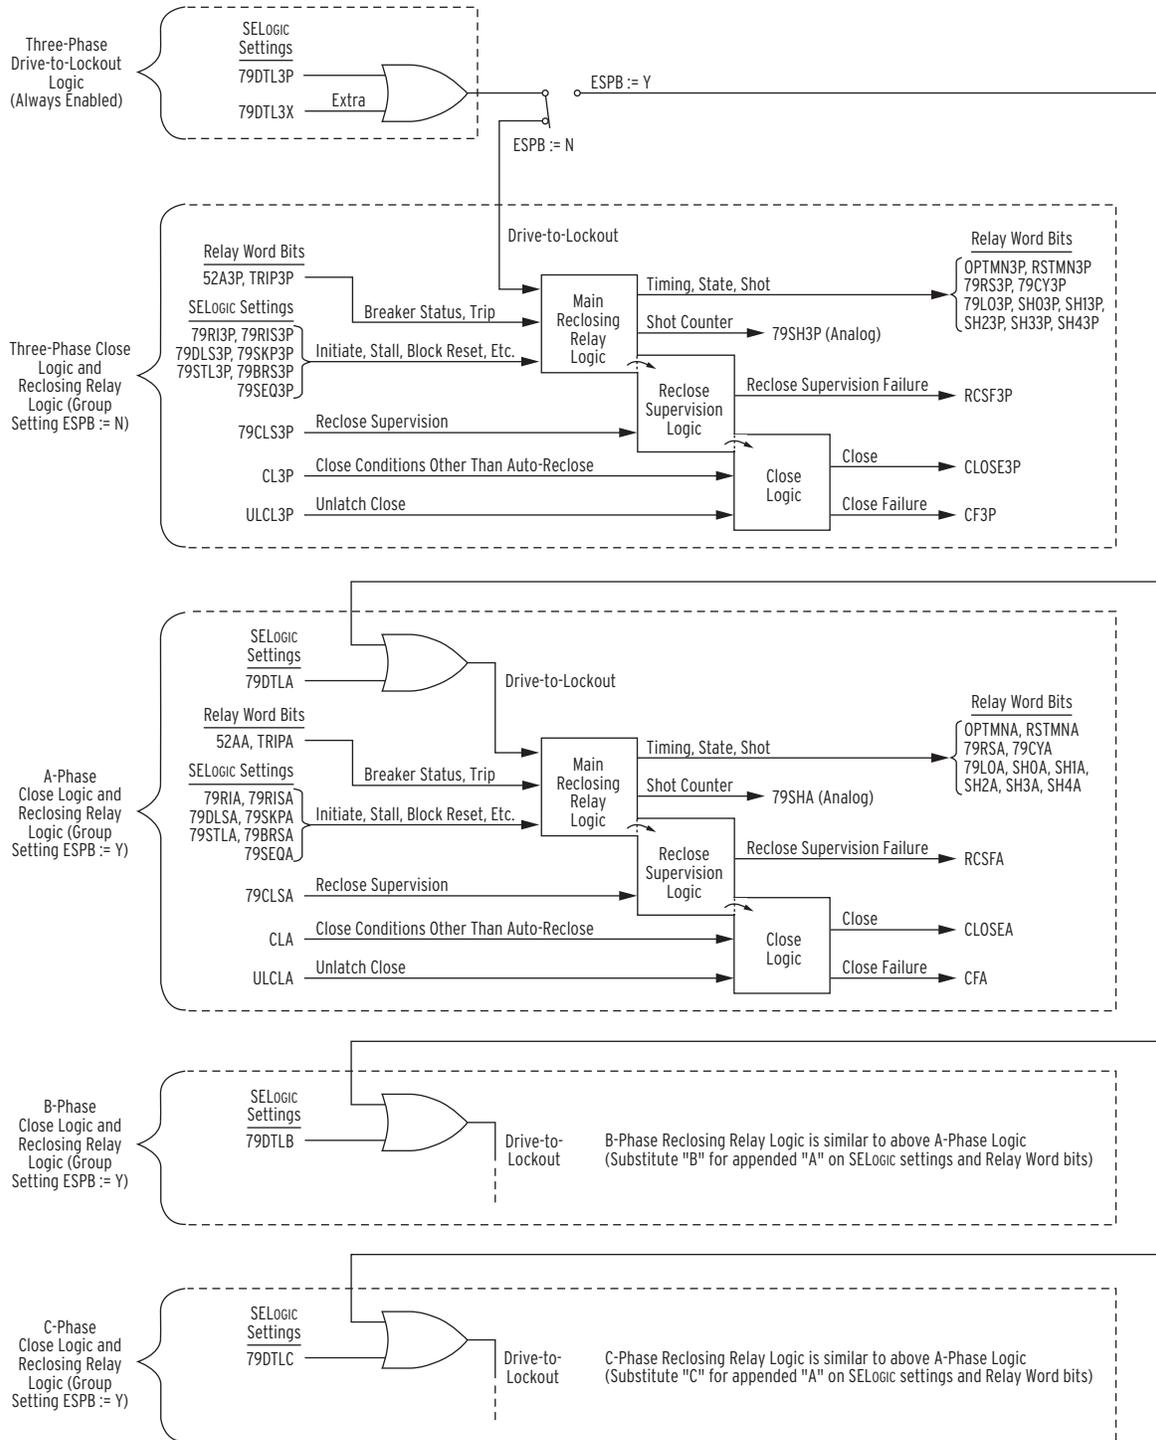
Wolfe


Figure 6.1   Close Logic and Reclosing Relay Logic Overview for Three-Phase and Single-Phase Reclosers

Three-Phase (3P) vs. Single-Phase (A, B, and C)

Figure 6.1 and *Figure 6.2* show specific SELOGIC settings and Relay Word bits for the three-phase and single-phase modes. Note the following in these figures:

➤ 3P is appended for the three-phase mode (ESPB := N)

➤ A, B, C are appended for the single-phase mode (ESPB := Y)

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 215 of 1080
Wolfe

Close and Reclose Logic   6.3
Breaker Status Logic

In the remaining figures and examples of this section, these appended characters are not always shown on the SELOGIC settings and Relay Word bits. For instance, 79RI is shown, rather than 79RI3P or 79RIA, 79RIB, 79RIC.

From *Figure 6.3* on, most of the figures demonstrate the three-pole mode. However, the logic is readily extrapolated and applicable to single-phase applications.

Breaker Status Logic

Table 6.1   Breaker Status Settings/Outputs

	Three-Phase Recloser (Global Setting BKTYP := 3)	Single-Phase Recloser (Global Setting BKTYP := 1)
SELOGIC Settings	52A_3P	52A_A, 52A_B, 52A_C
Relay Word Bits	52A3P	52AA, 52AB, 52AC

Figure 6.2 shows how settings:

➤ BKTYP: Breaker/recloser Trip Type (Global setting)

➤ ESPB: Enable Single-Phase Breaker/recloser settings (Group setting)

enable reclosing relays (and accompanying close logic—see *Figure 6.1*):

➤ Three separate reclosing relays enabled for single-phase reclosing

➤ One reclosing relay enabled for three-phase reclosing

and configure the required breaker status:

➤ Relay Word bits 52AA, 52AB, and 52AC for single-phase reclosing

➤ Relay Word bit 52A3P for three-phase reclosing

MULTI-RECLOSER INTERFACE
The breaker status settings in Table 2.7 are automatically set (and hidden), according to Global setting IPCONN, for the Multi-Recloser Interface on page 2.93. Also, Global setting BKTYP is automatically set to BKTYP := 1 (and hidden) for the Multi-Recloser Interface.

At the upper tier in *Figure 6.2*, the breaker/recloser type setting BKTYP makes the large demarcation for recloser type:

➤ BKTYP := **1** single-phase

➤ BKTYP := **3** three-phase

Note that even if a single-phase recloser (setting BKTYP := 1) is set for three-phase reclosing (setting ESPB := N), the single-phase breaker/recloser statuses (Relay Word bits 52AA, 52AB, and 52AC) are still available for monitoring. In this case, the one enabled reclosing relay (one reclosing relay to operate all three phases) uses the derived breaker status 52A3P.

Conversely, even if a single-phase recloser (setting BKTYP := 1) is set for single-phase reclosing (setting ESPB := Y), the three-phase breaker/recloser status (Relay Word bit 52A3P) is still available for monitoring. In this case, the three separate, enabled reclosing relays (one reclosing relay per phase) use respective breaker status 52AA, 52AB, and 52AC.

Page 316 of 1080
Wolfe

Figure 6.2   Breaker Status Logic

Factory 52A Settings Example (Traditional Retrofit Recloser)

Figure 2.50 shows the monitored trip and close circuit points on Traditional Retrofit reclosers. Switch SW1 is the 52a auxiliary contact in the trip circuit. Relay Word bit SW1 is derived from the monitored trip circuit points (inputs IN203 and IN204) and trip output (controlled by Relay Word bit RCTR1X) status:

SW1 = logical 1 (switch SW1 [52a auxiliary contact] closed)
SW1 = logical 0 (switch SW1 [52a auxiliary contact] open)

SELOGIC setting 52A_3P includes the close output (Relay Word bit RCCL1X) to delay the change of state of Relay Word bit 52A3P until the unlatch close logic (see *Figure 6.5*) unlatches the close signal output CLOSE3P (see *Figure 6.3*):

52A_3P := **SW1 AND NOT RCCL1X**

This ensures that the 52b auxiliary in the close circuit is open (as indicated by input IN201, connected to the close circuit in *Figure 2.50*) before the close signal output is unlatched (CLOSE3P = logical 0). Close signal output CLOSE3P drives the actual close output RCCL1X via SELOGIC setting RCCL1 := CLOSE3P (see *Figure 7.26*).

In *Figure 6.3*, if *all* the following are true:

➤ The unlatch close condition is not asserted (ULCL = logical 0).

➤ The circuit breaker is open (52A = logical 0).

➤ The reclose initiation condition (79RI) is not making a rising edge (logical 0 to logical 1) transition.

➤ And a close failure condition does not exist (Relay Word bit CF = 0).

then the CLOSE Relay Word bit asserts to logical 1 if either of the following occurs:

➤ A reclosing relay open-interval times out (qualified by SELOGIC control equation setting 79CLS—see *Figure 6.6*).

➤ Or SELOGIC control equation setting CL goes from logical 0 to logical 1 (rising edge transition).

Unlatch Close

In *Figure 6.3*, if the CLOSE Relay Word bit is asserted at logical 1, it stays asserted at logical 1 until *one* of the following occurs:

➤ The unlatch close condition asserts (ULCL = logical 1).

➤ The circuit breaker closes (52A = logical 1).

➤ The reclose initiation condition (79RI) makes a rising edge (logical 0 to logical 1) transition.

➤ Or the Close Failure Timer times out (Relay Word bit CF = logical 1).

The Close Failure Timer is inoperative if setting CFD := OFF.

Close and Reclose Logic 6.7
Page 319 of 1080
Close Logic
Wolfe

Factory-Default CL/ULCL Settings Example

The factory-default settings for the three-phase (3P) close logic SELOGIC control equation settings are as follows:

CL3P := **(PB11_PUL AND LT05 OR CC3) AND LT06 AND TCCAP**

ULCL3P := **TRIP3P OR (NOT IN201 AND SW1) OR NOT(LT06 AND TCCAP OR CLOSE3P) OR NOT(LT05 OR CLOSE3P OR CC3 OR 79CY3P)**

[= **TRIP3P OR (NOT IN201 AND SW1) OR (NOT LT06 OR NOT TCCAP) AND NOT(CLOSE3P) OR NOT(LT05) AND NOT(CLOSE3P) AND NOT(CC3) AND NOT(79CYC3P)**]

The (NOT IN201 and SW1) logic term in the above ULCL3P factory setting is just for Traditional Retrofit recloser applications—it is not present in factory settings for the other recloser applications.

The factory-default setting for the Close Failure Timer setting is:

CFD := **60.00 cycles**

Set Close

If the Reclosing Relay Open-Interval Time-Out logic input at the top of *Figure 6.3* is ignored (reclosing is discussed in detail in a following subsection), then SELOGIC control equation setting CL is the only logic input that can set the CLOSE Relay Word bit.

In SELOGIC control equation setting CL (see *Figure 6.4*), closing is provided by:

➤ **CLOSE** operator control (local)

➤ Serial port **CLOSE** command (remote)

Supervision of these local and remote close signals is provided by:

➤ **PUSHBUTTONS LOCKED** operator control—supervises **CLOSE** operator control

➤ **HOT LINE TAG** operator control and TCCAP Relay Word bit—supervise both the **CLOSE** operator control and the serial port **CLOSE** command

Other details:

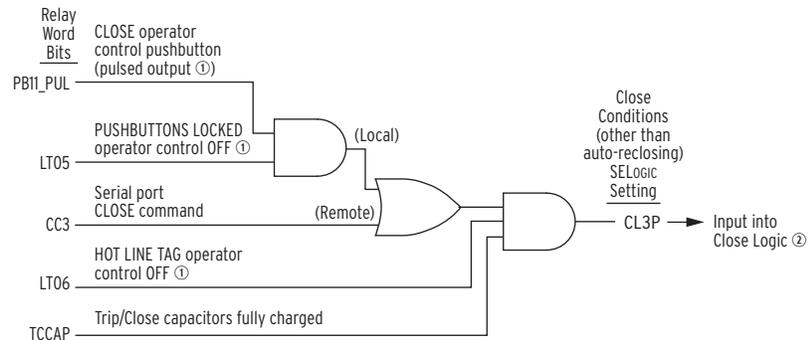
➤ The **PUSHBUTTONS LOCKED** operator control also supervises other front-panel operator controls (see *Table 11.9*).

➤ The **HOT LINE TAG** operator control also supervises automatic reclosing (see *Table 11.9*).

➤ No "standing close" is possible with the close logic in *Figure 6.4*. The **CLOSE** operator control (Relay Word bit PB11_PUL) and serial port **CLOSE** command (Relay Word bit CC3) pulse for only one processing interval (one quarter cycle) when activated.

Also, in *Figure 6.3*, SELOGIC control equation setting CL is rising-edge triggered. Thus, if the **PUSHBUTTONS LOCKED** operator control (Relay Word bit LT05) or the **HOT LINE TAG** operator control (Relay Word bit LT06) in *Figure 6.4* are turned ON or OFF, no unexpected close takes place, because there is no standing close condition waiting to get through.

6.8 | Close and Reclose Logic
Close Logic

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 320 of 1080
Wolfe


① See Table 11.9, ② See Table 6.3.

Figure 6.4   Close Conditions–Other Than Automatic Reclosing (Three-Phase, Factory Default)

Unlatch Close

Figure 6.5 shows the additional means to unlatch the close logic, besides those embedded in *Figure 6.3*. The TRIP3P Relay Word bit in setting ULCL3P keeps the TRIP3P and CLOSE3P Relay Word bits from being asserted at the same time—TRIP3P has priority.

The logic in the upper part of *Figure 6.5* is as follows:

ULCL3P := **... OR (NOT IN201 AND SW1) OR ...**

This logic delays unlatching of the close output signal (Relay Word bit CLOSE) in *Figure 6.3* until both auxiliary contacts SW1 (52a) and SW3 (52b) change state for the close operation (see *Figure 2.50*). Logic term (NOT IN201 and SW1) applies only to traditional retrofit reclosers.

The logic in the lower part of *Figure 6.5* is as follows:

ULCL3P := **... OR (NOT LT06 OR NOT TCCAP) AND NOT(CLOSE3P) OR NOT(LT05) AND NOT(CLOSE3P) AND NOT(CC3) AND NOT(79CYC3P)**

This logic is security against unwanted close initiations. The **HOT LINE TAG** operator control and trip/close capacitor monitor are preeminent; if there is no close in progress **and HOT LINE TAG** is on or the trip/close capacitors are not fully charged, no new closing can be initiated. The **PUSHBUTTONS LOCKED** operator control is less restrictive; serial port **CLOSE** commands and automatic reclosing are not affected by it. But, in *Figure 6.4*, the **CLOSE** operator control is still supervised by the **PUSHBUTTONS LOCKED** operator control.

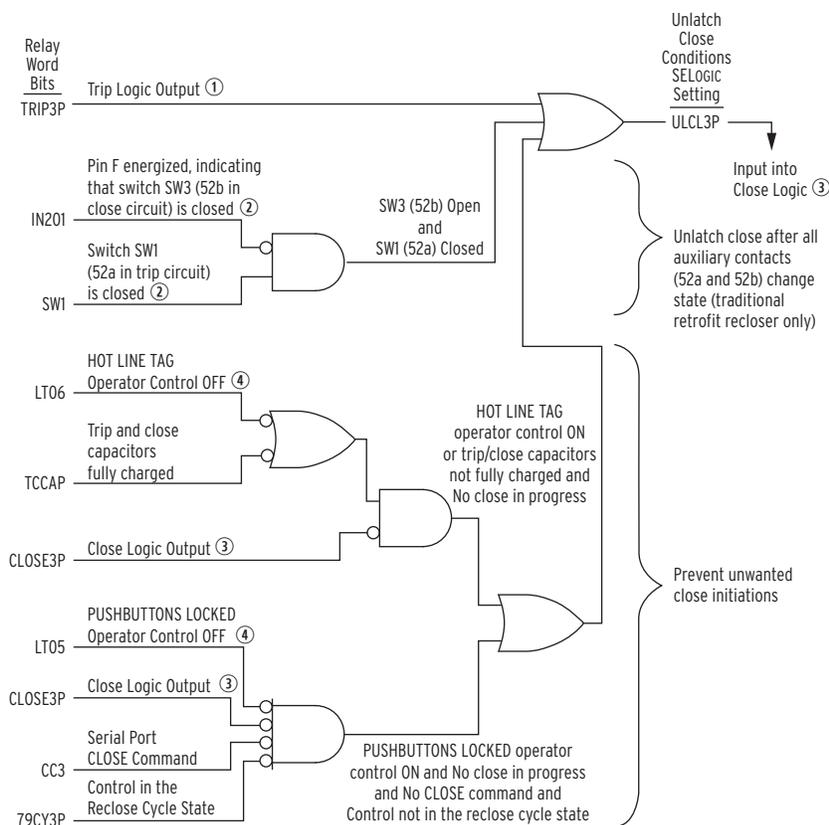
Close and Reclose Logic 6.9
Close Logic
Wolfe


① See Figure 5.1, ② See Figure 2.50, ③ See Figure 6.3, ④ See Table 11.9.

Figure 6.5   Unlatch Close Conditions (Three-Phase, Factory Default)

Close Failure

With setting CFD := 60.00 cycles, once the CLOSE Relay Word bit asserts in *Figure 6.3*, it remains asserted at logical 1 no longer than a *maximum* of 60 cycles. If the Close Failure Timer times out, Relay Word bit CF asserts to logical 1, forcing the CLOSE Relay Word bit to logical 0.

Defeat the Close Logic

Defeat the close logic and reclosing relay logic by setting the corresponding SELOGIC breaker auxiliary settings (52A_) directly to logical 0 (see *Figure 6.2*):

➤ For three-phase reclosers or single-phase reclosers operating in a three-phase mode (Group setting ESPB := N; one reclosing relay available: one for all three phases), set 52A_3P directly to logical 0 (52A_3P := 0).

➤ For single-phase reclosers operating in a single-phase mode (Group setting ESPB := Y; three separate reclosing relays available: one for each phase), set at least one of 52A_A, 52A_B, or 52A_C directly to logical 0 (e.g., 52A_B := 0).

Having one or more SELOGIC breaker auxiliary settings set directly to logical 0 (e.g., 52A_B := 0) defeats the close logic and reclosing relay logic for all three phases.

6.10 | Close and Reclose Logic
Reclose Supervision Logic

Program an Output Contact for Closing

See *Trip and Close Mapping and Output Logic on page 7.31* for more information on programming outputs for closing the recloser. Relay Word bits CLOSE3P, CLOSEA, CLOSEB, and CLOSEC from *Figure 6.1* are used to program close outputs.

Reclose Supervision Logic

NOTE: Review Three-Phase (3P) vs. Single-Phase (A, B, and C) on page 6.2.

Table 6.3   Reclose Supervision Settings/Outputs

	Three-Phase Reclosing (Factory-Default Setting ESPB := N)	Single-Phase Reclosing (Setting ESPB := Y)
Setting	79CLSD	79CLSD
SELOGIC Settings	79CLS3P	79CLSA, 79CLSB, 79CLSC
Relay Word Bits	RCSF3P	RCSFA, RCSFB, RCSFC

One of the inputs into the close logic in *Figure 6.3* is:

Reclosing Relay Open-interval Time-Out (qualified by 79CLS)

This input is the indication that a reclosing relay open interval has timed out (see *Figure 6.10*) and a qualifying condition (SELOGIC control equation setting 79CLS) has been met, and thus automatic reclosing of the circuit breaker should proceed by asserting the CLOSE Relay Word bit to logical 1. This input into the close logic in *Figure 6.3* is an output of the reclose supervision logic in the following *Figure 6.6*.

Attachment to Response to AG-2 Question No. 68(g)
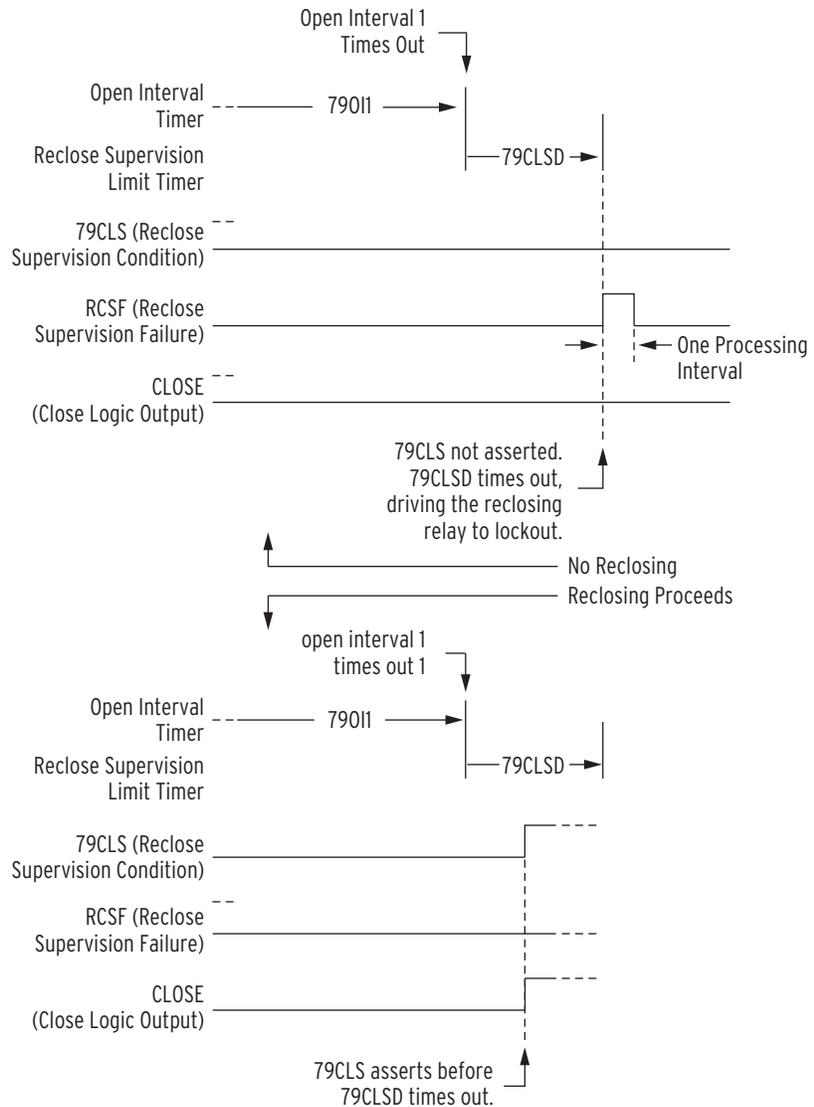
Page 324 of 1080
Wolfe


Figure 6.7 Reclose Supervision Limit Timer Operation (Refer to Bottom of Figure 6.6)

Settings and General Operation

Figure 6.6 contains the following SELOGIC control equation setting:

> 79CLS (reclose supervision conditions—checked after reclosing relay open-interval time-out)

and setting:

> 79CLSD (Reclose Supervision Limit Time)

See *Reclosing Relay on page SET.29* for setting ranges.

For Most Applications (Top of Figure 6.6)

For most applications, the Reclose Supervision Limit Time setting should be set to zero cycles:

> 79CLSD := **0.00**

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 1325 of 1080
Close and Reclose Logic 6.13
Reclose Supervision Logic
Wolfe

With this setting, the logic in the top of *Figure 6.6* is operative. When an open interval times out, the SELOGIC control equation reclose supervision setting 79CLS is *checked just once*.

If 79CLS is *asserted* to logical 1 at the instant of an open-interval time-out, then the now-qualified open-interval time-out will propagate onto the final close logic in *Figure 6.3* to automatically reclose the circuit breaker.

If 79CLS is *deasserted* to logical 0 at the instant of an open-interval time-out:

> ➤ No automatic reclosing takes place.

> ➤ Relay Word bit RCSF (Reclose Supervision Failure indication) asserts to logical 1 for one processing interval.

> ➤ The reclosing relay is driven to the Lockout State.

See *Factory-Default 79CLS Settings Example* and *Additional 79CLS Settings Example 1* for details.

For a Few, Unique Applications (Bottom of Figure 6.6 and Figure 6.7)

For a few unique applications, the Reclose Supervision Limit Time setting is *not* set to zero cycles, for example:

79CLSD := **60.00**

With this setting, the logic in the bottom of *Figure 6.6* is operative. When an open-interval times out, the SELOGIC control equation reclose supervision setting 79CLS is then *checked for a time window* equal to setting 79CLSD.

If 79CLS *asserts* to logical 1 at any time during this 79CLSD time window, then the now-qualified open-interval time-out will propagate onto the final close logic in *Figure 6.3* to automatically reclose the circuit breaker.

If 79CLS remains *deasserted* to logical 0 during this entire 79CLSD time window, when the time window times out:

> ➤ No automatic reclosing takes place.

> ➤ Relay Word bit RCSF (Reclose Supervision Failure indication) asserts to logical 1 for one processing interval.

> ➤ The reclosing relay is driven to the Lockout State.

The logic in the bottom of *Figure 6.6* is explained in more detail in the following text.

Set Reclose Supervision Logic (Bottom of Figure 6.6)

Refer to the bottom of *Figure 6.6*. If *all* the following are true:

> ➤ The close logic output CLOSE (also see *Figure 6.3*) is *not* asserted (Relay Word bit CLOSE = logical 0).

> ➤ The reclosing relay is *not* in the Lockout State (Relay Word bit 79LO = logical 0).

> ➤ The circuit breaker is open (52A = logical 0).

> ➤ The reclose initiation condition (79RI) is *not* making a rising edge (logical 0 to logical 1) transition.

> ➤ The Reclose Supervision Limit Timer is *not* timed out (Relay Word bit RCSF = logical 0).

6.14 | Close and Reclose Logic
Reclose Supervision Logic

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 326 of 1080
Wolfe

then a reclosing relay open-interval time-out seals in *Figure 6.6*. This allows any assertion of 79CLS to propagate through *Figure 6.6* and on to the close logic in *Figure 6.3*.

Unlatch Reclose Supervision Logic (Bottom of Figure 6.6)

Refer to the bottom of *Figure 6.6*. If the reclosing relay open-interval time-out condition is sealed-in, it stays sealed-in until *one* of the following occurs:

➤ The close logic output CLOSE (also see *Figure 6.3*) asserts (Relay Word bit CLOSE = logical 1).

➤ The reclosing relay goes to the Lockout State (Relay Word bit 79LO = logical 1).

➤ The circuit breaker closes (52A = logical 1).

➤ The reclose initiation condition (79RI) makes a rising edge (logical 0 to logical 1) transition.

➤ SELOGIC control equation setting 79CLS asserts (79CLS = logical 1).

➤ Or the Reclose Supervision Limit Timer times out (Relay Word bit RCSF = logical 1 for one processing interval).

⚠ WARNING

Setting 79CLSD = OFF can create an indefinite "standing close" condition. This is usually not desirable in practice.

The Reclose Supervision Limit Timer is inoperative if setting 79CLSD := OFF. With 79CLSD := OFF, reclose supervision condition 79CLS is not time limited. When an open-interval times out, reclose supervision condition 79CLS is checked indefinitely until one of the other above unlatch conditions comes true.

The unlatching of the sealed-in reclosing relay open-interval time-out condition by the assertion of SELOGIC control equation setting 79CLS indicates successful propagation of a reclosing relay open-interval time-out condition on to the close logic in *Figure 6.3*.

See *Additional 79CLS Settings Example 2* for more information.

Factory-Default 79CLS Settings Example

Refer to the top of *Figure 6.6*.

The factory-default settings for the SELOGIC reclose supervision setting are as follows:

For controls ordered with an ac power supply:

79CLS3P := **PWR_SRC1 AND TCCAP AND NOT (BTFAIL)** Traditional Retrofit recloser

79CLS3P := **TCCAP AND NOT (BTFAIL)** all others

For controls ordered with a dc power supply:

79CLS3P := **PWR_SRC1 AND TCCAP** Traditional Retrofit recloser

79CLS3P := **TCCAP** all others

Relay Word bit PWR_SRC1 indicates the presence of power to the control. Power to the control, such as 120 Vac power, is used by the Traditional Retrofit reclosers to provide the final close energy. If this power is not present for these reclosers, there is no need to proceed with the reclosure.

Relay Word bit TCCAP indicates that the trip and close capacitors have sufficient stored energy for trips/reclosures. The monitoring point for TCCAP incorporates the capacitor charger, the capacitors themselves, and the connection from the capacitors to the relay module (J205 in *Figure 2.5*,

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 327 of 1080
Close and Reclose Logic 6.15
Reclose Supervision Logic
Wolfe

Figure 2.8, and *Figure 2.9*). Relay Word bit TCCAP will deassert for a failure of any one of these elements. TCCAP may also momentarily deassert as a result of successive recloser operations drawing down the capacitor voltage. BTFAIL indicates some failure related to the battery or battery system. Controls ordered with a dc power supply do not have a battery, therefore BTFAIL is removed from the default 79CLS3P setting.

The factory-default setting for the reclose supervision time limit setting is as follows:

79CLSD := **900.00 cycles**

Within this 900-cycle time window, following the open-interval time (see *Figure 6.7*), if SELOGIC reclose supervision setting 79CLS3P effectively asserts to logical 1, then reclosing proceeds. Otherwise, if the reclose supervision time limit setting 79CLSD times out before SELOGIC reclose supervision setting 79CLS3P effectively asserts to logical 1, then no reclosure occurs and the reclosing relay is driven to lockout. If the 79CLS setting contains Relay Word bit TCCAP, setting 79CLSD should be set to at least a few seconds. This is to provide time for the capacitor voltage to recharge after successive recloser operations.

Additional 79CLS Settings Example 1

Refer to the top of *Figure 6.6* and *Figure 6.8*.

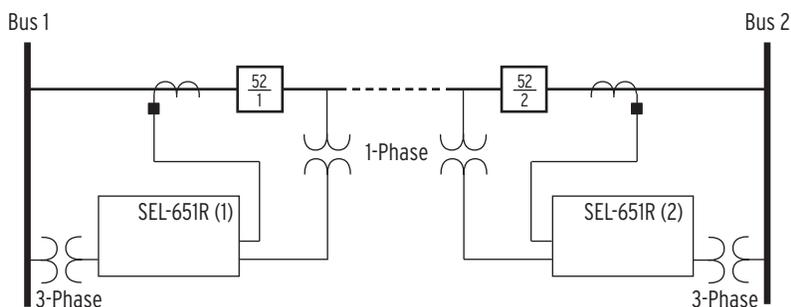
SEL-651R-2 controls are installed at both ends of a transmission line in a high-speed reclose scheme. After both circuit breakers open for a transmission line fault, the SEL-651R-2(1) recloses circuit breaker 52/1 first, followed by the SEL-651R-2(2) reclosing circuit breaker 52/2, after a synchronism check across circuit breaker 52/2.


Figure 6.8 SEL-651R-2 Recloser Controls Installed at Both Ends of a Transmission Line in a High-Speed Reclose Scheme

SEL-651R-2(1)

Before allowing circuit breaker 52/1 to be reclosed after an open-interval time-out, the SEL-651R-2(1) checks if Bus 1 voltage is hot and the transmission line voltage is dead. This requires reclose supervision settings:

79CLSD := **0.00 cycles** (only one check)

79CLS3P := **3P59Y AND 27ZA1 AND TCCAP AND NOT (BTFAIL)**

where:

    3P59Y = all three Bus 1 phase voltages are hot
    27ZA1 = monitored single-phase transmission line voltage is dead

6.16 | Close and Reclose Logic
Reclose Supervision Logic

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 328 of 1080
Wolfe

where:

TCCAP = trip and close capacitors have sufficient stored energy for trips/reclosures

NOT (BTFAIL) = no failure related to the battery or battery system

SEL-651R-2(2)

Before allowing circuit breaker 52/2 to be reclosed after the reclosing relay open interval times out, the SEL-651R-2(2) checks if Bus 2 voltage is hot, the transmission line voltage is hot, and both are in synchronism. This requires reclose supervision settings:

79CLSD := **0.00 cycles** (only one check)

79CLS3P := **25A1 AND TCCAP AND NOT (BTFAIL)**

where:

25A1 = selected Bus 2 phase voltage is in synchronism with monitored single-phase transmission line voltage and both are hot

Other Setting Considerations for SEL-651R-2(1) and SEL-651R-2(2)

Refer to *Skip-Shot and Stall Open-Interval Timing Settings (79SKP and 79STL, Respectively)*.

SELOGIC control equation setting 79STL stalls open-interval timing if it asserts to logical 1. If setting 79STL is deasserted to logical 0, open-interval timing can continue.

The SEL-651R-2(1) has no intentional open-interval timing stall condition (circuit breaker 52/1 closes first after a transmission line fault):

79STL := **0** (set directly to logical 0)

The SEL-651R-2(2) starts open-interval timing after circuit breaker 52/1 at the remote end has re-energized the line. The SEL-651R-2(2) has to see that Bus 2 voltage is hot, transmission line voltage is hot, and that these voltages are synchronized across open circuit breaker 52/2 for open-interval timing to begin. Thus, SEL-651R-2(2) open-interval timing is stalled when the transmission line voltage and Bus 2 voltage are *not* in synchronism across open circuit breaker 52/2:

79STL := **NOT 25A1 AND TCCAP AND NOT (BTFAIL)**

Note: A transient synchronism-check condition across open circuit breaker 52/2 could possibly occur if circuit breaker 52/1 recloses into a fault on one phase of the transmission line. The other two unfaulted phases would be briefly energized until circuit breaker 52/1 is tripped again. If the SEL-651R-2(2) is connected to one of these briefly energized phases, synchronism-check element 25A1 could momentarily assert to logical 1.

Ensure that the open-interval timers in the SEL-651R-2(2) are set to an appreciable time greater than the momentary energization time of the faulted transmission line to prevent the momentary assertion of synchronism-check element 25A1 from causing an inadvertent reclose of circuit breaker 52/2. Or, run the synchronism-check element 25A1 through a programmable timer before using it in the preceding 79CLS and 79STL settings for the SEL-651R-2(2). Note the built-in 3-cycle qualification of the synchronism-check voltages shown in *Figure 4.30*.

Additional 79CLS Settings Example 2

Refer to *Synchronism-Check Elements on page 4.38*. Also refer to *Figure 6.7* and *Figure 6.8*.

If the synchronizing voltages across open circuit breaker 52/2 are "slipping" with respect to one another, the Reclose Supervision Limit Timer setting 79CLSD should be set greater than zero so there is time for the slipping voltages to come into synchronism. For example:

79CLSD := **60.00 cycles**

79CLS3P := **25A1 AND TCCAP AND NOT (BTFAIL)**

The status of synchronism-check element 25A1 is checked continuously during the 60-cycle window. If the slipping voltages come into synchronism while timer 79CLSD is timing, synchronism-check element 25A1 asserts to logical 1 and reclosing proceeds.

In *Synchronism-Check Elements*, refer to *Synchronism-Check Element Outputs on page 4.48*, Voltages V_P and V_S are "Slipping and Setting TCLOSD ≠ 0.00." Item 3 describes a last attempt for a synchronism-check reclose before timer 79CLSD times out or setting 79CLSD := 0.00 and only one check is made.

Reclosing Relay

NOTE: Figure 6.1 shows one reclosing relay operative for three-phase reclosing (Group setting ESPB := N) and three separate reclosing relays operative for single-phase reclosing (Group setting ESPB := Y). Most of the examples in this reclosing relay subsection are three-phase reclosing examples, unless otherwise stated. These three-phase reclosing examples can be readily extrapolated to corresponding single-phase reclosing applications.

Table 6.4   Reclosing Relay Settings/Outputs (Sheet 1 of 2)

Table 6.4   Reclosing Relay Settings/Outputs (Sheet 2 of 2)

	Three-Phase Reclosing (Factory-Default Setting ESPB := N)	Single-Phase Reclosing (Setting ESPB := Y)
	SH33P	SH3A, SH3B, SH3C
	SH43P	SH4A, SH4B, SH4C
Analog Outputs	79SH3P	79SHA, 79SHB, 79SHC

Note that input:

Reclosing Relay Open-Interval Time-Out

in *Figure 6.6* is the logic input that is qualified by SELOGIC control equation setting 79CLS and then propagated on to the close logic in *Figure 6.3* to automatically reclose a circuit breaker. The explanation that follows in this reclosing relay subsection describes all the reclosing relay settings and logic that eventually result in this open-interval time-out logic output (see bottom of *Figure 6.10*), which becomes the logic input into *Figure 6.6*. Other aspects of the reclosing relay are also explained. As many as four (4) automatic reclosures (shots) are available.

Enable/Disable Reclosing

The reclose enable setting, E79, has setting choices N, 1, 2, 3, and 4. Setting choices 1–4 are the number of desired automatic reclosures, with corresponding open-interval time settings (see *Table 6.6* for details).

If *either* of the following reclosing relay settings is made:

➤ Reclose enable setting E79 := N

➤ Open-interval 1 time setting 79OI1 := OFF

then the reclosing relay is defeated and no automatic reclosing can occur. Open-interval time settings are explained in detail in *Open-Interval Timers*.

If the reclosing relay is defeated, the following also occur:

➤ All three reclosing relay state Relay Word bits (79RS, 79CY, and 79LO) are forced to logical 0 (see *Table 6.5*).

➤ All shot-counter Relay Word bits (SH0, SH1, SH2, SH3, and SH4) are forced to logical 0 (see *Table 6.7*).

➤ The analog output 79SH is set to –1 (see *Table 6.7*).

➤ The front-panel LEDs 79 RESET, 79 CYCLE, and 79 LOCKOUT are all extinguished.

Close Logic Can Still Operate When the Reclosing Relay Is Defeated

If the reclosing relay is defeated, the close logic (see *Figure 6.3*) can still operate if SELOGIC control equation circuit breaker status setting 52A__ is set to something other than logical 0. Making the setting 52A__ := 0 defeats the close logic *and* also defeats the reclosing relay (see *Defeat the Close Logic* for details).

Reclosing Relay States and General Operation

Table 6.5   Relay Word Bit and Front-Panel Correspondence to Reclosing Relay States

Reclosing Relay State	Corresponding Relay Word Bit	Corresponding Front-Panel LED
Reset	79RS	79 RESET
Reclose Cycle	79CY	79 CYCLE
Lockout	79LO	79 LOCKOUT

The reclosing relay is in one, and only one, of these states (listed in *Table 6.5*) at any time. When in a given state, the corresponding Relay Word bit asserts to logical 1, thus causing the corresponding LED to illuminate. Automatic reclosing only takes place when the relay is in the Reclose Cycle State. *Table 5.3* provides more information about front-panel LED programming.

Figure 6.9 explains in general the different states of the reclosing relay and its operation.

Reset State
The circuit breaker has been closed for a qualifying reset time. The SEL-651R is ready to go through an automatic reclosing sequence in the reclose cycle state if the circuit breaker trips open and reclose initiation is successful.

Relay Word bit 79RS = logical 1
Front-panel 79 RESET LED illuminated

Maintained Lockout Condition

Unsuccessful Reclose Initiation

Other Lockout Conditions

Reset Timer Times Out

Reset Timer Times Out

Successful Reclose Initiation

Successful Reclose Initiation

Lockout State
All automatic reclosing attempts are unsuccessful, reclose initiation is unsuccessful, other lockout conditions occur, or the SEL-651R powers up. The relay returns to the reset state after the circuit breaker is closed, the reset timer times out, and there are no maintained lockout conditions.

Relay Word bit 79LO = logical 1

Reclosing Relay Timer Settings

Table 6.6 shows the open-interval and reset timer factory-default settings.

Table 6.6   Reclosing Relay Timer Settings and Setting Ranges

Timer Setting (range)	Factory-Default Setting (in cycles)	Definition
79OI1 (OFF, 12.00–999999 cyc)	300.00	open-interval 1 time
79OI2 (OFF, 90.00–999999 cyc)	600.00	open-interval 2 time
79OI3 (OFF, 120.00–999999 cyc)	600.00	open-interval 3 time
79OI4 (OFF, 120.00–999999 cyc)	OFF	open-interval 4 time
79RSD (180.00–999999 cyc)	1800.00	reset time from reclose cycle state
79RSLD (0.00–999999 cyc)	600.00	reset time from lockout state

The operation of these timers is affected by SELOGIC control equation settings discussed later in this section.

Open-Interval Timers

The reclose enable setting, E79, determines the number of open-interval time settings that can be set. For example, if setting E79 := 3, the first three open-interval time settings in *Table 6.6*, are made available for setting (and 79OI4 is forced to OFF and hidden).

If an open-interval time is set to OFF, then that open-interval time is not operable *and* neither are the open-interval times that follow it.

In the factory-default settings in *Table 6.6*, the open-interval 4 time setting 79OI4 is the first open-interval time setting set to OFF:

79OI4 := **OFF**

Thus, open-interval time 79OI4 is not operable. But if the settings were:

79OI3 := **OFF**

79OI4 := **900.00 cycles** (set to some value other than OFF)

open-interval time 79OI4 would still be inoperative, because a preceding open-interval time is set to OFF (i.e., 79OI3 := OFF).

If open-interval 1 time setting, 79OI1, is set to OFF (79OI1 := OFF), no open-interval timing takes place and the reclosing relay is defeated.

The open-interval timers time consecutively; they do not have the same beginning time reference point. In the *Figure 6.10* example, open-interval 1 time setting, 79OI1 := 30, times first. If the subsequent first reclosure is not successful, then open-interval 2 time setting, 79OI2 := 600, starts timing. If the subsequent second reclosure is not successful, the relay goes to the Lockout State because 79OI3 := OFF (no third open interval and subsequently no third reclosure).

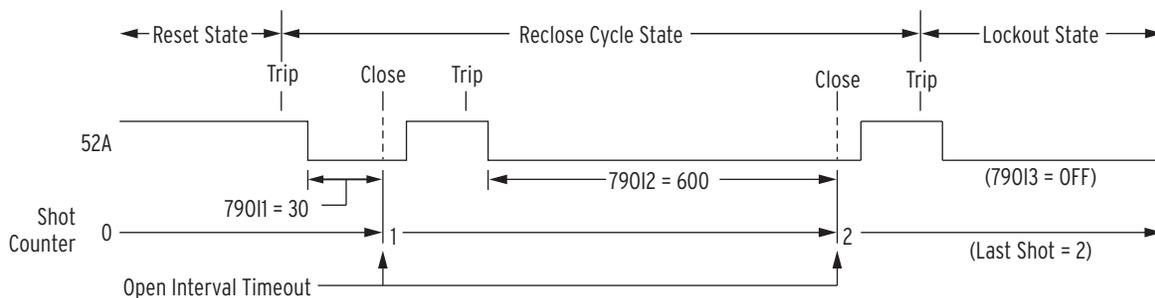
Page 333 of 1080
Close and Reclose Logic 6.21
Reclosing Relay
Wolfe


Figure 6.10 Example Reclosing Sequence From Reset to Lockout

SELOGIC control equation setting 79STL (stall open-interval timing) can be set to control open-interval timing.

Determination of Number of Reclosures (Last Shot)

The number of reclosures is equal to the number of open-interval time settings that precede the first open-interval time setting set to OFF. The "last shot" value is also equal to the number of reclosures.

In the *Figure 6.10* example, two set open-interval times precede open-interval 3 time, which is set to OFF (79OI3 := OFF):

> 79OI1 := **30.00**
>
> 79OI2 := **600.00**
>
> 79OI3 := **OFF**

For this example:

> Number of reclosures (last shot) = 2 = the number of set open-interval times that precede the first open-interval time set to OFF.

Observe Shot Counter Operation

Observe the reclosing relay shot counter operation, especially during testing, with the front-panel reclose count display (see *Table 11.2*).

Reset Timer

The reset timer qualifies circuit breaker closure before taking the relay to the Reset State from the Reclose Cycle State or the Lockout State. Circuit breaker status is determined by the SELOGIC control equation setting 52A.

Setting 79RSD:

> Qualifies closures when the relay is in the Reclose Cycle State. These closures are usually automatic reclosures resulting from open-interval time-out.
>
> Setting 79RSD is also the reset time used in sequence coordination schemes.

Setting 79RSLD:

> Qualifies closures when the relay is in the Lockout State. These closures are usually manual closures. These manual closures can originate externally to the relay, or via the SELOGIC control equation setting CL (see *Figure 6.3*).

6.22 | Close and Reclose Logic
Reclosing Relay

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 334 of 1080
Wolfe

Setting 79RSLD is also the reset timer used when the relay powers up, when it has individual settings changed for the active settings group, or when the active settings group is changed.

See *Momentary Drive-to-Lockout While Breaker Closed* for a description of a scenario in which there is no reset timing via setting 79RSLD to go from the lockout state to the reset state. In this scenario, the drive-to-lockout setting 79DTL causes the relay to transition between the reset and lockout states, while the breaker remains closed continuously.

Typically, setting 79RSLD is set less than setting 79RSD. Such setting of 79RSLD emulates reclosing relays with motor-driven timers that have a relatively short reset time from the lockout position to the reset position. The 79RSD and 79RSLD settings are set independently. Setting 79RSLD can even be set greater than setting 79RSD, if desired. SELOGIC control equation setting 79BRS (block reset timing) can be set to control reset timing.

Monitoring Open-Interval and Reset Timing

Monitor open-interval and reset timing with the following Relay Word bits:

Relay Word Bits	Definition
OPTMN	Indicates that the open-interval timer is actively timing
RSTMN	Indicates that the reset timer is actively timing

If the open-interval timer is actively timing, OPTMN asserts to logical 1. When the relay is not timing on an open interval (e.g., it is in the Reset State or in the Lockout State), OPTMN deasserts to logical 0. The relay can only time on an open interval when it is in the Reclose Cycle State, but just because the relay is in the Reclose Cycle State does not necessarily mean the relay is timing on an open interval. The relay only times on an open interval after successful reclose initiation and if no stall conditions are present.

If the reset timer is actively timing, RSTMN asserts to logical 1. If the reset timer is not timing, RSTMN deasserts to logical 0.

Reclosing Relay Shot Counter

Refer to *Figure 6.10*.

The shot counter increments for each reclose operation. For example, when the relay is timing on open-interval 1, 79OI1, it is at shot = 0. When the open interval times out, the shot counter increments to shot = 1 and so forth for the set open intervals that follow. The shot counter cannot increment beyond the last shot for automatic reclosing. The shot counter resets back to shot = 0 when the reclosing relay returns to the Reset State.

Table 6.7   Shot Counter Correspondence to Relay Word Bits and Open-Interval Times

Shot	Corresponding Relay Word Bit	Corresponding Open-Interval	Analog Output
0	SH0	79OI1	79SH = 0
1	SH1	79OI2	79SH = 1
2	SH2	79OI3	79SH = 2
3	SH3	79OI4	79SH = 3
4	SH4		79SH = 4
reclosing relay defeated	N/A	N/A	79SH = −1

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 1335 of 1480
Close and Reclose Logic 6.23
Reclosing Relay
Wolfe

When the shot counter is at a particular shot value (e.g., shot = 2), the corresponding Relay Word bit asserts to logical 1 (e.g., SH2 = logical 1).

The shot counter also increments for sequence coordination operation. The shot counter can increment beyond the last shot for sequence coordination, but only as high as shot = 4.

The analog output 79SH can be used in SELOGIC compares. For example, for a recloser operating in a three-phase mode (Group setting ESPB := N), the SELOGIC equation:

OUT202 := **79SH3P > 2**

would assert output contact OUT202 when the shot counter is at a value greater than 2.

Going to the Lockout State

The reclosing relay goes to the Lockout State if any *one* of the following occurs:

➤ The shot counter is equal to or greater than the last shot at time of reclose initiation. For example, all automatic reclosing attempts are unsuccessful (see *Figure 6.10*).

➤ Reclose initiation is unsuccessful because SELOGIC setting 79RIS (reclose initiation supervision) is effectively equal to logical 0.

➤ The circuit breaker opens without reclose initiation, such as happens with an external trip.

➤ The shot counter is equal to or greater than the last shot and the circuit breaker is open; for example, the shot counter is driven to last shot with SELOGIC control equation setting 79DLS while open-interval timing is in progress.

➤ The close failure timer (setting CFD) times out (see *Figure 6.3*).

➤ SELOGIC control equation setting 79DTL = logical 1.

➤ The Reclose Supervision Limit Timer (setting 79CLSD) times out (see *Figure 6.6* and top of *Figure 6.7*).

NOTE: Review Three-Phase (3P) vs. Single-Phase (A, B, and C) on page 6.2.

➤ A normal reclose initiation (e.g., SELOGIC control equation 79RI3P = TRIP3P) occurs and properly loads up an open-interval time (e.g., 79OI2 = 600 cycles; see *Figure 6.10*). Then, before the open-interval time has timed out completely (or even started timing), a subsequent unexpected reclose initiation occurs (e.g., flashover inside the circuit breaker tank while it is open).

Reclosing Relay States and Settings/Settings Group Changes

If individual settings are changed for the active settings group *or* the active settings group is changed, *all* of the following occur:

➤ The reclosing relay remains in the state it was in before the settings change.

➤ The shot counter is driven to last shot, with last shot corresponding to the new settings (see *Determination of Number of Reclosures (Last Shot)* for details on last shot).

➤ The reset timer is loaded with reset time setting 79RSLD (see *Reset Timer*).

6.24 | Close and Reclose Logic
Reclosing Relay

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 336 of 1080
Wolfe

If the relay happened to be in the Reclose Cycle State and was timing on an open interval before the settings change, the relay would be in the Reclose Cycle State after the settings change, but the relay would immediately go to the Lockout State. This is because the breaker is open and the relay is at last shot after the settings change, so no more automatic reclosures are available.

If the circuit breaker remains closed through the settings change, the reset timer times out on reset time setting 79RSLD after the settings change and goes to the Reset State (if it is not already in the Reset State), and the shot counter returns to shot = 0. If the relay happens to trip during this reset timing, the relay will immediately go to the Lockout State, because shot = last shot.

Reclosing Relay SELOGIC Control Equation Settings Overview

NOTE: The SELOGIC settings in Table 6.8 have an appended "3P" (three-phase).

Table 6.8   Reclosing Relay SELOGIC Control Equation Settings

SELOGIC Control Equation Setting	Factory-Default Setting	Definition
79RI3P	TRIP3P	Reclose Initiate
79RIS3P	52A3P OR 79CY3P	Reclose Initiate Supervision
79DTL3P	(NOT LT02 OR NOT LT06) AND (TRIP3P OR NOT 52A3P) OR PB12_PUL OR OC3	Drive-to-Lockout
79DTL3X (G&W Viper-ST, G&W Viper-LT, ABB Elastimold MVR, ABB OVR/Gridshield (32-pin), ABB Joslyn TriMod 600R, Siemens SDR Triple-Single, Eaton NOVA-TS or NOVA-STS Triple-Single)	R_TRIG SV02T	Drive-to-Lockout (extra)
79DTL3X (Multi-Recloser Interface)	R_TRIG SV02T AND (A1_CFG OR A3_CFG)	
79DTL3X (all others)	0	
79DLS3P	79LO3P	Drive-to-Last Shot
79SKP3P	(51PT OR 51G1T) AND NOT LT04 AND (79SH3P < MV01)	Skip Shot
79STL3P	TRIP3P	Stall Open-Interval Timing
79BRS3P	0	Block Reset Timing
79SEQ3P	0	Sequence Coordination
79CLS3P (Traditional Retrofit with ac power supply)	PWR_SRC1 AND TCCAP AND NOT (BTFAIL)	Reclose Supervision
79CLS3P (all others with ac power supply)	TCCAP AND NOT (BTFAIL)	
79CLS3P (Traditional Retrofit with dc power supply)	PWR_SRC1 AND TCCAP	
79CLS3P (all others with dc power supply)	TCCAP

Close and Reclose Logic 6.25
Reclosing Relay
Wolfe

The factory-default settings in *Table 6.8* are discussed in detail in the remainder of this section. They are for three-phase reclosing (factory-default setting ESPB := N).

Reclose Initiate and Reclose Initiate Supervision Settings (79RI and 79RIS, Respectively)

The reclose initiate setting 79RI is a rising-edge detect setting. The reclose initiate supervision setting 79RIS supervises setting 79RI. When setting 79RI detects a rising edge (logical 0 to logical 1 transition), setting 79RIS has to be at logical 1 (79RIS = logical 1) in order for open-interval timing to be initiated.

If 79RIS = logical 0 when setting 79RI detects a rising edge (logical 0 to logical 1 transition), the relay goes to the Lockout State.

Factory-Default 79RI/79RIS Settings Example

With factory-default settings:

79RI3P := **TRIP3P**

79RIS3P := **52A3P OR 79CY3P**

the transition of the TRIP3P Relay Word bit from logical 0 to logical 1 initiates open-interval timing only if the 52A3P or 79CY3P Relay Word bit is at logical 1.

The circuit breaker has to be closed (circuit breaker status 52A3P = logical 1) at the instant of the first trip of the automatic reclose cycle in order for the SEL-651R-2 to successfully initiate reclosing and start timing on the first open interval. The SEL-651R-2 is not yet in the reclose cycle state (79CY3P = logical 0) at the instant of the first trip.

Then for any subsequent trip operations in the automatic reclose cycle, the SEL-651R-2 is in the reclose cycle state (79CY3P = logical 1) and the SEL-651R-2 successfully initiates reclosing for each trip. Because of factory-default setting 79RIS3P := 52A3P OR 79CY3P, successful reclose initiation in the reclose cycle state (79CY3P = logical 1) is not dependent on the circuit breaker status (52A3P). This allows successful reclose initiation in the case of an instantaneous trip, but the circuit breaker status indication is slow: the instantaneous trip (reclose initiation) occurs before the SEL-651R-2 sees the circuit breaker close.

If a flashover occurs in a circuit breaker tank during an open interval (circuit breaker open) and the SEL-651R-2 calls for a trip, the SEL-651R-2 goes immediately to lockout.

Additional 79RI/79RIS Settings Example

The preceding settings example initiates open-interval timing on the rising edge of the TRIP3P Relay Word bit. The following is an example of reclose initiation on the opening of the circuit breaker.

With setting:

79RI3P := **NOT 52A3P**

the transition of the 52A3P Relay Word bit from logical 1 to logical 0 (breaker opening) initiates open-interval timing. Setting 79RI3P looks for a logical 0 to logical 1 transition, thus Relay Word bit 52A3P is inverted in the 79RI3P setting.

6.26 | Close and Reclose Logic
Reclosing Relay

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 338 of 1080
Wolfe

The reclose-initiate supervision setting 79RIS3P supervises setting 79RI3P. With settings:

79RI3P := **NOT 52A3P**

79RIS3P := **TRIP3P**

the transition of the 52A3P Relay Word bit from logical 1 to logical 0 initiates open-interval timing only if the TRIP3P Relay Word bit is at logical 1 (TRIP3P = logical 1). Thus, the TRIP3P Relay Word bit has to be asserted when the circuit breaker opens to initiate open-interval timing. With a long enough setting of the Minimum Trip Duration Timer (TDURD), the TRIP3P Relay Word bit will still be asserted to logical 1 when the circuit breaker opens (see *Figure 5.1* and *Figure 5.4*).

If the TRIP3P Relay Word bit is at logical 0 (TRIP3P = logical 0) when the circuit breaker opens (logical 1 to logical 0 transition), the relay goes to the Lockout State. This helps prevent reclose initiation for circuit breaker openings caused by trips external to the relay.

Other 79RI/79RIS Settings Considerations

1. If no reclose initiate supervision is desired, make the following setting:

   79RIS := **1** set directly to logical 1

   Setting 79RIS = logical 1 at all times. Any time a logical 0 to logical 1 transition is detected by setting 79RI, open-interval timing will be initiated, unless prevented by other means.

2. If the following setting is made:

   79RI := **0** set directly to logical 0

   reclosing is never initiated. The reclosing relay is effectively inoperative.

3. If the following setting is made:

   79RIS := **0** set directly to logical 0

   the reclosing relay goes directly to the lockout state any time reclosing is initiated. The reclosing relay is effectively inoperative.

Drive-to-Lockout and Drive-to-Last-Shot Settings (79DTL and 79DLS, Respectively)

When 79DTL = logical 1, the reclosing relay goes to the Lockout State (Relay Word bit 79LO = logical 1) and the front-panel **LOCKOUT** LED illuminates.

79DTL has a 60-cycle dropout time. This keeps the drive-to-lockout condition up 60 more cycles after 79DTL has reverted back to 79DTL = logical 0. This is useful for situations where both of the following are true:

➤ Any of the trip and drive-to-lockout conditions are pulsed conditions (e.g., the **OPEN** Command Relay Word bit, OC3, asserts for only 1/4 cycle; refer to *Figure 6.11*).

➤ Reclose initiation is by the breaker contact opening (e.g., 79RI3P := NOT 52A3P; refer to *Additional 79RI/79RIS Settings Example* for details).

Then the drive-to-lockout condition overlaps reclose initiation and the SEL-651R-2 stays in lockout after the breaker trips open.

When 79DLS = logical 1, the reclosing relay goes to the last shot, if the shot counter is not at a shot value greater than or equal to the calculated last shot.

Close and Reclose Logic 6.27
Page 339 of 1080
Reclosing Relay
Wolfe

Momentary Drive-to-Lockout While Breaker Closed

If the relay had previously been in the Reset State (Relay Word bit 79RS = logical 1) with the breaker closed and then a drive-to-lockout condition comes true (via setting 79DTL), the relay immediately goes to the Lockout State (Relay Word bit 79LO = logical 1). If the breaker continues to remain closed and then the drive-to-lockout condition (via setting 79DTL) goes away (after the previously discussed 60-cycle dropout time), the relay reverts immediately back to the Reset State.

No reset timing via setting 79RSLD is needed to return to the Reset State in this scenario because the breaker remains closed the entire time. The relay had previously timed on a reset time (setting 79RSD or 79RSLD) when it first went to the Reset State, before the drive-to-lockout logic (via setting 79DTL) started activating. Thus, there is no need to again reset-time-qualify a breaker that remained closed throughout such a transition (Reset State—Lockout State—Reset State), because of drive-to-lockout setting 79DTL.

Factory-Default 79DTL/79DLS Settings Example

The drive-to-lockout factory settings are as follows:

79DTL3P := **(NOT LT02 OR NOT LT06) AND (TRIP3P OR NOT 52A3P) OR PB12_PUL OR OC3**

79DTL3X := **R_TRIG SV02T** (G&W Viper-ST, G&W Viper-LT, ABB Elastimold MVR, ABB OVR/Gridshield (32-pin), ABB Joslyn TriMod 600R, Siemens SDR Triple-Single, Eaton NOVA-TS or NOVA-STS Triple-Single)

79DTL3X := **R_TRIG SV02T AND (A1_CFG OR A3_CFG)** (Multi-Recloser Interface)

79DTL3X := **0** (all others)

Settings 79DTL3P and 79DTL3X are functionally equivalent, as evidenced in *Figure 6.1*. Setting 79DTL3X is for extra three-phase drive-to-lockout logic and is seen as a supplement to 79DTL3P. For the single-phase drive-to-lockout logic, settings 79DTL3P and 79DTL3X provide convenient locations to insert three-phase drive-to-lockout conditions (see *Figure 6.1*), rather than repetitively inserting them in each single-phase drive-to-lockout setting (79DTLA, 79DTLB, and 79DTLC).

Figure 6.11 shows in more detail the programmed conditions that drive the reclosing relay to lockout:

➤ If either the **RECLOSE ENABLED** operator control is OFF or the **HOT LINE TAG** operator control is ON **and** a trip occurs or the breaker opens, the reclosing relay is driven to lockout.

➤ If the **TRIP** operator control is pressed or an **OPEN** command is sent to the serial port, the reclosing relay is driven to lockout. Both these operations are deemed manual operations, thus no automatic reclosing takes place.

➤ The explanation for the 79DTL3X factory-default setting is found in the side column notes adjacent to *Figure 5.2* and *Figure 6.11*.

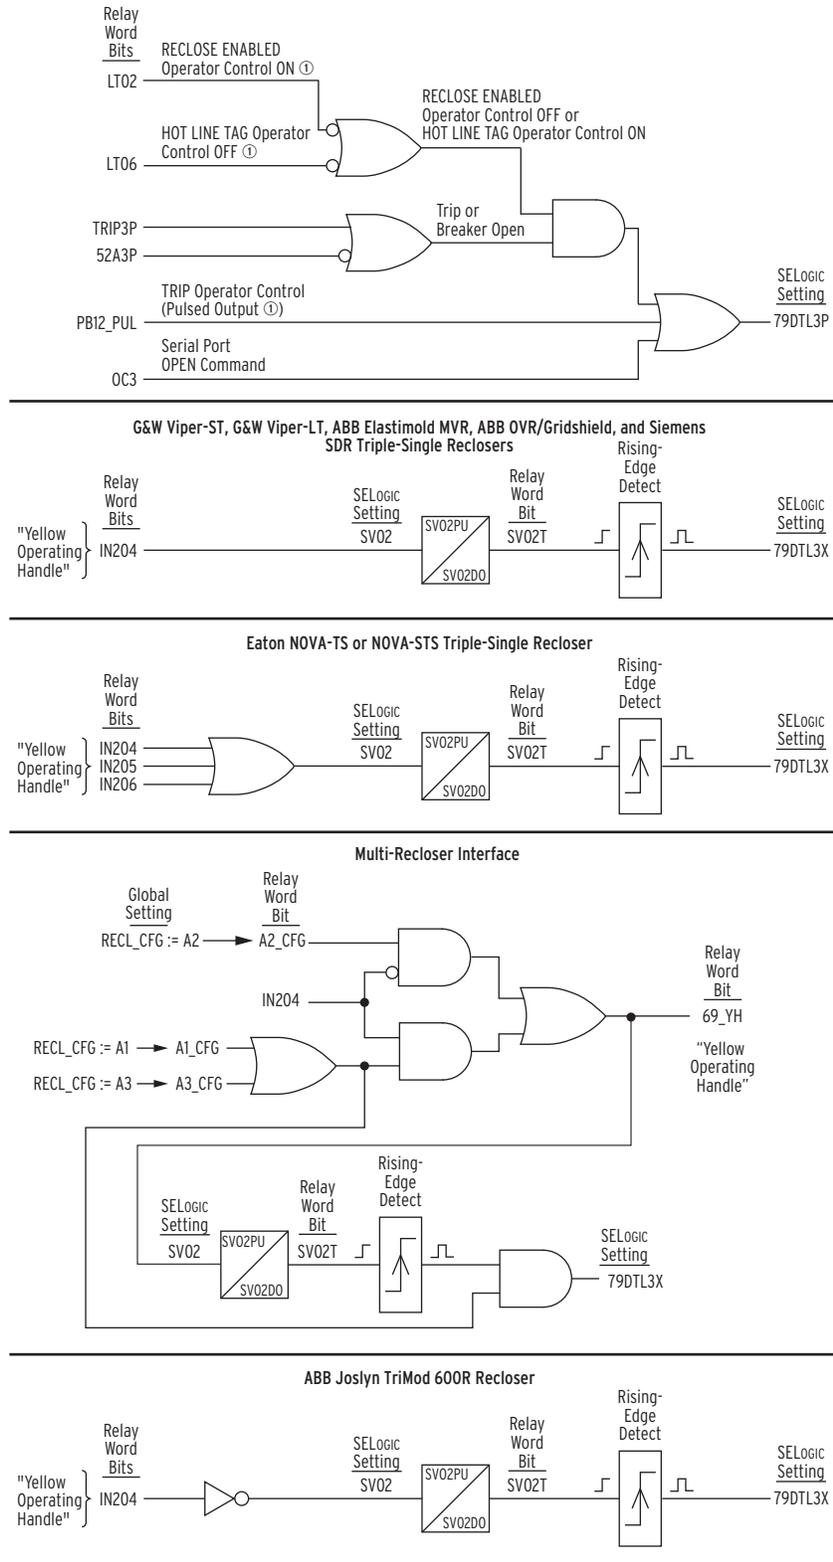
Page 340 of 1080
Wolfe

"YELLOW OPERATING HANDLE" TRIP AND DRIVE-TO-LOCKOUT

The factory-default TR3X trip setting (Figure 5.2) and 79DTL3X drive-to-lockout setting (Figure 6.11) are set the same for G&W Viper-ST, G&W Viper-LT, ABB Elastimold MVR, ABB OVR/Gridshield, Siemens SDR Triple-Single, Eaton NOVA-TS or NOVA-STS Triple-Single, and Multi-Recloser Interface reclosers. These settings propagate the pulling of a single yellow operating handle (on a single phase) to trip and lockout all three phases.

The ABB Joslyn TriMod 600R recloser does not need the TR3X "yellow operating handle" trip setting because the single yellow operating handle on the unit opens all three phases directly.


① See Table 11.9.

Figure 6.11   Factory-Default Drive-to-Lockout Logic Settings

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 1341 of 1080
Close and Reclose Logic 6.29
Reclosing Relay
Wolfe

The drive-to-last-shot factory-default setting is:

> 79DLS3P := **79LO3P**

Three open-intervals are also set in the factory-default settings, resulting in last shot = 3. Any time the relay is in the lockout state (Relay Word bit 79LO3P = logical 1), the relay is driven to last shot if the shot counter is not already at a shot value greater than or equal to shot = 3:

> 79DLS3P := **79LO3P** = Logical 1

Additional 79DTL Settings Example

To drive the relay to the Lockout State for fault current above a certain level when tripping (e.g., level of phase instantaneous overcurrent element 50P3), make settings similar to the following:

> 79DTL3P := **TRIP3P AND 50P3 OR ...**

Additionally, if the reclosing relay should go to the Lockout State for an underfrequency trip, make settings similar to the following:

> 79DTL3X := **81D1T OR ...**

Other 79DTL/79DLS Settings Considerations

If no special drive-to-lockout or drive-to-last-shot conditions are desired, make the following settings:

> 79DTL := **0** set directly to logical 0
>
> 79DLS := **0** set directly to logical 0

With settings 79DTL and 79DLS inoperative, the relay still goes to the Lockout State and to last shot if an entire automatic reclose sequence is unsuccessful.

Overall, settings 79DTL or 79DLS are needed to take the relay to the Lockout State or to last shot for immediate circumstances.

Skip-Shot and Stall Open-Interval Timing Settings (79SKP and 79STL, Respectively)

The skip-shot setting 79SKP causes a reclose shot to be skipped. Thus, an open-interval time is skipped, and the next open-interval time is used instead.

If 79SKP = logical 1 at the instant of successful reclose initiation (see preceding discussion on settings 79RI and 79RIS), the relay increments the shot counter to the next shot and then loads the open-interval time corresponding to the new shot (see *Table 6.7*). If the new shot is the last shot, no open-interval timing takes place and the relay goes to the Lockout State if the circuit breaker is open.

After successful reclose initiation, open-interval timing does not start until allowed by the stall open-interval timing setting 79STL. If 79STL = logical 1, open-interval timing is stalled. If 79STL = logical 0, open-interval timing can proceed.

If an open-interval time has not yet started timing (79STL = logical 1 still), the 79SKP setting is still processed. In such conditions (open-interval timing has not yet started timing), if 79SKP = logical 1, the relay increments the shot counter to the next shot and then loads the open-interval time corresponding to the new shot (see *Table 6.7*).

If the open interval still does not start timing (it is still fully loaded for the given shot) and 79SKP is still asserted (79SKP = logical 1), then each subsequent processing interval (1/4 cycle), the shot counter will increment and

6.30 | Close and Reclose Logic
Reclosing Relay

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 342 of 1080
Wolfe

the corresponding open-interval time will be loaded for that shot, superseding any previously loaded open intervals. With the preceding being true, the shot counter increments from shot = 0 to shot = 1 the first processing interval, from shot =1 to shot = 2 the second processing interval, and so forth until the last shot is reached.

If the new shot turns out to be the last shot, no open-interval timing takes place and the relay goes to the Lockout State if the circuit breaker is open (see *Going to the Lockout State*).

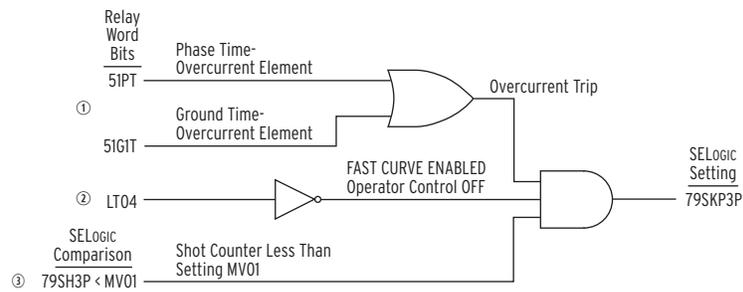
If the relay is in the middle of timing on an open interval and 79STL changes state to 79STL = logical 1, open-interval timing stops where it is. If 79STL changes state back to 79STL = logical 0, open-interval timing resumes where it left off. Use the OPTMN Relay Word bit to monitor open-interval timing (see *Monitoring Open-Interval and Reset Timing*).

Factory-Default 79SKP/79STL Settings Example

The skip-shot function factory-default setting is as follows:

79SKP3P := **(51PT OR 51G1T) AND NOT LT04 AND (79SH3P < MV01)**

MV01 := **2**

Refer to *Figure 6.12*. In a typical distribution protection scenario, there are two trips on fast curves, followed by two trips on delay curves. These operations can be phase (51PT) or ground (51G1T) time-overcurrent elements. How elements 51PT and 51G1T each convert between fast and delay curve operation is covered in *Time-Overcurrent Elements on page 4.13*.


① See Figure 4.16 and Figure 4.22; ② Table 11.9; ③ Table 7.2.

Figure 6.12 Factory-Default Skip-Shot Logic

If the fast curves are disabled (**FAST CURVE ENABLED** operator control turned off; LT04 = logical 0), we do not want four delay-curve trips (two additional delay-curve trips replacing the two disabled fast-curve trips). We only want the two remaining delay-curve trips, with their standard open interval between them (open interval 3, setting 79OI3). The logic in *Figure 6.12* (dramatized in *Figure 6.13*) accelerates the sequencing of the shot counter so that the third open interval is loaded after the first trip on a delay curve.

As shown in the *Figure 6.10* example of a standard reclose sequence:

➤ The first trip occurs and shot = 0 (and first open-interval time is then loaded)

➤ and the second trip occurs and shot = 1 (and the second open-interval time is loaded)

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 1343 of 1480
Wolfe

Close and Reclose Logic 6.31
Reclosing Relay

And it follows that the third open-interval (setting 79OI3) is loaded at the third trip, when shot = 2. So, to get the third open-interval loaded at the first trip rather than at the third trip, the shot counter has to be accelerated instantly from shot = 0 to shot = 2 (and then stop at shot = 2) at the time of the first trip. The comparison (79SH3P < MV01) at the bottom of *Figure 6.12* accomplishes this.

For *Figure 6.12*, math-variable setting MV01 is set to MV01 := 2, equal to the number of fast-curve trips. MV01 is compared to the reclosing relay shot counter, via analog output 79SH3P. Thus, if:

$$79SH3P < MV01 \; (= 2)$$

and the rest of the logic in *Figure 6.12* is true, then SELOGIC setting 79SKP3P effectively equals logical 1 (79SKP3P = logical 1). With 79SKP3P = logical 1, for the instant of the first trip, the shot counter increments from 79SH3P = 0 to 79SH3P = 1. The next processing interval (next quarter cycle), the overcurrent trip will still be on and the shot counter increments from 79SH3P = 1 to 79SH3P = 2. Now, the shot counter stops incrementing, because

$$79SH3P >= MV01 \; (= 2)$$

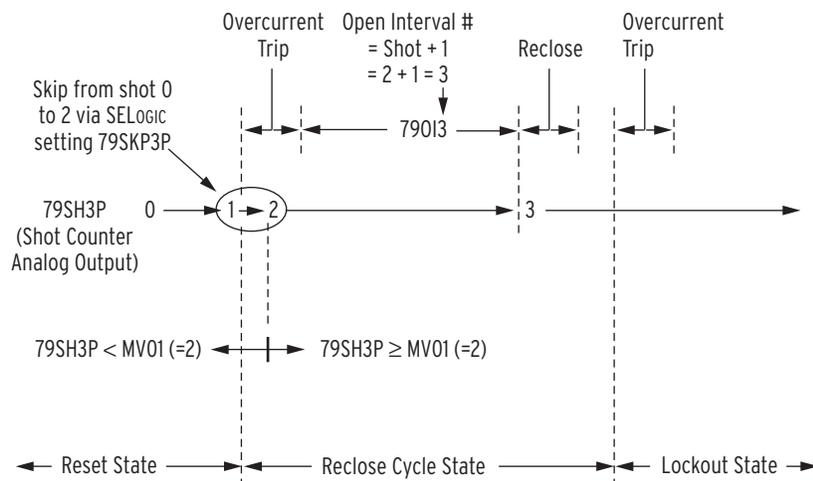
With the shot = 2, the third open-interval (setting 79OI3) is then loaded and timed, as shown in *Figure 6.13*. If the number of fast-curve trips is changed, math-variable setting MV01 is likewise changed.


Figure 6.13   Skip-Shot Sequence

The stall open-interval timing factory setting is as follows:

79STL3P := **TRIP3P**

After successful reclose initiation, open-interval timing does not start as long as the trip condition is present (Relay Word bit TRIP3P = logical 1). As discussed previously, if an open-interval time has not yet started timing (79STL3P = logical 1 still), the 79SKP3P setting is still processed. Once the trip condition goes away (Relay Word bit TRIP3P = logical 0), open-interval timing can proceed.

OPEN INTERVAL TIMING STALLED TOO LONG?
If open interval timing is stalled too long by factory setting 79STL3P := TRIP3P, change the controlling minimum trip duration time setting TDURD. See Minimum Trip Duration Timer on page 5.7 for more detail.

Additional 79SKP Settings Example

With skip-shot factory-set as follows,

79SKP3P := **50P2 AND SH03P**

if shot = 0 (Relay Word bit SH03P = logical 1) *and* phase current is above the phase instantaneous overcurrent element 50P2 threshold (Relay Word bit 50P2 = logical 1), at the instant of successful reclose initiation, the shot counter is incremented from shot = 0 to shot = 1. Then, open-interval 1 time (setting 79OI1) is skipped and the relay times on the open-interval 2 time (setting 79OI2) instead.

Table 6.9   Example Open-Interval Time Settings

Shot	Corresponding Relay Word Bit	Corresponding Open Interval	Open-Interval Time Setting
0	SH03P	79OI1	30 cycles
1	SH13P	79OI2	600 cycles

In *Table 6.9*, note that the open-interval 1 time (setting 79OI1) is a short time, while the following open-interval 2 time (setting 79OI2) is significantly longer. For a high-magnitude fault (greater than the phase instantaneous overcurrent element 50P2 threshold), open-interval 1 time is skipped and open-interval timing proceeds on the following open-interval 2 time. The longer open-interval time provides more time for the fault to dissipate (or the debris causing the fault to fall away from the line) and more equipment cooling time. Also, the skipped open interval reduces the number of potential reclosures back into the fault, thus reducing equipment stress.

Once the shot is incremented to shot = 1, Relay Word bit SH0 = logical 0 and then setting 79SKP3P = logical 0, regardless of Relay Word bit 50P2.

Additional 79STL Settings Example 1

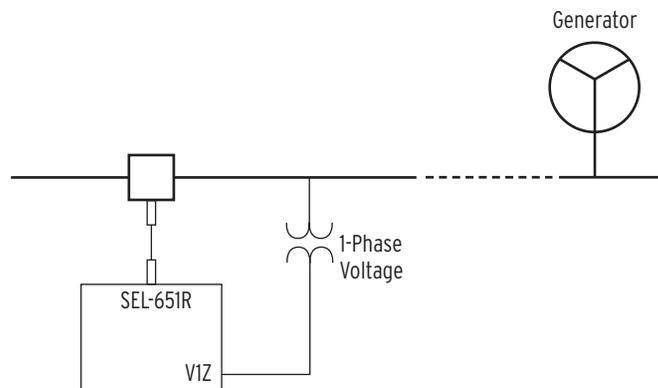
If the SEL-651R-2 is used on a feeder with a line-side independent power producer (cogenerator), the utility should not reclose into a line still energized by an islanded generator. To monitor line voltage and block reclosing, connect a line-side single-phase potential transformer to a voltage channel on the SEL-651R-2 as shown in *Figure 6.14*.


Figure 6.14   Reclose Blocking for Islanded Generator

If the line is energized, an overvoltage element can be set to assert. Make a setting like the following:

79STL3P := **59ZA1 OR ...**

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 1345 of 1080
Wolfe
Close and Reclose Logic   6.33
Reclosing Relay

If line voltage is present, Relay Word bit 59ZA1 asserts, stalling open-interval timing (reclose block). If line voltage is not present, Relay Word bit 59ZA1 deasserts, allowing open-interval timing to proceed unless some other set condition stalls open-interval timing.

Additional 79STL Settings Example 2

Refer to *Figure 6.8* and the accompanying setting example, showing an application for setting 79STL.

Other 79SKP/79STL Settings Considerations

If no special skip-shot or stall open-interval timing conditions are desired, make the following settings:

79SKP := **0**   set directly to logical 0

79STL := **0**   set directly to logical 0

Block-Reset Timing Setting (79BRS)

The block-reset timing setting 79BRS keeps the reset timer from timing. Depending on the reclosing relay state, the reset timer can be loaded with either reset time:

79RSD (Reset Time from Reclose Cycle)

or

79RSLD (Reset Time from Lockout)

Depending on how setting 79BRS is set, none, one, or both of these reset times can be controlled. If the reset timer is timing and then 79BRS asserts to:

79BRS = logical 1

reset timing is stopped and does not begin timing again until 79BRS deasserts to:

79BRS = logical 0

When reset timing starts again, the reset timer is fully loaded. Thus, successful reset timing has to be continuous. Use the RSTMN Relay Word bit to monitor reset timing (see *Monitoring Open-Interval and Reset Timing*).

Factory-Default 79BRS Settings Example

The block reset function is not enabled in the factory settings:

79BRS3P := **0**   set directly to logical 0

Additional 79BRS Settings Example 1

The block reset timing setting is:

79BRS3P := **(51P OR 51G1) AND 79CY3P**

Relay Word bit 79CY3P corresponds to the Reclose Cycle State. The reclosing relay is in one of the three reclosing relay states at any one time (see *Figure 6.9* and *Table 6.5*).

When the relay is in the Reset or Lockout States, Relay Word bit 79CY3P is deasserted to logical 0. Thus, the 79BRS3P setting has no effect when the relay is in the Reset or Lockout States. When a circuit breaker is closed from lockout, there could be cold-load inrush current that momentarily picks up a time-overcurrent element (e.g., phase time-overcurrent element 51PT pickup

6.34 | Close and Reclose Logic
Reclosing Relay

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 346 of 1080
Wolfe

[51P] asserts momentarily). But, this assertion of pickup 51P has no effect on reset timing because the relay is in the Lockout State (79CY3P = logical 0). The relay will time immediately on reset time 79RSLD and take the relay from the Lockout State to the Reset State with no additional delay because 79BRS3P is deasserted to logical 0.

When the relay is in the Reclose Cycle State, Relay Word bit 79CY3P is asserted to logical 1. Thus, the factory-default 79BRS3P setting can function to block reset timing if time-overcurrent pickup 51P or 51G1 is picked up while the relay is in the Reclose Cycle State. This helps prevent repetitive "trip-reclose" cycling.

Additional 79BRS Settings Example 2

If the block-reset timing setting is:

79BRS3P := **51P OR 51G1**

then reset timing is blocked if time-overcurrent pickup 51P or 51G1 is picked up, regardless of the reclosing relay state.

Sequence-Coordination Setting (79SEQ)

The sequence-coordination setting 79SEQ keeps the SEL-651R-2 in step with a downstream recloser in a sequence-coordination scheme. Sequence coordination prevents overreaching SEL-651R-2 overcurrent elements from tripping for faults beyond the downstream recloser. This is accomplished by incrementing the shot counter and supervising overcurrent elements with resultant shot-counter elements.

In order for sequence-coordination setting 79SEQ to increment the shot counter, both the following conditions must be true:

➤ No trip present (Relay Word bit TRIP = logical 0)

➤ Circuit breaker closed (SELOGIC control equation setting 52A = logical 1, effectively)

Sequence-coordination setting 79SEQ is usually set with some overcurrent element pickups. If the above two conditions are both true and a set overcurrent element pickup asserts for at least 1.25 cycles and then deasserts, the shot counter increments by one count. This assertion / deassertion indicates that a downstream device (e.g., downstream recloser—see *Figure 6.15*) has operated to clear a fault. Incrementing the shot counter keeps the SEL-651R-2 in step with the downstream device, as is shown in *Additional 79SEQ Settings Example 1* and *Additional 79SEQ Settings Example 2*.

Every time a sequence-coordination operation occurs, the shot counter is incremented and the reset timer is loaded up with reset time 79RSD. Sequence coordination can increment the shot counter beyond last shot, but no further than shot = 4. The shot counter returns to shot = 0 after the reset timer times out. Reset timing is subject to previously discussed SELOGIC control equation setting 79BRS.

Sequence-coordination operation does not change the reclosing relay state. For example, if the relay is in the Reset State and there is a sequence-coordination operation, it remains in the Reset State.

Factory-Default 79SEQ Settings Example

Sequence coordination is not enabled in the factory settings:

79SEQ3P := **0**

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Close and Reclose Logic 6.35
Page 347 of 1080
Reclosing Relay
Wolfe

Additional 79SEQ Settings Example 1

With sequence-coordination setting:

> 79SEQ3P := **79RS3P AND 51P**

sequence coordination is operable only when the SEL-651R-2 is in the Reset State (79RS3P = logical 1). Refer to *Figure 6.15* and *Figure 6.16*

NOTE: This example portrayed in Figure 6.15 and Figure 6.16 only shows operation with phase overcurrent elements. Sequence coordination can also work with ground overcurrent elements (e.g., add a ground time-overcurrent element pickup to the sequence-coordination setting: 79SEQ3P := 79RS3P AND (51P OR 51G1).

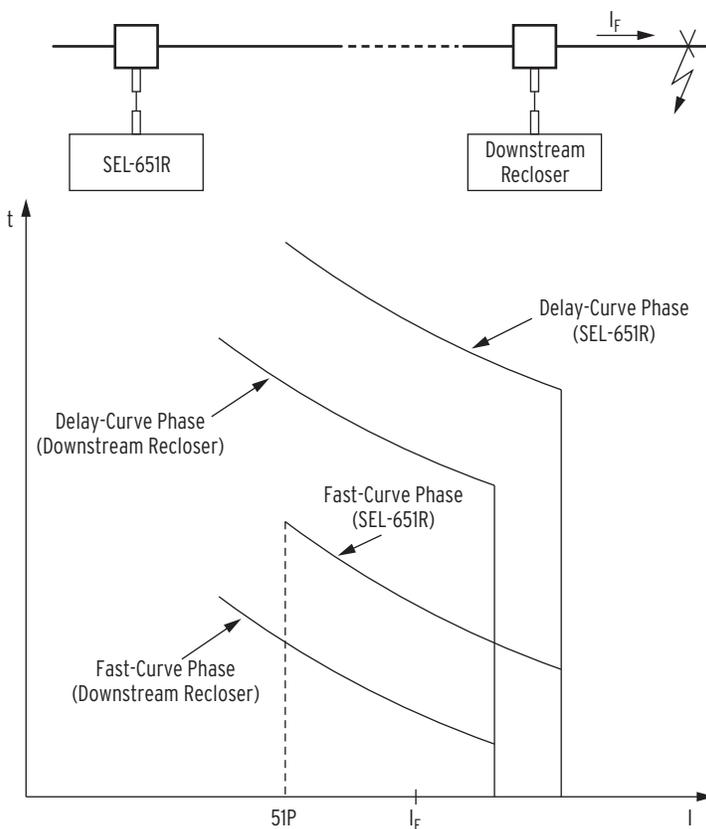
Assume that the downstream recloser is set to operate twice on the fast curve and then twice on the delay curve. The delay curve is allowed to operate after two fast-curve operations because the fast curves are then inoperative for tripping. The SEL-651R-2 fast curve is coordinated with the downstream recloser fast curve. The SEL-651R-2 delay curve is coordinated with the downstream recloser delay curve. How phase time-overcurrent element 51PT converts between fast and delay curve operation is covered in *Time-Overcurrent Elements on page 4.13*.


Figure 6.15   Sequence Coordination Between the SEL-651R-2 Recloser Control and a Downstream Recloser

① Fault occurs beyond downstream recloser.
② Fault cleared by downstream recloser fast curve.
③ Downstream recloser recloses into fault.
④ Fault cleared by downstream recloser delay curve.

6.36 | Close and Reclose Logic
Reclosing Relay

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 348 of 1080
Wolfe

If the SEL-651R-2 is in the Reset State (79RS3P = logical 1) and then a permanent fault beyond the downstream recloser occurs (fault current IF in *Figure 6.15*), the downstream recloser fast curve operates to clear the fault. The SEL-651R-2 also sees the fault. The phase time-overcurrent pickup 51P asserts and then deasserts without tripping, incrementing the SEL-651R-2 shot counter from:

shot = 0 to shot = 1

When the downstream recloser recloses, its fast curve operates again to clear the fault. The SEL-651R-2 also sees the fault again. The phase time-overcurrent pickup 51P asserts and then deasserts without tripping, incrementing the SEL-651R-2 shot counter from:

shot = 1 to shot = 2

At shot = 2, the SEL-651R-2 now operates on its delay curve, instead of its fast curve. This keeps the SEL-651R-2 in step with the downstream recloser, which now also operates on its delay curve, after two operations on its fast curve. If the fast curve was still active in the SEL-651R-2 for shot ≥ 2, it would overtrip for the fault beyond the downstream recloser (the SEL-651R-2 fast curve would operate before the downstream recloser delay curve).

Figure 6.16 shows the continuing operation of the sequence-coordination logic and subsequent incrementing of the shot counter to shot = 3 and shot = 4. The shot counter returns to shot = 0 after the reset timer (loaded with reset time 79RSD) times out.

Additional 79SEQ Settings Example 2

Review preceding Example 1.

The following example limits sequence-coordination shot-counter incrementing. Assume that the downstream recloser in *Figure 6.15* is set to operate twice on its fast curve and then twice on its delay curve for faults beyond it. Assume that the SEL-651R-2 is set to operate only once on its fast curve and then twice on its delay curve for faults between the SEL-651R-2 and the downstream recloser.

If the SEL-651R-2 sequence-coordination setting is:

79SEQ3P := **79RS3P AND 51P**

and there is a permanent fault beyond the downstream recloser, the shot counter of the SEL-651R-2 will increment all the way to shot = 4 (see *Figure 6.16*). If there is then a coincident fault between the SEL-651R-2 and the downstream recloser, the SEL-651R-2 will trip and go to the Lockout State. Any time the shot counter is at a value equal to or greater than last shot (last shot = 2, in this case) and the SEL-651R-2 trips, it goes to the Lockout State.

To avoid this problem, make the following sequence-coordination setting (refer to *Figure 6.17*):

79SEQ3P := **79RS3P AND 51P AND SH03P**

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Close and Reclose Logic 6.37
Page 349 of 1080
Reclosing Relay
Wolfe

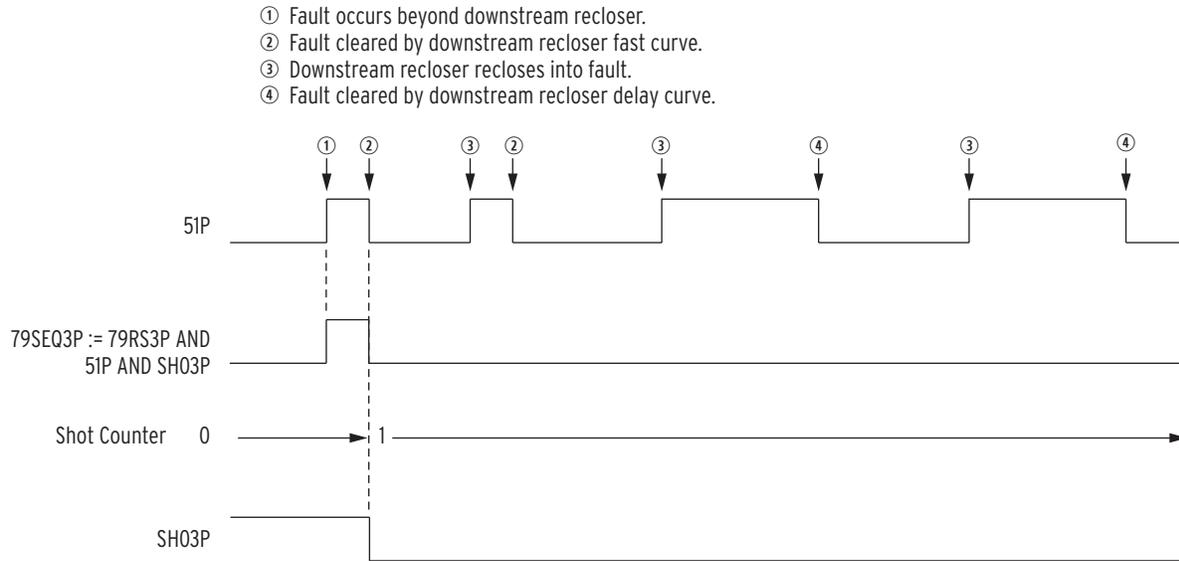
① Fault occurs beyond downstream recloser.
② Fault cleared by downstream recloser fast curve.
③ Downstream recloser recloses into fault.
④ Fault cleared by downstream recloser delay curve.


Figure 6.17 Operation of SEL-651R-2 Shot Counter for Sequence Coordination With Downstream Recloser (Additional 79SEQ Settings Example 2)

If the SEL-651R-2 is in the Reset State (79RS3P = logical 1) with the shot counter reset (shot = 0; SH03P = logical 1) and then a permanent fault beyond the downstream recloser occurs (fault current I_F in *Figure 6.15*), the downstream recloser fast curve operates to clear the fault. The SEL-651R-2 also sees the fault. The phase time-overcurrent pickup 51P asserts and then deasserts without tripping, incrementing the relay shot counter from:

shot = 0 to shot = 1

Now the SEL-651R-2 cannot operate on its fast curve because the shot counter is at shot = 1; it is now operating on its delay curve.

The downstream recloser continues to operate for the permanent fault beyond it, but the SEL-651R-2 shot counter does not continue to increment. Sequence-coordination setting 79SEQ3P is effectively disabled by the shot counter incrementing from shot = 0 (SH03P = logical 1) to shot = 1 (SH03P = logical 0).

79SEQ3P := **79RS3P AND 51P AND SH03P**

The shot counter stays at shot = 1.

Thus, if there is a coincident fault between the SEL-651R-2 and the downstream recloser, the SEL-651R-2 will operate on delay curve and then reclose once, instead of going straight to the Lockout State (shot = 1 < last shot = 2).

As stated earlier, the reset-time setting 79RSD takes the shot counter back to shot = 0 after a sequence-coordination operation increments the shot counter. Make sure that reset-time setting 79RSD is set long enough to maintain the shot counter at shot = 1 as shown in *Figure 6.17*.

Reclose Supervision Setting (79CLS)

See *Reclose Supervision Logic on page 6.10*.

Section 7

SELOGIC Control Equation Programming

Functions use operands (inputs) and operators to generate outputs. Complex functions are created by using the outputs of several functions as operands in the new function.

Embedded relay functions such as protection elements, tripping and closing logic, and event report triggering use logic built into the SEL-651R-2. In some cases, these embedded functions can be customized because they include SELOGIC control equations as inputs. The outputs of these functions and equations are generally made available as Relay Word bits. Each function and equation is discussed in the appropriate protection, control, and monitoring section.

Custom functions may be constructed with SELOGIC control equations by using operands such as SELOGIC variables and embedded relay functions.

NOTE: All SELOGIC control equations must be set to NA, 0, 1, a single Relay Word bit, or a combination of Relay Word bits.

This section describes use of SELOGIC control equation programming to customize relay operation and automate substations. This section covers the following topics:

> ➤ SELOGIC control equation operands

> ➤ SELOGIC control equation operators

> ➤ SELOGIC control equation functions

SELOGIC Control Equation Capacity

SELOGIC control equation available capacity is a measure of remaining execution capacity and settings storage capacity. For maximum efficiency, use parentheses only when necessary and set unused equations to NA rather than 0 or 1.

Each SELOGIC control equation has a 15-operand maximum. Use a SELOGIC control equation variable (SV01–SV64) as an intermediate setting step if more operands are required.

Because the relay executes the logic at a deterministic interval, there is a limit to the amount of SELOGIC control equation programming that the relay can execute. Rather than limit parameters to guarantee that an application does not exceed the maximum processing requirements, the relay measures and calculates the available capacity when SELOGIC control equations are entered. The relay will not allow entry of programming that will cause the relay to be unable to complete all SELOGIC control equations each processing interval. The relay calculates capacities based on the total amount of SELOGIC control equation programming executed in Global, Group, Logic, and several other settings areas.

Use the **STATUS S** command to view available execution capacity and settings storage.

SELOGIC Control Equation Operands

Outputs from embedded relay functions are generally available for use as operands in SELOGIC control equations. Some analog values are available as operands as well. Use these operands to customize the operation of your SEL-651R-2 and use the SEL-651R-2 to automate substation operation. The operands available for use in SELOGIC control equations are summarized in *Table 7.1*.

Table 7.1   Summary of SELogic Control Equation Operands

Operand Type	Relay Word Bit Operands
Constants	0, 1
Inputs	Status Inputs, Optoisolated Inputs
Inputs	Local Bits (see *Section 11: Front-Panel Operations*)
Inputs	Remote Bits (see *Section 10: Communications*)
Inputs	Receive MIRRORED BITS (see *Appendix D: MIRRORED BITS Communications*)
Inputs	Virtual Bits (see *Appendix L: IEC 61850*)
Elements	Protection and Control Elements (see *Section 4: Protection Functions*)
Functions	Variables/Timers, Latch Bits, Counters
Outputs	Trip and Close Outputs, Contact Outputs
Outputs	Transmit MIRRORED BITS (see *Appendix D: MIRRORED BITS Communications*)
Analog	Received, Measured, or Calculated Analog Values

Relay Word Bits

Data within the relay are available for use in SELOGIC control equations. Relay Word bits include received digital values including optoisolated inputs, control bits, and remote bits. They also include calculated digital values such as SELOGIC control equation variables, SELOGIC control equation functions, and protection and control elements. *Appendix F: Relay Word Bits* contains a list of Relay Word bits available within the SEL-651R-2.

Analog Quantities

Analog quantities are analog values within the relay, including set, measured, and calculated values. *Table 7.2* contains a list of analog quantities available for SELOGIC expressions within the SEL-651R-2.

Table 7.2   Analog Quantities (Sheet 1 of 2)

NOTE: The analog quantities available for use in SELOGIC equations, as shown in Table 7.2, are a subset of the complete list of analog quantities shown in Table G.1.

Quantities	Description
PFA, PFB, PFC	Power factor magnitude; A-, B-, C-phase
PF3	Power factor, magnitude three-phase
LDPFA, LDPFB, LDPFC	Power factor leading = 1; A-, B-, C-phase
LDPF3	Power factor leading = 1; three-phase
IAHT, IBHT, ICHT	THD, Current, A-, B-, C-phase, magnitude
INHT	THD Current, neutral, magnitude
VAYHT, VBYHT, VCYHT	THD Voltage, A-, B-, C-phase-to-neutral, Y-terminals, magnitude

SELogic Control Equation Programming   7.3
SELogic Control Equation Operators

Table 7.2   Analog Quantities (Sheet 2 of 2)

Quantities	Description
OPSCTRA, OPSCTRB, OPSCTRC	Total number of internal and external trips, A-, B-, C-phase, count
WEARA, WEARB, WEARC	Breaker contact wear, A-, B-, C-phase, percentage
MAXWEAR	Breaker contact wear, greatest value of A-, B-, C-phase, percentage
VAZHT, VBZHT, VCZHT	THD Voltage, A-, B-, C-phase-to-neutral, Z-terminals, magnitude
YEAR	Year number (0000–9999)
DAYY	Day of Year number (1–366)
WEEK[a]	Week number (1–53)
DAYW	Day of Week number (1–7)
MINSM	Minutes since Midnight
SC01–SC16	SELOGIC counter 01 to 16 present value (see *Analog Comparators and Checks on page 7.6* for more information)
MV01–MV64	Math Variable 01 to 64
79SHA, 79SHB, 79SHC	Shot counter—A-, B-, C-phase
79SH3P	Shot counter—three-phase
TCCAPV	Trip/Close capacitor voltage magnitude

[a] Per ISO 8601, years starting on a Thursday and leap years that start on a Wednesday have 53 weeks.

NOTE: Because ISO 8601 is used to determine the week of the year quantity, WEEK, certain corner cases can occur. For example, Sunday, January 1st, 2017, will be reported as occurring in WEEK 53, while the YEAR will report 2017. This is the result of ISO 8601 defining Sunday as the last day of the week.

SELOGIC Control Equation Operators

Use the analog comparators to create a Boolean result from an analog value, and Boolean operators to combine values with a resulting Boolean value. Edge-trigger operators provide a pulse output. Combine the operators and operands to form statements that evaluate complex logic. *Table 7.3* contains a summary of operators available in the SEL-651R-2.

Operator Precedence

When you combine several operators and operands within a single expression, the SEL-651R-2 evaluates the operators from left to right starting with the highest precedence operators working down to the lowest precedence. If you write an equation with three AND operators, for example SV01 AND SV02 AND SV03, each AND will be evaluated individually from left to right. If you substitute NOT SV04 for SV03 in the previous example, resulting in SV01 AND SV02 AND NOT SV04, the relay evaluates the NOT operation of SV04 first and uses the result in subsequent evaluation of the expression. Operator precedence is shown in *Table 7.3*.

Table 7.3   Operator Precedence (Sheet 1 of 2)

Operator	Description
( )	Parenthesis
NOT	Boolean Complement
R_TRIG	Rising Edge Trigger
F_TRIG	Falling Edge Trigger

7.4 | SELOGIC Control Equation Programming
SELOGIC Control Equation Operators

Table 7.3   Operator Precedence (Sheet 2 of 2)

Operator	Description
<, >, <=, >=	Analog Comparison
=	Analog Equality Check
<>	Analog Inequality Check
AND	Boolean AND
OR	Boolean OR

Parentheses Operators

Use paired parentheses to control the execution order of operations in a SELOGIC control equation. Use as many as 14 nested sets of parentheses in each SELOGIC control equation. The relay calculates the result of the operation on the innermost pair of parentheses first and then uses this result with the remaining operations.

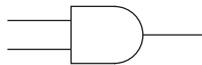
NOT Operator

Use the NOT operator to invert a Boolean value. Create a NOT function using the NOT operator. This function would be described mathematically by the equation $f(A) = NOT\ A$ and graphically by the following IEEE symbol:
AND Operator

Use AND to combine two Boolean values according to the truth table shown in *Table 7.4*.

Table 7.4   AND Operator Truth Table

Value A	Value B	A AND B
0	0	0
0	1	0
1	0	0
1	1	1

Create an AND function using the AND operator. This function would be described mathematically by the equation $f(A,B) = A\ AND\ B$ and graphically by the following IEEE symbol:


OR Operator

Use OR to combine two Boolean values according to the truth table shown in *Table 7.5*.

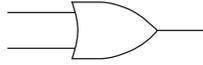
SELogic Control Equation Programming 7.5
SELogic Control Equation Operators

Create an OR function using the OR operator. This function would be described mathematically by the equation f(A,B) = A OR B and graphically by the following IEEE symbol:


R_TRIG Operator

R_TRIG is a time-based function that creates a pulse when a rising edge is detected, as shown in *Figure 7.1*. Use R_TRIG to sense when a value changes from logical 0 to logical 1 and take action only after the value changes state.

R_TRIG applies to individual Relay Word bits only, not to groups of elements within parentheses. For example, the SELOGIC control equation event report generation setting uses several rising-edge operators:

ER := **R_TRIG 51P OR R_TRIG 51G1 OR R_TRIG OUT103**

When a logical 0 to logical 1 transition of ER is detected, the SEL-651R-2 generates an event report (if the relay is not already generating a report that encompasses the new transition). The rising-edge operators in the ER equation enable detection of each individual transition.

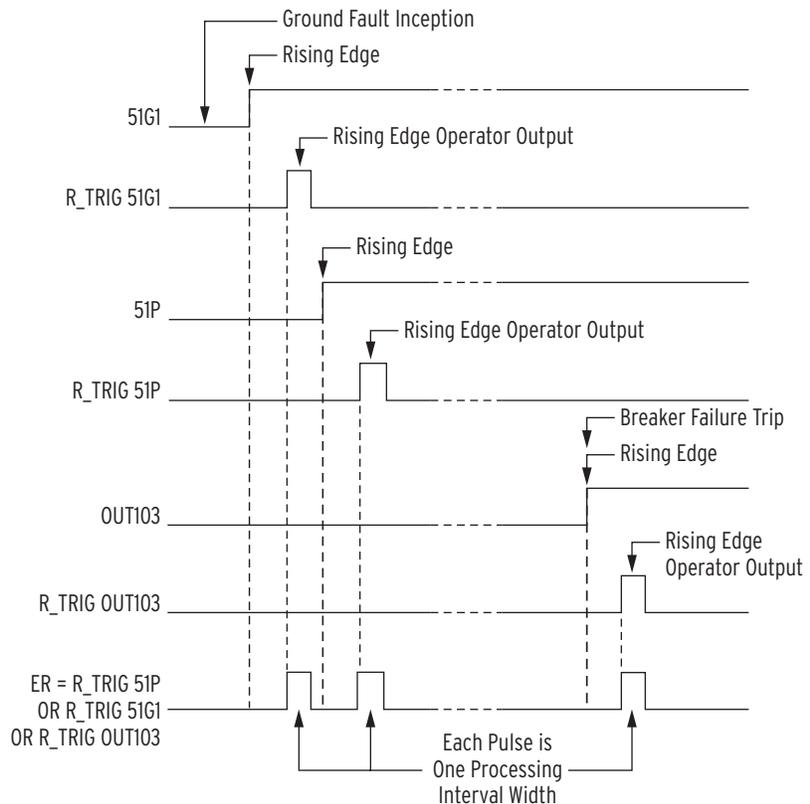
Suppose a ground fault occurs and a breaker failure condition finally results. *Figure 7.1* demonstrates the action of the rising-edge operator R_TRIG on the individual elements in setting ER.


Figure 7.1   Rising Edge Operator Example

Note in *Figure 7.1* that setting ER detects three separate rising edges, because of the application of rising-edge operators R_TRIG. The rising edge operator R_TRIG in front of a Relay Word bit detects this logical 0 to logical 1 transition as a rising edge and as a result asserts to logical 1 for one processing interval. The assertions of 51G1 and 51P are close enough that they will be on

Wolfe

the same event report (generated by 51G1 asserting first). The assertion of OUT103 for a breaker failure condition is some appreciable time later and will generate another event report, if the first event report capture has ended when OUT103 asserts.

If the rising-edge operators R_TRIG were not applied and setting ER was:

ER := **51P OR 51G1 OR OUT103**

the ER setting would not detect the assertion of OUT103, because 51G1 and 51P would continue to be asserted at logical 1.

F_TRIG Operator

F_TRIG is a time-based function that creates a pulse when a falling edge is detected, as shown in *Figure 7.2*. Use F_TRIG to sense when a value changes from logical 1 to logical 0 and take action only after the value changes state.

The argument of an F_TRIG statement must be a single Relay Word bit within the SEL-651R-2. An example of the relay detecting a falling edge of a calculated quantity is shown in *Figure 7.2*.

For example, suppose the SELOGIC control equation event report generation setting is set with the detection of the falling edge of an underfrequency element:

ER := **... OR F_TRIG 81D1T**

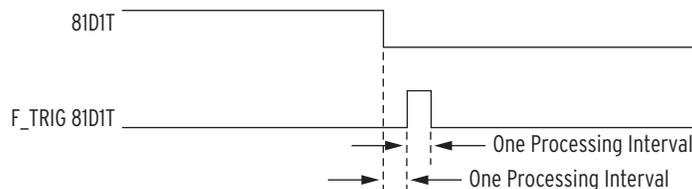
When frequency goes above the corresponding pickup level 81D1P, Relay Word bit 81D1T deasserts and an event report is generated (if the relay is not already generating a report that encompasses the new transition). This allows a recovery from an underfrequency condition to be observed. *Figure 7.2* demonstrates the action of the falling edge operator F_TRIG on the underfrequency element in setting ER.


Figure 7.2   Falling Edge Operator Example

Analog Comparators and Checks

The <, >, <=, => comparator operators are generally used to determine states to drive a sequence of actions. Use the = check operator to check whether an integer value is equal to another integer value. Do not use the = check operator for noninteger values, because it is unlikely that they will ever be equal.

Math variables (MV01–MV64) provide storage locations for constants that may be used in analog comparisons. The values in these storage locations may be changed but the SEL-651R-2 does not support mathematical operands and functions on these or any other analog value. See *Figure 6.12* for an example of how a mathematical variable can be used.

Use the analog comparators to create your own schemes. For example, monitor the current (IA, IB, IC) harmonics on your system by creating a THD (total harmonic distortion) SCADA system alarm that you may use to initiate the retrieval of harmonic meter data. The following equation is an example of how to implement this alarm.

SV33 : = **(IAHT >= 5) OR (IBHT >= 5) OR (ICHT >= 5)**

SELOGIC Control Equation Programming 7.7
SELOGIC Control Equation Functions

Comments

The pound symbol (#) is used as a comment operator. All characters entered after the # will be treated as text instead of logic.

SELOGIC control equation comments are very powerful tools for documenting and clarifying programming. Even programming that is well understood during installation and commissioning should have comments to help with any modifications needed later. These comments are stored in the SEL-651R-2.

SELOGIC Control Equation Functions

Variables/Timers

The SEL-651R-2 has sixty-four (64) SELOGIC control equation variables/timers. Each SELOGIC control equation variable/timer has a SELOGIC control equation setting input and variable/timer outputs as shown in *Figure 7.3*.

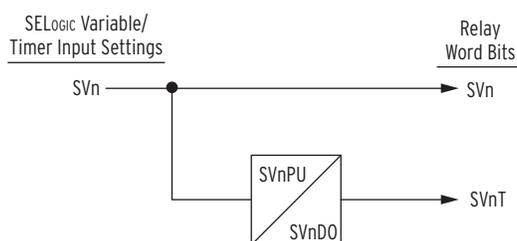
These timers have pickup and dropout time settings (SVnPU and SVnDO, n = 01 through 64).


Figure 7.3   SELOGIC Control Equation Variables/Timers

If power to the SEL-651R-2 is lost, settings are changed for the active settings group, or the active settings group is changed, the SELOGIC control equation variables/timers are reset. Relay Word bits SVn and SVnT (n = 01–64) are reset to logical 0 and corresponding timer settings SVnPU and SVnDO are reloaded after power restoration, settings change, or active settings group switch.

Example 1

In the SELOGIC control equation settings, a SELOGIC control equation timer can be used for a simple breaker failure scheme:

SV02 := **TRIP3P**

The TRIP3P Relay Word bit is run through a timer for breaker failure timing. Timer pickup setting SV02PU is set to the breaker failure time (SV02PU := 12.00 cycles). Timer dropout setting SV02DO is set for a 2-cycle dropout (SV02DO := 2.00 cycles). The output of the timer (Relay Word bit SV02T) operates output contact OUT103.

OUT103 := **SV02T**

Example 2

Another application idea is dedicated breaker failure protection (see *Figure 7.4*):

SV06 := **IN101** # breaker failure initiate

SV07 := **(SV07 OR IN101) AND (50P1 OR 50G1)**

7.8 │ SELOGIC Control Equation Programming
SELOGIC Control Equation Functions

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 358 of 1080
Wolfe

OUT101 := **SV06T** # retrip

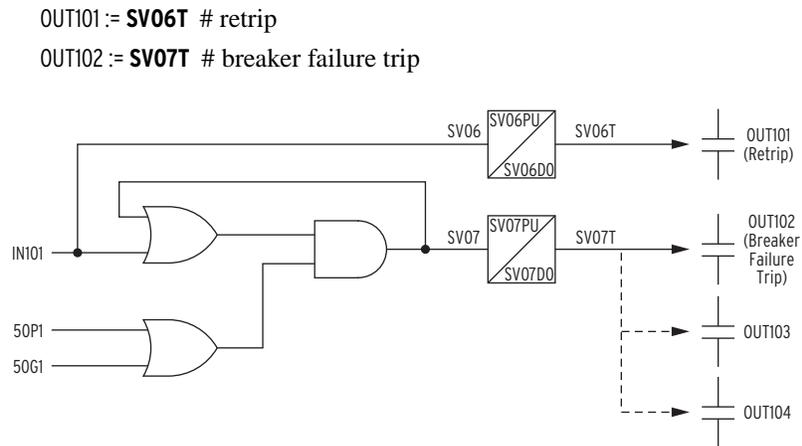
OUT102 := **SV07T** # breaker failure trip


Figure 7.4   Dedicated Breaker Failure Scheme Created With SELOGIC Control Equation Variables/Timers

Note that the above SELOGIC control equation setting SV07 creates a seal-in logic circuit (as shown in *Figure 7.4*) by virtue of SELOGIC control equation setting SV07 being set equal to Relay Word bit SV07 (SELOGIC control equation variable SV07):

SV07 := **(SV07 OR IN101) AND (50P1 OR 50G1)**

Optoisolated input IN101 functions as a breaker failure initiate input. Phase instantaneous overcurrent element 50P1 and ground instantaneous overcurrent element 50G1 function as fault detectors.

Timer pickup setting SV06PU provides retrip delay, if desired, but can also be set to zero. Timer dropout setting SV06DO holds the retrip output (output contact OUT101) closed for extra time, if needed, after the breaker failure initiate signal (IN101) deasserts.

Timer pickup setting SV07PU provides breaker failure timing. Timer dropout setting SV07DO holds the breaker failure trip output (output contact OUT102) closed for extra time, if needed, after the breaker failure logic unlatches (fault detectors 50P1 and 50G1 dropout).

Note that *Figure 7.4* suggests the option of having output contacts OUT103 and OUT104 operate as additional breaker failure trip outputs. To do this make the following SELOGIC control equation settings:

OUT103 := **SV07T** # breaker failure trip

OUT104 := **SV07T** # breaker failure trip

Example 3

The seal-in logic circuit in the dedicated breaker failure scheme in *Figure 7.4* can be removed by changing the SELOGIC control equation setting SV07 to:

SV07 := **IN101 AND (50P1 OR 50G1)**

If the seal-in logic circuit is removed, optoisolated input IN101 (breaker failure initiate) has to be continually asserted for a breaker failure time-out.

SELogic Control Equation Programming 7.9
SELogic Control Equation Functions

Timer Reset Conditions

The SELOGIC control equation variables/timers are reset to logical 0 if any of the following occur: power to the relay is lost, settings are changed for the active settings group, or the active settings group is changed. When Relay Word bits SVn and SVnT (n = 01–64) are reset to logical 0, corresponding timer settings SVnPU and SVnDO load up again.

Preceding *Figure 7.4* shows an effective seal-in logic circuit, created by use of Relay Word bit SV07 (SELOGIC control equation variable SV07) in SELOGIC control equation SV07:

SV07 := **(SV07 OR IN101) AND (50P1 OR 50G1)**

The seal-in logic circuit is broken by Relay Word bit SV07 being reset to logical 0 if any of the following occur: power to the relay is lost, settings are changed for the active settings group, or the active settings group is changed. Relay Word bit SV07T is also reset to logical 0 and timer settings SV07PU and SV07DO load up again. The inputs into this logic (IN101, 50P1, and 50G1) are then re-evaluated.

Latch Bits

Latch control switches (Latch Bits are the outputs of these switches) replace traditional latching relays. Traditional latching relays maintain their output contact state. The SEL-651R-2 latch control switches retain their state even when power to the relay is lost. If the latch control switch is set to a programmable output contact and power to the relay is lost, the state of the latch control switch is stored in nonvolatile memory, but the output contact will go to its de-energized state. When power to the relay is restored, the programmable output contact will go back to the state of the latch control switch after relay initialization.

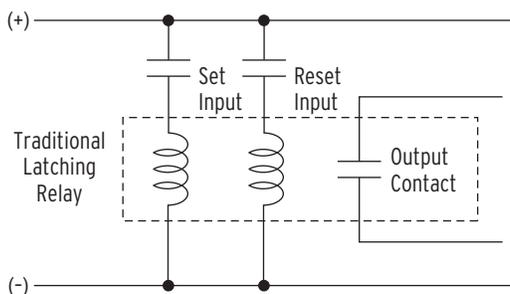
Traditional latching relay output contact states are changed by pulsing the latching relay inputs (see *Figure 7.5*). Pulse the set input to close (set) the latching relay output contact. Pulse the reset input to open (reset) the latching relay output contact. Often the external contacts wired to the latching relay inputs are from remote control equipment (e.g., SCADA, RTU).


Figure 7.5   Traditional Latching Relay

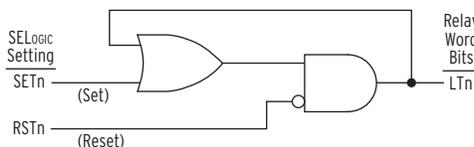
Thirty-two latch control switches in the SEL-651R-2 provide latching relay functionality (see *Latch Bits Set/Reset SELOGIC Equations on page SET.38*).


Figure 7.6   Latch Control Switches Drive Latch Bits LT01 Through LT032

7.10 SELᴏɢɪᴄ Control Equation Programming
SELᴏɢɪᴄ Control Equation Functions

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 360 of 1080
Wolfe

The output of the latch control switch in *Figure 7.6* is a Relay Word bit LT*n* (*n* = 01–32), called a latch bit. The latch control switch logic in *Figure 7.6* repeats for each latch bit LT01–LT32. Use these latch bits in SELᴏɢɪᴄ control equations.

These latch control switches each have the following SELᴏɢɪᴄ control equation settings:

SET*n* (set latch bit LT*n* to logical 1)

RST*n* (reset latch bit LT*n* to logical 0)

If setting SET*n* asserts to logical 1, latch bit LT*n* asserts to logical 1. If setting RST*n* asserts to logical 1, latch bit LT*n* deasserts to logical 0. If both settings SET*n* and RST*n* assert to logical 1, setting RST*n* has priority and latch bit LT*n* deasserts to logical 0.

Latch Bits: Application Ideas

Latch control switches can be used for such applications as:

➤ Reclosing relay enable/disable

➤ Ground relay enable/disable

➤ Sequence coordination enable/disable

Latch control switches can be applied to almost any control scheme. The following is an example of using a latch control switch to enable/disable the reclosing relay in the SEL-651R-2.

Example: Reclosing Relay Enable/Disable Setting

Use a latch control switch to enable/disable the reclosing relay in the SEL-651R-2. In this example, a SCADA contact is connected to optoisolated input IN104 as shown in *Figure 7.7*. Use a Remote Bit or Local Bit instead of an input if your application warrants it.

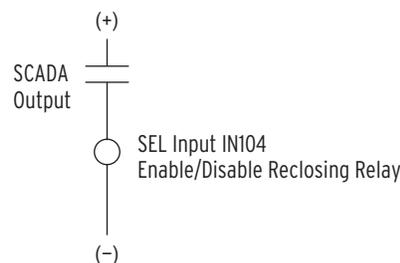
If the reclosing relay is enabled and the SCADA contact is pulsed, the reclosing relay is then disabled. If the SCADA contact is pulsed again, the reclosing relay is enabled again. Each pulse of the SCADA contact changes the state of the reclosing relay. The control operates in a cyclic manner. The SCADA contact is not maintained, just pulsed to enable/disable the reclosing relay.


Figure 7.7 SCADA Contact Pulses Input IN104 to Enable/Disable Reclosing Relay

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 361 of 1080
Wolfe
SELogic Control Equation Programming 7.11
SELogic Control Equation Functions

This reclosing relay logic is implemented in the following SELOGIC control equation settings and is displayed in *Figure 7.8*. Note that the figure includes an extra timer that is not included in the settings. This timer will be used in the next example. *Figure 7.9* shows the timing for this example.

SET01 := **(R_TRIG IN104) AND (NOT LT01)**

RST01 := **(R_TRIG IN104) AND LT01**

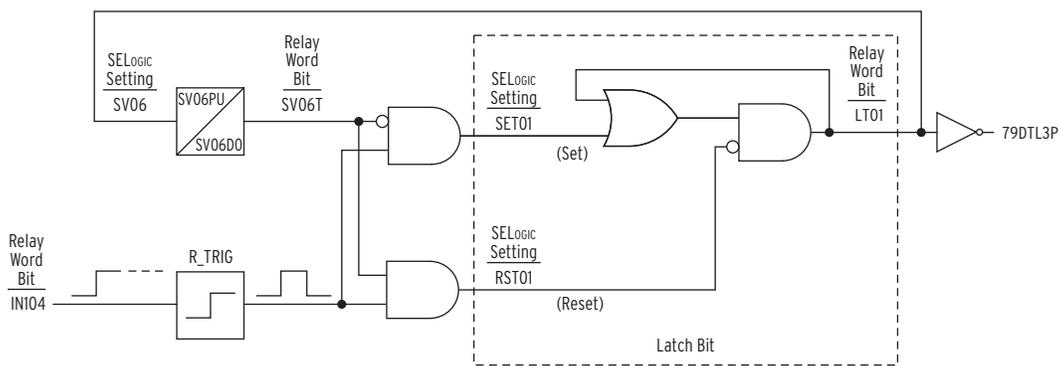
79DTL3P := **NOT LT01**


Figure 7.8   Single Input to Enable/Disable Reclosing
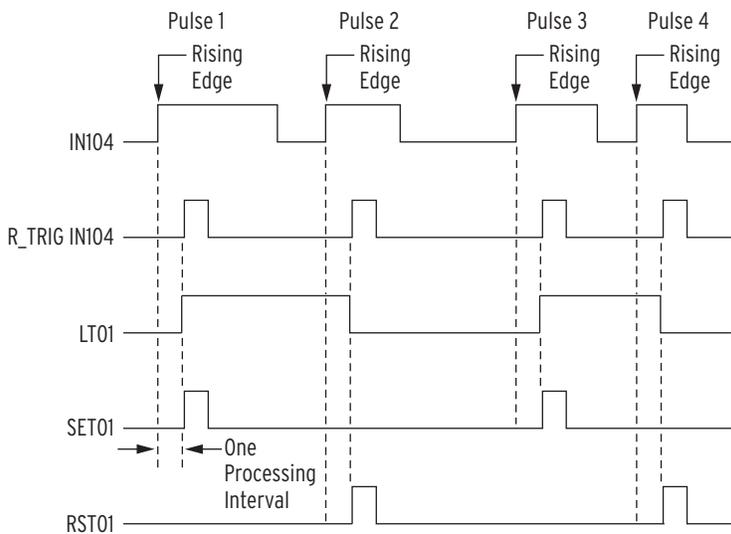

Figure 7.9   Latch Control Switch Operation Time Line

A variation of the previous example adds more security by adding a timer with equal pickup/dropout times as shown in *Figure 7.8*. Suppose that SV06PU and SV06DO are both set to 300 cycles. Then the SV06T timer keeps the state of latch bit LT01 from being able to be changed at a rate faster than once every 300 cycles (5 seconds). *Figure 7.10* shows the timing for this example.

SV06 := **LT01**

SET01 := **(R_TRIG IN104) AND (NOT SV06T)**

RST01 := **(R_TRIG IN104) AND SV06T**

79DTL3P := **NOT LT01**

Note that in *Figure 7.8* the latch control switch output (latch bit LT01) uses feedback for SELOGIC control equation settings SET01 and RST01. The feedback of latch bit LT01 determines whether input IN104 operates the

Page 362 of 1080
Wolfe

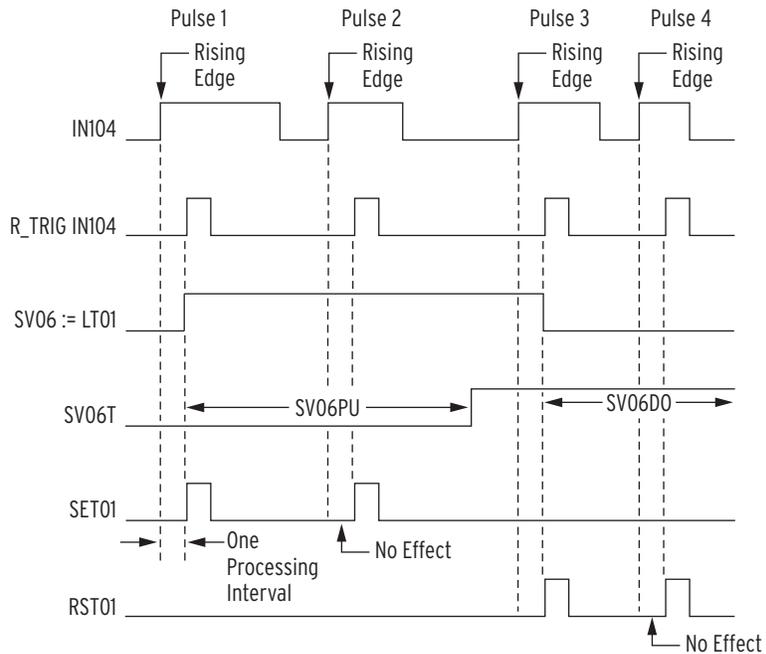
SET01 or RST01 input. If latch bit LT01 = logical 0, input IN104 operates SET01 (set latch bit LT01). If latch bit LT0 = logical 1, input IN104 operates RST01 (reset latch bit LT01).


Figure 7.10   Latch Control Switch (With Time-Delay Feedback) Operation Time Line

Latch Bits: Nonvolatile State

Power Loss

The states of the latch bits (LT01–LT32) are retained if power to the relay is lost and then restored. If a latch bit is asserted (e.g., LT02 = logical 1) when power is lost, it is asserted (LT02 = logical 1) when power is restored. If a latch bit is deasserted (e.g., LT03 = logical 0) when power is lost, it is deasserted (LT03 = logical 0) when power is restored. This feature makes the latch bit feature behave the same as traditional latching relays. In a traditional installation, if power is lost to the panel, the latching relay output contact position remains unchanged.

Note: If a latch bit is set to a programmable output contact, such as OUT103 := LT02, and power to the relay is lost, the state of the latch bit is stored in nonvolatile memory but the output contact will go to its de-energized state. When power to the relay is restored, the programmable output contact will go back to the state of the latch bit after relay initialization.

Settings Change or Active Settings Group Change

If individual settings are changed (for the active settings group or one of the other settings groups) or the active settings group is changed, the states of the latch bits (Relay Word bits LT01–LT32) are retained, much like in the preceding *Power Loss* explanation.

If individual settings are changed for a settings group other than the active settings group, there is no interruption of the latch bits (the relay is not momentarily disabled).

Enable Setting ELAT and Its Effect on Latch Bit Settings and Outputs

Presume ELAT := 2 and latch bit LT02 is asserted to logical 1 (because of the normal operation of corresponding settings SET02 and RST02). If ELAT is then changed to ELAT := 1, or N (settings SET02 and RST02 are no longer available for setting and are internally set: SET02 := NA, RST02 := NA), then latch bit LT02 retains the state it had before the settings change (LT02 remains asserted to logical 1). If ELAT is next changed back to ELAT := 2 (settings SET02 and RST02 are available again, but come forth set: SET02 := NA, RST02 := NA), then latch bit LT02 still retains the state it had before the settings change (LT02 remains asserted to logical 1). If settings SET02 and RST02 are then changed, latch bit LT02 can then change state, because of the normal operation of these corresponding settings.

Make Latch Control Switch Settings With Care

The latch bit states are stored in nonvolatile memory so they can be retained during power loss, settings change, or active settings group change. The nonvolatile memory is rated for a finite number of writes for all cumulative latch bit state changes. Exceeding the limit can result in a FLASH self-test failure. **An average of 70 cumulative latch bit state changes per day can be made for a 25-year relay service life**.

This requires that SELOGIC control equation settings SETn and RSTn for any given latch bit LTn (n = 01–32) be set with care. Settings SETn and RSTn must not result in continuous cyclical operation of latch bit LTn. Use timers to qualify conditions set in settings SETn and RSTn. If any optoisolated inputs IN101–IN107 are used in settings SETn and RSTn, the inputs have their own debounce timer that can help in providing the necessary time qualification.

In the preceding reclosing relay enable/disable example application (see *Figure 7.7*), the SCADA contact cannot be asserted/deasserted continuously, which would cause latch bit LT01 to change state continuously. Note that the rising-edge operators in the SET01 and RST01 settings keep latch bit LT01 from cyclically operating for any single assertion of the SCADA contact.

Counters

SELOGIC control equation counters are up- or down-counting elements. These counters conform to the standard counter function block in IEC 1131-3 First Edition 1993-03 International Standard for Programmable Controllers—Part 3: Programming Languages, as shown by the symbol in *Figure 7.11*.

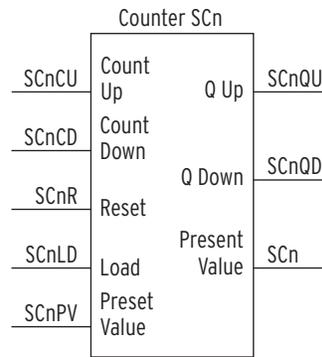
Wolfe


Figure 7.11   Up/Down Counters

Table 7.6 describes the Boolean input settings, counter value setting, and Boolean outputs of the counters. Sixteen counters are available, $n = 01$–16. See *SEL<small>OGIC</small> Counter Settings on page SET.47*.

Table 7.6   Counter Inputs and Outputs

Name	Type	Description
SCnLD	Active High Input	Load counter with the preset value (follows SELOGIC setting)
SCnPV	Input Value	This Preset Value is loaded when SCnLD pulsed. This Preset Value is used as a maximum count in the SCnQU comparison (follows SELOGIC setting)
SCnCU	Rising-Edge Input	Count Up increments the counter (follows SELOGIC setting)
SCnCD	Rising-Edge Input	Count Down decrements the counter (follows SELOGIC setting). The counter freezes if set to NA. See **NOTE** under *SELOGIC Counter Settings on page SET.47*.
SCnR	Active High Input	Reset counter to zero (follows SELOGIC setting).
SCnQU	Active High Output	This Q Up output asserts when the Preset Value (maximum count) is reached (SCn = SCnPV, $n = 01$ to 16).
SCnQD	Active High Output	This Q Down output asserts when the counter is equal to zero (SC$n = 0$, $n = 01$ to 16).
SCn	Output Value	This counter output is an analog value that may be used with analog comparison operators in a SELOGIC control equation, or viewed with the **COUNTER** command.

Viewing Counters

The serial port command **COUNTER** displays the present value of SC01–SC16 (see *COUNTER Command (View SEL<small>OGIC</small> Counters) on page 10.46*).

Counters: Application Ideas

Counters can be used for such applications as:

➤ Keeping track of a tap-changer position

➤ Switching and cycling of a capacitor bank

➤ Peak shaving with control of on-site generation

SELogic Control Equation Programming 7.15
SELogic Control Equation Functions

Examples

Example 7.1 illustrates how to use the SELOGIC control equation counters to limit the demand by starting an on-site 60 Hz diesel generator.

EXAMPLE 7.1

When the three-phase demand is greater than 100 kW for greater than 10 minutes, the diesel generator should start to pick up load. The generator should be started in 5 minutes when demand is greater than 125 kW. Also, if the demand is greater than 150 kW, the diesel generator should start immediately.

Figure 7.12 shows the logic required to create the 10-second periodic waveforms R_TRIG SV10 and F_TRIG SV10 shown in Figure 7.13. One periodic waveform is used to increment a counter when the three-phase power is above the 3PWR1 power element pickup (3PWR1P set equivalent to 100 kW primary) and both periodic waveforms are used when the three-phase power is above the 3PWR2 power element pickup (3PWR2P set equivalent to 125 kW primary). The R_TRIG SV10 waveform is used to decrement the counter when the three-phase power is below both thresholds.

SELOGIC Control Equation Functions

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 366 of 1080
Wolfe

Make the following settings to implement this function:

SV10PU := **300.00**

SV10DO := **300.00**

SV10 := **NOT SV10T** 10 second period

ESC := **1** enable one counter

ESV := **10** enable ten (or more) timers

SC01PV := **60** maximum counter value

SC01R := **IN101** disable the starting of the generator if desired (reset counter to zero)

SC01LD := **IN102 OR 3PWR3** start the generator immediately (set counter to maximum value; 3PWR3 asserts at the equivalent of 150 kW primary)

SC01CU := **R_TRIG SV01 AND 3PWR1 OR F_TRIG SV01 AND 3PWR2** increment counter SC01, faster when the demand is higher than 125 kW (3PWR1 asserts at the equivalent of 100 kW primary; 3PWR2 asserts at the equivalent of 125 kW primary)

SC01CD := **R_TRIG SV01 AND NOT 3PWR1** decrement counter SC01 when the demand is below 100 kW

OUT102 := **(SC01 > 48)** warning that diesel generator is about to start

OUT101 := **SC01QU** start generator signal

Settings for three-phase power elements 3PWR1, 3PWR2, and 3PWR3 are found in Table 4.21.

Because demands are slow-changing values, it does not make sense to check them continuously. The ten-second period makes the SV10T preset value setting easier to determine.

$$\text{Preset Value} = \frac{10 \text{ minutes} \cdot 60 \text{ s/minute}}{10 \text{ s/count}} = 60 \text{ counts}$$

Figure 7.14 is provided as a reference to this example.

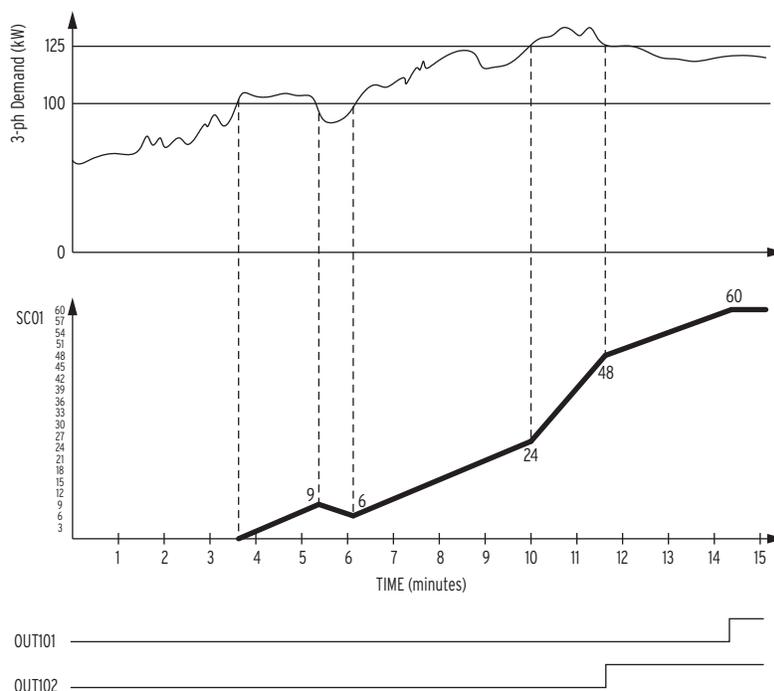

Figure 7.14   SELogic Control Equation Counter Example

Example 7.2 illustrates how to use SELOGIC timers and counters to pulse LEDs and lock pushbuttons.

EXAMPLE 7.2

Figure 7.15 shows the logic required to pulse the LED and lock the pushbuttons. Timing is shown in Figure 7.16. Pushbutton 6, labeled **PUSHBUTTONS LOCKED**, is used to lock the enable/disable selection state of pushbuttons 1, 2, 3, 5, 7, 8, 9, and 10. If pushbutton 6 is pressed and held, pushbutton 6 LED will flash two (2) times and remain illuminated on the third flash. The designated pushbuttons are now locked in the last state selected. If pushbutton 6 is pressed and held a second time, the pushbutton LED will flash on two (2) times, then remain off. The designated pushbuttons are now unlocked and each can be toggled between enable/disable.

Timer SV01 is used to generate an output pulse of 30 cycles on and 30 cycles off. The on-pulse illuminates the pushbutton 6 LED and increments the counter by one. The counter has a maximum range of three. The counter limits LED illumination to two flashes and a third illumination remaining on for lock conditions and two flashes, then remaining off for unlock conditions.

See partial logic and settings from relay default settings to clarify the example.

Counters: Volatile State and Disabled Behavior

Power Loss

SELOGIC counters SC01–SC16 are reset to a count value of zero after power
to the SEL-651R-2 control module is lost and then restored. The counter
output Relay Word bits behave as explained below for enabled and disabled
counters.

Settings Change or Active Group Change

SELOGIC counters SC01–SC16 are retained through settings changes and
active group changes.

Enabled and Disabled Counters

If a settings change or group change results in a different number of enabled
counters (logic enable setting ESC changes), the counters behave as follows:

➤ newly enabled counters (or enabled counters after power is
   restored) start at a count value of zero, with output
   SCnnQD = logical 1 and SCnnQU = logical 0

➤ disabled counters are set to zero, with both outputs SCmmQD
   and SCmmQU forced to logical 0

Recloser Status Inputs

Six recloser status inputs are provided for recloser control operations (see
Recloser Interface Connection Details (Control Cable Interface) on page 2.59
for the various configurations). These status inputs are rated for nominal

12 Vdc and are not optically isolated. Make use of these inputs by using their Relay Word bits IN201–IN206 in SELOGIC control equations (see ratings in *Specifications on page 1.9*).

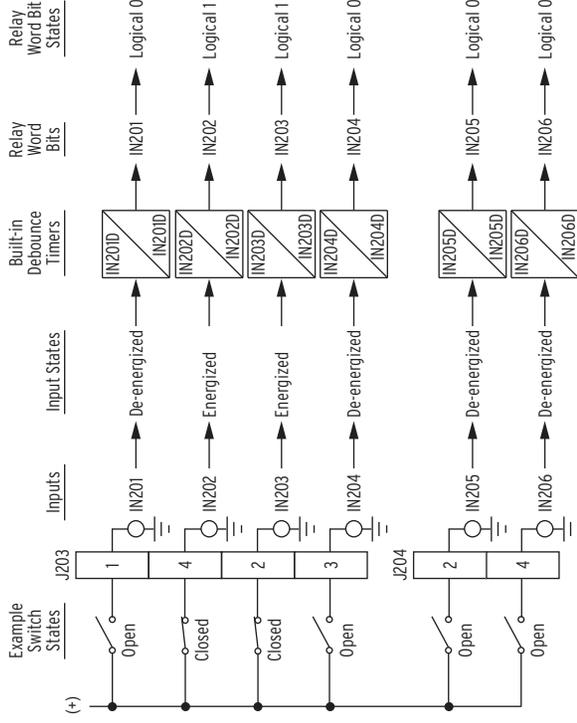
Figure 7.17 is used for the following discussion/examples and shows the resultant Relay Word bits (Relay Word bits IN201–IN206) that follow corresponding timers. The figure shows examples of energized and de-energized inputs and corresponding Relay Word bit states. Assert an input by applying rated control voltage to the appropriate connector pin.


Figure 7.17   Example Operation of Recloser Status Inputs

Each input has a dedicated pickup/dropout timer (IN201D–IN206D) that is used to help eliminate unnecessary transitions caused by bouncing contacts. In Global settings, set EICIS := Y to enable modification of these settings. Default time is 0.75 cycles, except for G&W Viper-ST, Tavrida OSM A1_2, Multi-Recloser Interface, and Siemens SDR (1.5 cycles). The pickup/dropout timers IN201D–IN206D have a setting range of 0.00–2.00 cycles.

The relay takes the entered timer setting and internally runs the timer at the nearest 1/16-cycle. For example, if setting IN205D = 0.80, internally the timer runs at the nearest 1/16-cycle: 13/16-cycles (13/16 = 0.8125). The relay processing interval is 1/4-cycle, so Relay Word bits IN201–IN206 are updated every 1/4-cycle.

For most applications, the input pickup/dropout debounce timers should be set in 1/4-cycle increments. For example, in the factory-default settings, all the input pickup/dropout debounce timers are set at 0.75-cycle, such as IN204D := 0.75.

If more than 2 cycles of debounce are needed, run Relay Word bit IN20*n* (*n* = 1–6) through a SELOGIC variable timer (see *Figure 7.3*) and use the output of the timer for input functions.

Optoisolated Inputs

You can order optoisolated inputs IN101–IN107 as an option. These inputs are located on the main board of the SEL-651R-2 (see *Figure 2.5* and *Figure 2.9*). These inputs have debounce timers similar to those described in Recloser Status Inputs; the default time is 0.5 cycles, except for IN105–IN107 on the Multi-Recloser Interface (1.5 cycles).

You can order the optoisolated inputs with IN101 and IN102 pickups of 125 Vdc as an option. The 125 Vdc option includes debounce settings range value AC. The AC setting allows the input to sense ac control signals. When you use the AC setting, the input has a maximum pickup time of 0.75 cycles and a maximum dropout time of 1.25 cycles. The AC setting qualifies the input by not asserting until 2 successive 1/16-cycle samples are higher than the optoisolated input voltage threshold and not deasserting until 16 successive 1/16-cycle samples are lower than the optoisolated input voltage threshold.

Figure 7.18 shows the resultant Relay Word bits (Relay Word bits IN101–IN107) that follow corresponding timers.

NOTE: Optoisolated inputs are level-sensitive, meaning that they require more than one half of rated voltage to assert. Refer to Specifications on page 1.9 for proper ac and dc voltages required for secure and dependable input operation.

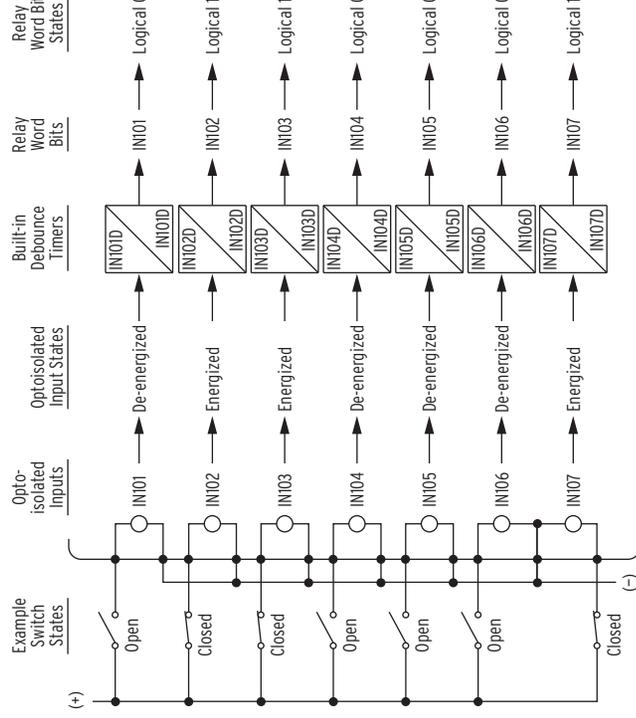
NOTE: Optoisolated inputs are not polarity-sensitive.


Figure 7.18   Example Operation of Optoisolated Inputs

Screw and torque information for optoisolated inputs IN101–IN107 is found in *Additional Relay Connections on page 2.50*.

Remote Bits

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 372 of 1080
Wolfe

Remote Bits

As many as 32 remote control switches are operated via the serial communications port only. They may be operated through use of any of the following:

➤ SEL ASCII command CONTROL as described in *Section 10: Communications*.

➤ Fast Operate commands as described in *Appendix C: Compressed ASCII Commands*.

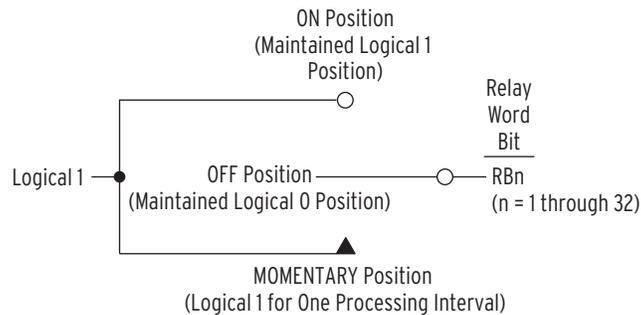
➤ DNP3 Objects 10 and 12 as described in *Appendix E: DNP3 Communications*.


Figure 7.19   ON/OFF/MOMENTARY Remote Control Switch

The output of the switch in *Figure 7.19* is a Relay Word bit (RB01–RB32) called a Remote Bit and repeats for each Remote Bit. Use these Remote Bits in SEL_{OGIC} control equations.

Remote Bit RBn may be in the ON (RBn = logical 1) position, in the OFF (RBn = logical 0) position, or maintained in the OFF (RBn = logical 0) position and pulsed to the MOMENTARY (RBn = logical 1) position for one processing interval (1/4 cycle).

The state of each remote bit (Relay Word bits RB01–RB32) is retained if relay settings are changed (for the active settings group or one of the other settings groups) or the active settings group is changed.

Remote Bits: Application Ideas

With SEL_{OGIC} control equations, the remote bits can be used in applications similar to those that use local bits.

Also, remote bits can be used much as optoisolated inputs are used in operating latch control switches. Pulse (momentarily operate) the remote bits for this application.

Remote Bits: Momentary Position

This subsection describes how the momentary position of the remote control switch operates via the SEL ASCII command **CONTROL**. It operates in the same manner when used with a Fast Operate or DNP3 pulse command.

Use the **CON n** command and **PRB n** subcommand to put the remote control switch in the momentary ON position for one processing interval, regardless of its initial state. The remote control switch is then placed in the OFF position.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 373 of 1080
Wolfe

SELogic Control Equation Programming 7.23
Multiple Settings Groups

If RB*n* is initially at logical 0, pulsing it with the **CON *n*** command and **PRB *n*** subcommand will change RB*n* to a logical 1 for one processing interval, and then return it to a logical 0. If RB*n* is initially at logical 1 instead, pulsing it with the **CON *x*** command and **PRB *x*** subcommand will change RB*n* to a logical 0.

Remote Bit: Volatile State

The states of the remote bits (Relay Word bits RB01–RB32) are not retained if power to the relay is lost and then restored. The remote control switches always come back in the OFF position (corresponding remote bit is deasserted to logical 0) when power is restored to the relay.

Multiple Settings Groups

The SEL-651R-2 has eight independent settings groups. Each settings group has complete relay (overcurrent, reclosing, frequency, etc.) and SELOGIC control equation settings. The active settings group can be:

➤ Shown or selected with the SEL ASCII serial port **GROUP** command as described in *Section 10: Communications*.

➤ Shown or selected with the MAIN menu Set/Show menu item and the Active Group submenu item as described in *Section 11: Front-Panel Operations*.

➤ Selected with SELOGIC control equation settings SS1–SS8. Settings SS1–SS8 have priority over the serial port **GROUP** command, the front-panel **ALT SETTINGS** pushbutton, and the DNP3 and Modbus controls in selecting the active settings group. Use remote bits in these equations to select settings groups with Fast Operate commands as described in *Appendix C: Compressed ASCII Commands*.

➤ Shown with DNP3 Objects 20 and 22 as described in *Appendix E: DNP3 Communications* and selected with Objects 40 and 41.

➤ Shown with Modbus function code 03h or 04h and selected with function code 06h or 10h as described in *Appendix K: Modbus RTU and TCP Communications*.

Settings Groups: Application Ideas

Settings groups can be used for such applications as:

➤ Sectionalizing, midpoint, and tie reclosers in energized and de-energized states

➤ Environmental conditions such as winter storms, periods of high summer heat, etc.

➤ Hot-line tag that disables closing and sensitizes protection

➤ Commissioning and operation

Active Settings Group Indication

Only one settings group can be active at a time. Relay Word bits SG1–SG8 indicate the active settings group, as shown in *Table 7.7*.

7.24 SELᴏɢɪᴄ Control Equation Programming
Multiple Settings Groups

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 374 of 1080
Wolfe

Table 7.7   Definitions for Active Settings Group Indication Relay Word Bits SG1 Through SG8

Relay Word Bit	Definition
SG1	Indication that Settings Group 1 is the active settings group
SG2	Indication that Settings Group 2 is the active settings group
SG3	Indication that Settings Group 3 is the active settings group
SG4	Indication that Settings Group 4 is the active settings group
SG5	Indication that Settings Group 5 is the active settings group
SG6	Indication that Settings Group 6 is the active settings group
SG7	Indication that Settings Group 7 is the active settings group
SG8	Indication that Settings Group 8 is the active settings group

For example, if Settings Group 4 is the active settings group, Relay Word bit SG4 asserts to logical 1 and the other associated Relay Word bits (SG1, SG2, SG3, SG5, SG6, SG7, and SG8) deassert to logical 0.

Active Settings Group Selection

The Global settings class contains the SELᴏɢɪᴄ control equation settings SS1–SS8, as shown in *Table 7.8*.

Table 7.8   Definitions for Active Settings Group Switching SELᴏɢɪᴄ Control Equation Settings SS1 Through SS8

Setting	Definition
SS1	go to (or remain in) Settings Group 1
SS2	go to (or remain in) Settings Group 2
SS3	go to (or remain in) Settings Group 3
SS4	go to (or remain in) Settings Group 4
SS5	go to (or remain in) Settings Group 5
SS6	go to (or remain in) Settings Group 6
SS7	go to (or remain in) Settings Group 7
SS8	go to (or remain in) Settings Group 8

The operation of these settings is explained with the following example:

Assume the active settings group starts out as Settings Group 3. Corresponding Relay Word bit SG3 is asserted to logical 1 as an indication that Settings Group 3 is the active settings group.

With Settings Group 3 as the active settings group, setting SS3 has priority. If setting SS3 is asserted to logical 1, Settings Group 3 remains the active settings group, regardless of the activity of settings SS1, SS2, SS4, SS5, SS6, SS7, and SS8. With settings SS1–SS8 all deasserted to logical 0, Settings Group 3 still remains the active settings group.

With Settings Group 3 as the active settings group, if setting SS3 is deasserted to logical 0 and one of the other settings (e.g., setting SS5) asserts to logical 1, the relay switches from Settings Group 3 as the active settings group to another settings group (e.g., Settings Group 5) as the active settings group, after qualifying time setting TGR:

TGR   Group Change   (settable from 0.00 to 16000.00 cycles)
            Delay Setting

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 375 of 1080
SELogic Control Equation Programming 7.25
Manage Settings Groups
Wolfe

In this example, TGR qualifies the assertion of setting SS5 before it can change the active settings group.

Active Settings Group Changes

The recloser control is disabled for less than 1 second while in the process of changing active settings groups. Relay elements, timers, and logic are reset, unless indicated otherwise in the specific logic description. For example, local bit (LB01–LB16), remote bit (RB01–RB32), and latch bit (LT01–LT32) states are retained during an active settings group change. The output contacts do not change state until the relay enables in the new settings group and the SELogic control equations are processed to determine the output contact status for the new group. For instance, if setting OUT105 := 1 (logical 1) in Group 2 and setting OUT105 := 1 (logical 1) in Group 3, and the relay is switched from Group 2 to Group 3, OUT105 stays energized before, during, and after the group change. However, if the Group 3 setting was OUT105 := 0 (logical 0) instead, then OUT105 remains energized until the relay enables in Group 3, solves the SELogic control equations, and causes OUT105 to de-energize. See *Figure 7.28* for examples of output contacts in the de-energized state (i.e., corresponding output contact coils de-energized).

Relay Word bit GRPSW will pulse for approximately 1 second when the active settings group is changed. Relay Word bit GRPSW is part of the default SALARM SELogic control equation setting (see *Global Settings on page SET.1*).

Example 1: Active Settings Group Switching

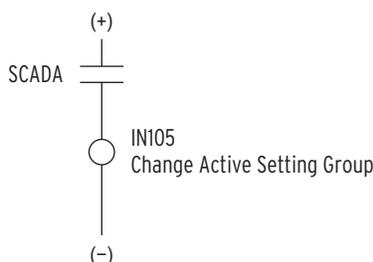
Use a single optoisolated input to switch between two settings groups in the SEL-651R-2. In this example, optoisolated input IN105 on the relay is connected to a SCADA contact in *Figure 7.20*. Each pulse of the SCADA contact changes the active settings group from one settings group, such as Settings Group 1, to another, such as Settings Group 4. The SCADA contact is not maintained, just pulsed to switch from one active settings group to another.


Figure 7.20   SCADA Contact Pulses Input IN105 to Switch Active Settings Group Between Settings Groups 1 and 4

If Settings Group 1 is the active Settings group and the SCADA contact is pulsed, Settings Group 4 becomes the active settings group. If the SCADA contact is pulsed again, Settings Group 1 becomes the active settings group again. The settings group control operates in a cyclical manner.

This logic is implemented in the SELogic control equation settings in *Table 7.9*.

Table 7.9   SELogic Control Equation Settings for Switching Active Settings Group Between Setting Groups 1 and 4 (Sheet 1 of 2)

Settings Group 1	Settings Group 4
SV08PU := 60.00	SV08PU := 60.00
SV08DO := 0.00	SV08DO := 0.00

SS3 := 0	
SS4 := IN105 AND SV08T AND NOT SG4	
SS5 := 0	
SS6 := 0	
SS7 := 0	
SS8 := 0	

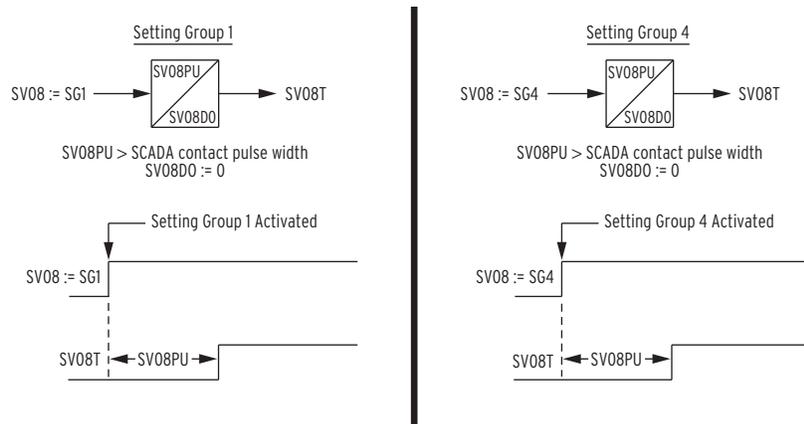
SELᴏɢɪᴄ control equation timer input setting SV08 in *Table 7.9* has logic output SV08T, shown in operation in *Figure 7.21* for both Settings Groups 1 and 4. The settings for SS1 and SS4 include expressions that steer the IN105 assertion to the appropriate setting. SS1 is only allowed to operate when the recloser control is not in Group 1, and SS4 is only allowed to operate when the recloser control is not in Group 4. These details are explained below *Figure 7.21*.


Figure 7.21   SELᴏɢɪᴄ Control Equation Variable Timer SV08T Used in Settings Group Switching

In this example, timer SV08T is used in both settings groups: different timers could have been used with the same operational result. The timers reset during the settings group change, allowing the same timer to be used in both settings groups.

Timer pickup setting SV08PU is set greater than the pulse width of the SCADA contact (see *Figure 7.20*). This allows only one active settings group change, such as from Settings Group 1 to 4, for each pulse of the SCADA contact and subsequent assertion of input IN105. The function of the SELᴏɢɪᴄ control equations in *Table 7.9* becomes more apparent in the following example scenario.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 377 of 1080
Wolfe

SELogic Control Equation Programming 7.27
Manage Settings Groups

Start Out in Settings Group 1

The recloser control has been in Settings Group 1 for some time, with timer logic output SV08T asserted to logical 1, thus enabling SELOGIC control equation setting SS4 for the assertion of input IN105. The inclusion of AND NOT SG1 in the setting for SS1 prevents SS1 from detecting the next IN105 assertion (see *Figure 7.22*).

Switch to Settings Group 4

The SCADA contact pulses input IN105, and the active settings group changes to Settings Group 4 after qualifying time setting TGR (perhaps set at a cycle or so to qualify the assertion of setting SS4). Optoisolated input IN105 also has its own built-in debounce timer (IN105D) available.

Note that *Figure 7.22* shows both Settings Group 1 and Settings Group 4 settings. The Settings Group 1 settings (near the top of *Figure 7.22*) are enabled only when Settings Group 1 is the active settings group and likewise for the Settings Group 4 settings near the bottom of the figure. The group selection settings, SS1 and SS4, are Global settings and are enabled in every settings group.

Settings Group 4 is now the active settings group, and Relay Word bit SG4 asserts to logical 1. After the relay has been in Settings Group 4 for a time period equal to SV08PU, the timer logic output SV08T asserts to logical 1, thus enabling SELOGIC control equation setting SS1 for a new assertion of input IN105. The inclusion of AND NOT SG4 in the setting for SS4 prevents SS4 from detecting the next IN105 assertion.

Note that input IN105 is still asserted because Settings Group 4 is activated. Pickup time SV08PU keeps the continued assertion of input IN105 from causing the active settings group to revert back again to Settings Group 1 for a single assertion of input IN105. This keeps the active settings group from being changed at a time interval less than time SV08PU.

Switch Back to Settings Group 1

The SCADA contact pulses input IN105 a second time, and the active settings group changes back to Settings Group 1 after qualifying time setting TGR, perhaps set at a cycle or so to qualify the assertion of setting SS1. Optoisolated input IN105 also has its own built-in debounce timer IN105D available. The timing is shown in *Figure 7.22*.

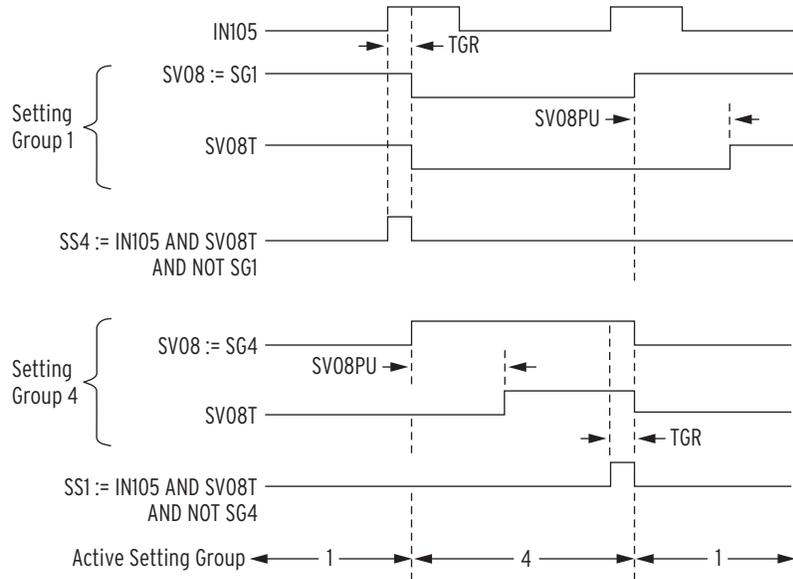
Page 378 of 1080
Wolfe


Figure 7.22 Active Settings Group Switching (With Single Input) Timing

Example 2: Active Settings Group Switching

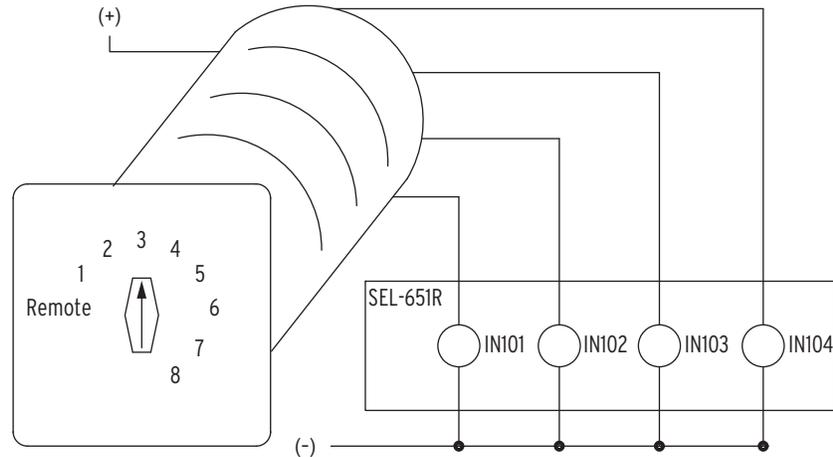
Use three optoisolated inputs to switch between the eight settings groups in the SEL-651R-2. In this example, optoisolated inputs IN101, IN102, IN103, and IN104 on the recloser control are connected to a rotating selector switch as shown in *Figure 7.23*.


Figure 7.23 Rotating Selector Switch Connected to Inputs IN1O1, IN1O2, IN1O3, and IN1O4 for Active Settings Group Switching

The selector switch has multiple internal contacts arranged to assert inputs IN101, IN102, IN103, and IN104, dependent on the switch position. As shown in *Table 7.10*, when the selector switch is moved from one position to another, a different settings group is activated. The logic is implemented in the SELogic control equation settings in *Table 7.10*.

Case No. 2018-00295

Page 379 of 1080
Wolfe
SELogic Control Equation Programming   7.29
Manage Settings Groups

Table 7.10 Active Settings Group Switching Input Logic

Input States				Active Settings Group	SELogic Settings
IN104	IN103	IN102	IN101		
0	0	0	0	Remote	
0	0	0	1	Group 1	SS1 := NOT IN104 AND NOT IN103 AND NOT IN102 AND IN101
0	0	1	0	Group 2	SS2 := NOT IN104 AND NOT IN103 AND IN102 AND NOT IN101
0	0	1	1	Group 3	SS3 := NOT IN104 AND NOT IN103 AND IN102 AND IN101
0	1	0	0	Group 4	SS4 := NOT IN104 AND IN103 AND NOT IN102 AND NOT IN101
0	1	0	1	Group 5	SS5 := NOT IN104 AND IN103 AND NOT IN102 AND IN101
0	1	1	0	Group 6	SS6 := NOT IN104 AND IN103 AND IN102 AND NOT IN101
0	1	1	1	Group 7	SS7 := NOT IN104 AND IN103 AND IN102 AND IN101
1	0	0	0	Group 8	SS8 := IN104 AND NOT IN103 AND NOT IN102 AND NOT IN101

The settings in *Table 7.10* are made in Global settings.

Selector Switch Starts Out in Position 3

If the selector switch is in position 3 in *Figure 7.23*, Settings Group 3 is the active settings group (Relay Word bit SG3 = logical 1). Inputs IN101 and IN102 are energized and inputs IN103 and IN104 are de-energized:

SS3 := **NOT IN104 AND NOT IN103 AND IN102 AND IN101**
  := **NOT (logical 0) AND NOT (logical 0) AND (logical 1) AND**
  (logical 1) = logical 1

To get from the position 3 to position 5 on the selector switch, the switch passes through the position 4. The switch is only briefly in position 4:

SS4 := **NOT IN104 AND IN103 AND NOT IN102 AND NOT IN101**
  := **NOT (logical 0) AND (logical 1) AND NOT (logical 0) AND NOT**
  (logical 0) = logical 1

but not long enough to be qualified by time setting TGR to change the active settings group to Settings Group 4 (see *Figure 7.24*). For such a rotating selector switch application, qualifying time setting TGR is typically set at 180 to 300 cycles. Set TGR long enough to allow the selector switch to pass through intermediate positions, without changing the active settings group, until the switch rests on the desired settings group position.

Selector Switch Switched to Position 5

If the selector switch rests on position 5 in *Figure 7.23*, Settings Group 5 becomes the active settings group (after qualifying time setting TGR; Relay Word bit SG5 = logical 1). Inputs IN101 and IN103 are energized and IN102 and IN104 are de-energized:

SS5 := **NOT IN104 AND IN103 AND NOT IN102 AND IN101**
  := **NOT (logical 0) AND NOT (logical 1) AND NOT (logical 0) AND**
  (logical 1) = logical 1

To get from position 5 to position REMOTE on the selector switch, the switch passes through the positions 4, 3, 2, and 1. The switch is only briefly in these positions, but not long enough to be qualified by time setting TGR to change the active settings group to any one of these settings groups (see *Figure 7.24*).

7.30 | SELogic Control Equation Programming
Multiple Settings Groups

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 380 of 1080
Wolfe

Selector Switch Now Rests on Position REMOTE

If the selector switch rests on position REMOTE in *Figure 7.23*, all inputs IN101, IN102, IN103, and IN104 are de-energized and all settings SS1–SS8 in *Table 7.10* are at logical 0. The last active settings group (Group 5 in this example) remains the active settings group (Relay Word bit SG5 = logical 1).

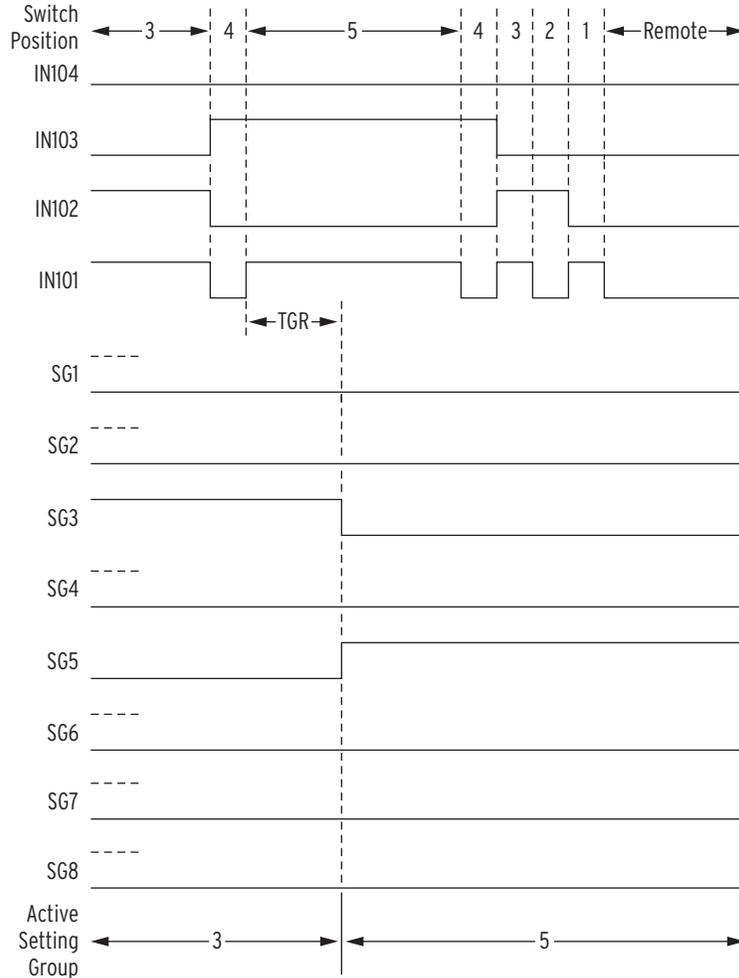
With settings SS1–SS8 all at logical 0, use the serial port **GROUP** command or the front-panel GROUP menu to switch the active settings group from Group 5, in this example, to another desired settings group. The timing is shown in *Figure 7.24*.


Figure 7.24   Active Settings Group Switching (With Rotating Selector Switch) Time Line

Active Setting: Nonvolatile State

Power Loss

The active settings group is retained if power to the relay is lost and then restored. If a particular settings group is active (e.g., Settings Group 5) when power is lost, the same settings group is active when power is restored.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 281 of 1080
SELogic Control Equation Programming 7.31
Trip and Close Mapping and Output Logic
Wolfe

Settings Change

If individual settings are changed for the active settings group or one of the other settings groups, the active settings group is retained, much like in the preceding explanation.

If individual settings are changed for a settings group other than the active settings group, there is no interruption of the active settings group, so the relay is not momentarily disabled.

If the individual settings change causes a change in one or more SELOGIC control equation settings SS1–SS8, the active settings group can be changed, subject to the newly enabled SS1–SS8 settings.

Make Active Settings Group Switching Settings With Care

The active settings group is stored in nonvolatile memory so it can be retained during power loss or settings change. The nonvolatile memory is rated for a finite number of writes for all settings group changes. Exceeding the limit can result in a FLASH self-test failure. **An average of four (4) settings group changes per day can be made for a 25-year relay service life**.

This requires that SELOGIC control equation settings SS1–SS8 be set with care. Settings SS1–SS8 must not result in continuous cyclical changing of the active settings group. Time setting TGR qualifies settings SS1–SS8 before changing the active settings group.

Trip and Close Mapping and Output Logic

Figure 7.25 and *Figure 7.26* contain the trip and close mapping and output logic that the SEL-651R-2 uses when connected to various reclosers (see *Section 2* figure references within *Figure 7.25* and *Figure 7.26* for the corresponding reclosers).

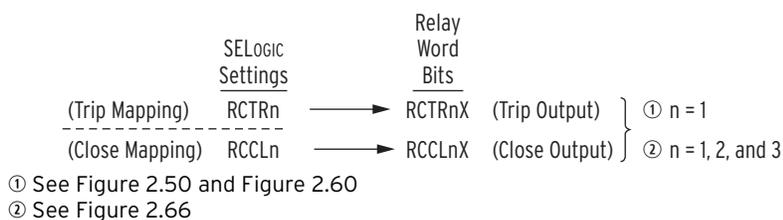
① See Figure 2.50 and Figure 2.60
② See Figure 2.66


Figure 7.25   Trip and Close Mapping and Output Logic

Note that in *Figure 7.26* there is a rising-edge detect on the RCCL*n* input into gate AND 2. This prevents standing close conditions.

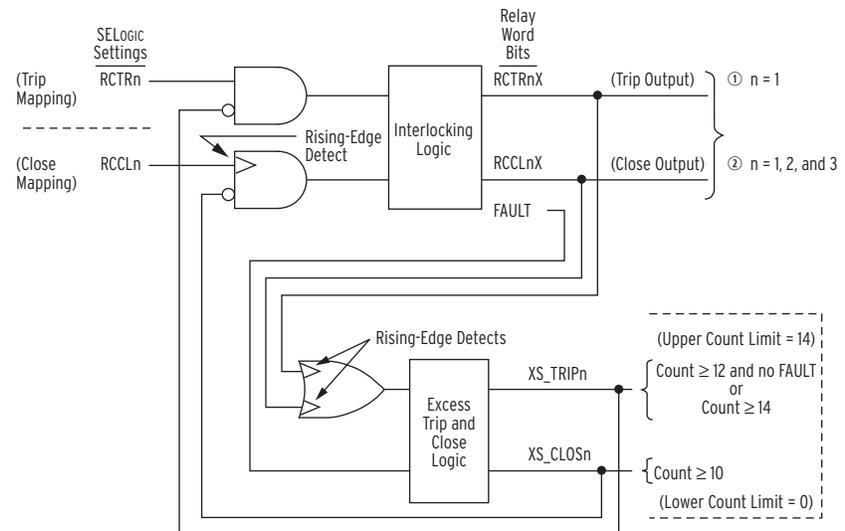
Page 382 of 1080
Wolfe


① See Figure 2.73.
② See Figure 2.53, Figure 2.56, Figure 2.63, Figure 2.69, Figure 2.72, and Figure 2.79.

Figure 7.26   Trip and Close Mapping and Output Logic With Interlocking Logic and Excess Trip and Close Logic

The term mapping in the preceding discussion refers to providing a transition between the A-B-C power system world outside the SEL-651R-2 and the A-B-C algorithm world inside the SEL-651R-2, as detailed in *Figure 9.26–Figure 9.28* and the accompanying text.

Factory Trip- and Close-Mapping Settings

The factory settings for the trip-mapping and close-mapping settings are as follows (see *Figure 5.1* and *Figure 6.1*):

RCTR1 := **TRIP3P OR TRIPA OR TRIPB OR TRIPC**

RCTR2 := **TRIP3P OR TRIPA OR TRIPB OR TRIPC**

RCTR3 := **TRIP3P OR TRIPA OR TRIPB OR TRIPC**

RCCL1 := **CLOSE3P**

RCCL2 := **CLOSE3P**

RCCL3 := **CLOSE3P**

As a conservative approach, all the trip logic outputs from *Figure 5.1* are entered in all preceding factory trip-mapping settings, ensuring three-phase tripping for all reclosers.

Making Three-Phase Recloser Trip- and Close-Mapping Settings

For three-phase reclosers (reclosers that can only trip and close all three phases in unison), the *Figure 5.1* Relay Word Bit outputs TRIPA, TRIPB, and TRIPC in the preceding factory trip-mapping setting RCTR1 are inoperative (Group setting ESPB := N). Thus, the recloser trip settings can be minimized to RCTRn := TRIP3P. The corresponding recloser close settings are already minimized to RCCLn := CLOSE3P.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 1383 of 1080
SELogic Control Equation Programming 7.33
Trip and Close Mapping and Output Logic
Wolfe

Making Single-Phase Recloser Trip- and Close-Mapping Settings

For single-phase reclosers (reclosers that can trip and close all three phases in unison or each phase individually), change the factory trip-mapping settings so that each setting is set to TRIPA, TRIPB, or TRIPC (refer to *Table 9.19*). For example:

RCTR1 := **TRIPA OR TRIP3P**

RCTR2 := **TRIPB OR TRIP3P**

RCTR3 := **TRIPC OR TRIP3P**

Such settings depend on correspondence with the power system, as detailed in *Figure 9.26–Figure 9.28* and accompanying text. Note that in *Figure 5.1* three-phase tripping (SELOGIC settings TR3P and TR3X) also flows through Relay Word Bit outputs TRIPA, TRIPB, and TRIPC.

In the preceding suggested trip settings example and in *Table 9.19*, the TRIP3P value is included in each trip-mapping setting, in case Group setting ESPB is changed between Y and N. As shown in *Figure 5.1*, changing Group setting ESPB changes the enabled Relay Word Bit outputs (switches between TRIP3P and TRIPA, TRIPB, TRIPC). If single-phase tripping is never used (Group setting ESPB:=N), the preceding suggested trip settings can all be minimized to TRIP3P only.

For single-phase reclosers, change the factory close-mapping settings so that each setting is set to CLOSEA, CLOSEB, or CLOSEC (refer to *Table 9.20*). For example:

RCCL1 := **CLOSEA OR CLOSE3P**

RCCL2 := **CLOSEB OR CLOSE3P**

RCCL3 := **CLOSEC OR CLOSE3P**

Such settings depend on correspondence with the power system, as detailed in *Figure 9.26–Figure 9.28* and accompanying text. Note that in *Figure 5.1*, three-phase close conditions other than auto reclose (SELOGIC setting CL3P) do not flow through CLOSEA, CLOSEB, and CLOSEC. Three-phase close conditions other than auto reclose have to be programmed in each SELOGIC setting CLA, CLB, and CLC if single-phase tripping and closing is enabled for the recloser (Group setting ESPB := Y).

In the preceding suggested close settings example and in *Table 9.20*, the CLOSE3P value is included in each close-mapping setting, in case Group setting ESPB is changed between Y and N. As shown in *Figure 6.1*, changing Group setting ESPB changes the enabled Relay Word Bit outputs (switches between CLOSE3P and CLOSEA, CLOSEB, CLOSEC). If single-phase closing is never used (Group setting ESPB:=N), the preceding suggested close settings can all be minimized to CLOSE3P only.

MULTI-RECLOSER INTERFACE

The trip settings in Table 9.19, and close settings in Table 9.20 are automatically set (and hidden), according to Global setting IPCONN, for the Multi-Recloser Interface on page 2.93. Also, Global setting BKTYP is automatically set to BKTYP := 1 (and hidden) for the Multi-Recloser Interface.

Interlocking Logic

The interlocking logic in *Figure 7.26* prevents Relay Word bit outputs RCTR*n*X and RCCL*n*X from being asserted at the same time. This is critical in situations such as that shown in *Figure 2.53*, where only one of the stacked trip or close FETs can be on at one time; otherwise, a short-circuit between 155 Vdc power and ground would result.

Excess Trip and Close Logic

Relay Word bit outputs XSTRIP*n* and XSCLOS*n* from the excess trip and close logic in *Figure 7.26* operate as feedback to the trip and close mapping logic, respectively, in the same figure. This excess trip and close logic feedback prevents Relay Word Bit outputs RCTR*n*X and RCCL*n*X from asserting too many times within a time period. This restriction prevents overheating of the recloser coils.

Page 384 of 1080
Wolfe

Realistically, such a restriction would most likely take effect during testing or any other time the front-panel **TRIP** and **CLOSE** operator controls are pushed an excessive number of times. Each assertion of trip output RCTRnX or close output RCCLnX is detected by the rising-edge detect inputs of the excess trip and close logic and is considered a count. These counts accumulate in the excess trip and close logic.

Any time the cumulative count increments (for a new trip or close), a 360-cycle timer in the excess trip and close logic starts timing. When the 360-cycle timer times out, the cumulative count decrements one (1) count. If the cumulative count is still greater than zero (0), the 360-cycle timer loads up again and times. When the 360-cycle timer times out, again, the cumulative count decrements one (1) count, again. This process repeats until the cumulative count eventually decrements down to zero (0).

The 360-cycle timer period makes room for one more count (one more trip or close operation) to be added to the cumulative counter every 360 cycles. Any time a new trip or close occurs, the cumulative counter increments and the 360-cycle timer is interrupted, if timing, and loaded up again. Conceivably, if the time period between trip or close operations is less than 360 cycles, the cumulative counter just continues incrementing, with no decrementing, until the cumulative count runs as high as the set limits shown in *Figure 7.26*.

Note that the assertion of XS_CLOSn (excess close for pole n) is at a lesser count (cumulative count = 10) than XS_TRIPn (excess trip for pole n). More trips are allowed, because tripping is a more critical function than closing. If a fault is present (Relay Word bit FAULT asserted), then two additional trip attempts (cumulative count as high as 14, instead of just to 12) are allowed before XS_TRIP is asserted. The 360-cycle timer works at bringing the cumulative count back down.

Virtual Bits

The SEL-651R-2 supports 128 virtual bits, VB001–VB128 for the IEC 61850 protocol.

These Relay Word bits are active only in relays ordered with IEC 61850.

When IEC 61850 is enabled, the relay uses the externally created CID file to define the behavior of these virtual bits (received GOOSE messages can be mapped to these bits).

Once defined, the virtual bits can be used in SELOGIC control equations like any other Relay Word bit.

The CID file also defines what information gets transmitted in GOOSE messages. See *Appendix L: IEC 61850* for details on the IEC 61850 protocol.

Output Contacts

The SEL-651R-2 comes standard with two Form C output contacts (OUT201 and OUT202). An ordering option adds 8 extra output contacts: five Form A (OUT101–OUT105) and three Form C (OUT106–OUT108). See *Figure 7.27* for a definition of the output contact forms.

Wolfe

SELogic Control Equation Programming 7.35
Output Contacts

Figure 7.27 Output Contact Forms

Figure 2.9 shows the output contact terminal locations on the SEL-651R-2 control module rear panel. Refer to *Additional Relay Connections on page 2.50* for connector and tightening torque information.

SEL-651R-2 output contacts are normally operated through the use of SELOGIC control equation OUT*n* (*n* = 101–108, 201–202) or one of several other methods.

These two methods are ordinarily only used in testing:

➤ SEL ASCII command **PULSE** as described in *Section 10: Communications*.

➤ Front-panel HMI Control menu and Output Contacts submenu as described in *Section 11: Front-Panel Operations*.

Figure 7.28 shows the example operation of Relay Word bits that in turn control corresponding output contacts. Output contacts OUT103–OUT106 are not shown in *Figure 7.28*, but are Form A type output contacts that operate similarly to output contacts OUT101 and OUT102.

SELOGIC control equation settings OUT*n* and serial port ASCII commands PULSE OUT*n* are shown as inputs into the logic in *Figure 7.28*. Front-Panel HMI, not shown in *Figure 7.28*, has the same logical effect as the serial port ASCII commands PULSE OUT*n* in *Figure 7.28*—it is just a different means to the same result (assertion of Relay Word bit OUT*n*).

SCADA Operation

The following methods can be used to operate output contacts via SCADA.

➤ Fast Operate commands as described in *Appendix C: Compressed ASCII Commands*.

➤ DNP3 Objects 10 and 12 as described in *Appendix E: DNP3 Communications*.

➤ Modbus Function code 05h as described in *Appendix K: Modbus RTU and TCP Communications*.

All three methods must first be programmed by using SELOGIC control equation OUT*n* (*n* = 101–108, 201–202). For example, remote bit RB01 may be used to control output OUT202 with the setting OUT202 := RB01. See *Remote Bits on page 7.22*. Modbus Function Code 05h may also directly control the output.

Output Contact Operation

The assertion of a Relay Word bit causes the energization of the corresponding output contact coil. Depending on the contact type (Form A or Form B), the output contact closes or opens. A Form A output contact is open when the output contact coil is de-energized and closed when the output contact coil is energized. A Form B output contact is closed when the output contact coil is de-energized and open when the output contact coil is energized.

Notice that *Figure 7.28* shows all four possible combinations of output contact coil states (energized or de-energized) and output contact types (Form A or Form B).

Only OUT201 is used in the SEL-651R-2 factory-default settings, and it functions as an alarm contact.

7.36 | SELᴏɢɪᴄ Control Equation Programming
Example SELᴏɢɪᴄ Control Equations

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 386 of 1080
Wolfe

The default settings are as follows:

OUT101–OUT108 := **0**

OUT201 := **NOT (SALARM OR HALARM)**

OUT202 := **0**

The output SELᴏɢɪᴄ equations are located in the logic settings class (see *Output Contact SELOGIC Equations on page SET.52*).

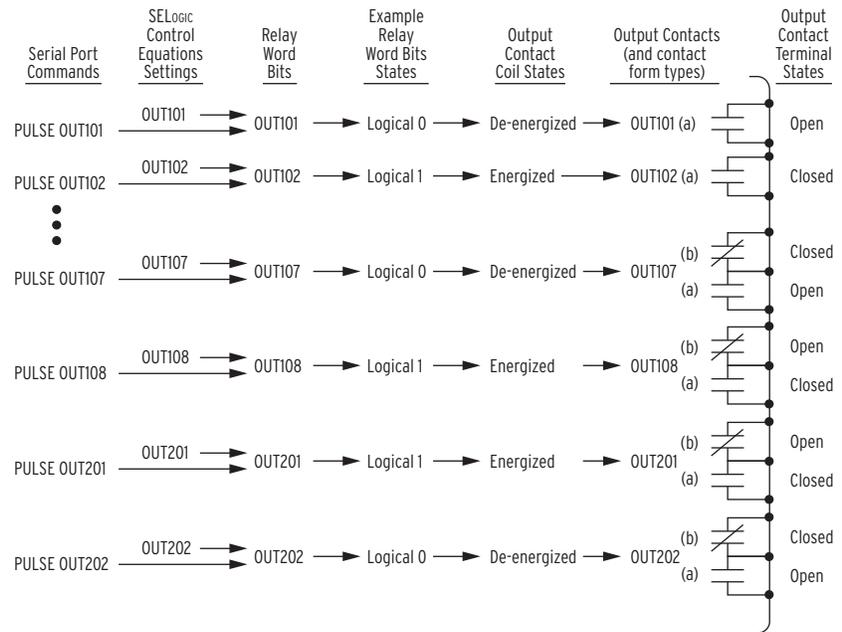
In most applications, monitor the normally closed side of the Form C contact (OUT201) for fail-safe alarm operation. When the SEL-651R-2 is not enabled (for example, if ac power and the battery are not connected), the normally closed contact would be in the closed position, indicating the alarm condition. When the SEL-651R-2 is powered-up and operational, the normally closed contact would be open, indicating a nonalarm condition.


Figure 7.28   Logic Flow for Example Output Contact Operation

If an ac transfer switch is installed, the Form B side of output contact OUT202 is wired to its control circuit (see *Figure 2.38*). This is done in case any future transfer switch control is needed. From the factory, no control is set for output contact OUT202 (see preceding factory-default output contact settings).

Example SELᴏɢɪᴄ Control Equations

Tripping

If tripping does not involve single-pole or switch-onto-fault trip logic, the SELᴏɢɪᴄ control equation trip setting TR3P is the only trip setting needed (see *Trip Logic on page 5.1*).

Note that *Figure 5.1* appears quite complex. Because tripping does not involve single-pole or switch-onto-fault trip logic in this example, however, the only effective inputs in *Figure 5.1* are SELᴏɢɪᴄ control equation trip settings TR3P and TR3X.

TR3P := **51PT OR 51G1T OR 50P1 AND SH03P** (fuse-saving example)

TR3X := **0** (not used—set directly to logical 0)

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 287 of 1080
Wolfe

SELogic Control Equation Programming   7.37
Example SELogic Control Equations

TRQL3P := **0**

TRSOTF := **0**

ULTR3P := **NOT (51P OR 51G1)**

TRA := **0**

TRB := **0**

TRC := **0**

Analysis of Trip Setting TR3P

Again, the example trip equation is as follows:

TR3P := **51PT OR 51G1T OR 50P1 AND SH03P**

The Relay Word bit definitions are as follows:

51PT	phase time-overcurrent element timed out
51G1T	residual ground time-overcurrent element timed out
50P1	phase instantaneous overcurrent element asserted
SH03P	reclosing relay shot counter at shot = 0

In the trip equation, the AND operator is executed before the OR operators:

50P1 AND SH03P

Element 50P1 can only cause a trip if the three-phase reclosing relay shot counter is at shot = 0. When the reclosing relay shot counter is at shot = 0, Relay Word bit SH03P is in the following state:

SH03P = 1

If maximum phase current is above the phase instantaneous overcurrent element pickup setting 50P1P, Relay Word bit 50P1 is in the following state:

50P1 = 1

With SH03P = 1 and 50P1 = 1, the logical AND operation results in

(50P1 AND SH0) = (1 AND 1) = 1

and an instantaneous trip results. This logic is commonly used in fuse-saving schemes for distribution feeders.

If the reclosing relay shot counter advances to shot = 1 for the reclose that follows the trip, Relay Word bit SH03P is in the following state:

SH03P = 0

If maximum phase current is above the phase instantaneous overcurrent element pickup setting 50P1P for the reoccurring fault, Relay Word bit 50P1 is in the following state:

50P1 = 1

With SH03P = 0 and 50P1 = 1, the logical AND operation results in

(50P1 AND SH03P) = (1 AND 0) = 0

and no trip results from phase instantaneous overcurrent element 50P1.

Example SELᴏɢɪᴄ Control Equations

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 388 of 1080
Wolfe

A trip will eventually result if time-overcurrent element 51PT or 51G1T times out. If residual ground time-overcurrent element 51G1T times out, Relay Word bit 51G1T is in the following state:

51G1T = 1

When shot = 1, SH03P = 0 and the result is:

$$
\begin{aligned}
\text{TR3P} \quad &= \text{(51PT OR 51G1T OR 50P1 AND SH03P)} \\
&= \text{(0 OR 1 OR 1 AND 0)} \\
&= \text{(0 OR 1 OR 0)} \\
&= 1
\end{aligned}
$$

and a time-delayed trip results from residual ground time-overcurrent element 51G1T.

Trip Output Contact

To assert output contact OUT101 to trip a circuit breaker, make the following SELᴏɢɪᴄ control equation output contact setting:

OUT101 := **TRIP3P**

Note that this simple output contact setting example is different from the standard recloser control trip/close output settings discussed in *Trip and Close Mapping and Output Logic on page 7.31*.

Phase Time-Overcurrent Element 51PT

Examine a phase time-overcurrent element as an example of protection element operation via the logic output of Relay Word bits. The following Relay Word bits are the logic outputs of the phase time-overcurrent element:

51P	indication that the maximum phase-current magnitude is above the level of the phase time-overcurrent pickup setting 51PJP or 51PKP
51PT	indication that the phase time-overcurrent element has timed out on its curve
51PR	indication that the phase time-overcurrent element is fully reset

Pickup Indication

If the maximum phase current is at or below the level of the phase time-overcurrent pickup setting 51PJP or 51PKP, Relay Word bit 51P is in state 0.

If the maximum phase current is above the level of the phase time-overcurrent pickup setting 51PJP or 51PKP, Relay Word bit 51P is in state 1.

The 51PT element is either timing on its curve or is already timed out.

Time-Out Indication

If phase time-overcurrent element 51PT is not timed out on its curve, Relay Word bit 51PT is in state 0.

If phase time-overcurrent element 51PT is timed out on its curve, Relay Word bit 51PT is in state 1.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
SELOGIC Control Equation Programming 7.39
Processing Order and Processing Interval
Page 389 of 1080
Wolfe

Reset Indication

If phase time-overcurrent element 51PT is not fully reset, Relay Word bit 51PR is in state 0. The 51PT element is either:

➤ Timing on its curve

➤ Already timed out

➤ Timing to reset (one-cycle reset or electromechanical emulation—see setting 51PRS)

If phase time-overcurrent element is fully reset, Relay Word bit 51PR is in state 1.

Relay Word Bit Applications

Common uses for Relay Word bits 51P, 51PT, and 51PR:

51P	Testing, such as assigning to an output contact for pickup testing, trip unlatch logic.
51PT	Trip logic.
51PR	Testing, such as assigning to an output contact for reset indication.

Processing Order and Processing Interval

The relay elements and logic (and corresponding SELOGIC control equation settings and resultant Relay Word bits) are processed in the order shown in *Table 7.11* (top to bottom). They are processed every quarter-cycle (1/4-cycle) and the Relay Word bit states (logical 1 or logical 0) are updated with each quarter-cycle pass. Thus, the relay processing interval is 1/4-cycle. Once a Relay Word bit is asserted, it retains the state (logical 1 or logical 0) until it is updated again in the next processing interval.

Metering and Monitoring

Introduction

The SEL-651R-2 Recloser Control includes extensive metering features and monitoring functions. The metering functions facilitate power system planning and operation, while the monitoring functions aid in maintenance planning and electrical load forecasting.

The metering functions include:

➤ *Fundamental (Instantaneous) Metering on page 8.2*

➤ *Demand Metering on page 8.6*

➤ *Energy Metering on page 8.15*

This section explains each of these features.

Dependence on Y and Z Voltage Inputs, Phase Connection Settings, and Scaling

The SEL-651R-2 is configured with six voltage inputs, labeled V1Y, V2Y, V3Y (called the "Y-side"); and V1Z, V2Z, V3Z (called the "Z-side"). Global settings determine which voltage(s) are used for the metered quantities that involve a voltage signal. Additionally, global current and voltage connection settings allow phase rolling of the current and voltage inputs (see *Current and Voltage Connections (Global Settings) on page 9.28*).

All metering and monitoring functions use the rolled voltages and currents, and the voltage signal names become VAY, VBY, VCY, VAZ, VBZ, and VCZ.

All metering functions are calculated in primary quantities, as determined by the CTR, CTRN, PTRY, and PTRZ Group settings. See *Settings Explanations on page 9.27* for details on these ratio settings.

Table 8.1 lists the metering quantities and which of the Global settings affect them.

Fundamental (Instantaneous) Metering

Description

The SEL-651R-2 performs current, voltage, symmetrical component, and power metering through use of the fundamental (filtered) signals obtained from the same cosine filter that is used in the protective relay algorithms. These values respond to the fundamental signal at the measured system frequency, which is usually near 50 Hz or 60 Hz. Frequency tracking ensures that frequency variations do not adversely affect metering accuracy.

The fundamental metering function updates the metering values approximately twice per second.

The SEL-651R-2 converts the metered values to primary units by using the current transformer ratio settings (CTR and CTRN) and potential transformer ratio settings (PTRY and PTRZ). The PTRY setting is entered in an adjusted

Metering and Monitoring 8.3
Fundamental (Instantaneous) Metering
Wolfe

fashion when low-energy analog (LEA) inputs are present, as described in *Potential Transformer (PT) Ratios (Group Settings) on page 9.42*. If LEA inputs are in use, the actual primary to secondary ratio of the voltage divider must be scaled down before entry as the PTRY setting.

The metered values are available in several forms:

> ➤ Serial port ASCII communications (see *MET Command (Metering Data) on page 10.57*)

> ➤ Serial port Fast Meter communications (see *Appendix C: Compressed ASCII Commands)*

> ➤ Serial port DNP3 (see *Reference Data Map on page E.30*)

> ➤ Front-panel LCD (see *Front-Panel Menus and Screens on page 11.4)*

Appendix G: Analog Quantities lists certain meter values that are available for:

> ➤ Display points (see *Rotating Display on page 11.13*)

> ➤ Load Profile Recorder (see *Load Profile Report on page 8.44*)

Table 7.2 lists certain meter values that are available for:

> ➤ SELOGIC Analog Comparisons (see *Analog Quantities on page 7.2*)

See *Specifications on page 1.9* for a listing of the fundamental metering accuracy in the SEL-651R-2.

These fundamental quantities are used in the Instantaneous Metering quantities, as well as the Demand, Energy, and Maximum/Minimum Metering functions, described later in this section.

Because the fundamental quantities are filtered to the power system frequency, they are immune to signal energy at dc and harmonic frequencies.

Harmonics and True RMS Metering on page 8.21, use the full signal spectrum (except dc) in the calculations. RMS metering quantities may differ from fundamental metering quantities if the system contains harmonic energy.

Effect of Global Settings EGNDSW, EPHANT, VSELECT, FSELECT, and METHRES on Fundamental Metering Functions

Ground Switch Option

GLOBAL SETTING EGNDSW
See Ground Switch Logic on page 4.76.

NOTE: Harmonics and rms metering functions are not affected by the EGNDSW setting.

Global setting EGNDSW is normally set to Y in the SEL-651R-2. This enables the ground switch logic for protection functions and fundamental current metering functions.

In fundamental metering, setting ENGDSW affects how the IG quantity is derived and how it relates to the IN and 3I0 quantities. These quantities (IN, 3I0, IG) are available in the various metering output formats, such as the serial port **MET** command.

8.4 | Metering and Monitoring
| **Fundamental (Instantaneous) Metering**

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 396 of 1080
Wolfe

Fundamental Metering When EGNDSW := Y

Use this selection when the neutral current input channel IN is wired residually (see *Figure 2.49* and *Figure 2.52* for sample configurations) and measures the zero-sequence current of the power system. The IA, IB, and IC current inputs are also capable of measuring the zero-sequence current, $3I0 = IA + IB + IC$.

Because the IN channel is more sensitive to small currents, it is more accurate for metering measurements. When currents are higher than the range of the IN channel, the 3I0 quantity is more accurate, because the IN channel will saturate.

Therefore, in the SEL-651R-2 fundamental metering subsystem, quantity IG is automatically switched between IN and 3I0, depending on the present size of the signal being measured. This is similar to the behavior of the IG quantity used in the overcurrent elements 50G1, 51G2, etc., when EGNDSW := Y.

If the current transformer ratio setting for the IN channel (CTRN) is different than the phase channels IA, IB, and IC (CTR), the proper ratio is used for each signal and the IG quantity is truly representing primary amperes.

Thus, when EGNDSW := Y, fundamental metering quantity IG will exactly match IN for small signals and 3I0 for large signals.

Fundamental Metering When EGNDSW := N

Use this selection when the neutral current input channel IN is not connected, or is not connected to a current source related to the phase channels IA, IB, IC.

In this mode, current input channel IN is not coupled with the fundamental metering quantity IG. Thus, when EGNDSW := N, fundamental metering quantity IG matches 3I0 at all times.

Phantom Voltage Function

A phantom setting allows three-phase voltages to be generated from a single metered quantity and the power quantities to be calculated from the generated voltages. The single-phase voltage must be connected to terminal V1Y or V1Z.

Global setting VYCONN or VZCONN is set as shown in *Table 8.2*, depending on the connected voltage signals. The magnitude adjustment factor is 1 for phase-to-neutral signals, and $1/(\sqrt{3})$ to convert phase-to-phase signals to phase-to-neutral signals.

Table 8.2 Phantom Voltage Adjustments (Sheet 1 of 2)

Voltage Connected V1Y-N or V1Z-N (Becomes "Reference" Voltage)	Setting VYCONN or VZCONN	Magnitude and Phase Displacement Adjustment, Multiplied By Reference Voltage to Create V$_{phnt}$	
		Systems With ABC Rotation	Systems With ACB Rotation
V$_A$	A	$1\angle 0°$	$1\angle 0°$
V$_B$	B	$1\angle 120°$	$1\angle(-120)°$
V$_C$	C	$1\angle(-120)°$	$1\angle 120°$
V$_{AB}$	AB	$\dfrac{1}{\sqrt{3}}\angle -30°$	$\dfrac{1}{\sqrt{3}}\angle 30°$

Wolfe

Metering and Monitoring | 8.5
Fundamental (Instantaneous) Metering

Table 8.2 Phantom Voltage Adjustments (Sheet 2 of 2)

Voltage Connected V1Y-N or V1Z-N (Becomes "Reference" Voltage)	Setting VYCONN or VZCONN	Magnitude and Phase Displacement Adjustment, Multiplied By Reference Voltage to Create V_{phnt}	
		Systems With ABC Rotation	Systems With ACB Rotation
V_{BC}	BC	$\frac{1}{\sqrt{3}} \angle 90°$	$\frac{1}{\sqrt{3}} \angle -90°$
V_{CA}	CA	$\frac{1}{\sqrt{3}} \angle -150°$	$\frac{1}{\sqrt{3}} \angle 150°$

The phantom voltage V_{phnt} signal created using *Table 8.2* is labeled as VAY or VAZ, depending on the EPHANT setting. The recloser control derives B- and C-phase signals by rotating V_{phnt} by either 120 or –120, depending on the phase rotation setting PHROT.

Figure 8.1 shows an example of the phantom voltage function with ABC phase rotation.

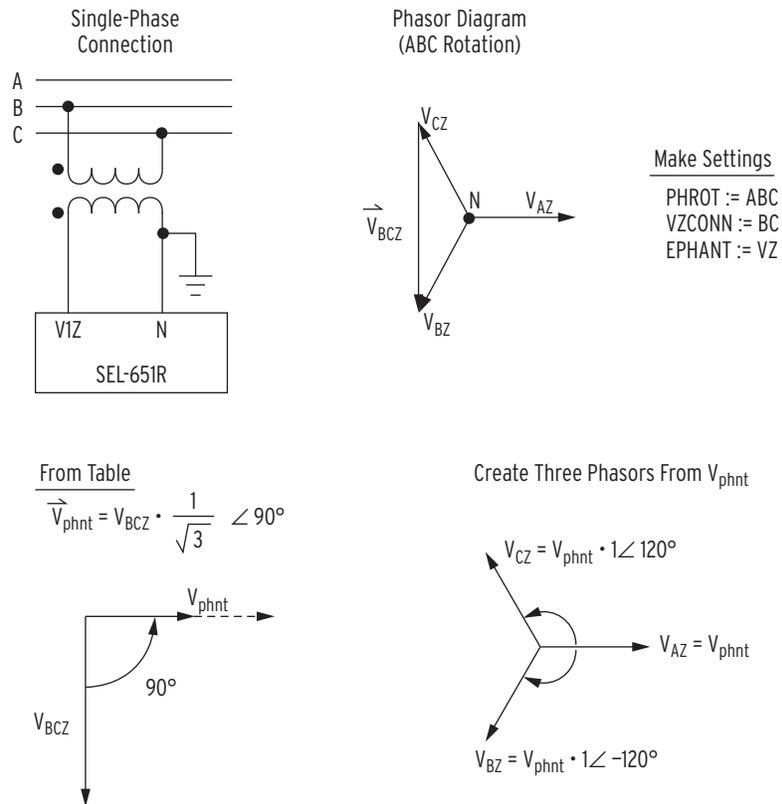
NOTE: Phantom voltages can only be enabled on one set of terminals at a time.


Figure 8.1   Example Phasor Diagram of Phantom Voltage Adjustment

When the phantom voltage option is being used (i.e., EPHANT is set to VY or VZ), the fundamental power and energy quantities are based on the derived phantom voltages.

When the phantom voltage option is being used (i.e., EPHANT is set to VY or VZ), symmetrical components (positive-, negative-, and zero-sequence voltages) are not calculated. In the example shown in *Figure 8.1*, EPHANT := VZ, thus V1Z, V2Z, and 3V0Z are set to zero internally, and they

NOTE: The phantom voltage settings have no effect on the protection elements in the SEL-651R-2. See Voltage Elements on page 4.31.

8.6 | Metering and Monitoring
Demand Metering

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 398 of 1080
Wolfe

are not displayed in the **MET** command. These values are hidden because they would look like a perfectly balanced three-phase system, which may be misleading.

Phantom Voltage Option Not in Service

If phantom voltage generation is not enabled (i.e., EPHANT := OFF) and three-phase voltages are connected, Global setting VSELECT selects the voltage input terminals (VY or VZ) that are used to calculate power and energy quantities.

If Global setting VSELECT := OFF when EPHANT := OFF, power and energy metering is disabled.

Frequency Measurement Selection

Global setting FSELECT determines the voltage input terminal that is used to measure frequency. This setting is unaffected by the phantom voltage setting (see *Frequency Source Selection Setting (FSELECT) on page 9.33*).

METHRES Setting

The relay applies a small-signal cutoff threshold to the voltage and current signals, which may affect subsequent uses of the measurement (see *Small-Signal Cutoff for Metering on page 8.19*).

Demand Metering

The SEL-651R-2 offers the choice between two types of demand metering, settable with the Group setting:

EDEM := **THM** Thermal Demand Meter

or

EDEM := **ROL** Rolling Demand Meter

The demand metering settings (see *Table 8.3*) are available via the **SET** command (see *Table 9.1* and also *Settings Sheet page SET.9* at the end of *Section 9*). Also refer to *MET Command (Metering Data) on page 10.57* and *MET D (Demand Metering) on page 10.59*.

The SEL-651R-2 provides demand and peak demand metering for the following values:

Currents

$I_{A,B,C,N}$ Input currents (A primary)

I_G Ground Current (A primary; IG = IN or 3I0, see *Ground Switch Option on page 8.3*)

$3I_2$ Negative-sequence current (A primary)

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Metering and Monitoring 8.7
Page 399 of 1080
Demand Metering
Wolfe

If three-phase voltage signals are connected and the Global settings VYCONN, VZCONN, EPHANT, and VSELECT are properly made, the SEL-651R-2 provides demand metering for the following values:

Power

$MVA_{A,B,C,3P}$		Single-phase and three-phase megavolt-amperes, primary
$MW_{A,B,C,3P}$	IN	Single-phase and three-phase megawatts, primary
$MW_{A,B,C,3P}$	OUT	Single-phase and three-phase megawatts, primary
$MVAR_{A,B,C,3P}$	IN	Single-phase and three-phase megavars, primary
$MVAR_{A,B,C,3P}$	OUT	Single-phase and three-phase megavars, primary

where IN and OUT correspond to the standard relay convention of OUT for positive power, and IN for negative power. Global setting CTPOL can change the direction of power (and energy) metering (see *Table 8.1*).

If a single-phase voltage is connected, and the settings VYCONN, VZCONN, and EPHANT are properly made, the same demand values are available by using the phantom voltage feature (see *Fundamental (Instantaneous) Metering on page 8.2*). Power demand metering accuracy degrades when the phantom feature is used. The accuracy error is proportional to the amount of system load unbalance and the zero-sequence source impedance.

Depending on enable setting EDEM, these demand and peak demand values are thermal demand or rolling demand values. The differences between thermal and rolling demand metering are explained in the following subsection.

Comparison of Thermal and Rolling Demand Meters

The example in *Figure 8.2* shows the response of thermal and rolling demand meters to a step current input. The current input is at a magnitude of zero and then suddenly goes to an instantaneous level of 1.0 per unit (a "step").

8.8 | Metering and Monitoring
Demand Metering

Case No. 2018-00295

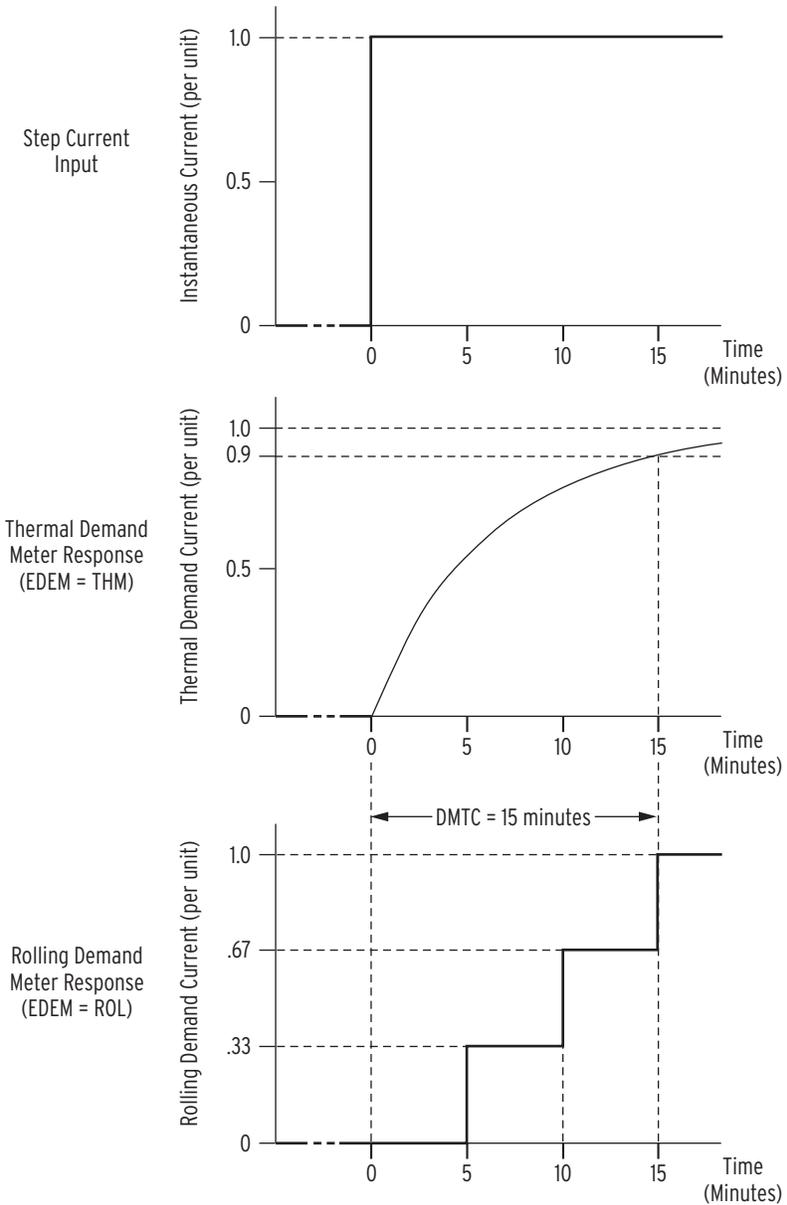

Figure 8.2 Response of Thermal and Rolling Demand Meters to a Step Input (Setting DMTC = 15 Minutes)

Thermal Demand Meter Response (EDEM := THM)

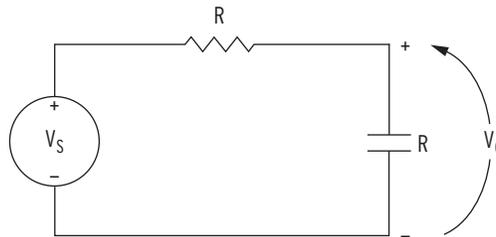
The response of the thermal demand meter in *Figure 8.2* (middle) to the step current input (top) is analogous to the series RC circuit in *Figure 8.3*.


Figure 8.3 Voltage V_S Applied to Series RC Circuit

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 401 of 1080
Metering and Monitoring
Demand Metering
8.9
Wolfe

In the analogy:

Voltage V_S in *Figure 8.3* corresponds to the step current input in *Figure 8.2* (top).

Voltage V_C across the capacitor in *Figure 8.3* corresponds to the response of the thermal demand meter in *Figure 8.2* (middle).

If voltage V_S in *Figure 8.3* has been at zero ($V_S = 0.0$ per unit) for some time, voltage V_C across the capacitor in *Figure 8.3* is also at zero ($V_C = 0.0$ per unit). If voltage V_S is suddenly stepped up to some constant value ($V_S = 1.0$ per unit), voltage V_C across the capacitor starts to rise toward the 1.0 per unit value. This voltage rise across the capacitor is analogous to the response of the thermal demand meter in *Figure 8.2* (middle) to the step current input (top).

NOTE: The examples in this section discuss demand current, but MVA, MW, and MVAR demand values are also available, as stated at the beginning of this subsection.

In general, because voltage V_C across the capacitor in *Figure 8.3* cannot change instantaneously, the thermal demand meter response is not immediate either for the increasing or decreasing applied instantaneous current. The thermal demand meter response time is based on the demand meter time constant setting DMTC (see *Table 8.3*). Note in *Figure 8.2*, the thermal demand meter response (middle) is at 90 percent (0.9 per unit) of full applied value (1.0 per unit) after a time period equal to setting DMTC := 15 minutes, referenced to when the step current input is first applied.

The SEL-651R-2 updates thermal demand values approximately every 2 seconds.

Rolling Demand Meter Response (EDEM := ROL)

The response of the rolling demand meter in *Figure 8.2* (bottom) to the step current input (top) is calculated with a sliding time-window arithmetic average calculation. The width of the sliding time window is equal to the demand meter time constant setting DMTC (see *Table 8.3*). Note in *Figure 8.2*, the rolling demand meter response (bottom) is at 100 percent (1.0 per unit) of full applied value (1.0 per unit) after a time period equal to setting DMTC := 15 minutes, referenced to when the step current input is first applied.

The rolling demand meter integrates the applied signal, such as step current, input in 5-minute intervals. The integration is performed approximately every 2 seconds. The average value for an integrated 5-minute interval is derived and stored as a 5-minute total. The rolling demand meter then averages a number of the 5-minute totals to produce the rolling demand meter response. In the *Figure 8.2* example, the rolling demand meter averages the three latest 5-minute totals because setting DMTC = 15 (15/5 = 3). The rolling demand meter response is updated every 5 minutes, after a new 5-minute total is calculated.

The following is a step-by-step calculation of the rolling demand response example in *Figure 8.2* (bottom).

8.10 | Metering and Monitoring
Demand Metering

Case No. 2018-00295

Time = 0 Minutes

Presume that the instantaneous current has been at zero for quite some time before "Time = 0 minutes" or that the demand meters were recently reset. The three 5-minute intervals in the sliding time-window at "Time = 0 minutes" each integrate into the following 5-minute totals:

5-Minute Totals	Corresponding 5-Minute Interval
0.0 per unit	–15 to –10 minutes
0.0 per unit	–10 to –5 minutes
0.0 per unit	–5 to 0 minutes
0.0 per unit	

Rolling demand meter response at "Time = 0 minutes" = 0.0/3 = 0.0 per unit.

Time = 5 Minutes

The three 5-minute intervals in the sliding time-window at "Time = 5 minutes" each integrate into the following 5-minute totals:

5-Minute Totals	Corresponding 5-Minute Interval
0.0 per unit	–10 to –5 minutes
0.0 per unit	–5 to 0 minutes
1.0 per unit	0 to 5 minutes
1.0 per unit	

Rolling demand meter response at "Time = 5 minutes" = 1.0/3 = 0.33 per unit.

Time = 10 Minutes

The three 5-minute intervals in the sliding time-window at "Time = 10 minutes" each integrate into the following 5-minute totals:

5-Minute Totals	Corresponding 5-Minute Interval
0.0 per unit	–5 to 0 minutes
1.0 per unit	0 to 5 minutes
1.0 per unit	5 to 10 minutes
2.0 per unit	

Rolling demand meter response at "Time = 10 minutes" = 2.0/3 = 0.67 per unit.

Time = 15 Minutes

The three 5-minute intervals in the sliding time-window at "Time = 15 minutes" each integrate into the following 5-minute totals:

5-Minute Totals	Corresponding 5-Minute Interval
1.0 per unit	0 to 5 minutes
1.0 per unit	5 to 10 minutes
1.0 per unit	10 to 15 minutes
3.0 per unit

Page 403 of 1080

Metering and Monitoring 8.11
Demand Metering
Wolfe

Rolling demand meter response at "Time = 15 minutes" = 3.0/3 = 1.0 per unit.

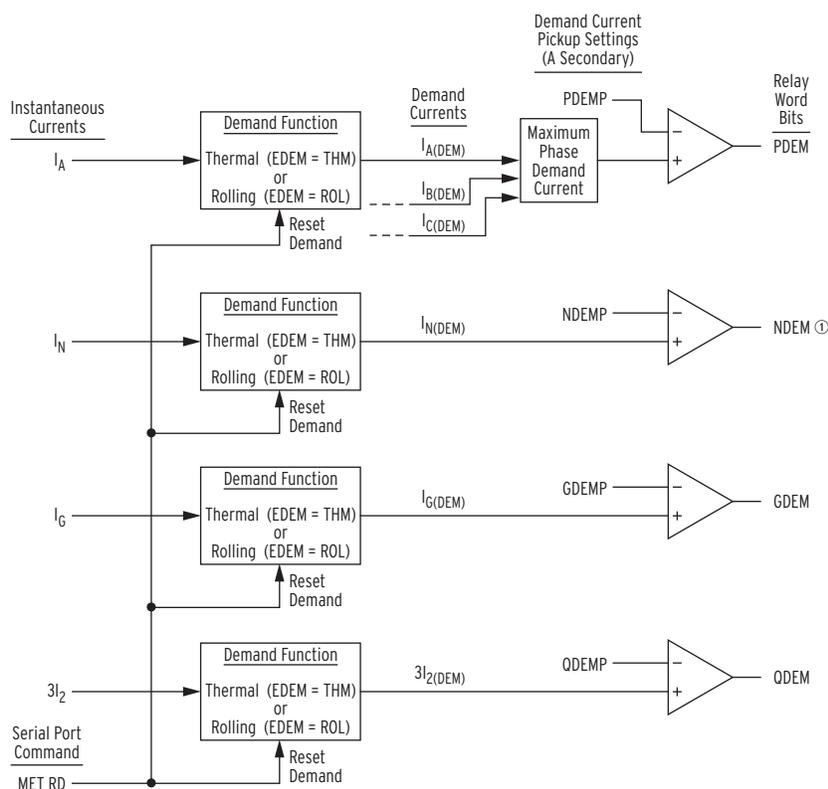
Demand Meter Settings

Table 8.3   Demand Meter Settings and Settings Range

Setting	Definition	Range
EDEM	Demand meter type	THM = thermal ROL = rolling
DMTC	Demand meter time constant	5, 10, 15, 30, or 60 minutes
PDEMP	Phase demand current pickup	0.10–3.20 A secondary
NDEMP	Neutral ground demand current pickup[a]	0.005–0.640 A secondary
GDEMP	Ground demand current pickup[b]	0.005–3.200 A secondary
QDEMP	Negative-sequence demand current pickup	0.10–3.20 A secondary

[a] NDEMP is only available when Global setting EGNDSW := N.
[b] GDEMP setting range shown is for factory-default settings, with EGNDSW := Y, and CTR = CTRN := 1000. See Settings Sheet page SET.32 at the end of Section 9 for details.

NOTE: Changing setting EDEM or DMTC resets the demand meter values to zero. This also applies to changing the active settings group, and setting EDEM or DMTC is different in the new active settings group. Demand current pickup settings PDEMP, NDEMP, GDEMP, and QDEMP can be changed without affecting the demand meters.

The demand current pickup settings in *Table 8.3* are applied to demand current meter outputs as shown in *Figure 8.4*. For example, when residual ground demand current $I_{G(DEM)}$ goes above corresponding demand pickup GDEMP, Relay Word bit GDEM asserts to logical 1. Use these demand current logic outputs (PDEM, NDEM, GDEM, and QDEM) to alarm for high loading or unbalance conditions. Use them in other schemes such as the following example.


① NDEM is only functional when Global setting EGNDSW := N.

Figure 8.4   Demand Current Logic Outputs

8.12 | Metering and Monitoring
Demand Metering

Attachment to Response to AG-2 Question No. 68(g)
Page 404 of 1080
Wolfe

Demand Current Logic Output Application: Raise Pickup for Unbalance Current

During times of high loading, the residual ground overcurrent elements can see relatively high unbalance current I_G ($I_G = 3I_0$). To avoid tripping on unbalance current I_G, use Relay Word bit GDEM to detect the residual ground (unbalance) demand current $I_{G(DEM)}$ and effectively raise the pickup of the residual ground time-overcurrent element 51G1T. This is accomplished with the following settings from *Table 8.3*, pertinent residual ground overcurrent element settings, and SELOGIC control equation torque-control setting 51G1TC:

EDEM := **THM**

DMTC := **5**

GDEMP := **1.000**

51G1JP := **1.50**

50G5P := **2.30**

51G1TC := **NOT(GDEM) OR GDEM AND 50G5**

51G1SW := **0**

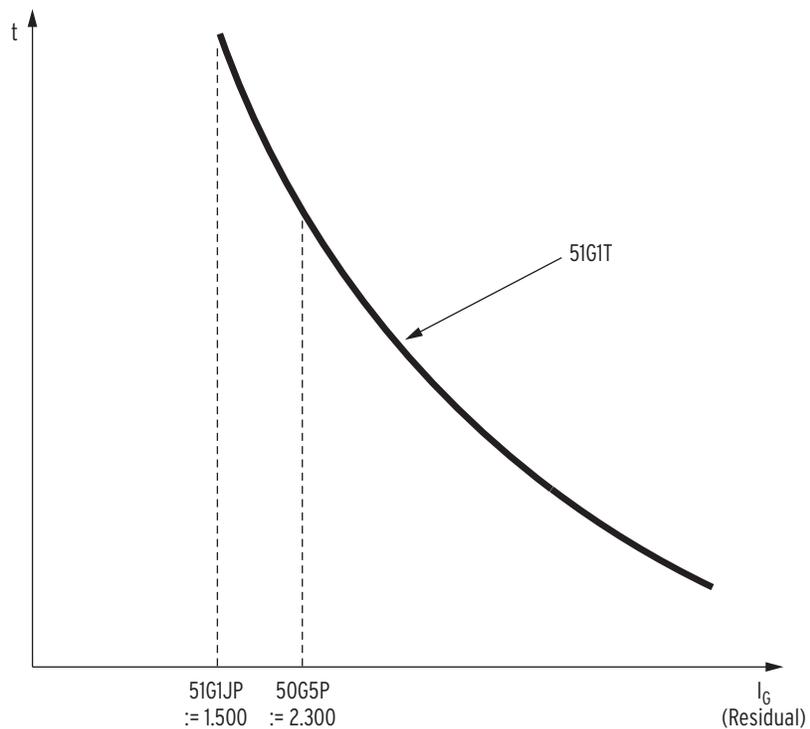
Refer to *Figure 8.4*, *Figure 8.5*, and *Figure 4.22*.


Figure 8.5   Raise Pickup of Residual Ground Time-Overcurrent Element for Unbalance Current

Residual Ground Demand Current Below Pickup GDEMP

When unbalance current I_G is low, unbalance demand current $I_{G(DEM)}$ is below corresponding demand pickup GDEMP = 1.000 A secondary, and Relay Word bit GDEM is deasserted to logical 0. This results in SELOGIC control equation torque-control setting 51G1TC being in the state:

51G1TC := NOT(GDEM) OR GDEM AND 50G5

:= NOT (logical 0) OR (logical 0) AND 50G5

:= logical 1   **Equation 8.1**

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Metering and Monitoring 8.13
Page 405 of 1080
Demand Metering
Wolfe

Thus, the residual ground time-overcurrent element 51G1T operates on its standard pickup:

$$51G1JP := 1.500 \text{ A Secondary}$$

<div align="right">**Equation 8.2**</div>

If a ground fault occurs, the residual ground time-overcurrent element 51G1T operates with the sensitivity provided by pickup 51G1JP := 1.500 A secondary. The thermal demand meter, even with setting DMTC = 5 minutes, does not respond fast enough to the ground fault to make a change to the effective residual ground time-overcurrent element pickup—it remains at 1.500 A secondary. Demand meters respond to more slow-moving general trends.

Residual Ground Demand Current Goes Above Pickup GDEMP

When unbalance current I_G increases, unbalance demand current $I_{G(DEM)}$ follows, going above corresponding demand pickup GDEMP = 1.000 A secondary, and Relay Word bit GDEM asserts to logical 1. This results in SELOGIC control equation torque-control setting 51GTC being in the state:

$$51G1TC := NOT(GDEM) \text{ OR GDEM AND 50G5}$$
$$:= NOT \text{ (logical 1) OR (logical 1) AND 50G5}$$
$$:= \text{logical 0 OR 50G5}$$
$$:= 50G5$$

<div align="right">**Equation 8.3**</div>

Thus, the residual ground time-overcurrent element 51G1T operates with an effective, less-sensitive pickup:

$$50G5P := 2.30 \text{ A Secondary}$$

<div align="right">**Equation 8.4**</div>

The reduced sensitivity keeps the residual ground time-overcurrent element 51G1T from tripping on higher unbalance current I_G.

Residual Ground Demand Current Goes Below Pickup GDEMP Again

When unbalance current I_G decreases again, unbalance demand current $I_{G(DEM)}$ follows, going below corresponding demand pickup GDEMP = 1.000 A secondary, and Relay Word bit GDEM deasserts to logical 0. This results in SELOGIC control equation torque-control setting 51G1TC being in the state:

$$51G1TC := NOT(GDEM) \text{ OR GDEM AND 50G5}$$
$$:= NOT \text{ (logical 0) OR (logical 0) AND 50G5}$$
$$:= \text{logical 1}$$

<div align="right">**Equation 8.5**</div>

Thus, the residual ground time-overcurrent element 51G1T operates on its standard pickup again:

$$51G1JP := 1.500 \text{ A secondary}$$

<div align="right">**Equation 8.6**</div>

View or Reset Demand Metering Information

Via Serial Port

The **MET D** command displays demand and peak demand metering (see *MET Command (Metering Data)*, *MET D (Demand Metering) on page 10.59*).

The **MET RD** command resets the demand metering values. The **MET RP** command resets the peak demand metering values.

After demand values are reset, if setting EDEM := ROL, there may be a delay of as long as two times the DMTC setting before the demand values are updated.

Via Front Panel

The information and reset functions available via the previously discussed serial port commands **MET D**, **MET RD**, and **MET RP** are also available via the front-panel menu (see *Human-Machine Interface on page 11.2*).

Via DNP3 or Modbus

The demand and peak demand metering values are available via DNP3 and Modbus. See the Demand Metering and Peak (Demand) Metering section of *Table G.1*.

The DNP3 binary output DRST_DEM and DRST_PDM can be used to reset the demand metering and peak demand metering, respectively. These controls are similar in function to the **MET RD** and **MET RP** commands. See *Appendix E: DNP3 Communications* for more details.

The Modbus protocol can be used to reset the demand metering and peak demand metering, with functions similar to the **MET RD** and **MET RP** commands. There are two methods available:

➤ Writing to the Reset Demands or Reset Demand Peaks output coil.

➤ Writing a specific analog value to the RSTDAT register.

See *Appendix K: Modbus RTU and TCP Communications* for details.

Via Fast Meter or IEC 61850

The demand and peak demand metering values are available via Fast Meter and IEC 61850. See the Demand Metering and Peak (Demand) Metering section of *Table G.1*.

Reset Via SELOGIC Control Equation

The RST_DEM and RST_PDM SELOGIC control equation settings can be used to reset the demand metering and peak demand metering respectively. The relay resets the function when the setting first asserts (rising edge, e.g., a logical 0 to a logical 1 transition).

Wolfe

Example Application of RST_DEM and RST_PDM

A control scheme requires:

➤ Demand metering to be reset when control input IN106 asserts, or when SV12T asserts.

➤ Peak demand metering to be reset when control input IN106 asserts, or when remote bit RB14 asserts.

Make the logic settings in the Global settings of the relay:

RST_DEM = **R_TRIG IN106 OR R_TRIG SV12T**

RST_PDM = **R_TRIG IN106 OR R_TRIG RB14**

The "R_TRIG" rising edge operators ensure that a maintained logical 1 on IN106 does not prevent SV12T from resetting the demand metering, and does not prevent RB14 from resetting the peak demand metering.

NOTE: To avoid unexpected clearing of metering data, the proposed SELOGIC control equations should be tested to ensure they do not assert after relay power-up.

Demand Metering Updating and Storage

The SEL-651R-2 updates demand values approximately every two seconds.

The SEL-651R-2 stores peak demand values to nonvolatile storage once per day and overwrites the previous stored value if it is exceeded. Should the recloser control lose control power, it will restore the peak demand values saved by the relay at 23:50 hours on the previous day.

Demand metering peak recording is momentarily suspended when SELOGIC control equation setting FAULT is asserted (= logical 1). See the explanation for the FAULT setting in *Maximum/Minimum Metering Update and Storage on page 8.18*.

Energy Metering

If three-phase voltages signals are connected and the Global settings VYCONN, VZCONN, EPHANT, and VSELECT are properly made, the SEL-651R-2 provides energy metering for the following values:

$MWH_{A,B,C,3P}$	IN	Single-phase and three-phase megawatt-hours, primary
$MWH_{A,B,C,3P}$	OUT	Single-phase and three-phase megawatt-hours, primary
$MVARH_{A,B,C,3P}$	IN	Single-phase and three-phase megavolt-ampere reactive hours, primary
$MVARH_{A,B,C,3P}$	OUT	Single-phase and three-phase megavolt-ampere reactive hours, primary

where IN and OUT correspond to the standard relay convention of OUT for positive power, and IN for negative power. Global setting CTPOL can change the direction of energy (and power) metering. See *Table 8.1*.

If a single-phase voltage is connected, and the settings VYCONN, VZCONN, and EPHANT are properly made, the same energy values are available by using the phantom voltage feature (see *Fundamental (Instantaneous) Metering on page 8.2*). Energy metering accuracy degrades when the phantom feature is used. The accuracy error is proportional to the amount of system load unbalance and the zero-sequence source impedance.

View or Reset Energy Metering Information

Via Serial Port

The **MET E** command displays accumulated single- and three-phase megawatt and megavolt-ampere reactive hours. The **MET RE** command resets the accumulated single- and three-phase megawatt and megavolt-ampere reactive hours (see *MET Command (Metering Data) on page 10.57*, *MET E (Energy Metering) on page 10.60*).

Via Front Panel

The information and reset functions available via the previously discussed serial port commands **MET E** and **MET RE** are also available via the front-panel menu (see *Human-Machine Interface on page 11.2*).

Via DNP3 or Modbus

The energy metering values are available via DNP3 and Modbus. See the Energy Metering section of *Table G.1*.

The DNP3 binary output DRST_ENE can be used to reset the energy metering, and is similar in function to the **MET RE** command (see *Appendix E: DNP3 Communications*).

The Modbus protocol can be used to reset the energy metering, with functions similar to the **MET RE** command. Two methods are available:

➤ Writing to the Reset Energy Data output coil.

➤ Writing a specific analog value to the RSTDAT register.

See *Appendix K: Modbus RTU and TCP Communications* for details.

Via IEC 61850

The energy metering values are available via IEC 61850. See the Energy Metering section of *Table G.1*.

Reset Via SELᴏɢɪᴄ Control Equation

The RST_ENE SELOGIC control equation setting can be used to reset the energy metering. The relay resets the function when the setting first asserts (rising edge, e.g., a logical 0 to a logical 1 transition).

Example Application of RST_ENE

NOTE: To avoid unexpected clearing of metering data, the proposed SELOGIC control equation should be tested to ensure it does not assert after relay power-up.

A control scheme requires energy metering to be reset when control input IN105 asserts, or when SV11T asserts.

Make the logic settings in the Global settings of the relay:

RST_ENE = **R_TRIG IN105 OR R_TRIG SV11T**

The "R_TRIG" rising edge operators ensure that a maintained logical 1 on IN105 does not prevent SV11T from resetting the energy metering.

Metering and Monitoring 8.17
Maximum/Minimum Metering

Energy Metering Updating and Storage

The SEL-651R-2 updates energy values approximately every two seconds.

The SEL-651R-2 stores energy values to nonvolatile storage once per day and overwrites the previous stored value. Should the recloser control lose control power, it will restore the energy values saved by the relay at 23:50 hours on the previous day.

Accumulated energy metering values function like those in an electromechanical energy meter. When the energy meter reaches 99999.999 MWh or 99999.999 MVARh, the SEL-651R-2 starts over at zero.

Maximum/Minimum Metering

The SEL-651R-2 includes a Maximum/Minimum metering function that records the excursions of certain fundamental metering quantities (see below). The date and time stamps at which each quantity reached its maximum and minimum value are also reported.

View or Reset Maximum/Minimum Metering Information

Via Serial Port

The **MET M** command displays Maximum/Minimum metering for the following values (see *MET M (Maximum/Minimum Metering) on page 10.61*):

Currents

$I_{A,B,C,N}$	Input currents (A primary)
I_G	Ground Current (A primary; IG = IN or 3I0, see *Ground Switch Option on page 8.3*)

Voltages

V_AY, V_BY, V_CY	Input voltages, Y-terminals (kV primary)
V_AZ, V_BZ, V_CZ	Input voltages, Z-terminals (kV primary)

Power

MW_{3P}	Three-phase megawatts
$MVAR_{3P}$	Three-phase megavolt-amperes reactive
MVA_{3P}	Three-phase megavolt-amperes

NOTE: If Global setting EPHANT := VY, the Y-terminal voltages are replaced by the calculated phantom voltages. Similarly, if EPHANT := VZ, the Z-terminal voltages are replaced by the calculated phantom voltages (see Phantom Voltage Function on page 8.4).

The **MET RM** command resets the Maximum/Minimum metering values.

The MW and MVAR maximum and minimum values can be negative or positive, indicating the range of power flow that has occurred since the last **MET RM** reset command. These functions simulate analog meter drag-hands, with the maximum value representing the upper drag-hand and the minimum value representing the lower drag-hand.

Table 8.4 shows the values that the recloser control would record for various power flow directions (either MW3P or MVAR3P).

8.18 | Metering and Monitoring
Maximum/Minimum Metering

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 410 of 1080
Wolfe

Table 8.4   Operation of Maximum/Minimum Metering With Directional Power Quantities

If Power Varies		Recorded MAX	Recorded MIN
From:	To:		
9.7	16.2	16.2	9.7
–4.2	1.4	1.4	–4.2
–25.3	–17.4	–17.4	–25.3
–6.2	27.4	27.4	–6.2

(For simplicity, the date and time stamps are not shown here.)

Via Front Panel

The metering and reset functions available via serial port commands **MET M** and **MET RM** are also available via the front-panel menu (see *Human-Machine Interface on page 11.2*).

Reset Via DNP3 or Modbus Control

The DNP3 binary output DRST_MML can be used to reset the Maximum/Minimum metering, and is similar in function to the **MET RM** command (see *Appendix E: DNP3 Communications*).

The Modbus protocol can be used to reset the Maximum/Minimum metering, with methods that are similar in function to the **MET RM** command. Two methods are available:

➤ Writing to the Reset Max/Min output coil.

➤ Writing a specific analog value to the RSTDAT register.

See *Appendix K: Modbus RTU and TCP Communications* for details.

Reset Via SELᴏɢɪᴄ Control Equation

The RST_MML SELᴏɢɪᴄ control equation setting can be used to reset the Maximum/Minimum metering. The relay resets the function when the setting first asserts (rising edge, e.g., a logical 0 to a logical 1 transition).

Example Application of RST_MML

A control scheme requires Maximum/Minimum metering to be reset when control input IN104 asserts, or when SV10T asserts.

Make the logic settings in the Global settings of the relay:

RST_MML = **R_TRIG IN104 OR R_TRIG SV10T**

The R_TRIG rising edge operators ensure that a maintained logical 1 on IN104 does not prevent SV10T from resetting the energy metering.

NOTE: To avoid unexpected clearing of metering data, the proposed SELᴏɢɪᴄ control equation should be tested to ensure it does not assert after relay power-up.

Maximum/Minimum Metering Update and Storage

The maximum/minimum metering function is intended to reflect normal load variations rather than fault conditions or outages. Therefore, the SEL-651R-2 updates maximum/minimum values only if Global SELᴏɢɪᴄ setting FAULT is deasserted (= logical 0) and has been deasserted for at least 3600 cycles.

The factory-default setting is set with time-overcurrent element pickups:

FAULT := **51P OR 51G1**

If there is a fault, 51P or 51G1 asserts and blocks updating of maximum/minimum metering values.

In addition to FAULT being deasserted for at least 3600 cycles, the following conditions must also be met:

➤ For voltage values V_AY, V_BY, V_CY, V_AZ, V_BZ, and V_CZ, the voltage is above the threshold: 25.0 V secondary (300 V base).

➤ For phase current values I_A, I_B, and I_C, the current is above the threshold: 0.01 A secondary.

➤ For neutral current value I_N, the current is above the threshold: 2 mA secondary.

➤ For ground current value I_G:

All three-phase currents I_A, I_B, and I_C are above threshold.

➤ For power values MW_{3P}, $MVAR_{3P}$, and MVA_{3P}:

All three-phase currents I_A, I_B, and I_C are above threshold, and the required voltages V_AY, V_BY, V_CY, or V_AZ, V_BZ, and V_CZ (depending on the EPHANT or VSELECT Global settings) are above threshold (see *Phantom Voltage Function on page 8.4*).

➤ The metering value is above the previous maximum or below the previous minimum for approximately one second.

The SEL-651R-2 stores maximum/minimum values to nonvolatile storage once per day and overwrites the previous stored value if that is exceeded. If the recloser control loses control power, it will restore the maximum/minimum values saved at 23:50 hours on the previous day.

Note: The values used by the maximum/minimum metering are the same fundamental metering values as used in the instantaneous metering function. The maximum/minimum metering function updates approximately twice per second. These values should be relatively immune to transient conditions.

Small-Signal Cutoff for Metering

Global setting METHRES controls how various metering functions respond when the metered value is small. Set METHRES to Y, N or E as explained below.

METHRES = Y

Make Global setting METHRES = Y to force instantaneous current and voltage metered values to zero when the applied signal is less than the values shown in *Table 8.5*.

Table 8.5 Metering Thresholds (Secondary Units)

Channels:	Metering Threshold
IA, IB, IC	0.005 A
IN	0.001 A
VAY, VBY, VCY VAZ, VBZ, VCZ	0.1 V (300 V nominal inputs)

VOLTAGE METERING THRESHOLDS
Calculate the metering threshold for 8 Vac LEA voltage inputs by using the threshold value 0.1 V as shown in Table 8.5:
$0.0027 \text{ V} = 0.1 \text{ V} \cdot (8/300)$

Threshold values for other LEA voltage inputs are calculated similarly. See Voltage-Related Settings and LEA Inputs (Group Settings) on page 9.47 for more information.

8.20 | Metering and Monitoring
Small-Signal Cutoff for Metering

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 412 of 1080
Wolfe

The metered values are forced to zero on a phase-by-phase basis. For example, if IA is below the applicable threshold shown in *Table 8.5* but IB, IC, and IN are all above their respective thresholds, then the fundamental magnitude and angle for IA are forced to zero, but the metered values for IB, IC, and IN are unchanged.

When a fundamental value is forced to zero, other metering displays are also impacted. In the above example, the A-phase current inputs to metered sequence values, power calculations, demand calculations, and energy calculations are also forced to zero. The changes impact all nonharmonic meter reports available from any interface on the relay including ASCII reports, the webpages, Fast Meter reports, etc. The changes do not affect harmonics metering, protection, synchrophasors, or event reporting.

METHRES = N

Make Global setting METHRES = N to disable all meter threshold checks. When METHRES = N, some energy may be accumulated and some small value is input to the demand models even if the breaker is open.

METHRES = E

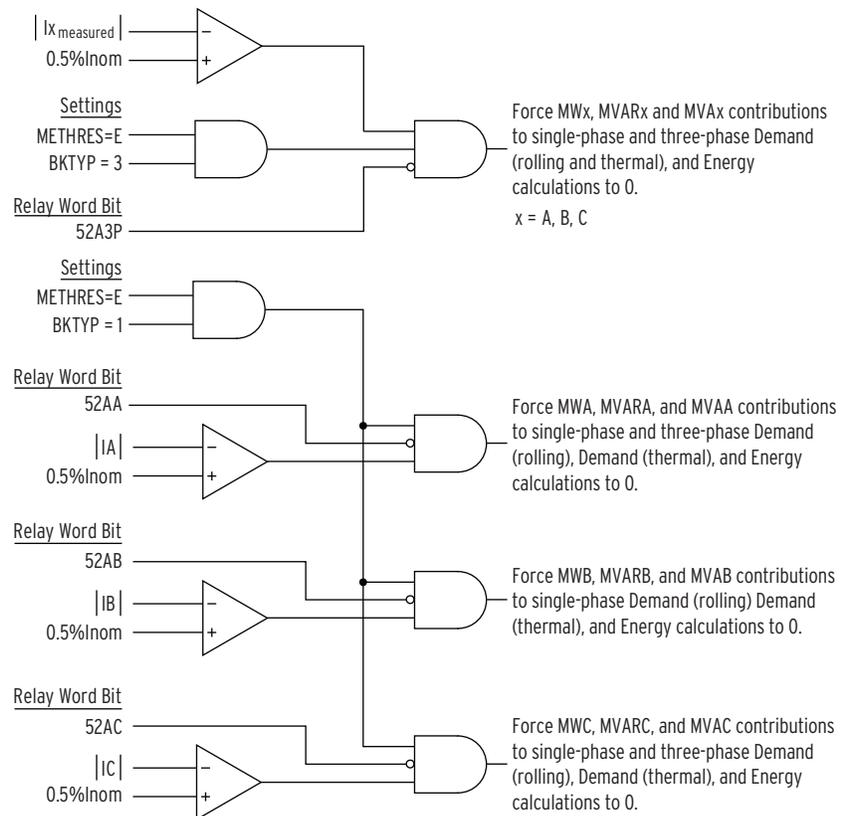
Make Global setting METHRES = E to force the inputs to the energy and power demand calculations to zero when currents drop below the thresholds shown in *Table 8.5* and when Relay Word bits 52AA, 52AB, 52AC, or 52A3P = 0. If 52AA, 52AB, 52AC, or 52A3P = 1 or current is above the levels shown in *Table 8.5*, then energy and power demand metering continue unaffected by any threshold check (see *Figure 8.6*). METHRES = E only impacts power demand and energy metering. Fundamental metering and current demand metering are not affected. Metered voltages are never forced to zero when METHRES = E.


Figure 8.6   Metering Threshold Logic for Energy and Demand Metering

Harmonics and True RMS Metering

The SEL-651R-2 is capable of measuring signal distortions as high as the 16th harmonic on the ten analog input channels.

The signals connected to the SEL-651R-2 terminals I1, I2, I3, IN, V1Y, V2Y, V3Y, V1Z, V2Z, and V3Z are first conditioned by analog low-pass filters, and then sampled at 32 times per power system cycle and placed into internal quantities with the following names:

➤ IA, IB, IC, IN

➤ VAY, VBY, VCY

➤ VAZ, VBZ, VCZ

according to the Global settings IPCONN, VYCONN, and VZCONN. See *Current and Voltage Connections (Global Settings) on page 9.28* for more details.

Every two seconds, a 1024-sample data set from each channel is processed to calculate:

➤ Fundamental root-mean-square (rms) magnitude (1st harmonic, in primary units)

➤ Harmonic content *n*, where *n* = 2–16 (in percent of fundamental)

➤ Total Harmonic Distortion (THD)

➤ True rms magnitude (in primary units)

Additionally, if Global setting VSELECT ≠ OFF:

➤ Average real power (in primary MW) is calculated.

Harmonic Metering

The harmonic calculations are visible in the serial port **MET H** command and through the front-panel METER menu. See *Section 10: Communications* for a sample **MET H** command response and *Section 11: Front-Panel Operations*. This command includes the fundamental rms, true rms, and THD values for each quantity, along with the individual harmonics.

The fundamental rms magnitude value is expressed in A primary for the current channels (IA, IB, IC, and IN) and kV primary for the voltage channels.

The individual harmonics (2nd–16th) are expressed as a percentage of the fundamental, with an upper limit of 500 percent.

There is no dc component calculated.

To avoid calculating meaningless harmonics during outages, if the fundamental magnitude of a channel is less than shown in *Table 8.6*, the harmonics and the THD calculations are set to zero for that channel.

Table 8.6   Harmonic and THD Calculation Thresholds (Sheet 1 of 2)

Channel	Threshold
IA, IB, IC	Setting CTR • 1 A • 0.02
IN	Setting CTRN • 0.2 A • 0.02

8.22 | Metering and Monitoring
Synchrophasor Metering

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 414 of 1080
Wolfe

Table 8.6 Harmonic and THD Calculation Thresholds (Sheet 2 of 2)

Channel	Threshold
VAY, VBY, VCY	Setting PTRY • 300 V • 0.02
VAZ, VBZ, VCZ	Setting PTRZ • 300 V • 0.02

The THD quantities are available for control functions by using them in SELOGIC control equations as part of an analog comparison. See *Table 7.2* for details. The THD quantities are calculated using the formula:

$$\mathrm{THD}_q = \left(\sqrt{\left(\frac{\mathrm{True\ RMS}_q}{\mathrm{Fundamental\ RMS}_q} \right)^2 - 1} \right) \bullet 100$$

where *q* is the current or voltage quantity for which the THD is to be determined.

True RMS Metering

The true rms calculations are visible in the serial port **MET RMS** command and through the front-panel METER menu. The true rms value is expressed in A primary for the current channels (IA, IB, IC, and IN) and kV primary for the voltage channels. See *Section 10: Communications* for a sample **MET RMS** command response and *Section 11: Front-Panel Operations*.

The rms meter calculations include the average per-phase and three-phase real power in primary MW based on currents IA, IB, and IC, and voltages VAY, VBY, and VCY if Global setting VSELECT := VY; and voltages VAZ, VBZ, and VCZ if Global setting VSELECT := VZ. The phantom voltage setting, EPHANT, has no effect on the average power calculations.

The true rms calculations are based on the same 1024-sample data set that is used in the harmonics calculations. The true rms values are scalar quantities, therefore no phase angle or polarity sign is included.

The true rms current and voltage readings will differ from the fundamental rms magnitude calculated in the harmonics metering function if there is any harmonic energy content in the signal.

NOTE: When testing the SEL-651R-2, remember that the SEL-651R-2 protection functions (overcurrent elements, undervoltage elements, etc.) are based on fundamental rms values, not true rms values.

Similarly, the average power quantities will differ from the fundamental power quantities when there is harmonic energy in voltage or current signals. The average power quantities are directional, so they are affected by the Global CT Polarity setting CTPOL (see *Table 8.1*).

Synchrophasor Metering

View Synchrophasor Metering Information Via Serial Port

The **MET PM** command (see *MET PM (Synchrophasor Metering) on page 10.62*) displays the synchrophasor measurements. For more information, refer to *View Synchrophasors by Using the MET PM Command on page J.17*.

High-Impedance Fault Metering
Wolfe

High-Impedance Fault Metering

View HIF Metering Information Via Command Line (Only Available in Relays That Support Arc Sense Technology)

The relay provides high-impedance fault detection data through the **MET HIF** command. The **MET HIF** command displays the instantaneous high-impedance alarm and fault detection values for each phase (ALG2. A, ALG2. B, and ALG2. C) as a percentage of their final pickup value. When an instantaneous value reaches 100 percent, the associated alarm/fault Relay Word bit (HIA2_A, HIA2_B, HIA2_C, HIF2_A, HIF2_B, or HIF2_C) asserts. The **MET HIF** command is available at Access Level 1 or higher. The command supports an optional number parameter 1–32767 that repeats the command the specified number of times.

If high-impedance fault detection is not enabled (EHIF = N), the response to the **MET HIF** command is "HIF Not Enabled". If high-impedance fault detection is enabled (EHIF = Y) and any of the initial tuning Relay Word bits, ITUNE_A, ITUNE_B, or ITUNE_C, are asserted, the response is "HIF Algorithm Tuning in Progress". The initial tuning period is 24 hours. (See *High-Impedance Fault Detection (Arc Sense Technology) on page 4.111* for details on high-impedance fault detection.)

Issuing the **MET HIF** command will display the following information, when the command is available:

```
=>>MET HIF <Enter>

FEEDER 1                        Date: 07/31/2012  Time: 16:21:25.256
STATION A                       Time Source: internal

Alarm (%)   18.59      34.78      12.56
Fault (%)   14.89      15.46       7.55
```

Breaker/Recloser Contact Wear Monitor

The breaker/recloser contact wear monitor in the SEL-651R-2 provides information that helps in scheduling circuit breaker or recloser maintenance. This monitoring function accumulates the number of internal and external trip operations and integrates the number of close-open operations and the per-phase current during each opening operation. The SEL-651R-2 compares the integrated close-open information to a predefined breaker or recloser maintenance curve to calculate the percent contact wear on a per-phase basis. The SEL-651R-2 updates and stores the contact wear information and the number of trip operations in nonvolatile memory. You can view this information through the front-panel display and by communicating with the SEL-651R-2 through any serial communications port with a computer.

Individual phase Breaker Contact Wear bits, BCWA, BCWB, and BCWC, assert when the contact wear percentage on their respective phases reaches 100 percent. You can use these individual phase elements or the combined result of these elements, BCW (which asserts when BCWA or BCWB or BCWC assert), in a SELOGIC control equation to alarm or control other functions, such as block reclosing.

Involved phase and ground/earth fault information is also tabulated for each breaker or recloser operation.

8.24 Metering and Monitoring
Breaker/Recloser Contact Wear Monitor

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 416 of 1080
Wolfe

This feature will be called "breaker monitor" for the remainder of this section and elsewhere in this instruction manual, except where a distinction must be made between breakers and reclosers.

The breaker monitor is enabled with the Global setting:

EBMON := **Y**

The breaker monitor settings in *Table 8.7* are available via the **SET G** command (see *Table 9.1*, the settings sheets at the end of *Section 9*, and *BRE Command (Breaker Monitor Data) on page 10.40*).

When setting EBMON := N, the breaker monitor is disabled from accumulating any new data. Any data previously recorded are unaffected and can still be accessed.

The breaker monitor is set with breaker or recloser maintenance information provided by the switchgear manufacturer. This breaker maintenance information lists the number of close/open operations that are permitted for a given current interruption level.

MULTI-RECLOSER INTERFACE
The BKMONx setting values in Table 9.15 are automatically set (and hidden), according to Global setting IPCONN, for the Multi-Recloser Interface on page 2.93.

Table 8.7   Breaker Monitor Settings and Settings Ranges

Setting	Definition	Range
COSP1	Close/Open set point 1—maximum	0–65000 close/open operations
COSP2	Close/Open set point 2—middle	0–65000 close/open operations
COSP3	Close/Open set point 3—minimum	0–65000 close/open operations
KASP1	kA Interrupted set point 1—minimum	0.00–999.00 kA in 0.01 kA steps
KASP2	kA Interrupted set point 2—middle	0.00–999.00 kA in 0.01 kA steps
KASP3	kA Interrupted set point 3—maximum	0.00–999.00 kA in 0.01 kA steps
BKMON3P BKMONA BKMONB BKMONC	SELOGIC control equation breaker monitor initiation settings	Relay Word bits referenced in *Appendix F: Relay Word Bits*

Setting notes:

➤ COSP1 must be set greater than COSP2.

➤ COSP2 must be set greater than or equal to COSP3.

➤ KASP1 must be set less than KASP2.

➤ If COSP2 is set the same as COSP3, then KASP2 must be set the same as KASP3.

➤ KASP3 must be set at least 5 times (but no more than 100 times) the KASP1 setting value.

➤ KASP2 must be set less than or equal to KASP3.

Table 8.8 lists the breaker monitor setting values for several common three-phase recloser types. Make the six settings (COSP1, COSP2, COSP3, KASP1, KASP2, and KASP3) in the Global settings after setting EBMON := Y.

VSO12	VACUUM	12000	10000	80	0.48	12.00
VSO16	VACUUM	16000	10000	80	0.64	16.00
G&W Viper-S or Viper-ST 15.5 or 27 kV	VACUUM	12500	10000	2510 64	1.25	2.00 12.50
G&W Viper-S or Viper-ST 38 kV	VACUUM	12000	10000	100	1.25	12.00

The parameters in *Table 8.8* are derived from ANSI C37.61-1973/IEEE Standard 321-1973, IEEE Standard Guide for the Application, Operation, and Maintenance of Automatic Circuit Reclosers.

For example, if the SEL-651R-2 is connected to a type WVE27 Recloser, use the **SET G** command to enter and save the following Global settings for the breaker wear monitor:

EBMON := **Y**

COSP1 := **10000**

COSP2 := **20**

COSP3 := **20**

KASP1 := **0.10**

KASP2 := **8.00**

KASP3 := **8.00**

MULTI-RECLOSER INTERFACE
The BKMONx setting values in Table 9.15 are automatically set (and hidden), according to Global setting IPCONN, for the Multi-Recloser Interface on page 2.93. Also, Global setting BKTYP is automatically set to BKTYP := 1 (and hidden) for the Multi-Recloser Interface.

If single-phase reclosers or breakers are connected to the SEL-651R-2, make Global setting BKTYP := 1. The same breaker monitor settings (COSP1, COSP2, COSP3, KASP1, KASP2, and KASP3) are used for all three phases.

Page 418 of 1080
Wolfe

The remaining breaker monitor settings are the SELOGIC control equations that control when the breaker monitor function accumulates data. These settings are BKMON3P for three-phase breakers, and BKMONA, BKMONB, and BKMONC for single-phase breakers (see *Operation of SELOGIC Control Equation Breaker Monitor Initiation Settings on page 8.29*).

Breaker Monitor Setting Example

If your recloser is not included in *Table 8.8*, or you adapt the SEL-651R-2 to operate a breaker, you can create a contact wear monitor curve for your specific breaker or recloser. The breaker/recloser contact wear monitor is set with breaker or recloser maintenance information provided by the switchgear manufacturer. This maintenance information lists the number of close/open operations that are permitted for a given current interruption level. The following is an example of breaker maintenance information for a 25 kV circuit breaker.

Table 8.9   Breaker Maintenance Information for a 25 kV Circuit

Current Interruption Level (kA)	Permissible Number of Close/Open Operations[a]
0.00–1.20	10,000
2.00	3,700
3.00	1,500
5.00	400
8.00	150
10.00	85
20.00	12

[a] The action of a circuit breaker closing and then later opening is counted as <u>one</u> close/open operation.

The breaker maintenance information in *Table 8.9* is plotted in *Figure 8.7*.

Connect the plotted points in *Figure 8.7* for a breaker maintenance curve. To estimate this breaker maintenance curve in the SEL-651R-2 breaker monitor, enter three set points:

Set Point 1—*maximum* number of close/open operations with corresponding current interruption level.

Set Point 2— number of close/open operations that correspond to some *midpoint* current interruption level.

Set Point 3— number of close/open operations that correspond to the *maximum* current interruption level.

Enter these three points with the settings in *Table 8.7*.

The following settings are made from the breaker maintenance information in *Table 8.9* and *Figure 8.7*:

COSP1 := **10000**

COSP2 := **150**

COSP3 := **12**

KASP1 := **1.20**

KASP2 := **8.00**

KASP3 := **20.00**

Figure 8.8 shows the resultant breaker maintenance curve.

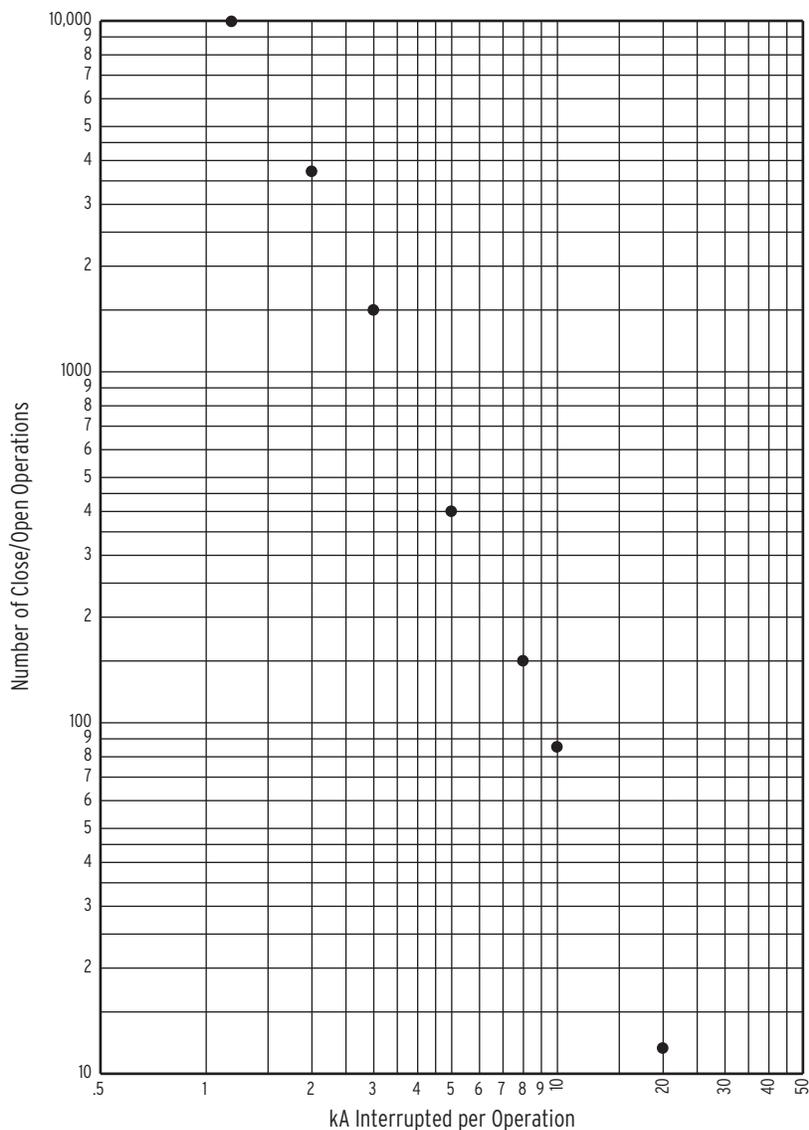
Page 419 of 1080
Metering and Monitoring 8.27
Breaker/Recloser Contact Wear Monitor
Wolfe


Figure 8.7   Plotted Breaker Maintenance Points for a 25 kV Circuit Breaker

Breaker Maintenance Curve Details

In *Figure 8.8*, note that set points KASP1, COSP1 and KASP3, COSP3 are set with breaker maintenance information from the two extremes in *Table 8.9* and *Figure 8.7*.

In this example, set point KASP2, COSP2 happens to be from an in-between breaker maintenance point in the breaker maintenance information in *Table 8.9* and *Figure 8.7*, but it does not have to be. Set point KASP2, COSP2 should be set to provide the best curve-fit with the plotted breaker maintenance points in *Figure 8.7*.

Regardless of the type of circuit breaker or recloser connected to the SEL-651R-2 (single-phase or three-phase), each phase (A, B, and C) has its own breaker maintenance curve (like that in *Figure 8.8*) because the separate circuit breaker interrupting contacts for phases A, B, and C do not necessarily interrupt the same magnitude current, depending on fault type and loading.

8.28 Metering and Monitoring
Breaker/Recloser Contact Wear Monitor

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 420 of 1080
Wolfe

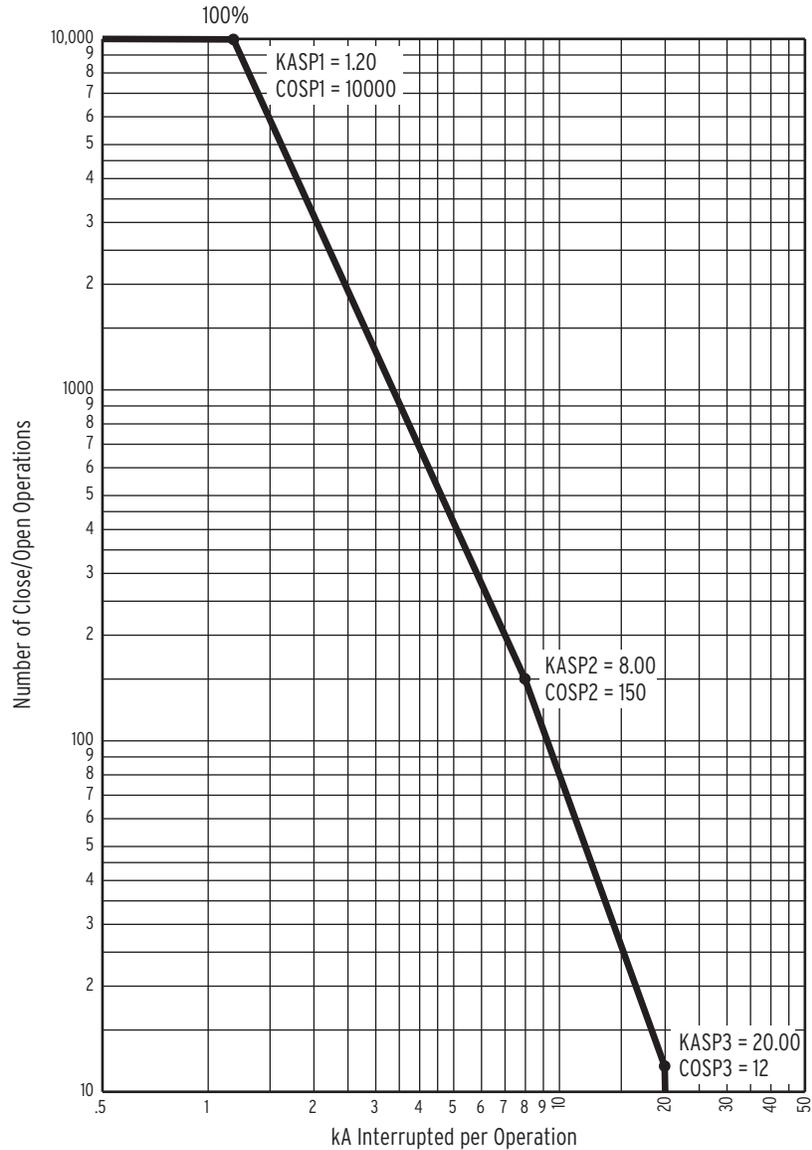
Also, in the case of single-phase breakers or reclosers, one or two phases may not even operate for certain faults, and the contacts and mechanisms are not subjected to any wear.


Figure 8.8   SEL-651R-2 Breaker Maintenance Curve for a 25 kV Circuit Breaker

In *Figure 8.8*, note that the breaker maintenance curve levels off horizontally below set point KASP1, COSP1. This is the close/open operation limit of the circuit breaker (COSP1 = 10000), regardless of interrupted current value.

Also, note that the breaker maintenance curve falls vertically above set point KASP3, COSP3. This is the maximum interrupted current limit of the circuit breaker (KASP3 = 20.00 kA). If the interrupted current is greater than setting KASP3, the interrupted current is accumulated as a current value equal to setting KASP3.

Metering and Monitoring   8.29
Breaker/Recloser Contact Wear Monitor

Operation of SELOGIC Control Equation Breaker Monitor Initiation Settings

The SELOGIC control equation breaker monitor initiation settings BKMON3P, BKMONA, BKMONB, and BKMONC in *Table 8.7* determine when the breaker monitor reads in current values (Phases A, B, and C) for the breaker maintenance curve (see *Figure 8.8*) and the breaker monitor accumulated currents/trips and involved phase/ground counters (see *BRE Command (Breaker Monitor Data) on page 10.40*).

As previously described, separate breaker wear models are maintained for each of the three power system phases. These models are independently triggered when single-phase breakers are connected, and are triggered together when three-phase breakers are connected.

When a **three-phase recloser or breaker is connected**, Global setting BKTYP must be set to 3 (see *Section 9: Settings*). When BKTYP :=3, Global setting BKMON3P is the only breaker monitor initiation setting that can be made. BKMON3P controls the breaker monitor logic for all three phases.

When **single-phase capable reclosers or breakers are connected**, Global setting BKTYP must be set to 1. When BKTYP :=1, global breaker monitor initiation settings BKMONA, BKMONB, and BKMONC can be accessed. These settings control the breaker monitor logic for each phase separately. These three settings are present even if single-phase tripping is not employed. In this case, they should be set to operate together, as shown in a later subsection. Setting BKMON3P is not available when BKTYP := 1.

Regardless of which type of breaker is in use, the three breaker monitor models act similarly, and will be described once using "BKMON*p*" in place of BKMON3P, BKMONA, BKMONB, and BKMONC to avoid repeating the same information (*p* = 3P, A, B, or C).

The BKMON*p* setting looks for a rising edge (logical 0 to logical 1 transition) as the indication to read in current values. The acquired current values are then applied to the breaker maintenance curve and the breaker monitor accumulated currents/trips.

In the factory-default settings, the SELOGIC control equation breaker monitor initiation setting is set:

BKMONA := **RCTR1X**   (RCTR1X is the logic output of *Figure 7.26*)

BKMONB := **RCTR2X**   (RCTR2X is the logic output of *Figure 7.26*)

BKMONC := **RCTR3X**   (RCTR3X is the logic output of *Figure 7.26*)

These settings must be modified in certain installations. The recommended settings for BKMON*p* are covered in *Breaker Monitor Initiate Settings (Global Settings) on page 9.38*.

When BKMON*p* asserts (Relay Word bit RCTR_X goes from logical 0 to logical 1), the breaker monitor reads in the current values and applies them to the breaker monitor maintenance curve and the breaker monitor accumulated currents/trips (refer to *Figure 8.9*).

As detailed in *Figure 8.9*, the breaker monitor actually reads in the current values one cycle after the assertion of BKMON*p*. This helps especially if an instantaneous trip occurs. The instantaneous element trips when the fault current reaches its pickup setting level. The fault current may still be climbing to its full value, at which it levels off. The one-cycle delay on reading in the current values allows time for the fault current to level off.

Attachment to Response to AG-2 Question No. 68(g)
Page 422 of 1080
Wolfe

Figure 8.9   Operation of SELOGIC Control Equation Breaker Monitor Initiation Setting

See *Figure 8.14* and accompanying text for more information on setting BKMON*p*. The operation of the breaker monitor maintenance curve, when new current values are read in, is explained in the following example.

Breaker Monitor Operation Example

As stated earlier, each phase (A, B, and C) has its own breaker maintenance curve. For this example, presume that the interrupted current values occur on a single phase in *Figure 8.10–Figure 8.13*. Also, presume that the circuit breaker interrupting contacts have no wear at first (brand new or recent maintenance performed).

Note that in *Figure 8.10–Figure 8.13* the interrupted current in a given figure is the same magnitude for all the interruptions. For example, in *Figure 8.11*, 2.5 kA is interrupted 290 times. This is not realistic, but helps in demonstrating the operation of the breaker maintenance curve and how it integrates for varying current levels.

0–10 Percent Breaker Wear

Refer to *Figure 8.10*. Current value 7.0 kA is interrupted 20 times (20 close/open operations = 20 – 0), pushing the breaker maintenance curve from the 0 percent wear level to the 10 percent wear level.

Compare the 100 percent and 10 percent curves and note that for a given current value, the 10 percent curve has only 1/10 of the close/open operations of the 100 percent curve.

10–25 Percent Breaker Wear

Refer to *Figure 8.11*. The current value changes from 7.0 kA to 2.5 kA, and 2.5 kA is interrupted 290 times (290 close/open operations = 480 –190), pushing the breaker maintenance curve from the 10 percent wear level to the 25 percent wear level.

Compare the 100 percent and 25 percent curves and note that for a given current value, the 25 percent curve has only 1/4 of the close/open operations of the 100 percent curve.

25–50 Percent Breaker Wear

Refer to *Figure 8.12*. The current value changes from 2.5 kA to 12.0 kA, and 12.0 kA is interrupted 11 times (11 close/open operations = 24 – 13), pushing the breaker maintenance curve from the 25 percent wear level to the 50 percent wear level.

Compare the 100 percent and 50 percent curves and note that for a given current value, the 50 percent curve has only 1/2 of the close/open operations of the 100 percent curve.

Attachment to Response to AG-2 Question No. 68(g)
Page 402 of 1080
Metering and Monitoring   8.31
Breaker/Recloser Contact Wear Monitor
Wolfe

50–100 Percent Breaker Wear

Refer to *Figure 8.13*. The current value changes from 12.0 kA to 1.5 kA, and 1.5 kA is interrupted 3000 times (3000 close/open operations = 6000 – 3000), pushing the breaker maintenance curve from the 50 percent wear level to the 100 percent wear level.

When the breaker maintenance curve reaches 100 percent for a particular phase, the percentage wear remains at 100 percent (even if additional current is interrupted), until reset by the **BRE R** command (see *View or Reset Breaker Monitor Information on page 8.36*). But the current and trip counts continue to be accumulated, until reset by the **BRE R** command.

Additionally, logic outputs assert for alarm or other control applications; see the following discussion.

Breaker Monitor Output

When the breaker maintenance curve for a particular phase (A, B, or C) reaches the 100 percent wear level (see *Figure 8.13*), a corresponding Relay Word bit (BCWA, BCWB, or BCWC) asserts.

Relay Word Bits	Definition
BCWA	Phase A breaker contact wear has reached the 100 percent wear level
BCWB	Phase B breaker contact wear has reached the 100 percent wear level
BCWC	Phase C breaker contact wear has reached the 100 percent wear level
BCW	BCWA OR BCWB OR BCWC

Example Applications

These logic outputs can be used to alarm:

OUT105 := **BCW**.

or to drive the recloser control to lockout the next time the recloser control trips:

79DTL3X := **TRIP3P AND BCW**. three-phase application

View or Reset Breaker Monitor Information

Accumulated breaker wear/operations data are retained if the recloser control loses power or the breaker monitor is disabled (setting EBMON := N). The accumulated data can only be reset if the **BRE R** command is executed; see the following discussion on the **BRE R** command.

Via Serial Port

The **BRE** command displays the following information (see *BRE Command (Breaker Monitor Data) on page 10.40*):

➤ Accumulated number of internal (recloser control) initiated trips

➤ Accumulated interrupted current from internal (recloser control) initiated trips

➤ Accumulated number of externally initiated trips

➤ Accumulated interrupted current from externally initiated trips

➤ Percent circuit breaker contact wear for each phase

➤ Accumulated number of trips involving A-phase, B-phase, and C-phase

➤ Accumulated number of trips involving ground (G)

➤ Date when the preceding items were last reset (via the **BRE R** command)

The **BRE W** command allows the trip counters, accumulated values, percent breaker wear, and involved phase/ground counters to be preloaded for each individual phase (see *BRE Command (Breaker Monitor Data) on page 10.40*).

The **BRE R** command resets the accumulated values and the percent wear for all three phases. For example, if breaker contact wear has reached the 100 percent wear level for A-phase, the corresponding Relay Word bit BCWA

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Metering and Monitoring 8.37
Page 1429 of 2102
Breaker/Recloser Contact Wear Monitor
Wolfe

asserts (BCWA = logical 1). Execution of the **BRE R** command resets the wear levels for all three phases back to 0 percent and consequently causes Relay Word bit BCWA to deassert (BCWA = logical 0).

Via Front Panel

The information and reset functions available via the previously discussed serial port commands **BRE** and **BRE R** are also available via the front-panel menu entry Monitor (see *SEL-651R-2 Menu on page 11.5*).

Determination of Internally Initiated Trips and Externally Initiated Trips

Note in the **BRE** command response that the accumulated number of trips and accumulated interrupted current are separated into two groups of data: those generated by *internally initiated trips* (Internal Trips) and those generated by *externally initiated trips* (External Trips). The categorization of these data is determined by the status of the TRIPp Relay Word bit when the SEL$_{OGIC}$ control equation breaker monitor initiation setting BKMONp operates (see *BRE Command (Breaker Monitor Data) on page 10.40*).

Refer to *Figure 8.9* and accompanying explanation. If BKMONp newly asserts (logical 0 to logical 1 transition), the recloser control reads in the current values (Phases A, B, and C). Now the decision has to be made: is this current and trip count information accumulated under *internally initiated trips* or *externally initiated trips*?

To make this determination, the status of the TRIPp Relay Word bit is checked at the instant BKMONp newly asserts (TRIPp is the logic output of *Figure 5.1*). If TRIPp is asserted (TRIPp = logical 1), the current and trip count information is accumulated under *internally initiated trips* (Int Trips). If TRIPp is deasserted (TRIPp = logical 0), the current and trip count information is accumulated under *externally initiated trips* (Ext Trips).

Regardless of whether the current and trip count information is accumulated under internally initiated trips or externally initiated trips, this same information is routed to the breaker maintenance curve for continued breaker wear integration (see *Figure 8.9–Figure 8.13*).

Internally initiated trips (Internal Trips) are also referred to as *Relay Initiated Trips* or *Control Initiated Trips*, and these terms are used interchangeably throughout this and other SEL instruction manuals.

Internal and External Trip Counters

When one of the BKMONp settings is newly asserted, the corresponding internal or external count is incremented using the method shown in the previous subsection to determine internal versus external trips.

To avoid multiple counting in single-phase trip applications, a new count is only recorded when a breaker is closed at the instant that the associated BKMONp setting asserts. For example, if the breaker on phase-B is already open and BKMONB asserts, the internal or external trip counter will not increment because the breaker was already open when BKMONB asserted. The Relay Word bits SPOA, SPOB, and SPOC are used to provide the breaker open status information.

8.38 | Metering and Monitoring
Breaker/Recloser Contact Wear Monitor

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 430 of 1080
Wolfe

Involved Phase and Ground Counters

The involved phase and ground counters are incremented whenever a current exceeds one of the time-overcurrent element settings one cycle after BKMONp asserts:

The A-phase counter is incremented if |IA| is greater than: 51PJP, 51PKP, 51AJP, or 51AKP.

The B-phase counter is incremented if |IB| is greater than: 51PJP, 51PKP, 51BJP, or 51BKP.

The C-phase counter is incremented if |IC| is greater than: 51PJP, 51PKP, 51CJP, or 51CKP.

The ground counter is incremented if |IG| is greater than: 51G1JP, 51G1KP, 51G2JP, or 51G2KP, and Relay Word bit SPO (single pole open) was deasserted at the rising edge of BKMONp.

If no time-overcurrent element pickup settings are enabled, this feature will not operate. To ensure that it operates, time-overcurrent element pickup values must be set, even if they are not used for tripping.

In single-phase tripping applications, if more than one of the BKMONp settings asserts, the phase involvement counters are updated one cycle after the first BKMONp setting asserts.

Factory-Default Setting Example

As discussed previously, the SELOGIC control equation breaker monitor initiation factory-default setting is:

BKMON3P := **RCTR1X** when BKTYP := 3

BKMONA := **RCTR1X** when BKTYP := 1

BKMONB := **RCTR2X** when BKTYP := 1

BKMONC := **RCTR3X** when BKTYP := 1

MULTI-RECLOSER INTERFACE
The BKMONx setting values in Table 9.15 are automatically set (and hidden), according to Global setting IPCONN, for the Multi-Recloser Interface on page 2.93. Also, Global setting BKTYP is automatically set to BKTYP := 1 (and hidden) for the Multi-Recloser Interface.

Thus, any new assertion of BKMONp will be deemed an internal trip, and the current and trip count information is accumulated under *internally initiated trips*.

Additional Example

Output contact OUT101 is set to provide tripping (refer to *Figure 8.14*):

OUT101 := **TRIP3P**

Note that optoisolated input IN106 monitors the trip bus. If the trip bus is energized by output contact OUT101, an external control switch, or some other external trip, then IN106 is asserted.

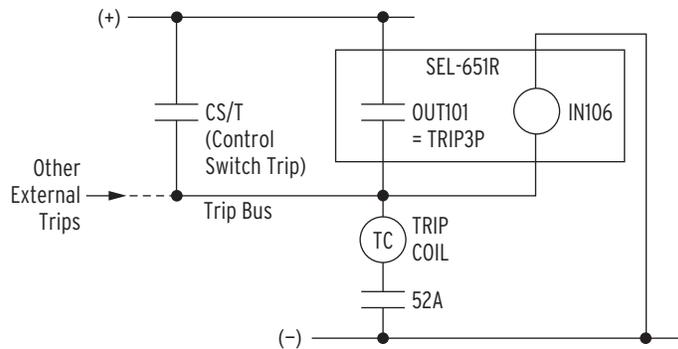
Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 1431 of 1080
Metering and Monitoring 8.39
Battery System Monitor
Wolfe


Figure 8.14   Input IN106 Connected to Trip Bus for Breaker Monitor Initiation

If the SELOGIC control equation breaker monitor initiation setting is set:

BKMON3P := **IN106**

then the SEL-651R-2 breaker monitor detects all trips.

If output contact OUT101 asserts, energizing the trip bus, the breaker monitor will deem it an *internally initiated trip*. This is because when BKMON3P is newly asserted (input IN106 energized), the TRIP3P Relay Word bit is asserted. Thus, the current and trip count information is accumulated under *internally initiated trips*.

If the control switch trip, or some other external trip, asserts, energizing the trip bus, the breaker monitor will deem it an *externally initiated trip*. This is because when BKMON3P is newly asserted (input IN106 energized), the TRIP3P Relay Word bit is deasserted. Thus, the current and trip count information is accumulated under *externally initiated trips*.

Battery System Monitor

NOTE: Units ordered with 125 Vdc or 48 Vdc power supplies do not contain a battery or the battery charging circuitry. These units will continuously assert the BTFAIL Relay Word bit, and some settings must be modified accordingly.

NOTE: If Global setting PWRDN_AC is changed while ac power is removed (SEL-651R-2 is operating off battery power), the new PWRDN_AC setting does not become active until the next loss of ac power. Likewise, if Global setting PWRDN_WU is changed while ac power is removed (SEL-651R-2 is operating off battery power), the new PWRDN_WU setting does not become active until the next press of the WAKE UP pushbutton.

The SEL-651R-2 monitors the internal battery system, which includes the battery charger and battery. This subsection describes how the battery system operates, how the battery system is automatically and manually checked, and what the SEL-651R-2 does when it detects a problem with the battery system.

The following settings are discussed in this subsection:

➤ Power-off Delay After AC Loss (OFF, 1–1440 min.)
PWRDN_AC := 180

➤ Power-off Delay After Wake Up (OFF, 1–1440 min.)
PWRDN_WU := 20

➤ Request Battery Test SELOGIC Control Equation
TESTBATT := NA

Battery System Monitor

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 432 of 1080
Wolfe

These Global settings are available via the **SET G** command, described in *Section 10: Communications*. The example setting values listed above will be used in the description that follows.

Battery System Operation

The 12 V lead-acid battery powers the SEL-651R-2 and provides trip and close power to the capacitors when the ac source is de-energized. The SEL-651R-2 includes a temperature-compensated 12 V battery charger powered from an external ac source. See *Section 1: Introduction and Specifications* for battery specifications.

When the ac source is energized, the SEL-651R-2 built-in battery monitor/charger controls charging current to the battery system. When ac power is present, the SEL-651R-2 will charge the battery in one of three modes:

➤ Constant current charge

➤ Fast charge

➤ Float charge

The transition between the charge modes is determined by measured battery current, voltage, temperature, and time spent in each mode.

The CHRGG Relay Word bit asserts when the battery is charging (when the ac source is energized). The DISCHG Relay Word bit asserts when the battery is discharging (when the ac source is de-energized and the SEL-651R-2 is operating from battery power).

The SEL-651R-2 tests the battery by subjecting it to a load test for 10 seconds. Relay Word bit DISTST asserts during a load test. If the battery voltage falls too low during the test, the discharge test failure Relay Word bit DTFAIL asserts. DTFAIL remains asserted until the next successful battery load test.

If the battery fails, or when you remove them temporarily during replacement, the ac source provides sufficient energy to trip and close most reclosers. However, the ac source voltage may dip significantly during a fault, reducing or eliminating the source voltage needed to power the SEL-651R-2 and trip the recloser. To counteract this, the SEL-651R-2 can ride through 0.5 seconds of ac source (and battery) loss. During this 0.5 seconds ride-through time, the SEL-651R-2 can still issue a trip—such a trip would likely be a high-current instantaneous or fast curve operation.

SEL-651R-2 Puts Itself to Sleep

If the ac source is de-energized, the SEL-651R-2 operates off battery power and initiates a countdown timer that starts with the Global setting value PWRDN_AC, in minutes. If the ac source does not re-energize before the countdown timer reaches zero, the SEL-651R-2 will shut itself off. The final action before the control shuts down is to make a Going to Sleep entry in the Sequential Events Records (SER) report. The example setting value of PWRDN_AC := 180 minutes provides a three-hour standby time before the unit shuts off.

The 12-volt dc auxiliary power source is also shut off whenever the SEL-651R-2 is off. See *+12 Vdc Auxiliary Power Supply on page 2.52* for details on the 12 Vdc power supply output.

This sleep feature allows the battery to be left in a partially charged state, rather than completely discharged, and allows power to be available for subsequent front-panel operator activities (see *Wake Up the SEL-651R-2*).

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 1433 of 1080
Metering and Monitoring   8.41
Battery System Monitor
Wolfe

When the countdown reaches one minute, the TOSLP (to sleep) Relay Word bit asserts and stays asserted, to allow some final control action to be taken before protection is disabled (see *Possible Application of TOSLP Relay Word Bit on page 8.41*).

During the ac outage, if the countdown timer has not reached 0 and the battery voltage drops too low, the control will be disabled and will shut off immediately to protect the battery. In this case, the TOSLP bit will not be asserted.

If ac power comes back after the TOSLP bit has asserted, but before the SEL-651R-2 shuts down, the TOSLP bit will be deasserted and the control will abort the countdown. If ac power fails again, the countdown timer will load with the PWRDN_AC setting and start over again.

Wake Up the SEL-651R-2

When the SEL-651R-2 is in the sleep mode, it wakes up when either of the following occurs:

➤ The ac source is re-energized

➤ The front-panel **WAKE UP** pushbutton is operated

After the SEL-651R-2 is awakened via the front-panel **WAKE UP** pushbutton, the SEL-651R-2 initiates a countdown timer that starts with the Global setting value PWRDN_WU, in minutes. If the ac source does not re-energize before the countdown timer reaches zero, the SEL-651R-2 will turn itself off.

The SEL-651R-2 will continue to operate on battery power until the countdown reaches zero. See the previous subsection for a description of the TOSLP Relay Word bit, which operates identically for the countdown timing after a wake-up operation. The example setting value of PWRDN_WU := 20 minutes provides a 20 minute standby time before the unit shuts off, unless the front panel is being used.

While ac is off, if a front-panel pushbutton is pressed and the present countdown is less than 15 minutes, the countdown timer is loaded with 15 minutes. This ensures that the control stays energized as long as an operator is using the front panel. If an operator is using a laptop computer to access data during an ac outage, a front-panel button (e.g., **ESC**) should be pressed periodically to ensure that the unit does not shut off before the data retrieval is completed.

If the SEL-651R-2 wakes up because the ac power source was energized and then de-energized before the SEL-651R-2 control completes the initialization routine, upon detecting that ac power is not present, it will function as if the **WAKE UP** pushbutton was pressed, described above.

If there is insufficient battery voltage when the **WAKE UP** pushbutton is pressed, the SEL-651R-2 will not wake up.

Possible Application of TOSLP Relay Word Bit

If allowed by system operating procedures, a possible application of the TOSLP Relay Word bit is to use it in a trip equation to open the recloser or circuit breaker. This action can improve the coordination on radial systems after the system is re-energized, because the line section beyond the SEL-651R-2 would be isolated while the recloser control is starting up.

Before tripping the breaker or recloser, a nonvolatile latch could be set to indicate that the recloser control performed the trip based on a loss of source power. When the power comes back on and the SEL-651R-2 initializes, it

8.42 | Metering and Monitoring
Battery System Monitor

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 434 of 1080
Wolfe

could reclose the breaker/recloser when it determines that the nonvolatile latch is in the asserted position. This function could be supervised by any Hot Line Tag or Reclose Block conditions.

Without this approach, the breaker or recloser is left in the closed position when the recloser control shuts down. The recloser control is then unable to protect the line for a few seconds after power is restored, while it performs the diagnostic checks that are part of its start-up sequence, which could lead to coordination difficulties if there is a fault on the load side of the recloser.

Battery System Diagnostics

The SEL-651R-2 monitors the 12 V battery system, including charge/discharge current, battery voltage, and temperature. The SEL-651R-2 automatically applies a battery load test approximately once per day and includes provisions to perform a battery load test via the serial communications ports or SELOGIC. You can obtain vital battery system information from the SEL-651R-2 status report via the front-panel and serial communications ports.

Automatic Battery Load Test

ISSUE STA C COMMAND AFTER REPLACING BATTERY
If the battery is replaced after a battery test failure, issue the **STA C** command to clear the battery test failure status.

The SEL-651R-2 automatically load tests the 12 V battery about every 24 hours. An internal 24-hour timer cumulatively times whenever the SEL-651R-2 is in the float-charge mode, such as when ac voltage is powering the SEL-651R-2 and charging the battery. Even if the battery is fully charged, the SEL-651R-2 maintains a low-rate charging current, so it is still in the float-charge mode.

If the 24-hour timer runs out and the SEL-651R-2 is still in the float-charge mode, the battery charger is shut off for ten seconds, which simulates an ac outage and tests the battery. If the battery voltage drops too quickly, the test is aborted and the DTFAIL Relay Word bit asserts. If the battery voltage is okay throughout the test period, the battery charger is turned back on.

Once the battery fails an automatic load test, automatic testing is no longer performed unless the battery tests successfully via one of the following described means (SELOGIC or serial port), or the battery is replaced.

Front-Panel Battery Load Test

Factory-Default Front-Panel Battery Load Test in Section 8: Metering and Monitoring in the SEL-651RA Recloser Control Instruction Manual details a front-panel battery load test capability that comes as a factory-default configuration for the SEL-651RA recloser control. Similar setting can be made for the SEL-651R-2 to realize such a battery load test capability with a front-panel operator pushbutton and the front-panel display. This capability came available for the SEL-651R-2 with the introduction of the DISTST Relay Word bit.

SELOGIC Battery Load Test

NOTE: If the TESTBATT equation is held in a continually asserted state (= logical 1), this will not impede initiation of the automatic battery load test nor the battery load test via serial port.

The Request Battery Test (TESTBATT) SELOGIC control equation is provided for entry of user-defined battery load test conditions. this function is useful for initiating a battery test from the front panel, at a set time of day, or remotely. This SELOGIC control equation is rising-edge qualified, meaning that it will only initiate a battery test when its state changes from logical 0 to 1. This prevents an asserted condition from continually initiating battery tests. Following a valid rising edge of the TESTBATT equation, the SEL-651R-2 will initiate a battery test if *all* of the following conditions are met.

Page 1435 of 1080

Metering and Monitoring   8.43
Battery System Monitor
Wolfe

➤ There is no battery test currently in progress.

➤ Battery charger is NOT in Discharge (ac off) or Startup (relay is starting up) mode.

➤ There have not been more than four battery tests in the last hour.

Battery Load Test via Serial Port

View the results of a battery test or request a new battery test by using the **BTT** or **BTT NOW** commands at the serial port.

See *BTT Command on page 10.41* for required serial port access levels and sample screen captures.

Battery Status

Check the battery status in several ways. On the front panel (with factory-default front-panel settings), the **BATTERY PROBLEM** LED (see *Figure 11.13*) illuminates when Relay Word bit BTFAIL is asserted. BTFAIL asserts for either of the following battery problems:

➤ Load test failure (Relay Word bit DTFAIL = logical 1)

➤ Cannot charge or is otherwise internally damaged

Use the STATUS menu on the front panel of the SEL-651R-2 to access more battery status information. Use the **Up Arrow** and **Down Arrow** pushbuttons to move to different status screens. Those status elements of interest for the battery are the following.

INPBV =	Input Power Bus Voltage (Vdc)
12VAUX =	12V Auxiliary Bus Voltage (Vdc)
MODE =	Battery Charger Mode
	STARTUP = Startup
	CUR_CHG = Constant Current Charge
	FST_CHG = Fast Charge
	FLT_CHG = Float Charge
	DISCHRG = Discharge
	BAT_FLR = Battery Failure
	BAT_TST = Battery Discharge Test
VBAT =	Battery Voltage (Vdc)
IBAT =	Battery Current (A dc, discharge if negative)
TCCAPV =	Trip/Close Capacitor Voltage (Vdc)

The same battery status information as described above is also available via serial port communications by using the **STATUS** command.

The battery voltage "VBAT" is also available as an analog quantity for use in the Load Profile Recorder (see *Table G.1*).

Include VBAT in the LDLIST setting (using the **SET R** command; see *Section 9: Settings*) to record the battery performance during source outages (see *Load Profile Report on page 8.44*).

Use the Sequential Events Recorder (see *Sequential Events Recorder (SER) on page 12.2*) to determine the moment that the power source outage began and ended, and the Load Profile Report to check the battery performance during the source outage.

Wolfe

Modifying Reclosing Logic

In addition to alarming, the recloser control elements associated with the battery and charging system can provide control functions such as disabling or blocking reclosing. For example, the factory-default logic settings include one of these following automatic reclose supervision settings:

Traditional
Retrofit reclosers: 79CLS3P := PWR_SRC1 AND TCCAP AND NOT(BTFAIL)

Other reclosers: 79CLS3P := TCCAP AND NOT(BTFAIL)

This is for three-phase trip applications (Group setting ESPB := N).

This SELOGIC control equation permits automatic reclosing to proceed after a reclose interval time out only if *all* the following conditions are present:

➤ (Traditional Retrofit reclosers only.) The AC voltage source is present; PWR_SRC1 = logical 1. This assumes the traditional installation where the low-voltage ac close power is wired to the same phase as the SEL-651R-2 power supply input (see *Figure 2.40*).

➤ The Trip and Close Capacitors are fully charged; TCCAP = logical 1.

➤ The Battery is healthy; BTFAIL = logical 0.

This is a factory-default setting because recloser tripping and closing require dc battery energy. Therefore, if the battery or charging system is not functioning properly, the control should not reclose after a trip because there might not be enough dc battery energy to trip again after a reclose.

Load Profile Report

The SEL-651R-2 Load Profile Recorder is capable of recording as many as 15 selectable analog quantities at a periodic rate and storing the data in a report in nonvolatile memory.

The load profile report is available via serial port communications by using the **LDP** command (see *LDP Command (Load Profile Report) on page 10.55*).

At the interval given by load profile acquisition rate setting LDAR, the recloser control adds a record to the load profile buffer. This record contains the time stamp, the present value of each of the analog quantities listed in the load profile list setting LDLIST, and a checksum. These settings are made and reviewed with the **SET R** and **SHO R** serial port commands, respectively. Setting LDAR can be set to any of the following values: 5, 10, 15, 30, and 60 minutes. Setting LDLIST may contain any of the quantities that are marked in the Load Profile column of *Table G.1* (see *Report Settings on page SET.64*).

Labels are entered into the setting as either comma or space delimited, but are displayed as comma delimited. Load profiling is disabled if the LDLIST setting is empty (i.e., set to NA or 0), which is displayed as LDLIST := 0. The load buffer is stored in nonvolatile memory and the acquisition is synchronized to the time of day, with a resolution of ±5 seconds. Changing the LDAR setting may result in as many as two acquisition intervals before resynchronization occurs. If the LDAR setting is increased, the next acquisition time does not have a complete interval; therefore, no record is

saved until the second acquisition time, which is a complete cycle. When the buffer fills up, newer records overwrite older records. The recloser control is able to store at least 26 days of data when LDAR = 5 minutes, assuming all 15 values are used. If less than 15 values are specified, the recloser control will be able to store more days of data before data overwrite occurs. Likewise, if the interval is set longer, the recloser control will be able to store more days of data before data overwrite occurs.

This page intentionally left blank

Section 9

Settings

Introduction

The SEL-651R-2 Recloser Control stores customer-entered settings in nonvolatile memory. Settings are divided into the following six setting classes:

1. Global

2. Group *n* (where *n* = 1–8)

3. Logic *n* (where *n* = 1–8)

4. Front Panel

5. Report

6. Port *p* (where *p* = 1, 2, 3, F(4), or 5)

Some setting classes have multiple instances. In the above list, there are eight settings groups for Group and Logic settings, and five Port setting instances (one for each of the four serial ports and one for Ethernet Port 5).

Settings may be viewed or set in several ways, as shown in *Table 9.1*.

Table 9.1   Methods of Accessing Settings

	Serial Port Commands	**Front-Panel HMI Set/Show Menu**	**QuickSet (PC software)**
Display Settings	All settings (**SHO** command)	Some settings[a,b]	All settings
Change Settings	All settings (**SET** command)	Some settings[a,b]	All settings

[a] Only Global, Group, Front-Panel, and Port setting classes can be accessed.
[b] SELogic control equations can only be viewed, not set, on the HMI.

See *Factory-Default Settings on page 9.61* for examples of the **SHO** command, including the factory-default settings.

The **SET** command is described in the next subsection. *Table 9.2* lists the settings classes with a brief description and the page numbers for the *Settings Sheets* included at the end of this section. The order of the setting sheets matches the numbered list above.

See *SET/SHOW Menu on page 11.12* for details on accessing settings via the front-panel HMI. See *Section 3: PC Software* for ACSELERATOR QuickSet SEL-5030 Software information.

Table 9.2   Serial Port SET Commands

Command	Settings Type	Description	Settings Sheets[a]
SET G	Global	System configuration, current and voltage connection settings, input debounce timers, breaker monitor, etc.	*SET.1–SET.7*
SET *n*	Group	Overcurrent and voltage elements, reclosing relay, tripping, closing, etc., for Settings Group *n* (n = 1, 2, 3, 4, 5, 6, 7, 8)	*SET.7–SET.37*
SET L *n*	Logic	General logic settings for Settings Group *n* (n = 1, 2, 3, 4, 5, 6, 7, 8)	*SET.38–SET.54*
SET F	Front-Panel	Front-panel default display, pushbutton and target LED settings, display points, and local control bits	*SET.54–SET.63*
SET R	Report	Sequential Events Recorder (SER) trigger conditions, event report settings, and Load Profile Recorder (LDP) settings	*SET.64*
SET P *n*	Port	Port *n* settings n = 1: EIA-485 serial port n = 2, 3, or F: EIA-232 serial ports n = 5: single or dual Ethernet options	*SET.65–SET.76*
SET D *n*	DNP3	DNP3 Map *n* settings (n = 1, 2, or 3)	See *Appendix E*
SET M	Modbus	Modbus map settings	See *Appendix K*

a Located at the end of this section.

NOTE: Although there is no dedicated settings class for the USB port, the Port F settings class contains two settings that affect the USB port (see Port Enable Settings (SET P n Command) on page 9.60).

View settings with the respective serial port **SHOW** commands (**SHO G**, **SHO**, **SHO L**, **SHO F**, **SHO R**, **SHO P**) (see *SHO Command (Show/View Settings) on page 10.68*).

Make Global Settings (SET G) First

For most applications, make Global settings (see *Global Settings on page SET.1*) before making the Group settings. Changing some of the Global settings can cause certain Group settings to be hidden from view or forced to default values. The Global settings, in general, define the overall physical connections and equipment type, while the Group settings define the application-specific details.

The SEL-651R-2 will display a specific warning message before allowing a Global setting to be changed that would affect Group settings. These warnings are shown in *Settings Explanations on page 9.27*.

Settings 9.3
Settings Changes Via the Serial Port

Settings Changes Via the Serial Port

See *Section 10: Communications* for information on serial port communications and recloser control access levels. The **SET** commands in *Table 9.2* operate at Access Level 2 (screen prompt: =>>). To change a specific setting, enter the command:

> **SET** *c n s* **TERSE**

where:

c =	class (G, 1–8, L, F, R, P, D, or M): Choices 1–8 select the Group (relay) settings 1 through 8. If class is not specified, the relay selects the Group settings for the active settings group.
n =	instance number (only valid for Class L, P, and D): (1–8) for *c*= L (Logic) class. If *n* is not specified, the relay selects the Logic settings from the active settings group. (1, 2, 3, 5, or F) for *c* = P (port) class. If *n* is not specified, the relay selects the present port. If this session is via the USB port, *n* must be specified. (1–3) for *c* = D (DNP3) class. If *n* is not specified, the relay selects DNP3 Map 1.
s =	the name of the specific setting you wish to jump to and begin setting. If *s* is not entered, the recloser control starts at the first setting.
TERSE =	instructs the SEL-651R-2 to skip the SHOW display after the last setting. Use this parameter to speed up the **SET** command. If you wish to review the settings before saving, do not use the **TERSE** option.

When you issue the **SET** command, the SEL-651R-2 presents a list of settings, one at a time. Enter a new setting, or press **<Enter>** to accept the existing setting. Editing keystrokes are shown in *Table 9.3*.

Table 9.3   Set Command Editing Keystrokes

Press Key(s)	Results
<Enter>	Retains setting and moves to the next setting.
^ <Enter>	Returns to previous setting.
< <Enter>	Returns to previous setting section.
> <Enter>	Moves to next setting section.
END <Enter>	Exits editing session, then prompts you to save the settings.
<Ctrl + X>	Aborts editing session without saving changes.

The recloser control checks each entry to ensure that it is within the setting range. If it is not, an Out of Range message is generated and the recloser control prompts for the setting again.

If a given setting is beyond 80 characters (like an SER trigger list setting, set with **SET R** command), then a backslash (\) and carriage return have to be made to complete the setting on the next line. The backslash does not have to be entered right at character position 81—it can be entered earlier and then the setting continued on the next line.

9.4 | Settings
Time-Overcurrent Curves

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 442 of 1080
Wolfe

When all the settings are entered, the recloser control displays the new settings and prompts for approval to enable them. Answer **Y <Enter>** to enable the new settings.

The SEL-651R-2 handles settings changes as shown in *Table 9.4*.

Table 9.4   Settings Changes Effects (SALARM Relay Word Bit, ENABLED LED, SER)

Settings Change	SALARM Relay Word Bit Pulsed for Approximately 1 Second?	ENABLED LED Extinguished for a Few Seconds?	Sequential Events Recorder (SER) "Settings Changed" Entry?
Global	Yes	Yes	Yes
Active Group	Yes	Yes	Yes
Inactive Group	Yes	No	Yes
Active Logic	Yes	Yes	Yes
Inactive Logic	Yes	No	Yes
Front Panel	Yes	Yes	Yes
Report	Yes	Yes	Yes
Port (any)	Yes	Yes	Yes
Copy from active to inactive group	Yes	No	Yes
Copy from inactive to active group	Yes	Yes	Yes
Group Change	Yes	Yes (less than 1 second)	Yes[a]

[a] SER entry for a group Change is "Group Changed."

In *Table 9.4*, an inactive group is one of the seven settings groups that is not the currently active group. For example, if Settings Group 2 is currently active, Settings Groups 1, 3, 4, 5, 6, 7, and 8 are inactive. A **SET L 4** command represents a change to Logic settings in inactive Settings Group 4.

The SALARM Relay Word bit is in the factory-default setting for OUT201. The SALARM Relay Word bit is driven by the Global SELOGIC control equation setting SALARM. The behavior of the SALARM Relay Word bit in *Table 9.4* presupposes factory-default settings for SELOGIC setting SALARM (see *Factory-Default Settings on page 9.61*).

If the **ENABLED** LED is extinguished, then SEL-651R-2 protection functions are disabled.

The SER is described in *Section 12: Analyzing Events*.

Time-Overcurrent Curves

Standard Inverse-Time Characteristic Curves

The information in *Table 9.5* and *Table 9.6* describes the curve timing for the curve and time-dial settings made for the time-overcurrent elements (see *Figure 4.16–Figure 4.24*). The time-overcurrent curves in *Figure 9.1– Figure 9.5* conform to IEEE Std C37.112-1996 (R2001) IEEE Standard Inverse-Time Characteristic Equations for Overcurrent Relays.

Case No. 2018-00295

Page 442 of 1080
Settings 9.5
Time-Overcurrent Curves
Wolfe

where:

T_p = Operating time in seconds

T_R = Electromechanical induction-disk emulation reset time in seconds (if you select electromechanical reset setting)

TD = Time-dial setting

M = Applied multiples of pickup current (for operating time [T_p], M > 1; for reset time [T_R], M ≤ 1)

Table 9.5   Equations Associated With U.S. Curves

Curve Type	Operating Time	Reset Time	Figure
U1 (Moderately Inverse)	$T_p = TD \cdot \left(0.0226 + \dfrac{0.0104}{M^{0.02} - 1} \right)$	$T_R = TD \cdot \left(\dfrac{1.08}{1 - M^2} \right)$	*Figure 9.1*
U2 (Inverse)	$T_p = TD \cdot \left(0.180 + \dfrac{5.95}{M^2 - 1} \right)$	$T_R = TD \cdot \left(\dfrac{5.95}{1 - M^2} \right)$	*Figure 9.2*
U3 (Very Inverse)	$T_p = TD \cdot \left(0.0963 + \dfrac{3.88}{M^2 - 1} \right)$	$T_R = TD \cdot \left(\dfrac{3.88}{1 - M^2} \right)$	*Figure 9.3*
U4 (Extremely Inverse)[a]	$T_p = TD \cdot \left(0.02434 + \dfrac{5.64}{M^2 - 1} \right)$	$T_R = TD \cdot \left(\dfrac{5.64}{1 - M^2} \right)$	*Figure 9.4*
U5 (Short-Time Inverse)	$T_p = TD \cdot \left(0.00262 + \dfrac{0.00342}{M^{0.02} - 1} \right)$	$T_R = TD \cdot \left(\dfrac{0.323}{1 - M^2} \right)$	*Figure 9.5*

[a] U.S. Curve U4 differs slightly from the SEL-351R Recloser Control and SEL-351 Relay family U4 curves.

Table 9.6   Equations Associated With IEC Curves

Curve Type	Operating Time	Reset Time	Figure
C1 (Standard Inverse)[a]	$T_p = TD \cdot \dfrac{0.14}{M^{0.02} - 1}$	$T_R = TD \cdot \left(\dfrac{13.5}{1 - M^2} \right)$	*Figure 9.6*
C2 (Very Inverse)[a]	$T_p = TD \cdot \dfrac{13.5}{M - 1}$	$T_R = TD \cdot \left(\dfrac{47.3}{1 - M^2} \right)$	*Figure 9.7*
C3 (Extremely Inverse)[a]	$T_p = TD \cdot \dfrac{80}{M^2 - 1}$	$T_R = TD \cdot \left(\dfrac{80}{1 - M^2} \right)$	*Figure 9.8*
C4 (Long-Time Inverse)	$T_p = TD \cdot \dfrac{120}{M - 1}$	$T_R = TD \cdot \left(\dfrac{120}{1 - M} \right)$	*Figure 9.9*
C5 (Short-Time Inverse)	$T_p = TD \cdot \dfrac{0.05}{M^{0.04} - 1}$	$T_R = TD \cdot \left(\dfrac{4.85}{1 - M^2} \right)$	*Figure 9.10*

[a] Recloser curves 200–202 are equivalent to IEC curves as follows: 200 = IEC Standard Inverse (C1), 201 = IEC Very Inverse (C2), 202 = IEC Extremely Inverse (C3).

Recloser Curves

Traditional recloser curves are available for the time-overcurrent elements (see *Figure 4.16–Figure 4.24*). The recloser curves in *Figure 9.11–Figure 9.20* can be specified with either the older electronic recloser control designation or the newer micro-processor-based recloser control designation (see *Table 9.7*). For example, a given recloser curve has the following two designations:

➤ Older electronic recloser control designation: A

➤ Newer microprocessor-based recloser control designation: 101

Recloser curve A and curve 101 are the same curve—use either designation in making curve settings in the SEL-651R-2.

The recloser curves have a time-dial setting range of 0.10 to 2.00, as is available in traditional microprocessor-based recloser controls. In traditional microprocessor-based recloser controls, the time-dial setting is often referred to as a "vertical multiplier" setting instead.

The recloser curves in *Figure 9.11–Figure 9.20* are shown with an effective time-dial setting of 1.00.

NOTE: The electromechanical reset setting is not available with recloser curves. It is only available with traditional electromechanical time-overcurrent relay curves (U1–U5 and C1–C5). See Table 4.3 and Table 4.5–Table 4.8 for further information.

SELOGIC Control Equation Settings

SELOGIC control equations appear in the Global, Group, Logic, and Front-Panel settings classes of the SEL-651R-2. This is different than the SEL-351R Recloser Control, which contains all of the SELOGIC control equation settings in one settings class.

The SEL-651R-2 offers enhanced SELOGIC control equation setting capabilities such as nested parentheses, analog comparisons, and the NA setting. The SELOGIC control equation setting syntax is fully described in *Section 7: SELOGIC Control Equation Programming*.

Relay Word Bits

Relay Word bits can be used in SELOGIC control equation settings. Numerous SELOGIC control equation settings examples are given in *Section 4: Protection Functions* through *Section 7: SELOGIC Control Equation Programming*. With a few exceptions, SELOGIC control equation settings can also be set directly to 1 (logical 1), 0 (logical 0), or NA (not applicable).

See *Table F.1* and *Table F.2* for a listing and description of the SEL-651R-2 Relay Word bits.

NA Setting

From a logic standpoint, setting an SELOGIC control equation to NA acts similarly to setting the equation to 0 (logical 0). The difference between 0 and NA is that the 0 setting consumes a small amount of microprocessor time every processing interval, while the NA setting consumes no microprocessor time. Thus, several SELOGIC control equation settings have factory-default values of NA, which allows more microprocessor time for other functions.

For example, setting TMB1A := NA (Channel A, Transmit Bit 1) will result in Relay Word bit TMB1A being "permanently deasserted."

See *SELOGIC Control Equation Capacity on page 7.1* for more information.

Analog Comparisons

Analog Quantities on page 7.2 describes the use of Analog Quantities in SELOGIC control equations.

Settings Explanations

Note that most of the settings in the settings sheets that follow include references for additional information. The following explanations are for settings that do not have reference information anywhere else in the instruction manual.

General (Global Settings)

Refer to *General Settings on page SET.1*.

The Global settings NFREQ and PHROT allow you to configure the SEL-651R-2 to your specific system.

Set NFREQ equal to your nominal power system frequency, either 50 Hz or 60 Hz.

9.28 | Settings
Settings Explanations

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 466 of 1080
Wolfe

NOTE: The PHROT setting describes the electrical rotation of the power system phases, as opposed to the IPCONN, VYCONN, and VZCONN settings, which describe the connections to the SEL-651R-2 current and voltage terminals.

Set PHROT equal to your power system phase rotation, either ABC or ACB.

Set DATE_F to format the date displayed in recloser control reports and the front-panel display. Set DATE_F to MDY to display dates in Month/Day/Year format; set DATE_F to YMD to display dates in Year/Month/Day format; set DATE_F to DMY to display dates in Day/Month/Year format.

Current and Voltage Connections (Global Settings)

Refer to *Current and Voltage Connection Settings on page SET.1.*

The SEL-651R-2 connection terminals are shown in *Figure 2.3* and *Figure 2.5* for dual-door enclosure and *Figure 2.9* for single-door enclosure. The connection terminal markings are designated with numeric labels and terminal labels. For the purpose of explaining the current and voltage connection settings, a simplified list of the SEL-651R-2 current and voltage input terminals is used:

➤ For currents: **I1, I2, I3, IN**

➤ For voltages: **V1Y, V2Y, V3Y, V1Z, V2Z, V3Z**

This simplified list does not include the polarity marks on the current inputs. For example, the current channel I1 includes the physical terminals numbered Z01 (I1 polarity, indicated with a dot above the terminal) and Z02 (I1 nonpolarity), but will be referred to as only the I1 channel.

See *Figure 2.49–Figure 2.77* for current and voltage connections.

Current Connection Setting (IPCONN)

NOTE: The IPCONN setting serves a different function than the PHROT setting. See the note in General (Global Settings) on page 9.27.

NOTE: Other SEL-651R-2 settings handle the phase rolling of voltages, trip signals, close signals, and breaker status readings (see the following subsections).

The current signals are normally brought into the SEL-651R-2 cabinet via a prewired control cable. The factory-default connection includes a residual connection to the channel **IN** terminals and the **I1, I2,** and **I3** phase current terminals, as shown in *Figure 2.49–Figure 2.77.*

The electrical phase orientation of the power system overhead line is usually not easy to change, so the resulting CT secondary signals coming from the recloser are not the same in every installation. To eliminate the need to make wiring changes at the back panel, Global setting IPCONN can be used to designate which phases are connected to each of the terminals **I1, I2,** and **I3.** *Table 9.8* shows the required setting for IPCONN for the various CT signal connections.

MULTI-RECLOSER INTERFACE
The settings in Table 2.7, Table 9.15, Table 9.19, and Table 9.20 are automatically set (and hidden), according to Global setting IPCONN, for the Multi-Recloser Interface on page 2.93.

Table 9.8 Current Connection Setting IPCONN

Phase CT Signal Connections			Required Global Setting
I1 Terminals	I2 Terminals	I3 Terminals	IPCONN
I_A	I_B	I_C	ABC
I_A	I_C	I_B	ACB
I_B	I_A	I_C	BAC
I_B	I_C	I_A	BCA
I_C	I_A	I_B	CAB
I_C	I_B	I_A	CBA

Note that setting IPCONN is deemed a "reference setting" in *Table 9.15, Table 9.18, Table 9.19,* and *Table 9.20.* Subsection *Pole Status (52a), Trip, and Close Mapping Variations for Single-Phase Trip Capable Reclosers (Group Settings) on page 9.51* explains this in greater detail.

9.29
Settings

Enable Ground Switch Setting (EGNDSW)

The SEL-651R-2 can operate with or without the **IN** channel connected to a current source. The factory-default wiring configuration employs a wired-residual connection to the **IN** terminals, allowing the measurement of zero-sequence current via the more sensitive **IN** channel. The effect of the EGNDSW setting is shown in *Table 9.16*, *Table 4.23*, and *Ground Switch Option on page 8.3*.

When setting EGNDSW is changed via the serial port **SET G** command, several functions in the Group settings class are disabled or changed.

The following warning is displayed when EGNDSW is changed from Y to N:

```
WARNING!  The global setting EGNDSW was changed to "N",
which will cause the E50G, E51G1, E51G2, 51G1JP,
51G1KP, E32, and GDEMP settings to be set to factory
default values in all settings groups.
```

The following warning is displayed when EGNDSW is changed from N to Y:

```
WARNING!  The global setting EGNDSW was changed to "Y",
which will cause E50N, E51N1, E51N2, NDEMP settings to
be set to OFF and CTRN setting to be set to the same
value as CTR in all settings groups.
```

Both warnings are followed by a confirmation prompt, which allows the technician to approve or cancel the changes.

CT Polarity Setting (CTPOL)

MULTI-RECLOSER INTERFACE
See Changing Global Setting RECL_CFG Changes the CTPOL Setting and the PTRY and PTRZ Settings for 8 Vac LEA Voltage Inputs on page 2.95.

The SEL-651R-2 uses directional information contained in current and voltage signals in these functions:

➤ Power measurement (see *Table 8.1*)

➤ Power elements

➤ Load encroachment

➤ Fault locator

➤ Directional control

The direction of the calculated power or impedance depends on the relative phase of the current measurements as compared to the voltage signals, which is normally a function of switchgear orientation. The CTPOL := (POS or NEG) setting provides an easy way to change the polarity of the measured current signals, and thus the resulting power direction and impedances.

Figure 2.49–Figure 2.77 show the SEL-651R-2 factory-default CT circuit wiring for supported reclosers. The directional arrows shown in the primary bus inside the switchgear identifies the forward or OUT direction, when Global setting CTPOL := POS.

The CTPOL setting functions by negating (or multiplying by –1) the current signals being read on the **I1**, **I2**, and **I3** current inputs (and the channel **IN** current if setting EGNDSW := Y) if setting CTPOL := NEG. The event report will show the polarity after the CTPOL adjustment is made, so any analysis tools, such as the ACSELERATOR Analytic Assistant SEL-5601 Software, will extract the same phase information that the SEL-651R-2 is using.

Breaker/Recloser Type Setting (BKTYP) and Enable Single-Phase Breaker Setting (ESPB)

Global setting BKTYP indicates the type of recloser the SEL-651R-2 interfaces with:

➤ BKTYP := 3 (three-phase)—interface with recloser that is capable of only tripping and closing all three phases in unison

➤ BKTYP := 1 (single-phase)—interface with recloser that is capable of tripping and closing all three phases in unison or each phase individually

MULTI-RECLOSER INTERFACE
Global setting BKTYP is automatically set to BKTYP := 1 (and hidden) for the Multi-Recloser Interface on page 2.93.

Figure 6.2, *Figure 7.25*, and *Figure 7.26* use the BKTYP setting to set up the processing structure of breaker/pole status inputs and trip/close outputs. If BKTYP := 1, then Group setting ESPB (see *Figure 9.29*) can be set:

➤ ESPB := Y—enable single-phase tripping and closing

➤ ESPB := N—enable three-phase tripping and closing

Even with setting ESPB := Y, three-phase tripping can still occur (note Three-Phase Trip settings TRQL3P, TR3P, and TR3X in *Figure 5.1* are always enabled).

If BKTYP := 3, then ESPB := N always.

Figure 5.1 and *Figure 6.1* use the ESPB setting to set up the internal trip/close logic. *Figure 6.2* uses the ESPB setting to further refine breaker/pole status for single-phase or three-phase closing/reclosing.

Voltage Connection Settings (VYCONN and VZCONN)

The SEL-651R-2 has six analog voltage inputs, broken into two sets of three-phase connections, called the VY and VZ terminals. *Figure 2.41–Figure 2.46* cover the actual wiring for these inputs. This section deals with the settings that determine how the SEL-651R-2 processes the signals measured on these terminals.

The SEL-651R-2 can be used with all six voltage inputs connected; use of fewer than six voltage inputs results in reduced functionality.

Like the current inputs, the voltage input terminals are labeled numerically (1, 2, 3) instead of by phase letter (A, B, C). This allows settings to be used that assign the measured signal to the correct phase quantity inside the SEL-651R-2. This reassignment is sometimes called phase rolling. It is much easier to change a setting than to change wiring, so the settings VYCONN and VZCONN have been provided in the SEL-651R-2.

Voltage Terminal Designations (simplified):

➤ VY terminals: **V1Y, V2Y, V3Y**

➤ VZ terminals: **V1Z, V2Z, V3Z**

Unlike the CT connections shown in *Table 9.8*, it is possible to operate the recloser control with less than three voltages on a set of terminals. *Table 9.9* shows the six combinations of three-phase voltage connections on the VY terminals, plus six more single phase voltage connection variations.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 469 of 1080

settings 9.31

Settings Explanations
Wolfe

The VZ-terminal voltages have a similar choice of settings as *Table 9.9*, except a "VZ" is used instead of a "VY." Thus, the VZCONN setting is independent of the VYCONN setting.

Table 9.9 Voltage Connection Setting VYCONN and Affected Settings

VY-Terminal Signal Connections			Required Global Setting	"VY" Available as Setting Choice for:		
V1Y	V2Y	V3Y	VYCONN :=	EPHANT	VSELECT	FSELECT
V_A	V_B	V_C	ABC	no	yes	yes
V_A	V_C	V_B	ACB	no	yes	yes
V_B	V_A	V_C	BAC	no	yes	yes
V_B	V_C	V_A	BCA	no	yes	yes
V_C	V_A	V_B	CAB	no	yes	yes
V_C	V_B	V_A	CBA	no	yes	yes
V_A	–	–	A	yes	no	yes
V_B	–	–	B	yes	no	yes
V_C	–	–	C	yes	no	yes
V_{AB}	–	–	AB	yes	no	yes
V_{BC}	–	–	BC	yes	no	yes
V_{CA}	–	–	CA	yes	no	yes
-	–	–	OFF	no	no	no

Single-Phase and Phase-to-Phase Voltage Connections

The bottom half of *Table 9.9* lists single-phase and phase-to-phase connection options for voltage input V1Y. These voltage input V1Y connections are actually between terminals V1Y and NY (*Figure 2.5* for dual-door enclosure; see *Figure 2.9* for single-door enclosure). Even though terminal NY is the "neutral" connection, there is no internal ground connection on terminal NY, so phase-to-phase voltage connections can be made between voltage terminals V1Y and NY.

Figure 9.21 shows the voltage terminal assignments for these single-phase and phase-to-phase voltage connections. Even voltage terminals V2Y and V3Y are assigned, with the aid of the system rotation setting PHROT.

The internal voltages in *Figure 9.21* are used in the voltage elements (see *Voltage Elements on page 4.31*, *Figure 4.26*, and *Figure 4.27*) and in the event report columns (see *Figure 12.8*). Even though single-phase and phase-to-phase connections to V1Y and NY are shown in *Figure 9.21* (and "no connections" are shown at bottom of *Figure 9.21*), all the voltage terminals and subsequent internal voltages are active for the aforementioned voltage elements and event report columns.

Again, the VZ-terminal voltages have the same choices as the VY-terminal voltages portrayed in *Figure 9.21*—just substitute "VZ" for "VY". *Transition Between A-B-C Worlds on page 9.52* goes into greater detail and example on terminal assignments.

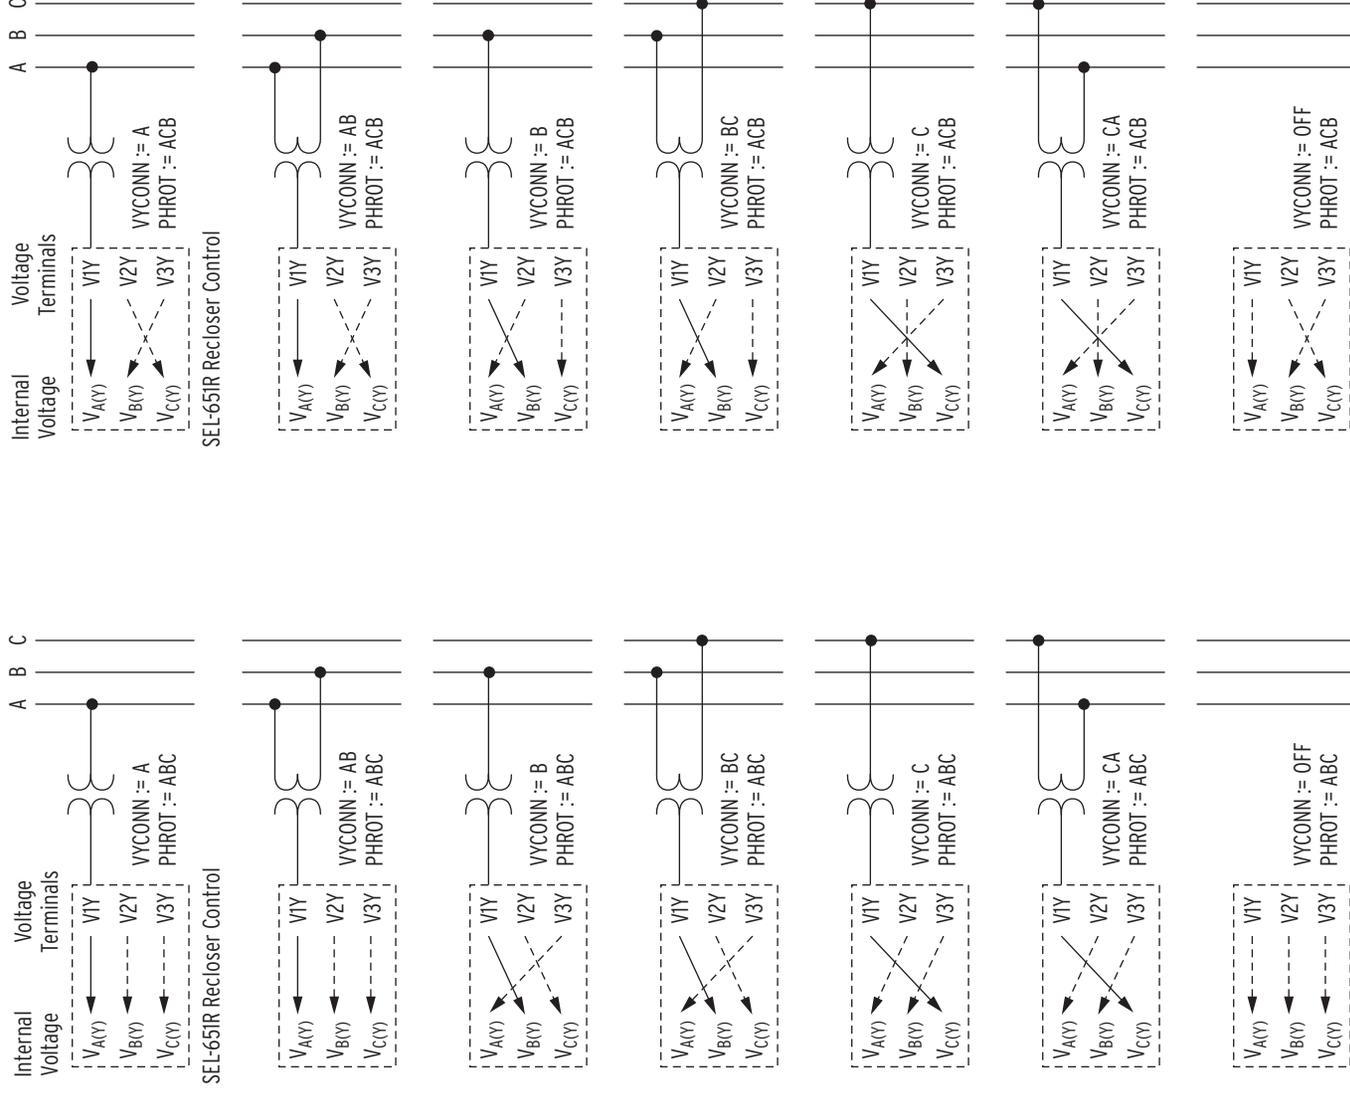
9.32 | Settings
Settings Explanations


Figure 9.21   Terminal Assignments for Single-Phase and Phase-to-Phase Voltage Connections

Troubleshooting Voltage and Current Connections

The ability to make setting changes instead of wiring changes is very convenient. However, some tools are required to help troubleshoot problems that may arise if mistakes are made in either the wiring or the setting of the SEL-651R-2 current and voltage inputs.

The serial port **MET** command is a convenient troubleshooting tool to use because it is possible to quickly see how the SEL-651R-2 is interpreting the signals. *Section 10: Communications* contains a sample **MET** command capture. *Metering Check on page 2.36* gives a quick troubleshooting routine.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 471 of 1080
Wolfe

Settings 9.33
Settings Explanations

Event Reports are also powerful diagnostic tools (see *Section 12: Analyzing Events*). Analytic Assistant allows graphical representation of compressed and COMTRADE event report data, including oscillography and phasor display.

QuickSet contains a phasor display function that operates directly from a serial port connection to the SEL-651R-2. It is found under the HMI menu.

Enable Phantom Voltage Setting (EPHANT)

The SEL-651R-2 can be configured to create phantom three-phase voltage signals from an applied single-phase voltage on either the VY terminals or the VZ terminals (but not both). *Table 9.9* shows the setting choices for VYCONN and VZCONN that allow the EPHANT setting to be made (see *Phantom Voltage Option Not in Service on page 8.6*).

The phantom voltage signals created are used only in fundamental metering functions (voltages, power, power factor, energy). The protection functions, including the under- and overvoltage elements, power elements, and event reports, are unaffected by the EPHANT setting.

Voltage Source Selection Setting (VSELECT)

The VSELECT setting is used to select which voltage terminals are used for the protection functions that require three-phase voltage:

- ➤ Power elements
- ➤ Load encroachment
- ➤ Fault locator
- ➤ Voltage Sag/Swell/Interruption elements
- ➤ Loss-of-potential
- ➤ Directional control

VSELECT also defines the voltage signals used in the power and energy metering functions, unless phantom voltages are selected (setting EPHANT ≠ OFF).

If VSELECT is changed to OFF, the following message is displayed.

```
WARNING!  The global setting VSELECT was changed to
"OFF". Settings ELOAD, E32, EFLOC, ELOP, EPWR, and ESSI
will be set to "N" in all settings groups.
```

The voltage elements are not affected by the VSELECT setting (see *Voltage Elements on page 4.31*).

The Relay Word bits VSELY and VSELZ are controlled by the VSELECT setting (see *Figure 9.29*).

Frequency Source Selection Setting (FSELECT)

The FSELECT setting is used to select which voltage terminals are used for the frequency tracking and frequency measurement functions:

- ➤ Frequency elements, including undervoltage block (see *Frequency Elements on page 4.50*)
- ➤ Synchronism-check elements (defines **VP** terminal; see *Synchronism-Check Elements on page 4.38*)

9.34 | Settings
Settings Explanations

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 472 of 1080
Wolfe

For FSELECT := VY or OFF, the relay defaults to using the voltage connected to V1Y for frequency tracking. If a disturbance causes V1Y voltage to drop below 10 V for more than 60 cycles, the relay will attempt to use V2Y for frequency tracking. If V2Y is also less than 10 V, the relay will attempt to use V3Y. Operation of the relay with V1Z, V2Z, and V3Z is similar if FSELECT := VZ.

If FSELECT is changed to OFF, the following message is displayed.

```
WARNING!  The global setting FSELECT was changed to
"OFF". Settings E81, E81R and E25 will be set to "N" in
all settings groups.
```

Frequency measurement for synchronism-check elements uses a zero-crossing detector on the corresponding voltage terminal used for frequency tracking.

Frequency tracking will default to the **V1Y**, **V2Y**, or **V3Y** terminal when FSELECT := OFF.

Enable Independent Control Input Settings (Global Settings)

For most applications, leave setting EICIS := N. This selection causes the debounce timers for the recloser status inputs (IN201–IN206, *Figure 7.17*) and optional optoisolated inputs (IN101–IN107, *Figure 7.18*) to be hidden from view and set to factory-default values. If different debounce time settings are required, then set EICIS := Y and make the appropriate debounce timer settings.

Voltage Ratio Correction Factors for VY- and VZ-Terminal Voltage Inputs (Global Settings)

Make the V1YRCF, V2YRCF, and V3YRCF ratio correction factor Global settings for the VY-terminal voltage inputs (V1Y, V2Y, and V3Y, respectively) when they are ordered as low-energy analog (LEA) voltage inputs (see *Figure 9.22*, *Figure 9.23*, and *Figure 9.25*). Make the V1ZRCF, V2ZRCF, and V3ZRCF ratio correction factor Global settings for VZ-terminal voltage inputs (V1Z, V2Z, and V3Z respectively) when they are ordered as LEA voltage inputs (see *Figure 9.22*, *Figure 9.24*, and *Figure 9.25*). Ratio correction factor (RCF) settings compensate for irregularities (on a per-phase basis) of voltage dividers connected between the primary voltage system and the LEA inputs. The derivation of the RCF value for a voltage divider for a particular phase is defined as follows:

NOTE: Ratio Correction Factors serve a different purpose than Potential Transformer Ratio settings– see also following subsection Potential Transformer (PT) Ratios (Group Settings) on page 9.42.

$$RCF = \frac{\text{true ratio}}{\text{marked ratio}}$$

$$= \frac{(\text{Vpri.}/\text{Vsec.})}{\text{PTR}_{LEA}}$$

$$= \frac{\text{Vpri.}}{\text{Vsec.} \cdot \text{PTR}_{LEA}}$$

Equation 9.1

where:

Vpri. = test voltage applied to the primary side of the voltage divider

Vsec. = resultant voltage measured on the secondary side of the voltage divider

true ratio = Vpri./Vsec.

marked ratio = PTR_{LEA}

= effective nominal potential transformer (PT) ratio of the voltage divider connected between the primary voltage system and the LEA input (e.g., PTR_{LEA} = 10000 for G&W Viper-ST and G&W Viper-LT).

The marked ratio of the voltage divider (PTR_{LEA}) is always provided by the manufacturer and often the per-phase RCF values are also provided.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 473 of 1080
Settings Explanation
Wolfe
9.35

If the voltage divider is perfect, then:

$$\frac{Vpri.}{Vsec.} = PTR_{LEA} \text{ and } RCF = 1.000$$

Equation 9.2

Thus, the measured voltage divider performance equals the marked ratio of the voltage divider, as given by the manufacturer. But such perfect conditions are usually not the case.

If the voltage divider is putting out more voltage (Vsec.) than nominally expected for an applied voltage input (Vpri.), then:

$$\frac{Vpri.}{Vsec.} < PTR_{LEA} \text{ and } RCF < 1.000$$

Equation 9.3

An example of an RCF value less than 1.000 is found in *Example 9.1*. In this example, setting V2YRCF := 0.883 brings down the too high voltage on voltage input V2Y (0.82 V is brought down to nominal 0.72 V).

If the voltage divider is putting out less voltage (Vsec.) than nominally expected for an applied voltage input (Vpri.), then:

$$\frac{Vpri.}{Vsec.} > PTR_{LEA} \text{ and } RCF > 1.000$$

Equation 9.4

An example of an RCF value greater than 1.000 is also found in following *Example 9.1*. In this example, setting V3YRCF := 1.112 brings up the too low voltage on voltage input V3Y (0.65 V is brought up to nominal 0.72 V).

In the SEL-651R-2 with LEA voltage inputs, RCF values for VY terminals (settings V1YRCF, V2YRCF, and V2YRCF) are applied to respective voltage inputs V1Y, V2Y, and V3Y, and the RCF values for VZ terminals (settings V1ZRCF, V2ZRCF, and V2ZRCF) are applied to respective voltage inputs V1Z, V2Z, and V3Z. The resultant secondary voltages from these voltage inputs are normalized by the RCF values. These normalized secondary voltages are used throughout the SEL-651R-2.

NOTE: At the end of the following subsection Voltage-Related Settings and LEA Inputs (Group Settings) on page 9.47 is a discussion concerning RCF values that are less than unity (1.000) and their possible effect on voltage-related settings.

EXAMPLE 9.1   Normalizing Voltages With Ratio Correction Factors

A voltage divider is connected to the 8 Vac LEA voltage inputs (see Figure 9.22). The RCF values per phase for the voltage divider are given as:

V1YRCF := 1.078 (voltage input V1Y; like Equation 9.4)
V2YRCF := 0.883 (voltage input V2Y; like Equation 9.3)
V3YRCF := 1.112 (voltage input V3Y; like Equation 9.4)

The marked ratio of the voltage divider is given as:

$$PTR_{LEA} = 10000$$

What are the true ratios of each phase of the voltage divider?

$$\text{true ratio (for a given phase)} = \frac{Vpri.}{Vsec.}$$

9.36 | Settings
Settings Explanations

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 474 of 1080
Wolfe

Vpri. and Vsec. are measured in manufacturer tests, to derive RCF values as shown in Equation 9.1 and accompanying explanation. From Equation 9.1:

$$RCF \cdot PTR_{LEA} = \frac{Vpri.}{Vsec.} = \text{true ratio}$$

1.078 · 10000 = 10780 (true ratio for voltage input V1Y)
0.883 · 10000 = 8830 (true ratio for voltage input V2Y)
1.112 · 10000 = 11120 (true ratio for voltage input V3Y)

Note these true ratios vary from 8830 to 11120, while the marked ratio of the voltage divider is given as 10000.

Consider what is happening in this example. First, assume the primary voltage (Vpri.) is the same magnitude for each phase. When this primary voltage is run through the respective true ratios, the secondary voltage outputs vary widely. Presuming primary voltage of 12.47 kV (7.2 kV line-to-neutral), the resultant secondary voltages are listed below:

7200 V/10780 = 0.67 V
(true secondary voltage to voltage input V1Y)
7200 V/8830 = 0.82 V
(true secondary voltage to voltage input V2Y)
7200 V/11120 = 0.65 V
(true secondary voltage to voltage input V3Y)

Note that the true secondary voltages to voltage inputs V1Y and V3Y are running low (below normalized secondary voltage 0.72 V = 7200 V/10000), while the voltage to voltage input V2Y is running high (above normalized secondary voltage 0.72 V). But, the RCF values adjust these true secondary voltages to normalized secondary voltage:

0.67 V · 1.078 = 0.72 V
(normalized voltage from voltage input V1Y)
0.82 V · 0.883 = 0.72 V
(normalized voltage from voltage input V2Y)
0.65 V · 1.112 = 0.72 V
(normalized voltage from voltage input V3Y)

Again, the normalized secondary voltage (0.72 V) is the same for all three phases in this example, because the primary voltage is assumed the same magnitude for each phase (7200 V). These normalized secondary voltages are used throughout the SEL-651R-2. The true secondary voltages cannot be seen (via the SEL-651R-2), unless the RCF values are set to unity (RCF = 1.000).

Voltage Phase Angle Correction Settings for VY- and VZ-Terminal Voltage Inputs (Global Settings)

Make the V1YPAC, V2YPAC, and V3YPAC voltage phase angle correction Global settings for the VY-terminal voltage inputs (V1Y, V2Y, and V3Y, respectively) when they are ordered as low-energy analog (LEA) voltage inputs (see *Figure 9.23* and *Figure 9.25*). Make the V1ZPAC, V2ZPAC, and V3ZPAC voltage phase angle correction Global settings for the VZ-terminal voltage inputs (V1Z, V2Z, and V3Z, respectively) when they are ordered as LEA voltage inputs (see *Figure 9.24* and *Figure 9.25*). These settings compensate for the lagging phase shift caused by the voltage divider and the shielded cable bringing the voltages to the SEL-651R-2.

Refer to *Table 9.10–Table 9.14* to make voltage phase angle correction settings.

For example, if the SEL-651R-2 is used to control a NOVA TS-27 with a 30-foot, 26-pin control cable and a 20-foot, 14-pin junction box cable, then calculate the phase angle correction setting from *Table 9.11* as follows.

$$V1YPAC = V2YPAC = V3YPAC = -3.3° + -0.8°\left(\frac{(30-10)\text{ ft}}{10\text{ ft}}\right) + -1.4°\left(\frac{(20-10)\text{ ft}}{10\text{ ft}}\right) = -6.3°$$

Table 9.14   Voltage Phase Angle Correction Settings for Siemens SDR Reclosers

Model	Global Settings V1ZPAC–V3ZPAC for Various Control Cable Lengths				
	3.05 m (10 ft)	**6.10 m (20 ft)**	**9.15 m (30 ft)**	**12.2 m (40 ft)**	**15.25 m (50 ft)**
Siemens SDR Triple-Single	–1.4°	–2.1°	–2.7°	–3.3°	–4.0°
Siemens SDR Three-Phase	–1.4°	–2.1°	–2.7°	–3.3°	–4.0°

Because the phase shift can vary depending on the type and length of shielded cable used for the application, phase angle correction settings for Lindsey SVMI can be made by using the phase angle values on the opposite voltage terminals as a reference (if available). For example, consider a system where the VY-terminal inputs are 300 Vac PTs and the VZ-terminal inputs are Lindsey SVMI LEAs, connected to either side of the same recloser. The VY-terminal inputs can be used as the phase angle reference to determine the phase angle correction necessary for the Lindsey SVMI LEAs.

Breaker Monitor Initiate Settings (Global Settings)

See *Breaker Monitor Initiate SELOGIC Equations on page SET.5*.

The function of the Breaker Monitor initiate settings is fully explained in *Section 8: Metering and Monitoring*. The recommended settings depend on Global setting BKTYP.

When BKTYP := 3, only make setting BKMON3P.

The factory-default setting is:

> BKMON3P := RCTR1X.

This setting should satisfy all regular recloser applications.

The RCTR1X Relay Word bit is the final trip output for three-phase reclosers (see *Figure 7.25*).

When BKTYP := 1, only make settings BKMONA, BKMONB, and BKMONC.

The factory-default settings are:

> BKMONA := RCTR1X
>
> BKMONB := RCTR2X
>
> BKMONC := RCTR3X

These settings may need to change, depending on setting IPCONN, as shown in *Table 9.15*. Subsection *Pole Status (52a), Trip, and Close Mapping Variations for Single-Phase Trip Capable Reclosers (Group Settings) on page 9.51* explains the use of setting IPCONN as a "reference setting" in greater detail.

MULTI-RECLOSER INTERFACE
Global setting BKTYP is automatically set to BKTYP := 1 (and hidden) for the Multi-Recloser Interface on page 2.93.

NOTE: The system phase rotation (and Global setting PHROT) have no impact on the recommended settings shown in Table 9.15.

MULTI-RECLOSER INTERFACE
The BKMONx setting values in Table 9.15 are automatically set (and hidden), according to Global setting IPCONN, for the Multi-Recloser Interface on page 2.93.

Table 9.15   Breaker Monitor Mapping Global Settings for Single-Phase Recloser (BKTYP := 1) (Sheet 1 of 2)

Reference Global Setting	Recommended Global Settings

CAB	RCTR2X	RCTR3X	RCTR1X
CBA	RCTR3X	RCTR2X	RCTR1X

Time and Date Management Settings (Global Settings)

The SEL-651R-2 supports several methods of updating the relay date and time.

For IRIG-B and Phasor Measurement Unit (PMU) synchrophasor applications, refer to *Configuring High-Accuracy Timekeeping on page J.21*.

For Simple Network Time Protocol (SNTP) applications, refer to *Simple Network Time Protocol (SNTP) on page 10.15*.

For time update from a DNP3 Master, see *Time Synchronization on page E.8*.

Coordinated Universal Time (UTC) Offset Setting (Global Settings)

The SEL-651R-2 has a Global setting UTC_OFF, settable from –24.00 to +24.00 hours, in 0.25-hour increments.

The relay HTTP (web) server uses the UTC_OFF setting to calculate UTC time stamps in request headers.

The relay also uses the UTC_OFF setting to calculate local (relay) time from the UTC source when configured for Simple Network Time Protocol (SNTP) updating via Ethernet. When a time source other than SNTP is updating the relay time, the UTC_OFF setting is not considered because the other time sources are defined as local time. When using IEEE C37.118-compliant IRIG-B signals (e.g., Global setting IRIGC = C37.118), the relay uses the UTC-to-local time offset provided as part of the time message to determine the local time. If the IRIG signal is lost, Global setting UTC_OFF is used.

Set UTC_OFF properly even if you expect some other time source, such as IRIG-B, to correct for the offset. If the time source fails, the relay will revert to SNTP or internal time and UTC_OFF will allow the relay to record and report the correct local time. If UTC_OFF is not set properly, some relay reports may show unexpected results.

Automatic Daylight-Saving Time Settings (Global Settings)

The SEL-651R-2 can automatically switch to and from daylight-saving time, as specified by the eight Global settings DST_BEGM–DST_ENDH. The first four settings control the month, week, day, and time that daylight-saving time shall commence, while the last four settings control the month, week, day, and time that daylight-saving time shall cease.

Once configured, the SEL-651R-2 will change to and from daylight-saving time every year at the specified time. Relay Word bit DST asserts when daylight-saving time is active.

The SEL-651R-2 interprets the week number settings DST_BEGW and DST_ENDW (1–3, L = Last) as follows:

➤ The first seven days of the month are considered to be in week 1.

➤ The second seven days of the month are considered to be in week 2.

9.40 | Settings
Settings Explanations

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 478 of 1080
Wolfe

➤ The third seven days of the month are considered to be in week 3.

➤ The last seven days of the month are considered to be in week "L".

This method of counting of the weeks allows easy programming of statements like "the first Sunday", "the second Saturday", or "the last Tuesday" of a month.

As an example, consider the following settings:

DST_BEGM = **3**

DST_BEGW = **L**

DST_BEGD = **SUN**

DST_BEGH = **2**

DST_ENDM = **10**

DST_ENDW = **3**

DST_ENDD = **WED**

DST_ENDH = **3**

With these example settings, the relay will enter daylight-saving time on the last Sunday in March at 0200 h and leave daylight-saving time on the third Wednesday in October at 0300 h. The relay asserts Relay Word bit DST when daylight-saving time is active.

When an IRIG-B time source is being used, the relay time follows the IRIG-B time, including daylight-saving time start and end, as commanded by the time source. If there is a discrepancy between the daylight-saving time settings and the received IRIG-B signal, the relay follows the IRIG-B signal.

When using IEEE C37.118 compliant IRIG-B signals (e.g., Global setting IRIGC = C37.118), the relay automatically populates the DST Relay Word bit, regardless of the daylight-saving time settings.

When using regular IRIG-B signals (e.g., Global setting IRIGC = NONE), the relay only populates the DST Relay Word bit if the daylight-saving time settings are properly configured.

Set daylight-saving time beginning and ending properly even if you expect some other time source, such as IRIG-B, to correct for daylight-saving time. The relay relies on these settings for correct time should the time source fail (for IRIGC = C37.118) and to calculate UTC time correctly (when IRIGC = NONE). If daylight-saving time settings are not correct, some relay reports may show unexpected results. Use the **TIME DST** command to confirm the daylight-saving time settings and status (see *TIM Command (View/Change Time) on page 10.78*).

Identifier Labels (Group Settings)

Refer to *Identifier Labels on page SET.7*.

The SEL-651R-2 has two identifier labels: the Relay Identifier (RID) and the Terminal Identifier (TID). The Relay Identifier is typically used to identify the recloser control or the type of protection scheme. Typical Terminal Identifiers include an abbreviation of the substation name and line terminal.

The SEL-651R-2 tags each report (event report, meter report, etc.) with the Relay Identifier and Terminal Identifier. This allows you to distinguish the report as one generated for a specific breaker and substation.

RID and TID settings may include the following characters: 0–9, A–Z, -, /, ., space.

Settings 9.41
Settings Explanations

Current Transformer (CT) Ratios (Group Settings)

Refer to *Current and Potential Transformer Ratios on page SET.7.*

Phase and neutral current transformer ratios are set independently. If neutral channel IN is connected residually with Terminals I1, I2, I3 (this matches the SEL-651R-2 factory-default wiring) then set CTR and CTRN the same. Group settings CTR and CTRN are used in SEL-651R-2 event reports and metering functions to scale secondary current quantities into primary values.

When channel IN is connected residually, make Global setting EGNDSW := Y. For ground protection (e.g., elements 50G1–50G6, 51G1, and 51G2), the channel IN signal will automatically be used for small signals and the calculated zero-sequence current (from terminals I1, I2, I3) will be used for large signals (see *Ground Switch Logic on page 4.76)*. Metering functions will follow a similar behavior for the IG-derived quantities (see *Ground Switch Option on page 8.3*).

For applications that require a high sensitivity to zero-sequence current, neutral channel IN is connected separately to a core-balance current transformer that encompasses the three phases. This type of current transformer typically has a lower ratio than the phase current transformers, which allows for more sensitivity in ground fault detection.

Make Global setting EGNDSW := Y for this application. Settings CTR and CTRN will be different in this case, with CTR being greater than CTRN. The setting limit for the ratio is:

$$1 \leq \frac{CTR}{CTRN} \leq 500$$

Equation 9.5

If channel IN is not connected, or it is connected to an unrelated current source (which is not measuring the zero-sequence current on the same electrical location as the phase CTs connected to terminals I1, I2, and I3), then make Global setting EGNDSW := N and set CTRN independently of CTR. Separate channel IN overcurrent elements, 50N1T–50N6T, 51N1T, and 51N2T, controlled by Enable settings E50N, E51N1, and E51N2, are available when EGNDSW := N.

Table 9.16 summarizes the above information.

Table 9.16   CTR and CTRN Settings in Relation to EGNDSW Setting

IN Channel Connection	EGNDSW Setting	CTRN Setting Requirements	50N Element Availability
Wired residually with terminals I1, I2, I3[a]	Y[a]	CTRN = CTR[a]	No[a]
Wired to a core-balance CT, measuring zero-sequence current on same line as CTs on terminals I1, I2, I3	Y	$1 \leq \frac{CTR}{CTRN} \leq 500$	No
Wired to a CT, unrelated to phase CTs	N	CTRN set independent of CTR	Yes
Not connected	N	CTRN setting not used	NA

[a] This is the factory-default configuration.

CT Sizing

The SEL-651R-2 is designed to work with switchgear-mounted CTs. If the SEL-651R-2 is being installed in a substation application where CTs can be individually specified, see the guidelines in the technical paper *The Impact of High Fault Current and CT Rating Limits on Overcurrent Protection*, available at selinc.com.

Potential Transformer (PT) Ratios (Group Settings)

Refer to *Current and Potential Transformer Ratios on page SET.7*.

Group setting PTRY is the potential transformer ratio from the primary system to the SEL-651R-2 VY-terminal voltage inputs. Group setting PTRZ is the potential transformer ratio from the primary system to the SEL-651R-2 VZ-terminal voltage inputs. Setting these for traditional 300 Vac voltage inputs is straightforward.

For example, on a 12.47 kV phase-to-phase primary system with wye-connected 7200:120 V PTs, the correct PTRY or PTRZ setting is 7200/120 = 60.00.

PT Ratio Setting Adjustments

The SEL-651R-2 can be ordered with different secondary input voltage configurations (see *Models and Options on page 1.4*). Low-energy analog (LEA) voltage inputs are suitable for high-impedance sensors, such as capacitive voltage dividers and resistive voltage dividers. See the following subsections (with *Figure 9.22–Figure 9.25*) for information on how to derive PT ratio settings for various LEA voltage inputs.

Derive PT Ratio Settings for 8 Vac LEA Voltage Inputs (on G&W and Tavrida Reclosers)

MULTI-RECLOSER INTERFACE
See Changing Global Setting RECL_CFG Changes the CTPOL Setting and the PTRY and PTRZ Settings for 8 Vac LEA Voltage Inputs on page 2.95.

Refer to *Figure 9.22*.

Vpri. and Vsec. are in-phase—no phase angle correction needed. Cable capacitance is negligible ($C_2 \gg C_C$).

Vpri./Vsec. = true ratio of voltage divider when connected to the VY-terminal or VZ-terminal (8 Vac LEA) voltage inputs.

where:
Vpri./Vsec. = 10000 for G&W Electric Viper-ST and G&W Viper-LT reclosers
= 8793.75 for Tavrida OSM Al_2 and Tavrida OSM Al_4 recloser

9.43
Settings Explanation

The SEL-651R-2 sees 8 Vac on the VY-terminal or VZ-terminal (8 Vac LEA) voltage inputs as 300 Vac. To realize accurate primary voltage metering, the corresponding potential transformer ratio settings (PTRY or PTRZ), are set as follows:

$$PTRY \text{ or } PTRZ = Vpri./Vsec. \cdot (8/300)$$

$$= \left(10000 \cdot \left(\frac{8}{300} \right) \right)$$

= 266.67 for G&W Electric Viper-ST and
    G&W Viper-LT reclosers

MULTI-RECLOSER INTERFACE
See Changing Global Setting RECL_CFG Changes the CTPOL Setting and the PTRY and PTRZ Settings for 8 Vac LEA Voltage Inputs on page 2.95.

The SEL-651R-2 sees 8 Vac on the VY-terminal or VZ-terminal (8 Vac LEA) voltage inputs as 300 Vac. To realize accurate primary voltage metering, the corresponding potential transformer ratio settings (PTRY or PTRZ), are set as follows:

$$\text{PTRY or PTRZ} = \text{Vpri./Vsec.} \cdot (8/300)$$

$$= \left(10000 \cdot \left(\frac{8}{300}\right)\right)$$

$$= 266.67 \text{ for ABB OVR/Gridshield (32-pin and 42-pin)}$$
$$\text{and ABB OVR-3/VR-3S (24-pin) reclosers}$$

Equation 9.8

Derive PT Ratio Settings for 8 Vac LEA Voltage Inputs
(on Eaton NOVA NX-T)

Vsec. lags Vpri. because of cable capacitance and the voltage divider being resistive—phase angle correction is needed (see *Table 9.13*).

Vpri./Vsec. = true ratio of voltage divider when connected to the VY-terminal or VZ-terminal (8 Vac LEA) voltage inputs.

where:

Vpri./Vsec. = 1476 for Eaton NOVA NX-T (15.5 kV models)
             = 2955 for Eaton NOVA NX-T (27 kV and 38 kV models)

MULTI-RECLOSER INTERFACE
See Changing Global Setting RECL_CFG Changes the CTPOL Setting and the PTRY and PTRZ Settings for 8 Vac LEA Voltage Inputs on page 2.95.

The SEL-651R-2 sees 8 Vac on the VY-terminal or VZ-terminal (8 Vac LEA) voltage inputs as 300 Vac. To realize accurate primary voltage metering, the corresponding potential transformer ratio settings (PTRY or PTRZ), are set as follows:

$$\text{PTRY or PTRZ} = \text{Vpri./Vsec.} \cdot (8/300)$$

$$= \left(1476 \cdot \left(\frac{8}{300}\right)\right)$$

$$= 39.36 \text{ for Eaton NOVA NX-T (15.5 kV models)}$$

Equation 9.9

$$= \left(2955 \cdot \left(\frac{8}{300}\right)\right)$$

$$= 78.8 \text{ for Eaton NOVA NX-T}$$
$$\text{(27 kV and 38 kV models)}$$

Equation 9.10

Derive PT Ratio Settings for Eaton NOVA LEA Voltage Inputs

NOTE: The Eaton NOVA NX-T recloser uses 8 V LEA inputs. See Derive PT Ratio Settings for 8 Vac LEA Voltage Inputs (on Eaton NOVA NX-T) for NOVA NX-T LEA PTR settings.

Refer to *Figure 9.23*.

Vsec. lags Vpri. because of the voltage divider resistance R1 and cable capacitance CC—phase angle correction is needed (see *Table 9.10– Table 9.12*).

Vpri./Vsec. = true ratio of voltage divider when connected to the VY-terminal (Eaton NOVA LEA) voltage inputs.

$$\text{Vpri./Vsec.} = 607 \text{ for Eaton NOVA 15 recloser}$$
$$= 1213 \text{ for Eaton NOVA 15*, NOVA 27,}$$
$$\text{NOVA 27*, and NOVA 38 reclosers}$$
$$\text{* with extended BIL}$$

The SEL-651R-2 sees 37.09 Vac on the VY-terminal (Eaton NOVA LEA) voltage inputs as 300 Vac. To realize accurate primary voltage metering, the corresponding potential transformer ratio setting (PTRY) is set as follows:

$$\text{PTRY} = \text{Vpri./Vsec.} \cdot (37.09/300)$$
$$= \left(607 \cdot \left(\frac{37.09}{300}\right)\right)$$
$$= 75.04 \text{ (round to 75.00) for Eaton NOVA 15 recloser}$$

Equation 9.11

$$= \left(1213 \cdot \left(\frac{37.09}{300}\right)\right)$$
$$= 149.96 \text{ (round to 150.00) for Eaton NOVA 15*,}$$
$$\text{NOVA 27, NOVA 27*, and NOVA 38 reclosers}$$

Derive PT Ratio Settings for 120 Vac, 1M Lindsey SVMI LEA Voltage Inputs

Refer to *Figure 9.25*.

Vsec. lags Vpri. because of voltage divider resistances R1 and R2 (R1 >> R2) and cable capacitance CC—phase angle correction is needed (see Lindsey SVMI discussion following *Table 9.14*).

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Settings 9.47
Page 485 of 1080
Settings Explanation
Wolfe

Vpri./Vsec. = true ratio of voltage divider when connected to the VY-terminal or VZ-terminal (120 Vac, 1M Lindsey SVMI LEA) voltage inputs.

The SEL-651R-2 sees the voltage applied on the VY-terminal or VZ-terminal (120 Vac, 1M Lindsey SVMI LEA) voltage inputs as exactly that voltage (e.g., 120 Vac applied appears as 120 Vac to the SEL-651R-2). The corresponding potential transformer ratio settings (PTRY or PTRZ) are set directly to the ratio of the Lindsey SVMI voltage sensor:

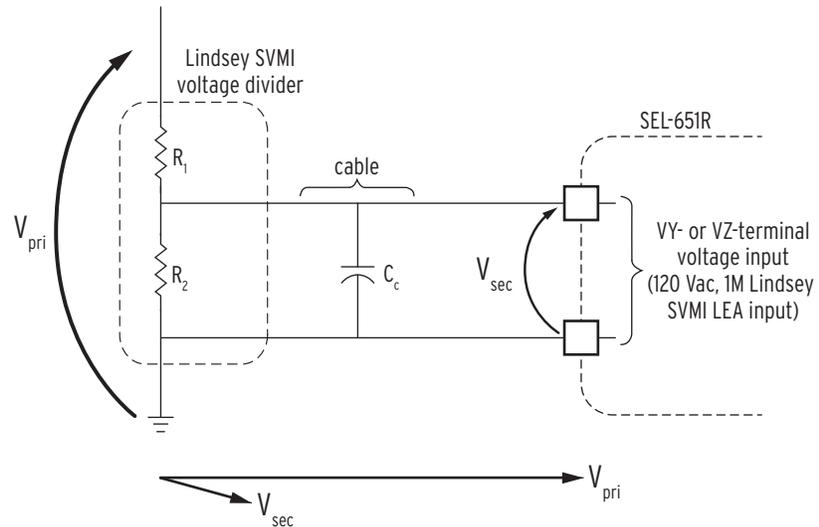
PTRY or PTRZ := Vpri./Vsec. **Equation 9.15**


Figure 9.25   Voltage Divider Connections and Relative Voltage Phase Angles for 120 Vac, 1M Lindsey SVMI LEA Voltage Inputs

Voltage-Related Settings and LEA Inputs (Group Settings)

Study *Figure 9.22* in preparation for the following example.

When the voltage inputs are 8 Vac LEA inputs, any voltage-related setting tied to the voltage inputs (e.g., VY-terminal voltage inputs; see *Table 9.17*) is adjusted by a factor of 300/8.

EXAMPLE 9.2   Voltage Setting Conversion to 300 V Base

This example uses much of the same information in Figure 9.22. A voltage divider (10000 ratio) is connected between a 12.47 kV system (7.2 kV line-to-neutral) and the LEA inputs.

$$\frac{7200 \text{ V}}{10000} = 0.72 \text{ V}$$ (actual voltage divider output to the 8 Vac LEA inputs; 8 V base)

$$0.72 \text{ V} \cdot \frac{300}{8} = 27 \text{ V}$$ (the relay thinks it is looking at 27 V on a 300 V base, not 0.72 V on an 8 V base)

27 V is the nominal adjusted secondary voltage–adjusted by the 300/8 factor from an 8 V base to a 300 V base. For this same example, if a 0.8 V output of the 8 Vac LEA (8 V base) is deemed an overvoltage condition, then an overvoltage element pickup setting (e.g., 59YP1P) could be set at:

$$59\text{YP1P} := 0.8 \text{ V} \cdot \frac{300}{8} = 30 \text{ V}$$ (300 V base)

9.48 | Settings
Settings Explanations

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 486 of 1080
Wolfe

This 300/8 adjustment factor also applies to power elements (see *Table 4.21* and accompanying text), if power element pickup settings (3PWR1P–3PWR4P) are initially computed using the actual voltage values connected to the 8 Vac LEA inputs.

Table 9.17   Adjust Voltage-Related Settings When the Voltage Inputs Are 8 Vac LEA Inputs (VY-Terminal Example)

Setting	Multiply 8 Vac Base Voltage Value by 300/8 Factor:	Setting Sheet
VNOM *(nominal voltage)*	When VSELECT := VY	*Page SET.7*
27YP1P, 27YP2P, 27YPP1P, 59YP1P, 59YP2P, 59YPP1P, 59YN1P, 59YN2P, 59YQ1P, 59YV1P *(for voltage elements)*	Always	*Page SET.25*
27B81P *(for blocking frequency elements)*	When FSELECT := VY	*Page SET.26*
3PWR1P, 3PWR2P, 3PWR3P, 3PWR4P *(for power elements)*	When VSELECT := VY	*Page SET.28*
25VPLO, 25VPHI	When FSELECT := VY	*Page SET.28*
25VSLO, 25VSHI *(for supervising synchronism-check elements)*	When FSELECT := VZ	

Table 9.17 is an example of modifying VY-terminal voltage-related settings for 8 Vac LEA inputs. Similar modifications can be made for VZ-terminal voltage-related settings for 8 Vac LEA inputs. Similar modifications can also be made for other LEA input types by applying like factors to the particular LEA base voltage value:

➤ Eaton NOVA LEA:

  multiply *37.09 Vac base* voltage value by 300/37.09 factor (see *Figure 9.23*)

➤ Siemens LEA:

  multiply *8.49 Vac base* voltage value by 300/8.49 factor (see *Figure 9.24*)

➤ 120 Vac, 1M Lindsey SVMI LEA:

  No adjustment needed (see *Figure 9.25*)

Voltage-Related Settings Possibly Limited by RCF Settings

Read the preceding subsection *Voltage Ratio Correction Factors for VY- and VZ-Terminal Voltage Inputs (Global Settings) on page 9.34*.

If most of the voltage range for VY-terminal voltage inputs (ordered as 8 Vac LEA voltage inputs) is used in a particular installation (i.e., the nominal applied secondary voltage is close to or equal to 8 V), then a ratio correction factor (RCF) set below unity (RCF < 1.000) can effectively limit the upper setting range of a voltage-related setting.

This subsection, together with *Example 9.2* and *Table 9.17*, discusses making voltage-related settings for LEA 8 V inputs by applying an adjustment factor of 300/8. This adjustment factor puts the setting on a 300 V base. Thus, an 8 V signal on an 8 Vac LEA voltage input translates to a 300 V signal on a base of 300 V, the upper setting range for the phase-to-neutral voltage-related settings.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 1487 of 2102
Settings 9.49
Setting Explanations
Wolfe

For example, if the RCF for voltage input V2Y is set to

Global setting V2YRCF $= 0.900$ $(< 1.000;$ set below unity)

and 8 V is applied to voltage input V2Y, then this applied voltage is normalized to

$8\text{ V} \cdot 0.900 = 7.2\text{ V}$ (normalized voltage from voltage input V2Y)

The upper limit for voltage that can be applied to the VY-terminal voltage inputs is 8 V. Assuming the 0.900 RCF in the previous equations is the lowest RCF for the VY-terminal voltage inputs and that the normalized voltages for all the voltage inputs should be the same (7.2 V in this example), then the maximum applied voltages for the other two channels (RCF's > 0.900) must be less than 8 V:

$$\frac{7.2\text{ V}}{\text{RCF}} < 8\text{ V} \qquad (\text{RCF} > 0.900)$$

The 7.2 V normalized voltage in this example translates to 270 V on a 300 V base:

$$7.2\text{ V} \cdot \frac{300}{8} = 270\text{ V} \quad (300\text{ V base})$$

The effective upper setting range is 270 V for the phase-to-neutral voltage-related settings in this example. A phase-to-neutral voltage-related setting can be set higher (e.g., 290 V), but for voltage input V2Y such a setting would be indistinguishable from a 270 V setting, in this example. The VY-terminal voltage inputs (ordered as 8 Vac LEA voltage inputs) cannot distinguish voltages above 8 V.

$$8\text{ V} \cdot 0.900 \cdot \frac{300}{8} = 270\text{ V} \quad (300\text{ V base})$$

Preceding *Example 9.2* is *not* an example of this possible effective limiting of the upper setting range of voltage-related settings. In *Example 9.2*, the nominal applied secondary voltage to the VY-terminal voltage inputs is 0.72 V, nowhere near the 8 V upper limit for VY-terminal voltage inputs (ordered as 8 Vac LEA voltage inputs).

Line Length (Group Setting)

Refer to *Line Parameter Settings on page SET.10*.

Line length setting LL is used in the fault locator function (see *Fault Location on page 12.8*). The line length is associated with the line impedance settings (described in next subsection).

Line length setting LL is unitless and corresponds to the line impedance settings. For example, if a particular line length is 15 miles, enter the line impedance values (Ω secondary) and then enter the corresponding line length:

LL = **15.00** (miles)

If this length of line is measured in kilometers rather than miles, then enter:

LL = **24.14** (kilometers)

Line Impedance Conversions (Group Settings)

Refer to *Line Parameter Settings on page SET.10*, *Load-Encroachment Elements on page SET.24* and *Directional Elements on page SET.24*.

The SEL-651R-2 has eight settings that are in units of ohms, secondary (impedance). The settings are Z1MAG and Z0MAG (used in the Fault Locator), ZLF and ZLR (used in the Load-Encroachment logic), and Z2F, Z2R, Z0F, and Z0R (used in Directional Control).

Impedance values are converted from primary ohms to secondary ohms using either *Equation 9.16* or *Equation 9.17*.

When VSELECT := VY

$$\Omega \text{ primary} \bullet \left(\frac{\text{CTR}}{\text{PTRY}} \right) = \Omega \text{ secondary}$$

Equation 9.16

> **NOTE**: The derived Ω secondary values in Equation 9.16 and Equation 9.17 are on a 300 V base. This even holds true when the VY-terminal voltage inputs are LEA inputs, because the PTRY setting has already been adjusted to 300 V (see Equation 9.6–Equation 9.14). Lindsey SVMI LEA inputs need no adjustment (see Equation 9.15).

where:

CTR = phase (IA, IB, IC) current transformer ratio setting
PTRY = phase (V1Y, V2Y, V3Y) potential transformer ratio setting (see note)

When VSELECT := VZ

$$\Omega \text{ primary} \bullet \left(\frac{\text{CTR}}{\text{PTRZ}} \right) = \Omega \text{ secondary}$$

Equation 9.17

where:

CTR = phase (IA, IB, IC) current transformer ratio setting
PTRZ = phase (V1Z, V2Z, V3Z) potential transformer ratio setting

When VSELECT := OFF, the fault locator and load-encroachment logic will not be available and the associated settings cannot be accessed.

Math Variables (Group Settings)

Refer to *Math Variable Settings on page SET.34*.

The math variable settings in the SEL-651R-2 are controlled by enable setting EMV = 1–64. In the SEL-651R-2, these variables are numeric settings in the range –16000.00 to +16000.00. There are no units associated with the math variable settings. These settings create analog quantities (with the same name as the setting) that are available for use in analog comparisons in SELOGIC control equations (see *Table 7.2*).

> **NOTE**: The context of a math variable is completely defined by its application. In the SEL-651R-2, math variables are not mathematical expressions. They are numeric constants. The SEL-651R-2 does not offer mathematical operations in SELOGIC control equation expressions.

The math variable MV01 := 2.00 is the only one used in the SEL-651R-2 factory-default settings. This setting selects the number of phase and ground time-overcurrent element operations on the fast curve, by virtue of being included in the factory-default setting for 51PSW, 51G1SW, and 79SKP3P. This default logic is described in *Figure 6.12* and related example in *Section 6: Close and Reclose Logic*.

Settings 9.51
Settings Explanation

Pole Status (52a), Trip, and Close Mapping Variations for Single-Phase Trip Capable Reclosers (Group Settings)

NOTE: If a single-phase trip capable recloser is ordered (Global setting BKTYP := 1), and the application does not require single-phase tripping and closing, make Group setting ESPB := N. The remainder of this subsection could be skipped, although it is recommended that these settings be followed if possible at commissioning time. If a single-phase trip scheme is specified in the future (ESPB := Y), then the recloser control is properly configured.

NOTE: The ABB OVR-3/VR-3S (24-pin, 15 and 27 kV models), and Tavrida OSM AI_2 reclosers use 52b style contacts. 52A_x equation should use the inverse of the inputs (NOT IN20x).

NOTE: The system phase rotation (and Global setting PHROT) has no impact on the recommended settings shown in Table 9.18, Table 9.19 and Table 9.20.

MULTI-RECLOSER INTERFACE
The settings in Table 2.7, Table 9.15, Table 9.19, and Table 9.20 are automatically set (and hidden), according to Global setting IPCONN, for the Multi-Recloser Interface on page 2.93. Also, Global setting BKTYP is automatically set to BKTYP := 1 (and hidden) for the Multi-Recloser Interface on page 2.93.

Refer to *Close Logic Settings on page SET.36* and *Recloser Interface Trip and Close Settings on page SET.37*. Review *Breaker Status Logic on page 6.3* and *Trip and Close Mapping and Output Logic on page 7.31*.

In *Figure 9.27* and *Figure 9.28*, notice that the control cables bring in current, pole status (52a), and trip/close signals together for each single phase. For example, in *Figure 9.28*, current I3, pole status 52a3, and Trip 3/Close 3 are all associated with B-phase:

$\quad$ IPCONN := CA**B** $\quad$ (current channel I**3** connected to **B**-phase)

$\quad$ 52A_**B** := IN20**3** $\quad$ (pole status 52a**3** connected to IN20**3**)

$\quad$ RCTR**3** := TRIP**B** OR ... $\quad$ (drives output RCTR**3**X, connected to Coil **3**)

$\quad$ RCCL**3** := CLOSE**B** OR ... $\quad$ (drives output RCCL**3**X, connected to Coil **3**)

Global setting IPCONN associates the current channels with the power system. For example, in *Figure 9.28*, IPCONN := CAB with current channels:

➤ I1 connected to C-phase

➤ I2 connected to A-phase

➤ I3 connected to B-phase

This same IPCONN Global setting information can be used to make similar breaker monitor, pole status (52a), trip, and close mapping settings, as shown in *Table 9.15*, *Table 9.18*, *Table 9.19*, and *Table 9.20*, respectively.

BCA	CLOSEB OR CLOSE3P	CLOSEC OR CLOSE3P	CLOSEA OR CLOSE3P
CAB	CLOSEC OR CLOSE3P	CLOSEA OR CLOSE3P	CLOSEB OR CLOSE3P
CBA	CLOSEC OR CLOSE3P	CLOSEB OR CLOSE3P	CLOSEA OR CLOSE3P

It is important to test that pole status (52a) and trip/close signals for a particular phase correspond to the proper current channel, before placing the unit into service. If the mapping settings shown in *Table 9.18*, *Table 9.19*, and *Table 9.20* are set incorrectly, tripping and closing may misoperate. *Table 9.18*, *Table 9.19*, and *Table 9.20* presume that the wiring from the control cable to the SEL-651R-2 relay module is not changed (see the various trip/close and recloser pole status figures in *Section 2: Installation*).

The SEL-651R-2 issues the following warning message when the IPCONN Global setting is changed (when Global setting BKTYP := 1):

```
WARNING!  The IPCONN setting was changed. Recloser trip
(RCTR_), close (RCCL_), status (52A_), and breaker
monitor initiate (BKMON_) SELogic Equation settings may
also need to be changed.
```

MULTI-RECLOSER INTERFACE
This warning for an IPCONN Global setting change is not displayed for the Multi-Recloser Interface on page 2.93. Also, Global setting BKTYP is automatically set to BKTYP := 1 (and hidden) for the Multi-Recloser Interface on page 2.93.

Also, the SEL-651R-2 issues the following warning message when the BKTYP Global setting is changed:

```
WARNING!  The global setting BKTYP was changed.
Settings ESPB, SPOD, and 52A_ will be affected.
Settings related to trip, close, and reclose logic, and
the breaker status (52A_) and breaker monitor initiate
(BKMON_) settings may need to be changed.
```

Transition Between A-B-C Worlds

In *Figure 9.26*, the SEL-651R-2 "1-2-3" connections provide a transition between the:

"A-B-C" power system world, outside

and the

"A-B-C" algorithm world, inside the SEL-651R-2

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 491 of 1080
Wolfe

Settings 9.53
Settings Explanation

Figure 9.26   Overview of Transition Between A-B-C Worlds Inside and Outside the SEL-651R-2

Wiring to the power system (potential transformer connections and recloser primary bushing connections) can be rather random, but correct power system "A-B-C" designation is still needed within the SEL-651R-2 algorithms. Preceding *Table 9.8–Table 9.15*, *Figure 9.21*, and *Table 9.18–Table 9.20* list the settings and all the possible settings combinations that realize the correct "A-B-C" designations within the SEL-651R-2 for the numerous possible power system connections.

Figure 9.27 and *Figure 9.28* are a more in depth look at the transition idea given in *Figure 9.26*. The underlying assumption in *Figure 9.27* and *Figure 9.28* is that the wiring from the control cable is factory-standard in its connection to both the SEL-651R-2 Recloser Control and the recloser (i.e., there is no rearrangement of the factory-default cable wiring). Note that the currents, trip/close signals, and pole status (52a) come through the control cable, but the voltage connections are separate. Thus, for a given phase, the current, trip/close signal, and pole status (52a) remain grouped together.

Straight-Through Phase Connections

From inspection of the SEL-651R-2 settings and connections in *Figure 9.27*, the correspondence between the power system world and the SEL-651R-2 connections is:

$$A \longleftrightarrow 1$$
$$B \longleftrightarrow 2$$
$$C \longleftrightarrow 3$$

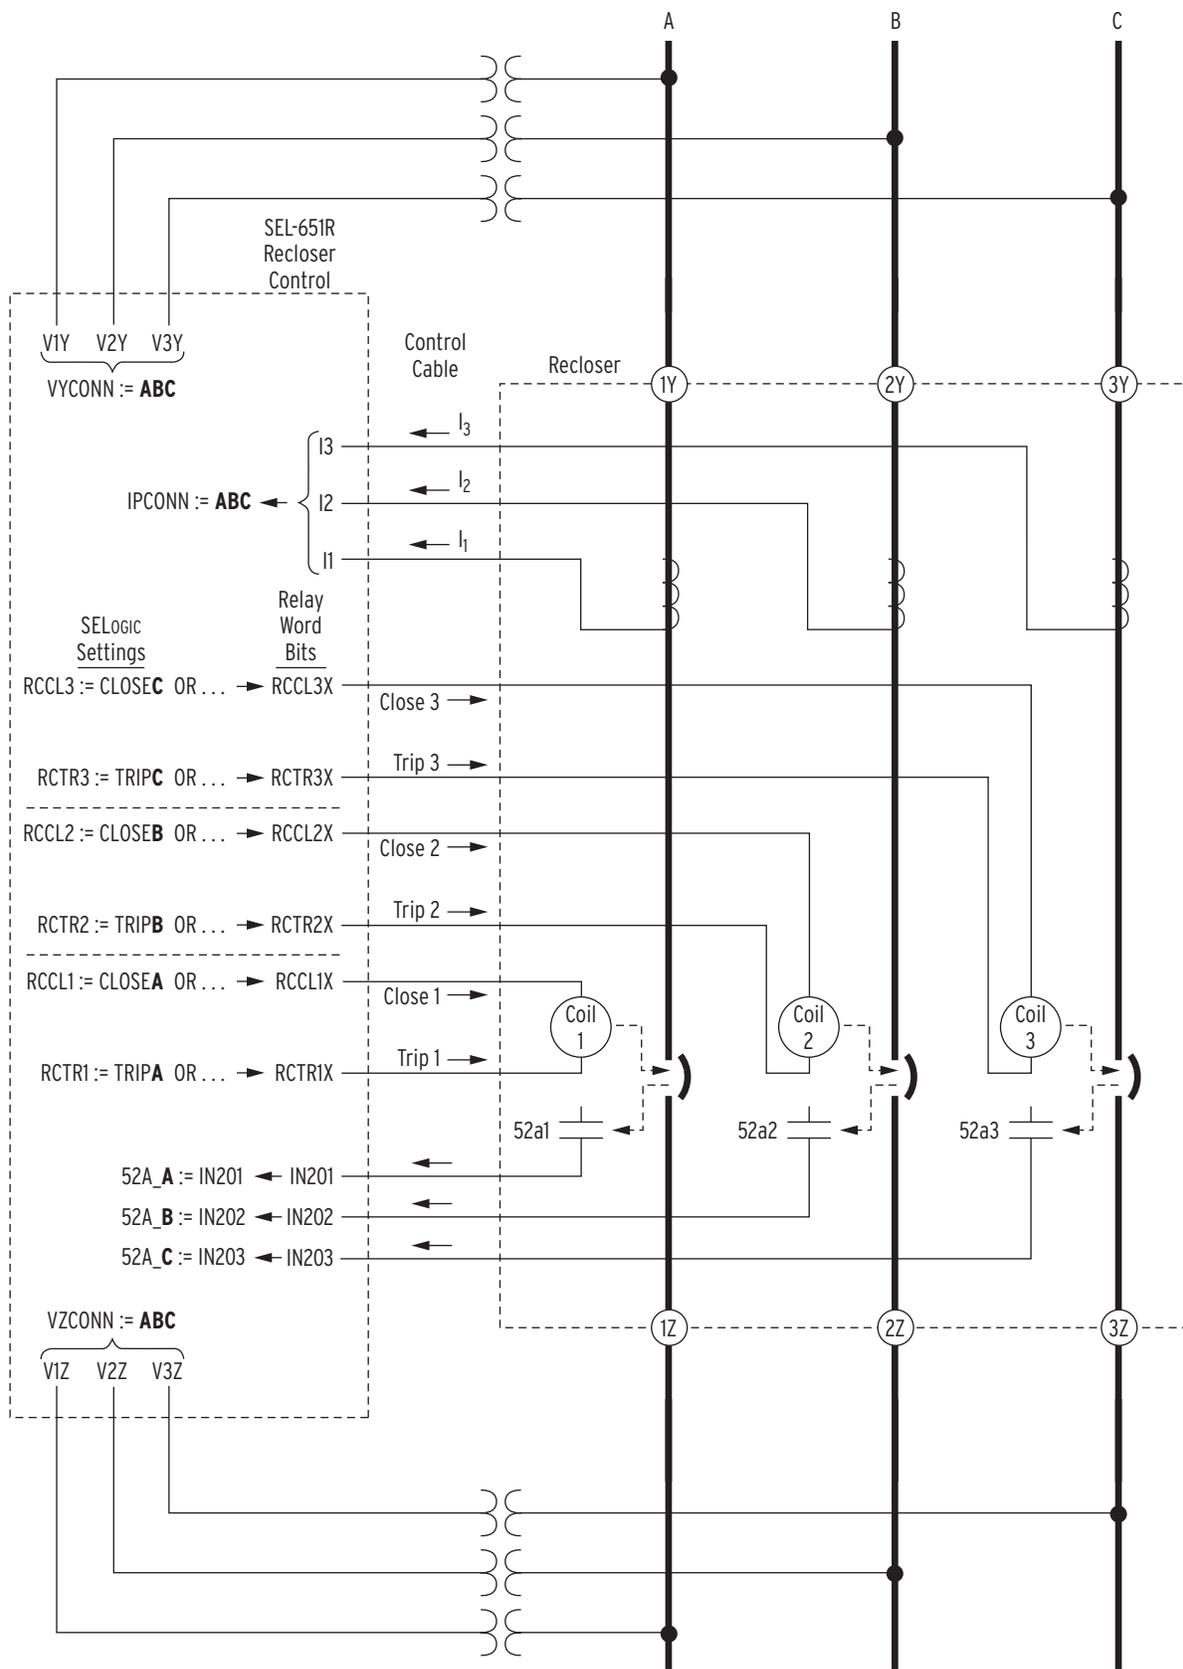
Wolfe


Figure 9.27 Single-Phase Trip Capable Recloser With Straight-Through Connections

Settings 9.55
Settings Explanation

Complex Phase Connections

Figure 9.28 is similar to *Figure 9.27*, but with the added complication of primary phase swapping. The correspondence between the power system world and the SEL-651R-2 connections is first, at the top of *Figure 9.28*:

A ←→ 1
B ←→ 2
C ←→ 3

with Global settings VYCONN := ABC
(voltage terminals: V1Y ≈A-phase, V2Y ≈B-phase, V3Y ≈C-phase)

Then after the first primary phase swap at the top of the recloser, the correspondence between the power system world and the SEL-651R-2 connections is (via the control cable in *Figure 9.28*):

C ←→ 1
A ←→ 2
B ←→ 3

with Global settings IPCONN := CAB (current terminals: I1 ≈C-phase, I2 ≈A-phase, I3 ≈B-phase) and:

Coil 1 ←→ C-phase
Coil 2 ←→ A-phase
Coil 3 ←→ B-phase

The following close circuit example traces "B ←→ 3" correspondence in *Figure 9.28*:

CLOSE**B** → RCCL**3** → RCCL**3**X (Close **3**) → Coil **3** → **B**-phase

"A-**B**-C"　　　　　　　　"1-2-**3**"　　　　　　　　"A-**B**-C"
algorithms　　　　connections/transitions　　　power system

The following trip circuit example traces "C ←→ 1" correspondence in *Figure 9.28*:

TRIP**C** → RCTR**1** → RCTR**1**X (Trip **1**) → Coil **1** → **C**-phase

"A-B-**C**"　　　　　　　　"**1**-2-3"　　　　　　　　"A-B-**C**"
algorithms　　　　connections/transitions　　　power system

The following pole status circuit example traces "A ←→ 2" correspondence in *Figure 9.28*:

52A_**A** ← IN202 ← 52a**2** ← Coil **2** ← **A**-phase

"**A**-B-C"　　　　　　　　"1-**2**-3"　　　　　　　　"**A**-B-C"
algorithms　　　　connections/transitions　　　power system

After the primary phase swap at the bottom of the recloser in *Figure 9.28*, the correspondence between the power system world and the SEL-651R-2 connections is lastly:

B → 1
C → 2
A → 3

with Global settings VZCONN := BCA
(voltage terminals: V1Z ≈B-phase, V2Z ≈C-phase, V3Z ≈A-phase)

Settings Explanation

Three-Phase vs. Single-Phase Operation

The trip and close settings (RCTR*n* and RCCL*n*, respectively) in *Figure 9.27* and *Figure 9.28* imply single-phase operation. But, three-phase operation can be realized, too, as shown in the settings possibilities in *Table 9.19* and *Table 9.20* ("… OR TRIP3P" and "… OR CLOSE3P").

Three-Phase Recloser Considerations

If a three-phase recloser is substituted for a single-phase recloser in *Figure 9.27* and *Figure 9.28*, the voltage and current connections and associated settings are essentially the same (although there are some current polarity connection differences; compare *Figure 2.49* with *Figure 2.52*). The major differences are with the trip/close signals and pole status (52a) coming through the control cable; compare with *Figure 2.50* with *Figure 2.54*.

Traditional Retrofit, Control-Powered Eaton NOVA, and G&W Control Power Viper -S reclosers are three-phase reclosers only (Global setting BKTYP := 3 and Group setting ESPB := N), where all three phases trip and close together. These reclosers have only one trip and close circuit and 52a status (see *Figure 2.50* and *Figure 2.60*, respectively). Three-phase operation in these reclosers is typically realized with settings:

RCTR1 := **TRIP3P** (see *Figure 5.1*)

RCCL1 := **CLOSE3P** (see *Figure 6.1*)

52A_3P := **SW1 AND NOT RCCL1X** (see *Figure 6.2*) Traditional Retrofit

or

52A_3P := **IN201** (see *Figure 6.2*) Control-Powered Eaton NOVA and G&W Control Power Viper-S

Display Point Settings

Refer to *Settings Sheet page SET.54* and *SET.60*.

The factory-default front-panel settings for DP01 and DP02 cause the message `FACTORY DEFAULT SETTINGS` to appear on the SEL-651R-2 rotating display. This message is not automatically disabled when settings are changed. The message is intended to remind the technician that the SEL-651R-2 needs to have settings applied before placing the recloser control into service. One of the first tasks the technician should perform is to defeat the display of the `FACTORY DEFAULT SETTINGS` message.

The message can be defeated by making Front-Panel settings

DP01 := **NA**

DP02 := **NA**

More details and instructions on display points are available in *Rotating Display on page 11.13*.

Enable Settings

Refer to the settings sheets that follow this section.

Several of the following Enable settings help limit the number of settings that must be entered when a feature is not required.

Global Enable Settings (SET G Command)

The Global settings class contains eight enable settings. These settings control other settings as follows:

➤ EGNDSW: Enable Ground Current Switch. Group settings E50N and NDEMP are available for setting only if EGNDSW := N. Controls Relay Word bit GNDSW (see *Table 4.23* and associated text).

MULTI-RECLOSER INTERFACE
Global setting BKTYP is automatically set to BKTYP := 1 (and hidden) for the Multi-Recloser Interface on page 2.93.

➤ BKTYP: Breaker Type. Group settings ESPB, SPOD, 52A_A, 52A_B, and 52A_C are available for setting only if BKTYP := 1. Group setting 52A_3P is available for setting only if BKTYP := 3.

➤ VSELECT: Voltage Source Selection. Group settings VNOM, ELOAD, E32, EFLOC, ELOP, EPWR, ESSI, and Line Parameters are available for setting only if VSELECT is not set to OFF.

➤ FSELECT: Frequency Source Selection. Group settings E81, E81R, and E25 are available for setting only if FSELECT is not set to OFF.

➤ EICIS: Enable Independent Control Input Settings. Global settings IN101D–IN107D and IN201D–IN206D are available for setting only if EICIS := Y.

➤ EBMON: Breaker Monitor (Y, N). Hides ten settings when set to N.

➤ EPMU: Synchronized Phasor Measurement (Y, N). Hides as many as 16 settings when set to N. Also affects Port enable settings PROTO and EPMIP.

➤ DST_BEGM: Month to Begin DST (NA, 1–12). Hides seven settings when set to NA.

Group Enable Settings (SET n Command)

➤ ESPB: Enable Single Phase Breaker Settings. Numerous single-phase Group settings for auto-reclosing, tripping, and other close conditions are available for setting only if ESPB := Y. Numerous three-phase Group settings for auto-reclosing, tripping, and other close conditions are available for setting only if ESPB := N.

➤ E50P, E50N, E50G, E50Q: Instantaneous/Definite-Time Overcurrent Elements

➤ E51P, E51ABC, E51N1, E51N2, E51G1, E51G2, E51Q: Time-Overcurrent Elements

➤ ELOAD: Load Encroachment

➤ E32: Directional Control

➤ EVOLT: Voltage Elements

➤ E81: Frequency Elements

➤ E81R: Rate-of-Change-of-Frequency Elements

➤ EFLOC: Fault Location (does not hide any settings)

➤ ELOP: Loss-of-Potential

➤ EPWR: Power Elements

➤ E25: Synchronism Check

➤ E79: Autoreclosing

➤ ESOTF: Switch-Onto-Fault

➤ EDDSOTF: SOTF Disturbance Detector Supervision

➤ EDEM: Demand Metering (does not hide any settings)

➤ ESSI: Voltage Sag/Swell/Interruption

➤ EHIF: High-Impedance Fault Detection

➤ EHBL2: Second-Harmonic Blocking

➤ EMV: Math Variable Settings

Logic Enable Settings (SET L n Command)

➤ ELAT: Enable SELOGIC Latches

➤ ESV: Enable SELOGIC Variables/Timers

➤ ESC: Enable SELOGIC Counters

Front-Panel Enable Settings (SET F Command)

➤ EDP: Enable Display Points

➤ ELB: Enable Local Bits

Port Enable Settings (SET P n Command)

Serial Port Settings (Port 1, 2, 3, or F; Port F and Port 4 Are the Same Front-Serial Port)

NOTE: The Access jumper overrides the EPORT = N setting for the front-panel ports. Installing the Access jumper also causes the front-panel EIA-232 port to revert to factory-default settings for PROTO, SPEED, BITS, PARITY, STOP, and RTSCTS when EPORT = N.

NOTE: The Access jumper overrides the MAXACC setting for any enabled ports and allows the highest access level (C = Calibration).

➤ EPORT: Enable Port (Y, N). Disables the port and hides all port settings when set to N. The EPORT setting for Port F controls both the front-panel EIA-232 serial port F and the USB port.

➤ PROTO: Protocol. Controls availability of subsequent settings. When PROTO is set to SEL or DNP, another enable setting appears:

MAXACC: Maximum Access Level (0, 1, B, 2, C). Selects highest access level allowed on port by limiting the availability of commands **ACC**, **BAC**, **2AC**, or **CAL**. MAXACC for Port F can be set to 1, B, 2, or C and affects both serial port F and the USB port.

Ethernet Port Settings (Port 5)

➤ EPORT: Enable Port (Y, N). Hides all port settings when set to N.

➤ ETELNET: Enable Telnet (Y, N). Hides six settings when set to N. When ETELNET is set to Y, another enable setting appears:

NOTE: When ETELNET = Y, the Access jumper overrides the MAXACC setting and allows the Telnet session(s) to attain the highest access level (C = Calibration).

MAXACC: Maximum Access Level (0, 1, B, 2, C). Selects highest access level allowed on a Telnet session by limiting the availability of commands **ACC**, **BAC**, **2AC**, or **CAL**.

➤ EFTPSERV: Enable FTP (Y, N). Hides three settings when set to N.

➤ EHTTP: Enable HTTP Server (Y, N). Hides five settings when set to N. When EHTTP is set to Y, another enable setting appears:

HTTPACC: HTTP Maximum Access Level (1, 2). Selects highest access level allowed over the web server interface.

➤ E61850: Enable IEC 61850 Protocol (Y, N). Hides two settings when set to N (setting only present on relays ordered with IEC 61850).

➤ EDNP: Enable DNP Sessions (0–6). Controls availability of subsequent settings (as many as 33 settings per session).

➤ EPMIP: Enable PMU Processing (Y, N). Controls availability of as many as eight subsequent settings.

➤ EMODBUS: Enable Modbus (0–3). Controls availability of as many as seven subsequent settings.

➤ ESNTP: Enable SNTP client (OFF, UNICAST, MANYCAST, BROADCAST). Controls availability of as many as five subsequent settings.

PC Software

These enable settings are also present in the SEL-651R-2 driver for QuickSet. The effect of changing an enable setting is easy to see, because the associated setting field turns gray when it is unavailable. See *Section 3: PC Software* for more information on QuickSet.

Settings
Factory-Default Settings

USB Port

No port settings are required for the USB port. However, the USB port is controlled by the previously described Port F (front-panel EIA-232 serial port) settings EPORT and MAXACC.

The PC operating system should prompt for a USB driver when a PC is connected to the relay. See *Establishing Communications Through Use of the USB Port on page 10.2* for further details on using the USB port.

Factory-Default Settings

Factory-default settings for a particular SEL-651R-2 are configured per the unit's part number. The factory-default settings in *Figure 9.30–Figure 9.39* are for an SEL-651R-2 configured with the following part number options (taken from the SEL-651R-2 Model Option Table):

➤ Control Cable Interface = Traditional Retrofit (14-pin)

➤ Secondary Input Voltage = (3) Eaton NOVA LEA inputs and (3) 120 Vac, 1M Lindsey SVMI LEA inputs

➤ Communications Port = 3 EIA-232, USB

➤ Communications Interface = (2) 100BASE-FX, EIA-485

➤ Power Supply = 120 Vac

Additional comments are included in *Figure 9.30–Figure 9.33*, touching primarily on setting variations because of:

➤ Interfacing with different recloser controls (corresponding to different Control Cable Interface options in the SEL-651R-2 Model Option Table)

➤ Connecting to different voltage sources (corresponding to different Secondary Input Voltage options in the SEL-651R-2 Model Option Table)

Settings Sheets

NOTE: If the QuickSet settings editor is being used in conjunction with these settings sheets, some differences in setting order will be seen between the two formats, especially in the location of the enable settings. The Print option in QuickSet will list the settings in a similar order as these settings sheets.

The settings sheets that follow include the definition and input range for each setting in the SEL-651R-2. Many of the settings categories in the settings sheets include a reference to a page, table, or figure (in parentheses) that further explains the settings.

SEL-651R-2 Settings Sheets

Global Settings

(Serial Port Command SET G and Front-Panel SET/SHOW Global Menu*)

* SELOGIC control equations can be viewed, but not changed, via the front-panel `Set/Show > Global Menu`.
For most applications, make Global settings (page *SET.1–SET.7*) before making the Group 1–8 settings.

General Settings

See General (Global Settings) on page 9.27.

Nominal Frequency (50, 60 Hz)	**NFREQ**	:= _____
Phase Rotation (ABC, ACB)	**PHROT**	:= _____
Date Format (MDY, YMD, DMY)	**DATE_F**	:= _____

See Battery System Monitor on page 8.39.

Power-Off Delay After AC Loss (OFF, 1–1440 min)	**PWRDN_AC**	:= _____
Power-Off Delay After Wake Up (OFF, 1–1440 min)	**PWRDN_WU**	:= _____

Request Battery Test SELOGIC Equation
   TESTBATT   := _____

See SELOGIC Control Equation Setting FAULT on page 5.18.

Fault Condition SELOGIC Equation
   FAULT   := _____

Current and Voltage Connection Settings

See Multi-Recloser Interface on page 2.93.

Recloser Configuration (A1, A2, A3)	**RECL_CFG**	:= _____

See Current and Voltage Connections (Global Settings) on page 9.28.

I1, I2, I3 Current Terminal Connections (ABC, ACB, BAC, BCA, CAB, CBA)	**IPCONN**	:= _____
Enable Ground Current Switch (Y, N)	**EGNDSW**	:= _____
Current Transformer Polarity (POS, NEG)	**CTPOL**	:= _____
Breaker Type (Single-Phase = 1, Three-Phase = 3)	**BKTYP**	:= _____
VY Voltage Terminal Connections (OFF, Combination of A, B, C) *Valid combinations: ABC, ACB, BAC, BCA, CAB, CBA, A, B, C, AB, BC, CA*	**VYCONN**	:= _____

VZ Voltage Terminal Connections   **VZCONN**   := _____
(OFF, Combination of A, B, C)
Valid combinations: ABC, ACB, BAC,
BCA, CAB, CBA, A, B, C, AB, BC, CA

Enable Phantom Voltage Source (OFF, VY, VZ)   **EPHANT**   := _____
Setting EPHANT is only available when one or both of VYCONN or
VZCONN is set to single-phase voltages A, B, C, AB, BC, or CA

Voltage Source Selection (OFF, VY, VZ)   **VSELECT**   := _____
Setting VSELECT is only available when one or both of VYCONN or
VZCONN is set to three-phase combinations ABC, ACB, BAC, BCA,
CAB, or CBA

Frequency Source Selection (OFF, VY, VZ)   **FSELECT**   := _____
Setting FSELECT is only available when one or both of VYCONN or
VZCONN is not set to OFF

Meter Cutoff Threshold (Y, N, E)   **METHRES**   := _____
(see *Small-Signal Cutoff for Metering on page 8.19*)

Global Enable Settings

Independent Control Input Settings (Y, N)   **EICIS**   := _____

Breaker Monitor (Y, N)   **EBMON**   := _____

Alarm SELOGIC Equation
  SALARM   := _____

Optoisolated Input Timers

See Figure 7.18.

Make the following settings when the SEL-651R-2 is ordered with extra input/outputs, and if preceding enable
setting EICIS := Y.

Input IN101–IN102 Debounce Time Settings   **IN101D**   := _____
  (AC, 0.00–2.00 cycles in 0.0625-cycle steps; when ordered   **IN102D**   := _____
  with 125 Vdc inputs)
  (0.00–2.00 cycles in 0.0625-cycle steps when ordered *without*
  125 Vdc inputs)

Input IN103–IN107 Debounce Time Settings   **IN103D**   := _____
  (0.00–2.00 cycles in 0.0625-cycle steps)   **IN104D**   := _____
                                                    IN105D   := _____
                                                    IN106D   := _____
                                                    IN107D   := _____

Status Input Timers

See Figure 7.17.

Make the following settings when the preceding enable setting EICIS := Y.

Input IN201–IN206 Debounce Time   **IN201D**   := _____
  (0.00–2.00 cycles in 0.0625-cycle steps)   **IN202D**   := _____
                                                    IN203D   := _____

Voltage Ratio Correction Factors for VY-Terminal Voltage Inputs

See Voltage Ratio Correction Factors for VY- and VZ-Terminal Voltage Inputs (Global Settings) on page 9.34.

Make the following settings when the SEL-651R-2 is ordered with LEA ac inputs on the VY terminals.

Ratio Correction Factor (0.500–1.500)   **V1YRCF**   := _____

Ratio Correction Factor (0.500–1.500)   **V2YRCF**   := _____

Ratio Correction Factor (0.500–1.500)   **V3YRCF**   := _____

Voltage Ratio Correction Factors for VZ-Terminal Voltage Inputs

See Voltage Ratio Correction Factors for VY- and VZ-Terminal Voltage Inputs (Global Settings) on page 9.34.

Make the following settings when the SEL-651R-2 is ordered with LEA ac inputs on the VZ terminals.

Ratio Correction Factor (0.500–1.500)   **V1ZRCF**   := _____

Ratio Correction Factor (0.500–1.500)   **V2ZRCF**   := _____

Ratio Correction Factor (0.500–1.500)   **V3ZRCF**   := _____

Voltage Phase Angle Correction for VY Terminals

See Voltage Phase Angle Correction Settings for VY- and VZ-Terminal Voltage Inputs (Global Settings) on page 9.36.

Make the following settings when the SEL-651R-2 is ordered with LEA ac inputs on the VY terminals.

Phase Angle Correction (–10.0 to 0 degrees)	**V1YPAC**	:= _____
Phase Angle Correction (–10.0 to 0 degrees)	**V2YPAC**	:= _____
Phase Angle Correction (–10.0 to 0 degrees)	**V3YPAC**	:= _____

Voltage Phase Angle Correction for VZ Terminals

See Voltage Phase Angle Correction Settings for VY- and VZ-Terminal Voltage Inputs (Global Settings) on page 9.36.

Make the following settings when the SEL-651R-2 is ordered with LEA ac inputs on the VZ terminals.

Phase Angle Correction (–10.0 to 0 degrees)	**V1ZPAC**	:= _____
Phase Angle Correction (–10.0 to 0 degrees)	**V2ZPAC**	:= _____
Phase Angle Correction (–10.0 to 0 degrees)	**V3ZPAC**	:= _____

Breaker Monitor Settings

See Breaker Monitor Setting Example on page 8.26.

Make the following settings if preceding enable setting EBMON := Y.

Close/Open Set Point 1—Max. (0–65000 operations)	**COSP1**	:= _____
Close/Open Set Point 2—Mid. (0–65000 operations)	**COSP2**	:= _____
Close/Open Set Point 3—Min. (0–65000 operations)	**COSP3**	:= _____

kA Interrupted Set Point 1—Min. (0.00–999.00 kA primary in 0.01 kA steps)	**KASP1**	:= _____
kA Interrupted Set Point 2—Mid. (0.00–999.00 kA primary in 0.01 kA steps)	**KASP2**	:= _____
kA Interrupted Set Point 3—Max. (0.00–999.00 kA primary in 0.01 kA steps)	**KASP3**	:= _____

NOTES:

➤ COSP1 must be set greater than COSP2.

➤ COSP2 must be set greater than or equal to COSP3.

➤ KASP1 must be set less than KASP2.

➤ If COSP2 is set the same as COSP3, then KASP2 must be set the same as KASP3.

➤ KASP3 must be set at least 5 times (but no more than 100 times. the KASP1 setting value.

➤ KASP2 must be set less than or equal to KASP3.

See Table 9.17 for proper VNOM setting adjustment when LEA inputs are used.

Enable Settings

Set Global setting BKTYP := 1 for single-phase reclosers–see Breaker/Recloser Type Setting (BKTYP) and Enable Single-Phase Breaker Setting (ESPB) on page 9.30.

Make ESPB setting when Global setting BKTYP := 1.

Single Phase Breaker Settings (Y, N) **ESPB** := _____
When BKTYP := 3, ESPB := N

Instantaneous/Definite-Time Overcurrent Enable Settings

Phase Element Levels (N, 1–6) **E50P** := _____
(see *Figure 4.1–Figure 4.7*)

Make E50N setting when Global setting EGNDSW is set to N.

Neutral Element Levels—Channel IN (N, 1–6) **E50N** := _____
(When EGNDSW := Y, E50 := N; see *Figure 4.10* and
Figure 4.11)

Ground Element Levels (N, 1–6) **E50G** := _____
(see *Figure 4.12* and *Figure 4.13*)

Negative-Sequence Element Levels (N, 1–6) **E50Q** := _____
(see *Figure 4.14* and *Figure 4.15*)

Time-Overcurrent Enable Settings

See Table 4.1.

Maximum-Phase Elements (N, 1, 2) **E51P** := _____

Single-Phase Elements (N, 1, 2) **E51ABC** := _____

Neutral #1 Elements (N, 1, 2) **E51N1** := _____
(*When EGNDSW = Y, E51N1 := N*)

Neutral #2 Elements (N, 1, 2) **E51N2** := _____
(*When EGNDSW = Y, E51N2 := N*)

Ground #1 Elements (N, 1, 2) **E51G1** := _____

Ground #2 Elements (N, 1, 2) **E51G2** := _____

Negative-Sequence Elements (N, 1, 2) **E51Q** := _____

Other Enable Settings

Load Encroachment (Y, N)   **ELOAD**   := _____
  (*When VSELECT := OFF, ELOAD := N*; see *Figure 4.48*)

Directional Elements (Y, AUTO, AUTO2, N)   **E32**   := _____
  (*When VSELECT := OFF, E32 := N*;
  see *Figure 4.51–Figure 4.61*)

Voltage Elements (N, VY, VZ, BOTH)   **EVOLT**   := _____
  (see *Figure 4.26–Figure 4.29*)

Frequency Elements (N, 1–6)   **E81**   := _____
  (*When FSELECT := OFF, E81 := N*; see *Figure 4.38*)

Rate-of-Change-of-Frequency (N, 1–4)   **E81R**   := _____
  (*When FSELECT := OFF, E81R := N*; see *Figure 4.39*)

Fault Location (Y, N)   **EFLOC**   := _____
  (*When VSELECT = OFF, EFLOC := N*;
  see *Fault Location on page 12.8*)

Loss-of-Potential (Y, Y1, N)   **ELOP**   := _____
  (*When VSELECT = OFF, EFLOP := N*; see *Figure 4.50*)

Power Element Levels (N, 3P1–3P4)   **EPWR**   := _____
  (*When VSELECT = OFF, EPWR := N*;
  see *Power Elements on page 4.64*)

Synchronism Check (Y, N)   **E25**   := _____
  (*When FSELECT = OFF, E25 := N*;
  see *Figure 4.30* and *Figure 4.31*)

Reclosures (N, 1– 4)   **E79**   := _____
  (see *Reclosing Relay on page 6.17*)

Switch-Onto-Fault (Y, N)   **ESOTF**   := _____
  (see *Figure 5.7*)

Make EDDSOTF setting when setting ESOTF := Y.

Switch-Onto-Fault Disturbance Detector Supervision (Y, N)   **EDDSOTF**   := _____
  (*when ESOTF := N, EDDSOTF := N*; see *Figure 5.1*)

Demand Metering (THM = Thermal, ROL = Rolling)   **EDEM**   := _____
  (see *Figure 8.4*)

Voltage Sag/Swell/Interruption (Y, N)   **ESSI**   := _____
  (*when VSELECT := OFF, ESSI := N*;
  see *Figure 4.40*, *Figure 4.41*, and *Figure 4.42*)

High-Impedance Fault Detection (Y, N, T) (Ordering Option)   **EHIF**   := _____
  (see *High-Impedance Fault Detection (Arc Sense Technology) on page 4.111*)

Second-Harmonic Blocking (Y, N)   **EHBL2**   := _____
  (see *Figure 4.25*)

Math Variable Settings (N, 1–64)   **EMV**   := _____
  (see *Analog Comparators and Checks on page 7.6*)

SEL<small>OGIC</small> Counter Settings

See Counters on page 7.13.

Number of SEL<small>OGIC</small> counter settings dependent on preceding enable setting ESC := 1–16)

NOTE: For any counter, if the last setting (e.g., SC12CD) is set to NA, the entire counter (SC12, in this example) is disabled and the counter value (if SC12 = 10, when setting SC12CD to NA, SC12 will be frozen at 10) will be frozen. If the count-down function is not needed for a particular counter application, set the count-down setting to logical 0 (e.g., SC12CD := 0) to allow the rest of the counter to function.

of 76
Wolfe

Port n Settings

(Serial Ports 1, 2, 3 and F (4) Serial Port SET P n Command and Front Panel)

Make Port 1 settings only if the relay is ordered with the EIA-485 port.

Port F and Port 4 are the same front-panel serial port.

Port Enable Settings

Enable Port (Y, N)   **EPORT**   := _____

NOTE: Setting EPORT = N completely disables the serial port, and hides all remaining port settings.

NOTE: The front-panel (Port F) EPORT setting controls both the EIA-232 serial port and the optional USB port.

NOTE: If the Access Jumper is not installed when EPORT is set to "N" on the front port and all other ports are disabled, or MAXACC < 2 on all enabled ports, the port can only be re-enabled via the HMI or by installing the Access Jumper and cycling power.

Protocol Selection

Protocol   **PROTO**   := _____
(SEL, DNP, MOD, MBA, MBB, MB8A, MB8B, PMU)

NOTE: Modbus protocol (PROTO = MOD) cannot be selected for the front-panel serial port (Port F).

Set PROTO = SEL for standard SEL ASCII protocol. Refer to Section 10: Communications for details on SEL ASCII protocol.

Set PROTO = DNP for Distributed Network Protocol (DNP). As many as six DNP sessions are available, shared between the serial ports and the Ethernet port. Refer to Appendix E: DNP3 Communications for details on DNP protocol.

Set PROTO = MOD for Modbus communications. As many as three Modbus sessions are available, shared between the serial ports and the Ethernet port. Refer to Appendix K: Modbus RTU and TCP Communications for details on Modbus protocol.

Set PROTO = MBA, MBB, MB8A, or MB8B for MIRRORED BITS. Only one port can be set to MBA or MB8A at a time. Only one port can be set to MBB or MB8B at a time. Refer to Appendix D: MIRRORED BITS Communications for details on MIRRORED BITS.

Set PROTO = PMU for IEEE C37.118 Synchrophasors. You must first make Global setting EPMU = Y to make this setting available. See Appendix J: Synchrophasors for details.

Make the following setting when PROTO = SEL or DNP on Port 1, 2, 3, or F.

Maximum Access Level (0, 1, B, 2, C)   **MAXACC**   := _____

NOTE: The MAXACC setting controls the availability of **ACC**, **BAC**, **2AC**, and **CAL** commands on this port.

NOTE: MAXACC for Port F (only) can be set to 1, B, 2, or C, and affects both Serial Port F and the USB port.

SEL Protocol Settings

Make the following settings when PROTO = SEL.

Data Rate (300, 1200, 2400, 4800, 9600, 19200, 38400, 57600)   **SPEED**   := _____

Data Bits (6, 7, 8)   **BITS**   := _____

Parity (O, E, N) {Odd, Even, None}   **PARITY**   := _____

Stop Bits (1, 2)   **STOP**   := _____

Enable Hardware Handshaking (Y, N)   **RTSCTS**   := _____

Set RTSCTS = Y to enable hardware handshaking. With RTSCTS = Y, the relay will not send characters until the CTS input is asserted. Also, if the relay is unable to receive characters, it deasserts the RTS line (see Hardware Handshaking on page 10.9).

NOTE: The RTSCTS setting is not available on Port 1.

Minutes to Port Time-out (0–30 minutes)   **T_OUT**   := _____

Set T_OUT to the number of minutes of serial port inactivity for an automatic log out. Set T_OUT = 0 for no port time out.

Send Auto Messages to Port (Y, N)   **AUTO**   := _____

Set AUTO = Y to allow automatic messages at the serial port. See Serial Port and Telnet Session Automatic Messages on page 10.21.

Fast Operate Enable (Y, N)   **FASTOP**   := _____

Set FASTOP = Y to enable binary Fast Operate messages at the serial port. Set FASTOP = N to block binary Fast Operate messages. Refer to Appendix I: Configuration, Fast Meter, and Fast Operate Commands for the description of the SEL-651R-2 Fast Operate commands.

DNP Settings

Make the following settings when PROTO = DNP.

Data Rate (300, 1200, 2400, 4800, 9600, 19200, 38400, 57600)   **SPEED**   := _____

Parity (O, E, N) {Odd, Even, None}   **PARITY**   := _____

Stop Bits (1, 2)   **STOP**   := _____

Minutes to Port Time-out (0–30 minutes)   **T_OUT**   := _____

Set T_OUT to the number of minutes of serial port inactivity for an automatic log out. Set T_OUT = 0 for no port time out. T_OUT applies to DNP virtual terminal only.

DNP Address (0–65519)   **DNPADR**   := _____

DNP Address to Report to (0–65519)   **REPADR**   := _____

DNP Session Map (1–3)   **DNPMAP**   := _____

Analog Input Default Variation (1–6)   **DVARAI**   := _____

Class for Binary Event Data (0–3)   **ECLASSB**   := _____

Class for Counter Event Data (0–3)   **ECLASSC**   := _____

Class for Analog Event Data (0–3)   **ECLASSA**   := _____

Make the following setting when ECLASSA > 0 or ECLASSC > 0.

Miscellaneous Data Reporting Dead Band Counts (0–32767)	**ANADBM**	:= _____
Minutes for Request Interval (I, M, 1–32767)	**TIMERQ**	:= _____

NOTE: TIMERQ = I: Disables time-sync requests and ignores syncs from master.

NOTE: TIMERQ = M: Disables time-sync requests and processes time syncs from master.

NOTE: TIMERQ = m = 1–32767: Relay requests a time-sync every m minutes.

Seconds to Select/Operate Time-out (0.0–30.0 seconds in 0.1 second steps)	**STIMEO**	:= _____
Data Link Retries (0–15)	**DRETRY**	:= _____

Make the following setting when DRETRY > 0.

Seconds to Data Link Time-out (0–5 seconds in 1 second steps)	**DTIMEO**	:= _____
Max Response Size (200–2411 in bytes)	**RESPSZ**	:= _____
Event Message Confirm Time-out (1–120 seconds in 1 second steps)	**ETIMEO**	:= _____

Make the following setting when ECLASSB > 0, ECLASSC > 0 or ECLASSA > 0.

Enable Unsolicited Reporting (Y, N)	**UNSOL**	:= _____

Make the following nine settings when UNSOL = Y.

Enable Unsolicited Reporting at Power-Up (Y, N)	**PUNSOL**	:= _____
Number of Class 1 Events to Transmit On (1–200)	**NUM1EVE**	:= _____
Oldest Class 1 Event to Transmit On (0.0–99999.0 seconds in 0.1 second steps)	**AGE1EVE**	:= _____
Number of Class 2 Events to Transmit On (1–200)	**NUM2EVE**	:= _____
Oldest Class 2 Event to Transmit On (0.0–99999.0 seconds in 0.1 second steps)	**AGE2EVE**	:= _____
Number of Class 3 Events to Transmit On (1–200)	**NUM3EVE**	:= _____
Oldest Class 3 Event to Transmit On (0.0–99999.0 seconds in 0.1 second steps)	**AGE3EVE**	:= _____
Unsolicited Message Maximum Retry Attempts (2–10)	**URETRY**	:= _____
Unsolicited Message Offline Time-out (OFF, 2–5000 seconds in 1 second steps)	**UTIMEO**	:= _____

NOTE: UTIMEO must be greater than ETIMEO.

Minimum Seconds from DCD to Transmit (0.00–1.00 seconds in 0.01 second steps)	**MINDLY**	:= _____
Maximum Seconds from DCD to Transmit (0.00–1.00 seconds in 0.01 second steps)	**MAXDLY**	:= _____

NOTE: MAXDLY must be greater than MINDLY.

Settle Time from RTS ON to Transmit (OFF, 0.00–30.00 seconds in 0.01 second steps)	**PREDLY**	:= _____

Make the following setting when PREDLY ≠ OFF.

Settle Time from Transmit to RTS OFF (0.00–30.00 seconds in 0.01 second steps)	**PSTDLY**	:= _____

Port 5 Settings

(Serial Port SET P 5 Command (for Ethernet Port 5, or 5A and 5B))

Port Enable Setting

Enable Port (Y, N)   **EPORT**   := _____

NOTE: Setting EPORT = N completely disables the Ethernet port, and hides all remaining port settings.

Ethernet Port Settings

IP addresses are entered as zzz.yyy.xxx.www, where zzz = 1-126, 128-223; yyy = 0-255; xxx = 0-255; www = 0-255.

Device IP Address (zzz.yyy.xxx.www)   **IPADDR**   := _____

Subnet Mask (zzz.yyy.xxx.www)   **SUBNETM** := _____

Default Router (zzz.yyy.xxx.www)   **DEFRTR**   := _____

NOTE: Setting DEFRTR = 0.0.0.0 disables the default router.

Enable TCP Keep-Alive (Y, N)   **ETCPKA**   := _____

TCP Keep-Alive is enabled with default range settings for PMU sessions even when ETCPKA = N.

Make the following three settings when ETCPKA = Y.

TCP Keep-Alive Idle Range (1–20 seconds in 1 second steps)   **KAIDLE**   := _____

TCP Keep-Alive Interval Range
(1–20 seconds in 1 second steps)   **KAINTV**   := _____

TCP Keep-Alive Count Range (1–20)   **KACNT**   := _____

Make the following setting when the relay has dual Ethernet.

Operating Mode (FIXED, FAILOVER, SWITCHED)   **NETMODE** := _____

Make the following setting when NETMODE = FAILOVER.

Failover Time-out
(OFF, 0.10–65.00 seconds in 0.01 second steps)   **FTIME**   := _____

Make the following setting when NETMODE = FIXED or FAILOVER.

Primary Net Port (A, B)   **NETPORT** := _____

Make the following settings for each enabled port when the relay has dual 10/100BASE-T (copper).

Port 5A Speed (AUTO, 10, 100 Mbps)   **NET5ASPD** := _____

Port 5B Speed (AUTO, 10, 100 Mbps)   **NET5BSPD** := _____

Make the following setting when the relay has single 10/100BASE-T (copper).

Port 5 Speed (AUTO, 10, 100 Mbps)   **NET5SPD** := _____

Telnet Settings

Enable Telnet (Y, N)   **ETELNET**   := _____

Make the following settings when ETELNET = Y.

Maximum Access Level (0, 1, B, 2, C)   **MAXACC**   := _____

NOTE: The MAXACC setting controls the availability of the **ACC**, **BAC**, **2AC**, and **CAL** commands in the Telnet session.

Telnet Port (23, 1025–65534)   **TPORT**   := _____

Telnet Connect Banner (254 characters maximum. Use "\n" to create a new line).

TCBAN   := _____

_____

Telnet Port Time-out (1–30 minutes in 1 minute steps)   **TIDLE**   := _____

Send Auto Messages to Port (Y, N)   **AUTO**   := _____

Set AUTO = Y to allow automatic messages on the Telnet session (similar to serial port auto message–see Serial Port and Telnet Session Automatic Messages on page 10.21).

Fast Operate Enable (Y, N)   **FASTOP**   := _____

Set FASTOP = Y to enable binary Fast Operate messages on the Telnet session. Set FASTOP = N to block binary Fast Operate messages. Refer to Appendix I: Configuration, Fast Meter, and Fast Operate Commands for the description of the SEL-651R-2 Fast Operate commands.

See Section 10: Communications for full settings explanations and other required settings.

File Transfer Protocol (FTP) Server Settings

Enable FTP (Y, N)   **EFTPSERV**   := _____

Make the following settings when EFTPSERV = Y.

FTP User Name (20 characters maximum)   **FTPUSER**   := _____

FTP Connect Banner (254 characters maximum) Use "\n" to create a new line).

FTPCBAN := _____

_____

FTP Idle Timeout (5–255 minutes)   **FTPIDLE**   := _____

Hypertext Transfer Protocol (HTTP) Web Server Settings

Enable HTTP Server (Y, N)   **EHTTP**   := _____

Make the following settings when EHTTP = Y)

HTTP Maximum Access Level (1, 2)   **HTTPACC**   := _____

TCP/IP Port (1–65535)   **HTTPPORT**   := _____

NOTE: HTTPPORT may not be set to reserved port numbers 20, 21, 102, 502, or the same as other settings listed in Table SET.1.

Make the following settings when EMODBUS ≥ 2.

Ethernet Modbus Settings: Master 2

    IP Address (zzz.yyy.xxx.www)   **MODIP2**   := _____

NOTE: MODIP1, MODIP2, and MODIP3 cannot share an address (except 0.0.0.0).

    Modbus Session Time-out (15–900 seconds in 1 second steps)   **MTIMEO2**   := _____

Make the following settings when EMODBUS = 3.

Ethernet Modbus Settings: Master 3

    IP Address (zzz.yyy.xxx.www)   **MODIP3**   := _____

NOTE: MODIP1, MODIP2, and MODIP3 cannot share an address (except 0.0.0.0).

    Modbus Session Time-out (15–900 seconds in 1 second steps)   **MTIMEO3**   := _____

SNTP Client Protocol Settings

    Enable SNTP Client (OFF, UNICAST, MANYCAST,   **ESNTP**   := _____
      BROADCAST)

Make the following settings when ESNTP ≠ OFF.

    Primary Server IP Address (zzz.yyy.xxx.www)   **SNTPPSIP** := _____

NOTE: To accept updates from any server when ESNTP = BROADCAST, set SNTPPSIP to 0.0.0.0. Only IP
        addresses in the range 224.0.0.1 through 239.255.255.255 are valid when ESNTP = MANYCAST.

Make the following setting when ESNTP = UNICAST.

    Backup Server IP Address (zzz.yyy.xxx.www)   **SNTPBSIP** := _____

    SNTP IP (Local) Port Number (1–65534)   **SNTPPORT** := _____

NOTE: SNTPPORT cannot be set to the same value as DNPNUM when EDNP > 0.

    SNTP Update Rate (15–3600 seconds in 1 second steps)   **SNTPRATE** := _____

Make the following setting when ESNTP = UNICAST or MANYCAST.

    SNTP Timeout (5–20 seconds in 1 second steps)   **SNTPTO**   := _____

NOTE: SNTPTO must be less than setting SNTPRATE.

Port Number Settings Must Be Unique

When making the SEL-651R-2 Port 5 settings, port number settings cannot be used for more than one protocol. The relay checks all of the settings shown in *Table SET.1* before saving changes. If a port number is used more than once, the relay will display an error message, and return to the first setting that contains the duplicate value.

Table SET.1 Port Number Settings That Must Be Unique

Setting	Name	Setting Required When...
TPORT	Telnet Port	ETELNET = Y
HTTPPORT	TCP/IP Port	EHTTP = Y
DNPNUM	DNP TCP and UDP Port	EDNP > 0
PMOTCP1	PMU Output 1 TCP/IP (Local) Port Number	PMOTS1 = TCP, UDP_T, or UDP_U
PMOTCP2	PMU Output 2 TCP/IP (Local) Port Number	PMOTS2 = TCP, UDP_T, or UDP_U

Section 10

Communications

Introduction

The SEL-651R-2 Recloser Control has as many as seven communications ports as shown in *Table 10.1*. Use the communications ports to establish local and remote communications with the relay using numerous communications protocols.

Table 10.1   SEL-651R-2 Communications Ports

Port Number	Type	Location	Standard/ Optional
1	EIA-485 Serial		Standard
2	EIA-232 Serial	For the locations of the communications ports, see *Figure 2.4* and *Figure 2.5* for dual-door enclosure models, and *Figure 2.8* for single-door enclosure models.	Standard
3	EIA-232 Serial		Standard
4 or F	EIA-232 Serial		Standard
5	Single Ethernet	**Note:** When the SEL-651R-2 is ordered with the Dual Ethernet option, Port 5 is replaced by Ports 5A and 5B.	Optional[a]
5A/5B	Dual Ethernet		Optional[a]
N/A	USB		Standard

[a]   Select either single or dual Ethernet.

The first part of this section shows how to establish local communications with the relay using serial, USB, Ethernet ports and the SEL ASCII communications protocol, or the built-in web server. Other parts of this section provide reference information to help you use recloser control communications ports to establish local and remote communications for engineering access, SCADA communications, teleprotection, and synchrophasor data collection. Use of actual communications protocols such as IEC 61850, DNP, Modbus, or SEL MIRRORED BITS communications is covered in various appendices of this manual.

Establishing Communications Using a Serial Port

Use the front serial port and any terminal emulation program or the ACSELERATOR QuickSet SEL-5030 Software to begin communicating with the relay. Connect an SEL-C234 or SEL-C662 cable between the relay and a personal computer. The serial port default communications parameters are:

➤ Data Rate = 9600

➤ Data Bits = 8

➤ Parity = N

➤ Stop Bits = 1

Use the **SET P** command to change the recloser control communications port parameters.

Establishing Communications Through Use of the USB Port
USB Port Overview

The USB port has no settings and is faster than the serial ports, especially for operations requiring transport of large blocks of data such as long event reports or firmware upgrades.

Each time you connect a relay to your PC USB port, Windows determines if a driver has already been installed and is ready for use. There are three possibilities:

1. Connect a PC for the first time to a relay USB port.

   Windows launches the **Found New Hardware Wizard**. The wizard guides you through the USB driver installation process and creates a new virtual COM port (e.g., COM 4).

   See *Detailed Instructions for USB Port Driver Installation* below before connecting the relay to your PC USB port.

2. Reconnect a PC to a relay USB port by using a different physical USB port on a PC (i.e., same PC, different physical USB port on the PC).

   Windows launches the **Found New Hardware Wizard**. Select **Install the software automatically (Recommended)** and click **Next**. Windows locates the required INF file and driver and creates a new virtual COM port (e.g., COM 5).

   Windows creates a new virtual COM port (e.g., COM 6, COM 7) each time you connect a relay to a physical USB port that has not previously been connected to a relay. The virtual COM port number remains associated with the same physical USB port until you uninstall the driver.

3. Reconnect a PC to a relay USB port using a physical USB port on the PC that has already been connected to a relay (i.e., same PC, same physical USB port on the PC).

   Windows recognizes that the driver is already installed and creates the same virtual COM port created the first time you connected a relay to that particular physical USB port (e.g., COM 4). No action is required on your part.

The USB driver exposes normal communications port settings to the personal computer operating system, such as data rate, parity, etc. to maintain compatibility with many PC applications. Changing these settings in the PC does not change how the recloser control USB port operates. You may use a PC Terminal Emulator program or dedicated software to connect to the SEL-651R-2 via USB port. The USB port offers a subset of the functionality of a standard serial port. See *Table 10.6* for details.

USB uses a connection-based protocol. Under certain circumstances, such as power cycling the relay, the USB connection may be terminated. If the USB connection is terminated it may be necessary to reconnect to the relay by using the PC application software, or disconnect and then reconnect the USB connector at either the PC or the relay.

Case No. 2018-00295

Page 585 of 1080
Communications | 10.3
Introduction
Wolfe

QuickSet is more tolerant of unexpected USB device disconnections than most other PC applications. While using QuickSet, it is possible to disconnect the USB cable from one relay and move it to another relay without the need to restart the application, reselect the COM port, or even disconnect and reconnect at the application level.

Detailed Instructions for USB Port Driver Installation

The following detailed instructions for USB driver installation are specifically for the Windows XP operating system. Some steps may be different and some screens may be changed for other Windows operating systems. For USB driver installation instructions for Windows 7, see the SEL-651R-2 product page at selinc.com/products/651R/.

Step 1.   Retrieve the USB driver file "SEL Fast CDC USB Device.INF" from the SEL-651R-2 product page on the SEL website (selinc.com), from the SEL-651R-2 Product Literature CD, or from the SEL-5030 Installation CD. Place the INF file in any convenient directory, such as C:\SEL\Drivers\Relay_USB.

NOTE: The SEL-651R-2 USB driver is different than the driver used for the SEL-C662 (EIA-232 serial-to-USB converter cable) and the driver used for the SEL-2440 Discrete Programmable Automation Controller.

Step 2.   Connect the relay to your PC with an SEL-C664 cable, or any standard A to B USB cable. Your PC will recognize that a new device has been connected and will start the **Found New Hardware Wizard**. Select **No, not this time** and click **Next**. Some Windows XP systems will skip this screen and go to the screen shown in *Step 3*.

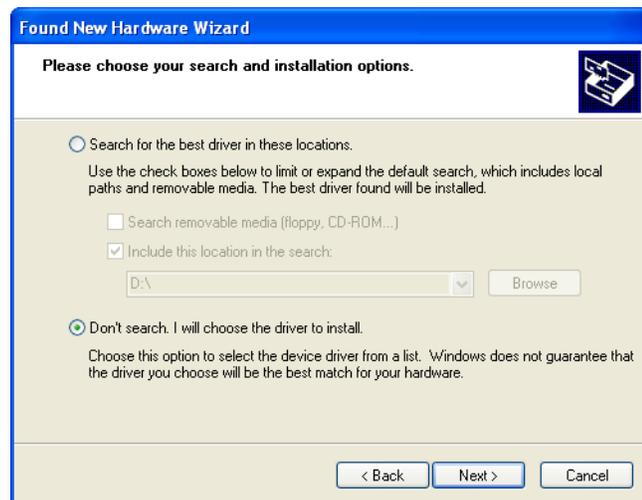
10.4 | Communications
Introduction

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 586 of 1080
Wolfe

Step 3.   Select **Install from a list or specific location (Advanced)**.
Click **Next**.

Step 4.   Select **Don't search. I will choose the driver to install**. Click
Next.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 587 of 1080

Communications 10.5
Introduction
Wolfe


Step 5.   If prompted for a hardware type, select **Ports (COM & LPT)** and click **Next**. Some Windows XP systems will skip this screen and go to the next screen.

Step 6.   If necessary, click the **Have Disk** button and direct the wizard to the folder containing the INF file you copied to your local drive in *Step 1*. After you locate the INF file, the **Found New Hardware Wizard** will return to the screen shown below. Verify the selected **Model** is **SEL Fast CDC USB Device**. Click **Next**.

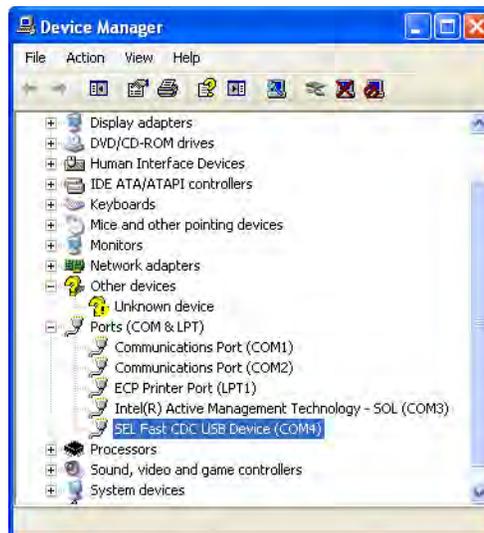
Step 7.   If Windows warns that the driver has not passed Windows Logo testing, verify that the name **SEL Fast CDC USB Device** matches the Model selected in *Step 6*, and then click **Continue Anyway**.

Step 8.   Wait while the wizard installs the driver software.

10.6 | Communications
Introduction

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 588 of 1080
Wolfe

Step 9.   Click **Finish** to finish the installation process.

The USB port driver is now installed and a new virtual COM port (e.g., COM 4) is ready for use. To see what virtual COM port has been created, launch any communications program that allows selection of a COM port and view the available ports, or go to the Windows Device Manager and inspect the available COM ports as shown below. Use Device Manager to verify which virtual COM port is associated with a particular physical USB port. Device Manager updates the available COM ports each time a cable is inserted or removed.


To test the USB port and the newly installed driver follow these steps:

Step 1.   Launch QuickSet and select **Communications > Parameters** from the menu or click the **Communications Parameters** icon from the opening screen. See *Section 3: PC Software* for more information on QuickSet. Select the new COM port created by the driver installation process, e.g., COM 4 in the screen capture. Ignore other settings like parity and data rate. They have no effect on how the USB port operates and are only presented to the operating system to retain compatibility with certain applications.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Communications 10.7
Page 589 of 1080
Introduction
Wolfe

Step 2.   Select **Communications > Terminal** from the menu, or click the terminal icon on the tool bar. Log into the relay normally. The USB port should work similarly to an EIA-232 port, only much faster. See *Table 10.6* for a list of features available from the USB port.

Establishing Communications Using an Ethernet Port and Telnet or the Web Server

Factory-default settings for the Ethernet ports disable all Ethernet protocols except PING. Enable the Telnet and web server protocols with the **SET P 5** command using any of the serial ports or the USB port. Command **SET P 5** accesses settings for Ethernet ports on the SEL-651R-2: Port 5, or Ports 5A and 5B (when ordered with the Dual Ethernet option).

See *SHO Command (Show/View Settings)* for a sample of the **SHO P 5** command, with factory-default settings. See *Port 5 Settings on page SET.70* for the Port 5 settings sheets.

Make the following settings using the **SET P 5** command:

➤   IPADDR := IP Address assigned by network administrator

➤   SUBNETM := Subnet mask assigned by network administrator

➤   DEFRTR := Default router IP Address assigned by network administrator

➤   NETMODE := SWITCHED (available with dual Ethernet ports)

➤   ETELNET := Y

➤   EHTTP := Y

Leave all other settings at their default values.

NOTE: Telnet and the web server work with other NETMODE settings also, but NETMODE := SWITCHED is easiest to begin communications. The relay hides setting NETMODE when equipped with a single Ethernet port.

Connect an Ethernet cable between your PC or a network switch and any Ethernet port on the relay. Verify that the amber Link LED illuminates on the connected relay port. Many computers and most Ethernet switches support auto crossover, so nearly any CAT5 Ethernet cable with RJ45 connectors, such as an SEL-C627, will work. When the computer does not support auto crossover, use a crossover cable, such as an SEL-C628. For fiber-optic Ethernet ports use an SEL-C807 62.5-µm fiber-optic cable with LC connectors. If your relay is equipped with dual Ethernet ports, connect to either port. Use a Telnet application or QuickSet on the host PC to communicate with the relay. To terminate a Telnet session, use the command **EXI <Enter>** from any access level.

Launch a web browser and navigate to http://IPADDR, where IPADDR is the Port 5 IPADDR setting. To terminate the session, close the web browser.

Using Redundant Ethernet Ports

The SEL-651R-2 is optionally equipped with two 10/100BASE-T copper or 100BASE-FX fiber-optic Ethernet ports. Use two Ethernet ports in redundant network architectures, or force the relay to use a single Ethernet port even though it is equipped with two ports.

Redundant Ethernet Network Using SWITCHED Mode

Make Port 5 setting NETMODE := SWITCHED to activate the internal Ethernet switch. The internal switch connects a single Ethernet stack inside the relay to the two external Ethernet ports. The combination of relay and internal switch operate the same as if a single Ethernet port on a relay were connected to an external unmanaged Ethernet switch. Use the internal switch to create "self-healing rings" as shown in *Figure 10.1*.

10.8 | Communications
Introduction

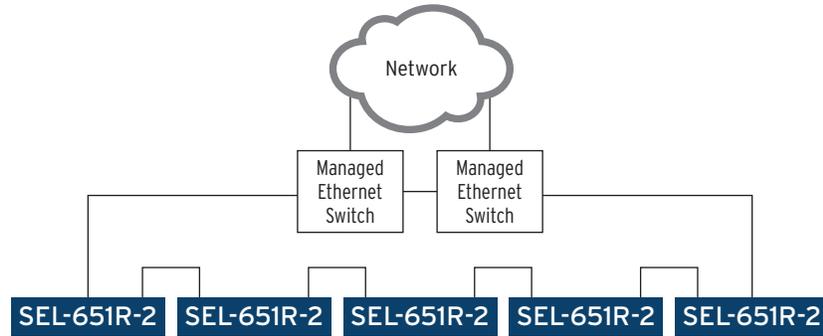
Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 590 of 1080
Wolfe


Figure 10.1   Self-Healing Ring Using Internal Ethernet Switch

Using this topology the network can still connect to any relay even if another relay, cable, or switch fails. The external managed network switches select which of the two relay Ethernet ports are used for what purpose. That selection is invisible to the relay and does not require special relay configuration (other than making setting NETMODE = SWITCHED).

Redundant Ethernet Network Using FAILOVER Mode

Make the following settings in Port 5 to configure the relay for FAILOVER mode.

➤ NETMODE := FAILOVER

➤ FTIME := desired timeout for the active port before failover to the backup port (0.10–65.00 seconds and OFF)

➤ NETPORT := the preferred network interface (A for Port 5A, B for Port 5B)

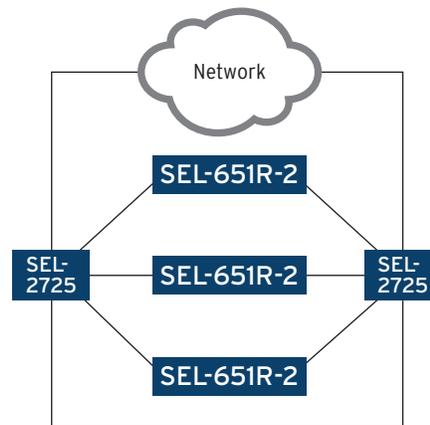
Use the internal failover switch to connect the relay to redundant networks as shown in *Figure 10.2*.


Figure 10.2   Failover Network Topology

On startup the relay communicates using the primary network interface selected by the NETPORT setting. If the relay detects a link failure on the primary interface and the link status on the standby interface is healthy, the relay activates the standby network interface after time FTIME. If the link status on the primary interface returns to normal before time FTIME, the failover timer resets and operation continues on the primary network interface.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Communications 10.9
Page 591 of 1080
Port Connectors and Communications Cables
Wolfe

Setting FTIME = OFF allows fast port switching (with no intentional delay). Fast port switching can occur within one processing interval (typically 4 to 5 ms) and can help with IEC 61850 GOOSE performance.

After failover, while communicating via the standby interface, if the relay detects a link failure on the standby interface and the link status on the primary interface is healthy, the relay activates the primary network interface after time FTIME. The choice of active port is re-evaluated after settings are changed or the relay is restarted.

Network Connection Using Fixed Connection Mode

Force the relay to use a single Ethernet port even when it is equipped with two Ethernet ports by making settings NETMODE = FIXED. When NETMODE = FIXED, only the interface selected by NETPORT is active. The other interface is disabled.

Ethernet Status Relay Word Bits

The SEL-651R-2 Ethernet status is available through the Relay Word bits shown in *Table 10.2*.

Table 10.2 Ethernet Status Indicators

Relay Word Bit	Available by Relay Model	Description	Valid When
LINK5	Single Ethernet	Asserts when a valid Ethernet link is detected on Port 5	Port 5 setting EPORT := Y
LINK5A	Dual Ethernet	Asserts when a valid Ethernet link is detected on Port 5A	Port 5 setting EPORT := Y
LINK5B	Dual Ethernet	Asserts when a valid Ethernet link is detected on Port 5B	Port 5 setting EPORT := Y
LNKFAIL	Single or Dual Ethernet	Asserts when the active port is down	Port 5 setting EPORT := Y
P5ASEL	Dual Ethernet	Asserts when Port 5A is selected	Port 5 setting NETMODE := FAILOVER
P5BSEL	Dual Ethernet	Asserts when Port 5B is selected	Port 5 setting NETMODE := FAILOVER

Port Connectors and Communications Cables

Hardware Handshaking

All EIA-232 serial ports support RTS/CTS hardware handshaking. RTS/CTS handshaking is not supported on the EIA-485 Serial Port 1.

To enable hardware handshaking, use the **SET P** command (or front-panel **SET** pushbutton) to set RTSCTS := Y. Disable hardware handshaking by setting RTSCTS := N.

➤ If RTSCTS := N, the relay permanently asserts the RTS line.

➤ If RTSCTS := Y, the relay deasserts RTS when it is unable to receive characters.

➤ If RTSCTS := Y, the relay does not send characters until the CTS input is asserted.

Communications Port Pinouts

Figure 10.3 and *Table 10.3–Table 10.5* show the functions of the pins and terminals of the serial ports.

RTS	Request To Send
CTS	Clear To Send

IRIG-B

Demodulated IRIG-B time code can be input into the IRIG-B BNC connector on the SEL-651R-2 rear panel (see *Figure 2.5* and *Figure 2.9*). Connect the IRIG-B BNC input to a high-quality time source such as the SEL-2401 Satellite Synchronized Clock to enable microsecond accurate time synchronization and to enable the SEL-651R-2 to create C37.118 Synchrophasors (see *Appendix J: Synchrophasors*).

Demodulated IRIG-B time code can be input into Serial Port 2 (pin functions +IRIG-B and –IRIG-B; see *Table 10.3*). This is handled adeptly by connecting Serial Port 2 of the SEL-651R-2 to an SEL-2032 by using an SEL-C273A cable (see cable diagrams that follow in this section).

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 593 of 1080
Communications
Port Connectors and Communications Cables
10.11
Wolfe

If IRIG-B is input at both Serial Port 2 and the IRIG-B BNC connector, the relay uses the IRIG-B time code received on the BNC connector.

Simple Network Time Protocol (SNTP) can act as a reduced-accuracy backup to IRIG-B. See *Simple Network Time Protocol (SNTP)* for more information on configuring SNTP.

Relay Word Bit TIRIG

TIRIG asserts when the relay time is based on an IRIG-B time source. If the relay is not synchronized to a connected IRIG-B time source, TIRIG deasserts. See *Configuring High-Accuracy Timekeeping on page J.21* for more details on TIRIG.

Relay Word Bit TSOK

TSOK asserts to indicate that the IRIG-B time source is of sufficient accuracy for synchrophasor measurement (see *Appendix J: Synchrophasors*).

Communications Cables

The following cable diagrams show several types of communications cables that connect the SEL-651R-2 to other devices. These and other cables are available from SEL. Contact the factory for more information.

The 1300 nm fiber-optic Ethernet ports are designed for 62.5 μm fiber with LC connectors. The total link budget is 11 dB. See the *Fiber-Optic Products and Applications Data Sheet* at selinc.com for instructions on how to calculate fiber system losses.

For long-distance communications as far as 500 meters and for electrical isolation of communications ports, use the SEL-2800 family of Fiber-Optic Transceivers. For IRIG-B connections and cable details, refer to the instruction manuals for the SEL-2407 Satellite-Synchronized Clock, SEL-2401 Satellite-Synchronized Clock, or other clocks. Contact SEL for more details on these devices.

Communications Protocols

The SEL-651R-2 supports many communications protocols, as shown in *Table 10.6*.

Table 10.6 Supported SEL-651R-2 Communications Protocols (Sheet 1 of 2)

SEL ASCII, Compressed ASCII, and Fast protocols are available when the serial port PROTO setting is SEL, or when using Telnet.

Session Limits

The SEL-651R-2 supports multiple simultaneous sessions of many of the protocols listed in *Table 10.6*. The number of allowed protocol sessions depends on what other protocols are enabled, as shown in *Table 10.7*.

Table 10.7 Protocol Session Limits

Protocol	Sessions Supportedª
DNP3	The relay supports six total DNP sessions (combined serial and Ethernet sessions).
IEC 61850	The relay supports six simultaneous sessions of MMS.
Modbus	The relay supports three total Modbus sessions (combined serial and Ethernet). No Port 5 Ethernet Modbus sessions can take place (Port 5 Ethernet Modbus setting EMODBUS must remain EMODBUS := 0) if more than three Ethernet DNP sessions are enabled (Port 5 Ethernet DNP setting EDNP > 3).
FTP	The relay supports one session of File Transfer Protocol on Port 5.
Telnet	The number of available simultaneous Telnet sessions depends on Port 5 relay settings E61850, EHTTP (read-only web server), EDNP (DNP over Ethernet), and EMODBUS (Modbus TCP) as follows: ➤ When Port 5 setting E61850 = Nᵇ, the relay supports three simultaneous Telnet sessions. ➤ When Port 5 settings E61850 = Y, EHTTP = N, EDNP = 0, and EMODBUS = 0, the relay supports three simultaneous Telnet sessions. ➤ When Port 5 settings E61850 = Y, EHTTP = Y, EDNP = 0, and EMODBUS = 0, the relay supports two simultaneous Telnet sessions. ➤ When Port 5 settings E61850 = Y, EHTTP = N, and one or both of EDNP and EMODBUS are greater than 0, the relay supports two simultaneous Telnet sessions. ➤ When Port 5 settings E61850 = Y, EHTTP = Y, and one or both of EDNP > 0, EMODBUS > 0, the relay supports one Telnet session.
Web Server (HTTP)	The relay supports three simultaneous web server sessions.
C37.118 Synchrophasors	The relay supports two C37.118 synchrophasor sessions on Port 5 if Port 5 setting E61850 = Nᵇ. When Port 5 setting E61850 = Y, the relay supports one C37.118 synchrophasor session on Port 5.
SNTP	The relay supports one session of SNTP on Port 5. Some operation modes of SNTP allow the relay to synchronize to one of multiple NTP servers.

ª When properly configured (enable settings, IP addresses, etc.).
ᵇ Recloser controls ordered without IEC 61850 are treated as if E61850 = N.

Communications 10.15
Communications Protocols
Wolfe

SEL Fast Meter Protocol

SEL Fast Meter protocol supports binary messages to transfer metering and control messages. The protocol is described in *Appendix I: Configuration, Fast Meter, and Fast Operate Commands*.

SEL Compressed ASCII Protocol

SEL Compressed ASCII protocol provides compressed versions of some of the relay ASCII commands. The protocol is described in *Appendix C: Compressed ASCII Commands*.

SEL Fast Sequential Events Recorder (SER) Protocol

SEL Fast Sequential Events Recorder (SER) Protocol, also known as SEL Unsolicited Sequential Events Recorder, provides SER events to an automated data collection system. SEL Fast SER Protocol is available on any serial or Ethernet port. The protocol is described in *Appendix H: Fast SER Protocol*.

Distributed Network Protocol (DNP3)

The relay provides Distributed Network Protocol (DNP3) slave support. DNP is described in *Appendix E: DNP3 Communications*.

Modbus Protocol

The relay provides Modbus protocol as described in *Appendix K: Modbus RTU and TCP Communications*.

MIRRORED BITS Communications

The SEL-651R-2 supports MIRRORED BITS relay-to-relay communications on two ports simultaneously (see *Appendix D: MIRRORED BITS Communications*).

IEEE C37.118 Synchrophasor Protocol

The relay supports the C37.118 protocol at as many as 60 messages per second as described in *Appendix J: Synchrophasors*.

IEC 61850 Protocol

The relay supports IEC 61850 protocol, including GOOSE, as described in *Appendix L: IEC 61850*. The IEC 61850 protocol is only available on relays with two copper Ethernet ports, or with one or two fiber copper Ethernet ports.

Simple Network Time Protocol (SNTP)

When Port 5 setting ESNTP is not OFF, the relay internal clock conditionally synchronizes to the time of day served by a Network Time Protocol (NTP) server. The relay uses a simplified version of NTP called the Simple Network Time Protocol (SNTP). SNTP is not as accurate as IRIG-B (see *Configuring High-Accuracy Timekeeping on page J.21*). The relay can use SNTP as a less accurate primary time source, or as a backup to the higher accuracy IRIG-B time source.

SNTP as Primary or Backup Time Source

If an IRIG-B time source is connected and either Relay Word bits TSOK or TIRIG assert, then the relay synchronizes the internal time-of-day clock to the incoming IRIG-B time-code signal, even if SNTP is configured in the relay and an NTP server is available. If the IRIG-B source is disconnected (if both TSOK and TIRIG deassert) then the relay synchronizes the internal time-of-day clock to the NTP server if available. In this way an NTP server acts as either the primary time source, or as a backup time source to the more accurate IRIG-B time source.

Creating an NTP Server

Three SEL application notes, available from the SEL website, describe how to create an NTP server.

AN2009-10: Using an SEL-2401, SEL-2404, or SEL-2407® to Serve NTP Via the SEL-3530 RTAC

AN2009-38: Using SEL Satellite-Synchronized Clocks With the SEL-3332 or SEL-3354 to Output NTP

AN2010-03: Using an SEL-2401, SEL-2404, or SEL-2407® to Create a Stratum 1 Linux® NTP Server

Configuring SNTP Client in the Relay

To enable SNTP in the relay make Port 5 setting ESNTP = UNICAST, MANYCAST, or BROADCAST. *Table 10.8* shows each setting associated with SNTP.

Table 10.8   Settings Associated With SNTP

Setting	Range	Description
ESNTP	UNICAST, MANYCAST, BROADCAST	Selects the mode of operation of SNTP. See descriptions in *SNTP Operation Modes*.
SNTPPSIP	Valid IP Address	Selects primary NTP server when ENSTP = UNICAST, or broadcast address when ESNTP = MANYCAST or BROADCAST.
SNTPPSIB	Valid IP Address	Selects backup NTP server when ESNTP = UNICAST.
SNTPPORT	1–65534	Ethernet port used by SNTP. Leave at default value unless otherwise required.
SNTPRATE	15–3600 seconds	Determines the rate at which the relay asks for updated time from the NTP server when ESNTP = UNICAST or MANYCAST. Determines the time the relay will wait for an NTP broadcast when ENSTP = BROADCAST.
SNTPTO	5–20 seconds	Determines the time the relay will wait for the NTP master to respond when ENSTP = UNICAST or MANYCAST.

SNTP Operation Modes

The following sections explain the setting associated with each SNTP operation mode (UNICAST, MANYCAST, and BROADCAST).

ESNTP := UNICAST

In unicast mode of operation the SNTP client in the relay requests time updates from the primary (IP address setting SNTPPSIP) or backup (IP address setting SNTPBSIP) NTP server at a rate defined by setting SNTPRATE. If the NTP server does not respond within the period defined by setting SNTPTO then the relay tries the other SNTP server. When the relay successfully synchronizes to the primary NTP time server, Relay Word bit TSNTPP asserts. When the relay successfully synchronizes to the backup NTP time server, Relay Word bit TSNTPB asserts.

ESNTP := MANYCAST

In manycast mode of operation the relay initially sends an NTP request to the broadcast address contained in setting SNTPPSIP. The relay continues to broadcast requests at a rate defined by setting SNTPRATE. When a server replies, the relay considers that server to be the primary NTP server and switches to UNICAST mode, asserts Relay Word bit TSNTPP, and thereafter

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 599 of 1080
Wolfe
Communications 10.17
Communications Port 5080

requests updates from the primary server. If the NTP server stops responding for time SNTPTO, the relay deasserts TSNTPP and begins to broadcast requests again until the original or another server responds.

ESNTP := BROADCAST

If setting SNTPPSIP = 0.0.0.0 while setting ESNTP = BROADCAST, the relay will listen for and synchronize to any broadcasting NTP server. If setting SNTPPSIP is set to a specific IP address while setting ESNTP = BROADCAST, then the relay will listen for and synchronize to only NTP server broadcasts from that address. When synchronized the relay asserts Relay Word bit TSNTPP. Relay Word bit TSNTPP deasserts if the relay does not receive a valid broadcast within five seconds after the period defined by setting SNTPRATE.

SNTP Accuracy Considerations

SNTP time synchronization accuracy is limited by the accuracy of the SNTP Server and by the networking environment. The highest degree of SNTP time synchronization can be achieved by minimizing the number of switches and routers between the SNTP Server and the SEL-651R-2. Network monitoring software can also be used to ensure average and worst-case network bandwidth utilization is moderate.

When installed on a network configured with one Ethernet switch between the SEL-651R-2 and the SNTP Server, and when using ESNTP = UNICAST or MANYCAST, the relay time synchronization error with the SNTP server is typically less than ±1 millisecond.

File Transfer Protocol (FTP) and MMS File Transfer

File Transfer Protocol (FTP) is a standard protocol for exchanging files between computers over a TCP/IP network. The SEL-651R-2 operates as an FTP server, presenting files to FTP clients. The recloser control supports one FTP session at a time. Requests to establish additional FTP sessions are denied.

Manufacturing Messaging Specification (MMS) is used in IEC 61850 applications and provides services for the transfer of real-time data, including files, within a substation LAN.

File Structure

The file structure is organized as a directory and subdirectory tree similar to that used by Windows and other common operating systems. See *Virtual File Interface on page 10.24* for information on available files.

File dates within the last 12 months are displayed with month, day, hour, and minutes. Dates older than twelve months have the year, month, and day. The times are UTC.

Access Control

To log in to the FTP server, enter the value of the Port 5 setting FTPUSER as the user name in your FTP application. Enter the Level 2 password as the password in your FTP application. Note that FTP does not encrypt passwords before sending them to the server.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 600 of 1080
Wolfe

10.18 | Communications
Communications Protocols

MMS is enabled when Port 5 setting E61850 is set to Y. No authentication is required. MMS File Transfer is enabled when setting EMMSFS is set to Y. If MMS Authentication is enabled via the CID file, then an authenticated connection must be established via MMS for MMS file transfer to take place.

Using FTP and MMS

A free FTP application is included with most web browser software and PC operating systems. You can also obtain free or inexpensive FTP applications from the Internet. Once you have retrieved the necessary files, be sure to close the FTP connection by using the disconnect function of your FTP application or completely closing the application. Failure to do so can cause the FTP connection to remain open, which blocks subsequent connection attempts until FTPIDLE time expires.

See *Appendix L: IEC 61850* for information about using MMS.

Using the Embedded Web Server (HTTP)

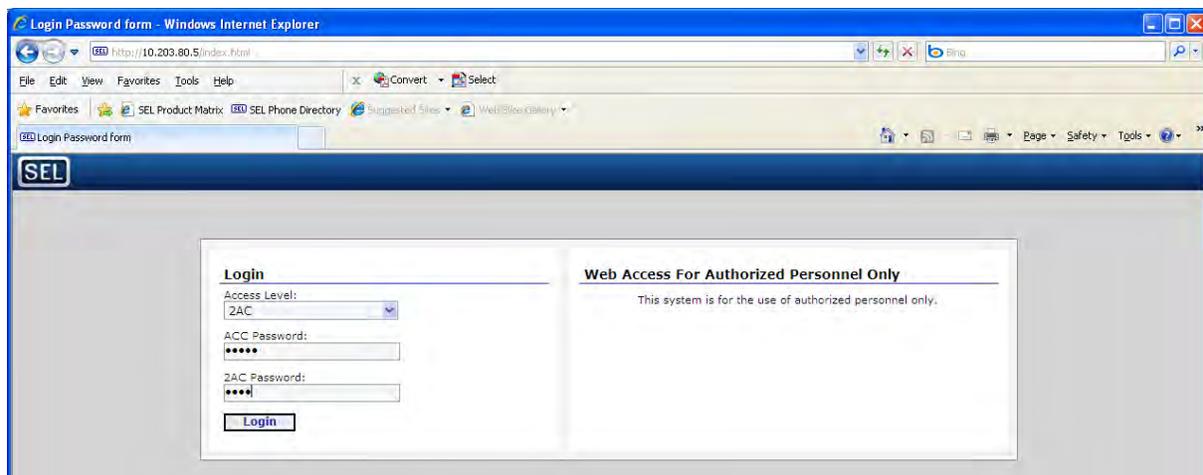
When Port 5 setting EHTTP := Y, the relay serves webpages displaying certain settings, metering, and status reports. The relay embedded web server has been optimized and tested to work with the most popular web browsers, but should work with any standard web browser. As many as three users can access the embedded web server simultaneously. Access Level 2 allows the user to upgrade firmware over the web server interface (see method three in *Appendix B: Firmware Upgrade Instructions*). Port 5 setting HTTPACC determines the maximum access level available to the web server, and its default is level 2. To begin using the embedded web server, launch your web browser and navigate to http://IPADDR, where IPADDR is the Port 5 setting IPADDR (e.g., http://192.168.1.2). The relay responds with a login screen as shown in *Figure 10.4*.


Figure 10.4   Web Server Login Screen

The HTTPACC Port 5 setting determines the access level available to the web server and defaults to Access Level 2. If HTTPACC is set to 2, Access Level 1 (ACC) or Access Level 2 (2AC) can be chosen from the Access Level drop down box. Enter the appropriate password(s) in the text box(es) below the Access Level drop down box. If 2AC is chosen, both the ACC and 2AC passwords must be entered to login, as shown in *Figure 10.4*. Note that access level passwords are not encrypted in any way by the web server when logging in. Once you have entered the correct Password(s), the relay responds with the meter display home page. While you remain logged into the relay, the webpage displays the approximate time as determined by the relay time-of-

Wolfe
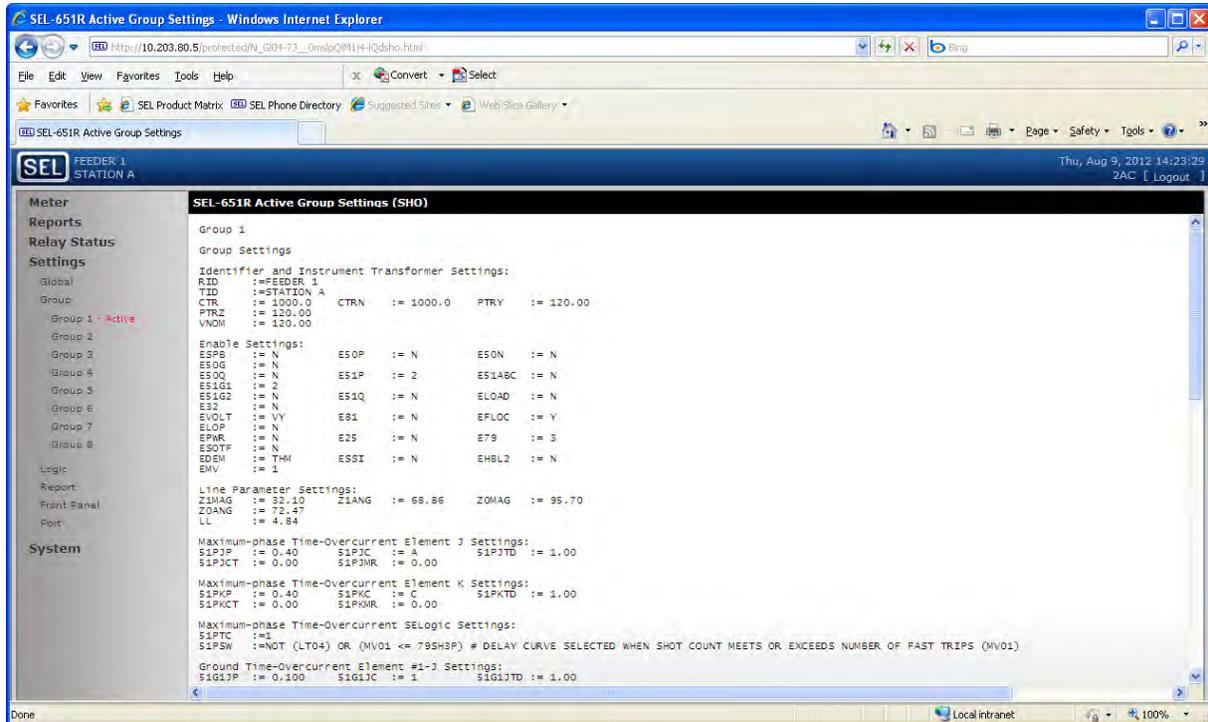

Figure 10.6   Web Server Show Settings Screen

The Meter Reports screens update automatically about every five seconds.

To log out, either close the web browser window or click on **[Logout]** in the banner bar near the top of the webpage.

SEL ASCII Protocol

SEL ASCII protocol is designed for manual and automatic communications.

All commands received by the relay must be of the form:

<command><CR>   or   <command><CRLF>

NOTE: The **<Enter>** key on most keyboards is configured to send the ASCII character 13 (^M) for a carriage return. This manual instructs you to press the **<Enter>** key after commands, which should send the proper ASCII code to the relay.

A command transmitted to the relay should consist of the command followed by either a CR (carriage return) or a CRLF (carriage return and line feed). You may truncate commands to the first three characters. For example, **HISTORY 1 <Enter>** would become **HIS 1 <Enter>**. Upper- and lowercase characters may be used without distinction, except in passwords.

Software Flow Control

The SEL-651R-2 implements XON/XOFF flow control. You can use the XON/XOFF protocol to control the relay during data transmission. When the relay receives XOFF during transmission, it pauses until it receives an XON character. If there is no message in progress when the relay receives XOFF, it blocks transmission of any message presented to its buffer. Messages will be accepted after the relay receives XON.

The relay transmits XON (ASCII hex 11) and asserts the RTS output (if hardware handshaking is enabled) when the relay input buffer drops below 25 percent full.

The relay transmits XOFF (ASCII hex 13) when the buffer is more than 75 percent full. If hardware handshaking is enabled, the relay deasserts the RTS output when the buffer is approximately 95 percent full. Automatic

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Communications
Page 603 of 1080
Communications Port
10.21
Wolfe

transmission sources should monitor for the XOFF character to avoid overwriting the buffer. Transmission should terminate at the end of the message in progress when XOFF is received and can resume when the relay sends XON.

The CAN character (ASCII hex 18) aborts a pending transmission. This is useful for terminating an unwanted transmission.

Control characters can be sent from most keyboards with the following keystrokes:

➤ XOFF: **<Ctrl+S>** (hold down the **<Ctrl>** key and press **S**)

➤ XON: **<Ctrl+Q>** (hold down the **<Ctrl>** key and press **Q**)

➤ CAN: **<Ctrl+X>** (hold down the **<Ctrl>** key and press **X**)

Serial Port and Telnet Session Automatic Messages

When the Telnet or serial port AUTO setting is Y, the relay sends automatic messages to indicate specific conditions. The automatic messages are described in *Table 10.9*.

Table 10.9   Serial Port Automatic Messages

Condition	Description
Power Up	The relay sends a message containing the present date and time, Relay and Terminal Identifiers, and the Access Level 0 prompt when the relay is turned on.
Event Trigger	The relay sends an event summary each time an event report is triggered (see *Section 12: Analyzing Events*).
Group Switch	The relay displays the active settings group after a group switch occurs (see *GRO Command (Display Active Settings Group Number)*).
Self-Test Warning or Failure	The relay sends a status report each time a self-test warning or failure condition is detected (see *STA Command (Relay Self-Test Status)*).

Port Access Levels

Commands can be issued to the relay via the serial port, USB port, or Telnet session to view metering values, change relay settings, etc. The available commands are listed in *Table 10.18*. The commands can be accessed only from the corresponding access level as shown in *Table 10.18*. The access levels are:

➤ Access Level 0 (the lowest access level)

➤ Access Level 1

➤ Access Level B

➤ Access Level 2 (the highest access level)

➤ Access Level C (restricted access level, should be used under direction of SEL only)

Limit Maximum Access Level or Disable Any Port

Disable any port by using the EPORT setting. For example, if EPORT := N on Port 5, then Port 5, 5A, and 5B will be nonresponsive.

10.22 | Communications
Communications Protocols

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 604 of 1080
Wolfe

Limit the maximum allowable access level on any enabled port configured for Telnet or SEL ASCII protocols by using the MAXACC setting. For example, if MAXACC := 1 on Port 5, then the maximum access level attainable from a Telnet session on Port 5, 5A, and 5B is limited to Access Level 1. The MAXACC setting on Port 5 does not limit FTP. FTP is always able to read and write settings files even if MAXACC := 1.

For serial port sessions and Ethernet port Telnet sessions, changing a port MAXACC setting to a lower access level will cause the relay to terminate any active session(s) on that port that exceed the new MAXACC level. Any new access level attempts on the port are only granted up to the MAXACC allowed level.

For the USB port, changing the Port F MAXACC setting to a lower access level does not terminate a USB session in progress. After a **QUIT** command or timeout, any new access level attempts on the USB port are only granted up to the Port F MAXACC allowed level.

When MAXACC = 0, the port (serial or Ethernet) is available for SEL Fast Messaging and Fast Operate only.

See *Port Enable Settings (SET P n Command) on page 9.60* for more information about these and other port settings.

Access Level 0

Once ASCII communications are established with the relay, the relay sends the following prompt:

```
=
```

This is referred to as Access Level 0. Enter the **ACC** command at the Access Level 0 prompt:

```
=ACC <Enter>
```

The **ACC** command takes the relay to Access Level 1 (see *ACC, BAC, 2AC, and CAL Commands (Go to Access Level 1, B, 2, or C)* for more detail).

Access Level 1

When the relay is in Access Level 1, the relay sends the following prompt:

```
=>
```

Commands available from Access Level 1 are shown in *Table 10.18*. For example, enter the **MET** command at the Access Level 1 prompt to view metering data:

```
=>MET <Enter>
```

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 605 of 1080
Wolfe
Communications
Communications Protocols
10.23

The **2AC** command allows the relay to go to Access Level 2 (see *ACC, BAC, 2AC, and CAL Commands (Go to Access Level 1, B, 2, or C)* for more detail). Enter the **2AC** command at the Access Level 1 prompt:

```
=>2AC <Enter>
```

The **BAC** command allows the relay to go to Access Level B (see *ACC, BAC, 2AC, and CAL Commands (Go to Access Level 1, B, 2, or C)* for more detail). Enter the **BAC** command at the Access Level 1 prompt:

```
=>BAC <Enter>
```

Access Level B

When the relay is in Access Level B, the relay sends the prompt:

```
==>
```

Commands available from Access Level B are shown in *Table 10.18*. For example, enter the **CLO** command at the Access Level B prompt to close the circuit breaker:

```
==>CLO <Enter>
```

While in Access Level B, any of the Access Level 1 commands are also available.

The ACCESSP Relay Word bit will pulse for approximately one second when the access level is increased to Access Level B or higher. The ACCESS Relay Word bit will assert and remain asserted when the access level is B or higher. When you attempt to go to Access Level B or higher, entry of an incorrect password causes the PASNVAL Relay Word bit to pulse for approximately one second. If an incorrect password is entered three consecutive times, the BADPASS Relay Word bit will pulse for approximately one second. ACCESSP, PASNVAL, and BADPASS are part of the default SELOGIC control equation for SALARM (see *Factory-Default Settings on page 9.61*).

The **2AC** command allows the relay to go to Access Level 2 (see *ACC, BAC, 2AC, and CAL Commands (Go to Access Level 1, B, 2, or C)* for more detail). Enter the **2AC** command at the Access Level B prompt:

```
==>2AC <Enter>
```

Access Level 2

When the relay is in Access Level 2, the relay sends the prompt:

```
=>>
```

10.24 | Communications
Virtual File Interface

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 606 of 1080
Wolfe

Commands available from Access Level 2 are shown in *Table 10.18*. For example, enter the **SET** command at the Access Level 2 prompt to make relay settings:

```
=>>SET <Enter>
```

While in Access Level 2, any of the Access Level 1 and Access Level B commands are also available.

The ACCESSP Relay Word bit will pulse for approximately one second when the access level is increased to Access Level B or higher. The ACCESS Relay Word bit will assert and remain asserted when the access level is B or higher. When you attempt to go to Access Level B or higher, entry of an incorrect password causes the PASNVAL Relay Word bit to pulse for approximately one second. If an incorrect password is entered three consecutive times, the BADPASS Relay Word bit will pulse for approximately one second. ACCESSP, PASNVAL, and BADPASS are part of the default SELOGIC equation for SALARM (see *Factory-Default Settings on page 9.61*).

Access Level C

The CAL access level is intended for use by the SEL factory and SEL field service personnel to help diagnose troublesome installations. A list of commands available at the CAL level is available from SEL upon request. Do not enter the CAL access level except as directed by SEL.

The **CAL** command allows the relay to go to Access Level C (see *ACC, BAC, 2AC, and CAL Commands (Go to Access Level 1, B, 2, or C)* for more detail). Enter the **CAL** command at the Access Level 2 prompt:

```
=>>CAL <Enter>
```

Virtual File Interface

You can retrieve and send data as files through the relay virtual file interface. Devices with embedded computers can also use the virtual file interface. When using serial ports or virtual terminal links, use the **FIL DIR** command to access the file interface. When you use a communications card, the file transfer protocol(s) supported by the card can present the file structure and send and receive files.

Send and receive files by using the following three protocols:

1. File Transfer Protocol (FTP)

2. MMS File Transfer

3. Ymodem

FTP and MMS File Structure

FTP and MMS have a two-level file structure. Files are available at the root level and subdirectories. *Table 10.10* shows the directories and their contents.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Communications 10.25
Page 607 of 1080

Wolfe

Table 10.10   FTP and MMS Virtual File Structure

Directory	Contents
/ (Root)	CFG.TXT[a] file, CFG.XML file, ERR.TXT file and SET_61850.CID and the SETTINGS, REPORTS, DIAGNOSTICS, EVENTS, and COMTRADE[b] directories
/SETTINGS[a]	Relay settings
/REPORTS	SER, LDP, SSI, target, metering, circuit breaker, and history reports
/DIAGNOSTICS	Relay status and vector reports
/EVENTS	CEV, COMTRADE, HIF, and history reports
/COMTRADE[b]	COMTRADE events

[a] Only available in FTP file structure.
[b] The COMTRADE directory is only available in MMS file structure.

Root Directory

The root directory (/) contains files and subdirectories as shown in *Table 10.10*.

CFG.TXT File (Read-Only)

The CFG.TXT file contains general configuration information about the relay and each settings class. External support software retrieves the CFG.TXT file to interact automatically with the relay. The relay calculates a checksum, or hash code, for each settings class and lists the codes in the CFG.TXT file (see *Figure 10.7*). Calibration settings are included only when the file is read at Access Level C. Improve system security by periodically reading the CFG.TXT file and comparing the current hash codes to those in a secured copy of the file. See *Appendix M: Cybersecurity Features* for more information.

Page 608 of 1080
Wolfe

CFG.XML File (Read-Only)

Present only in units with the Ethernet card installed, the CFG.XML file is supplementary to the CFG.TXT file. The CFG.XML file describes the IED configuration and any options such as the Ethernet port, and includes firmware identification, settings class names, and configuration file information.

ERR.TXT (Read-Only) and SET_61850.CID File

Present if ordered with the IEC 61850 protocol option. The ERR.TXT file contents is based on the most recent SET_61850.CID file written to the relay. If there were no errors, the file is empty. If errors occurred, the relay logs these errors in the ERR.TXT file. The SET_61850.CID file contains the IEC 61850 configured IED description in XML. ACSELERATOR Architect SEL-5032 Software generates and then downloads this file to the relay. See *Appendix L: IEC 61850* for more information.

Settings Directory (Only Available for FTP)

You can access the relay settings through files in the SETTINGS directory. We recommend that you use support software to access the settings files, rather than directly accessing them via other means. External settings support software reads settings from all of these files to perform its functions. The relay only allows you to write to the individual SET_*cn* files, where *c* is the settings class code and *n* is the settings instance. Except for the SET_61850 CID file, changing settings with external support software involves the following steps:

Step 1. The PC software reads the CFG.TXT and SET_ALL.TXT files from the relay.

Step 2. You modify the settings at the PC. For each settings class that you modify, the software sends a SET_*cn*.TXT file to the relay.

Step 3. The PC software reads the ERR.TXT file. If it is not empty, the relay detects errors in the SET_*cn*.TXT file.

Step 4. For any detected errors, modify the settings and send the settings until the relay accepts your settings.

Step 5. Repeat *Step 2–Step 4* for each settings class that you want to modify.

Step 6. Test and commission the relay.

SET_ALL.TXT File (Read-Only)

The SET_ALL.TXT file contains the settings for all of the settings classes in the relay. Calibration settings are included only when the file is read at Access Level C.

SET_cn.TXT Files (Read and Write)

There is a file for each instance of each setting class. *Table 10.11* summarizes the settings files. The settings class is designated by *c*, and the settings instance number is designated by *n*.

ERR.TXT (Read-Only)

The ERR.TXT file contents are based on the most recent SET_*cn*.TXT file written to the relay. If there were no errors, the file is empty. If errors occurred, the relay logs these errors in the ERR.TXT file.

SET_ALL.TXT	All instances of all settings classes
ERR.TXT	Error log for most recently written settings file

Reports Directory (Read-Only)

Use the REPORTS directory to retrieve files that contain the reports shown in *Table 10.12*. Note that the relay provides a report file that contains the latest information each time you request the file. Each time you request a report, the relay stores its corresponding command response in the designated text file.

Table 10.12   Reports Directory Files

File Name	Description	Equivalent Command Response
BRE.TXT	Breaker Report	**BRE**
CHISTORY.TXT	Compressed ASCII History Report	**CHI**

[a] Available only when ordered with Arc Sense technology (high-impedance fault detection).

Events Directory (Read-Only)

The relay provides history, event reports, and oscillography files in the EVENTS directory as shown in *Table 10.13*.

10.28

Communications
Virtual File Interface

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 610 of 1080
Wolfe

Event reports are available in the following formats:

➤ Compressed SEL ASCII

➤ Binary COMTRADE format (IEEE C37.111-1999)

The size of each event report file is determined by the LER setting in effect at the time the event is triggered.

Compressed SEL ASCII event report files are generated, when requested, by storing the appropriate command response shown in *Table 10.13*. Oscillography files are generated at the time the event is triggered (see *Event Report Triggering on page 12.4*). Higher resolution oscillography is available with SEL Compressed ASCII 128 sample/cycle raw event reports and binary COMTRADE files.

COMTRADE event files are available to read as a batch. See *Batch File Access on page 10.30*.

Table 10.13   Event Directory Files

File Name	Description	Equivalent Command Response
CHISTORY.TXT[a]	Compressed ASCII History Report	**CHI**
CHISTORY_HIF.TXT[a,b]	Compressed HIF ASCII History Report	**CHI HIF**
HISTORY. TXT[a]	History Report	**HIS**
HISTORY_HIF.TXT[a,c]	HIF History Report	**HIS HIF**
C4_*nnnnn*.CEV	Compressed 4-samples/cycle ASCII filtered event report; event ID number = *nnnnn*	**CEV *nnnnn***
CHF_*nnnnn*.CEV[c]	Compressed HIF ASCII event report	**CEV HIF *nnnnn***
CR_*nnnnn*.CEV	Compressed 128-samples/cycle ASCII raw event report; event ID number = *nnnnn*	**CEV R S128 *nnnnn***
HF_*nnnnn*.CFG[b,c]	HIF COMTRADE configuration file; event ID number = *nnnnn*	N/A
HF_*nnnnn*.DAT[b,c]	HIF COMTRADE binary data file; event ID number = *nnnnn*	N/A
HF_*nnnnn*.HDR[b,c]	HIF COMTRADE header file; event ID number = *nnnnn*	N/A
HR_*nnnnn*.CFG[c]	COMTRADE configuration file; event ID number = *nnnnn*	N/A
HR_*nnnnn*.DAT[c]	COMTRADE binary data file; event ID number = *nnnnn*	N/A
HR_*nnnnn*.HDR[c]	COMTRADE header file; event ID number = *nnnnn*	N/A

[a] Also available in the Reports directory for convenience.
[b] Available in the units ordered with Arc Sense technology (high-impedance fault detection).
[c] Also available in the COMTRADE directory for MMS only.

HR_nnnnn.* (Read-Only)

The three files HR_*nnnnn*.CFG, HR_*nnnnn*.DAT, and HR_*nnnnn*.HDR shown in *Table 10.13* are used to create an event report that conforms to the COMTRADE standard. The event is an unfiltered (raw) 128 samples/cycle event. The field, *nnnnn*, corresponds to the unique event identification number displayed by the **HIS E** command. For details on event reports see *Section 12: Analyzing Events*.

HF_nnnnn.* (Read-Only)

The three files HF_*nnnnn*.CFG, HF_*nnnnn*.DAT, and HF_*nnnnn*.HDR shown in *Table 10.13* are used to create a high-impedance event report that conforms to the COMTRADE standard. The field, *nnnnn*, corresponds to the unique event identification number displayed by the **HIS HIF** command. For details on event reports see *Section 12: Analyzing Events*.

ᵃ Calibration settings are included only when accessed at Access Level C.

SWCFG.ZIP

SWCFG.ZIP file is only available for Ymodem protocol and is not available in the FTP and MMS file structure. The SWCFG.ZIP file is a fixed name, general purpose file that can be as large as 2 MB in length. Users may store any type of data or information file they choose in this file, even if it is not a zipped file, as long as it is named SWCFG.ZIP. QuickSet uses the SWCFG.ZIP file to store template files created by the licensed version of QuickSet. The SWCFG.ZIP file is only visible in the **FIL DIR** command when a user has loaded it onto the relay.

Batch File Access

Files can be accessed as a batch by using the supported wildcard characters * or ?.

FTP and MMS Wildcard Usage

Table 10.16 shows examples using supported wildcards. Note that these wildcards may be appended to a directory path (e.g., /specified_directory/ *.txt).

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Communications 10.31
Page 613 of 1080
Command Summary
Wolfe

Table 10.16   FTP and MMS Wildcard Usage Examples

Usage	Description	Example	Note
*xyz	Lists all files and/or subdirectories, within a specified directory, whose names (including extension) end with *xyz*.	/*.TXT	List all files with the .TXT extension.
abc*	Lists all files and/or subdirectories, within a specified directory, whose names begin with *abc*.	/SETTINGS/SET*	List all settings files that start with SET.
mno	Lists all files and/or subdirectories, within a specified directory, whose names contain *mno*.	/EVENTS/*_100*	List all events that contain _100 in the ID number.
abc?.xyz	Lists all files, within a specified directory, whose names begin with *abc* and whose names (including extension) end with *xyz* and have any one single character following the letter *c*.	/EVENTS/C?_10007.CEV	Retrieves both the filtered and raw compressed event reports pertaining to the unique event number 10007.

Ymodem Wildcard Usage

Event, report, and diagnostic files can also be accessed as a batch by using wildcards.

NOTE: Ymodem protocol does not support wildcards for settings files.

Table 10.17   Ymodem Wildcard Usage Examples

Usage	Description	Example	Note
*xyz	Lists all files whose names (including extension) end with *xyz*.	FILE DIR MET*.TXT	Lists all of the metering files (MET.TXT, MET_D.TXT, etc.)
abc*	Lists all files whose names begin with *abc*.	FILE READ HR_10007*	Retrieves all of the three files for the COMTRADE event 10007 (HR_10007.CFG, HR_10007.DAT, and HR_10007.HDR)
mno	Lists all files whose names contain *mno*.	FILE READ *10007*	Retrieves all event files pertaining to the unique event number 10007 (including both the filtered and raw compressed event reports and all three comtrade files).
abc?.xyz	Lists all files whose names begin with *abc* and whose names (including extension) end with *xyz* and have any one single character following the letter c.	FILE READ C?_10007.CEV	Retrieves both the filtered and raw compressed event reports pertaining to the unique event number 10007.

Command Summary

Table 10.18 alphabetically lists the ASCII commands, the required access level, and the prompt at the access level. All commands available at lower access levels are also available from higher access levels.

Table 10.18 includes some commands not normally issued by operators. These commands are used during the firmware upgrade process or are used by SEL communications processors or PC software to communicate with intelligent electronic devices (IEDs) and are covered in *Appendix B: Firmware Upgrade Instructions*, *Appendix I: Configuration, Fast Meter, and Fast Operate Commands*, and *Appendix C: Compressed ASCII Commands*.

Table 10.18 ASCII Command Summary (Sheet 1 of 6)

Command	Access Level	Prompt	Command Description
2AC	1	=>	Enter Access Level 2.
ACC	0	=	Enter Access Level 1.
BAC	1	=>	Enter Breaker Access Level (Access Level B).
BNA	0	=	Display names of status bits in the A5D1 Fast Meter Message.
BRE	1	=>	Display breaker/recloser contact wear report.
BRE R	B	==>	Reset breaker/recloser contact wear monitor.
BRE W	B	==>	Preload breaker/recloser contact wear monitor data.
BTT	B	==>	Display latest battery load test results and time remaining until next discharge test.
BTT NOW	B	==>	Force a battery test and view the results.
CAL	2	=>>	Enter Access Level C. Reserved for SEL use only.
CAS	0	=	Display Compressed ASCII configuration message.
CEV *n*	1	=>	Display event report *n* in Compressed ASCII format. Parameter *n* can correspond to the number from the **HIS** command or the unique event number from the **HIS E** command.
CEV HIF *n*	1	=>	Display HIF event report *n* in Compressed ASCII format. Parameter *n* corresponds to the event number from the **HIS HIF** command.
CHI	1	=>	Display history data in Compressed ASCII format.
CHI HIF	1	=>	Display HIF history data in Compressed ASCII format.
CLO, CLO A, CLO B, CLO C	B	==>	Momentarily assert Relay Word bit CC3, CCA, CCB, or CCC).
COM *c*	1	=>	Show communications summary report (COM report) on MIRRORED BITS Channel *c* (*c* = A or B) using all failure records in the channel calculations.
COM *c row1*	1	=>	Show COM report for MIRRORED BITS Channel *c* using the latest *row1* failure records (*row1* = 1–255, where 1 is the most recent entry).
COM *c row1 row2*	1	=>	Show COM report for MIRRORED BITS Channel *c* using failure records *row1–row2* ([*row1* and *row2*] = 1–255).
COM *c date1*	1	=>	Show COM report for MIRRORED BITS Channel *c* using failures recorded on date *date1* (see **DAT** command for date format).
COM *c date1 date2*	1	=>	Show COM report for MIRRORED BITS Channel *c* using failures recorded between dates *date1* and *date2,* inclusive.
COM *c* C	1	=>	Clears communications records for MIRRORED BITS Channel *c* (or both channels if *c* is not specified).
COM *c* L …	1	=>	For all **COM** commands (except **COM *c* C**), **L** causes the specified COM report records to be listed after the summary.
CON *n*	B	==>	Set, clear, or pulse internal Remote Bit *n* (*n* is the Remote Bit number from 01–32). The control will respond with `CONTROL RBn:`. Reply with the following: `SRB n` (to set Remote Bit *n* (assert RB*n*)) `CRB n` (to clear Remote Bit *n* (deassert RB*n*)) `PRB n` (to pulse Remote Bit *n* (assert RB*n* for 1/4 cycle))
COP *m n*	2	=>>	Copy settings from Group *m* to Group *n*.
COP D *m n*	2	=>>	Copy DNP Map *m* to Map *n*.
COU *k*	1	=>	Show the SELOGIC counter values. Enter *k* for repeat count.
CST	1	=>	Display the recloser control status in Compressed ASCII format.
CSU *n*	1	=>	Display the event summary for event report *n* (with label lines) in Compressed ASCII format. If *n* is omitted, the default is 1 (most recent). Parameter *n* can correspond to the number from the **HIS** command or the unique event number from the **HIS E** command.

Communications 10.33
Page 615 of 1080
Command Summary
Wolfe

Table 10.18   ASCII Command Summary (Sheet 2 of 6)

Command	Access Level	Prompt	Command Description
CSU HIF *n*	1	=>	Display the HIF event summary for event report *n* in Compressed ASCII format. If *n* is omitted, the default is 1 (most recent). Parameter *n* corresponds to the event number from the **HIS HIF** command.
DAT	1	=>	Display the internal clock date.
DAT *date*	1	=>	Set the internal clock date to *date* (Date Format setting DATE_F = MDY, YMD, or DMY).
DNA X or T	0	=	Display ASCII names of all Relay Word bits digital I/O. Either X or T is mandatory and results are identical.
ETH	1	=>	Displays information about Ethernet port(s).
ETH C	1	=>	Clears Ethernet port sent and received packets, bytes, and error statistics.
EVE *n*	1	=>	Show event report *n* with 4 samples per cycle (*n* = 1 to highest numbered event report, where 1 is the most recent report: see **HIS** command). If *n* is omitted (**EVE** command), the most recent report is displayed.
EVE *n* **A**	1	=>	Show event report *n* with analog section only.
EVE *n* **C**	1	=>	Show event report *n* in Compressed ASCII format with 16 samples-per-cycle analog resolution and 4 samples-per-cycle digital resolution.
EVE *n* **D**	1	=>	Show event report *n* with digital section only.
EVE *n* **L**	1	=>	Show event report *n* with 32 samples per cycle (similar to **EVE** *n* **S32**).
EVE *n* **L***y*	1	=>	Show first *y* cycles of event report *n* (*y* = 1 to Global setting LER).
EVE *n* **M**	1	=>	Show event report *n* with communications section only.
EVE *n* **P**	1	=>	Show event report *n* with synchrophasor-level accuracy time adjustment.
EVE *n* **R**	1	=>	Show event report *n* in raw (unfiltered) format with 32 samples-per-cycle resolution.
EVE *n* **S***x*	1	=>	Show event report *n* with *x* samples per cycle (*x* = 4, 16, 32, or 128). Must append R parameter for S128 (**EVE S128 R**).
EVE *n* **V**	1	=>	Show event report *n* with variable scaling for analog values.
EXI	0	=	Exit active Telnet session.
FIL DIR	1	=>	Display a list of available files.
FIL READ *filename*	1	=>	Transfer settings file or event file *filename* from the relay to the PC.
FIL SHOW *filename*	1	=>	Display contents of the ASCII file *filename*.
FIL WRITE *filename*	2	=>>	Transfer settings file *filename* from the PC to the relay.
GOO	1	=>	Display GOOSE information.
GOO *k*	1	=>	Display GOOSE information *k* times.
GOO S	1	=>	Display a list of GOOSE subscriptions with their ID.
GOO S *n*	1	=>	Display GOOSE statistics for subscription ID *n*.
GOO S *n* **C**	1	=>	Clear GOOSE statistics for subscription ID *n*.
GOO S *n* **L**	1	=>	Display GOOSE statistics for subscription ID *n* including error history.
GOO S ALL	1	=>	Display GOOSE statistics for all subscriptions.
GOO S ALL C	1	=>	Clear GOOSE statistics for all subscriptions.
GOO S ALL L	1	=>	Display GOOSE statistics for all subscriptions including error history.
GRO	1	=>	Display active group number.
GRO *n*	B	==>	Change the active group to Group *n* (*n* = 1–8).

Table 10.18 ASCII Command Summary (Sheet 3 of 6)

Command	Access Level	Prompt	Command Description
HIS	1	=>	Display event histories with the oldest at the bottom of the list and the most recent at the top of the list.
HIS *n*	1	=>	Display event histories with the oldest at the bottom of the list and the most recent at the top of the list beginning at event *n*.
HIS C	1	=>	Clear/reset the event history and all corresponding event reports from nonvolatile memory.
HIS E	1	=>	Same as **HIS**, but events are identified with a unique number in the range 10000–65535.
HIS HIF	1	=>	Display HIF event histories with the oldest at the bottom of the list and the most recent at the top of the list.
HIS HIF *n*	1	=>	Display *n* HIF event histories with the oldest at the bottom of the list and the most recent at the top of the list.
HIS HIF C	1	=>	Clear/reset the HIF event history and all corresponding event reports from nonvolatile memory.
HIZ	1	=>	Display HIZ event reports with the oldest at the bottom of the list and the most recent at the top of the list.
HIZ *n*	1	=>	Display *n* HIZ event reports with the oldest at the bottom of the list and the most recent at the top of the list.
HIZ C	1	=>	Clear/reset the HIZ event reports from nonvolatile memory.
ID	0	=	Display the firmware id, user id, device code, part number, and configuration information.
INI HIF	2	=>>	Force HIF algorithm into initial tuning mode.
L_D	2	=>>	Prepares the relay to receive new firmware.
LDP	1	=>	Show entire Load Profile (LDP) report.
LDP *n*	1	=>	Show latest *n* rows in the LDP report (*n* = 1 to several thousand, where 1 is the most recent entry).
LDP *row1 row2*	1	=>	Show rows *row1*–*row2* in the LDP report ([*row1* and *row2*] = 1 to several thousand).
LDP *date1*	1	=>	Show all rows in the LDP report recorded on the specified date *date1* (see **DAT** command for date format).
LDP *date1 date2*	1	=>	Show all rows in the LDP report recorded between dates *date1* and *date2*, inclusive.
LDP C	1	=>	Clear the Load Profile data from memory.
LDP D	1	=>	Display the number of days of Load Profile memory capacity remaining before data over-write occurs.
LOG HIF	1	=>	Display the HIF alarm and fault calculations as a percentage of their final value.
LOG HIF *n*	1	=>	Display the *n* most recent **LOG HIF** entries.
LOG HIF C	1	=>	Clear the **LOG HIF** data from memory.
LOO *c t*	2	=>>	Set Mirrored Bits Channel *c* to loopback (*c* = A or B). The received Mirrored Bits elements are forced to default values during the loopback test; *t* specifies the loopback duration in minutes (*t* = 1–5000, default is 5).
LOO *c t* **DATA**	2	=>>	Set Mirrored Bits Channel *c* to loopback for duration *t* minutes. **DATA** allows the received Mirrored Bits elements to change during the loopback test.
LOO *c* **R**	2	=>>	Cease loopback on Mirrored Bits Channel *c* and return the channel to normal operation.
MAC	1	=>	Display Ethernet port MAC address.
MET *k*	1	=>	Display instantaneous metering data *k* times.
MET D	1	=>	Display demand and peak demand metering data.
MET E	1	=>	Display energy metering data.
MET H	1	=>	Display fundamental magnitudes, root-mean-square (rms) magnitudes, Total Harmonic Distortion, and harmonic magnitudes for the first 16 harmonics.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)

Command Summary
Wolfe

Table 10.18 ASCII Command Summary (Sheet 4 of 6)

Command	Access Level	Prompt	Command Description
MET HIF *k*	1	=>	Display the HIF alarm and fault calculations as a percentage of their final value. Enter *k* for repeat count (k = 1–32767; if not specified, default is 1).
MET M	1	=>	Display maximum and minimum metering data.
MET PM *k*	1	=>	Display synchrophasor measurements (available when TSOK = logical 1). Enter *k* for repeat count.
MET PM *time*	1	=>	Display synchrophasor measurements (available when TSOK = logical 1). Enter *time* to display the synchrophasor for an exact specified time, in 24-hour format.
MET PM HIS	1	=>	Display the most recent MET PM synchrophasor report.
MET RD	1	=>	Reset demand metering data.
MET RE	1	=>	Reset energy metering data.
MET RM	1	=>	Reset maximum metering data. All values will display RESET until new maximum/minimum values are recorded.
MET RMS	1	=>	Display root-mean-square (rms) metering data.
MET RP	1	=>	Reset peak demand metering data.
OPE, OPE A, OPE B, OPE C	B	==>	Momentarily assert Relay Word bit OC3, OCA, OCB, or OCC).
PAR	2	=>>	Change the device part number. Use only under the direction of SEL.
PAS 1	2	=>>	Change the Access Level 1 password.
PAS B	2	=>>	Change the Access Level B password.
PAS 2	2	=>>	Change the Access Level 2 password.
PAS C	C	==>>	Change the Access Level C password.
PUL *n s*	B	==>	Pulse output contact OUT*n* (n = 201, 202 [all models]; 101–108 [models with extra I/O]) for *s* (1–30) seconds. Parameter OUT*n* must be specified; *s* defaults to 1 if not specified.
QUI	0	=	Reduce access level to Access Level 0 (exit relay control).
R_S	2	=>>	Restore factory-default settings and passwords and reboot the system. Use only under the direction of SEL. Only available after a settings or critical RAM failure.
SER	1	=>	Show entire Sequential Events Recorder (SER) report.
SER *n*	1	=>	Show latest *n* rows in the SER report (n = 1–1024, where 1 is the most recent entry).
SER *row1 row2*	1	=>	Show rows *row1–row2* in the SER report.
SER *date1*	1	=>	Show all rows in the SER report recorded on the specified date *date1* (see **DAT** command for date format).
SER *date1 date2*	1	=>	Show all rows in the SER report recorded between dates *date1* and *date2*, inclusive.
SER C	1	=>	Clears SER report from nonvolatile memory.
SET *n*	2	=>>	Change relay settings (overcurrent, reclosing, timers, etc.) for Group *n* (n = 1–8; if not specified, default is the active settings group).
SET D *n*	2	=>>	Change DNP Map *n* settings (n = 1, 2, or 3).
SET F	2	=>>	Change Front-Panel settings.
SET G	2	=>>	Change Global settings.
SET L *n*	2	=>>	Change SELOGIC control equation settings for Group *n* (n = 1–8; if not specified, default is the active settings group).
SET M	2	=>>	Change Modbus settings.
SET P *p*	2	=>>	Change Port settings for Serial Port *p* (p = 1, 2, 3, F, or 5; if not specified, default is the active port).
SET R	2	=>>	Change SER and LDP Recorder settings.

Command Summary

Table 10.18 ASCII Command Summary (Sheet 5 of 6)

Command	Access Level	Prompt	Command Description
SET … *name*	2	=>>	For all **SET** commands, jump ahead to specific setting by entering setting name.
SET … TERSE	2	=>>	For all **SET** commands, the **TERSE** command disables the automatic **SHO** command after settings entry.
SHO *n*	1	=>	Show relay settings (overcurrent, reclosing, timers, etc.) for Group *n* (*n* = 1–8; if not specified, default is active settings group).
SHO D *n*	1	=>	Show DNP Map *n* settings (*n* = 1, 2, or 3).
SHO F	1	=>	Show Front-Panel settings.
SHO G	1	=>	Show Global settings.
SHO L *n*	1	=>	Show SELOGIC control equation settings for Group *n* (*n* = 1–8; if not specified, default is the active settings group).
SHO M	1	=>	Show Modbus settings.
SHO P *p*	1	=>	Show Port settings for Serial Port *p* (*p* = 1, 2, 3, F, or 5; if not specified, default is the active port).
SHO R	1	=>	Show SER and LDP Recorder settings.
SHO … *name*	1	=>	For all **SHO** commands, jump ahead to specific setting by entering setting name.
SNS	0	=	Display the Fast Message name string of the SER settings.
SSI	1	=>	Show entire Voltage Sag/Swell/Interruption (SSI) report.
SSI *n*	1	=>	Show latest *n* rows in SSI report (*n* = 1 to several thousand, where 1 is the most recent entry).
SSI *row1 row2*	1	=>	Show rows *row1–row2* in SSI report.
SSI *date1*	1	=>	Show all rows in SSI report recorded on the specified date *date1* (see **DAT** command for date format).
SSI *date1 date2*	1	=>	Show all rows in SSI report recorded between dates *date1* and *date2*, inclusive.
SSI C	1	=>	Clears SSI report from nonvolatile memory.
SSI R	1	=>	Reset the VSSI recorder logic and clear the Vbase value.
SSI T	1	=>	Trigger the SSI recorder.
STA *k*	1	=>	Display the recloser control self-test information *k* times (*k* = 1–32767; if not specified, default is 1).
STA C	2	=>>	Clear status warning or failure and reboot the recloser control.
STA S	1	=>	Display the memory and execution utilization for the SELOGIC control equations.
SUM HIF *n*	1	=>	Display the HIF summary message for event *n*.
TAR	1	=>	Display Relay Word row 0 or last displayed target row.
TAR *n k*	1	=>	Display Relay Word row number *n*. Enter *k* for repeat count (*k* = 1–32767; if not specified, default is 1).
TAR *name k*	1	=>	Display Relay Word row containing *name*. Enter *k* for repeat count (*k* = 1–32767; if not specified, default is 1).
TAR LIST	1	=>	Shows all the Relay Word bits in all of the rows.
TAR R	1	=>	Reset front-panel tripping targets.
TAR ROW …	1	=>	Shows the Relay Word row number at the start of each line, with other selected **TAR** commands as described above, such as *n*, *name*, *k*, and **LIST**.
TES DB	B	==>	Display the present status of digital and analog overrides.
TES DB A *name value*	B	==>	Override analog label *name* with *value* in communications interface.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 619 of 1080
Wolfe

Communications 10.37
Command Summary

Table 10.18 ASCII Command Summary (Sheet 6 of 6)

Command	Access Level	Prompt	Command Description
TES DB A *row_x value*	B	==>	Override all Relay Word bits in Relay Word row number *row_x* with *value*.
TES DB D *name value*	B	==>	Override Relay Word bit *name* with *value* in communications interface, where *value* = 0 or 1.
TES DB *name* **OFF**	B	==>	Clear (analog or digital) override for element *name*.
TES DB OFF	B	==>	Clear all analog and digital overrides.
TIM	1	=>	Display the present internal clock time.
TIM *hh:mm*	1	=>	Set the internal clock to *hh:mm*.
TIM *hh:mm:ss*	1	=>	Set the internal clock to *hh:mm:ss*.
TIM Q	1	=>	Display time statistics.
TIM DST	1	=>	Display daylight-saving time information.
TRI	1	=>	Trigger event report data capture.
TRI *time*	1	=>	Trigger an event report data capture at specified *time*.
TRI HIF	1	=>	Trigger an HIF event report data capture. Only available in recloser controls that support Arc Sense technology.
TRI STA	1	=>	Display the status of a previous **TRI** *time* command.
VEC D	2	=>>	Display the standard Vector Report.
VEC E	2	=>>	Display the Extended Vector Report.
VER	1	=>	Display information about the configuration of the recloser control.

The recloser control responds with `Invalid Access Level` if a command is entered from an access level lower than the specified access level for the command. The recloser control responds with `Invalid Command` to commands not listed above or entered incorrectly.

Many of the command responses display the following header at the beginning:

```
[RID Setting]                    Date: mm/dd/yyyy  Time: hh:mm:ss.sss
[TID Setting]                    Time Source: external
```

The definitions follow:

[RID Setting]: This is the RID (Relay Identifier) setting. The recloser control is shipped with the default setting RID = FEEDER 1 (see *Identifier Labels (Group Settings) on page 9.40*).

[TID Setting]: This is the TID (Terminal Identifier) setting. The recloser control is shipped with the default setting TID = STATION A (see *Identifier Labels (Group Settings) on page 9.40*).

Date: This is the date when the command response was given, except for recloser control response to the **EVE** command (Event), when it is the date the event occurred. You can modify the date display format (Month/Day/Year, Year/Month/Day, or Day/Month/Year) by changing the DATE_F Global setting.

Command Explanations

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 620 of 1080
Wolfe

[RID Setting]:   This is the RID (Relay Identifier) setting. The recloser control is shipped with the default setting RID = FEEDER 1 (see *Identifier Labels (Group Settings) on page 9.40*).

Time: This is the time when the command response was given, except for recloser control response to the **EVE** command, when it is the time the event occurred.

Time Source: This is internal if no time-code input is attached and external if an input is attached.

Command Explanations

ACC, BAC, 2AC, and CAL Commands (Go to Access Level 1, B, 2, or C)

The **ACC**, **BAC**, **2AC**, and **CAL** commands provide entry to the multiple access levels. Different commands are available at the different access levels as shown in *Table 10.18*. Commands **ACC**, **BAC**, **2AC**, and **CAL** are explained together because they operate similarly.

Command	Description
ACC	Enter Access Level 1.
BAC	Enter Breaker access level (Access Level B).
2AC	Enter Access Level 2.
CAL	Enter Access Level C. Reserved for SEL use only.

Password Requirements

Passwords are required if the main board Access jumper is *not* in place (Access jumper = OFF). Passwords are not required if the main board Access jumper is in place (Access jumper = ON). Refer to *Figure 2.48* for Access jumper information. See *PAS Command (Change Passwords)* for the list of default passwords and for more information on changing passwords.

Access Level Attempt (Password Required)

Assume the following conditions: Access jumper = OFF (not in place), Access Level = 0.

At the Access Level 0 prompt, enter the **ACC** command:

```
=ACC <Enter>
```

Because the Access jumper is not in place, the relay asks for the Access Level 1 password to be entered:

```
Password: ?
```

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 621 of 1080
Wolfe
Communications
10.39
Command Explanations

The relay is shipped with the default Access Level 1 password shown in the table under *PAS Command (Change Passwords)*. At the prompt above, enter the default password and press the **<Enter>** key. The relay responds:

```
FEEDER 1                        Date: 02/02/09 Time: 08:31:10.361
STATION A
Level 1
=>
```

The => prompt indicates the relay is now in Access Level 1.

If the entered password is incorrect, the relay asks for the password again (Password: ?). If the incorrect password is entered when attempting to enter Access Level B or higher the PASNVAL Relay Word bit will pulse for approximately one second. The relay will ask as many as three times. If the requested password is incorrectly entered three times in a row, the Relay Word bit BADPASS will pulse for approximately one second. After three attempts, the relay displays an invalid access message and prevents further access attempts for 30 seconds. The PASNVAL and BADPASS Relay Word bits are part of the default SALARM SELOGIC equation (see *Factory-Default Settings on page 9.61*).

Access Level Attempt (Password Not Required)

Assume the following conditions: Access jumper = ON (in place), Access Level = 0.

At the Access Level 0 prompt, enter the **ACC** command:

```
=ACC <Enter>
```

Because the Access jumper is in place, the relay does not ask for a password; it goes directly to Access Level 1. The relay responds:

```
FEEDER 1                        Date: 03/05/09 Time: 08:31:10.361
STATION A
Level 1
=>
```

The => prompt indicates the relay is now in Access Level 1.

The recloser control pulses the ACCESSP Relay Word bit for approximately one second after a successful Level B, Level 2, or Level C access. The above two examples demonstrate how to go from Access Level 0 to Access Level 1. Refer to *Port Access Levels* for more access level examples.

BNAMES Command

The **BNA** command produces ASCII names of all relay status bits reported in the Fast Meter Data Block (A5D1) message in Compressed ASCII format (see *Appendix I: Configuration, Fast Meter, and Fast Operate Commands*).

Command	Description	Access Level
BNA	Display names of status bits in the A5D1 Fast Meter Message.	0

BTT Command

Use the **BTT** commands to display battery test results or force a battery test.
See *Section 8: Metering and Monitoring* for details on how the battery system
monitor operates.

BTT (View Battery Test Results)

Use the **BTT** command to display the daily battery test results.

Command	Description	Access Level
BTT	Display latest battery load test results and time remaining until next discharge test.	B

➤ If the most recent battery test passed, the following message is
displayed:

```
Battery test state is:  OK
Time until next battery test:  XX hours
```

where XX is the estimated time until the next automatic battery
test, in hours.

➤ If the DTFAIL Relay Word bit is already asserted (most recent
test failed), the following message is displayed:

```
Battery Failure
```

Wolfe

➤ If a battery test is in progress, the following message is displayed:

```
Battery test in progress
```

BTT NOW (Initiate Battery Test)

Use the **BTT NOW** command to request an immediate battery test.

Command	Description	Access Level
BTT NOW	Force a battery test and view the results.	B

1. If a battery test is already in progress, the following message is displayed:

   ```
   Battery test in progress
   ```

2. If the battery charger is in Discharge mode or Startup mode, no test is performed and the following message is displayed:

   ```
   Command Failed: Battery charger in Discharge or
   Startup mode.
   ```

3. If neither (1) nor (2) apply, a test is performed. The following message is displayed and a new period appears after the message for each second of the battery test.

   ```
   Battery test initiated...
   ```

4. At the end of the test, the display will be one of the following:

   ```
   Battery test state is:  OK
   ```
   or
   ```
   Battery test state is:  FAILED
   ```

CASCII Command

The **CAS** command produces the Compressed ASCII configuration message. This configuration instructs an external computer on the method for extracting data from other Compressed ASCII commands.

Command	Description	Access Level
CAS	Display Compressed ASCII configuration message.	0

CEV Command (Compressed Event Reports)

Use the **CEV** command to retrieve event reports in compressed format. See *Section 12: Analyzing Events* for details on retrieving event reports, including additional parameters.

Command	Description	Access Level
CEV *n*	Display event report *n* in Compressed ASCII format. Parameter *n* can correspond to the number from the **HIS** command or the unique event number from the **HIS E** command.	1

CEV HIF (Compressed HIF Event Reports; Only Available in Relays That Support Arc Sense Technology)

Use the **CEV HIF** command to retrieve high-impedance (HIF) event reports in compressed format. See *HIF Event Reporting on page 12.52* for details on retrieving HIF event reports.

Command	Description	Access Level
CEV HIF *n*	Display HIF event report *n* in Compressed ASCII format. Parameter *n* corresponds to the event number from the **HIS HIF** command.	1

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 625 of 1080
Communications 10.43
Command Explanation
Wolfe

CHISTORY Command

The **CHI** command is the **HISTORY** command for the Compressed ASCII command set.

Command	Description	Access Level
CHI	Display history data in Compressed ASCII format.	1

CHISTORY HIF Command (Only Available in Relays That Support Arc Sense Technology)

The **CHI HIF** command is the **HISTORY HIF** command for the Compressed ASCII command set. See *HIF Event History on page 12.51*.

Command	Description	Access Level
CHI HIF	Display HIF history data in Compressed ASCII format.	1

CLO Command (Close Breaker)

Use the close command (**CLO**, **CLO A**, **CLO B**, or **CLO C**) to assert the specified Relay Word bit (CC3, CCA, CCB, or CCC) for 1/4 cycle.

Command	Description	Access Level
CLO	Momentarily assert the three-phase close Relay Word bit CC3.	B
CLO *n*	This command asserts a single-phase close Relay Word bit (**CLO A** asserts CCA, **CLO B** asserts CCB, **CLO C** asserts CCC).	B

Program the close command Relay Word bit into the close control equation (CL3P, CLA, CLB, or CLC) to enable assertion of the close Relay Word bit (CLOSE3P, CLOSEA, CLOSEB, or CLOSEC) with the close command. Program the close Relay Word bit to enable assertion of an output contact (e.g., OUT201 := CLOSE3P) to close a recloser/circuit breaker. See *Section 6: Close and Reclose Logic* for a detailed explanation of the close logic.

To issue the **CLO** command, enter the following:

```
==>CLO <Enter>
Close Breaker  (Y/N) ? Y <Enter>
Are you sure (Y/N) ? Y <Enter>
==>
```

Typing **N <Enter>** after either of the Y/N prompts aborts the command.

The main board breaker jumper supervises the **CLO** command (see *Figure 2.48*). If the breaker jumper is not in place (breaker jumper = OFF), the recloser control does not perform the **CLO** command and responds with the following message:

```
Aborted: No Breaker Jumper
```

COM Command (Communication Data)

The **COM** command displays integral relay-to-relay (MIRRORED BITS) communications data. For more information on MIRRORED BITS communications, see *Appendix D: MIRRORED BITS Communications*. To get a summary report, enter the command with the channel parameter (**A** or **B**).

Command	Description	Access Level
COM *c* **COM** *c row1 row2* **COM** *c date1 date2*	Show communications summary report (COM report) on MIRRORED BITS Channel *c* (*c* = A or B).	1
COM *c* **L …**	For all **COM** commands (except **COM** *c* **C**), **L** causes the specified report records to be listed after the summary.	1
COM *c* **C**	Clear/reset communications buffer data for MIRRORED BITS Channel *c* (or both channels if *c* is not specified).	1

Parameter	Description
c	Parameter *c* is A for Channel A and B for Channel B. If only one MIRRORED BITS port is enabled the channel specifier may be omitted.
row1 row2	Append *row1* to return a chronological progression of the first *row1* rows. Append *row1* and *row2* to return all rows between *row1* and *row2*, beginning with *row1* and ending with *row2*. Enter the smaller number first to display a numeric progression of rows through the report. Enter the larger number first to display a reverse numeric progression of rows.
date1 date2	Append *date1* to return all rows with this date. Append *date1* and *date2* to return all rows between *date1* and *date2* beginning with *date1* and ending with *date2*. Enter the oldest date first to display a chronological progression through the report. Enter the newest date first to display a reverse chronological progression. Date entries are dependent on the date format setting DATE_F.

```
=>COM A <Enter>

```

There may be as many as 255 records in the extended report.

CON Command (Control Remote Bit)

The **CON** command is a two-step command that allows you to control Relay Word bits RB01–RB32 (see Rows 94–97 in *Table F.1*).

Command	Description	Access Level
CON *n*[a]	First step of a two-command sequence. The SEL-651R-2 will prompt for the second step (sub-command), shown below.	B

[a] Parameter n is a number from 1 to 32 representing RB01–RB32.

Step 1.   At the Access Level B prompt, type:

      a. **CON**

      b. a space

      c. the number of the remote bit you wish to control (1–32)

Step 2.   Press the **<Enter>** key on your computer.

The relay responds by repeating your command followed by a colon.

Step 3.   At the colon, type the Control subcommand you wish to perform (see *Table 10.19*).

The following example shows the steps necessary to pulse Remote Bit 5 (RB5):

```
==>CON 5 <Enter>
CONTROL RB5: PRB 5 <Enter>
==>
```

You must enter the same remote bit number in both steps in the command. If the bit numbers do not match, the relay responds:

```
Invalid Command
```

Table 10.19   SEL-651R-2 Control Subcommand

Subcommand	Description
SRB *n*	Set Remote Bit *n* ("ON" position)
CRB *n*	Clear Remote Bit *n* ("OFF" position)
PRB *n*	Pulse Remote Bit *n* for 1/4 cycle ("MOMENTARY" position)

See *Remote Bits on page 7.22* for more information.

COP Command (Copy Settings Group or DNP Map)

NOTE: If EZ settings are not enabled in the source Group m, but are enabled in the destination Group n, the COP command is not allowed.

Copy relay and SELOGIC control equation settings from source Settings Group *m* to destination Settings Group *n* with the **COP *m n*** command. Copy DNP map settings from Map *m* to Map *n* with the **COP D *m n*** command. Settings group numbers range from 1 to 8 and DNP maps range from 1 to 3. After entering settings into one settings group or map with the **SET** command, copy them to the other group(s) or map(s) with the **COP** command. Use the **SET** command to modify the copied settings. The relay disables for a few seconds and the ALARM output pulses if you copy settings into the active group. This is similar to a Group Change (see *Multiple Settings Groups on page 7.23*).

Command	Description	Access Level
COP *m n*	Copy settings from Group *m* to Group *n*.	2
COP D *m n*	Copy DNP Map *m* to Map *n*.	2

Parameter	Description
m	Parameter *m* is a group number from 1 to 8 or a map number from 1 to 3.
n	Parameter *n* is a group number from 1 to 8 or a map number from 1 to 3.

For example, to copy settings from Group 1 to Group 3 issue the following command:

```
=>>COP 1 3 <Enter>
Copy 1 to 3
Are you sure (Y/N) ? Y <Enter>

Please wait...
Settings copied
=>>
```

COUNTER Command (View SELOGIC Counters)

The **COU** command displays the present value of the SELOGIC counters.

Command	Description	Access Level
COU *k*	Show the SELOGIC counter values. Enter *k* for repeat count.	1

Command Explanations

NOTE: The counter data displayed by the **COU** command may not be from the same processing interval for each counter.

The **COU** command is convenient to use while testing the SEL<small>OGIC</small> Counter settings (see *Counters on page 7.13*). Below is a sample of the **COU** command response.

```
=>COU <Enter>
FEEDER 1                                      Date: 08/05/2003  Time: 12:07:32.532
STATION A                                     Time Source: internal

     SC01      SC02      SC03      SC04      SC05      SC06      SC07      SC08
        0        14         0         0         0         0         0         0

     SC09      SC10      SC11      SC12      SC13      SC14      SC15      SC16
        0         0         0         0         0         0         0         0

=>
```

CST Command (Compressed Status)

The **CST** command generates a recloser control status report in Compressed ASCII format.

Command	Description	Access Level
CST	Display the recloser control status in Compressed ASCII format.	1

CSU Command

The **CSU** command retrieves the event summary information event report *n* in Compressed ASCII format (see *Section 12: Analyzing Events*).

Command	Description	Access Level
CSU *n*	Display the event summary for event report *n* (with label lines) in Compressed ASCII format. If *n* is omitted, the default is 1 (most recent). Parameter *n* can correspond to the number from the **HIS** command or the unique event number from the **HIS E** command.	1

CSU HIF Command (Only Available in Relays That Support Arc Sense Technology)

The **CSU HIF** command retrieves the HIF event summary information for event report *n* in Compressed ASCII format (see *HIF Event Summary on page 12.48*).

Command	Description	Access Level
CSU HIF *n*	Display the HIF event summary for event report *n* in Compressed ASCII format. If *n* is omitted, the default is 1 (most recent). Parameter *n* corresponds to the event number from the **HIS HIF** command.	1

DAT Command (View/Change Date)

DAT displays the date stored by the internal calendar/clock. If the Global setting DATE_F is set to MDY, the date is displayed as month/day/year. If the date format setting DATE_F is set to YMD, the date is displayed as year/month/day.

Command	Description	Access Level
DAT	Display the internal clock date.	1
DAT *date*	Set the internal clock date to *date* (DATE_F set to MDY, YMD, or DMY).	1

Communications
Command Explanations

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 630 of 1080
Wolfe

NOTE: After setting the date, allow at least 60 seconds before powering down the relay or the new setting may be lost.

To set the date:

➤ Type **DAT mm/dd/yyyy <Enter>** if the DATE_F setting is MDY.

➤ If the DATE_F is set to YMD, enter **DAT yyyy/mm/dd <Enter>**.

➤ If the DATE_F is set to DMY, enter **DAT dd/mm/yyyy <Enter>**.

To set the date to May 20, 2016, enter the following:

```
=>DAT 5/20/2016 <Enter>
05/20/2016
=>
```

You can separate the month, day, and year parameters with spaces, commas, slashes, colons, and semicolons. Set the year in 4-digit format (for dates 2000–2099).

If an IRIG-B or SNTP time synchronization signal is connected to the relay, the **DAT** command cannot alter the month or day portion of the date. If the IRIG-B or SNTP time source is IEEE C37.118 compliant and Global setting IRIGC = C37.118, or if an SNTP time source is connected, the **DAT** command cannot alter the year. See *Configuring High-Accuracy Timekeeping on page J.21* for more details on IRIG time sources.

DNAMES Command

The **DNA** command produces the ASCII names of all Relay Word bits reported in a Fast Meter message in Compressed ASCII format (see *DNA Message on page I.13*).

Command	Description	Access Level
DNA X or **T**	Display ASCII names of all Relay Word bits digital I/O. Either X or T is mandatory and results are identical.	0

ETH Command (View Ethernet Port Information)

Use the **ETH** command when troubleshooting Ethernet connections. The report shown is for a relay with dual copper Ethernet ports with Port 5 setting NETMODE = FAILOVER. Different Ethernet configurations and different NETMODE settings result in slightly different information being displayed. See *Establishing Communications Using an Ethernet Port and Telnet or the Web Server* for a description of the settings and operating modes related to the Ethernet port.

Command	Description	Access Level
ETH	Displays information about Ethernet port(s)	1
ETH C	Clears Ethernet port sent and received packets, bytes, and error statistics	1

```
=>ETH <Enter>
SEL-651R-2                    Date: 8/27/13   Time: 05:40:00.603

EVE Command (Event Reports)

Use the **EVE** command to view event reports. See *Section 12: Analyzing Events* for further details on retrieving event reports, including additional parameters.

Command (Parameter n Is Optional)	Description	Access Level
EVE *n*	Return event report *n* (including settings and summary) at full length with 4-samples/cycle data. Parameter *n* can correspond to the number from the **HIS** command or the unique event number from the **HIS E** command.	1

EXI Command

Use the **EXI** command to exit a Telnet session on any of the Ethernet ports.

Command	Description	Access Level
EXI	Exit active Telnet session	0

FIL Command

The **FIL** command provides an efficient means of transferring files between the relay and a PC. Software applications, such as QuickSet, use the **FIL** command to send and receive settings files to and from the relay.

The **FIL** command uses Ymodem transfer protocol to transfer setting files and to retrieve event files (see *Retrieving COMTRADE Event Files on page 12.15*). Reports, event, and diagnostic files are available to read via Ymodem as a batch. See the *Ymodem File Structure on page 10.29* for more information on using wildcards.

Command	Description	Access Level
FIL DIR	Display a list of available files.	1
FIL READ *filename*	Transfer settings or event file *filename* from the relay to the PC.	1
FIL WRITE *filename*	Transfer settings file *filename* from the PC to the relay.	2
FIL SHOW *filename*	Displays contents of the ASCII file *filename*.	1

The following response shows the available reports, events, and settings available with the **FIL** command. For more information on these files, see *Virtual File Interface on page 10.24*.

Command Explanations

GOOSE Command

Use the GOOSE (**GOO**) command to display transmit and receive GOOSE messaging and statistics information, which can be used for troubleshooting. The GOOSE command variants and options are shown below.

Command Variant	Description	Access Level
GOO	Display GOOSE information.	1
GOO *k*	Display GOOSE information *k* times.	1
GOO S	Display a list of GOOSE subscriptions with their ID.	1
GOO S *n*	Display GOOSE statistics for subscription ID *n*.	1
GOO S ALL	Display GOOSE statistics for all subscriptions.	1
GOO S *n* **L**	Display GOOSE statistics for subscription ID *n* including error history.	1
GOO S ALL L	Display GOOSE statistics for all subscriptions including error history.	1
GOO S *n* **C**	Clear GOOSE statistics for subscription ID *n*.	1
GOO S ALL C	Clear GOOSE statistics for all subscriptions.	1

The information displayed for each GOOSE IED is described in the following table.

Information Field	Description
`Transmit GOOSE Control Reference`	This field represents the GOOSE control reference information that includes the IED name, ldInst (Logical Device Instance), LN0 lnClass (Logical Node Class), and GSEControl name (GSE Control Block Name) (e.g., SEL_651R_1CFG/LLN0GOGooseDSet13).
`Receive GOOSE Control Reference`	This field represents the goCbRef (GOOSE Control Block Reference) information that includes the iedName (IED name), ldInst (Logical Device Instance), LN0 lnClass (Logical Node Class), and cbName (GSE Control Block Name) (e.g., SEL_651R_1CFG/LLN0GOGooseDSet13).
`MultiCastAddr` (Multicast Address)	This hexadecimal field represents the GOOSE multicast address.
`Ptag`	This three-bit decimal field represents the priority tag value, where spaces are used if the priority tag is unknown.
`Vlan`	This 12-bit decimal field represents the virtual LAN (Local Area Network) value, where spaces are used if the virtual LAN is unknown.
`StNum` (State Number)	This hexadecimal field represents the state number that increments with each state change.
`SqNum` (Sequence Number)	This hexadecimal field represents the sequence number that increments with each retransmitted GOOSE message sent.
`TTL` (Time to Live)	This field contains the time (in ms) before the next message is expected.
`Code`	When appropriate, this text field contains warning or error condition text that is abbreviated as follows:

Code Abbreviation	Explanation
OUT OF SEQUENC	Out of sequence error
CONF REV MISMA	Configuration Revision mismatch
NEED COMMISSIO	Needs Commissioning
TEST MODE	Test Mode
MSG CORRUPTED	Message Corrupted
TTL EXPIRED	Time to live expired

Information Field	Description
`Transmit Data Set Reference`	This field represents the DataSetReference (Data Set Reference) that includes the IED name, LN0 lnClass (Logical Node Class), and GSEControl datSet (Data Set Name) (e.g., SEL_651R_1CFG/LLN0$DSet13).

Information Field	Description
Receive Data Set Reference	This field represents the datSetRef (Data Set Reference) that includes the iedName (IED name), ldInst (Logical Device Instance), LN0 lnClass (Logical Node Class), and datSet (Data Set Name) (e.g., SEL_651R_1CFG/LLN0$DSet13).
Ctrl Ref/ ControlBlockReference	This is the GOOSE control block reference. It is a concatenation of the logical device name, LLN0 (logical node containing the control block), GO (functional constraint), and the GSEControl name. (e.g., SEL_651R_1CFG/LLN0GOGooseDSet13)
AppID	This is the application identifier as a decimal number.
From	This is the date and time the current statistics collection started.
To	This is the date and time the GOOSE statistics command was executed.
Accumulated downtime duration	This represents the total amount of time a subscription was in an error state. The duration is displayed in the format: hhhh:mm:ss.zzz.
Maximum downtime duration	This represents the maximum amount of time a subscription was continuously in error state. The duration is displayed in the format: hhhh:mm:ss.zzz.
Date & time maximum downtime began	This is the date and time the recorded maximum downtime started.
Number of messages received out-of-sequence (OOS)	This represents the total number of messages received with either the state number and/or sequence number out-of-sequence. This includes cases where more than one instance of a message is received within a single relay processing interval. In this case, the most recent message is processed and the others are discarded.
Number of time-to-live (TTL) violations detected	This represents the total number of times a message was not received within the expected period/interval.
Number of messages incorrectly encoded or corrupted	This represents the total number of messages that were identified with this subscription but were either incorrectly encoded or encoded with a wrong dataset.
Number of messages lost due to receive overflow	This represents the total number of messages that were not processed because memory resources were exhausted. This includes cases where more than one instance of a message is received within a single relay processing interval. In this case, the most recent message is processed and the others are discarded.
Calculated max. sequential messages lost due to OOS	This represents the maximum estimated number of messages that were missed after receiving a message with a higher state or sequence number than expected.
Calculated number of messages lost due to OOS	This represents the total of all estimated number of messages lost as a result of state or sequence number skip in received messages.

An example response to the GOOSE commands is shown in *Figure 10.9*.

Figure 10.9   GOOSE Command Response

GRO Command (Display Active Settings Group Number)

Use the **GRO** command to display the active settings group number. The **GRO** *n* command changes the active settings group to Settings Group *n*.

Command	Description	Access Level
GRO	Display active group number.	1
GRO *n*	Change the active group to Group *n* (*n* = 1–8).	B

See *Multiple Settings Groups on page 7.23* for further details on settings groups.

To change to Settings Group 2, enter the following:

```
==>GRO 2 <Enter>
Change to Group 2
Are you sure (Y/N) ? Y <Enter>
Active Group = 2
==>
```

The relay switches to Group 2 and pulses the **ALARM** contact. If the serial port AUTO setting = Y, the relay sends the group switch report:

```
==>
FEEDER 1                        Date: 02/02/09   Time: 09:40:34.611
STATION A

Active Group = 2
==>
```

If any of the SELOGIC control equations settings SS1–SS8 are asserted to logical 1, the active settings group may not be changed with the **GRO** command—SELOGIC control equations settings SS1–SS6 have priority over the **GRO** command in active settings group control.

10.54 Communications
Command Explanations

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 636 of 1080
Wolfe

For example, assume Settings Group 1 is the active settings group and the SS1 setting is asserted to logical 1 (e.g., SS1 = IN101 and optoisolated input IN101 is asserted). An attempt to change to Settings Group 2 with the **GRO 2** command will not be accepted:

```
==>GRO 2 <Enter>
No group change (see manual)
Active Group = 1
==>
```

For more information on settings group selection, see *Multiple Settings Groups on page 7.23*.

HIS Command (Event Summaries/History)

HIS displays event summaries or allows you to clear event summaries (and corresponding event reports) from nonvolatile memory. See *Event History (HIS) on page 12.10*.

Command	Description	Access Level
HIS	Display event histories with the oldest at the bottom of the list and the most recent at the top of the list.	1
HIS *n*	Display event histories with the oldest at the bottom of the list and the most recent at the top of the list beginning at event *n*.	1
HIS E	Same as HIS, but events are identified with a unique number in the range 10000–65535.	1
HIS C	Clear/reset the event history and all corresponding event reports from nonvolatile memory.	1

HIS HIF Command (HIF Event Summaries/History; Only Available in Relays That Support Arc Sense Technology)

HIS HIF displays high-impedance fault (HIF) summaries or allows you to clear HIF event summaries (and corresponding event reports) from nonvolatile memory. See *HIF Event History on page 12.51*.

Command	Description	Access Level
HIS HIF	Display HIF event histories with the oldest at the bottom of the list and the most recent at the top of the list.	1
HIS HIF *n*	Display *n* HIF event histories with the oldest at the bottom of the list and the most recent at the top of the list.	1
HIS HIF C	Clear/reset the HIF event history and all corresponding event reports from nonvolatile memory.	1

HIZ Command

HIZ displays the ground overcurrent, high-impedance (50G HIZ) event reports or allows you to clear the HIZ event reports from nonvolatile memory. See *50G High-Impedance (HIZ) Fault Detection on page 4.116*.

Command	Description	Access Level
HIZ	Display HIZ event reports with the oldest at the bottom of the list and the most recent at the top of the list.	1
HIZ *n*	Display *n* HIZ event reports with the oldest at the bottom of the list and the most recent at the top of the list.	1
HIZ C	Clear/reset the HIZ event reports from nonvolatile memory.	1

Page 637 of 1080
Command Explanation
Wolfe

ID Command

Use the **ID** command to extract device identification codes (see *Appendix I: Configuration, Fast Meter, and Fast Operate Commands*).

Command	Description	Access Level
ID	Display the firmware id, user id, device code, part number, and configuration information.	0

INI HIF Command (Only Available In Relays That Support Arc Sense Technology)

Use the **INI HIF** command to force the high-impedance fault detection algorithm into initial tuning mode. See *High-Impedance Fault Detection (Arc Sense Technology) on page 4.111* for details.

Command	Description	Access Level
INI HIF	Force HIF algorithm into initial tuning mode.	2

L_D Command (Load Firmware)

Use the **L_D** command to load firmware. See *Appendix A: Firmware and Manual Versions* for information on changes to the firmware and instruction manual. See *Appendix B: Firmware Upgrade Instructions* for further details on downloading firmware.

Command	Description	Access Level
L_D	Prepare the relay to receive new firmware.	2

LDP Command (Load Profile Report)

Use the **LDP** command to view the Load Profile report. For more information on Load Profile reports, see *Section 8: Metering and Monitoring*.

Command	Description	Access Level
LDP	Display a numeric progression of all load profile report rows.	1
LDP *row1 row2* **LDP** *date1 date2*	Display a chronological or reverse chronological subset of the load profile rows.	1
LDP D	Display the number of days of Load Profile memory capacity remaining before data overwrite occurs.	1
LDP C	Clear the Load Profile data from memory.	1

LOG HIF Command (Only Available In Relays That Support Arc Sense Technology)

The **LOG HIF** command displays the instantaneous high-impedance alarm and fault detection values as a percentage of their final pickup value and the state of Relay Word bits, HIA2_A, HIA2_B, HIA2_C, HIF2_A, HIF2_B, and HIF2_C. The HI2 column indicates the state of the alarm and fault bits for the A, B, and C phases. The A-phase bits are represented by the left row, the B-phase bits are represented by the middle row, and the C-phase bits are represented by the right row. The command can display as many as 500 entries. If a high-impedance fault detecting bit (HIF2_A, HIF2_B, HIF2_C, HIA2_A, HIA2_B, or HIA2_C) is asserted, a new entry is logged in the **LOG HIF** command every one second. An entry is also logged if the percentage of detection changes by more than 10 percent.

Command	Description	Access Level
LOG HIF	Display the HIF alarm and fault calculations as a percentage of their value.	1
LOG HIF *n*	Display the *n* most recent LOG HIF entries.	1
LOG HIF C	Clear the LOG HIF data from memory.	1

LOO Command (Loop Back)

The **LOO** (LOOP) command is used for testing the MIRRORED BITS communications channel. For more information on MIRRORED BITS, see *Appendix D: MIRRORED BITS Communications*.

Command	Description	Access Level
LOO *c t*	Set MIRRORED BITS Channel *c* (*c* = A or B) to loopback for duration *t* minutes (*t* = 1–5000; default is 5). The received MIRRORED BITS elements are forced to default values during the loopback test.	2
LOO *c t* **DATA**	Set MIRRORED BITS Channel *c* to loopback for duration *t* minutes. **DATA** allows the received MIRRORED BITS elements to change during the loopback test.	2
LOO *c* **R**	Cease loopback on MIRRORED BITS communications Channel *c*. Reset the channel to normal use.	2

Parameter	Description
c	Append this parameter (*c* = A or B) to specify which channel to use if more than one MIRRORED BITS communications channel is enabled.
t	Append this parameter to specify the time-out period in *t* minutes (*t* = 1–5000; if not specified, default is 5).

With the transmitter of the communications channel physically looped back to the receiver, the MIRRORED BITS addressing will be wrong and ROK will deassert. The **LOO** command tells the MIRRORED BITS software to temporarily expect to see its own data looped back as its input. In this mode, LBOK will assert if error-free data are received. The **LOO** command with just the channel specifier enables looped back mode on that channel for five minutes, while the inputs are forced to the default values.

MAC Command

The **MAC** command returns the Media Access Control (MAC) address of the Ethernet port. If IEC 61850 GOOSE messaging is enabled, an additional GOOSE MAC address is also displayed.

Command	Description	Access Level
MAC	Display Ethernet port MAC address	1

```
=>MAC <Enter>

Port 5 MAC Address: 00-30-A7-00-00-00
```

MET Command (Metering Data)

The **MET** commands provide access to recloser control metering data. Metered quantities include phase voltages and currents, sequence component voltages and currents, power, frequency, energy, demand, and maximum/minimum logging of selected quantities. To make the extensive amount of meter information manageable, the recloser control divides the displayed information into seven groups:

➤ Fundamental

➤ Demand

➤ Energy

➤ THD/Harmonics

➤ Maximum/Minimum

➤ RMS

➤ High-Impedance Fault (HIF)

Metering data retrieval and display are described in the following subsections. See *Section 8: Metering and Monitoring* for details on metering.

MET (Fundamental Metering)

Use the **MET** command to display fundamental metering data.

Command	Description	Access Level
MET *k*	Display instantaneous metering data *k* times.	1

The **MET** *k* command displays instantaneous magnitudes, and angles if applicable, of the following quantities:

NOTE: See Ground Switch Option on page 8.3 for details on the IG quantity used in the SEL-651R-2 metering functions.

Currents	IA,B,C,N	Input currents (A primary)
	IG	Ground current (A primary; $I_G = 3I_0 = I_A + I_B + I_C$ when Relay Word bit GNDSW = 0; I_G = IN when GNDSW = 1)
Voltages	VAY, VBY, VCY, VAZ, VBZ, VCZ	Phase-to-neutral voltages (kV primary)
	VABY, VBCY, VCAY, VABZ, VBCZ, VCAZ	Calculated phase-to-phase voltages (kV primary)

Page 640 of 1080
Wolfe

	Vbase	Demand average value based on V_1, (subject to the operating logic of the *Voltage Sag, Swell, and Interruption Elements on page 4.59*) when setting ESSI :=Y in the active settings group. Vbase registers a value only after valid three-phase voltage signals have been present since the last Vbase initialization.
Power	MVAA,B,C	Single-phase MVA
	MVA3P	Three-phase MVA
	MWA,B,C	Single-phase megawatts
	MW3P	Three-phase megawatts
	MVARA,B,C	Single-phase megavars
	MVAR3P	Three-phase megavars
Power Factor	PFA,B,C	Single-phase power factor; leading or lagging
	PF3P	Three-phase power factor; leading or lagging
Sequence	I1, 3I2, 3I0	Positive-, negative-, and zero-sequence currents (A primary)
	V1Y, V2Y, V1Z, V2Z	Positive- and negative-sequence voltages (kV primary)
	3V0Y, 3V0Z	Zero-sequence voltage (kV primary)
Frequency	FREQ (Hz)	Instantaneous power system frequency (measured on Y voltage terminal or Z voltage terminal—see *Table 8.1*).

NOTE: Three-phase MVA (MVA3P) is the arithmetic sum of the single-phase measurements MVAA, MVAB, and MVAC. Three-phase power factor (PF3P) is calculated with MW3P and MVAR3P (not MVA3P).

The recloser control references metering angles to voltage VAY or VAZ (according to Global setting VSELECT), if the reference voltage is greater than 13 V secondary; if VSELECT := OFF, angles are referenced to A-phase current. Angles range from –179.99 to 180.00 degrees.

To view instantaneous metering values, use the **MET *k*** command, where *k* is an optional parameter to specify the number of times (1–32767) to repeat the meter display. The recloser control displays the meter report once if *k* is not specified. Below is a sample of metering data from the SEL-651R-2.

```
=>MET <Enter>

MET D (Demand Metering)

Use the following commands to view or reset demand and peak demand metering values.

Command	Description	Access Level
MET D	Display demand and peak demand metering data.	1
MET RD	Reset demand metering data.	1
MET RP	Reset peak demand metering data.	1

The **MET D** command displays the demand and peak demand values of the following quantities:

Currents	IA,B,C,N	Input currents (A primary)
	IG	Ground current (A primary; $I_G = 3I_0 = I_A + I_B + I_C$ when Relay Word bit GNDSW = 0; I_G = IN when GNDSW = 1)
	3I2	Negative-sequence current (A primary)
Power	MVAA,B,C	Single-phase MVA
	MVA3P	Three-phase MVA
	MWA,B,C	Single-phase megawatts
	MW3P	Three-phase megawatts
	MVARA,B,C	Single-phase megavars
	MVAR3P	Three-phase megavars
Reset Time	Demand, Peak	Last reset times for the demands and peak demands

Below is a sample of demand metering data from the SEL-651R-2.

```
    =>MET D <Enter>

MET M (Maximum/Minimum Metering)

Use the following commands to view or reset maximum and minimum metering values.

Command	Description	Access Level
MET M	Display maximum and minimum metering data.	1
MET RM	Reset maximum and minimum metering data. All values will display RESET until new maximum/minimum values are recorded.	1

Maximum and minimum values include:

Currents	IA,B,C,N	Input currents (A primary)
	IG	Ground current (A primary; $IG = 3I0 = IA + IB + IC$ when Relay Word bit $GNDSW = 0$; $IG = IN$ when $GNDSW = 1$)
Voltages	VAY, VBY, VCY, VAZ, VBZ, VCZ	Voltages (kV primary)
Power	MW3P	Three-phase megawatts
	MVAR3P	Three-phase megavars
	MVA3P	Three-phase megavolt-amperes
Reset Time		Last maximum/minimum reset time

Below is a sample of maximum/minimum metering data from the SEL-651R-2:

```
=>MET M <Enter>

FEEDER 1                                  Date: 08/29/2003  Time: 08:00:00.000

For more information on recloser control maximum/minimum metering quantity calculations, see *Maximum/Minimum Metering on page 8.17*.

MET RMS (RMS Metering)

Use the **MET RMS** command to display rms (root-mean-square) quantities.

Command	Description	Access Level
MET RMS	Display root-mean-square (rms) metering data.	1

Below is a sample of rms metering data from the SEL-651R-2:

```
=>MET RMS <Enter>

FEEDER 1                            Date: 08/29/2003  Time: 08:00:00.000
STATION A                           Time Source: internal

```

MET PM (Synchrophasor Metering)

The **MET PM** command (available when TSOK = logical 1 and EPMU = Y) displays the synchrophasor measurements. For more information, see *View Synchrophasors by Using the MET PM Command on page J.17*.

Command	Description	Access Level
MET PM	Display synchrophasor measurements.	1
MET PM *k*	Display synchrophasor measurements *k* times.	1
MET PM *time*	Display synchrophasor measurements at specific time.	1
MET PM HIS	Display the most recent **MET PM** synchrophasor report.	1

Use the **MET PM** command to help with commissioning. The command:

```
=>MET PM time <Enter>
```

triggers a synchrophasor meter command at precisely the time specified. Parameter `time` must be in 24-hour format, e.g., 15:11:00.000. Compare magnitudes and phases of quantities displayed in response to the **MET PM** command to reports from other relays triggered at the same instant to verify correct phasing and polarity of current and voltage connections. To help facilitate comparing meter reports between several relays, the command:

```
=>MET PM HIS <Enter>
```

recalls the most recently triggered synchrophasor meter report. Values displayed reflect present relay settings, not settings in effect at the time of the original **MET PM** command.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 645 of 1080
Witness: Charles A. Wolfe

10.63
Communications
Command Explanations

For exploratory testing, the command:

```
=>MET PM k <Enter>
```

repeats the **MET PM** command *k* times. The trigger times of the *k* reports are not carefully controlled, but the trigger times are still accurately displayed in the reports.

The output from an SEL-651R-2 is shown:

```
=>MET PM <Enter>

FEEDER 1                                Date: 08/05/2011  Time: 14:38:27.000

```

OPE Command (Open Breaker)

Use the open command (**OPE**, **OPE A**, **OPE B**, or **OPE C**) to assert the specified Relay Word bit (OC3, OCA, OCB, or OCC) for 1/4 cycle.

Command	Description	Access Level
OPE	Momentarily assert the three-phase open Relay Word bit OC3.	B
OPE *n*	Assert a single-phase close Relay Word bit (**OPE A** asserts OCA, **OPE B** asserts OCB, **OPE C** asserts OCC).	B

Program the open command Relay Word bit into the trip control equation (TR3P, TRA, TRB, or TRC) to enable assertion of the trip Relay Word bit (TRIP3P, TRIPA, TRIPB, or TRIPC) with the open command. Program the trip Relay Word bit to enable assertion of an output contact (e.g., OUT201 := TRIP3P) to trip a recloser/circuit breaker. See *Section 5: Trip and Target Logic* for a detailed explanation of the trip logic.

To issue the **OPE** command, enter the following:

```
==>OPE <Enter>

Open Breaker (Y/N) ? Y <Enter>
Are you sure (Y/N) ? Y <Enter>
==>
```

Typing **N <Enter>** after either of the Y/N prompts aborts the command.

The main board breaker jumper supervises the **OPEN** command (see *Figure 2.48*). If the breaker jumper is not in place (breaker jumper is OFF), the recloser control does not perform the **OPEN** command and responds with the following:

```
Aborted: No Breaker Jumper
```

NOTE: Though the intention of serial port commands **OPE A**, **OPE B**, and **OPE C** is to provide tripping for separate recloser Poles A, B, and C, respectively, there is no direct connection. Rather, these commands receive their function by virtue of how their corresponding Relay Word bits OCA, OCB, and OCC are programmed, as inferred above.

Also, no settings have control over the **OPE** serial port commands or their resultant Relay Word bits. Thus, settings such as Global setting BKTYP (breaker type), though involved in structuring single-phase or three-phase logic, have no effect on the **OPE** serial port commands or their resultant Relay Word bits.

PAS Command
(Change Passwords)

The relay is shipped with factory-default passwords for Access Levels 1, B, 2, and C. These passwords are shown in *Table 10.20*.

Command	Description	Access Level
PAS *level*	Change the password for Access Level *level*.	2

Table 10.20   Factory-Default Passwords for Access Levels 1, B, 2, and C

Access Level	Factory-Default Password
1	OTTER
B	EDITH
2	TAIL
C	CLARKE

The **PAS** command allows you to change existing Level 1, B, and 2 passwords at Access Level 2 and allows you to change the Level C password from Level C. To change passwords, enter **PAS *x***, where *x* is the access level whose password is being changed. The relay will prompt for the old password, the new password, and a confirmation of the new password.

To change the password for Access Level 1, enter the following:

```
=>>PAS 1 <Enter>

Old Password: *********

New Password: ******
Confirm New Password: ******

Password Changed
=>>
```

The new password will not echo on the screen and passwords cannot be viewed from the device. When the password is changed for any access level the Relay Word bit CHGPASS will pulse for approximately one second. Record the new password in a safe place for future reference.

If the passwords are lost or you wish to operate the relay without password protection, put the main board Access jumper in place (Access jumper = ON). Refer to *Figure 2.48* for Access jumper information. With the Access jumper in place, issue the **PAS *x*** command at Access Level 2. The relay will prompt for a new password and a confirmation of the new password.

Passwords may include as many as 12 characters. See *Table 10.21* for valid characters. Upper- and lowercase letters are treated as different characters. Strong passwords consist of 12 characters, with at least one special character or digit and mixed-case sensitivity, but do not form a name, date, acronym, or word. Passwords formed in this manner are less susceptible to password guessing and automated attacks. Examples of valid, distinct strong passwords include:

➤ Ot3579A24.68

➤ Ih2d&s4u-Iwg

➤ .651r.Nt9g-t

Page 648 of 1080
Wolfe

Table 10.21 Valid Password Characters

Alpha	ABCDEFGHIJKLMNOPQRSTUVWXYZ abcdefghijklmnopqrstuvwxyz
Numeric	0123456789
Special	! " # $ % & ' ( ) * , - . / : ; < = > ? @ [\ ] ^ _ ` {	} ~

The relay shall issue a weak password warning if the new password does not include at least one special character, number, lowercase letter, and uppercase letter.

```
=>>PAS 1 <Enter>

Old Password: *********

New Password: ******
Confirm New Password: ******

Password Changed
=>>

CAUTION:  This password can be strengthened.  Strong passwords do not include a name,
    date, acronym, or word.  They consist of the maximum allowable characters, with
    at least one special character, number, lower-case letter, and upper-case
    letter.  A change in password is recommended.

=>>
```

PUL Command (Pulse Output Contact)

The **PUL** command allows you to pulse any of the output contacts for a specified length of time. The selected contact will close or open depending on the output contact type (a or b) (see *Output Contacts on page 7.34*).

Command	Description	Access Level
PUL *n s*	Pulse output *n* for *s* seconds. (*n* = output name; OUT201, OUT202 [all models]; OUT101–OUT108 [models with extra I/O]; *s* = 1–30 seconds)	B

To pulse **OUT101** for five seconds:

```
==>PUL OUT101 5 <Enter>
Are you sure (Y/N) ? Y <Enter>
==>
```

If the response to the `Are you sure (Y/N) ?` prompt is **N** or **n**, the command is aborted.

The **PUL** command is supervised by the main board Breaker Control jumper (see *Figure 2.48*). If the Breaker Control jumper is not in place (OFF), the relay does not execute the **PUL** command and responds:

```
Aborted:  No Breaker Jumper
```

The relay generates an event report if any of the output contacts are pulsed. The **PUL** command is primarily used for testing purposes.

QUI Command (Quit Access Level)

The **QUI** command returns the relay to Access Level 0.

Command	Description	Access Level
QUI	Go to Access Level 0.	0

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Communications 10.67
Page 649 of 1080
Command Explanations
Wolfe

To return to Access Level 0, enter the command:

```
=>QUI <Enter>
```

The relay sets the port access level to 0 and responds:

```
FEEDER 1                          Date: 02/02/09 Time: 08:55:33.986
STATION A

=
```

The = prompt indicates the relay is back in Access Level 0.

R_S Command (Restore Factory Defaults)

Use the **R_S** command to restore factory-default settings.

Command	Description	Access Level
R_S	Restore the factory-default settings and passwords and reboot the system.[a]	2

[a] Only available after a settings or critical RAM failure.

SER Command (Sequential Events Recorder Report)

Use the **SER** command to view the Sequential Events Recorder report. For more information on SER reports (see *Section 12: Analyzing Events*).

Command	Description	Access Level
SER	Display a chronological progression of all available SER rows (as many as 1024 rows). Row 1 is the most recently triggered row and row 1024 is the oldest.	1
SER *n* **SER** *row1 row2* **SER** *date1* **SER** *date1 date2*	Display a chronological or reverse chronological subset of the SER rows.	
SER C	Clear/reset the SER records.	1

SET Command (Change Settings)

The **SET** command allows the user to view or change the relay settings (see *Table 9.2*).

Command	Description	Access Level
SET *n*	Change Group *n* settings, beginning at the first setting in each instance (*n* = 1–8; if not specified, default is the active settings group).	2
SET D *n*	Change DNP Map *n* settings (*n* = 1, 2, or 3).	2
SET F	Change Front-Panel settings.	2
SET G	Change Global settings.	2
SET L *n*	Change Logic settings for Settings Group *n* (*n* = 1–8; if not specified, default is the active settings group).	2
SET M	Change Modbus settings.	2
SET P *p*	Change Port settings for Serial Port *p* (*p* = 1, 2, 3, F, or 5; if not specified, default is the active port).	2
SET R	Change Report settings.	2

Command Explanations

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 650 of 1080
Wolfe

Command	Description	Access Level
SET … *name*	For all **SET** commands, jump ahead to specific setting by entering setting *name*.	2
SET … TERSE	For all **SET** commands, the **TERSE** command disables the automatic **SHO** command after settings entry.	2

SHO Command (Show/View Settings)

Use the **SHO** command to view relay settings, SELOGIC control equations, Global settings, Serial Port settings, Sequential Events Recorder (SER) settings, and Text Label settings.

Command	Description	Access Level
SHO *n*	Show Group *n* settings (*n* = 1–8; if not specified, default is the active settings group).	1
SHO D *n*	Show DNP Map *n* settings (*n* = 1, 2, or 3).	1
SHO F	Show Front-Panel settings.	1
SHO G	Show Global settings.	1
SHO L *n*	Show Logic settings for Settings Group *n* (*n* = 1–8; if not specified, default is the active settings group).	1
SHO M	Show Modbus settings.	1
SHO P *p*	Show Port settings for Serial Port *p* (*p* = 1, 2, 3, F, or 5; if not specified, default is the active port).	1
SHO R	Show Report settings.	1
SHO … *name*	For all **SHO** commands, jump ahead to specific setting by entering setting *name*.	

You may append a setting name to each of the commands to specify the first setting to display (e.g., **SHO 1 E50P** displays the setting Group 1 relay settings starting with setting E50P). The default is the first setting.

The **SHO** commands display only the enabled settings. To display all settings, including disabled/hidden settings, append an **A** to the **SHO** command (e.g., **SHO 1 A**).

See *Figure 9.30–Figure 9.39* for example **SHO** command responses for the SEL-651R-2 with factory-default settings.

SNS Command

Use the **SNS** command to view the name string of the SER (SER1, SER2, SER3, and SER4) settings (see *Appendix I: Configuration, Fast Meter, and Fast Operate Commands*).

Command	Description	Access Level
SNS	Display the name string of the SER settings.	0

SSI Command (Voltage Sag/Swell/Interruption Report)

View and manage voltage SSI data with the **SSI** commands. See *Sag/Swell/Interruption (SSI) Report on page 12.42* for further details on the SSI report, and *Voltage Sag, Swell, and Interruption Elements on page 4.59* for details on the VSSI elements and Vbase value.

Command	Description	Access Level
SSI *n* **SSI** *row1 row2* **SSI** *date1* **SSI** *date1 date2*	Display a chronological progression of all SSI report rows. Use the **SSI** command with parameters to display a chronological or reverse chronological subset of the SSI report rows.	1
SSI T	Manually trigger the VSSI recorder.	1
SSI C	Clear the SSI report from nonvolatile memory.	1
SSI R	Reset the VSSI recorder logic and clear the Vbase value.	1

Parameter	Description
n	Append *n* to return latest n rows in SSI report (n = 1 to several thousand, where 1 is the most recent entry).
row1 row2	Append *row1* and *row2* to return all rows between *row1* and *row2*, beginning with *row1* and ending with *row2*. Enter the smaller number first to display a numeric progression of rows through the report. Enter the larger number first to display a reverse numeric progression of rows.
date1 *date1 date2*	Append *date1* to return all rows with this date. Append *date1* and *date2* to return all rows between *date1* and *date 2* beginning with *date1* and ending with *date2*. Enter the oldest date first to display a chronological progression through the report. Enter the newest date first to display a reverse chronological progression. Date entries are dependent on the date format setting DATE_F.

Viewing the SSI Report

The recorded voltage SSI data can be viewed from any settings group, even if setting ESSI := N. Row 1 is the most recently triggered row. View the SSI report by date or by SSI row number.

See *Figure 12.12* for an example SSI report.

If the requested SSI event report rows do not exist, the recloser control responds with the following:

```
No Voltage Sag/Swell/Interruption Data
```

Clearing the SSI Report

Clear the SSI report from nonvolatile memory with the **SSI C** command, as shown in the following example:

```
=>SSI C <Enter>
Clear the Voltage/Sag/Swell Interruption buffer
Are you sure (Y/N)? Y <Enter>
Clearing Complete
```

The **SSI C** command is available in any settings group and on any serial port.

10.70 | Communications
Command Explanations

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 652 of 1080
Wolfe

If the **SSI C** command is issued on one serial port while another serial port is being used to display an SSI report, the clearing action will terminate the SSI report retrieval.

Triggering the SSI Recorder

Manually trigger the voltage SSI Recorder by using the **SSI T** command. The **SSI T** command is available only if Group setting ESSI := Y in the active settings group.

If an **SSI T** command is issued when setting ESSI := N, the recloser control responds as follows:

```
Command is not available
```

If an **SSI T** command is issued before Vbase has initialized, the recloser control responds as follows:

```
Did Not Trigger
```

See *Vbase Initialization on page 4.62* for details on the initializing conditions.

Resetting the SSI Recorder Logic

After the recloser control detects satisfactory voltage signals for at least 12 seconds, the SSI Recorder is armed and a Ready entry is written to the SSI archive.

The **SSI R** command is available only if Group setting ESSI := Y in the active settings group. Attempting the **SSI R** command when ESSI := N will display the following:

```
Command is not available
```

See *Positive-Sequence Reference Voltage, Vbase on page 4.61* for more details.

STA Command (Relay Self-Test Status)

The **STA** command displays the status report, showing the relay self-test information.

Command	Description	Access Level
STA k	Display the recloser control self-test information k times (k = 1–32767; if not specified, default is 1).	1
STA S	Display the memory and execution utilization for the SELOGIC control equations.	1
STA C	Reboot the recloser control and clear self-test warning and failure status results.	2

STA Command Row and Column Definitions

Serial Number	Recloser Control Serial Number.
FID	Firmware identifier string containing the module firmware revision number.
CID	Firmware checksum identifier.
Channel Offsets	Display measured dc offset voltages in millivolts for the current and voltage channels. The MOF (master) status is the dc offset in the A/D circuit when a grounded input is selected.
Power Supply Voltages	Display power supply voltages in Vdc for the power supply outputs.
Temperature	Displays the internal module temperature in degrees Celsius.
Integrated Circuit and Board Status	RAM, ROM, CR_RAM, FLASH, FPGA—These tests verify the SEL-651R-2 memory components. The columns display OK if memory is functioning properly; the columns display FAIL if the memory area has failed. A/D—Analog to Digital convert status. INT_BRD—Interface board status. USB_BRD—USB board port status, if supplied. COM_BRD—Dual copper, and dual or single fiber-optic Ethernet ports status, if supplied.

10.72 Communications
Command Explanations

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 654 of 1080
Wolfe

Mains, Battery Monitor, and Capacitor Monitor	INPBV	DC POWER IN voltage (see *Figure 2.9*)
	12VAUX	AUXILIARY POWER SUPPLY (see *Figure 2.9*)
	CMODE	Battery charger mode:

		STARTUP	Startup
		CUR_CHG	Constant current charge
		FST_CHG	Fast charge
		FLT_CHG	Float charge
		DISCHRG	Discharge
		BAT_FLR	Battery failure
		BAT_TST	Battery discharge test

	VBAT	BATTERY voltage (see *Figure 2.9*)
	IBAT	BATTERY current in mA dc (see *Figure 2.9*). If the battery is discharging, a minus sign precedes the current value.
	TCCAPV	CAPACITORS voltage (see *Figure 2.9*)

Note: W (Warning) or F (Failure) is appended to the values to indicate an out-of-tolerance condition.

The relay latches all self-test warnings and failures to capture transient out-of-tolerance conditions. To reset the self-test statuses, use the **STA C** command from Access Level 2:

```
=>>STA C <Enter>
```

The relay responds:

```
Reboot the relay and clear status
Are you sure (Y/N) ?
```

If you select "N" or "n", the relay displays the following and aborts the command:

```
Canceled
```

If you select "Y", the relay displays:

```
Rebooting the relay
```

The relay then restarts (just like powering down, then powering up relay) and all diagnostics are re-run before the relay is enabled.

Refer to *Table 13.2* for self-test thresholds and corrective actions.

SUM HIF Command (Only Available in Relays That Support Arc Sense Technology)

The **SUM HIF** command displays a long summary of an HIF event report. The long summary contains more information than is available from the **HIS HIF** command, but it is shorter than the full HIF event report. A sample report is shown below. *HIF Event Summary on page 12.48* describes the various fields of information available in the HIF summary event report.

Command	Description	Access Level
SUM HIF *n*	Displays the HIF summary event report *n*, where *n* is the unique event number from the HIS HIF report in the range 10000 to 65535. SUM HIF with no *n* displays the most recent HIF summary event report.	1

```
=>>SUM HIF <Enter>

Attachment to Response to AG-2 Question No. 68(g)
Page 656 of 1080
Wolfe

TAR Command (Display Relay Element Status)

The **TAR** command displays the status of front-panel target LEDs or relay elements, whether they are asserted or deasserted.

Command	Description	Access Level
TAR	Display Relay Word row 0 or last displayed target row.	1
TAR name k	Display the Relay Word row containing *name*. Enter *k* for repeat count (*k* = 1–32767; if not specified, default is 1).	1
TAR n k	Display Relay Word row number *n*. Enter *k* for repeat count (*k* = 1–32767; if not specified, default is 1).	1
TAR LIST	Display all target rows. If ROW is specified, the relay includes the target row number on each line.	1
TAR R	Clears front-panel tripping targets. Shows Relay Word Row 0.	1
TAR ROW …	Shows the Relay Word row number at the start of each line, with other selected **TAR** commands as described above, such as **n**, **name**, **k**, and **LIST**.	1

The target row elements are listed in rows of eight. The first four rows (0, 1, 2, and 3) correspond to the relay front-panel target LEDs shown in *Table 10.22*. The target row elements are asserted when the corresponding front-panel target LED is illuminated.

The remaining target rows (4–135) correspond to the Relay Word as described in *Table F.1* and *Table F.2*. A Relay Word bit is either at a logical 1 (asserted) or a logical 0 (deasserted). Relay Word bits are used in SELOGIC control equations (see *Relay Word Bits on page 7.2*).

The **TAR** command does not remap the front-panel target LEDs, as is done in some previous SEL relays.

The **TAR** command options are:

TAR n k
or
TAR ROW n k

Shows Relay Word row number *n* (0–135). *k* is an optional parameter to specify the number of times (1–32767) to repeat the Relay Word row display. If *k* is not specified, the Relay Word row is displayed once. Adding **ROW** to the command displays the Relay Word Row number at the start of each line.

TAR name k
or
TAR ROW name k

Shows Relay Word row containing Relay Word bit name (e.g., TAR 50C1 displays Relay Word Row 4). Valid names are shown in *Table 10.22*, *Table F.1*, and *Table F.2*. The value *k* is an optional parameter to specify the number of times (1–32767) to repeat the Relay Word row display. If *k* is not specified, the Relay Word row is displayed once. Adding **ROW** to the command displays the Relay Word Row number at the start of each line.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 657 of 1080
Communications 10.75
Command Explanations
Wolfe

TAR LIST or **TAR ROW LIST**	Shows all the Relay Word bits in all of the rows. Adding **ROW** to the command displays the Relay Word Row number at the start of each line.	

NOTE: The **TAR R** command cannot reset the latched Targets if a TRIP condition is present.

TAR R — Clears front-panel tripping target LEDs **TRIP, A FAULT, B FAULT, C FAULT, GROUND, SEF, FAST CURVE, DELAY CURVE, HIGH CURRENT, OVER/UNDER FREQUENCY,** and **OVER/UNDER VOLTAGE.** Unlatches the trip logic for testing purposes (see *Figure 5.1*). Shows Relay Word Row 0.

Table 10.22 Front-Panel Targets and the TAR Command

TAR 0 (Front-Panel LEDs)	EN	TRIPLED	*	*	*	*	*	*
TAR 1 (Front-Panel LEDs)	TLED_08	TLED_07	TLED_06	TLED_05	TLED_04	TLED_03	TLED_02	TLED_01
TAR 2 (Front-Panel LEDs)	TLED_16	TLED_15	TLED_14	TLED_13	TLED_12	TLED_11	TLED_10	TLED_09
TAR 3 (Front-Panel LEDs)	TLED_24	TLED_23	TLED_22	TLED_21	TLED_20	TLED_19	TLED_18	TLED_17

Command **TAR SH13P 10** is executed in the following example:

```
=>TAR SH13P 10 <Enter>

79RS3P    79CY3P    79LO3P    SH03P     SH13P     SH23P     SH33P     SH43P
0         0         1         0         0         0         1         0
0         0         1         0         0         0         1         0
0         0         1         0         0         0         1         0
0         0         1         0         0         0         1         0
0         0         1         0         0         0         1         0
0         0         1         0         0         0         1         0
0         0         1         0         0         0         1         0
0         0         1         0         0         0         1         0

79RS3P    79CY3P    79LO3P    SH03P     SH13P     SH23P     SH33P     SH43P
0         0         1         0         0         0         1         0
0         0         1         0         0         0         1         0

=>
```

Note that the Relay Word row containing the SH13P bit is repeated 10 times. In this example, the reclosing relay is in the Lockout State (79LO3P = logical 1) and the shot is at shot = 3 (SH33P = logical 1). Command **TAR 64** will report the same data because the SH33P bit is in Row 64 of the Relay Word.

=>
```

TEST DB Command

Use the **TEST DB** command to temporarily force the relay to send fixed analog and/or digital values over communications interfaces for protocol testing.

Command	Description	Access Level
TES DB	Display the present status of digital and analog overrides.	B
TES DB A *name value*	Override analog label *name* with *value* in communications interface.	B
TES DB A *row_x value*	Override all Relay Word bits in Relay Word row number *row_x* with *value*.	B
TES DB D *name value*	Override Relay Word bit *name* with *value* (Modbus, DNP, and IEC 61850 only).	B
TES DB *name* **OFF**	Clear (analog or digital) override for element *name*.	B
TES DB OFF	Clear all analog and digital overrides.	B

The **TEST DB** command provides a method to override Relay Word bits or analog values to aid testing of communications interfaces. The command overrides values in the communications interfaces (SEL Fast Message, DNP, Modbus, and IEC 61850) only. The actual values used by the relay for protection and control are not changed. However, remote devices may use these analog and digital signals to make control decisions. Ensure that remote devices are properly configured to receive the overridden data before using the **TEST DB** command.

To override analog data in a communications interface, enter the following from Access Level B or higher:

```
=>>TEST DB A name value <Enter>
```

where *value* is a numerical value and *name* is an analog label from *Table G.1*, Analog Quantities, with an "x" in the DNP, Modbus, Fast Meter, or IEC 61850 column.

AVOID FALSE OPERATIONS
To reduce the chance of a false operating decision when using the **TEST DB** command, ensure that protocol master device(s) flag the data as "forced or test data." One possible method is to monitor the TESTDB Relay Word bit.

NOTE: When using the **TEST DB** command to generate values for Fast Meter testing, you may need to override all current and voltage angles (IAFA, VAYFA, etc.) to ensure the expected phase relationship.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 659 of 1080
Communications | 10.77
Command Explanations
Wolfe

For example, the **TEST DB** command can be used to force the value of Phase A current magnitude transmitted to a remote device to 100 A:

```
=>>TES DB A IA 100 <Enter>
```

To override digital data in a Modbus, DNP, or IEC 61850 communications interface, enter the following from Access Level B or higher:

```
=>>TES DB D name value <Enter>
```

where *name* is a Relay Word bit (see *Table F.1*) and *value* is 1 or 0.

For example, if Relay Word bit 51PT = logical 0, the **TEST DB** command can be used to effectively force the communicated status of this Relay Word bit to logical 1 to test the communications interface:

```
=>>TES DB D 51PT 1 <Enter>
```

Values listed in the SER triggers SER1, SER2, SER3, and SER4 cannot be overridden.

To override digital data in a Modbus, DNP, SEL Fast Messaging, or IEC 61850 communications interface, enter the following from Access Level B or higher:

```
=>>TES DB A Row_x value <Enter>
```

where *Row_x* is a Relay Word row number (see *Table F.1*) and *value* is 1 to 255 (the integer sum of the individual Relay Word bits to be set).

For example, Relay Word bits 51PR and 51PT are bits 2 and 0, respectively, of Relay Word Row 11. The **TEST DB** command can be used to effectively force the communicated status of these Relay Word bits to logical 1 to test the communications interface:

```
=>>TES DB A Row_11 5 <Enter>
```

where the value of 5 is the integer value to set bits 2 and 0 of the Relay Word row ($2^2 + 2^0 = 5$).

Values listed in the SER triggers SER1, SER2, SER3, and SER4 cannot be overridden.

When the relay is not in Test Mode, the relay responds to either the digital or analog override request with the following message:

```
WARNING:  TEST MODE is not a regular operation.
Communication outputs of the device will be overridden by simulated values.

Are you sure (Y/N)? Y <Enter>
```

The relay responds:

```
Test Mode Active.  Use Test DB OFF command to exit Test Mode.
Override Added
```

10.78 | Communications
Command Explanations

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 660 of 1080
Wolfe

Relay Word bit TESTDB will also assert to indicate that Test Mode is active. If the relay is already in the test mode (overrides are already active), the relay responds:

```
Override Added
```

The **TEST DB** command alone displays the present status of digital and analog overrides. An example **TEST DB** response after two analogs follows:

```
==>TES DB <Enter>

FEEDER 1                        Date: 02/02/09 Time: 16:24:38.764
STATION A                       Time Source:  internal

NAME          OVERRIDE VALUE
IA              100.0000
FREQ             60.0000

==>
```

Individual overrides are cleared by using the **TEST DB** command with the OFF parameter:

```
=>>TES DB D or A name OFF <Enter>
```

Entering **TEST DB OFF** without name will clear all overrides. The relay will automatically exit the Test Mode and clear all overrides if there are no **TEST DB** commands entered for 30 minutes.

TIM Command (View/ Change Time)

TIM displays the relay clock. If a valid IRIG-B or SNTP time synchronization signal is connected to the relay, the **TIM** command cannot be used to set the relay time. See *Configuring High-Accuracy Timekeeping on page J.21* for more details on IRIG time sources.

Command	Description	Access Level
TIM	Display the present internal clock time.	1
TIM *hh:mm*	Set the internal clock to *hh:mm*.	1
TIM *hh:mm:ss*	Set the internal clock to *hh:mm:ss*.	1
TIM Q	Display time statistics.	1
TIM DST	Display daylight-saving time information.	1

NOTE: After setting the time, allow at least 60 seconds before powering down the relay or the new setting may be lost.

Separate the hours, minutes, and seconds with colons, semicolons, spaces, commas, or slashes. To set the clock to 23:30:00, enter:

```
=>TIM 23:30:00 <Enter>
23:30:00
=>
```

If **TIM** is entered with the Q parameter, time statistics are displayed.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 661 of 1080

Command Explanations
Wolfe

```
=>TIM Q <Enter>

PTR 10000                          Date: 04/27/2012  Time: 12:52:29.272
651R-2                             Time Source: external

FID=SEL-651R-2-Rxxx-Vx-Zxxxxxx-Dxxxxxxxx   CID=4629

UTC: 19:52:29
UTC Offset: -7.00 hrs

Time Source: HIRIG
Last Update Source: HIRIG
Active IRIG Port: BNC

Last Update Time: 19:52:29  04/27/2012

IRIG Time Quality: 0.001 ms

Internal Clock Period: 20.000172 ns
=>
```

Time Source is HIRIG when Relay Word bit TSOK is asserted. Otherwise, Time Source is OTHER. Last Update Source indicates the source of the last time or date update. Valid update sources are HIRIG, IRIG, DNP, MODBUS, SNTP, ASCII DATE, ASCII TIME, FRONT PANEL DATE, and FRONT PANEL TIME. If the relay time was last updated from the battery-backed clock, such as after a loss of power, Last Update Source is NONV CLK.

When at least one source of IRIG-B time signal is connected, Active IRIG Port displays which source is in use (BNC or Port 2).

If setting IRIGC = C37.118 and TIRIG or TSOK is asserted, IRIG Time Quality displays the time error calculated based on information contained in the control fields of the IRIG-B signal (see *Configuring High-Accuracy Timekeeping on page J.21*).

The internal clock period shows the time associated with the processor clock. This time may change slightly when an IRIG signal is connected.

If **TIM** is entered with the DST parameter and daylight-saving time is enabled (see *Automatic Daylight-Saving Time Settings (Global Settings) on page 9.39*), daylight-saving time information is displayed.

```
=>TIM DST <Enter>

12:51:46

Daylight Saving Time Begin Rule: 2nd Sunday of March at 02:00
Daylight Saving Time End Rule:   1st Sunday of November at 02:00

```

TRI Command (Trigger Event Report)

Command	Description	Access Level
TRI	Trigger an event report data capture.	1
TRI *time*	Trigger an event report data capture at specified *time*.	1
TRI STA	Display the status of a previous **TRI** *time* command.	1

10.80 | Communications
Command Explanations

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 662 of 1080
Wolfe

Issue the **TRI** command to generate an event report:

```
=>TRI <Enter>
Triggered
=>
```

Use the optional *time* parameter to specify the exact time to trigger an event. If *time* is not specified, the event is triggered at the current time. The *time* should be input in 24-hour format (i.e., 15:11:00). If fractional seconds are input, they will be ignored.

```
=>TRI 16:00:00 <Enter>
An event will trigger at 16:00:00
=>
```

Only one **TRI** *time* command may be pending on a single port at any one time. If a **TRI** *time* command is entered while another command is pending, the old request will be canceled and the new request will be pending. **TRI** commands entered without the time parameter will not affect any pending **TRI** *time* commands.

A **TRI STA** command may be used if a **TRI** *time* command is pending.

The following shows the output from an SEL-651R-2:

```
=>TRI STA <Enter>
An event will trigger at 16:00:00
=>
```

If the trigger has already been executed, or no trigger was set, the relay responds as follows:

```
=>TRI STA <Enter>
No trigger time set
=>
```

If the serial port AUTO setting = Y, the relay sends the summary event report:

```
=>
FEEDER 1                                    Date: 08/05/2011  Time: 14:38:27.000
STATION A                                   Time Source: external

Event: TRIG  Location: $$$$$  Shot: 0  Frequency: 60.0
Targets: 10 100000000000 001000000000
Currents (A Pri), ABCGQ:      1     1     1     2     0
=>
```

See *Section 12: Analyzing Events* for more information on event reports.

TRI HIF (Only Available in Relays That Support Arc Sense Technology)

The **TRI HIF** command is used to trigger an HIF event report. The **TRI HIF** command does not support the time or STA parameters. See *High-Impedance Fault (HIF) Event Reporting on page 12.47* for more information on HIF event reports.

Command	Description	Access Level
TRI HIF	Trigger HIF event report data capture.	1

Case No. 2018-00295

VEC Command (Show Diagnostic Information)

Issue the **VEC** command only under the direction of SEL.

Command	Description	Access Level
VEC D	Display the standard Vector Report.	2
VEC E	Display the Extended Vector Report.	2

The information contained in a vector report is formatted for SEL in-house use only. Your SEL application engineer or the factory may request a **VEC** command capture to help diagnose a relay or system problem.

VER Command (Show Relay Configuration and Firmware Version)

The **VER** command provides relay configuration and information such as nominal current input ratings.

Command	Description	Access Level
VER	Display information about the configuration of the relay.	1

An example printout of the **VER** command for an SEL-651R-2 follows:

```
=>VER <Enter>

Part Number:  0651R263XAA83A11X3XXXX
Serial Number:  xxxxxxxxxxxxxx

Analog Voltage Inputs (PT):  300 Vac(VY)-300 Vac(VZ)
Analog Current Inputs (CT):  1 Amp Phase, 0.2 Amp Neutral
Main Board I/O:  3 Form C Outputs, 5 Form A Outputs, 7 Inputs

Relay Features:
  Mirrored Bits
  DNP
  Modbus
  IEEE C37.118
  Fast SER
  Power Quality Monitoring
  Tri-Color LEDs
  One 10/100BASE-T Port

SELboot checksum  OK

Section 11

Front-Panel Operations

Introduction

The SEL-651R-2 Recloser Control front panel makes power system data collection and system control quick and efficient. Use the front panel to analyze power system operating information, view and change recloser control settings, and perform control functions. The SEL-651R-2 features a straightforward menu-driven control structure presented on the front-panel liquid crystal display (LCD). Front-panel targets and other LED indicators give a quick look at SEL-651R-2 operation status. Perform often-used control actions rapidly by using the large direct-action pushbuttons. The features that help you operate the recloser control from the front panel include the following:

➤ Reading metering

➤ Inspecting targets

➤ Accessing settings

➤ Controlling recloser control operations

Front-Panel Layout

Figure 11.1 shows and identifies the following regions:

➤ EIA-232 serial port. See *Section 10: Communications* for details on the serial port.

➤ Human-machine interface (HMI)

➤ Status and trip target LEDs

➤ Operator control pushbuttons and LEDs

11.2 | Front-Panel Operations
Human-Machine Interface

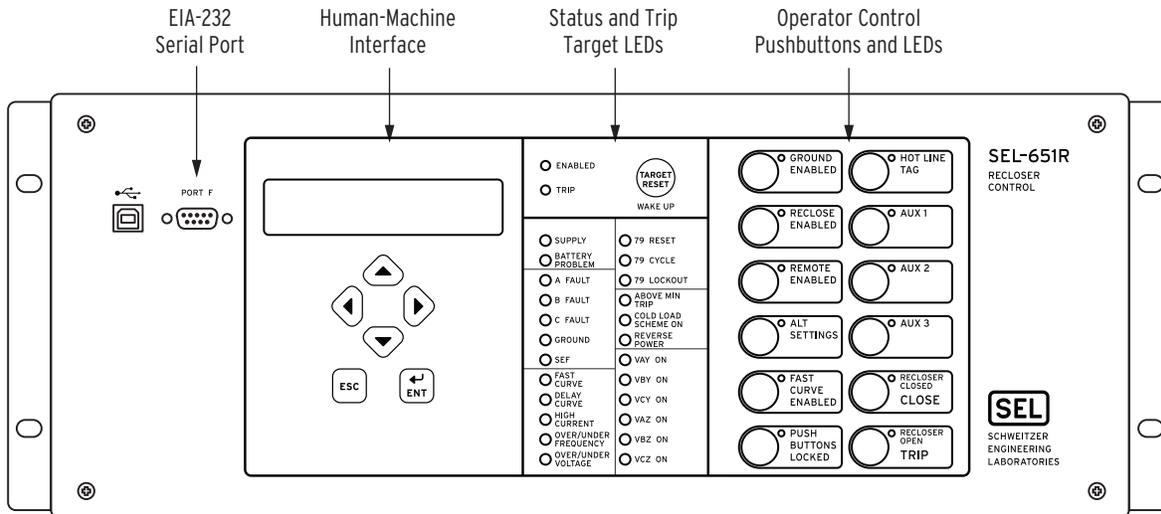
Attachment to Response to AG-2 Question No. 68(g)
Page 666 of 1080
Wolfe


Figure 11.1   SEL-651R-2 Front-Panel Pushbuttons—Overview

This versatile front panel supports the following features so you can customize it for your needs:

➤ Rotating display and control points on the HMI

➤ Programmable status and trip target LEDs

➤ Programmable operator control pushbuttons and LEDs

➤ Slide-in configurable front-panel labels to change the identification of status and trip target LEDs and operator control pushbuttons and LEDs.

Human-Machine Interface

Contrast

NOTE: See the Preface for an explanation of typographic conventions used to describe menus, the front-panel display, and the front-panel pushbuttons.

You can adjust the LCD screen contrast to suit your viewing angle and lighting conditions. To change screen contrast, press and hold the **ESC** pushbutton for two seconds. The SEL-651R-2 displays a contrast adjustment box. Pressing the **Right Arrow** pushbutton increases the contrast. Pressing the **Left Arrow** pushbutton decreases the screen contrast. When you are finished adjusting the screen contrast, press the **ENT** pushbutton; this process is a short cut for changing the LCD contrast setting FP_CONT in the front-panel settings.

Front-Panel Automatic Messages

The recloser control displays an automatic message if a self-test failure occurs.

Front-Panel Security

Front-Panel Access Levels

The SEL-651R-2 front panel typically operates at Access Level 1 and provides viewing of recloser control measurements and settings. Some activities, such as editing settings and controlling output contacts, are restricted to those operators who know the Access Level B or Access Level 2 passwords, or can disable these passwords from the front panel.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 667 of 1080
Front Panel Operations 11.3
Human-Machine Interface
Wolfe

In the figures that follow, restricted activities that require the Access Level B password are marked with the padlock symbol shown in *Figure 11.2*. Restricted activities that require the Access Level 2 password are marked with the padlock symbol with the word Set above it.

Figure 11.2   Access Level Security Padlock Symbol

Before you can perform a front-panel menu activity that is marked with the padlock symbol, you must enter the correct Access Level B or Access Level 2 passwords. After you have correctly entered the password, you can perform other Access Level B or Access Level 2 activities without reentering the password.

Access Level Password Entry

When you try to perform an Access Level B or Access Level 2 activity, the recloser control determines whether you have entered the correct Access Level B or Access Level 2 password since the front-panel inactivity timer expired. If you have not, the recloser control displays the screen shown in *Figure 11.3* for you to enter the password.

Figure 11.3   Password Entry Screen

See *PAS Command (Change Passwords) on page 10.65* for the list of default passwords and for more information on changing passwords.

Attachment to Response to AG-2 Question No. 68(g)
Page 668 of 1080
Wolfe

Front-Panel Time-Out

To help prevent unauthorized access to password-protected functions, the SEL-651R-2 provides a front-panel time-out, setting FP_TO. A timer is reset every time a front-panel pushbutton is pressed. Once the time-out period has expired, the access level is reset to Access Level 1. Manually reset the access level by selecting `Reset Access Lvl` from the `MAIN` menu.

Front-Panel Menus and Screens

Navigating the Menus

The SEL-651R-2 front panel gives you access to most of the information that the recloser control measures and stores. You can also use front-panel controls to view or modify recloser control settings.

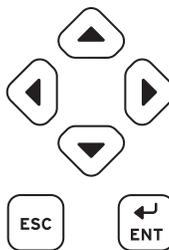
All of the front-panel functions are accessible using the six-button keypad and LCD display. Use the keypad (shown in *Figure 11.4*) to maneuver within the front-panel menu structure, described in detail throughout the remainder of this section. *Table 11.1* describes the function of each front-panel pushbutton.


Figure 11.4   Front-Panel Pushbuttons

Table 11.1   Front-Panel Pushbutton Functions

Pushbutton	Function
Up Arrow	Move up within a menu or data list.
	While editing a setting value, increase the value of the underlined digit.
Down Arrow	Move down within a menu or data list.
	While editing a setting value, decrease the value of the underlined digit.
Left Arrow	Move the cursor to the left.
Right Arrow	Move the cursor to the right.
ESC	Escape from the current menu or display.
	Hold for 2 seconds to display contrast adjustment screen.
ENT	Move from the rotating display to the `MAIN` menu.
	Select the menu item at the cursor.
	Select the displayed setting to edit that setting.

Page 669 of 1080
Wolfe
Front Panel Operations 11.5
Human-Machine Interface

The SEL-651R-2 automatically scrolls information that requires more space than provided by a 16-character LCD line. Use the **Left Arrow** and **Right Arrow** pushbuttons to suspend automatic scrolling and enable manual scrolling of this information.

SEL-651R-2 Menu

Figure 11.5 describes the menu hierarchy. Menus and displays are available for most SEL-651R-2 functions. Several of these menus and displays are described in detail later in this section.

Figure 11.5   SEL-651R-2 Front-Panel Menu Hierarchy

Front Panel Operations 11.7
Human Machine Interface

Reclosing Display

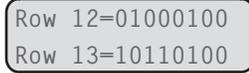
Use the RECLOSING display to see the shot counter progression during reclosing relay testing. Select the RECLOSING menu to access this display on the MAIN menu. *Table 11.2* shows example reclosing displays.

Table 11.2   Reclosing Display

The number (2) in the example display corresponds to the last shot value, which is a function of the number of open intervals, setting E79. There are two set open intervals in these example settings, thus two reclosures (shots) are possible in a reclose sequence.	Set Reclosures 2
For three-phase reclosers, the number (0) in the example display corresponds to the present shot value. If the breaker is closed and the reclosing relay is reset, then RECLOSE COUNT = 0. If the breaker is open and the reclosing relay is locked out after a reclose sequence, then RECLOSE COUNT = 2.	Reclose Count 3P 0
For single-phase reclosers, the number (0) in the example displays corresponds to the present shot value for each phase.	Reclose Count A 0
	Reclose Count B 0
	Reclose Count C 0
The example display shows the front-panel LCD when reclosing is disabled.	No Reclosing Set

Targets Menu

Select the TARGETS menu item on the MAIN menu to access the target rows (Relay Word bits). Use the following features to monitor the recloser control during operation and testing.

Navigate to the target row that contains the Relay Word bit you want to access. Monitor two consecutive rows that contain 16 Relay Word bits with this display.	Row 12=01000100 Row 13=10110100
Display the Relay Word bit names and status of two consecutive bits by pressing **ENT** while the cursor is at the row you want to access. Use the **Up Arrow** or **Down Arrow** to navigate to any of the Relay Word bits in the selected row.	51G1S=0 51G1R=1


Control Menu

The SEL-651R-2 provides great flexibility in power system control through the Control menu. Use the front-panel Control menu to perform these functions:

➤ Operate local control switches. The output states of these switches are known as local bits.

➤ Test output contacts (password required).

11.8 | Front-Panel Operations
Human-Machine Interface

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 672 of 1080
Wolfe

Local Bits: Menu

Use the local bits menu option to operate as many as 16 local control switches. These local control switches replace traditional panel-mounted control switches. The SEL-651R-2 saves the output states of the local control switches in nonvolatile memory and restores these states at power-up.

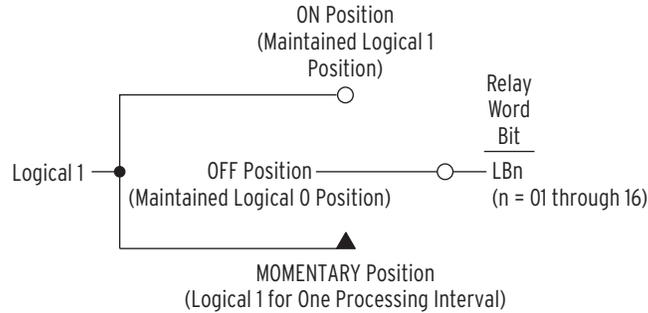
> **NOTE:** Any unused local control bits default to the clear (logical 0) state.
>
> Also, any reconfigured local bit retains the existing bit state after you change the bit setting. Disabling a local bit sets that bit to the clear (logical 0) state.


Figure 11.6   OFF/MOMENTARY Local Control Switch

The output of the switch in *Figure 11.6* is a Relay Word bit (LB01–LB16), called a local bit, and repeats for each local bit.

Local Bits: Switch Types

Use the settings in *Table 11.3* to create menu items that aid in using on, off, or momentary switches. Set ELB to the required number of local bits to enable the local bits settings. Use the **SET F** command (see *Table 9.2*).

Table 11.3   Local Bits Labels

Local Bits Switch Position	Label Setting	Setting Definition	Logic State
	NLBn	Name of local bit	
OFF	CLBn	"Clear" local bit LBn	Logical 0
ON	SLBn	"Set" local bit LBn	Logical 1
MOMENTARY	PLBn	"Pulse" local bit LBn	Logical 1 for one processing interval

Setting NLBn, the local bit name, must always contain a valid name. Enter other local bit label settings to configure the local bit switch type in accordance with *Table 11.4*. Enter **NA** to clear a setting.

Table 11.4   Local Bits Switch Configuration

Local Bits Switch Type	Label NLBn	Label CLBn	Label SLBn	Label PLBn
ON/OFF	x	x	x	
OFF/MOMENTARY	x	x		x
ON/OFF/MOMENTARY	x	x	x	x

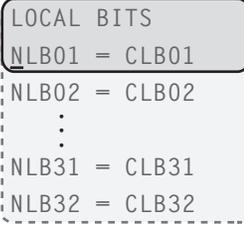
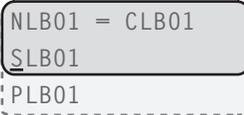
Page 674 of 1080
Wolfe

Table 11.5   Local Bits Menu

Select the `Local Bits` menu item on the `CONTROL` menu to access the local control switches.	`CONTROL` `Local Bits`
The LCD displays a menu empty of local bits if no local bits are enabled or programmed.	`LOCAL BITS`

The LCD will display a menu of local bits in numerical order if at least one local bit is enabled and programmed. The menu also shows the present position of the local control switches. Use the cursor keys to move to the desired local bit and press **ENT** to select it.	`LOCAL BITS`
	`NLB01 = CLB01`
	`NLB02 = CLB02`
	`⋮`
	`NLB31 = CLB31`
	`NLB32 = CLB32`


Use the cursor keys to move to the desired position (SLB01, CLB01, or PLB01) and press **ENT** to select that position.	`NLB01 = CLB01`
	`SLB01`
	`PLB01`


Use the cursor keys to move to `Yes` and press **ENT** to activate that position. The local bit present state updates to the new position.	`SLB01` `No Yes`

Local Bits: Nonvolatile State

The SEL-651R-2 stores local bit states in nonvolatile memory and retains these switch states during power loss. When power is restored, the recloser control restores the local bit states. If a local control switch is in the ON position (corresponding local bit is asserted to logical 1) when power is lost, this switch returns to the ON position (corresponding local bit is still asserted to logical 1) when power is restored. If a local control switch is in the OFF position (corresponding local bit is deasserted to logical 0) when power is lost, this switch returns to the OFF position (corresponding local bit is still deasserted to logical 0) when power is restored. This feature makes the local bit feature behave as a traditional installation with panel-mounted control switches. If power is lost to the panel, the front-panel control switch positions remain unchanged.

If a local bit is routed to a programmable output contact and control power is lost, the SEL-651R-2 stores the state of the local bit in nonvolatile memory but the output contact goes to the de-energized state. When the control power is reapplied to the recloser control, the programmed output contact returns to the local bit state after recloser control initialization.

Local Bits: Application Example

An example of manual trip and close functions using local bits LB03 and LB04 follows. The following label settings configure the local bits as OFF/ MOMENTARY switches (enable local bits first with front-panel setting ELB := 4 or greater).

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Front Panel Operations 11.11
Page 675 of 1080

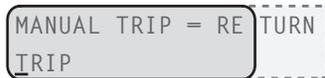
Wolfe

Table 11.6   Local Bits Example Settings

Local Bit	Function	Setting
LB03	Name	NLB03 = MANUAL TRIP
	OFF Position	CLB03 = RETURN
	ON Position	SLB03 =
	MOMENTARY Position	PLB03 = TRIP
LB04	Name	NLB04 = MANUAL CLOSE
	OFF Position	CLB04 = RETURN
	ON Position	SLB04 =
	MOMENTARY Position	PLB03 = CLOSE

Use the following steps to change the local bits state.

Select the `Local Bits` menu item on the `CONTROL` menu to access the local control switches.	`LOCAL BITS` `MANUAL TRIP = RE`TURN
Press the **Down Arrow** cursor key to display both the `MANUAL TRIP` and `MANUAL CLOSE` local bits.	`MANUAL TRIP = RE`TURN `MANUAL CLOSE = RE`TURN
Use the cursor keys to select the `MANUAL CLOSE` menu item and press **ENT** to select that item.	`MANUAL CLOSE = RE`TURN `CLOSE`
Use the cursor keys to move to `Yes` and press **ENT** to activate that position. This is an OFF/ MOMENTARY switch; the `MANUAL CLOSE` switch moves momentarily to the `CLOSE` position and then moves back to the `RETURN` position.	`CLOSE` `No Yes`
Press **ESC** to return to the `CONTROL` menu. Use the cursor keys to move to the `MANUAL TRIP` menu item and press **ENT** to select that item.	`MANUAL TRIP = RE`TURN `TRIP`
Use the cursor keys to move to `Yes` and press **ENT** to activate that position. This is an OFF/ MOMENTARY switch; the `MANUAL TRIP` switch moves momentarily to the `TRIP` position and then moves back to the `RETURN` position.	`TRIP` `No Yes`


Local Bits: Application Ideas

The preceding settings example is for an OFF/MOMENTARY switch. Local bits configured as ON/OFF switches can be used for other applications, such as the following:

➤ Reclosing relay enable/disable

➤ Ground element enable/disable

➤ Remote control supervision

➤ Sequence coordination enable/disable

11.12 | Front-Panel Operations
Human-Machine Interface

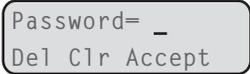
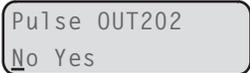
Output Contacts: Menu

Use the `Output Contacts` menu item to test recloser control output contacts and associated circuits. You can pulse trip outputs, close outputs, and general-purpose contact outputs from this menu.

Press the **ENT** pushbutton to pulse the output.	`OUTPUT CONTACTS` `Pulse OUT202`
The LCD displays a password screen if a password is required. Enter your Level B or Level 2 password.	`Password= _` `Del Clr Accept`
Press the **Right Arrow** to select `Yes` and then press **ENT**.	`Pulse OUT202` `No Yes`




SET/SHOW Menu

The SEL-651R-2 settings are arranged in easy-to-understand categories. The settings structure simplifies setting the recloser control. Access the settings class (group, global, port, or front-panel) and instance (i.e., Group 1, Group 2, etc.) required by performing the following steps, which are similar to issuing the appropriate **SET/SHOW** command:

Step 1. Select the `SET/SHOW` menu item on the `MAIN` menu to view or modify the settings (refer to *SEL-651R-2 Menu on page 11.5*).

Step 2. Select the settings class or select the active group, date/time, or password settings from the `SET/SHOW` menu.

Step 3. If necessary, select an instance of the setting class.

Each settings class includes headings that create subgroups of associated settings. These headings are displayed in the settings screen captures in *Factory-Default Settings on page 9.61*. Select the heading that contains the setting of interest. An example of the GROUP 1 headings is shown in *Figure 11.10*.

```
Identifier and Instrument Transformer Settings:
Enable Settings:
Line Parameter Settings:
...
```

Figure 11.10 GROUP 1 Heading Example

Navigate to the setting of interest. View or edit the setting by pressing **ENT**. For text settings, use the four navigation pushbuttons to scroll through available alphanumeric and special character settings. For numeric settings, use the **Left Arrow** and **Right Arrow** pushbuttons to select the digit to change and the **Up Arrow** and **Down Arrow** pushbuttons to change the value. Press **ENT** to enter the new setting.

Setting changes can also be made by using ACSELERATOR QuickSet SEL-5030 Software or ASCII communications commands.

Rotating Display

Meters and indicating panel lights can be replaced by the SEL-651R-2 rotating display. This feature rotates screens of information on the LCD when the front-panel menus are not in use.

After front-panel time-out, the LCD presents each of the display screens in the following sequence:

➤ Any active (filled) display points screens

➤ Enabled metering screens

Screen Scrolling

The rotating display has two screen scrolling modes: auto-scrolling mode and manual-scrolling mode.

Press the **ESC** pushbutton while in the `MAIN` menu to enter the rotating display mode. The SEL-651R-2 automatically begins auto-scrolling the enabled metering and display points screens.

Press the **Up Arrow** or **Down Arrow** pushbutton while in the rotating display mode to begin manual scrolling and to navigate to the desired screen. The recloser control remains in manual scrolling mode for 60 seconds, at which time the front-panel LCD resumes auto-scrolling.

The front-panel setting SCROLD determines how long each screen of the rotating display mode is displayed, settable from 1 to 60 seconds.

Press the **ENT** or **ESC** key to exit the rotating display and view the `MAIN` menu.

Display Points

Use the 32 display points to show the status of Relay Word bits or display the value of analog quantities (analog values, settings). Set EDP to the required number of display points to enable the display point settings.

See *Table F.1* for a list of digital quantities that can be used with display points. Select the following:

➤ Relay Word bit

➤ Alias

➤ String to display when bit is set

➤ String to display when bit is cleared

See *Table G.1* for a list of analog quantities that can be used with display points. Select the following:

➤ Analog quantity

➤ Formatting, scaling, and programmable text

Status Indications

Circuit breaker auxiliary contacts, front-panel switches, SCADA contacts, and other devices activate traditional indicating panel lights. These indicators signal conditions, such as the following:

➤ Circuit Breaker or Recloser Open/Closed

➤ Reclosing Relay Enabled/Disabled

11.14 | Front-Panel Operations
Human-Machine Interface

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 678 of 1080
Wolfe

Figure 11.11 shows traditional indicating panel lights wired in parallel with SEL-651R-2 optoisolated inputs. Input IN101 provides circuit breaker status to the recloser control and input IN102 enables/disables reclosing via the following SELOGIC control equation settings:

52A_3P := **IN101** (Circuit breaker status)

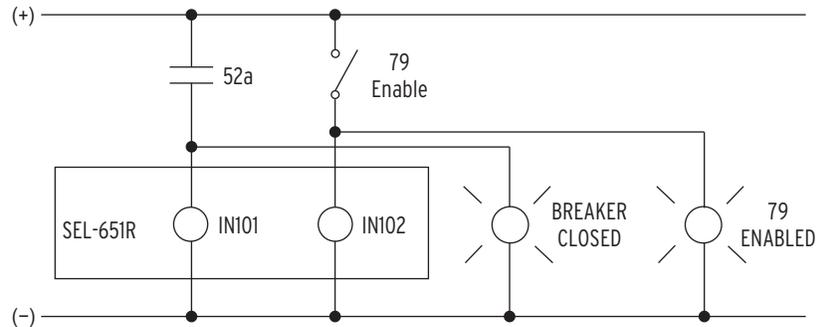
79DTL3P := **NOT IN102** (Reclosing Drive-to-Lockout Setting)


Figure 11.11   Traditional Panel Light Installations

The **79 ENABLED** panel light illuminates when the **79 ENABLE** switch is closed. When the **79 ENABLE** switch is open, the **79 ENABLED** panel light extinguishes, indicating that the reclosing relay is disabled.

The **BREAKER CLOSED** panel light illuminates when the 52a circuit breaker auxiliary contact is closed. When the 52a circuit breaker auxiliary contact is open, the **BREAKER CLOSED** panel light extinguishes and it is understood that the breaker is open.

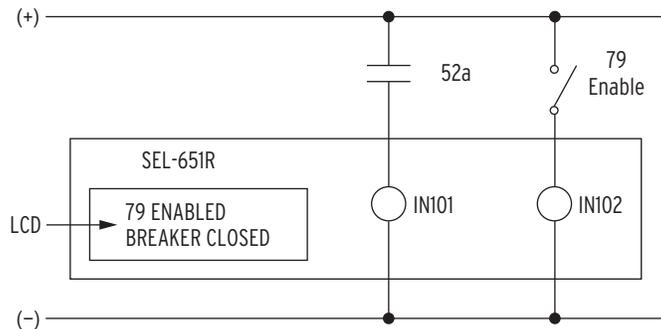
The indicating panel lights are not needed with the rotating display feature in the SEL-651R-2. *Figure 11.12* shows how to eliminate the indicating panel lights by using the rotating display.


Figure 11.12   Rotating Display Replaces Traditional Panel Light Installations

Setting Syntax

NOTE: DPxx indicates DP01 ... DP32.

Use the following syntax to display the given entry (Relay Word bits or analog quantities) exactly as seen in the navigational menu (name, value, and units).

DPxx := **Name** (see examples later in this section)

Use the following syntax to display the given entry (Relay Word bits or analog quantities) as seen in the navigational menu, replacing the name of the value with the given alias string. Relay Word bits require one row, while analog quantities require two rows.

DPxx := **Name, "Alias"** (see examples later in this section)

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 679 of 1080
Front Panel Operations 11.15
Human Machine Interface
Wolfe

Use the following syntax to display the given entry (Relay Word bits only), with the given alias. If the Relay Word bit is asserted (logical 1), the LCD displays the set string in the place of the value. If the Relay Word bit is deasserted (logical 0), the LCD displays the clear string in the place of the value. One or all of Alias, Set String, or Clear String can be empty. If Alias is empty, then the LCD displays only the Set or Clear Strings. If either Set String or Clear String is empty, then the item is not visible when the bit matches that state. If an empty line is required in this case, instead of hiding the line altogether, then use empty curly braces ({}) for the Set or Clear String. This entry requires at most one display row.

> DPxx := **Name, "Alias", "Set String", "Clear String"** (see examples later in this section)

Use the following syntax to display the given entry (analog quantities only) with the given text and formatting. Formatting must be in the form {Width.Decimal,Scale} with the value of Name, scaled by *Scale*, formatted with total width *Width* and *Decimal* decimal places. The width value includes the decimal point and sign character, if applicable. The scale value is optional; if omitted, the scale factor is processed as 1. If the numeric value is smaller than the field size requested, the field is padded with spaces to the left of the number. If the numeric value will not fit within the field width given, the field grows (to the left of the decimal point) to accommodate the number. All display points formatted in this manner occupy one, and only one, line on the display at all times. You can use multiple display points to simulate multiple lines.

> DPxx := **Name, "Text1 {Width.Decimal,Scale} Text2"** (see examples later in this section)

Relay Word Bits Settings Examples

The following settings examples use optoisolated inputs IN101 and IN102 in the display points settings. Local bits (LB01–LB16), latch bits (LT01–LT16), remote bits (RB01–RB16), settings group indicators (SG1–SG6), and any other Relay Word bits can also be used. These examples use the following syntax:

> DPxx := **Name, "Alias", "Set String", "Clear String"**

Example: Continually Display a Message. To always display the message SEL-651R CONTROL on the rotating display, enter the display point setting DP01 as follows:

Setting	
DP01 := 1, "SEL-651R CONTROL"	SEL-651R CONTROL

11.16 Front-Panel Operations
Human-Machine Interface

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 680 of 1080
Wolfe

Example: Reclosing Relay Status Indication. Enter SEL~OGIC~ control equation display point setting DP02 as follows to display 79 ENABLED when input IN102 asserts and display 79 DISABLED when IN102 deasserts.

Settings	IN1O2 is Asserted	IN1O2 is Deasserted
DP02 := IN102, , "79 ENABLED", "79 DISABLED"	79 ENABLED	79 DISABLED

Example: Circuit Breaker Status Indication. Use one of the following setting methods to display the circuit breaker status.

Settings	IN1O1 is Asserted	IN1O1 is Deasserted
52A_3P := IN101 DP03 := 52A3P	52A3P=1	52A3P=0
52A_3P := IN101 DP03 := 52A3P, , "BREAKER CLOSED", "BREAKER OPEN"	BREAKER CLOSED	BREAKER OPEN
52A_3P := IN101 DP03 := 52A3P, "BREAKER", "CLOSED", "OPEN"	BREAKER=CLOSED	BREAKER=OPEN

Example: Display Only One Message. Enter settings 52A_3P and DP03 as follows to display BREAKER CLOSED when input IN101 asserts, but display nothing when input IN101 deasserts.

Settings	IN1O2 is Asserted	IN1O2 is Deasserted
52A_3P := IN101 DP03 := 52A3P, , "BREAKER CLOSED"	BREAKER CLOSED	

Analog Quantities Settings Examples

These examples use the following setting syntax:

DPxx := **Name, "Text1 {Width.Decimal,Scale} Text2"**

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 681 of 1080
Front Panel Operations 11.17
Human Machine Interface
Wolfe

Example: Display A-Phase RMS Current.   Set display point DP04 by using one of the following methods to display IA rms current.

Setting	
DP04 := IAR	`IA` `        xxx.x A`
DP04 := IAR, "IA={7.2} A RMS" DP05 := IBR, "IB={7.2} A RMS"	`IA=xxxx.xx A RMS` `IB=xxxx.xx A RMS`
DP04 := IAR, "IA={6.2,0.001} KA RMS" DP05 := IBR, "IB={6.2,0.001} KA RMS"	`IA=xxx.xx KA RMS` `IB=xxx.xx KA RMS`
DP04 := IAR, "A-PH RMS Current"	`A-PH RMS CURRENT` `        xxx.x A`

Example: Display Time-Overcurrent Pickup.   Set display point DP06 by using one of the following methods to display time-overcurrent pickup current:

Setting	
DP06 := 51PJP	`51PJP` `        x.xx A sec`
DP06 := 51PJP, "TOC PICKUP J={3.0}" DP07 := 51PKP, "TOC PICKUP K={3.0}"	`TOC PICKUP J=xxx` `TOC PICKUP K=xxx`
DP06 := 51PJP, "TIMEO/C Pickup J"	`TIMEO/C PICKUP J` `        x.xx A sec`

Example: Display Time-Overcurrent Curve and Time Dial.   Set display points DP07–DP10 by using one of the following methods to display time-overcurrent curve and time dial for a "fast" phase curve (e.g., 51PJC = A, 51PJTD = 0.94) and a "slow" phase curve (e.g., 51PKC = U3, 51PKTD = 13.58).

Setting	
DP07 := 51PJC	`51PJC` `        A curve`
DP08 := 51PJTD	`51PJTD` `  0.94 time dial`

11.18 | Front-Panel Operations
Human-Machine Interface

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 682 of 1080
Wolfe

Setting	
DP09 := 51PKC	51PKC U3 curve
DP10 := 51PKTD	51PKTD 13.58 time dial
DP07 := 51PJC, "fast ph curve = {}" DP08 := 51PJTD, "Fast PH Time DL = {0.2}"	FAST PH CURVE = A FAST PH TIME DL = 0.94
DP09 := 51PKC, "Slow Ph Curve={}" DP10 := 51PKTD, "Slow ph Time dl={0.2}"	SLOW PH CURVE=U3 SLOW PH TIME DL=13.58
DP07 := 51PJC, "fast Curve-phase"	FAST CURVE-PHASE A curve
DP08 := 51PJTD, "fast time Dial-phase"	FAST TIME DIAL-PHASE 0.94 time dial
DP09 := 51PKC, "Slow curve-phase"	SLOW CURVE-PHASE U3 curve
DP10 := 51PKTD, "slow time dial-phase"	SLOW TIME DIAL-PHASE 13.58 time dial

Some of the examples above show text continuing to the right of the front-panel display (longer than the 16 horizontal spaces of the front-panel display). In these display situations, the text will automatically scroll to the left to display all the text.

In the examples above, where all the information for a curve or time dial value is displayed in a single line, note the bracket values {} for curve display settings and {0.2} for time-dial display settings. No other variation of these bracket values is needed for displaying curve or time-dial values, respectively, in a single-line fashion.

Metering Screens

The SEL-651R-2 displays enabled metering screens in the following order:

Setting	
Use setting FPNGD to select IA, IB, IC, IN or IA, IB, IC, IG currents or to disable the screen.	IA=xxxx IB=xxxx IC=xxxx IN=xxxx or IA=xxxx IB=xxxx IC=xxxx IG=xxxx

Status and Trip Target LEDs

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 684 of 1080
Wolfe

You can reprogram all of these indicators except the **ENABLED** and **TRIP** LEDs to reflect operating conditions other than the factory-default programming described in this subsection. This front-panel region provides tricolor (red, green, or amber) LEDs for the **ENABLED** and **TRIP** LEDs. Use settings LEDENAC and LEDTRAC to select the assert color. The target LED color setting LEDTRAC (for the **TRIP** LED) is only present when tricolor LEDs are ordered for the SEL-651R-2. If tricolor LEDs are not ordered, the **TRIP** LED is red.

Settings Tn_LED are SELOGIC control equations that, when asserted during a recloser control trip event, illuminate the corresponding LED. Parameter n is a number from 1–24 that indicates each LED. Program setting TnLEDL := Y to latch the LEDs during trip events; when you set TnLEDL := N, trip latch supervision has no effect and the LED follows the state of the Tn_LED SELOGIC control equation. With the tricolor LED option, target LED settings Tn_LEDC select the assert color. After setting the target LEDs, issue the **TAR R** command to reset the target LEDs. For a concise listing of the default programming on the front-panel LEDs, see *Table 5.3*.

The SEL-651R-2 features slide-in labels for custom LED designations that match custom LED logic. Use the slide-in labels to mark the LEDs with these custom names. Included on the SEL-651R-2 Product Literature CD are Configurable Label Templates to print labels for the slide-in label carrier.

The **ENABLED** LED indicates that the recloser control is powered correctly, is functional, and has no self-test failures. Trip events illuminate the **TRIP** LED. The prominent location of the **TRIP** LED in the top target area aids in recognizing trip events quickly. See *Front-Panel Target LEDs ENABLED and TRIP on page 5.15*.

Figure 11.13 shows the arrangement of the status and trip target LEDs region into seven areas. See *Table 11.7* for a description of these areas.

Table 11.7   Target LED Areas

Target LED Area	Description
Operational	**ENABLED**, **TRIP**
Power	**SUPPLY** and **BATTERY PROBLEM** LEDs indicate whether the control is powered from the power supply mains and whether the battery is healthy.
Fault Type	Use these LEDs to determine whether **A FAULT**, **B FAULT**, **C FAULT**, **GROUND**, or **SEF** were involved in the fault.
Protection Type	Use these LEDs to determine whether **FAST CURVE**, **DELAY CURVE**, **HIGH CURRENT**, **OVER/UNDERFREQUENCY**, or **OVER/UNDERVOLTAGE** protection caused the trip.
Recloser State	**79 RESET**, **79 CYCLE**, and **79 LOCKOUT** LEDs indicate the state of the recloser.
Status	**ABOVE MIN TRIP**, **COLD LOAD SCHEME ON**, and **REVERSE POWER** indicate important operating conditions.
Voltage State	**VAY ON**, **VBY ON**, **VCY ON**, **VAZ ON**, **VBZ ON**, and **VCZ ON** LEDs indicate whether the phase voltages are above a programmable threshold.

See *Front-Panel Target LEDs on page 5.13* for additional details on the functionality of these status and trip target LEDs.

Status and Trip Target
Wolfe

TARGET RESET
Pushbutton

TARGET RESET

For a trip event, the SEL-651R-2 latches the trip-involved target LEDs. Press the **TARGET RESET** pushbutton to reset the latched target LEDs. When a new trip event occurs and the previously latched trip targets have not been reset, the recloser control clears the latched targets and displays the new trip targets. Pressing and holding the **TARGET RESET** pushbutton illuminates all the LEDs. Upon release of the **TARGET RESET** pushbutton, two possible trip situations can exist: the conditions that caused the recloser control to trip have cleared, or the trip conditions remain present at the recloser control inputs. If the trip conditions have cleared, the latched target LEDs turn off. If the trip event conditions remain, the recloser control re-illuminates the corresponding target LEDs.

Lamp Test

The **TARGET RESET** pushbutton also provides a front-panel lamp test. Pressing and holding **TARGET RESET** illuminates all the front-panel LEDs, and these LEDs remain illuminated for as long as **TARGET RESET** is pressed. The target LEDs return to a normal operational state after release of the **TARGET RESET** pushbutton.

Wake Up

Use this pushbutton to reconnect the battery to the recloser control when external power is not present and the recloser control has disconnected the battery. Once the battery has been reconnected, the SEL-651R-2 will automatically initiate its startup sequence and then enable protection. The battery was initially disconnected after external power was removed and the PWRDN_AC (power-off delay after ac loss) timer expired. The battery will be disconnected again when the PWRDN_WU (power-off delay after wake up) timer expires or 15 minutes after the last front-panel pushbutton is pushed, once the timer begins running. Use these timers to manage the remaining battery capacity. See *Battery System Monitor on page 8.39* for more information.

Other Target Reset Options

Use the ASCII command **TAR R** to reset the target LEDs; see *TAR Command (Display Relay Element Status) on page 10.74* for more information. Programming specific conditions in the SELOGIC control equation RSTTRGT is another method for resetting the targets LEDs. Access RSTTRGT in the Global settings (Data Reset Control). See *Section 9: Settings* for further information. The target LEDs can also be reset by performing a target reset through the DNP or Modbus protocols (see *Appendix E: DNP3 Communications* and *Appendix K: Modbus RTU and TCP Communications*.)

Factory-Default Settings

With the tricolor LED option, pushbutton LED settings PB*n*LEDC select the asserted and deasserted colors.

Factory-default programming associates specific recloser control functions with the 12 pushbuttons and LEDs, as listed in *Table 11.8*. *Table 11.9* describes the factory-default settings for the operator controls.

Table 11.8   Operator Control Pushbuttons and LEDs—Factory Defaults

LED	Pushbutton	Function
GROUND ENABLED	GROUND ENABLED	Enable ground overcurrent tripping
RECLOSE ENABLED	RECLOSE ENABLED	Enable auto reclosing
REMOTE ENABLED	REMOTE ENABLED	Enable remote control
ALT SETTINGS	ALT SETTINGS	Change to alternate settings
FAST CURVE ENABLED	FAST CURVE ENABLED	Enable fast curve
PUSHBUTTONS LOCKED	PUSHBUTTONS LOCKED	Engage/disengage pushbutton lock
HOT LINE TAG	HOT LINE TAG	Enable hot-line tag
AUX 1	AUX 1	Programmable
AUX 2	AUX 2	Programmable
AUX 3	AUX 3	Programmable
RECLOSER CLOSED	CLOSE	Close recloser or circuit breaker
RECLOSER OPEN	TRIP	Open recloser or circuit breaker

Press the operator control pushbuttons momentarily to toggle on and off the functions listed adjacent to each LED/pushbutton combination. This applies to all operator control pushbuttons except the **PUSHBUTTONS LOCKED**, which must be pressed continually for three or more seconds, and the **AUX 1**, **AUX 2**, **AUX 3**, and **REMOTE ENABLED** pushbuttons, which are not programmed with factory-default functionality. The **CLOSE** and **TRIP** pushbuttons momentarily assert the close and trip outputs.

Table 11.9 Operator Controls (Sheet 1 of 2)

Operator Control Pushbutton	Relay Word Bit Output	SELogic Factory-Default LED Setting and Color	Function
— LED ○ GROUND ENABLED Operator Control Pushbutton	PB01 PB01_PUL	PB01_LED := LT01 PB01LEDC := AO (AO is Amber, Off)	Press the **GROUND ENABLED** operator control pushbutton to enable/disable ground overcurrent element tripping. The corresponding LED illuminates to indicate the enabled state.
○ RECLOSE ENABLED	PB02 PB02_PUL	PB02_LED := LT02 PB02LEDC := AO (AO is Amber, Off)	Press the **RECLOSE ENABLED** operator control pushbutton to enable/disable auto reclosing. The corresponding LED illuminates to indicate the enabled state. The **RECLOSE ENABLED** operator control is overridden by operating the **HOT LINE TAG** operator control in the following scenario: Initial state: **RECLOSE ENABLED** is on or off and **HOT LINE TAG** is off. Action: Press the **HOT LINE TAG** operator control pushbutton. Result: **RECLOSE ENABLED** is off and **HOT LINE TAG** is on. The **RECLOSE ENABLED** operator control is now nonfunctional (remains off). **RECLOSE ENABLED** cannot be turned on again until **HOT LINE TAG** is turned off. Once **HOT LINE TAG** is off, the **RECLOSE ENABLED** operator control is then functional, but remains off until the **RECLOSE ENABLED** operator control pushbutton is pressed again.
○ REMOTE ENABLED	PB03 PB03_PUL	PB03_LED := 0 PB03LEDC := AO (AO is Amber, Off)	Press the **REMOTE ENABLED** operator control pushbutton to enable/disable remote control. The corresponding LED illuminates to indicate the enabled state. **Note:** This operator control does not perform any function with the factory settings.
○ ALT SETTINGS	PB04 PB04_PUL	PB04_LED := NOT(SG1) PB04LEDC := AO (AO is Amber, Off)	Press the **ALT SETTINGS** operator control pushbutton to switch the active settings group between the main settings group (Settings Group 1) and the alternate settings group (Settings Group 2). The corresponding LED illuminates to indicate that the alternate settings group is active.
○ FAST CURVE ENABLED	PB05 PB05_PUL	PB05_LED := LT04 PB05LEDC := AO (AO is Amber, Off)	Press the **FAST CURVE ENABLED** operator control pushbutton to enable/disable the fast curve; this leaves the slow curve enabled. The corresponding LED illuminates to indicate the enabled state.

Operator Controls
Page 689 of 1080
Wolfe

Table 11.9 Operator Controls (Sheet 2 of 2)

Operator Control Pushbutton	Relay Word Bit Output	SELOGIC Factory-Default LED Setting and Color	Function
PUSH BUTTONS LOCKED	PB06 PB06_PUL	PB06_LED := NOT(LT05 AND NOT(SV01T AND PB06 AND NOT(SC01QU)) OR NOT(LT05) AND SV01T AND PB06 AND NOT(SC01QU)) PB06LEDC := AO (AO is Amber, Off)	Continually press the **PUSHBUTTONS LOCKED** operator control pushbutton for three (3) or more seconds to engage/disengage the lock function. While this pushbutton is pressed, the corresponding LED flashes on and off, indicating a pending engagement or disengagement of the lock function. The LED illuminates constantly to indicate the engaged state. While the lock function is engaged, the following operator controls are locked in position (assuming factory-default settings): GROUND ENABLED HOT LINE TAG / RECLOSE ENABLED AUX 1 / REMOTE ENABLED AUX 2 / ALT SETTINGS AUX 3 / FAST CURVE ENABLED. While locked in position, these operator controls cannot change state if pressed—the corresponding LEDs remain in the same state. When the lock function is engaged, the **CLOSE** operator control cannot close the breaker, but the **TRIP** operator control can still trip the breaker.
HOT LINE TAG	PB07 PB07_PUL	PB07_LED := NOT(LT06) PB07LEDC := AO (AO is Amber, Off)	Press the **HOT LINE TAG** operator control pushbutton to enable/disable the hot-line tag function. The corresponding LED illuminates to indicate the enabled state. While the hot-line tag function is enabled, no closing or auto reclosing can take place via the control (e.g., the **CLOSE** operator control is inoperative). The **HOT LINE TAG** operator overrides the **RECLOSE ENABLED** operator control (see previous **RECLOSE ENABLED** operator control description).
AUX 1	PB08 PB08_PUL	PB08_LED := 0 PB08LEDC := AO (AO is Amber, Off)	Press the **AUX 1**, **AUX 2**, or **AUX 3** operator control pushbutton to enable/disable user-programmed auxiliary control. Program the corresponding LED to indicate the required state. **Note:** These operator controls do not perform any function with the factory settings.
AUX 2	PB09 PB09_PUL	PB09_LED := 0 PB09LEDC := AO (AO is Amber, Off)	
AUX 3	PB010 PB010_PUL	PB10_LED := 0 PB10LEDC := AO (AO is Amber, Off)	
RECLOSER CLOSED CLOSE	PB011 PB011_PUL	PB11_LED := 52A3P PB11LEDC := RO (RO is Red, Off)	Press the **CLOSE** operator control pushbutton to close the breaker. The corresponding **RECLOSER CLOSED** LED illuminates to indicate the breaker is closed.
RECLOSER OPEN TRIP	PB012 PB012_PUL	PB12_LED := NOT(52A3P) PB12LEDC := GO (GO is Green, Off)	Press the **TRIP** operator control pushbutton to trip the breaker and take the SEL-651R-2 to the lockout state. The corresponding **RECLOSER OPEN** LED illuminates to indicate the breaker is open. If the recloser is a regular Traditional Retrofit recloser, SELOGIC setting PB12_LED can be changed, if desired. See the *Motor-Operated Traditional Retrofit Reclosers on page 2.60* for more detail.

Page 690 of 1080
Wolfe

Behavior of Operator Control Pushbutton Logic Outputs

Refer to the Relay Word Bit Output column in *Table 11.9*. Each operator control pushbutton has two corresponding Relay Word bit outputs. For example, the **GROUND ENABLED** operator control pushbutton has Relay Word bit outputs PB01 and PB01_PUL:

➤ PB01 asserts and remains asserted (= logical 1) as long as the **GROUND ENABLED** operator control pushbutton is pressed.

➤ PB01_PUL asserts to logical 1 for only a processing interval (PB01_PUL "pulses") when the **GROUND ENABLED** operator control pushbutton is initially pressed. PB01_PUL can only "pulse" again if the **GROUND ENABLED** operator control pushbutton is released (not pressed) and then pressed again.

The Relay Word bits corresponding to the other operator control pushbuttons operate similarly.

Custom Settings

Use SELOGIC control equations to change the default pushbutton and LED functions. Use the slide-in labels to mark the pushbuttons and pushbutton LEDs with custom names to reflect any programming changes. The Operator Control Labels are keyed and can be inserted in only one position on the front panel. Included on the SEL-651R-2 Recloser Control Product Literature CD are word processor templates for printing slide-in labels. See SEL-651R-2 Configurable Labels instructions for more information on changing the slide-in labels.

Change the function of the operator control LEDs with settings PB01_LED through PB12_LED, found in the SELOGIC Factory-Default LED Setting and Color column in *Table 11.9*. You can change the LED indications to fit specific control and operational requirements. This programmability allows great flexibility and provides operator confidence and safety, especially in indicating the status of functions that are controlled both locally and remotely. The **RECLOSER CLOSED** and **RECLOSER OPEN** LEDs feature tricolor LEDs. Use settings PB11LEDC and PB12LEDC to select whether the asserted and deasserted colors are red, green, or amber. Additional asserted/deasserted color settings PB01LEDC–PB10LEDC are available when the tricolor option is ordered.

Section 12

Analyzing Events

Introduction

The SEL-651R-2 Recloser Control features numerous reports to analyze power system conditions. The relay provides the following analysis tools:

➤ Standard 15/30/60-Cycle Event Reports

➤ Sequential events recorder (SER) report

➤ Sag/Swell/Interruption (SSI) report

➤ High-Impedance Fault Event Reporting

All four reports are stored in nonvolatile memory, ensuring that a loss of power supply to the SEL-651R-2 module will not result in lost data.

Standard 15/30/60-Cycle Event Reporting

Event reports capture highly detailed information over a relatively brief period of time (15, 30, or 60 cycles). Information stored includes the following:

➤ Date and time of the event report trigger with 1 ms resolution.

➤ Individual sample analog input oscillography (currents and voltages, plus frequency) at 4, 16, 32, or 128 samples per cycle.

➤ Digital element states of all Relay Word bits at 4 samples per cycle and optoisolated inputs as fast as 16 samples per cycle.

➤ Event summary, including the front-panel target states at the time of tripping, fault location, and fault type.

➤ Group, logic, global, and report settings (that were in service when the event was recorded).

➤ 10 µs precision trigger time stamp and relative sample times (available when a high-accuracy IRIG-B time source is connected to the control).

An adjustable prefault recording period allows system conditions to be captured prior to the actual event report trigger. Event reports are stored to nonvolatile memory a short time after an event trigger is processed.

Event reports are useful in commissioning tests, system disturbance analysis, and protective device or scheme performance analysis. ACSELERATOR Analytic Assistant SEL-5601 Software and ACSELERATOR QuickSet SEL-5030 Software can read Compressed ASCII and COMTRADE file format versions of the event report, which contain even more information than the standard ASCII event report. With this software, oscillographic traces and digital element traces can be produced on the PC display. A phasor analysis screen allows the protection engineer to analyze the prefault, fault, and post-fault intervals, observing both the directly measured inputs, as well as the calculated sequence component signals.

Standard 15/30/60-Cycle Event Reports

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 692 of 1080
Wolfe

Sequential Events Recorder (SER)

The SER report captures detailed digital element state changes over a long time period. Programmable trigger lists allow as many as 96 Relay Word bits to be monitored, in addition to the automatically generated triggers for recloser control startup, settings changes, and active settings group changes. State changes are time-tagged to the nearest millisecond.

SER report data are useful in commissioning tests and during operation for system monitoring and control.

SER information is stored when state changes occur.

Sag/Swell/Interruption (SSI) Report

NOTE: SSI is not available on models ordered with a single voltage input.

The SSI report captures power quality data related to voltage disturbances over a long period of time. Data captured includes the magnitude of currents, one set of three-phase voltages, a reference voltage, and the status of the voltage sag/swell/interrupt (VSSI) Relay Word bits (see *Voltage Sag, Swell, and Interruption Elements on page 4.59*).

SSI report information is useful for analyzing power quality disturbances, or protective device actions that last longer than the time window of a conventional event report.

The SSI recording rate varies from fast to slow, depending on changes in the triggering elements. SSI data are stored to nonvolatile memory just after this information is generated.

High-Impedance Fault Event Reporting

HIF event information is available when the relay supports HIF detection. The relay provides user-programmable event report sizes and triggering conditions; stores a historical summary of HIF events with summary information available of each individual event; and generates Compressed ASCII and COMTRADE file format event reports to display analog data and the state of related Relay Word bits from the nonharmonic HIF fault detection and load reduction algorithms. HIF event data are stored to nonvolatile memory. Use QuickSet and AC SELERATOR Analytic Assistant SEL-5601 Software to collect and analyze event data for HIF alarm and fault conditions.

Standard 15/30/60-Cycle Event Reports

See *Figure 12.8* for an example event report. Note that *Figure 12.8* is on multiple pages.

Filtered and Unfiltered Event Reports

The SEL-651R-2 samples the basic power system measurands (ac voltage and ac current) 128 times per power system cycle. The recloser control filters the measurands at 32 samples-per-cycle to remove transient signals. The recloser control operates on the filtered fundamental values and reports them in the event report.

To view the raw inputs to the recloser control, select the unfiltered event report (e.g., **CEV R**). Use the unfiltered event reports to observe:

➤ Power system transients on channels IA, IB, IC, IN, VAY, VBY, VCY, VAZ, VBZ, and VCZ.

➤ Decaying dc offset during fault conditions on channels IA, IB, and IC.

Attachment to Response to AG-2 Question No. 68(g)
Page 693 of 1080
Standard 15/30/60 Cycle Event Reports

Analyzing Events 12.3
Voltage Event Reports
Wolfe

➤ Voltage transducer response to power system transients.

➤ Power system harmonics (with appropriate analytical PC software tools).

➤ For unfiltered event reports (e.g., **CEV R**), optoisolated input contact bounce on channels IN101–IN107 and IN201–IN206 updated at 16 samples per cycle.

The filters for ac current and voltage are fixed. You can adjust the optoisolated input debounce via debounce settings (see *Figure 7.17* and *Figure 7.18*).

Current and Voltage Connection Settings: Effect on Event Reports

The Global settings IPCONN, EGNDSW, CTPOL, VYCONN, VZCONN, EPHANT, VSELECT, and FSELECT are fully described in *Settings Explanations on page 9.27*. These settings are briefly presented in this section to allow their effects on the event report analog values to be explained.

The IPCONN setting controls which of the three current input terminals (I1, I2, and I3) gets routed to each of the internal analog channels IA, IB, and IC. This feature is called phase rolling for the current channels, and it allows system phasing and current transformer (CT) connections to be matched inside the SEL-651R-2 without the need to rewire. All SEL-651R-2 event reports display the rolled current values.

GLOBAL SETTING EGNDSW
See Ground Switch Logic on page 4.76.

The EGNDSW setting selects the function of the neutral (IN) channel. When the IN channel is connected to a zero-sequence current source, such as the standard residual connection with terminals I1, I2, and I3, set EGNDSW := Y. In this state, the IG column in SEL-651R-2 event reports will automatically switch between displaying the IN channel data for small signals and the calculated (residual) $3I_0$ data for large signals, such as most ground faults.

Relay Word bit GNDSW captures the IG source for each row of the event report: when GNDSW = logical 1, IG = IN; when GNDSW = logical 0, IG = calculated $3I_0$. Setting EGNDSW := N disables the "ground switch" feature, and the IG column will always display the calculated $3I_0$ data (and GNDSW is permanently = logical 0).

The CTPOL setting allows the current phase polarity to be reversed to facilitate utility or industrial metering direction preferences, without the need to disconnect and reconnect CT wires. In the SEL-651R-2 event reports, channels IA, IB, and IC are always affected by the CTPOL setting. Channel IN is only affected by the CTPOL setting when Global setting EGNDSW := Y.

The VYCONN setting controls which of the three Y-terminal voltage inputs (V1Y, V2Y, and V3Y) get routed to each of the internal analog channels VAY, VBY, and VCY. The VZCONN setting performs a similar function with the V1Z, V2Z, V3Z terminals and VAZ, VBZ, VCZ channels.

This feature is called phase rolling for the voltage channels, and it allows system phasing and potential transformer (PT) connections to be matched inside the SEL-651R-2 without the need to rewire. All SEL-651R-2 event reports display the rolled voltage values.

NOTE: All 6 voltage terminals are represented in the event report analog channels, even if VYCONN and/or VZCONN is set to contain fewer than three phase letters. See Figure 9.21 for further detail.

The EPHANT setting allows three-phase metering to be performed with only a single PT connected. The EPHANT setting has **no effect** on event reports— it is only used in the metering functions (see *Phantom Voltage Function on page 8.4*).

12.4 | Analyzing Events
Standard 15/30/60-Cycle Event Reports

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 694 of 1080
Wolfe

The VSELECT setting designates which set of input terminals (VY or VZ) are used in various recloser control functions. The only effect VSELECT has on event reports is to determine which set of voltages (VAY, VBY, VCY; or VAZ, VBZ, VCZ) is used in the fault locator function.

The FSELECT setting determines which voltage input is used for frequency measurement and frequency tracking (see *Frequency Source Selection Setting (FSELECT) on page 9.33*). The frequency column in the event report and event summary is affected by this setting.

Event Report Length (Settings LER and PRE)

The SEL-651R-2 provides user-selectable event report length and prefault length. Event report length is either 15, 30, or 60 cycles. Prefault length ranges from 1 to 59 cycles, depending upon LER setting (see *Table 12.1*). Prefault length is the first part of the total event report length (LER) and precedes the event report triggering point.

Raw event reports display one extra cycle of data at the beginning of the report (or two extra cycles when 128 samples per cycle is specified).

Set the prefault length with the PRE setting. See the **SET R** command in *Table 9.2* and corresponding *Report Settings on page SET.64* for instructions on setting the LER and PRE settings.

Changing the LER setting erases all events stored in nonvolatile memory. Changing the PRE setting has no effect on the stored reports.

Event Report Capacity

NOTE: During testing, be aware that once the relay event report memory is full, triggering a new event can displace the oldest events.

The event report capacity depends on the selected event report length (LER) setting, as shown in *Table 12.1*.

Table 12.1   Event Report Length Settings

LER Setting	Prefault Length (PRE setting) Range	Number of Event Reports Stored
15 cycles (factory default)	1–14	40
30 cycles	1–29	25
60 cycles	1–59	15

The SEL-651R-2 stores event reports in nonvolatile memory soon after the events are captured. If the power supply is interrupted during the saving of an event report, the relay reports `Invalid Data` for the event that was not fully stored.

Event Report Triggering

The recloser control triggers (generates) a standard event report when any of the following occur:

➤ Relay Word bit TRIP3P, TRIPA, TRIPB, or TRIPC asserts

➤ Programmable SELOGIC control equation setting ER asserts to logical 1 (in Report settings)

➤ **TRI** (Trigger Event Reports) serial port command executed

➤ Output contacts OUT101–OUT108, OUT201, or OUT202 are pulsed via the serial port or front-panel **PUL** (Pulse Output Contact) command

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 695 of 1080
Analyzing Events 12.5
Standard 15/30/60 Cycle Event Reports
Wolfe

Relay Word Bits TRIP3P, TRIPA, TRIPB, TRIPC

Refer to *Figure 5.1*. If Relay Word bit TRIP3P, TRIPA, TRIPB, or TRIPC asserts to logical 1, an event report is automatically generated. Thus, any condition that causes a trip does **not** have to be entered in SELOGIC control equation setting ER.

For example, SELOGIC control equation trip setting TR3P is unsupervised. Any trip condition that asserts in setting TR3P causes the TRIP3P Relay Word bit to assert immediately. The factory-default setting for trip setting TR3P is:

> TR3P := **51PT OR 51G1T OR PB12_PUL OR OC3**

If any of the individual conditions 51PT, 51G1T, PB12_PUL, or OC3 assert, Relay Word bit TRIP3P asserts, and an event report is automatically generated. Thus, these conditions do **not** have to be entered in SELOGIC control equation setting ER.

Relay Word bit TRIP3P (in *Figure 5.1*) is usually assigned to an output for tripping a recloser (such as SELOGIC control equation setting RCTR1 := TRIP3P, in Group settings).

Programmable SELOGIC Control Equation Setting ER

The programmable SELOGIC control equation event report trigger setting ER is set to trigger standard event reports for conditions other than trip conditions (see *Report Settings on page SET.64*). When setting ER detects a logical 0 to logical 1 transition, it generates an event report (if the SEL-651R-2 is not already generating a report that encompasses the new transition). The factory-default setting is:

> ER := **R_TRIG 51P OR R_TRIG 51G1**

The elements in this example setting are:

> 51P Maximum phase current above pickup setting 51PJP or 51PKP for phase time-overcurrent element 51PT (see *Figure 4.16*).

> 51G1 Ground current above pickup setting 51G1JP or 51G1KP for residual ground time-overcurrent element 51G1T (see *Figure 4.22* or *Figure 4.23*).

Note the rising edge operator R_TRIG in front of each of these elements. See *R_TRIG Operator on page 7.5* for more information on rising edge operators and SELOGIC control equations in general.

Rising edge operators are especially useful in generating an event report at fault inception and then generating another later if a breaker failure condition occurs. For example, at the inception of a ground fault, pickup indicator 51G1 asserts and an event report is generated:

> ER := **... OR R_TRIG 51G1 OR ... = logical 1** (for one processing interval)

Even though the 51G1 pickup indicator will remain asserted for the duration of the ground fault, the rising edge operator R_TRIG in front of 51G1 (R_TRIG 51G1) causes setting ER to be asserted for only one processing interval.

Falling edge operators F_TRIG are also used to generate event reports. See *F_TRIG Operator on page 7.6* for more information on falling edge operators.

Page 696 of 1080
Wolfe

12.6 Analyzing Events
Standard 15/30/60-Cycle Event Reports

TRI (Trigger Event Report) and PUL (Pulse Output Contact) Commands

The sole function of the **TRI** serial port command is to generate event reports, primarily for testing purposes.

The **PUL** command asserts the output contacts for testing purposes or for remote control. If output contact OUT101–OUT108, OUT201, or OUT202, asserts via the **PUL** command, the recloser control triggers a standard event report. The **PUL** command is available at the serial port and the recloser control front panel via `MAIN > Control > Output Contacts`.

See *Section 10: Communications* for more information on the **TRI** (Trigger Event Report) and **PUL** (Pulse Output Contact) commands. See *Control Menu on page 11.7* for front-panel-initiated output contact testing.

Back-to-Back Event Report Capability

The SEL-651R-2 is capable of recording successive "back-to-back" event reports for as many as 300 cycles. When back-to-back events are triggered, the relay shortens the prefault portion of the latter event report(s).

Figure 12.1 shows an example of back-to-back event report behavior with factory-default Global settings LER := 15 cycles and PRE := 4 cycles. When the first event report is triggered, the relay records data from 4 cycles before the trigger to 11 cycles after the trigger. An additional event report trigger received during the 15-cycle event report time is ignored. The next event report trigger received after the end of the 11-cycle post-trigger recording period is processed in one of two ways:

➤ If the next trigger processed is within the 4-cycle (PRE) period from the end of the previous event report, the second event report shall contain fewer than 4 cycles of pretrigger data, and the second event report analog data shall be a continuation of the first event report.

➤ If the next trigger is processed beyond the 4-cycle (PRE) period from the end of the previous event report, the second event report shall contain the usual 4 cycles of PRE data, and there will be an unrecorded period between the event reports.

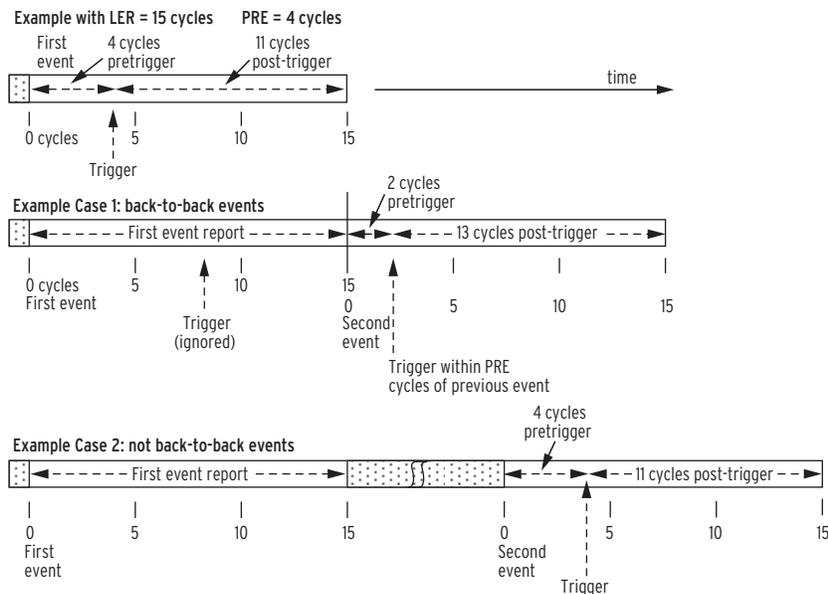
Wolfe


Figure 12.1 Example Behavior for Back-to-Back Event Reports

Event Summaries

Each time the recloser control generates a standard event report, it also generates a corresponding event summary (see *Figure 12.2*). Event summaries contain the following information:

➤ Recloser control and terminal identifiers (settings RID and TID)

➤ Date and time when the event was triggered

➤ Event type

➤ Fault location

➤ Recloser shot count at the trigger row of the event report

➤ System frequency at the start of the event report

➤ Front-panel fault targets at the time of trip

➤ Phase (IA, IB, IC), ground ($I_G = 3I_0$), and negative-sequence ($3I_2$) current magnitudes in amperes primary measured at the largest phase current magnitude in the triggered event report

The recloser control includes the event summary in the standard event report. The identifiers, date, and time information is at the top of the standard event report, and the other information follows at the end. See *Figure 12.8*.

The example event summary in *Figure 12.2* corresponds to the full-length standard 15-cycle event report in *Figure 12.8*.

Attachment to Response to AG-2 Question No. 68(g)
Page 698 of 1080
Wolfe

The recloser control sends event summaries to all serial ports with setting AUTO := Y each time an event triggers.

Event Type

The `Event:` field shows the event type. The possible event types and their descriptions are shown in *Table 12.2*. Note the correspondence to the preceding event report triggering conditions (see *Event Report Triggering on page 12.4*).

Table 12.2   Event Types

Event Type	Description
AG, BG, CG	Single phase-to-ground faults. Appends T if TRIPp[a] asserted.
ABC	Three-phase faults. Appends T if TRIPp[a] asserted.
AB, BC, CA	Phase-to-phase faults. Appends T if TRIPp[a] asserted.
ABG, BCG, CAG	Phase-to-phase-to-ground faults. Appends T if TRIPp[a] asserted.
TRIP	Assertion of Relay Word bit TRIPp[a] (phase involvement is indeterminate, so just TRIP is displayed).
ER	SELOGIC control equation setting ER. Phase involvement is indeterminate.
TRIG	Execution of **TRIGGER** command.
PULSE	Execution of **PULSE** command.

[a] p = A, B, C, or 3P.

The event type designations AG–CAG in *Table 12.2* are only entered in the `Event:` field if the fault type is determined successfully. If the fault type is not determined successfully, just TRIP or ER is displayed.

Fault Location

NOTE: The fault locator will not operate properly unless three-phase voltages are connected.

NOTE: The fault locator is most accurate when the fault currents last longer than two cycles.

The recloser control reports the fault location if the EFLOC setting := Y and the fault locator operates successfully after an event report is generated. If the fault locator does not operate successfully, or if EFLOC := N, $$$$$$ is listed in the field. Fault location is based upon the line impedance settings Z1MAG, Z1ANG, Z0MAG, and Z0ANG; and corresponding line length setting LL (see *Line Length (Group Setting) on page 9.49* and *Line Impedance Conversions (Group Settings) on page 9.50* and *Line Parameter Settings on page SET.10*).

Fault Detector Elements

The fault locator algorithm uses the overcurrent elements 50P1–50P4, 51P, 51A, 51B, 51C, 50G1–50G4, 51G1, 51G2, 50Q1T, 50Q2T, 50Q3T, 50Q4T, and 51Q as fault detectors. If any of these elements are set to low pickup values for use as load indicators, they may be asserted during nonfault conditions. In this situation, even though these elements are not being used for tripping the relay, they may still affect the operation of the fault locator, because the start of the disturbance may be unclear. If load detectors are required in your application, use the highest-numbered instantaneous overcurrent elements 50P5, 50P6, 50N5, 50N6, 50G5, 50G6, 50Q5, or 50Q6, because these are not used by the fault locator algorithm.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 699 of 1080
Analyzing Events 12.9
Standard 15/30/60 Cycle Event Reports
Wolfe

Fault Locator Operating Window

NOTE: Do not use the phase overcurrent elements discussed in Section 4: Protection Functions for load current detection if the fault locator is enabled (setting EFLOC := Y). Set these elements above load current levels, so that the fault locator will work correctly. Use the 50L element instead for load current detection (see Figure 5.6).

NOTE: Do not use the ground- and negative-sequence overcurrent elements discussed in Section 4: Protection Functions for load unbalance current detection if the fault locator is enabled (setting EFLOC := Y). Set these elements above load unbalance current levels so that the fault locator will work correctly.

The SEL-651R-2 uses a 15-cycle subset of the event report data to calculate the event type and fault location. For Global setting LER = 30 and LER = 60, the relay processes the portion of stored data that includes the event report trigger. For LER = 15, the entire event report is available for calculation of the event type and fault location. The relay calculates fault location by using a number of event report rows from the 15-cycle subset. When the fault evolves, the fault location is calculated using rows that represent the predominant fault type.

It is possible for the event type or fault location to be calculated from a different portion of the event report than expected. For example (with default settings), when the event report is first triggered by overcurrent element pickup (ER := R_TRIG 51P OR R_TRIG 51G1), but the trip occurs more than 12 cycles later, the conditions at the time of trip are not considered (unless covered by a new event report). If the fault type changed between pickup and tripping, the event type may not match the front-panel target LEDs. See *Front-Panel Target LEDs on page 5.13* for details on the target LED operation.

Shot Count

NOTE: The SEL-651R-2 uses the trigger row to determine the shot count for event reports. This is different than legacy SEL-651R recloser controls.

When three-phase reclosing is enabled, the SEL-651R-2 reports the reclosing recloser control shot count present at the trigger row of the event report. When single-phase reclosing is enabled, the SEL-651R-2 reports the highest reclosing recloser control shot count present at the trigger row of the event report. When the reclosing recloser control is defeated, the shot count field contains a blank.

Targets

The recloser control reports the targets from the last row of the event report. The targets are displayed in binary format. The order of the binary targets is shown in *Figure 12.3* and *Table 12.3*. See Front-Panel LEDs in *Table 5.3* and *Figure 11.13*.

Currents

The `Currents (A pri), ABCGQ:` field shows the currents present in the event report row containing the maximum phase current. The listed currents are:

Phase (A = channel IA, B = channel IB, C = channel IC)

Ground ($I_G = 3I_0$; calculated from channels IA, IB, and IC; or I_G = channel IN; depending on the state of the GNDSW Relay Word bit in the peak current row. See *Ground Switch Logic on page 4.76*.)

Negative-sequence ($Q = 3I_2$; calculated from channels IA, IB, and IC)

Event History (HIS)

The event history gives you a quick look at recent recloser control activity. The recloser control labels each new event in reverse chronological order with 1 as the most recent event. If the **E** parameter is used with the **HIS** command, the event number is replaced by a unique event identification number from 10000 to 65535 (see *HIS Command (Event Summaries/History) on page 10.54* for details). The unique identifier increments by 1 for each new event. See *Figure 12.4* for a sample event history.

Page 701 of 1080
Wolfe

Analyzing Events 12.11
Standard 15/30/60-Cycle Event Reports

The event history contains the following:

➤ Standard report header

➢ Recloser control and terminal identification

➢ Date and time of report

➤ Event number or unique event identification

➤ Event date and time

➤ Event type

➤ Location of fault (if applicable)

➤ Maximum phase current from summary fault data

➤ Power system frequency at start of event report

➤ Active group at the trigger instant

➤ Reclosing recloser control shot count (same as standard Event Report Summary)

➤ Targets

Figure 12.4 is a sample event history from a terminal.

Unique Event Number | Event Number | Event Type | Maximum Current | Active Settings Group | Shot Count | Target LEDs (See Table 12.3 and Figure 12.3)

Figure 12.4 Sample Event History

Fault location data can be indeterminate (for example, when you trigger an event and there is no fault on the power system). If this is the case, the recloser control displays $$$$.$$ for the location entry in the event history. The SEL-651R-2 also displays $$$$.$$ if the fault location enable setting EFLOC := N.

The event types in the event history are the same as the event types in the event summary. See *Table 12.2* for event types.

Viewing the Event History

Access the history report from the communications ports or the Human Machine Interface. View and download history reports from Access Level 1 and higher. You can also clear or reset history data from Access Levels 1 and higher. Clear/reset history data at any communications port.

12.12 | *Analyzing Events*
Standard 15/30/60-Cycle Event Reports

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 702 of 1080
Wolfe

Use the **HIS** command from a terminal to obtain the event history. You can specify the number of the most recent events that the recloser control returns. See *HIS Command (Event Summaries/History) on page 10.54* for information on the **HIS** command.

Use the front-panel `MAIN > Events > Display Events` menu to display event history data on the SEL-651R-2 LCD (see *Figure 11.5*).

Use the QuickSet software to retrieve the recloser control event history. View the Recloser Control Event History dialog box via the **Analysis > Get Event Files** menu (see *QuickSet Event Analysis on page 3.18*).

Clearing Standard Event Report Buffer

Via SEL ASCII

The **HIS C** command clears the event summaries and corresponding standard event reports from nonvolatile memory. The **HIS C** command does not reset the unique event identification number to 10000. See *Section 10: Communications* for more information on the **HIS** (Event Summaries/History) command.

Via DNP or Modbus

The DNP binary output DRST_HIS can be used to reset the event summaries and corresponding standard event reports from nonvolatile memory, and is similar in function to the **HIS C** command. See *Appendix E: DNP3 Communications* for more details.

The Modbus protocol can be used to reset the event summaries and corresponding standard event reports from nonvolatile memory, with functions similar to the **HIS C** command. Two methods are available:

➤ Writing to the Reset History Data output coil.

➤ Writing a specific analog value to the RSTDAT register.

See *Appendix K: Modbus RTU and TCP Communications* for details.

Reset Via SELOGIC Control Equation

The Global setting RST_HIS SELOGIC control equation setting can be used to reset the event summaries and corresponding standard event reports from nonvolatile memory. The relay resets the function when the setting first asserts (rising edge, e.g., a logical 0 to a logical 1 transition).

Accessing Event Reports

The relay generates event reports to display analog data, digital data, and relay settings. The event reports provide a complete description of the data that the relay recorded in response to an event trigger. The standard event reports in the SEL-651R-2 can be retrieved in the following formats:

➤ COMTRADE File Format Reports

➤ ASCII Format Report

  ➢ Event Reports (EVE)

  ➢ Compressed Event Reports (CEV)

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 703 of 1080
Standard 15/30/60-Cycle Event Reports
Wolfe
Analyzing Events 12.13

Use a terminal or SEL-supplied PC software to retrieve event report files stored in the relay and transfer these files to your computer. Both QuickSet and Analytic Assistant read the compressed and binary event files that the relay generates for an event. See *QuickSet Event Analysis on page 3.18* for instructions on viewing event report oscillography with QuickSet.

COMTRADE File Format Event Reports

The SEL-651R-2 stores high-resolution raw data oscillography in binary format and uses COMTRADE file types to output these data:

➤ .HDR—header file

➤ .CFG—configuration file

➤ .DAT—high-resolution raw data file

The .HDR file contains summary information about the event in ASCII format. The .CFG file is an ASCII configuration file that describes the layout of the .DAT file. The .DAT file is in binary format and contains the values for each input channel for each sample in the record. These data conform to the IEEE C37.111-1999 COMTRADE standard.

.HDR File

The .HDR file contains the summary and relay settings (comma-delimited) information that appears in the event report for the data capture (see *HIF Event Summary on page 12.48*). *Figure 12.5* shows a sample COMTRADE .HDR file.

SAM/CYC_INPUTS = 16
```

Figure 12.5   Sample COMTRADE .HDR Header File

.CFG File

The .CFG file contains data that are used to reconstruct the input signals to the relay and status of Relay Word bits during the event report (see *Figure 12.6*). A <CR><LF> follows each line. If control inputs or control outputs are not available because of board loading and configuration, the relay does not report these inputs and outputs in the analog and digital sections of the .CFG file.

```

[1] scale_factor is the value used to convert the equivalent channel analog data in the DAT file to primary units (A or kV peak-to-peak).

[2] rwb_label will be replaced with Relay Word bit labels as seen in Table F.1.

[3] Place holders denoted by asterisk (*), will be labeled as UNUSEDxxx (where xxx is the number of the associated label).

[4] nnnn = number of the last Relay Word bit.

Figure 12.6   Sample COMTRADE .CFG Configuration File Data

The configuration file has the following format:

➤ Station name, device identification, COMTRADE standard year

➤ Number and type of channels

➤ Channel name units and conversion factors

➤ Digital relay word bit names

➤ System frequency

➤ Sample rate and number of samples

➤ Date and time of first data point

➤ Date and time of trigger point

➤ Data file type

➤ Time stamp multiplication factor

.DAT File

The .DAT file follows the COMTRADE binary standard. The format of the binary data files is sample number, time stamp, data value for each analog channel, and digital channel status data for each sample in the file. There are no data separators or carriage return/line feed characters in the binary file. The sequential position of the data in the binary file determines the data translation. Refer to the *IEEE Standard Common Format for Transient Data Exchange (COMTRADE) for Power Systems, IEEE C37.111–1999* for more information. Many programs read the binary COMTRADE files. These programs include Analytic Assistant and QuickSet.

Page 705 of 1080
Analyzing Events 12.15
Standard 15/30/60-Cycle Event Reports
Wolfe

Retrieving COMTRADE Event Files

COMTRADE files are available as read-only files that can be retrieved using the **FILE** command and Ymodem file transfer, Ethernet File Transfer Protocol (FTP), or Manufacturing Messaging Specification (MMS). MMS is only available in models that support IEC 61850 and only when IEC 61850 is enabled (E61850 = Y). See *FIL Command on page 10.49*, *File Transfer Protocol (FTP) and MMS File Transfer on page 10.17*, and *MMS on page L.4* for additional information. You can also use QuickSet (see *QuickSet Event Analysis on page 3.18*).

ASCII Event Reports

The latest event reports are stored in nonvolatile memory. Each event report includes five sections:

➤ Analog values of current, voltage, and frequency, and digital states of the various trip, close, 52A_, and ground switch Relay Word bits (**EVE** command option A).

➤ Digital states of the Protection and Control elements, including overcurrent, voltage, synchronism check, and frequency elements, plus reclosing recloser control status and digital output and input states (**EVE** command option D).

➤ Digital states of the MIRRORED BITS, Communications, and Automation Elements, including power elements, and operator control pushbutton status (**EVE** command option M).

➤ Event Summary.

➤ Recloser Control Settings in service at the time of event trigger, consisting of Group, Logic, Global, and Report settings classes.

NOTE: Use the **HIS** command to obtain a brief listing of all of the event reports in nonvolatile memory, including the event number "n" (see HIS Command (Event Summaries/History) on page 10.54).

Use the **EVE** command to retrieve the reports. There are several options to customize the report format. The general command format is:

EVE [*n* S*x* L*y* L R P A D V C M]

where:

    n Event number (1–number of events stored) or unique event identifier (10000–65535). Defaults to 1 if not listed, where 1 is the most recent event.

    S*x* Display *x* samples per cycle (4, 16, 32, or 128), defaults to 4 if not listed. If S*x* parameter is present, it overrides the L parameter. S128 is available as unfiltered (raw) data only and thus must be accompanied by the R parameter (EVE S128 R).

    L*y* Display *y* cycles of data (1–LER). Defaults to LER value if not listed. Unfiltered reports (R parameter) display one extra cycle of data, and S128 unfiltered reports display two extra cycles of data.

    L Display 32 samples per cycle; same as the S32 parameter.

    R Specifies the unfiltered (raw) event report. Defaults to 32 samples per cycle unless overridden with the S*x* parameter.

    A Specifies that only the analog section of the event is displayed.

    D Specifies that only the digital section (Protection and Control Elements) of the event is displayed.

    V Specifies variable scaling for analog values.

    C Display the report in Compressed ASCII format. Defaults to 1/16-cycle analog and 1/4-cycle digital resolution.

12.16 Analyzing Events
Standard 15/30/60-Cycle Event Reports

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 706 of 1080
Wolfe

where:

M	Specifies only the MIRRORED BITS, Communication, and Automation Elements section of the event is displayed.
P	Precise to synchrophasor level accuracy for signal content at nominal frequency. This option is available only for events triggered when TSOK = logical 1. The P option implies R as only raw analog data are available with this accuracy. When M or D are specified with P, then the P option is ignored because it only pertains to analog data.

Below are **EVE** command examples:

NOTE: SEL-651R-2 ASCII event reports (**EVE** command) will not display properly in Analytic Assistant. When retrieving events for use with PC software, use the Compressed ASCII **CEV** command.

NOTE: **EVE** options have no specific order (e.g., **EVE 2 D** functions the same as **EVE D 2**).

Serial Port Command	Description
EVE	Display the most recent event report at 1/4-cycle resolution (analog and digital).
EVE 2	Display the second event report at 1/4-cycle resolution.
EVE S32 L10	Display 10 cycles of the most recent report at 1/32-cycle resolution.
EVE C 2	Display the second report in Compressed ASCII format at 1/16-cycle resolution.
EVE L	Display most recent report at 1/32-cycle resolution.
EVE S128 R	Display most recent report at 1/128-cycle resolution; analog data are unfiltered (raw).
EVE 2 D L10	Display 10 cycles of the protection and control elements section of the second event report at 1/4-cycle resolution.
EVE 2 A R S4 V	Display the unfiltered analog section of the second event report at 1/4-cycle resolution, with variable scaling of the analog values.

If an event report is requested that does not exist, the recloser control responds:

```
Invalid Event
```

Standard EVE Report Column Definitions

Refer to the example event report in *Figure 12.8* to view event report columns. This example event report displays rows of information each 1/4 cycle and was retrieved with the **EVE** command.

NOTE: Figure 12.8 is on multiple pages.

The columns contain ac current, ac voltage, frequency, output, input, and protection and control element information.

Current, Voltage, and Frequency Columns. *Table 12.4* summarizes the event report current, voltage, and frequency columns.

Table 12.4 Standard Event Report Current, Voltage, and Frequency Columns (Sheet 1 of 2)

Column Heading	Definition
IA	Current measured by channel IA[a] (primary A)
IB	Current measured by channel IB[a] (primary A)
IC	Current measured by channel IC[a] (primary A)

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 707 of 1080
Analyzing Events 12.17
Standard 15/30/60-Cycle Event Reports
Wolfe

Table 12.4   Standard Event Report Current, Voltage, and Frequency Columns (Sheet 2 of 2)

Column Heading	Definition
IG	Ground current IG = 3I0; calculated from channels IA, IB, and IC when Relay Word bit GNDSW = logical 0; or IG = channel IN; when GNDSW = logical 1 (primary A)
VAY	Voltage measured on Y-terminal, A-phase[b] (primary kV)
VBY	Voltage measured on Y-terminal, B-phase[b] (primary kV)
VCY	Voltage measured on Y-terminal, C-phase[b] (primary kV)
VAZ	Voltage measured on Z-terminal, A-phase[b] (primary kV)
VBZ	Voltage measured on Z-terminal, B-phase[b] (primary kV)
VCZ	Voltage measured on Z-terminal, C-phase[b] (primary kV)
Freq[c]	Frequency measured on VY terminals when FSELECT := VY or OFF, VZ terminals when FSELECT := VZ
DT[d]	Difference time referenced to previous row (microseconds)

[a] Global setting IPCONN determines the current phase assignment (see Table 9.8).
[b] Global settings VYCONN or VZCONN determine the voltage phase assignment (see Table 9.9).
[c] Not available with P parameter.
[d] Only available with P parameter (see Synchrophasor-Level Accuracy in Event Reports on page 12.31).

Note that the ac values change from plus to minus (–) values in *Figure 12.8*, indicating the sinusoidal nature of the waveforms.

Other figures help in understanding the information available in the event report current columns:

Figure 12.9 shows how event report current column data relate to the actual sampled current waveform and rms current values.

Figure 12.10 shows how event report current column data can be converted to phasor rms current values.

Variable Scaling for Analog Values.   The following example shows the difference between two cycles of the analog values of an event report without variable scaling (command **EVE**) and with variable scaling (command **EVE V**). Variable scaling event reports display data for currents less than 10 A with two decimal places and data for voltages less than 10 kV with three decimal places.

Example without variable scaling (**EVE**):

```
 =>EVE <Enter>

Output, Input, and Protection, and Control Columns.

Table 12.5 summarizes the event report output, input, protection and control columns. See *Table F.1* and *Table F.2* for more information on Relay Word bits shown in *Table 12.5*.

Table 12.5   Output, Input, and Protection, and Control Element Event Report Columns (Sheet 1 of 14)

Column Heading	Corresponding Elements (Relay Word Bits)	Symbol	Definition
All columns		•	Element/input/output not picked up or not asserted, unless otherwise stated
TR	TRIP3P	*	Trip (TRIP3P asserted)
	TRIPA	A	A-phase trip (TRIPA asserted)
	TRIPB	B	B-phase trip (TRIPB asserted)
	TRIPC	C	C-phase trip (TRIPC asserted)
		a	A and B-phase trip (TRIPA and TRIPB asserted)
		b	B and C-phase trip (TRIPB and TRIPC asserted)
		c	C and A-phase trip (TRIPC and TRIPA asserted)
		3	Three-phase trip (TRIPA, TRIPB, and TRIPC asserted)
CL	CLOSE3P	*	Close (CLOSE3P asserted)
	CLOSEA	A	A-phase close (CLOSEA asserted)
	CLOSEB	B	B-phase close (CLOSEB asserted)
	CLOSEC	C	C-phase close (CLOSEC asserted)
		a	A and B-phase close (CLOSEA and CLOSEB asserted)
		b	B and C-phase close (CLOSEB and CLOSEC asserted)
		c	C and A-phase close (CLOSEC and CLOSEA asserted)
		3	Three-phase close (CLOSEA, CLOSEB, and CLOSEC asserted)

NOTE: TRIP3P is only available when Group setting ESPB := N.

NOTE: TRIPA, TRIPB, and TRIPC are only available when Group setting ESPB := Y.

NOTE: CLOSE3P is only available when Group setting ESPB := N.

NOTE: CLOSEA, CLOSEB, and CLOSEC are only available when Group setting ESPB := Y.

Compressed ASCII Event Reports, Event Summaries, and History

NOTE: Compressed event reports contain analog data from the IN channel, in addition to the IG quantity. (Regular ASCII event reports do not include a separate IN column.)

The SEL-651R-2 provides Compressed ASCII event reports to facilitate event report storage and display. SEL communications processors, QuickSet, and Analytic Assistant take advantage of the Compressed ASCII format. Use the **CHIS** command to display Compressed ASCII event history information. Use the **CSUM** command to display Compressed ASCII event summary information. Use the **EVE C** command or **CEVENT** command to display Compressed ASCII event reports.

NOTE: Compressed ASCII Event Reports contain all of the Relay Word bits and automatic variable analog scaling and are easily analyzed using no-cost software. Regular, uncompressed event reports only contain a subset of the Relay Word bits, do not have automatic variable scaling, and are not fully supported by software. SEL recommends that you use compressed event reports for all event analysis.

See the Compressed ASCII commands in *Appendix C: Compressed ASCII Commands* for further information. You can also use the **Tools > Events > Get Events** menu in QuickSet to collect events.

Use of Compressed ASCII event reports is the preferred means for retrieving event data because the machine-readable format allows the use of time-saving software. Standard ASCII event reports are best suited for rapid analysis, and for situations where only a portion of the event data is under study.

Synchrophasor-Level Accuracy in Event Reports

The SEL-651R-2 provides the option to display event report data aligned to a high-accuracy time source by adding the P parameter. The header indicates the availability of a high-accuracy time source by displaying the status of Relay Word bit TSOK. The `Time:` value in the header includes three additional digits. These represent 100 μs, 10 μs, and 1 μs. The `Time:` value contains the time stamp of the analog value associated with the trigger point.

Furthermore, the `FREQ` column in the analog section of the report is replaced by a `DT` column. DT means "difference time." It represents the difference time in units of microseconds from another row. The trigger point shall have a DT value of 0000 because the trigger time corresponds to the time displayed in the event report header. The DT value for rows preceding the trigger point is referenced to the following row (so they increment backwards in time). The DT value for rows following the trigger point is referenced to the previous row (so they increment forward in time). If TSOK = logical 0, this event report display option is not available.

Figure 12.7 shows how an event report is modified with the P parameter. Because event report information is stored at a sample rate that depends on the power system frequency, the DT data show a minimally changing number when the power system frequency is stable. If the power system frequency changes during the event reporting window and the relay is connected to a voltage reference, the sample rate may vary during the event report and the DT values may vary accordingly.

Figure 12.7 Example Synchrophasor−Level Precise Event Report 1/32-Cycle Resolution

Example 15-Cycle Event Report

The following example standard 15-cycle event report in *Figure 12.8* also corresponds to the example SER report in *Figure 12.11*. The circled numbers in *Figure 12.8* correspond to the SER row numbers in *Figure 12.11*. The row explanations follow *Figure 12.11*.

In *Figure 12.8*, the arrow (>) in the column following the Freq column identifies the "trigger" row. This is the row that corresponds to the Date and Time values at the top of the event report.

The asterisk (*) in the column following the Freq column identifies the row with the maximum phase current. The maximum phase current is calculated from the row identified with the asterisk and the row one quarter-cycle previous (see *Figure 12.9* and *Figure 12.10*). These currents are listed at the end of the event report in the

Attachment to Response to AG-2 Question No. 68(g)
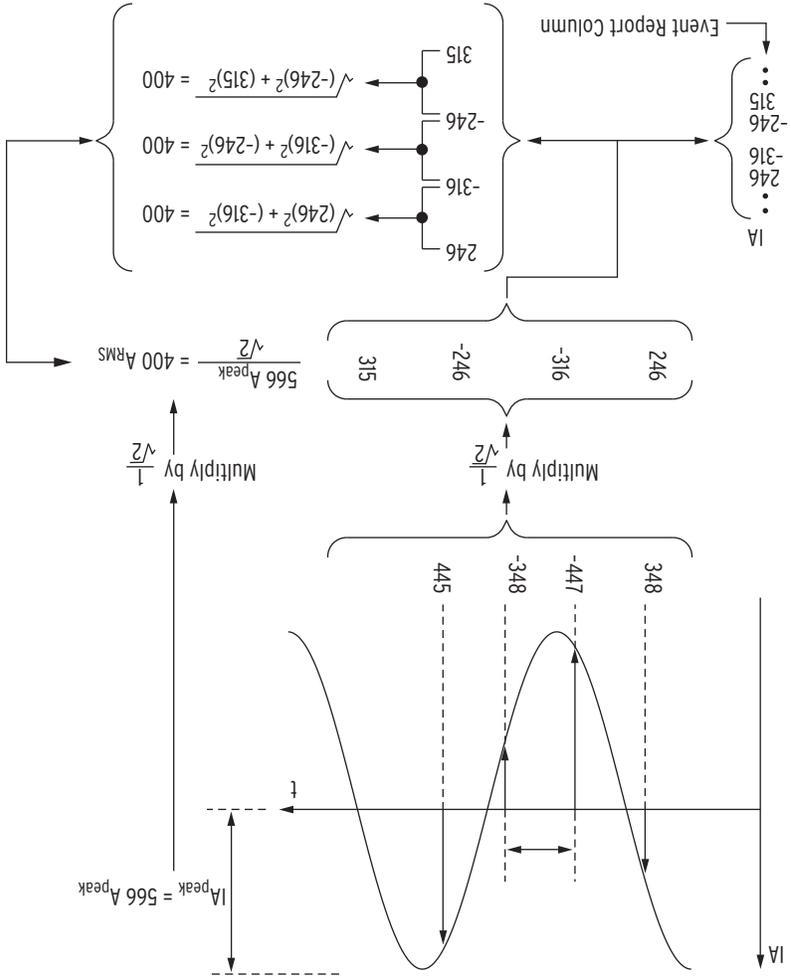
Page 728 of 1080
Wolfe

NOTE: The arctan function of many calculators and computing programs does not return the correct angle for the second and third quadrants (when X is negative). When in doubt, graph the X and Y quantities to confirm that the angle that your calculator reports is correct.


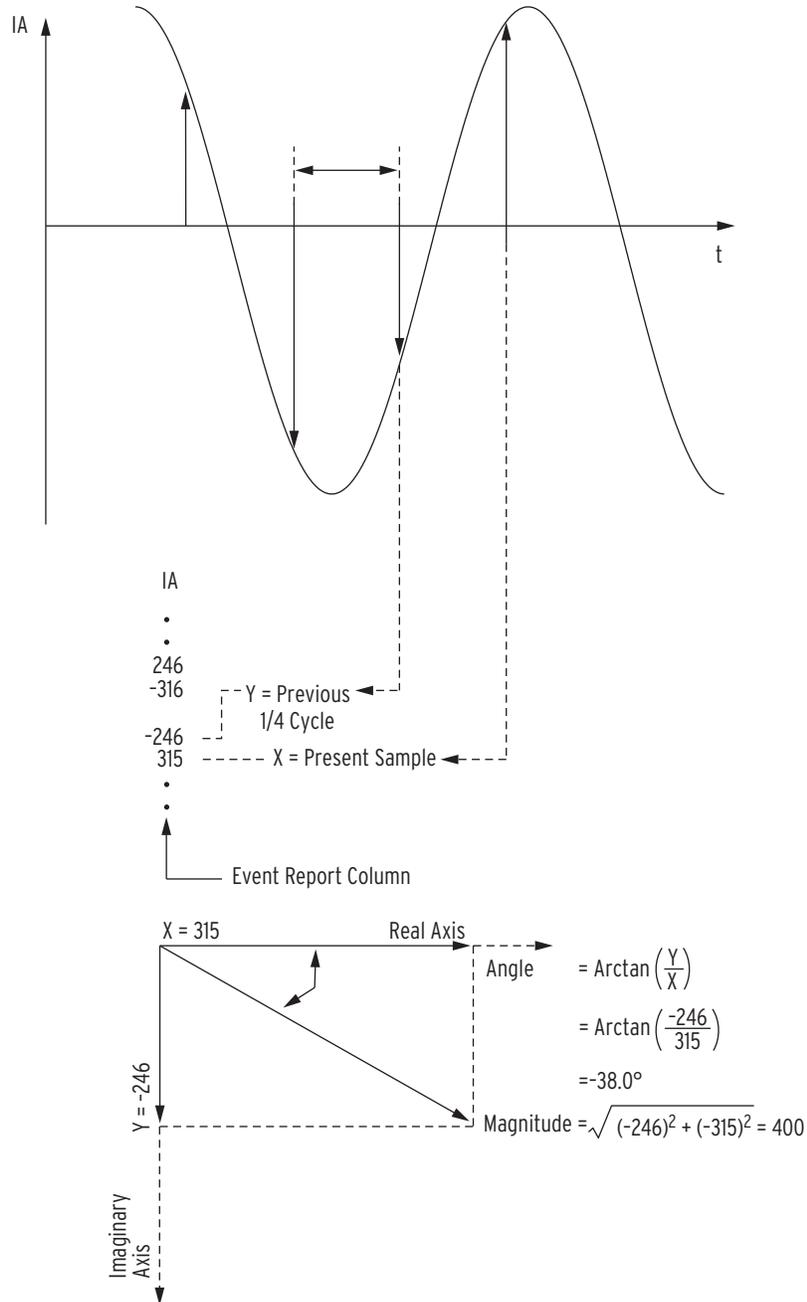


Figure 12.10   Derivation of Phasor RMS Current Values From Event Report Current Values

In *Figure 12.10*, note that two rows of current data from the event report in *Figure 12.8*, 1/4 cycle apart, can be used to calculate phasor rms current values. In *Figure 12.10*, at the present sample, the phasor rms current value is:

$$IA \ = \ 400 \text{ A} \ \angle -38.0°$$

Equation 12.1

The present sample (IA = 315 A) is a real rms current value that relates to the phasor rms current value:

$$400 \text{ A} * \cos(-38.0°) \ = \ 315 \text{ A}$$

Equation 12.2

Sequential Events Recorder (SER) Report
Wolfe

Sequential Events Recorder (SER) Report

See *Figure 12.11* for an example SER report.

SER Triggering

The recloser control triggers (generates) an entry in the SER report for a change of state of any one of the elements listed in the SER1, SER2, SER3, and SER4 trigger settings. The factory-default settings are:

SER1 := **TRIP3P, 51P, 51PT, 51G1, 51G1T, PB12_PUL, OC3**

SER2 := **CLOSE3P, 52A3P, CF3P, 79RS3P, 79CY3P, 79LO3P, RCSF3P, SHO3P, SH13P, SH23P, SH33P, SH43P, PB11_PUL, CC3**

SER3 := **PWR_SRC1, TOSLP, BTFAIL, DTFAIL**

SER4 := **0**

The elements are Relay Word bits referenced in *Table F.1*. The recloser control monitors each element in the SER lists every 1/4 cycle. If an element changes state, the recloser control time-tags the changes in the SER. For example, setting SER1 contains:

➤ Ground time-overcurrent element picked-up status (51G1)

➤ Ground time-overcurrent element timed-out status (51G1T)

If a ground fault occurs, the 51G1 element will assert and the change will be time-tagged in the SER (shown as `51G1 Asserted`). If the fault clears before the ground time-overcurrent element times-out (indicating that a load-side device or another element operated to clear the fault), the 51G1 element deassertion is time-tagged in the SER (shown as `51G1 Deasserted`).

If the ground fault did not get cleared by another device, then the 51G1T element would have asserted, and this state change would also appear in the SER (51G1T Asserted).

In addition to the programmable SER trigger lists, the recloser control adds preprogrammed messages to the SER for certain occurrences, as shown in *Table 12.6*.

Table 12.6   Automatic SER Triggers

Event	SER Entry[a]	Reference
Recloser control powered up after being shut off	`Relay restarted`	*Section 9: Settings*
Recloser control settings changed (except port settings)	`Settings changed`	*Section 9: Settings*, *Appendix L: IEC 61850*
Active settings group changed	`Group changed`	*Section 7: SELOGIC Control Equation Programming*
SER C command issued	`SER archive cleared`	*Clearing SER Report on page 12.40*
Start of SER data loss	`SER data loss begin`	*SER Memory Operation on page 12.40*
End of SER data loss	`SER data loss end`	
Invalid SER data	`Invalid Data`	
Data overwritten while recloser control is responding to **SER** command	`Command aborted, data overwrite occurred`	
Diagnostic restart	`Diagnostic restart`	*Section 13: Testing and Troubleshooting*
Recloser control shuts down while running on batteries	`Going to sleep`	*Section 13: Testing and Troubleshooting*

[a] Each entry in the SER except `Invalid Data` and `Command aborted, data overwrite` occurred includes a date and time stamp.

Wolfe

Making SER Trigger Settings

Enter as many as 24 element names in each of the SER settings via the **SET R** command. See *Table F.1* for references to valid recloser control element (Relay Word bit) names. See the **SET R** command in *Table 9.2* and corresponding *Report Settings on page SET.64*. Use commas to delimit the elements. For example, if you enter setting SER1 as:

SER1 := **51P,51G1,51PT,,51G1T , 50P1, , 50P2**

The recloser control displays the setting as:

```
SER1 := 51P,51G1,51PT,51G1T,50P1,50P2
```

The recloser control can monitor as many as 96 elements in the SER (24 in each of SER1, SER2, SER3, and SER4).

Make SER Settings With Care

The recloser control triggers a row in the SER report for any change of state in any one of the elements listed in the SER1, SER2, SER3, or SER4 trigger settings. Nonvolatile memory is used to store the latest 1024 rows of the SER report so they can be retained during power loss. The nonvolatile memory is rated for a finite number of write cycles. Exceeding the limit can result in a FLASH self-test failure. *An average of one (1) state change every three minutes can be made for a 25-year recloser control service life.*

Retrieving SER Reports

See *SER Command (Sequential Events Recorder Report) on page 10.67* for details on the **SER** command.

Clearing SER Report

NOTE: If any elements change state during the clearing process, the SER entries for these elements may be reported with time stamps that are prior to the `SER archive cleared` message.

Clear the SER report from nonvolatile memory with the **SER C** command as shown in the following example:

```
=>SER C <Enter>
Clear the SER
Are you sure (Y/N) ? Y <Enter>
Clearing Complete
```

To indicate when the SER memory was cleared, an entry is added to the SER as shown in *Table 12.6*.

SER Memory Operation

The Sequential Events Recorder (SER) nonvolatile memory is updated soon after new SER data are generated. During some conditions, such as during event report capture, the update of SER data is momentarily interrupted, and then SER updating of nonvolatile memory resumes.

In rare cases with rapidly occurring SER triggers, the new SER information may arrive faster than the memory system can store it. When this occurs, the relay inserts a pair of entries in the SER to indicate the start and end of data loss, as shown in *Table 12.6*. This is normally seen only during testing. Normal SER operation resumes after the data loss.

Another situation that can affect SER data storage is when the power supply to the SEL-651R-2 is interrupted while data are being recorded. If this results in incomplete data, the **SER** command may report `Invalid Data` for the incomplete entry, as shown in *Table 12.6*. Normal SER operation resumes after the relay is powered up.

Example SER Report

The following example SER report in *Figure 12.11* also corresponds to the example standard 15-cycle event report in *Figure 12.8*.

Figure 12.11   Example SER Report

The SER report rows in *Figure 12.11* are explained in *Table 12.7*, numbered in correspondence to the # column. The circled comments in *Figure 12.8* also correspond to the # column numbers in *Figure 12.11*. The SER report in *Figure 12.11* contains records of events that occurred before and after the standard event report in *Figure 12.8*.

Table 12.7   Example SER Detailed Description[a]

SER Row No.	Explanation
22–20	SEL-651R-2 powered up.[b]
19–14	Reclosing relay initialization after turning on.
13	Ground #1 time-overcurrent element pickup (51G1). Starts timing at fault inception.
12	Maximum-phase time overcurrent element pickup (51P). Also starts timing.
11–8	Ground #1 time-overcurrent element times out (51G1T) and asserts trip logic (TRIP3P). Reclosing relay goes into the lockout state. Lockout occurs because **Reclose Enabled** operator control (= LT02) is deasserted.
7–6	Reclosing relay shot counter moves to last shot.
5–4	Time overcurrent elements drop out (51P and 51G1) as recloser contacts interrupt the fault current.
3	Recloser status change—52A3P registers as open.
2	Ground #1 time-overcurrent element completes 1-cycle reset interval (51G1T deasserts).
1	Trip logic drops out.

[a] Corresponds to Figure 12.13.
[b] The date is a few months before the event report in Figure 12.8.

Wolfe

Sag/Swell/Interruption (SSI) Report

See *Figure 12.12* for an example SSI report.

SSI Triggering and Recording

NOTE: SSI is not available on models ordered with a single voltage input.

The SEL-651R-2 can perform automatic voltage disturbance monitoring for three-phase systems. The SSI Recorder uses the SSI Relay Word bits to determine when to start (trigger) and when to stop recording. The recorded data are available through the SSI Report.

See *Voltage Sag, Swell, and Interruption Elements on page 4.59* for details on the operation of the SSI Relay Word bits.

The SSI recorder operates (adds new entries to the stored SSI report) only when Group setting ESSI := Y in the active settings group, although the SSI report can be viewed at any time.

The SSI recorder uses nonvolatile memory, so any stored SSI data will not be erased by de-energizing the recloser control. The recloser control needs some time to store new SSI data in nonvolatile memory, so if a system power outage also causes the recloser control power to fail, there may not be an SSI record of the disturbance. The battery system in the SEL-651R-2 will normally keep the recloser control operating through any voltage disturbances.

The recloser control triggers (generates) entries in the SSI report upon the assertion of any sag, swell, or interruption element (Relay Word bits SAGp, SWp, INTp, where p = A, B, or C), when manually triggered by the **SSI T** command or when the SSI_TRIG SELOGIC control equation solves to logical 1. See *Voltage Sag/Swell/Interrupt on page SET.33* for the SSI_TRIG equation.

SSI Report Entries

➤ Entry number (1 is the most recent entry)

➤ Date and time stamp of entry

➤ Phase current magnitudes (Ia, Ib, Ic) as a percentage of the nominal current rating of the phase current inputs (1 A)

➤ Ground current magnitude (Ig) as a percentage of the nominal current rating of the phase current inputs (1 A)

GLOBAL SETTING EGNDSW
See Ground Switch Logic on page 4.76.

Note: When Global setting EGNDSW := Y, the Ig percentage magnitude is based on channel IN data for small signals when Relay Word bit GNDSW is asserted. The percentage value displayed will be 1/5 of the displayed In percentage value, because of the difference in nominal channel ratings; the 1 A phase channel nominal rating is five times the 0.2 A nominal neutral channel rating.

For large signals, the Ig quantity is based on a calculated residual zero-sequence current 3I0 = IA + IB + IC when Relay Word bit GNDSW is deasserted. When Global setting EGNDSW := N, Ig is always based on the calculated 3I0 quantity.

➤ Neutral current magnitude (In) as a percentage of the nominal current rating of the neutral current input (0.2 A)

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 733 of 1080
Wolfe

Analyzing Events 12.43
Sag/Swell/Interruption (SSI) Report

➤ Phase-neutral voltage magnitudes (Va, Vb, Vc) as a percentage of Vbase

Global setting VSELECT determines which input terminals are monitored by the SSI elements, as shown in the SSI report. For example, if VSELECT := VZ, quantities VAZ, VBZ, and VCZ are reported. The other three voltage quantities (VAY, VBY, and VCY) have no effect on the SSI elements or the SSI report.

➤ Base voltage magnitude (Vbase) in kV primary
Vbase = memorized positive-sequence voltage, V_1

➤ Phase A, B, and C SSI element status columns (see *Table 12.8)*

➤ Trigger state, ⋆ if present (in the column marked S)

➤ SSI recorder status (see *Table 12.9*)

NOTE: Any current or voltage value greater than 999 percent will be replaced by "$$$" in the SSI report.

Table 12.8   SSI Element Status Columns

Symbol	Meaning (for Each Column A, B, or C)
	Column A represents p = A Column B represents p = B Column C represents p = C
•	No SSI bits asserted for phase p
O	Overvoltage (SWp asserted)
U	Undervoltage (SAGp asserted)
I	Interruption (INTp asserted; SAGp asserted, unless setting VSAG := OFF)

Table 12.9   Recorder Status Column

Symbol	Meaning (Action)	Duration
R	Ready (when the SSI logic first acquires a valid V_{BASE} value)	Single entry
P	Predisturbance (4 samples per cycle). Always signifies a new disturbance.	12 samples (3 cycles)
F	Fast recording mode (4 samples per cycle)	Varies. At least one SSI element must be asserted.
E	End (post-disturbance at 4 samples per cycle)	As long as 16 samples (4 cycles). No SSI elements asserted.
M	Medium recording mode (one sample per cycle)	Maximum of 176 cycles
S	Slow recording mode (one sample per 64 cycles)	Maximum of 4096 cycles
D	Daily recording mode (one sample per day, just after midnight)	Indefinite
X	Data overflow (single entry that indicates that data were lost prior to the present entry)	Single entry

See *Figure 12.12* for an example SSI report.

SSI Recorder Operation: Overview

The SSI recorder operation can be summarized as follows: When power is first applied to the recloser control and setting ESSI := Y, (or setting ESSI is changed from N to Y), the recloser control measures the voltage inputs specified by Global setting VSELECT to determine if a valid three-phase signal is present. When the conditions are satisfied for at least twelve seconds,

12.44 | Analyzing Events
Sag/Swell/Interruption (SSI) Report

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 734 of 1080
Wolfe

the positive-sequence voltage, V_1, is memorized as the Vbase reference voltage. This causes a single R entry to be placed in the SSI archive, which indicates that the recorder is armed, or ready. The Vbase value is allowed to change on a gradual basis to follow normal system voltage variations, but is locked when a disturbance occurs.

When any SSI Relay Word Bit asserts, the SSI_TRIG SELOGIC control equation is asserted, or the **SSI T** serial port command is issued, the recorder will begin recording.

When operating, the SSI Recorder archives the following information:

➤ Currents Ia, Ib, Ic, Ig, and In as a percentage of the nominal current rating (shown in the report heading)

➤ Voltages Va, Vb, and Vc as a percentage of the Vbase quantity

➤ The Vbase quantity in kV primary

➤ The state of the SSI Relay Word bits by phase

➤ The trigger status

➤ The recorder status

Entries are made at a varying recording rate: fastest when the SSI Relay Word bits are changing states, and slowest if the SSI Relay Word bits are quiet. Eventually, it can get as slow as one sample per day. The faster recording mode will be initiated from any of the slower recording modes, as soon as any SSI bit or the **SSI T** condition changes state.

Recording is stopped when all SSI Relay Word bits and the trigger condition stay deasserted for at least four cycles.

The Group setting SSI_TRIG is a SELOGIC control equation that can be used to force the SSI recorder to trigger, regardless of the applied voltages, provided that the recorder was previously armed. The SSI_TRIG setting is treated the same as a Sag/Swell/Interruption Relay Word bit. An example application is to set SSI_TRIG := PB08_PUL for testing purposes. When the Operator Control pushbutton **AUX 1** is pressed, the SSI recorder would act as if the **SSI T** command was issued (see *Table 11.9*).

Make SSI_TRIG Setting With Care

Take care to set the SSI_TRIG equation so that it does not constantly assert and deassert, because the resulting stream of SSI triggers causes excessive data recording. Excessive recording reduces the usefulness of the SSI report for actual power system disturbance analysis because real disturbance data could be overwritten before an operator could retrieve the information. Additionally, because the SSI data are stored in nonvolatile memory that is rated for a finite number of write cycles, constant SSI triggering could lead to a FLASH self-test failure and a reduction in the recloser control service life.

Analyzing Events   12.45
Sag/Swell/Interruption (SSI) Report

SSI Recorder Operation: Detailed Description

From the SSI Recorder Ready state, upon the initial assertion of one of the SSI Relay Word bits or a manual trigger condition, the recloser control records SSI data in the following sequence:

➤ **Predisturbance recording:** Record pretrigger entries at ¼-cycle intervals with the SSI recorder status field displaying P. Because no SSI elements are asserted, columns A, B, and C display "." (a period). The predisturbance state lasts for a total of 12 samples, or 3 cycles, unless there are back-to-back disturbances that reduce the number of P entries.

➤ **Fast recording (also End recording):** Record one entry every ¼-cycle, with the SSI recorder status field displaying F (if any SSI elements are asserted or the trigger condition is asserted), or E (if none of the SSI elements are asserted). If the trigger condition is present, a * is recorded. The SSI element status columns show one of ., 0, U, I. The Fast/End recording mode continues until four cycles elapse with no SSI element or trigger condition changing state. The recloser control then proceeds to the state determined by the following tests (processed in the order shown):

  ➤ If INT3P is asserted, switch to daily recording mode. This keeps the recloser control from recording medium and slow speed detailed information during a complete outage.

  ➤ Otherwise, if any SSI elements or the SSI_TRIG setting are asserted, switch to the medium recording mode.

  ➤ Otherwise, stop recording.

➤ **Medium recording:** Record one entry per cycle, with the SSI recorder status field displaying M. The phase columns show one of ., 0, U, I. The medium recording mode continues for 176 cycles, unless one of the SSI elements or the trigger condition changes state, which causes the recorder to start over in Fast mode (with as many as three samples prior to the change). At the end of medium recording mode, the recorder switches to the slow recording mode.

➤ **Slow recording:** Record one entry every 64 cycles, with the SSI recorder status field displaying S. The phase columns show one of ., 0, U, I. The slow recording mode continues for 4,096 cycles (64 entries), unless one of the SSI elements or the manual trigger condition changes state, which causes the recorder to start over in fast mode (with as many as eight samples prior to the change). At the end of slow recording mode, the recorder switches to the daily recording mode.

➤ **Daily recording:** Record one entry every day just past midnight (00:00:00), with the SSI recorder status field displaying D. The phase columns show one of ., 0, U, I. The daily recording mode continues until any SSI relay element or the manual trigger condition changes state, which causes the recorder to start over in fast mode with as many as eight samples prior to the change.

An overflow condition can occur when the SSI recorder cannot keep up with the data generated during disturbances that create a large number of SSI entries. The nonvolatile memory that is used for the SSI archive has a longer write time than the random-access memory (RAM) that is used to temporarily store the SSI data, so it is possible that the recloser control will overwrite the

12.46 | Analyzing Events
| Sag/Swell/Interruption (SSI) Report

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 736 of 1080
Wolfe

data in RAM if the transfer to Flash memory gets too far behind. The SSI report shows an X in the REC column if this happens, and it is on the first entry after the overflow. The overflow condition may also occur if the recloser control is saving an event report to nonvolatile memory, because the memory can only be used by one procedure at a time.

SSI Report Memory Details

The recloser control retains a minimum of 4000 of the most recent SSI entries in nonvolatile memory. The recloser control can hold a maximum of approximately 8000 entries. When the recorder memory reaches 8000 entries and further entries occur, the oldest 4000 memory locations are cleared in a block to make room for newer entries. Therefore, the apparent SSI memory size can vary between 4000 and approximately 8000 entries. If the SSI recorder memory clears while an SSI report is being displayed, the SSI report stops and displays this message:

```
Command Aborted, Data overwrite occurred
```

Capacity of the SSI Report

If maximum SSI recorder capacity is desired, the SSI report should be checked periodically, with the data captured to a computer file by using a terminal emulation program. Once the data have been viewed or captured, use the **SSI C** command to clear the SSI recorder.

Clearing the SSI recorder makes it easier to tell if any new disturbances have been recorded, and it also allows the SSI archive to record the maximum of 8000 entries. If more than 8000 entries occur, the oldest half of the SSI archive will be erased to make room for the new entries. The most recent 4000 entries are always available.

Retrieving the SSI Report

See *SSI Command (Voltage Sag/Swell/Interruption Report) on page 10.69* for details on the **SSI** command. See *Figure 12.12* for an example SSI report.

Commissioning Testing

The **SSI T** command is useful for testing, because it provides an easy method of creating some SSI report entries without the need to remove voltage signals or connect a test set, providing Vbase has already been initialized.

During recloser control commissioning or test procedures, the SSI recorder may memorize the Vbase quantity when test voltages or settings are applied. This could cause the recorder to declare a false SAG or SWELL condition when normal system voltages are applied. Reset the SSI recorder logic and clear the Vbase value by issuing the **SSI R** command.

Example SSI Report

The SSI report in *Figure 12.12* shows the voltage disturbances caused by the same fault simulation used for *Figure 12.8* (example event report) and *Figure 12.11* (example SER report). Notice in *Figure 12.12* that the Vb column shows the voltage sag, and the Ph B column shows a U, representing the SAGB Relay Word bit. Currents Ib and Ig display the fault current.

Figure 12.12   Example Sag/Swell/Interruption (SSI) Report

High-Impedance Fault (HIF) Event Reporting

High-impedance fault event information is available when the relay supports HIF detection. The relay stores event information in nonvolatile memory. High-impedance fault event information can be viewed in one or more of the following forms:

➤ HIF event summary

➤ HIF event history

12.48 | Analyzing Events
High-Impedance Fault (HIF) Event Reporting

Wolfe

➤ Compressed ASCII HIF Event Report

➤ COMTRADE File Format HIF Event Report

HIF Event Report Storage

The SEL-651R-2 provides user-selectable HIF event report length. Report setting HIFLER determines the length of the event report. HIF event report length is either 2, 5, 10, or 20 minutes. The prefault length, contrary to the standard event report, is fixed at 90 seconds and is included in addition to the HIFLER setting (i.e., when HIFLER equals 2 minutes, the total event report will be 3 minutes and 30 seconds).

See the **SET R** command in *Table 9.2* and corresponding *Report Settings on page SET.64* for instructions on setting the HIFLER setting. Changing the HIFLER setting erases all HIF events stored in nonvolatile memory.

The HIF event report capacity depends on the selected report length (HIFLER) setting, as shown in *Table 12.10*.

NOTE: During testing, be aware that once the relay HIF event report memory is full, triggering a new HIF event can displace the oldest events.

Table 12.10   HIF Event Report Length Settings

HIFLER settings (minutes):	2	5	10	20
Minimum Number of Event Reports Stored:	28	14	7	3

HIF Event Summary

The **SUM HIF** command displays a shortened version of a stored high-impedance fault event report. These short-form reports present vital information about a triggered event. See *Figure 12.13* for a sample HIF event summary.

```
=>>SUM HIF <Enter>

Wolfe
Analyzing Events 12.49
High-Impedance Fault (HIF) Event Reporting

➤ Downed Conductor

➤ System frequency

➤ Breaker status at trigger time of the event

➤ Pretrigger and post-trigger phase RMS currents and sum of difference currents (from the first row and the initial trigger row of the event report)

Table 12.11 lists event types in fault reporting priority. The entire length of the event report is examined to determine the event type. For example, alarm event types have reporting priority over triggered events when both conditions are present in an event. Events may be triggered in one of two ways. The **TRI HIF** command triggers an event (see *TRI Command (Trigger Event Report) on page 10.79* for complete information on the **TRI** command) locally. Report setting HIFER allows for triggering an event automatically at the assertion of the corresponding Relay Word bit (see *Table 4.26 on page 4.112*).

Table 12.11   HIF Event Types

Event	Event Trigger
HIF FAULT	Assertion of any one of the following Relay Word bits: HIF2_A, HIF2_B, HIF2_C
HIF ALARM	Assertion of any one of the following Relay Word bits and if no HIF fault has occurred: HIA2_A, HIA2_B,HIA2_C
HIF Ext. TRI	Assertion of HIFER SELOGIC variable.
HIF TRI	Execution of the **TRI HIF** command.

Table 12.12 lists HIF phase involvement conditions. The phase involvement is determined by examining the entire event report. Multiple phases may be listed if more than one phase involvement is detected. If an HIF event occurs (Relay Word bits HIF2_A, HIF2_B, or HIF2_C assert), alarmed phases are not listed. When an event report is triggered, Relay Word bit HIFREC is asserted until the HIF event report is finished being collected. The relay does not generate additional event reports for triggering conditions that follow the initial triggering condition and are within the same report.

Table 12.12   HIF Event Phases

Phase	Conditions
A	Assertion of any one of the following Relay Word bits: HIA2_A, HIF2_A
B	Assertion of any one of the following Relay Word bits: HIA2_B, HIF2_B
C	Assertion of any one of the following Relay Word bits: HIA2_C, HIF2_C

When a high-impedance fault is caused by a down-conductor, there may be a load current reduction. Depending on the position of the down conductor and the amount of load dropped, this load reduction event may or may not be detectable at the recloser location. The Load Reduction Element is used to detect any load reduction at the time that a high-impedance fault is detected. The element is used to report a possible down-conductor event. *Table 12.13* lists HIF downed conductor conditions.

12.50 Analyzing Events
High-Impedance Fault (HIF) Event Reporting

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 740 of 1080

Table 12.13   HIF Downed Conductor

Downed Conductor	Conditions
YES	Assertion of any one of the following Relay Word bits: HIA2_A, HIA2_B, HIA2_C, HIF2_A, HIF2_B, HIF2_C, AND LRX (LRA, LRB, LRC) bit asserts where X is the same phase as the alarmed or faulted phase.
NO	When the above is not true.

The system frequency is displayed as measured at the time of trigger to two decimal places. Pretrigger currents are obtained from the first row in the event report, while post-trigger currents are obtained from the initial trigger row.

Viewing the HIF Event Summary

Access the history report from the communications ports by using the **HIS HIF** command or the analysis menu within QuickSet. View and download HIF history reports from Access Level 1 and higher.

The **SUM HIF** command can be used to retrieve HIF event summaries by event number. (The relay labels each new event with a unique number as reported in the **HIS HIF** command history report; see *HIF Event History on page 12.51*.) *Table 12.14* lists the **SUM HIF** commands.

Table 12.14   SUM HIF Command

Command	Description
SUM HIF	Return the most recent HIF event summary.
SUM HIF *n*	Return an event summary for HIF event *n*[a].

[a] The parameter *n* indicates the event unique event identification number.

CSUMMARY HIF

The relay outputs a Compressed ASCII HIF summary report for SCADA and other automation applications. Issue ASCII command **CSU HIF** to view the Compressed ASCII HIF summary report. A sample of the summary report appears in *Figure 12.14*; this is a comma-delimited ASCII file. The relay appends a four digit hex checksum at the end of the lines in the Compressed ASCII report.

Items included in the Compressed ASCII summary report are similar to those included in the summary report.

See *CSUMMARY HIF Command (Only Available in Relays That Support Arc Sense Technology) on page C.10* for more information on the Compressed ASCII command set.

Analyzing Events 12.51
High-Impedance Fault (HIF) Event Reporting

HIF Event History

The HIF event history gives a quick look at recent relay activity. See *Figure 12.15* for a sample event history. The HIF event history contains the following:

- ➤ Standard report header
  - ➢ Relay and terminal identification
  - ➢ Date and time of report
  - ➢ Relay Time Source
- ➤ Event number
- ➤ Date and time when event triggered
- ➤ Event type
- ➤ Downed Conductor
- ➤ Active settings group at time of event trigger

```
=>>HIS HIF <Enter>

Figure 12.15   Sample HIF Event History

The event types and downed conductor status in the event history are determined in the same manner as in the event summary (see *HIF Event Summary on page 12.48*).

Viewing the HIF Event History

Access the history report from the communications ports by using the **HIS HIF** command or the analysis menu within QuickSet. View and download history reports from Access Level 1 and higher.

Use the **HIS HIF** command from a terminal to obtain the event history. The optional parameter *n* specifies the number of the most recent events that the relay returns.

Table 12.15   HIS HIF Command

Command	Description
HIS HIF	Return event histories with the oldest at the bottom of the list and the most recent at the top of the list.
HIS HIF *n*	Return the *n* most recent event summaries with the oldest at the bottom of the list and the most recent at the top of the list.
HIS HIF C	Clears the HIF event history. The unique event identifier is not reset to 10000.

```

Figure 12.16   Sample Compressed HIF History Report

HIF Event Reporting

High-impedance fault oscillography files are available when the relay supports HIF detection. In the SEL-651R-2, HIF events are available as Compressed ASCII reports and binary format via COMTRADE files. HIF event reports are available at the rate of 1-sample/2 cycles.

Use a terminal or SEL-supplied PC software to retrieve event report files stored in the relay and transfer these files to your computer. Both QuickSet and Analytic Assistant read the compressed event files that the relay generates for an event. See *QuickSet Event Analysis on page 3.18* for instructions on viewing event report oscillography with QuickSet.

High-Impedance Fault Compressed Event Report

The SEL-651R-2 provides Compressed ASCII event reports to facilitate event report storage and display. SEL communications processors and Analytic Assistant take advantage of the Compressed ASCII format. Use the **CEV HIF** command to display Compressed ASCII HIF event reports.

The relay generates compressed event reports to display analog data and the state of the HIF Relay Word bits.

The relay provides user-programmable event report triggering conditions. An event report is triggered for all conditions listed for the **SUM HIF** command. When an event report is triggered for any of these conditions, Relay Word bit, HIFREC, asserts, and stays asserted until the HIF event report has finished collecting. The relay does not generate additional event reports for triggering conditions that follow the initial triggering condition and are within the same report.

High-Impedance Fault COMTRADE File Format Reports

The SEL-651R-2 stores high-impedance fault oscillography in binary format and uses COMTRADE file types to output these data:

➤ .HDR–header file

➤ .CFG–configuration file

➤ .DAT–data file

The .HDR file contains summary information about the event in ASCII format. The .CFG file is an ASCII configuration file that describes the layout of the .DAT file. The .DAT file is in binary format and contains the values for each input channel for each sample in the record. These data conform to the IEEE C37.111-1999 COMTRADE standard.

.HDR File

The .HDR file contains the output of the HIF summary command (**SUM HIF**) and settings relevant to the high-impedance fault detection logic as illustrated in *Figure 12.17*.

Page 745 of 1080
Analyzing Events 12.55
High-Impedance Fault (HIF) Event Reporting
Wolfe

The configuration file has the following format:

➤ Station name, device identification, COMTRADE standard year

➤ Number and type of channels

➤ Channel name units and conversion factors

➤ HIF digital relay word bit names

➤ Nominal frequency

➤ Number of samples

➤ Date and times of first data point and event trigger

The .CFG file references analog quantities that are particular to High-impedance fault detection. See *High-Impedance Fault Compressed Event Report on page 12.52* for description of HIF analog and digital values.

.DAT File

The .DAT file follows the COMTRADE binary standard. The format of the binary data files is sample number, time stamp, data value for each analog channel, and digital channel status data for each sample in the file. There are no data separators or carriage return/line feed characters in the binary file. The sequential position of the data in the binary file determines the data translation. Refer to the *IEEE Standard Common Format for Transient Data Exchange (COMTRADE) for Power Systems, IEEE C37.111-1999* for more information. Many programs read the binary COMTRADE files. These programs include Analytic Assistant.

Section 13

Testing and Troubleshooting

Introduction

This section contains guidelines for determining and establishing test routines for the SEL-651R-2 Recloser Control. Follow the standard practices of your company in choosing testing philosophies, methods, and tools. The recloser control incorporates self-tests to help you diagnose potential difficulties should these occur. *Recloser Control Troubleshooting on page 13.11* contains a quick-reference table for common recloser control operation problems.

Topics, tests, and troubleshooting procedures presented in this section include the following:

➤ *Testing Philosophy on page 13.1*

➤ *Self-Tests on page 13.7*

➤ *Recloser Control Troubleshooting on page 13.11*

➤ *Recloser Control Calibration on page 13.15*

➤ *Technical Support on page 13.15*

Testing Philosophy

Recloser control testing may be divided into three categories: acceptance, commissioning, and maintenance testing. The categories are differentiated by when they take place in the life cycle of the recloser control as well as by the test complexity.

The paragraphs below describe when to perform each type of test, the goals of testing at that time, and the recloser control functions that you need to test at each point. This information is intended as a guideline for testing SEL recloser controls.

Acceptance Testing

When: When qualifying a recloser control model to be used on the utility system.

Goals:

1. Ensure that the recloser control meets published critical performance specifications such as operating speed and element accuracy.

2. Ensure that the recloser control meets the requirements of the intended application.

3. Gain familiarity with recloser control settings and capabilities.

13.2 | Testing and Troubleshooting
Testing Philosophy

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 748 of 1080
Wolfe

What to test: All protection elements and logic functions critical to the intended application.

SEL performs detailed acceptance testing on all new recloser control models and versions. We are certain that the recloser controls we ship meet their published specifications. It is important to perform acceptance testing on a recloser control if you are unfamiliar with its operating theory, protection scheme logic, or settings. This helps ensure the accuracy and correctness of the recloser control settings when you issue them.

Commissioning Testing

When: When installing a new protection system.

Goals:

1. Ensure that all system ac and dc connections are correct.

2. Ensure that the recloser control functions as intended using your settings.

3. Ensure that all auxiliary equipment operates as intended.

What to test: All connected or monitored inputs and outputs, polarity and phase rotation of ac connections, simple check of protection elements.

SEL performs a complete functional check and calibration of each recloser control before it is shipped. This helps ensure that you receive a recloser control that operates correctly and accurately. Commissioning tests should verify that the recloser control is properly connected to the power system and all auxiliary equipment. Verify control signal inputs and outputs. Check breaker auxiliary inputs, SCADA control inputs, and monitoring outputs. Use an ac connection check to verify that the recloser control current and voltage inputs are of the proper magnitude and phase rotation.

Brief fault tests ensure that the recloser control settings are correct. It is not necessary to test every recloser control element, timer, and function in these tests.

At commissioning time:

1. Use the recloser control **METER** command to verify the ac current and voltage magnitude and phase rotation.

2. Use the **PULSE** command to verify recloser control output contact operation.

3. Use the **TARGET** command to verify optoisolated input operation.

Maintenance Testing

When: At regularly scheduled intervals or when there is an indication of a problem with the recloser control or system.

Goals:

1. Ensure that the recloser control is measuring ac quantities accurately.

2. Ensure that scheme logic and protection elements are functioning correctly.

3. Ensure that auxiliary equipment is functioning correctly.

What to test: Anything not shown to have operated during an actual fault within the past maintenance interval.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 749 of 1080
Testing and Troubleshooting 13.3
Testing Methods and Tools
Wolfe

SEL recloser controls use extensive self-testing capabilities and feature detailed metering and event reporting functions that lower dependence on routine maintenance testing.

1. Use the SEL recloser control reporting functions as maintenance tools.

    Periodically verify that the recloser control is making correct and accurate current and voltage measurements by comparing the recloser control METER output to other meter readings on that line.

2. Review recloser control event reports in detail after each fault.

    Using the event report current, voltage, and recloser control element data, you can determine that the recloser control protection elements are operating properly.

    Using the event report input and output data, you can determine that the recloser control is asserting outputs at the correct instants and that auxiliary equipment is operating properly.

3. At the end of your maintenance interval, the only items that need testing are those that have not operated during the maintenance interval.

The basis of this testing philosophy is simple: If the recloser control is correctly set and connected, is measuring properly, and no self-test has failed, there is no reason to test it further.

Each time a fault occurs, the protection system is tested. Use event report data to determine areas requiring attention. Slow breaker auxiliary contact operations and increasing or varying breaker operating time can be detected through detailed analysis of recloser control event reports.

Because SEL recloser controls are microprocessor based, their operating characteristics do not change over time. Time-overcurrent operating times are affected only by the recloser control settings and applied signals. It is not necessary to verify operating characteristics as part of maintenance checks.

At SEL, we recommend that maintenance tests on SEL recloser controls be limited under the guidelines provided above. The time saved may be spent analyzing event data and thoroughly testing those systems that require more attention.

Testing Methods and Tools

Test Features

The following features assist you during recloser control testing.

METER Command. The **METER** command shows the ac currents and voltages (magnitude and phase angle) presented to the recloser control in primary values. In addition, the command shows power system frequency. Compare these quantities against other devices of known accuracy. The **METER** command is available at the serial ports and front-panel display (see *Section 10: Communications* and *Section 11: Front-Panel Operations)*.

EVENT Command. The recloser control generates a 15-, 30-, or 60-cycle event report in response to faults or disturbances. Each report contains current and voltage information, recloser control element states, and input/output contact information. If you question the recloser control

13.4 Testing and Troubleshooting
Testing Methods and Tools

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 750 of 1080
Wolfe

response or your test method, use the event report for more information. The **EVENT** command is available at the serial ports (see *Section 12: Analyzing Events*).

SER Command. The recloser control provides a Sequential Events Recorder (SER) event report that time-tags changes in recloser control element and input/output contact states. The SER provides a convenient means to verify the pickup/dropout of any element in the recloser control. The **SER** command is available at the serial ports. (see *Section 12: Analyzing Events*).

TARGET Command. Use the **TARGET** command to view the state of recloser control inputs, recloser control outputs, and recloser control elements individually during a test. The **TARGET** command is available at the serial ports and the front panel (see *Section 10: Communications* and *Section 11: Front-Panel Operations)*.

PULSE Command. Use the **PULSE** command to test the contact output circuits. The **PULSE** command is available at the serial ports and the front panel (see *Section 10: Communications* and *Section 11: Front-Panel Operations*).

Test Methods

Test the pickup and dropout of recloser control elements by using one of the three following methods:

➤ Target command indication

➤ Output contact closure

➤ Sequential Events Recorder (SER)

The examples below show the settings necessary to route the phase time-overcurrent element 51PT to the output contacts and the SER. The 51PT element, like many in the SEL-651R-2, is controlled by enable settings and/or torque-control SELOGIC control equations. To enable the 51PT element, set the E51P enable setting and 51PTC torque-control settings to the following:

➤ E51P := 1 (via the **SET** command)

➤ 51PTC := 1 (set directly to logical 1, via the **SET L** command)

Testing Via TARGET Commands

Display the state of recloser control elements, inputs, and outputs by using the front-panel or serial port **TAR** commands. Use this method to verify the pickup settings of protection elements.

Testing With the Front-Panel TAR Command

You can use the front-panel display and navigation pushbuttons to check Relay Word bit elements. See *Section 11: Front-Panel Operations* for more information on using the recloser control front panel.

Display the MAIN menu. If the recloser control LCD is in the Rotating Display, press the **ENT** pushbutton to display the MAIN menu as shown in *Figure 13.1*.

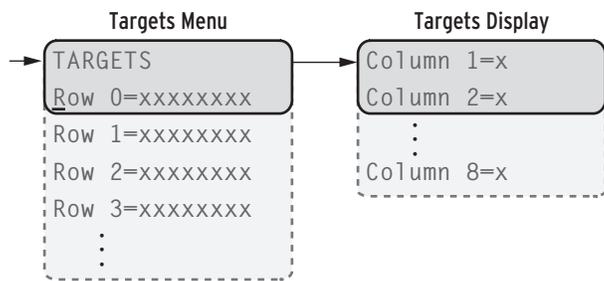
Row 0=xxxxxxxx             Column 2=x
Row 1=xxxxxxxx                 ⋮
Row 2=xxxxxxxx             Column 8=x
Row 3=xxxxxxxx
    ⋮
```


Figure 13.2   TARGETS Menu and TARGETS Display

See *Table F.1* for the correspondence between the Relay Word elements and the **TAR** command.

Testing With the Serial Port TAR Command

To view the 51PT element status from the serial port, issue the **TAR 51PT** command. The recloser control will display the state of all elements in the Relay Word row containing the 51PT element.

Review **TAR** command descriptions in *Section 10: Communications* and *Section 11: Front-Panel Operations* for further details on displaying element status via the **TAR** commands.

Testing Via Output Contacts

You can set the recloser control to operate an output contact for testing a single element. Use the **SET L** command (SELOGIC control equations) to set an output contact (e.g., OUT101–OUT108) to the element under test. The available elements are the Relay Word bits referenced in *Table F.1*.

Use this method especially for time testing time-overcurrent elements. For example, to test the phase time-overcurrent element 51PT via output contact OUT104, make the following setting:

OUT104 := 51PT

13.6 | Testing and Troubleshooting
Testing Methods and Tools

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 752 of 1080
Wolfe

Time-overcurrent curve and time-dial information can be found in *Section 9: Settings*.

Do not forget to reenter the correct recloser control settings when you are finished testing and ready to place the recloser control in service.

Testing Via Sequential Events Recorder

You can set the recloser control to generate an entry in the Sequential Events Recorder (SER) for testing recloser control elements. Use the **SET R** command to include the element(s) under test in any of the SER trigger lists (SER1–SER3) (see *Section 12: Analyzing Events*).

To test the phase time-overcurrent element 51PT with the SER, make the following setting:

> SER1 := 51P 51PT

Element 51P asserts when phase current is above the pickup of the phase time-overcurrent element. Element 51PT asserts when the phase time-overcurrent element times out. The assertion and deassertion of these elements is time-stamped in the SER report. Use this method to verify timing associated with time-overcurrent elements, reclosing relay operation, etc.

Do not forget to reenter the correct recloser control settings when you are ready to place the recloser control in service.

Low-Level Test Interface

NOTE: The SEL-4000 Relay Test System, which includes the SEL Adaptive Multichannel Source, appropriate cables, and PC software, is specifically designed for use with the low-level test interface.

INTENDED USE FOR LOW-LEVEL TEST INTERFACE
The low-level test interface is intended for use in a laboratory or office setting. For example the interface may be used for qualifying relay features and settings during acceptance and/or validation testing. The test interface is not intended to be used in the field for commissioning or maintenance testing.

⚠**CAUTION**
The relay contains devices sensitive to Electrostatic Discharge (ESD). When working on the relay with the front panel removed, work surfaces and personnel must be properly grounded or equipment damage may result.

⚠**CAUTION**
Never apply voltage signals greater than 9 V peak-peak to the low-level test interface (**J14**) or equipment damage may result.

The SEL-651R-2 has a low-level test interface between the input module and the processing module. You may test the relay in either of two ways:

> ➤ By applying ac current signals to the relay inputs, or

> ➤ By applying low magnitude ac voltage signals to the low-level test interface. See *Relay Module Main Board Jumpers and Clock Battery on page 2.52* for information on accessing the relay main board and test interface.

Figure 2.48 shows the location of the processing module input connector (**J14**) for low-level test interface connections. The connector (**J8**) of the interface module is below connector **J14** and the output connector **J11** for the input module is below connector **J8**.

Figure 13.3 shows the low-level test interface (**J8** and **J14**) connector information. *Table 13.1* shows the output (**J11**) value of the input module (for a given input value into the relay rear panel). The processing module input (**J14**) has a maximum 9 V p-p voltage damage threshold. Remove the ribbon cable between the three modules to access the outputs (**J11**) of the input module and the inputs (**J14** and **J8**) to the processing module (relay main board) and interface module (recloser interface board), respectively.

You can test the relay-processing module (via input **J14**) by using signals from the SEL-4000 Relay Test System. The power supply for the relay main board is provided through the ribbon cable between **J8** and **J14**. An SEL-C737 cable is used to connect the relay to the SEL-4000 Relay Test System while maintaining the power supply connection. *Table 13.1* shows the resultant signal scale factor information for the calibrated input module. These scale factors are used in the SEL-5401 program, which is part of the SEL-4000.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 753 of 1080
Testing and Troubleshooting 13.7
Self-Tests
Wolfe

You can test the input module two different ways:

1. Measure the outputs from the input module with an accurate voltmeter (measure signal pin to GND pin) and compare the readings to accurate instruments in the relay input circuits.

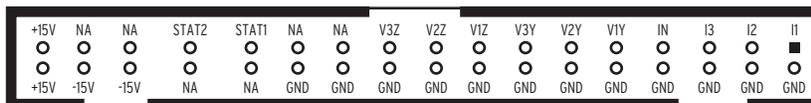
2. Replace the ribbon cable, press the front-panel METER pushbutton, and compare the relay readings to other accurate instruments in the relay input circuits.


Figure 13.3   Low-Level Test Interface (J8 or J14) Connector

Table 13.1   Resultant Scale Factors for Input Module

Input Channels (Relay Rear Panel)	Input Channel Nominal Rating	Input Value	Corresponding J11 Output Value	Scale Factor (Input/ Output)
I1, I2, I3	1 A	1 A	101.2 mV	9.88 A/V
IN	0.2 A	200 mA	114.1 mV	1752.78 mA/V[a]

V1Y, V2Y, V3Y, V1Z, V2Z, V3Z	8 V LEA	3.2 V_{LN}	1.196 V	2.68 V/V
V1Y, V2Y, V3Y, V1Z, V2Z, V3Z	120 V Lindsey SVMI LEA	120 V_{LN}	1.196 V	100.34 V/V
V1Y, V2Y, V3Y	37.09 V Eaton NOVA LEA	14.836 V_{LN}	1.196 V	12.40 V/V
V1Z, V2Z, V3Z	8.49 V Siemens LEA	3.396 V_{LN}	1.196 V	2.84 V/V

[a]   SEL-5401 neutral channel input currents must be entered in mA when using the given scale factor.

Scale factor calculation examples:

$$\frac{120 \text{ V}}{1.196 \text{ V}} = 100.34\left(\frac{V}{V}\right)$$

Equation 13.1

$$\frac{1 \text{ A}}{0.1012 \text{ V}} = 9.88\left(\frac{A}{V}\right)$$

Equation 13.2

Self-Tests

The SEL-651R-2 continuously runs many self-tests to detect out-of-tolerance conditions. These tests run at the same time as recloser control protection and automation logic, but do not degrade SEL-651R-2 performance.

Status Warning and Status Failure

The recloser control reports out-of-tolerance conditions as a status warning or a status failure. For conditions that do not compromise recloser control protection, yet are beyond expected limits, the recloser control issues a status warning and continues to operate. A severe out-of-tolerance condition causes the recloser control to declare a status failure and enter a protection-disabled

13.8 | Testing and Troubleshooting
Self-Tests

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 754 of 1080
Wolfe

state. During a protection-disabled state, the recloser control suspends protection element processing and trip/close logic processing and de-energizes all control outputs. When disabled, the `ENABLED` front-panel LED is not illuminated.

The recloser control signals a status warning by pulsing the HALARMP Relay Word bit (hardware alarm) to logical 1 for five seconds. In addition, the HALARMA Relay Word bit is pulsed for five seconds every minute once a diagnostic warning condition has occurred and until RST_HAL is asserted or the relay is power cycled. For a Status Failure, the recloser control latches the HALARML Relay Word bit at logical 1. The HALARM Relay Word bit is the logical OR of the HALARML and HALARMP Relay Word bits. To provide remote status indication, connect the b contact of OUT201 to your control system remote alarm input and program the output SELOGIC control equation to respond to NOT (SALARM OR HALARM).

If you repeatedly receive status warnings, check the recloser control operating conditions as soon as possible. Take preventive action early during the development of potential problems to avoid system failures. For any status failure, contact your Technical Service Center or the SEL factory immediately (see *Technical Support on page 13.15*).

The recloser control generates an automatic status report at the serial ports for a self-test status failure if you set Port setting AUTO := Y. The recloser control issues a status message with a format identical to the **STATUS** command output.

For certain failures, the relay automatically restarts as many as three times within 24 hours. In many instances, this will correct the failure. A "diagnostic restart" entry is recorded in the Sequential Events Recorder (SER), but the automatic restart may occur before Relay Word bits HALARM and HALARML are recorded in the SER and before failure messages are displayed.

Use the serial port **STATUS** and **CSTATUS** commands, the ACSELERATOR QuickSet SEL-5030 Software **HMI Status** button, the **Self-Test Status Report** from the left pane of the web server, or the front-panel `STATUS` menu to display status warnings and status failures. See *Section 10: Communications* for more information on automatic status notifications and on viewing recloser control status.

Firmware Version Number

At the top of each status report the recloser control displays the present firmware version number that identifies the software program that controls recloser control functions. The firmware version is the four-place designator immediately following the recloser control model number (the first characters in the firmware identification string). The first character in the four-place firmware version number is "R" (representing "Release"). SEL numbers subsequent firmware releases sequentially; the next revision following R101 is R102. See *Appendix A: Firmware and Manual Versions* for firmware version information.

Status

Use the serial port **STATUS** command, select the `STATUS` menu item from the `MAIN` menu on the front-panel HMI, or choose the **Self-Test Status Report** from the left pane of the web server to view the self-test status report. An

example status report is shown in *STA Command (Relay Self-Test Status) on page 10.70*. Use *Table 13.2* and *Table 13.3* to interpret the self-test results and measurements.

Table 13.2   Status Report Results (Sheet 1 of 3)

Self-Test	Condition	Description	Normal Range	Hardware Alarm Relay Word Bit(s)[a]	Protection Disabled on Failure	Port Auto Message	Front-Panel Message	Corrective Action
Channel Offsets I1, I2, I3, V1Y, V2Y, V3Y, V1Z, V2Z, V3Z	Warning	DC offset on A/D channel outside of normal range	< 30 mV for current channels and < 50 mV for voltage channels other than 8 Vac LEA; < 175 mV for 8 Vac LEA voltage channels	HALARMP, HALARMA	No	Yes		
MOF (Master Offset)	Warning	DC offset on A/D ground channel outside normal range	< 10 mV	HALARMP, HALARMA	No	Yes		
MOF (Master Offset)	Failure	DC offset on A/D ground channel outside normal range	< 30 mV	HALARML	Yes	Yes	STATUS FAIL A/D FAILURE	
+5V_PS	Warning	+5 V Power Supply outside warning range	4.71 to 5.29 V	HALARMP, HALARMA	No	Yes		
+5V_PS	Failure	+5 V Power Supply outside failure range	4.31 to 5.73 V	HALARML	Yes	Yes	STATUS FAIL +5V_PS FAIL	
+5V_REG	Warning	5 V Regulated Power Supply outside warning range	4.76 to 5.24 V	HALARMP, HALARMA	No	Yes		
+15V_PS	Warning	+15 V Power Supply outside warning range	13.96 to 16.06 V	HALARMP, HALARMA	No	Yes		
–15V_PS	Warning	–15 V Power Supply outside warning range	–13.96 to –16.06 V	HALARMP, HALARMA	No	Yes		
+12V_TC	Warning	12 V Trip/Close Control Supply outside warning range	11.12 to 12.91 V	HALARMP, HALARMA	No	Yes		
+12V_TC	Failure	12 V Trip/Close Control Supply outside failure range	< 8.96 V	HALARML	Yes	Yes	STATUS FAIL +12V_TC FAIL	
12VAUX	Warning	12 V Auxiliary Power Supply outside warning range	10.29 to 17.65 V	HALARMP, HALARMA	No	No		
TCCAP	Failure	Trip/Close Capacitor below coil voltage for one minute or more	Coil Voltage (see *Trip and Close Outputs on page 1.10*)	HALARML	No	Yes	STATUS FAIL TCCAP FAIL	
+5VA_PS	Warning	+5 V Analog Power Supply outside warning range	4.59 to 5.42 V	HALARMP, HALARMA	No	Yes		
–5VA_PS	Warning	–5 V Analog Power Supply outside warning range	–4.59 to –5.42 V	HALARMP, HALARMA	No	Yes		
Temperature	Warning	Relay Temperature outside normal range	–40° to 100°C	HALARMP, HALARMA	No	Yes

Testing and Troubleshooting 13.11
Recloser Control Troubleshooting

Wolfe

Table 13.2   Status Report Results (Sheet 3 of 3)

Self-Test	Condition	Description	Normal Range	Hardware Alarm Relay Word Bit(s)[a]	Protection Disabled on Failure	Port Auto Message	Front-Panel Message	Corrective Action
Communications Board	Failure	Communications board has failed			No	Yes	`STATUS FAIL COM FAILURE`	STA C
Exception	Failure	CPU Error		HALARML	Yes	Yes	`CPU ERROR RELAY DISABLED`	Automatic restart

[a] See Status Warning and Status Failure on page 13.7 for an explanation.

Table 13.3   Status Report Measurements

INPBV	This value is the Input Power Bus Voltage.
12VAUX	This value is the 12 V Auxiliary Bus Voltage.
CMODE	Battery State—This value is the charger mode (see *Battery Status on page 8.43* for a list and description of modes).
VBAT	This value is the battery voltage.
IBAT	This value is the battery charging or discharging current. If the battery is discharging it shall be shown with a preceding minus sign.
TCCAPV	This value is the Trip/Close Capacitor Voltage.

Recloser Control Troubleshooting

Inspection Procedure

Complete the following procedure before disturbing the recloser control. After you finish the inspection, proceed to the *Troubleshooting Procedure*.

Step 1.   Measure and record the power supply voltage at the power input terminals.

Step 2.   Check to see that the power is on. Do not turn the recloser control off.

Step 3.   Measure and record the voltage at all control inputs.

Step 4.   Measure and record the state of all output relays.

Step 5.   Inspect the serial communications ports cabling to be sure that a communications device is connected to at least one communications port.

Troubleshooting Procedure

Troubleshooting procedures for common problems are listed in *Table 13.4*. The table lists each symptom, possible causes, and corresponding diagnoses/solutions. Related SEL-651R-2 commands are listed in bold capitals. See *Section 10: Communications* for details on SEL-651R-2 commands and *Section 9: Settings* for details on recloser control settings.

Table 13.4   Troubleshooting Procedures (Sheet 1 of 5)

Symptom/Possible Cause	Diagnosis/Solution
Dark Front Panel	
Power is off and recloser control has shut down to conserve the battery.	Restore power or press **WAKE UP**.
Input power is not present.	Verify that power is present at the rear-panel terminal strip.

13.12 | Testing and Troubleshooting
Recloser Control Troubleshooting

Attachment to Response to AG-2 Question No. 68(g)
Page 758 of 1080
Wolfe

Table 13.4   Troubleshooting Procedures (Sheet 2 of 5)

Symptom/Possible Cause	Diagnosis/Solution
Blown power supply fuse.	Replace the fuse (see *Battery and Fuse Replacement on page 2.57*).
Poor contrast adjustment.	Press and hold **ESC** for two seconds. Press the **Up Arrow** and **Down Arrow** pushbuttons to adjust contrast.
Status Failure Notice on Front Panel	
Self-test failure.	Contact the SEL factory or your Technical Service Center. The OUT201 recloser control b contacts will be closed if "NOT HALARM" is programmed to OUT201.
Alarm Output Asserts	
Power is off.	Restore power or press **WAKE UP**.
Blown power supply fuse.	Replace the fuse (see *Battery and Fuse Replacement on page 2.57*).
Power supply failure.	LCD displays STATUS FAILURE screen. Contact the SEL factory or your Technical Service Center.
Main board or interface board failure.	LCD displays STATUS FAILURE screen. Contact the SEL factory or your Technical Service Center.
Other self-test failure.	LCD displays STATUS FAILURE screen. Contact the SEL factory or your Technical Service Center.
System Does Not Respond to Commands From Device Connected to Communications Port	
No communication.	Confirm cable connections and types. If OK, type **<Ctrl+X>**, then **<Enter>**. This resets the terminal program.
Communications device is not connected to the system.	Connect a communications device.
Incorrect data speed (baud rate) or other communications parameters.	Configure your terminal port parameters to the particular recloser control port settings. Use the front panel to check port settings (see *SET/SHOW Menu on page 11.12*).
Incorrect communications cables.	Use SEL communications cables, or cables you build according to SEL specifications (see *Port Connectors and Communications Cables on page 10.9*).
Communications cabling error.	Check cable connections.
Handshake line conflict; system is attempting to transmit information, but cannot do so.	Check communications cabling. Use SEL communications cables, or cables you build according to SEL specifications (see *Section 10: Communications*).
System is in the XOFF state, halting communications.	Type **<Ctrl+Q>** to put the system in the XON state.
The relay communications port is disabled (setting EPORT := N).	Change the setting by entering the **SET P** *n* command from another communications interface (serial port, USB, or Telnet session) or by using the front-panel interface. When Port F is disabled, the USB is also disabled and cannot be used to change the EPORT setting (see *Port 5 Settings on page SET.70*).
Relay Does Not Respond to Commands From Device Connected to USB Port	
The USB driver is not installed on the PC, or an incorrect driver was installed.	Install the correct USB driver (see *Establishing Communications Through Use of the USB Port on page 10.2*)
The USB cable was disconnected while a PC application was communicating with the relay.	Reconnect the USB cable.
The relay USB port is disabled (Port F setting EPORT := N).	Change the setting by entering the **SET P F** command from another communications interface (serial port or Telnet session) or by using the front-panel interface (see *Port Enable Settings (SET P n Command) on page 9.60*).
The USB cable is faulty or is not USB 2.0 compliant.	Install a proper USB 2.0 compliant cable. Use an SEL-C664 or equivalent cable.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 750 of 1080
Testing and Troubleshooting 13.13
Recloser Control Troubleshooting
Wolfe

Table 13.4   Troubleshooting Procedures (Sheet 3 of 5)

Symptom/Possible Cause	Diagnosis/Solution
The relay USB Board has failed. Use these steps to attempt to correct the problem:	a. Check USB Board status by entering the **STATUS** command from a serial port or Ethernet connection. b. If STATUS is FAIL, issue a **STA C** command to attempt to clear the condition. c. If STATUS is OK, connect the USB cable between the PC and the relay and use Windows Device Manager to verify that the Schweitzer Engineering Laboratories Fast CDC USB device appears under Ports. d. Use the Task Manager (if necessary) to confirm that any PC application that was using the port has terminated. If any such application remains running, close the application. e. Disconnect the USB cable. Use Windows Device Manager to verify that the Schweitzer Engineering Laboratories Fast CDC USB device does not appear under Ports. Reconnect the USB cable and verify that Schweitzer Engineering Laboratories Fast CDC USB device appears under Ports. f. If these steps fail to correct the problem, contact SEL for further assistance.
Relay Does Not Respond Via Telnet or HTTP (Web Server) Interface	
Communications device is not connected to the relay.	Connect a communications device to the relay. See *Section 10: Communications* for details on connecting and configuring communications.
The relay Ethernet port is disabled (setting EPORT = N).	Change the setting by entering the **SET P 5** command from another communications interface (serial port or USB session) or by using the front-panel interface (see *Port Enable Settings (SET P n Command) on page 9.60*).
Relay or communications device is not properly configured for Ethernet connection.	Check the relay settings for the port, including ETELNET or EHTTP and associated settings.
Maximum number of sessions is exceeded.	See *Session Limits on page 10.14*.
Firmware upgrade option is not available on the web server	Check HTTPACC setting.
Terminal Displays Meaningless Characters	
Data speed (baud rate) is set incorrectly.	Check the terminal parameters configuration (see *Establishing Communications Using a Serial Port on page 10.1*).
Terminal emulation is not optimal.	Try other terminal types, including VT-100 and VT-52 terminal emulations.
System Does Not Respond to Faults	
Recloser control is set improperly.	Review the recloser control settings (see *Section 9: Settings*).
Improper test settings.	Restore operating settings.
PT or CT connection wiring error.	Confirm PT and CT wiring.
Input voltages and currents phasing, and rotation errors.	Use recloser control metering. Use the **TRI** event trigger command and examine the generated event report.
The analog input (flat multi-pin ribbon) cable between the input module board and the main board is loose or defective.	Reseat both ends of the analog input cable, observing proper ESD precautions.
Check the recloser control self-test status.	Take preventive action as directed by recloser control Status Warning and Status Failure information.
Tripping Output Remains Closed Following a Fault	
Auxiliary contact control inputs are improperly wired.	Check circuit breaker auxiliary contacts wiring.
Recloser control outputs have burned closed.	Remove recloser control power. Remove the control output connection. Check continuity; a contacts will be open and b contacts will be closed. Contact the SEL factory or your Technical Service Center if continuity checks fail.
I/O interface board failure.	LCD displays STATUS FAILURE screen. Contact the SEL factory or your Technical Service Center.

Table 13.4 Troubleshooting Procedures (Sheet 4 of 5)

Symptom/Possible Cause	Diagnosis/Solution
Power Supply Voltage Status Warning	
Power supply voltage(s) are out-of-tolerance.	Log the Status Warning. If repeated warnings occur, take preventive action.
A/D converter failure.	LCD displays STATUS FAILURE screen. Contact the SEL factory or your Technical Service Center.
Power Supply Voltage Status Failure	
Power supply voltage(s) are out-of-tolerance.	LCD displays STATUS FAILURE screen. Contact the SEL factory or your Technical Service Center.
A/D converter failure.	LCD displays STATUS FAILURE screen. Contact the SEL factory or your Technical Service Center.
Trip/Close Capacitor (TCCAP) Failure	
Trip/Close capacitors are below nominal voltage or the J205 cable is disconnected.	LCD displays STATUS FAIL TCCAP FAILURE screen, or TCCAPV status is reported as a failure state. Check **J205** cable connection. If cable is loose or disconnected, perform the following: a. Reattach the **J205** cable. b. Issue a **STA C** command from a serial port or Ethernet connection. c. Wait two minutes. d. Issue a **STA** command and check for a failure condition. If the error returns or the cable was securely connected, contact the SEL factory or your Technical Service Center.
A/D OFFSET WARN Status Warning	
Loose ribbon cable between the input module board and the main board.	Reseat both ends of the analog input cable.
A/D converter drift.	Log the Status Warning. If repeated warnings occur, contact the SEL factory or your Technical Service Center.
Master offset drift.	LCD displays STATUS FAILURE screen. Contact the SEL factory or your Technical Service Center.
Battery Problem LED Illuminated	
Discharge test failure caused by an on-load battery voltage measurement < 10.5 V or a measurement of < 11 V after 10 seconds on-load. Open-circuit measurement must be > 11.58 V to begin test.	Replace failed battery.
Battery voltage measurement < 5 V.	Battery is either deeply discharged or failed. Replace battery.
Excessive current draw for excessive time during float charge mode.	Battery has probably failed. Test battery and replace if failed.
Meter Command Does Not Respond as Expected	
Sequence current or voltage magnitudes are incorrect.	Global settings NFREQ or PHROT not set correctly.
Current phase polarity or connection compensation is incorrect.	Global settings IPCONN or CTPOL not set correctly.
Voltage connection compensation is incorrect.	Global settings VYCONN, VZCONN, VSELECT or FSELECT not set correctly.
Current or voltage magnitudes are incorrect.	Group settings CTR, CTRN, PTRY or PTRZ not set correctly.
Current or voltage angles or power magnitudes are incorrect.	Recloser control analog inputs not connected correctly.
LEA voltage magnitudes are incorrect.	Global settings VxYRCF or VxZRCF (where x = 1, 2, 3) not set correctly. The neutral input on the LEA channel is not properly grounded.

Testing and Troubleshooting 13.15
Recloser Control Calibration

Table 13.4   Troubleshooting Procedures (Sheet 5 of 5)

Symptom/Possible Cause	Diagnosis/Solution
Relay Time Stamp Entries Appear Out of Order for Fast Changes in SER	
Simple Network Time Protocol (SNTP) is changing the system time too frequently, and that time source is not sufficiently accurate.	Consider changes to the SNTP configuration. See *Section 10: Communications* for more information on SNTP.
DNP is updating the system time too frequently, and that time source is not sufficiently accurate.	Consider changes to the TIMERQ and TIMERQ*n* settings (see *Appendix E: DNP3 Communications*).

Recloser Control Calibration

The SEL-651R-2 is factory-calibrated. If you suspect that the control is out of calibration, please contact the factory.

Technical Support

Appendix A
Firmware and Manual Versions

Firmware

Determining the Firmware Version in Your Relay

To determine the firmware version, view the status report by using the serial port **STATUS** command or the front panel **STATUS** pushbutton. The status report displays the Firmware Identification (FID) number.

The firmware version will be either a standard release or a point release. A standard release adds new functionality to the firmware beyond the specifications of the existing version. A point release is reserved for modifying firmware functionality to conform to the specifications of the existing version.

A standard firmware release is identified by a change in the R-number of the device FID number.

Existing firmware:

FID=SEL-651R-2-**R100**-Vx-Zxxxxxx-Dxxxxxxxx

Standard release firmware:

FID=SEL-651R-2-**R101**-Vx-Zxxxxxx-Dxxxxxxxx

A point release is identified by a change in the V-number of the device FID number.

Existing firmware:

FID=SEL-651R-2-Rxxx-**V0**-Zxxxxxx-Dxxxxxxxx

Point release firmware:

FID=SEL-651R-2-Rxxx-**V1**-Zxxxxxx-Dxxxxxxxx

The release date is after the D. For example, the following is firmware version number R100, release date December 10, 2003.

FID=SEL-651R-2-R100-Vx-Zxxxxxx-**D20031210**

Revision History

Table A.1 lists the firmware versions, revision descriptions, and corresponding instruction manual date codes.

Table A.1   Firmware Revision History (Sheet 1 of 5)

Firmware Identification (FID) Number	Summary of Revisions	Manual Date Code
SEL-651R-2-R407-V0-Z007003-D20180131	➤ Added support for the Eaton NOVA NX-T Recloser on the Multi-Recloser Interface. ➤ Made Voltage Phase Angle Correction settings available for 8 Vac LEA. ➤ Resolved an issue where ASCII commands could report the time source as internal when an external time source is connected. ➤ ASCII commands now report SNTP as an external time source.	20180131

Firmware

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 764 of 1080
Wolfe

Table A.1   Firmware Revision History (Sheet 2 of 5)

Firmware Identification (FID) Number	Summary of Revisions	Manual Date Code
	➤ Operation counters and Breaker Wear quantities are now available for Load Profile and SELOGIC expressions. ➤ SELOGIC counters are now available for Load Profile and Display points. ➤ Added feature to allow anonymous TCP connection from DNP masters when DNPIP*x* is set to 0.0.0.0. ➤ Modified the 12V_TC and +5V_PS self-test diagnostic failure conditions to disable protection. ➤ Added a Trip/Close Capacitor (TCCAP) self-test diagnostic failure condition.	
SEL-651R-2-R406-V1-Z006003-D20170818	Includes all the functions of SEL-651R-2-R406-V0-Z006003-D20160810 with the following addition: ➤ Resolved an issue where certain Ethernet traffic could cause diagnostic restarts.	20170818
SEL-651R-2-R406-V0-Z006003-D20160810	➤ Changed the lower end of the phase and negative-sequence time-overcurrent element pickup setting (51PJP, 51PKP, 51AJP, 51AKP, 51BJP, 51BKP, 51CJP, 51CKP, 51QJP, and 51QKP) ranges from 0.10 to 0.05 A, secondary. ➤ Made FWVNUM (Relay Firmware Version Number) available via DNP and Modbus protocols. ➤ Added setting option AUTO2 for directional elements enable setting E32. ➤ Added Relay Word bit DISTST, indicating that a battery discharge test is in progress. ➤ Made Group settings RID (Relay Identifier) and TID (Terminal Identifier) available for Display Points. ➤ Group setting EHIF := N no longer prevents existing high-impedance fault event reports from being accessed. ➤ Virtual bits now reset when a new CID file is sent to the control. ➤ Changed default MMS inactivity time-out from 2 minutes to 15 minutes.	20160810
SEL-651R-2-R405-V3-Z005003-D20170818	Includes all the functions of SEL-651R-2-R405-V2-Z005003-D20150722 with the following addition: ➤ Resolved an issue where certain Ethernet traffic could cause diagnostic restarts.	20170818
SEL-651R-2-R405-V2-Z005003-D20150722	Includes all the functions of SEL-651R-2-R405-V1-Z005003-D20150709 with the following addition: ➤ Updated field upgrade process for R405-V1.	20150722
SEL-651R-2-R405-V1-Z005003-D20150709	Includes all the functions of SEL-651R-2-R405-V0-Z005003-D20140306 with the following addition: ➤ Resolved an issue where latch bits may be restored to an incorrect state after power is restored to the control or the control is restarted. **Note:** Firmware version R405-V1 is not intended for field upgrades.	20150709

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 766 of 1080
Wolfe

Table A.1   Firmware Revision History (Sheet 4 of 5)

Firmware Identification (FID) Number	Summary of Revisions	Manual Date Code
	➤ Added feature to retain the existing valid CID file when an invalid CID file is sent. ➤ Modified virtual bits so that they no longer deassert temporarily after group or settings change. ➤ Added FLTRDRE and HIFRDRE logical nodes to indicate the presence of regular and high-impedance fault event reports. ➤ Changed dead band for IEC 61850 VBAT logical node from 100 to 5. ➤ Modified minimum negotiated MMS PDU size to 512 bytes. ➤ Modified maximum number of MMS variables that can be read or written to 256. **Note:** Firmware version R404 did not production release.	
SEL-651R-2-R403-V2-Z004002-D20170818	Includes all the functions of SEL-651R-2-R403-V1-Z004002-D20150722 with the following addition: ➤ Resolved an issue where certain Ethernet traffic could cause diagnostic restarts.	20170818
SEL-651R-2-R403-V1-Z004002-D20150722	Includes all the functions of SEL-651R-2-R403-V0-Z004002-D20150722 with the following addition: ➤ Resolved an issue where latch bits may be restored to an incorrect state after power is restored to the control or the control is restarted.	20150722
SEL-651R-2-R403-V0-Z004002-D20130624	➤ Extended range of ETIMEO and ETIMEOn port settings from 1–50 seconds to 1–120 seconds. ➤ Added RESPSZ port setting for limiting the packet size of DNP messages. ➤ Corrected handling of unrecognized Ethertype frames that can cause Ethernet to stop responding.	20130624
SEL-651R-2-R402-V1-Z003002-D20150722	Includes all the functions of SEL-651R-2-R402-V0-Z003002-D20150722 with the following addition: ➤ Resolved an issue where latch bits may be restored to an incorrect state after power is restored to the control or the control is restarted.	20150722
SEL-651R-2-R402-V0-Z003002-D20121219	➤ Added SEL Arc Sense Technology (AST) to detect high-impedance faults. ➤ Added ground overcurrent element (50G HIZ) to detect high-impedance faults. ➤ Added second harmonic elements for blocking sensitive overcurrent elements during transformer inrush. ➤ Added IEEE COMTRADE standard event reports. ➤ Extended the lower range of setting 79RSLD from 180 cycles to 0 cycles. ➤ Added COMTRADE event report to FTP and MMS file transfer. ➤ Global setting PMSTN now accepts upper and lower case characters. ➤ Reformatted relay web server. ➤ Relay now accepts IRIG-B signals with either even or odd parity. ➤ Corrected issue in which enabled front-panel display points can incorrectly be skipped in the rotating display. ➤ Corrected issue with scale factors not being applied to pickup settings in front-panel display points. ➤ Corrected issue with front-panel contrast not being retained when a TARGET RESET is executed. ➤ Added Multi-Recloser Interface compatibility.	20121219

Table A.1   Firmware Revision History (Sheet 5 of 5)

Firmware Identification (FID) Number	Summary of Revisions	Manual Date Code
	➤ Global settings VYCOMP and VZCOMP are no longer hidden based on Global setting PHVOLT. ➤ Added Relay Word bit rows 124–135 to accommodate new features. ➤ Included new Compressed ASCII commands, CSU HIF, CEV HIF, and CHI HIF, in the **CAS** command response. ➤ Relay now reports the shot count from the trigger row of the event report.	
SEL-651R-2-R401-V1-Z002001-D20180615	Includes all the functions of SEL-651R-2-R401-V0-Z002001-D20120831 with the following addition: ➤ Resolved an issue where latch bits may be restored to an incorrect state after power is restored to the control or the control is restarted.	20180615
SEL-651R-2-R401-V0-Z002001-D20120831	➤ Made improvements for manufacturability.	20120831
SEL-651R-2-R400-V1-Z001001-D20180615	Includes all the functions of SEL-651R-2-R400-V0-Z001001-D20120518 with the following addition: ➤ Resolved an issue where latch bits may be restored to an incorrect state after power is restored to the control or the control is restarted.	20180615
SEL-651R-2-R400-V0-Z001001-D20120518	➤ Initial version.	20120518

Instruction Manual

The date code at the bottom of each page of this manual reflects the creation or revision date.

Table A.2 lists the instruction manual versions and revision descriptions. The most recent instruction manual version is listed first.

Table A.2   Instruction Manual Revision History (Sheet 1 of 8)

Revision Date	Summary of Revisions
20180615	**Appendix A** Updated for firmware versions R400-V1 and R401-V1.
20180131	**Preface** ➤ Added *Technical Assistance*. **Section 1** ➤ Added *Eaton NOVA NX-T Rating* to *Trip and Close Outputs* in *Specifications*. **Section 2** ➤ Added *Table 2.5: Default Global Setting CTPOL*. ➤ Added *Figure 2.78: Current Connections and Polarity for the Multi-Recloser Interface (Global Setting RECL_CFG := A3; Optional Voltage Connections Also Shown)*. **Section 5** ➤ Updated *Figure 5.2: Factory-Default Trip Logic Settings*. **Section 6** ➤ Updated *Table 6.8: Reclosing Relay SELOGIC Control Equation Settings*. ➤ Updated *Factory-Default 79DTL/79DLS Settings Example* in *Reclosing Relay*. ➤ Updated *Figure 6.11: Factory-Default Drive-to-Lockout Logic Settings*.

Table A.2 Instruction Manual Revision History (Sheet 2 of 8)

Revision Date	Summary of Revisions
	Section 7 ➤ Updated *Table 7.2: Analog Quantities*. **Section 9** ➤ Updated *Figure 9.32: Logic Settings (SHO L) With Factory-Default Values*. **Appendix E** ➤ Updated *DNP3 Settings* under *DNP3 in the SEL-651R-2*. ➤ Added note explaining negative values in the FTIME*x* and FTYPE registers in *DNP3 Documentation*. **Appendix F** ➤ Added A3_CFG to *Table F.1: Relay Word Bit Mapping* and *Table F.2: Alphabetic List of Relay Word Bits*. **Appendix G** ➤ Updated *Table G.1: Analog Quantities*.
20171017	**General** ➤ Replaced references to Cooper/Kyle with Eaton. ➤ Added support and compatibility information for ABB OVR/Gridshield (32-pin and 42-pin version) reclosers. ➤ Updated base model offerings. **Preface** ➤ Updated *Trademarks*. **Section 1** ➤ Updated *Specifications*.
20170818	**Appendix A** Updated for firmware versions R403-V2, R405-V3, and R406-V1.
20170613	**Section 2** ➤ Added note about LEA circuit grounding to ABB OVR-3/VR-3S (15 and 27 kV Models) Reclosers discussion. ➤ Updated *Figure 2.55: Current Connections and Polarity From ABB OVR-3/VR-3S (15 and 27 kV Models) Recloser Primary to SEL-651R-2 Recloser Control Current Inputs*. ➤ Updated *Figure 2.57: Recloser Pole Status Connections Between ABB OVR-3/VR-3S (15 and 27 kV Models) Recloser and SEL-651R-2 Recloser Control*. ➤ Updated *Figure 2.61: 120 Vac Power Circuit Connections Between SEL-651R-2 Recloser Control and Control-Powered Kyle NOVA or G&W Control Power Viper-S Recloser*. ➤ Added note about shielded cables to G&W Viper-ST, G&W Viper-LT, or Elastimold MVR Reclosers discussion.
20161220	**Section 2** The following additions/changes make the de facto standard connections for ABB reclosers. ➤ Added current transformer secondary circuit ground and LEA sensor option for VY voltages to *Figure 2.55: Current Connections and Polarity From ABB OVR-3/VR-3S (15 and 27 kV Models) Recloser Primary to SEL-651R-2 Recloser Control Current Inputs*. ➤ Added yellow operating handle (ANSI device number 69) operation and 52a contact monitoring to *Figure 2.57: Recloser Pole Status Connections Between ABB OVR-3/VR-3S (15 and 27 kV Models) Recloser and SEL-651R-2 Recloser Control*. ➤ Changed ac power connections for recloser heater circuits from terminals C02/C03 to the actual connected terminals C01/C04 in *Figure 2.58: 120 Vac Power Circuit Connections Between SEL-651R-2 Recloser Control and ABB OVR-3/VR-3S (15 and 27 kV Models) Recloser*.
20160810	**Section 1** ➤ Updated *Communications Ports* in *Specifications* to clarify that 100BASE-FX rear ports use multimode LC fiber. ➤ Updated *Time-Overcurrent Elements (51)* in *Specifications* to change the lower end of the phase and negative-sequence pickup ranges from 0.10 to 0.05 A, secondary. ➤ Added 4 A specification to *AC Current Inputs* in *Specifications*. ➤ Added *AC Output Ratings* to *Output Contacts (Except Trip and Close)* in *Specifications*. ➤ Updated *Type Tests* information in *Specifications*.

Table A.2   Instruction Manual Revision History (Sheet 3 of 8)

Revision Date	Summary of Revisions
	Section 2
	➤ Updated *Figure 2.3: Rear View of SEL-651R-2 Power Module (Dual-Door Enclosure, Optional Features Shown)*.
	➤ Updated NEMA 3R and 3RX enclosure ratings in *Dual-Door Enclosure Overview* and *Single-Door Enclosure Overview*.
	➤ Clarified battery installation and connection steps accompanying *Figure 2.29: Battery Wiring Harness Connections (Shown Connected to Relay Module)*.
	Section 4
	➤ Updated *Figure 4.30: Synchronism-Check Voltage Window and Slip Frequency Elements* to clarify that the output of the 2 CYC timer is also the input into the AND gates for Relay Word bits SFAST, SSLOW, and SF.
	➤ Updated *Figure 4.31: Synchronism-Check Elements* and accompanying text to clarify that the slip frequency comparisons use absolute value of slip frequency.
	➤ Updated *Table 4.3: Maximum-Phase Time-Overcurrent Element Settings*, *Table 4.5: A- B-, or C-Phase Time-Overcurrent Element Settings*, and *Table 4.8: Negative-Sequence Time-Overcurrent Element Settings* to change the lower end of the phase and negative-sequence pickup ranges from 0.10 to 0.05 A, secondary.
	➤ Updated *Directional Control Settings* to include setting option E32 := AUTO2 and to explain its significance for the Z2F, Z2R, Z0F, and Z0R settings.
	Section 6
	➤ Clarified the realization of Relay Word bit 52A3P in *Figure 6.2: Breaker Status Logic*.
	Section 7
	➤ Added Relay Word bit DISTST to *Table 7.12: Asynchronous Processing Order of Relay Elements*.
	Section 8
	➤ Updated *Battery System Monitor* to define new Relay Word bit DISTST and describe how it can be used to provide a front-panel battery load test capability.
	Settings Sheets
	➤ Updated Maximum-Phase, A-Phase, B-Phase, C-Phase, and Negative-Sequence Time-Overcurrent Element settings to change the lower end of the phase and negative-sequence pickup ranges from 0.10 to 0.05 A, secondary.
	➤ Added setting option AUTO2 for directional elements enable setting E32.
	Section 10
	➤ Added wildcard usage examples in *Table 10.16: FTP and MMS Wildcard Usage Examples* and *Table 10.17: Ymodem Wildcard Usage Examples*.
	Appendix A
	➤ Updated for firmware version R406-V0.
	Appendix C
	➤ Added REF_NUM to *CHISTORY*, *CEVENTS*, and *CSU Command* outputs.
	➤ Added Relay Word bit DISTST to the CEVENT command output.
	Appendix E
	➤ Updated EXTTB and EXTTC phase designations in *Table E.11: DNP3 Reference Data Map*.
	➤ Added FWVNUM (Relay Firmware Version Number) to *Table E.11: DNP3 Reference Data Map*.
	Appendix F
	➤ Added Relay Word bit DISTST to Row 38 in *Table F.1: Relay Word Bit Mapping* and *Table F.2: Alphabetical List of Relay Word Bits*.
	Appendix G
	➤ Added FWVNUM (Relay Firmware Version Number) to *Table G.1: Analog Quantities*.
	➤ Removed erroneous "h" at the end of listings MVAR through kVAR in *Table G.1: Analog Quantities*.
	➤ Corrected listings KW3MND_[x] and KW3MNT_[z] in *Table G.1: Analog Quantities* (changed "X" to "N").
	➤ Added Group settings RID (Relay Identifier) and TID (Terminal Identifier) to *Table G.1: Analog Quantities*.
	Appendix I
	➤ Removed erroneous "VDC" in the description for "88 bytes" data in *Table I.5: A5D1 Fast Meter Data Block*.
	➤ Added Relay Word bit DISTST to the DNA command output.

Table A.2 Instruction Manual Revision History (Sheet 4 of 8)

Revision Date	Summary of Revisions
	Appendix K
	➤ Added FWVNUM (Relay Firmware Version Number) to *Table K.22: Modbus Quantities Table*.
	Appendix L
	➤ Clarified that the Integer data type in *Table L.11* is Integer (INT8).
	➤ Added Logical Nodes BSASCBR1, BSBSCBR2, and BSCSCBR3 to *Table L.19: Logical Device: PRO (Protection*.
	➤ Added Logical Nodes BSASCBR1, BSBSCBR2, and BSCSCBR3 (with Data Source OC3) to *Table L.24: Logical Nodes by Data Source Names*.
	➤ Added Relay Word bit DISTST to *Table L.22: Logical Device: ANN (Annunciation)* and *Table L.24: Logical Nodes by Data Source Names*.
20160526	**Section 2**
	➤ Updated *Figure 2.41: Three-Phase Voltage Connections for 300 Vac Voltage Inputs*, *Figure 2.43: 8 Vac LEA Voltage Connections for VY-Terminal Voltages*, and *Figure 4.25: Lindsey SVMI LEA Voltage Connections for VZ-Terminal Voltages* with Terminals NY and NZ for new voltage input fuse blocks with wire insertion connections. The fuse blocks, along with shielded cables for LEA voltage inputs, are initially installed with the Multi-Recloser Interface.
20150722	**Appendix A**
	➤ Updated for firmware versions R405-V2, R403-V2, and R402-V1.
20150709	**Appendix A**
	➤ Updated for firmware version R405-V1.
	Appendix B
	➤ Updated *Overview* to include point release information.
20140731	**Section 1**
	➤ Updated specifications for *Optoisolated Inputs*, *Electromagnetic Compatibility Immunity*, and *Environmental Type Tests*.
	Section 2
	➤ Corrected Serial Port 2 and Port 3 voltage jumper label.
	➤ Modified *Figure 2.60: Trip/Close and Recloser Status Circuit Connections Between Control-Powered Kyle NOVA or G&W Control Power Viper-S Recloser and SEL-651R-2 Recloser Control* for additions to the 19-pin control cable interface.
	➤ Modified *Figure 2.73: Trip/Close, Recloser Status, and Lockout Handle Status Circuit Connections Between Siemens SDR Three-Phase Recloser and SEL-651R-2 Recloser Control*.
	Section 7
	➤ Expanded *Optoisolated Inputs* to include the 125 Vdc option.
20140306	**Section 1**
	➤ Added maximum rate-of-change under Frequency and Rotation in *Specifications*.
	➤ Added neutral channel under Time-Overcurrent Elements in *Specifications*.
	➤ Added rate-of-change-of-frequency element in *Specifications*.
	➤ Added Radiated Radio Frequency Immunity under Electromagnetic Compatibility Immunity in *Specifications*.
	Section 2
	➤ Changed the outline and re-organized entire section.
	Section 4
	➤ Added *Neutral Time-Overcurrent Elements* subsection.
	➤ Added *Rate-of-Change-of-Frequency (81R) Protection* subsection.
	➤ Changed Z0ANG to Z0MTA in *Figure 4.56: Zero-Sequence Voltage-Polarized Directional Element for Ground Overcurrent Elements* and *Figure 4.63: Zero-Sequence Impedance Plot for Solidly Grounded, Mostly Inductive System*.
	➤ Added *Z0MTA—Zero-Sequence Maximum Torque Angle* subsection.
	Section 6
	➤ Added missing figure for the Joslyn TriMod 600R recloser in *Figure 6.11: Factory Default Drive-to-Lockout Logic Settings*.

Table A.2   Instruction Manual Revision History (Sheet 5 of 8)

Revision Date	Summary of Revisions
	Section 7
	➤ Changed the number of math variables from 32 to 64 in *Table 7.2: Analog Quantities*.
	➤ Added *Processing Order and Processing Interval* subsection.
	Section 9
	➤ Updated warning message displayed when EGNDSW changed from N to Y.
	➤ Added 0 to the MAXACC setting range.
	➤ Added default settings to detect control cable disconnection and yellow handle operation in *Figure 9.32: Logic Settings (SHO L) With Factory Default Values* and *Figure 9.33: Front-Panel Settings (SHO F) With Factory Default Values (Without Tricolor LED Option)*.
	➤ Added Group setting Neutral Time-Overcurrent Elements, Z0MTA, in *SEL-651R Settings Sheets*.
	➤ Added Group settings Rate-of-Change-of-Frequency Element, MV32–MV64, in *SEL-651R Settings Sheets*.
	➤ Added Port setting EMMSFS in *SEL-651R Settings Sheets*.
	Section 10
	➤ Added explanation for setting MAXACC = 0.
	➤ Added *Virtual File Interface* subsection.
	➤ Added **ETH C** command, and updated **ETH** command response.
	Section 13
	➤ Corrected errors for Input Channels column in *Table 13.1: Resultant Scale Factors for Input Module*.
	Appendix A
	➤ Updated for firmware version R405-V0.
	Appendix E
	➤ Updated *Figure E.3: Sample Response to SHO D Command* and *Figure E.8: Binary Output Map Entry in ACSELERATOR QuickSet Software*.
	➤ Clarified switching between single- and multi-event modes under *Reading Relay Events* subsection.
	➤ Added Pickup settings as primary quantities under *Settings Data* subsection under *Analog Inputs*.
	➤ Added MAXWEAR and updated number of math variables from 32 to 64 in *Table E.11: DNP3 Reference Data Map*.
	➤ Added clarification for upper byte before *Table E.12: Object 30, Fault Type Upper Byte—Event Cause*.
	➤ Added explanation for setting RSTDNPE under *Reading Relay Events* subsection.
	➤ Updated the number of binary outputs to 71 in *Table E.16: SEL-651R-2 DNP3 Default Data Map*.
	Appendix F
	➤ Added Relay Word bits for neutral time-overcurrent elements, rate-of-change-of-frequency (81R) elements, and RSTDNPE.
	Appendix G
	➤ Added MAXWEAR, FLREP, FLRNUM, HIFLREP, HIFLRNUM, Primary Quantities of Time-Overcurrent Pickup settings to *Table G.1: Analog Quantities*.
	➤ Updated number of Math Variables to 64 in *Table G.1: Analog Quantities*.
	Appendix I
	➤ Corrected message length to 28 in *Table I.3: A5CO Relay Definition Block*.
	Appendix J
	➤ Added *Table J.17: Time Quality Decoding* to decode time quality.
	Appendix K
	➤ Added MAXWEAR and updated math variables to 64 in *Table K.22: Modbus Quantities Table*.

Table A.2   Instruction Manual Revision History (Sheet 6 of 8)

Revision Date	Summary of Revisions
	Appendix L
	➤ Added explanation for MMS file transfer services under *File Services* subsection.
	➤ Added *GOOSE Receive and Transmit Capacity* subsection under *GOOSE Processing and Performance*.
	➤ Added EMMSFS setting to *Table L.14: IEC 61850 Settings*.
	➤ Added explanation on retaining the CID file when a bad CID file is loaded in *Settings* under the *IEC 61850 Configuration* subsection.
	➤ Added an explanation for MMS authentication in ACSELERATOR Architect under the *IEC 61850 Configuration* subsection.
	➤ Added neutral time-overcurrent elements to *Table L.19: Logical Device: PRO (Protection)*.
	➤ Updated the number of math variables to 64 in *Table L.22: Logical Device: ANN (Annunciation)*.
	➤ Added 51N1, 51N1T, 51N2, 51N2T, FLREP, FLRNUM, HIFLREP, HIFLRNUM, and MAXWEAR to *Table L.24: Logical Nodes by Data Source Names*.
20130624	**Settings Sheets**
	➤ Added Setting RESPSZ.
	Appendix A
	➤ Updated for firmware version R403-V0.
	Appendix E
	➤ Updated *Table E.6: SEL-651R-2 Port DNP Protocol Settings*.
	➤ Update *Table E.9: SEL-651R-2 DNP3 Device Profile*.
20130508	**Section 2**
	➤ Modified *Figure 2.63 Trip/Close and Recloser Pole Status Circuit Connections Between Kyle NOVA-TS or NOVA-STS Triple-Single Recloser and SEL-651R-2 Recloser Control* and *Figure 2.64 Yellow Lockout Handle Circuit Connections Between Kyle NOVA-TS or NOVA-STS Triple-Single Recloser and SEL-651R-2 Recloser Control* by adding 53 Vdc to Pin C to support Kyle NOVA-STS recloser.
	➤ Verified connection of pins D, N, P, L, and R in *Figure 2.63 Trip/Close and Recloser Pole Status Circuit Connections Between Kyle NOVA-TS or NOVA-STS Triple-Single Recloser and SEL-651R-2 Recloser Control*.
20121219	**Section 1**
	➤ Added *Second Harmonic Blocking Logic* and the *Tavrida OSM Al_4* to *Specifications*.
	Section 2
	➤ Added *Multi-Recloser Interface* subsection
	Section 4
	➤ Added *Second Harmonic Blocking Logic* subsection.
	➤ Enhanced *Generator Application for SSLOW and SFAST* in the *Synchronism Check Elements* subsection.
	➤ Added *Load Encroachment for Directionally Controlled Elements* and *Load Encroachment for Nondirectional Elements* with examples to the *Load-Encroachment Logic* subsection.
	➤ Added *High-Impedance Fault Detection (Arc Sense Technology)* subsection.
	➤ Added *50G High-Impedance (HIZ) Fault Detection* subsection.
	Section 5
	➤ Added Multi-Recloser Interface "Yellow Operating Handle" trip logic to *Figure 5.2*, and *69_YH Relay Word bit for Multi-Recloser Interface* subsection.
	Section 6
	➤ Added Multi-Recloser Interface note to *Breaker Status Logic*.
	➤ Changed 79RSLD "reset time from lockout" lower range to 0 cycles in *Table 6.6*.
	➤ Added Multi-Recloser Interface "Yellow Operating Handle" drive-to-lockout logic to *Table 6.8* and *Figure 6.11*.
	Section 7
	➤ Added Multi-Recloser Interface note to *Trip and Close Mapping and Output Logic* subsection.
	Section 8
	➤ Added *High-Impedance Fault Metering* subsection.
	➤ Added Multi-Recloser Interface notes to *Breaker/Recloser Contact Wear Monitor* subsection.

Table A.2 Instruction Manual Revision History (Sheet 7 of 8)

Revision Date	Summary of Revisions
	Section 9
	➤ Added notes to *Current and Voltage Connections (Global Settings)*, *Breaker Monitor Initiate Settings (Global Settings)*, *Potential Transformer (PT) Ratios (Group Settings)*, and *Pole Status (52a), Trip, and Close Mapping Variations for Single-Phase Trip Capable Reclosers (Group Settings)* subsections to explain settings differences for the Multi-Recloser Interface.
	➤ Added settings for High-Impedance Fault Detection, 50G High-Impedance (HIZ) Detection, Second Harmonic Blocking, and the Multi-Recloser Interface (Global setting RECL_CFG) to the *SEL-651R-2 Settings Sheets*.
	➤ Changed 79RSLD "reset time from lockout" lower range to 0 cycles in *SEL-651R-2 Settings Sheets*.
	Section 10
	➤ Updated *Figure 10.5* and *Figure 10.6* to reflect new web server display.
	➤ Updated **FILE** command explanation to include HF_nnnnn.* (high-impedance fault) and HR_nnnnn.* (standard raw) COMTRADE event reports.
	➤ Added **HIS E** command, and updated **CEV** and **EVE** commands to accept unique event numbers.
	➤ Added **CEV HIF**, **CHI HIF**, **HIS HIF**, **INI HIF**, **LOG HIF, MET HIF**, **SUM HIF**, and **TRI HIF** commands for High-Impedance Fault (HIF) Detection to *Command Summary* and *Command Explanations* subsections.
	➤ Added **HIZ** command for 50G High-Impedance (HIZ) Fault Detection to *Command Summary* and *Command Explanations* subsections.
	Section 12
	➤ Added COMTRADE file format event reports to the *Standard 15/30/60-Cycle Event Reports* subsection and modified outline of subsection.
	➤ Added **HIS E** command (unique event numbers).
	➤ Added *High-Impedance Fault Event Reporting* subsection.
	➤ Changed the event report row that is used to determine the shot count.
	Section 13
	➤ Added the *Low-Level Test Interface* subsection.
	Appendix A
	➤ Updated for firmware version R402-V0.
	Appendix B
	➤ Added Important Note regarding upgrade path from R400 via Web Server.
	Appendix C
	➤ Added compressed reports for High-Impedance Fault Detection throughout section.
	Appendix F
	➤ Added Relay Word bits for High-Impedance Fault Detection, 50G High-Impedance (HIZ) Detection, Second Harmonic Blocking, and the Multi-Recloser Interface throughout section.
	Appendix I
	➤ Added note regarding communications processor compatibility.
	Appendix J
	➤ Revised PMSTN setting to allow mixed case.
	➤ Added *Table J.6: C37.118 Data Frame*.
	➤ Revised *Configuring High-Accuracy Timekeeping* for change in parity checking.
	Appendix K
	➤ Added new Relay Element Status Rows to *Table K.7* and *Table K.22* for High-Impedance Fault Detection, 50G High-Impedance (HIZ) Detection, Second Harmonic Blocking, and the Multi-Recloser Interface Relay Word bits.

Firmware Upgrade Instructions

Overview

These instructions guide you through the process of upgrading firmware in the device. The firmware upgrade will be either a standard release or a point release. A standard release adds new functionality to the firmware beyond the specifications of the existing version. A point release is reserved for modifying firmware functionality to conform to the specifications of the existing version.

A standard release is identified by a change in the R-number of the device firmware identification (FID) number.

Existing firmware:

FID=SEL-651R-2-**R100**-Vx-Zxxxxxx-Dxxxxxxxx

Standard release firmware:

FID=SEL-651R-2-**R101**-Vx-Zxxxxxx-Dxxxxxxxx

A point release is identified by a change in the V-number of the device FID number.

Existing firmware:

FID=SEL-651R-2-Rxxx-**V0**-Zxxxxxx-Dxxxxxxxx

Point release firmware:

FID=SEL-651R-2-Rxxx-**V1**-Zxxxxxx-Dxxxxxxxx

The release date is after the D. For example, the following is firmware version number R100, release date December 10, 2003.

FID=SEL-651R-2-R100-Vx-Zxxxxxx-**D20031210**

The instructions that follow explain how you can install new firmware in your SEL-651R-2 Recloser Control with Ethernet. These instructions are for firmware upgrades only and do not provide complete instructions for part number changes. If a part number change is required, contact SEL for assistance.

This appendix contains the following subsections:

➤ *Relay Firmware Upgrade Methods on page B.2*

➤ *Method One: Using QuickSet Firmware Loader on page B.3*

➤ *Method Two: Using a Terminal Emulator on page B.8*

➤ *Method Three: Using a Web Browser on page B.14*

➤ *Solving Firmware Upgrade Issues on page B.18*

B.2 | Firmware Upgrade Instructions
Relay Firmware Upgrade Methods

Relay Firmware Upgrade Methods

Introduction

These firmware upgrade instructions apply to SEL-651R-2 recloser controls with at least one Ethernet port.

SEL occasionally offers firmware upgrades to improve the performance of your relay. Changing physical components is unnecessary because the relay stores firmware in Flash memory.

A firmware loader program called SELBOOT resides in the relay. To upgrade firmware, use the SELBOOT program to download an SEL-supplied file from a personal computer to the relay via the USB port, a serial port, or use the built-in web server over an Ethernet port.

Keep the AC Power On!

When upgrading firmware, make sure to keep the SEL-651R-2 energized with ac power—do not have it running just off the battery. Otherwise, when the **L_D** command is issued later in the firmware upgrade procedure (to disable the unit to receive new firmware), the unit goes immediately "to sleep," thus aborting the firmware upgrade procedure.

NOTE: SEL strongly recommends that you upgrade firmware at the location of the relay and with a direct connection from the personal computer to the USB port or one of the relay serial ports. Do not load firmware from a remote location while the control is in service. Problems can arise that you may not be able to address from a distance. When upgrading at the substation, do not attempt to load the firmware into the relay through an SEL communications processor.

IMPORTANT NOTE: When upgrading firmware from R400 via the web server, to maintain user settings, upgrade to R401 first, then upgrade to the desired release (e.g., to upgrade from R400 to R4xx, upgrade from R400 to R401, and then upgrade from R401 to R4xx). Failure to comply will result in loss of user settings and default settings will be restored. Therefore, web server communication will be disabled (default setting EHTTP = N).

The firmware upgrade can be performed one of three ways:

➤ Method One: Use the Firmware Loader provided within ACSELERATOR QuickSet SEL-5030 Software. The Firmware Loader automates the firmware upgrade process.

➤ Method Two: Connect to the relay in a terminal session and upgrade the firmware by using the steps documented in *Method Two: Using a Terminal Emulator*.

➤ Method Three: Establish an Ethernet connection and use a web browser to access the embedded web server. Upgrade the firmware by using the steps documented in *Method Three: Using a Web Browser*. This is the fastest method to complete an upgrade.

The same basic actions are required in all methods:

A. Obtain the firmware file

B. Remove relay from service

C. Establish communications with the relay

D. Prepare the relay (save settings and other data)

E. Perform firmware upgrade

F. Check relay self-tests

G. Verify relay settings

H. Return the relay to service

Required Equipment

Gather the following equipment before starting this firmware upgrade:

➤ Personal computer

➤ To use Method One, QuickSet

➤ To use Method Two, terminal emulation software that supports 1K Xmodem or Xmodem (these instructions use HyperTerminal from a Microsoft Windows operating system)

Case No. 2018-00295

Firmware Upgrade Instructions   B.3
Digitally Signed Firmware Files

➤ For Methods One and Two, serial communications cable (SEL-C234A, SEL-C662 USB-to-232 converter, or equivalent) or USB cable (SEL-C664 or equivalent)

➤ To use Method Three, an Ethernet connection and compatible web browser

➤ Disk containing the firmware upgrade (.zds) file

➤ Firmware Upgrade Instructions (these instructions)

➤ Your relay instruction manual

Digitally Signed Firmware Files

This device supports digitally signed firmware upgrades. These firmware upgrade files are compressed to reduce file transfer times and digitally signed by SEL using a secure hash algorithm. The signature ensures that the file has been provided by SEL and that its contents have not been altered. Once uploaded to the relay, the signature (and thus validity) of the firmware is verified with a public key number that is stored on the relay from the factory. If the signature cannot be verified, the file is rejected.

The name of the digitally signed firmware file is of the form Rxxx651R.zds or Rxxx-Vy651R.zds, where Rxxx is the firmware revision number, Vy is the point release revision number, 651R indicates the relay type, and .zds is the file extension reserved for digitally signed files.

Method One: Using QuickSet Firmware Loader

To use the QuickSet Firmware Loader, you must have QuickSet. See *Section 3: PC Software* for instructions on how to obtain and install the software. Once the software is installed, perform the firmware upgrade as follows.

A. Obtain Firmware File

The firmware file is usually provided on a CD-ROM. Locate the firmware file on the disc. Copy the firmware file to an easily accessible location on the PC.

Firmware is designed to be used with specific relays. A list of relay serial numbers is provided as part of the firmware upgrade package. The firmware provided is for use with the listed relays only. Attempts to upgrade relays not listed will not be successful and can result in relay failure.

B. Remove Relay From Service

Step 1. If the relay is in use, follow your company practices for removing a relay from service. Typically, these include changing settings, or disconnecting external voltage sources or output contact wiring, to disable relay control functions.

Step 2. Apply ac power to the control.

B.4 | Firmware Upgrade Instructions
Method One: Using QuickSet Firmware Loader

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 778 of 1080
Wolfe

Step 3.   Connect a communications cable and determine the port speed.

If using the EIA-232 front port to upgrade firmware, determine the port speed as follows:

   a.   From the relay front panel, press the ENT pushbutton.

   b.   Use the arrow pushbuttons to navigate to Set/Show and press the ENT pushbutton.

   c.   Use the arrow pushbuttons to navigate to **PORT**.

   d.   Press the ENT pushbutton.

   e.   Use the arrow pushbuttons to navigate to the relay serial port you plan to use (usually the front port).

   f.   Press the ENT pushbutton.

   g.   With **Communication Settings** selected, press the ENT pushbutton.

   h.   Press the down arrow pushbutton to scroll through the port settings; write down the value for each setting.

   i.   Connect an SEL-C234A EIA-232 serial cable, SEL-C662 USB-to-232 converter, or equivalent communications cable to the relay serial port and to the PC.

If using the relay front-panel USB port to upgrade firmware, connect an SEL-C664 cable between the relay and the PC. The USB port appears as a serial connection. Any data rate will be accepted by the relay.

C. Establish Communications With the Relay

Use the **Communications > Parameters** menu of QuickSet to establish a connection. See *Section 3: PC Software* for additional information.

D. Prepare the Relay (Save Relay Settings and Other Data)

It is possible for data to be lost during the firmware upgrade process. Follow the steps in this section carefully to ensure that important data are saved.

Step 1.   Select **Tools > Firmware Loader** and follow the on-screen prompts.

Step 2.   In the Step 1 of 4 window of the Firmware Loader, click the ellipsis button and navigate to the location of the firmware file. Select the file and click **Open** (see *Figure B.1*).

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 770 of 1080
Wolfe
Firmware Upgrade Instructions   B.5
Method One: Using QuickSet Firmware Loader

Figure B.1   Prepare the Device (Step 1 of 4)

Step 3.   Select the **Save calibration settings** check box in the Step 1 of 4 window of the Firmware Loader. These factory-default settings are required for proper operation of the relay and must be reentered in the unlikely event they are erased during the firmware upgrade process. The Firmware Loader saves the settings in a text file on the PC.

Step 4.   Select the **Save device settings** check box if you do not have a copy of the relay settings. It is possible for relay settings to be lost during the upgrade process.

Step 5.   Select the **Save events** check box if there are any event reports that have not been previously saved. It is possible for event reports to be lost during the upgrade process.

Step 6.   Click **Next**.

The Firmware Loader reads the calibration settings and saves them in a text file on the PC. Make note of the file name and the location.

If **Save device settings** was selected, the Firmware Loader reads all of the settings from the relay. The software may ask if you wish to merge the settings read from the relay with existing design templates on the PC. Click **No, do not merge settings with Design Template**. The Firmware Loader will suggest a name for the settings, but the suggested name can be modified as desired.

If **Save events** was selected, the Event History window will open to allow the events to be saved. See *QuickSet Event Analysis on page 3.18* for more information.

Step 7.   If you use the Breaker Wear Monitor, click the **Terminal** button in the lower left portion of the Firmware Loader to open the terminal window. From the Access Level 1 prompt, issue the **BRE** command and record the internal and external trip counters, internal and external trip currents for each phase, and breaker wear percentages for each phase.

B.6 | Firmware Upgrade Instructions
Method One: Using QuickSet Firmware Loader

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 780 of 1080
Wolfe

Step 8. Enable Terminal Logging capture (see *QuickSet Terminal on page 3.5*) and issue the following commands to save stored data. It is possible for these data to be lost during the firmware upgrade process. (Some of these features are not available on all relay models.)

   a. **MET E**—accumulated energy metering

   b. **MET D**—demand and peak demand

   c. **MET M**—maximum/minimum metering

   d. **COMM A** and **COMM B**—MIRRORED BITS communications logs

   e. **LDP**—Load Profile

   f. **SSI**—Voltage sag, swell, interrupt recorder

   g. **SER**—Sequential Events Report

E. Start SELBOOT

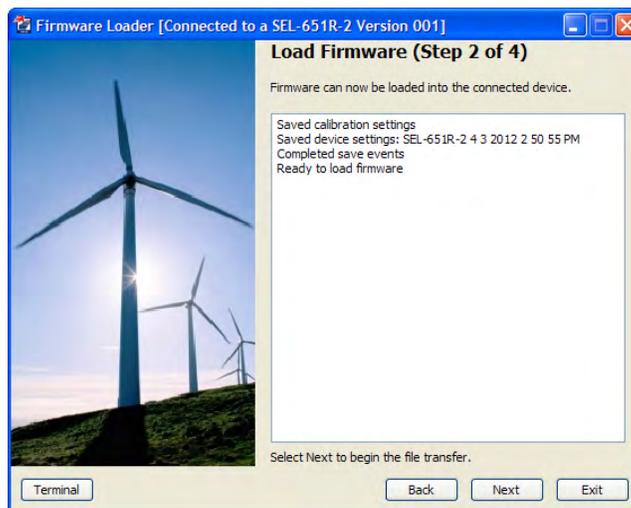
In the Step 2 of 4 window of the Firmware Loader, click **Next** to disable the relay and enter SELBOOT (see *Figure B.2*).


Figure B.2   Load Firmware (Step 2 of 4)

G. Upload New Firmware

This step is performed automatically by the software. The software will erase the existing firmware and start the file transfer to upload the new firmware. Upload progress will be shown in the **Transfer Status** window.

When the firmware upload is complete, the relay will restart. The Firmware Loader will automatically re-establish communications and issue a **STA** command to the relay.

If the relay does not restart within two minutes of the firmware upload completion (as indicated by the PC application) and no error messages appear on the relay HMI, cycle power to the relay. The firmware loader application should then resume. Click **Yes** if the Firmware Loader prompts you to continue.

H. Check Relay Self-Tests

The Step 3 of 4 window of the Firmware Loader will indicate that it is checking the device status and when the check is complete (see *Figure B.3*). The software will notify you if any problems are detected. You can view the

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Firmware Upgrade Instructions B.7
Page 781 of 1080
Method One: Using QuickSet or Firmware Loader
Wolfe

relay status by clicking the **Terminal** button in the lower left portion of the Firmware Loader. If status failures are shown, open the terminal and see *Solving Firmware Upgrade Issues*.

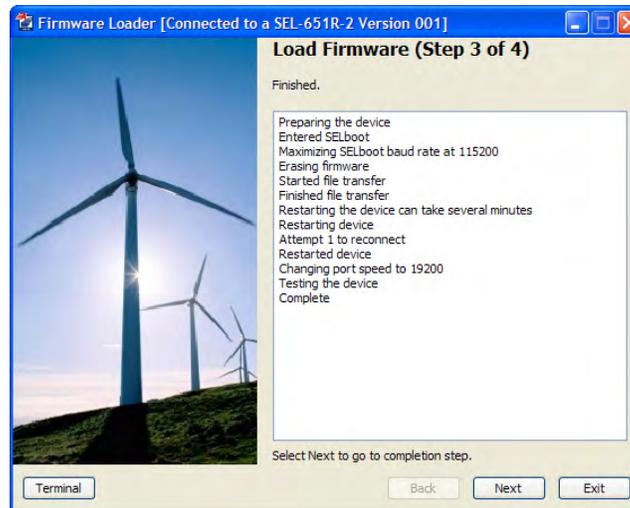
Click **Next** to go to the completion step.


Figure B.3   Load Firmware (Step 3 of 4)

I. Verify Relay Settings

If there are no failures, the relay will enable. In the Step 4 of 4 window (see *Figure B.4*), the Firmware Loader will give you the option to compare the device settings. If any differences are found, the software will provide the opportunity to restore the settings.

Figure B.4   Verify Device Settings (Step 4 of 4)

J. Return Relay to Service

Step 1.   Open the terminal window by clicking the **Terminal** button in the lower left portion of the Firmware Loader.

Step 2.   Use the **ACC** command with the associated password to enter Access Level 1.

B.8 | Firmware Upgrade Instructions
Method Two: Using a Terminal Emulator

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 782 of 1080
Wolfe

Step 3. Issue the **ID** command and compare the firmware revision (Rxxx) displayed in the FID string against the number from the firmware envelope label. If the numbers match, proceed to *Step 5*.

Step 4. For a mismatch between a displayed FID and the firmware envelope label, reattempt the upgrade or contact SEL for assistance.

Step 5. If you use the Breaker Wear Monitor, type **BRE <Enter>** to check the data to see if the relay retained breaker wear data through the upgrade procedure. If the relay did not retain these data, use the **BRE W** command to reload the percent contact wear values recorded in *D. Prepare the Relay (Save Relay Settings and Other Data) on page B.4*.

Step 6. Apply current and voltage signals to the relay.

Step 7. Type **MET <Enter>** or use the QuickSet HMI to verify that the current and voltage signals are correct.

Step 8. Use the **TRI** and **EVE/CEV** commands or **Tools > Events > Get Events** menu in QuickSet to verify that the magnitudes of the current and voltage signals you applied to the relay match those displayed in the event report. If these values do not match, check the relay settings and wiring.

Step 9. Autoconfigure the SEL communications processor port if you have an SEL communications processor connected to the relay. This step reestablishes automatic data collection between the SEL communications processor and the relay. Failure to perform this step can result in automatic data collection failure when cycling communications processor power.

Step 10. Follow your company procedures for returning a relay to service.

Method Two: Using a Terminal Emulator

The instructions for this section use HyperTerminal as a terminal emulator. If HyperTerminal is not used, certain instructions may have to be modified (different menu names used) to execute the step.

A. Obtain Firmware File

Follow the directions under *A. Obtain Firmware File on page B.3*.

B. Remove Relay From Service

Follow the directions under *B. Remove Relay From Service on page B.3*.

C. Establish Communications With the Relay

Refer to *Establishing Communications Using a Serial Port on page 10.1*. If using the relay front-panel USB port, a port driver must be installed on the PC (see *Establishing Communications Through Use of the USB Port on page 10.2*).

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 783 of 1080
Wolfe

Firmware Upgrade Instructions B.9
Method Two: Using Terminal Emulator

D. Prepare the Relay (Save Relay Settings and Other Data)

It is possible for data to be lost during the firmware upgrade process. Follow the steps in this section carefully to ensure that important data are saved.

Before upgrading firmware, retrieve and record any History (**HIS**) or Event (**EVE**, **CEV**) data that you want to retain. See *Section 10: Communications* for an explanation of the commands. During this process, you may find it helpful to use the Capture Text feature of Terminal Emulator. See additional instructions for using Capture Text in *Backup Relay Settings and Other Data*.

Enter Access Level 2

NOTE: If the relay does not prompt you for Access Level 1 and Access Level 2 passwords, check whether the relay Access jumper is in place. With this jumper in place, the relay is unprotected from unauthorized access (see Section 2: Installation).

Step 1. Type **ACC <Enter>** at the Access Level 0 = prompt.

Step 2. Type the Access Level 1 password and press **<Enter>**.

You will see the Access Level 1 => prompt.

Step 3. Type **2AC <Enter>**.

Step 4. Type the Access Level 2 password and press **<Enter>**.

You will see the Access Level 2 =>> prompt.

Backup Relay Settings and Other Data

The relay preserves settings and passwords during the firmware upgrade process. However, interruption of relay power during the upgrade process can cause the relay to lose settings. Make a copy of the original relay settings in case you need to reenter the settings. Use either the SEL-5010 Relay Assistant software or QuickSet to record the existing relay settings and proceed to *E. Start SELBOOT*. Otherwise, perform the following steps:

Step 1. From the **Transfer** menu in **HyperTerminal**, select **Capture Text**.

Step 2. Enter a directory and file name for a text file where you will record the existing relay settings.

Step 3. Click **Start**.

The **Capture Text** command copies all the information you retrieve and all the keystrokes you type until you send the command to stop capturing text. The terminal emulation program stores these data in the text file.

Step 4. Execute the Show Calibration (**SHO C**) command to retrieve the relay calibration settings.

Use the following Show commands to retrieve the relay settings: **SHO F**, **SHO G**, **SHO 1**, **SHO L 1**, **SHO 2**, **SHO L 2**, **SHO 3**, **SHO L 3**, **SHO 4**, **SHO L 4**, **SHO 5**, **SHO L 5**, **SHO 6**, **SHO L 6**, **SHO 7**, **SHO L 7**, **SHO 8**, **SHO L 8**, **SHO P 1**, **SHO P 2**, **SHO P 3**, **SHO P F**, **SHO P 5**, **SHO R**, **SHO D 1**, **SHO D 2**, **SHO D 3**, and **SHO M**.

Step 5. Issue the following commands to save stored data. It is possible for these data to be lost during the firmware upgrade process. (Some of these features are not available on all relay models.)

a. **MET E**—accumulated energy metering

b. **MET D**—demand and peak demand

c. **MET M**—maximum/minimum metering

B.10 | Firmware Upgrade Instructions
Method Two: Using a Terminal Emulator

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 784 of 1080
Wolfe

d. **COMM A** and **COMM B**—MIRRORED BITS communications logs

e. **LDP**—Load Profile

f. **SSI**—Voltage sag, swell, interrupt recorder

g. **SER**—Sequential Events Report

h. **BRE**—Breaker Wear Monitor data

Step 6. From the **Transfer** menu in **HyperTerminal**, select **Capture Text** and click **Stop**.

Step 7. The computer saves the text file you created to the directory you specified in *Step 2*.

Step 8. Write down the present relay data transmission setting (SPEED) for the port to be used for the firmware upgrade.

The SPEED setting is included in the **SHO P** relay settings output. The SPEED value should be the same as the value you recorded in *B. Remove Relay From Service on page B.8*.

E. Start SELBOOT

NOTE: A message similar to the following may be displayed when you type **L_D <Enter>**: "WARNING: Settings were not properly saved – Settings upgrade may fail. Please contact an SEL representative if assistance is required." Some relays have an automatic settings backup routine. This message indicates that the backup was not successful. If you saved settings as instructed in Backup Relay Settings and Other Data on page B.9, continue with the firmware upgrade process. Otherwise, type **EXI** at the prompt to exit SELBOOT. Follow the instructions under Backup Relay Settings and Other Data on page B.9 to ensure that the existing settings are available after the firmware upgrade.

Step 1. From the computer, start the SELBOOT program:

a. From the Access Level 2 =>> prompt, type **L_D <Enter>**.

The relay responds with the following:

```
Disable relay to send or receive firmware
(Y/N)?
```

b. Type **Y <Enter>**.

The relay responds with the following:

```
Are you sure (Y/N)?
```

c. Type **Y <Enter>**.

The relay responds with the following:

```
Relay Disabled
```

Step 2. Wait for the SELBOOT program to load.

The front-panel LCD screen displays SELBOOT. The computer will display the SELBOOT !> prompt after SELBOOT loads.

Step 3. Press **<Enter>** to confirm that the relay is in SELBOOT.

You will see another SELBOOT !> prompt.

Commands Available in SELBOOT

For a listing of commands available in SELBOOT, type **HELP <Enter>**. You should see a screen similar to *Figure B.5*.

Case No. 2018-00295

BFID=SLBT-3CF1-Rxxx-Vx-Zxxxxxx-Dxxxxxxxx
USBID=1.1 (015)

Baud                   - Set to a standard baud rate from 300 to 115200 bps.
Erase                  - Erase the existing firmware.
Exit                   - Exit this program and restart the device.
FID                    - Display the firmware identification (FID).
Receive [BOOT | KEY] - Receive new firmware/key for the device using Xmodem.
Help                   - Print this help list.

Program Memory Size: 01000000
Firmware Checksum = B9DC  OK

!>
```

Figure B.5   List of Commands Available in SELBOOT

F. Maximize Port Data Rate for EIA-232 Ports

Step 1.   Type **BAU 115200 <Enter>** at the SELBOOT !> prompt.

Step 2.   Change the **Bits per second** setting in the **Com Properties** of the terminal emulator software to 115200.

> **NOTE:** The USB port speed is fixed. If you are using the USB port for the firmware upgrade, continue to G. Upload New Firmware.

G. Upload New Firmware

Step 1.   Type **REC <Enter>** at the SELBOOT !> prompt to command the relay to receive new firmware.

```
!>REC <Enter>
Caution! -  This command erases the relays firmware.
If you erase the firmware, new firmware must be loaded into the relay
before it can be put back into service.
```

The relay asks whether you want to erase the existing firmware.

```
Are you sure you wish to erase the existing firmware? (Y/N) Y
```

Step 2.   Type **Y** to erase the existing firmware and load new firmware. (To abort, type **N** or press **<Enter>**).

The relay responds with the following:

```
Erasing
Erase successful
Press any key to begin transfer, then start transfer at the PC <Enter>
```

Step 3.   Press **<Enter>** to start the file transfer routine.

Step 4.   Send new firmware to the relay.

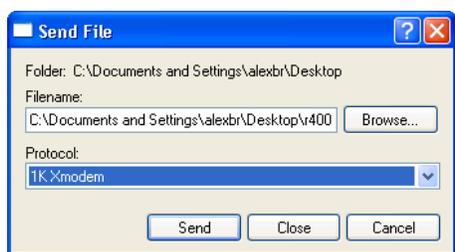
    a.   From the **Transfer** menu in HyperTerminal, choose **Send File** (see *Figure B.6*).


Figure B.6   Selecting New Firmware to Send to the Relay

B.12 Firmware Upgrade Instructions
Method Two: Using a Terminal Emulator

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 786 of 1080
Wolfe

b. In the **Filename** text box, type the location and filename of the new firmware or use the **Browse** button to select the firmware file.

c. In the **Protocol** text box, select **1K Xmodem** if this protocol is available.

If the computer does not have **1K Xmodem**, select **Xmodem**.

d. Click **Send** to send the file containing the new firmware.

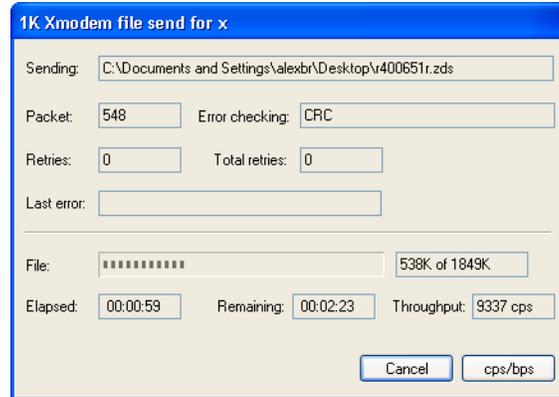
NOTE: The relay restarts in SELBOOT if relay power fails while receiving new firmware. Upon power-up, the relay serial port will be at the default 9600 bps. Perform the steps beginning in C. Establish Communications With the Relay to increase the serial connection data speed. Then resume the firmware upgrade process at G. Upload New Firmware.


Figure B.7   Transferring New Firmware to the Relay

You should see a dialog box similar to *Figure B.7*. Incrementing numbers in the **Packet** box and a bar advancing from left to right in the **File** box indicate that a transfer is in progress.

If you see no indication of a transfer in progress within a few minutes after clicking **Send**, use the **REC** command again and reattempt the transfer.

Step 5.   Wait for the transfer to be completed.

a. If you are using an EIA-232 port, the relay displays the following:

```
Upload completed successfully. Attempting a restart.
```

b. If you are using the front-panel USB port, the relay displays the following after the transfer is completed:

```
Upload completed successfully. Press any key to restart.
```

After a key is pressed, the relay displays:

```
Close the USB port and remove the USB cable.
Attempting a restart in 5 seconds.
```

From the **Call** menu of HyperTerminal, choose **Disconnect** and remove the USB cable from the front of the relay.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Firmware Upgrade Instructions B.13
Page 787 of 1080
Method Two: Using Terminal Emulation
Wolfe

Step 6.   Wait for relay to restart.

A successful restart sequence can take as long as two minutes, after which time the relay leaves SELBOOT. You will see no display on your PC to indicate a successful restart. A successful restart is indicated when the **ENABLED** LED illuminates. This LED is labeled either **EN** or **ENABLED**, depending on the relay model.

If the relay does not restart within two minutes of the firmware upload completion (as indicated by the PC terminal emulator) and no error messages appear on the relay HMI, cycle power to the relay. Re-establish your connection in HyperTerminal and continue with Step 7.

In some cases, the **ENABLED** LED may not illuminate and a `FAIL` message will be displayed on the relay LCD screen, if equipped.

Step 7.   Change the **Bits per second** setting in the **Com Properties** of the terminal emulator software to match what was recorded in *Step 8* of *Backup Relay Settings and Other Data on page B.9*. Press **<Enter>** and confirm that the Access Level 0 = prompt appears on the computer screen.

If you are using the relay front-panel USB port, you will need to reestablish the connection.

   a.   Reinstall the cable.

   b.   From the **Call** menu of HyperTerminal, choose **Call** and press **<Enter>** several times, until you see the `Access Level 0 =` prompt.

Step 8.   If you see the `Access Level 0 =` prompt, proceed to *H. Check Relay Self-Tests*.

No Access Level 0 = Prompt

If no `Access Level 0 =` prompt appears in the terminal emulation window, one of several things could have occurred. Refer to *Table B.1* to determine the best solution:

Table B.1   Troubleshooting New Firmware Upload (Sheet 1 of 2)

Problem	Solution
The restart was successful, but the relay data transmission rate reverted to the rate at which the relay was operating prior to entering SELBOOT (the rate you recorded in *B. Remove Relay From Service*).	Change the computer terminal speed to match the relay data transmission rate you recorded in *B. Remove Relay From Service*. Step 1. From the **Call** menu, choose **Disconnect** to terminate relay communication. Step 2. Change the communications software settings to the values you recorded in *B. Remove Relay From Service*. Step 3. From the **Call** menu, choose **Call** to reestablish communication. Step 4. Press **<Enter>** to check for the Access Level 0 = prompt indicating that serial communication is successful.
The restart was successful, but the relay data transmission rate reverted to 9600 bps (the settings have been reset to default).	Match the computer terminal speed to a relay data transmission rate of 9600 bps. Step 1. From the **Call** menu, choose **Disconnect** to terminate relay communication. Step 2. Change the communications software settings to 9600 bps, 8 data bits, no parity, and 1 stop bit (see *F. Maximize Port Data Rate for EIA-232 Ports*). Step 3. From the **Call** menu, choose **Call** to reestablish communication. Step 4. Press **<Enter>** to check for the Access Level 0 = prompt indicating successful serial communication.

B.14 | Firmware Upgrade Instructions
Method Three: Using a Web Browser

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 788 of 1080
Wolfe

Table B.1   Troubleshooting New Firmware Upload (Sheet 2 of 2)

Problem	Solution
The restart was unsuccessful, in which case the relay is in SELBOOT, indicated by a SELBOOT !> prompt.	If you see a SELBOOT !> prompt, type **EXI <Enter>** to exit SELBOOT. Check for the Access Level 0 = prompt. If you see the Access Level 0 = prompt, proceed to *H. Check Relay Self-Tests*. If the relay will not exit SELBOOT, reattempt to upload the new firmware (beginning at *Step 1* under *G. Upload New Firmware*) or contact the factory-default for assistance.
Cannot communicate with relay via front-panel USB port.	From the **Call** menu of HyperTerminal, choose Disconnect and remove the USB cable from the front of the relay. Reinstall the cable and see *C. Establish Communications With the Relay*. See *Section 13: Testing and Troubleshooting* for additional troubleshooting tips.

H. Check Relay Self-Tests

The relay can display various self-test fail status messages. The troubleshooting procedures that follow depend upon the status message the relay displays.

Step 1.   Enter the **STATUS** command (**STA <Enter>**) at Access Level 1 to view relay status messages.

If the relay displays no fail status message, proceed to *I. Verify Relay Settings*.

If failures are displayed in the status message, proceed to *Solving Firmware Upgrade Issues*.

I. Verify Relay Settings

Step 1.   Use the **SHO** command to view the relay settings and verify that these match the settings you saved earlier (see *Backup Relay Settings and Other Data*).

If the settings do not match, reenter the settings you saved earlier.

J. Return the Relay to Service

Step 1.   Open the terminal window.

Step 2.   Follow *Step 2–Step 10* under *J. Return Relay to Service on page B.7*.

Method Three: Using a Web Browser

A. Set Port 5 Setting HTTPACC to 2

To upgrade firmware by using a web browser, the Port 5 setting HTTPACC must be set to 2. If this setting is set to 2, the FWFPC setting becomes available. FWFPC determines whether front-panel confirmation is required for firmware upgrades and defaults to Y. If FWFPC is set to N, the firmware upgrade process will take place without the need for front-panel confirmation. See *F. Upload New Firmware* for details on the front-panel confirmation process.

B. Obtain Firmware File

Follow instructions under *A. Obtain Firmware File on page B.3*.

C. Remove Relay From Service

Step 1.   If the relay is in use, follow your company practices for removing a relay from service. Typically, these include changing settings, or disconnecting external voltage sources or output contact wiring, to disable relay control functions.

Step 2. Apply ac power to the control.

Step 3. Establish an Ethernet connection to the device. See *Establishing Communications Using an Ethernet Port and Telnet or the Web Server on page 10.7* for more detailed instructions.

D. Establish Communications With the Relay

Establish communication between your personal computer and the relay by using a web browser. See *Using the Embedded Web Server (HTTP) on page 10.18* for more information. Establish a Telnet session with HyperTerminal (or an equivalent) using the TCP/IP connection, with the Host address and Port number set to match the Port 5 settings IPADDR (e.g., 192.168.1.2) and TPORT (e.g., 23), respectively.

E. Prepare the Relay (Save Relay Settings and Other Data)

Using the Telnet session, follow *D. Prepare the Relay (Save Relay Settings and Other Data) on page B.9*.

F. Upload New Firmware

NOTE: Access Level passwords are not encrypted in any way by the web server when logging in.

IMPORTANT NOTE: When upgrading firmware from R400 via the web server, to maintain user settings, upgrade to R401 first, then upgrade to the desired release (e.g., to upgrade from R400 to R4xx, upgrade from R400 to R401, and the upgrade from R401 to R4xx). Failure to comply will result in loss of user settings and default settings will be restored. Therefore, web server communication will be disabled (default setting EHTTP = N).

Step 1. To upload new firmware, log in to Access Level 2 of the web server. Select **2AC** from the Access Level drop-down box. Enter the respective **ACC** and **2AC** passwords and click the **Login** button.

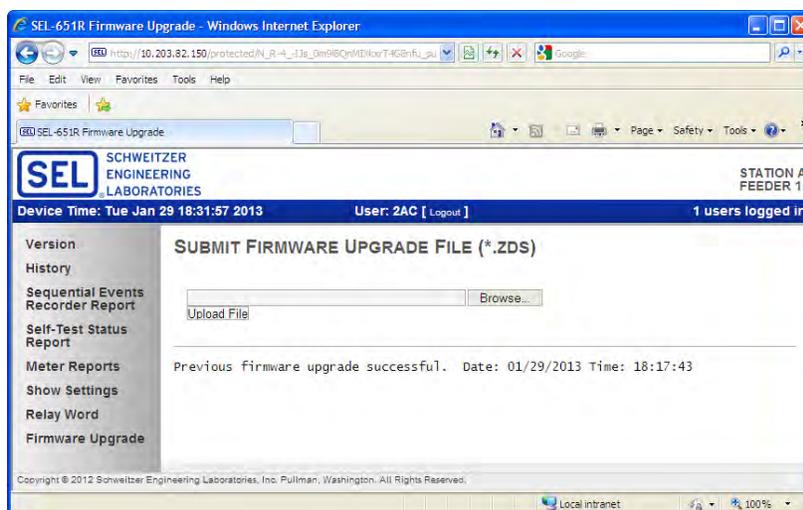
Step 2. Once logged in verify communication with the correct control by checking the Relay Identifier (RID setting) and Terminal Identifier (TID setting). Choose **Firmware Upgrade** from the left pane, which will bring up the page shown in *Figure B.8*. This page also displays feedback from the previous firmware upgrades. If the prior firmware upgrade was successful, the page will display the message shown in *Figure B.8*. If the prior firmware upgrade failed, the page will display `Previous firmware upgrade failed. Date: xx/xx/xxxx Time: hh:mm:ss`, with an error message below. See *Solving Firmware Upgrade Issues* for possible error messages and their descriptions. If no prior firmware upgrade has occurred (which is the case for a new unit from the factory), the page will display `Previous firmware upgrade information is unavailable`.


Figure B.8   Firmware Upload File Selection Page

B.16 | Firmware Upgrade Instructions
Method Three: Using a Web Browser

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 790 of 1080
Wolfe

Step 3. To search for your firmware file, click on the **Browse** button. The format of this file must be .zds.

Step 4. To submit, click **Upload File**. Once the upload has started, it cannot be canceled. During the upload process the control will remain enabled and continue normal operation.

Step 5. Once the firmware file is transferred to the device, the relay will attempt to restart using the new firmware. This process will complete in as fast as 45 seconds.

Step 6. If front-panel confirmation is enabled (setting FWFPC = Y) and the file upload is complete, the web server will display the message shown in *Figure B.8* and the following message will be displayed on the relay's LCD:

```
CONFIRM UPGRADE?
ESC = N; ENT = Y
```

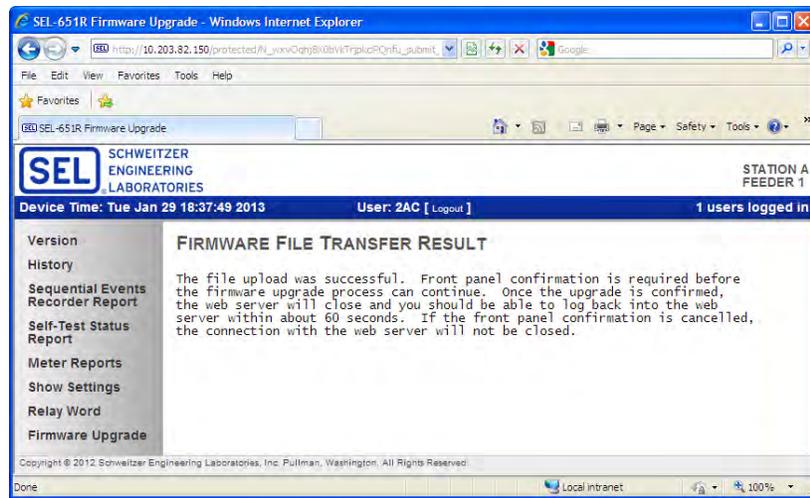

Figure B.9   Firmware Upgrade With Front-Panel Confirmation Required

a. Press the **ENT** button to confirm the firmware upgrade. Once front-panel confirmation is given, the HTTP session will close and the firmware upgrade will take place.

b. If front-panel confirmation is not given within 60 seconds, the message shown in *Figure B.9* will be displayed by the web server at the Firmware Upgrade page. The HTTP session will remain open and the firmware upgrade will not take place.

c. The control will remain enabled and in normal operation until the upgrade is confirmed via the front panel. If confirmation times out, the control will stay enabled and continue normal operation.

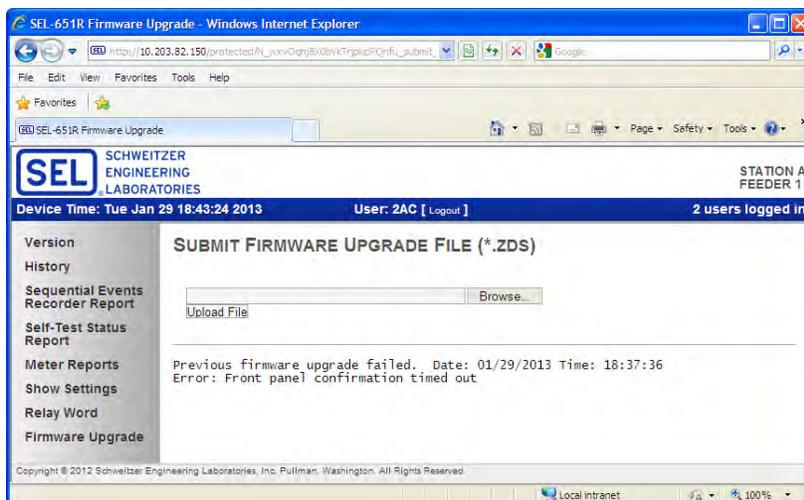
Page 1791 of 2102
Wolfe
Firmware Upgrade Instructions   B.17
Method Three: Using a Web Browser


Figure B.10   Front-Panel Confirmation Time-Out Message

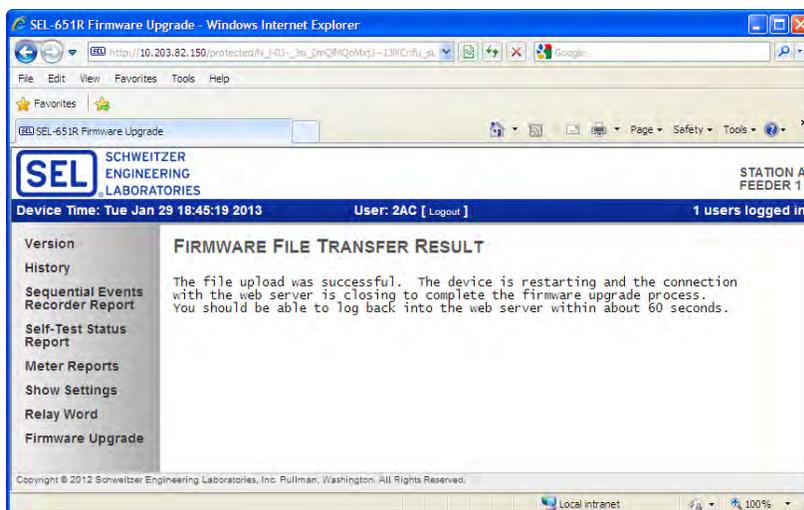
Step 7.   If front-panel confirmation is not enabled (FWFPC = N), the message shown in *Figure B.11* will be displayed by the web server. The HTTP session will close after the upload is complete and the firmware upgrade will take place.


Figure B.11   Firmware Upgrade Without Front-Panel Confirmation Required

G. Check Relay Self-Tests

After the firmware upgrade is completed and once you have logged back in to Access Level 1 of the web server, you can check the relay self-tests by clicking **Self-Test Status Report** in the left pane. If the relay displays no fail status message, proceed to *H. Verify Relay Settings*. If failures are displayed in the status message, proceed to *Solving Firmware Upgrade Issues*.

H. Verify Relay Settings

To verify the settings are correct for your relay, click **Show Settings** in the left pane. Verify that these match the settings you saved earlier (see *Backup Relay Settings and Other Data on page B.9*). Note that Calibration settings are not viewable via the web server, a terminal connection will be needed to verify these settings. If the settings do not match, reenter the settings you saved earlier.

Solving Firmware Upgrade Issues

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 792 of 1080
Wolfe

I. Return Relay to Service

Step 1. Begin a Telnet session by opening the terminal window. Type **telnet IPADDR**, where IPADDR is the Port 5 setting IPADDR (e.g., 192.168.1.2).

Step 2. Follow *Step 2–Step 10* under *J. Return Relay to Service on page B.7*.

Solving Firmware Upgrade Issues

If a `FAIL` message is returned in response to the **STA** command, perform the following steps.

Step 1. Use the **ACC** and **2AC** commands with the associated passwords to enter Access Level 2.

Step 2. Type **STA C <Enter>**. Answer **Y <Enter>** to the `Reboot the relay and clear status` prompt. The relay will respond with `Rebooting the relay`. Wait for about 30 seconds, then press **<Enter>** until you see the Access Level 0 = prompt.

Step 3. Use the **ACC** command with the associated password to enter Access Level 1.

Step 4. Type **STA <Enter>**.

If there are no fail messages and you are using Method One, click **Next** in Step 3 of 4 of the Firmware Loader and go to *I. Verify Relay Settings on page B.7*.

If there are no fail messages and you are using Method Two, go to *I. Verify Relay Settings on page B.14*.

If there are no fail messages and you are using Method Three, go to *H. Verify Relay Settings on page B.17*.

If there are fail messages, continue with *Step 5*.

Step 5. Use the **2AC** command with the associated password to enter Access Level 2.

Step 6. Type **R_S <Enter>** to restore factory-default settings in the relay.

The relay asks whether to restore default settings. If the relay does not accept the **R_S** command, contact SEL for assistance.

LOSS OF SETTINGS
Step 6 will cause the loss of settings and other important data. Be sure to retain relay settings and other data downloaded from the relay at the start of the firmware upgrade process.

Step 7. Type **Y <Enter>**.

The relay can take as long as two minutes to restore default settings. The relay then reinitializes and the **ENABLED** LED illuminates. Contact SEL for assistance if the relay does not enable.

Step 8. Press **<Enter>** to check for the Access Level 0 = prompt indicating that serial communication is successful.

Step 9. Use the **ACC** and **2AC** commands and type the corresponding passwords to reenter Access Level 2.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Firmware Upgrade Instructions   B.19
Page 793 of 1080
Solving Firmware Upgrade Issues
Wolfe

Step 10. Type **SHO C <Enter>** to verify the relay calibration settings.

If using Method One and the settings do not match the settings contained in the text file you recorded in *D. Prepare the Relay (Save Relay Settings and Other Data) on page B.4*, contact SEL for assistance.

If using Method Two and the settings do not match the settings contained in the text file you recorded in *D. Prepare the Relay (Save Relay Settings and Other Data) on page B.9*, contact SEL for assistance.

Step 11. Use the **PAS** command to set the relay passwords.

Step 12. Restore the relay settings:

 a. If you have SEL-5010 Relay Assistant software or QuickSet, restore the original settings by following the instructions for the respective software.

 b. If you do not have the SEL-5010 Relay Assistant software or QuickSet, restore the original settings by issuing the necessary **SET *n*** commands.

Step 13. If any failure status messages still appear on the relay display, see *Section 13: Testing and Troubleshooting* or contact SEL for assistance.

If the firmware upgrade process fails, one of the error messages in *Table B.2* will be displayed on the **Firmware Upgrade** page accessible from the left pane of the web server.

Table B.2   Firmware Upgrade Process Error Messages

Error Message	Description
`Invalid digital signature`	The digital signature verification failed.
`Invalid firmware file`	The firmware file failed one of many possible integrity checks.
`Front panel confirmation canceled`	The user canceled the front-panel confirmation process.
`Front panel confirmation timed out`	The user did not confirm or cancel the firmware upgrade process before the time-out period expired.

This page intentionally left blank

Appendix C

Compressed ASCII Commands

Overview

The SEL-651R-2 provides Compressed ASCII versions of some of the relay ASCII commands. The Compressed ASCII commands allow an external device to obtain data from the relay in a format that directly imports into spreadsheet or database programs and which can be validated with a checksum.

The SEL-651R-2 provides the following Compressed ASCII commands:

Command	Description
CASCII	Configuration message
CSTATUS	Status message
CHISTORY	History message
CHISTORY HIF[a]	HIF history message
CEVENT	Event message
CEVENT HIF[a]	HIF event message
CSUMMARY	Event summary message
CSUMMARY HIF[a]	HIF event summary message

[a] The relay must support Arc Sense technology for command to be available.

CASCII Command—General Format

The Compressed ASCII configuration message provides data for an external computer to extract data from other Compressed ASCII commands. To obtain the configuration message for the Compressed ASCII commands available in an SEL relay, type:

CAS <CR>

C.2 | Compressed ASCII Commands
CASCII Command—General Format

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 796 of 1080
Wolfe

The relay sends the following message:

```
<STX>"CAS",n,"yyyy"<CR><LF>
"COMMAND 1",ll,"yyyy"<CR><LF>
"#H","xxxxx","xxxxx",......,"xxxxx","yyyy"<CR><LF>
"#D","ddd","ddd","ddd","ddd",......,"ddd","yyyy"<CR><LF>
"COMMAND 2",ll,"yyyy"<CR><LF>
"#h","ddd","ddd",......,"ddd","yyyy"<CR><LF>
"#D","ddd","ddd","ddd","ddd",......,"ddd","yyyy"<CR><LF>
.
.
.
"COMMAND n",ll,"yyyy"<CR><LF>
"#H","xxxxx","xxxxx",......,"xxxxx","yyyy"<CR><LF>
"#D","ddd","ddd","ddd","ddd",......,"ddd","yyyy"<CR><LF><ETX>
```

where:

n	is the number of Compressed ASCII command descriptions to follow.
COMMAND	is the ASCII name for the Compressed ASCII command as sent by the requesting device. The naming convention for the Compressed ASCII commands is a C preceding the typical command. For example, **CSTATUS** (abbreviated to **CST**) is the compressed **STATUS** command.
ll	is the minimum access level at which the command is available.
#H	identifies a header line to precede one or more data lines; # is the number of subsequent ASCII names. For example, 21H identifies a header line with 21 ASCII labels.
#h	identifies a header line to precede one or more data lines; # is the number of subsequent format fields. For example, 8h identifies a header line with 8 format fields.
xxxxx	is an ASCII name for corresponding data on following data lines. Maximum ASCII name width is 10 characters.
#D	identifies a data format line; # is the maximum number of subsequent data lines.
ddd	identifies a format field containing one of the following type designators: I Integer data F Floating point data mS String of maximum m characters (e.g., 10S for a 10 character string)
yyyy	is the 4-byte hex ASCII representation of the checksum.

A Compressed ASCII command may require multiple header and data configuration lines.

If a Compressed ASCII request is made for data that are not available, (e.g., the history buffer is empty or invalid event request), the relay responds with the following message:

```
<STX>"No Data Available","yyyy"<CR><LF><ETX>
```

```

where:

xxxx   are the data values corresponding to the first line labels

yyyy   is the 4-byte hex ASCII representation of the checksum

ssss   the highest phase shot counter

C.6 | Compressed ASCII Commands
CEVENT Command

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 800 of 1080
Wolfe

If the history buffer is empty, the relay responds:

```
<STX>"No Data Available","0668"<CR><LF><ETX>
```

Parameter *n* is an optional numeric parameter that specifies the number of records to return. If *n* is less than or equal to the number of records available in the history, the relay returns *n* records.

CHISTORY HIF Command (Only Available in Relays That Support Arc Sense Technology)

Display HIF history data in Compressed ASCII format by sending:

CHI HIF [n] <CR> (parameters in [] are optional)

Refer to *HIF Event History on page 12.51* for details on the **CHI HIF** command.

If the specified event does not exist, the relay responds:

```
<STX>"No Data Available","0668"<CR><LF><ETX>
```

CEVENT Command

Display event report in Compressed ASCII format by sending:

CEV [*n* S*x* L*y* L R C P]   (parameters in [ ] are optional)

where:

n	is event number or unique event identification number, defaults to 1
S*x*	is *x* samples per cycle (4, 16, 32, or 128); defaults to 4. If the S*x* parameter is present, it overrides the L parameter. S128 must be accompanied by the R parameter (**CEV S128 R**)
L*y*	is *y* cycles event report length (1 to LER) for filtered event reports, (1 to LER + 1) for raw event reports; defaults to LER if not specified. Raw reports always contain one extra cycle of data, except for raw reports with S128 parameter, which contain two extra cycles of data.
L	is 32 samples per cycle; overridden by the S*x* parameter, if present
R	specifies raw (unfiltered) data; defaults to 32 samples per cycle unless overridden by the S*x* parameter. Defaults to LER + 1 cycles in length unless overridden with the L*y* parameter.
C	specifies 16 samples per cycle analog data, 4 samples per cycle digital data, LER-cycle length, unless overridden by the S*x*, L*y*, L, or R parameters.
P	precise to synchrophasor-level accuracy for signal content at nominal frequency. This option is available when TSOK = logical 1 when the event report was triggered.

The relay responds to the **CEV** command with the *n*th event report as shown below.

xxxx,xxxx,xxxx,xxxx,xxxx,xxxx,xxxx,xxxx,xxxx,xxxx,xxxx,xxxx,z,
"HEX-ASCII Relay Word","yyyy"<CR>
"Analog and digital data repeated for each row of event report"
"SETTINGS","yyyy"<CR>
"Relay group, logic, global, and report settings, and Part Number as displayed
with the SHO command or PAR command (surrounded by quotes)","yyyy"<CR>
<ETX>
```

where:

xxxx	are the data values corresponding to the line labels
yyyy	is the 4-byte hex ASCII representation of the checksum
REF_NUM	is the unique identification number
FREQ	is the power system frequency at the trigger instant
SAM/CYC_A	is the number of analog data samples per cycle
SAM/CYC_D	is the number of digital data samples per cycle
NUM_OF_CYC	is the number of cycles of data in the event report
EVENT	is the event type
LOCATION	is the fault location
SHOT	is the recloser shot counter
TARGETS	are the front-panel tripping targets
IA, IB, IC, IG, 3I2	is the fault current
TRIG	refers to the trigger record
z	is ">" for the trigger row, "*" for the fault current row and empty for all others. If the trigger row and fault current row are the same, both characters are included (e.g., ">*")
HEX-ASCII Relay Word	is the hex ASCII format of the Relay Word. The first element in the Relay Word is the most significant bit in the first character.

For filtered events, if samples per cycle are specified as 16, the analog data are displayed at 1/16-cycle intervals and digital data at 1/4-cycle intervals.

If samples per cycle are specified as 32, the analog data are displayed at 1/32-cycle intervals and digital data are displayed at 1/4-cycle intervals.

For raw events, both analog and digital data are displayed at the interval specified by the Sx parameter. Digital data are updated every 1/4 cycle. Optoisolated inputs IN101–IN107 and IN201–IN206 are updated every 1/16 cycle.

The digital data are displayed as a series of hex ASCII characters. The relay displays digital data only when they are available. When no data are available, the relay sends only the comma delimiter in the digital data field.

RSTDNPE
```

These names are listed in *Table F.1* and *Table F.2*.

An example of a portion of a *HEX-ASCII Relay Word* is shown below:

C0014000000000000000444C0000000000000E1100000000000100000
000000002003800202180400000000000000000004000000000000000000
00000008000002200000000000010000000000004000800F0000000000000
000000000000000000000000000000000000000F000000000000000000000
00000000000000000

Each bit in the *HEX-ASCII Relay Word* reflects the status of a Relay Word bit. The order of the labels in the "*Names of elements in the relay word separated by spaces*" field matches the order of the *HEX-ASCII Relay Word*. In the example above, the eleventh byte in the *HEX-ASCII Relay Word* is "44." In binary, this evaluates to 01000100. Mapping the labels to the bits yields:

Table C.1   Mapping Labels to Bits

Labels	51AS	51AR	51A	51AT	51BS	51BR	51B	51BT
Bits	0	1	0	0	0	1	0	0

In this example, the 51AR and 51BR elements are asserted (logical 1); all others are deasserted (logical 0).

CEVENT HIF Command (Only Available in Relays That Support Arc Sense Technology)

Display the HIF event report in Compressed ASCII format by sending:

CEV HIF [*n*]

where:

    n displays the HIF event report with the corresponding event number from the **HIS HIF** command.

The relay responds to the **CEV HIF** command with the *n*th HIF event report.

Refer to *HIF Event Reporting on page 12.52* for details on the **CEV HIF** command.

If the specified event does not exist, the relay responds:

```
<STX>"No Data Available","0668"<CR><LF><ETX>
```

CSU Command

Display summary event reports in Compressed ASCII format by sending:

CSU [*n*]

where:

No parameters outputs the newest chronological event summary

    n displays event summary with this corresponding number in the **HIS** command.

```

If the specified event does not exist, the relay responds:

```
<STX>"No Data Available","0668"<CR><ETX>
```

CSUMMARY HIF Command (Only Available in Relays That Support Arc Sense Technology)

Display the HIF summary report in Compressed ASCII format by sending:

CSU HIF [*n*]

where:

No parameters outputs the newest chronological event summary

n displays the event summary with the corresponding number in the **HIS HIF** command.

The relay responds to the **CSU HIF** command with the *n*th HIF long summary event report.

Refer to *HIF Event Summary on page 12.48* for details on the **CSU HIF** command.

If the specified event does not exist, the relay responds:

```
<STX>"No Data Available","0668"<CR><ETX>
```

Appendix D

MIRRORED BITS Communications

Overview

MIRRORED BITS communications is a direct relay-to-relay communications protocol that allows protective relays to exchange information quickly and securely and with minimal expense. Use MIRRORED BITS communications for remote control and remote sensing or communications-assisted protection schemes.

SEL products support several variations of MIRRORED BITS communications protocols. Through port settings, you can set the SEL-651R-2 Recloser Control for compatible operation with all SEL devices that communicate MIRRORED BITS. These devices use MIRRORED BITS communications to exchange the states of eight logic bits.

The PROTO := MBc option (c = A or B) is provided for compatibility with older SEL products that only support this version of MIRRORED BITS. Use the RTSCTS := MBT option if your application includes Pulsar MBT9600 modems. Use PROTO = MB8c if each relay supports this MIRRORED BITS version.

SEL Application Guide *AG2002-23, Applying Two SEL-351S Relays to Provide Automatic Source Transfer for Critical Loads*, provides an example of how to use MIRRORED BITS in the SEL-351S Relay. These same principles may be used with the SEL-651R-2.

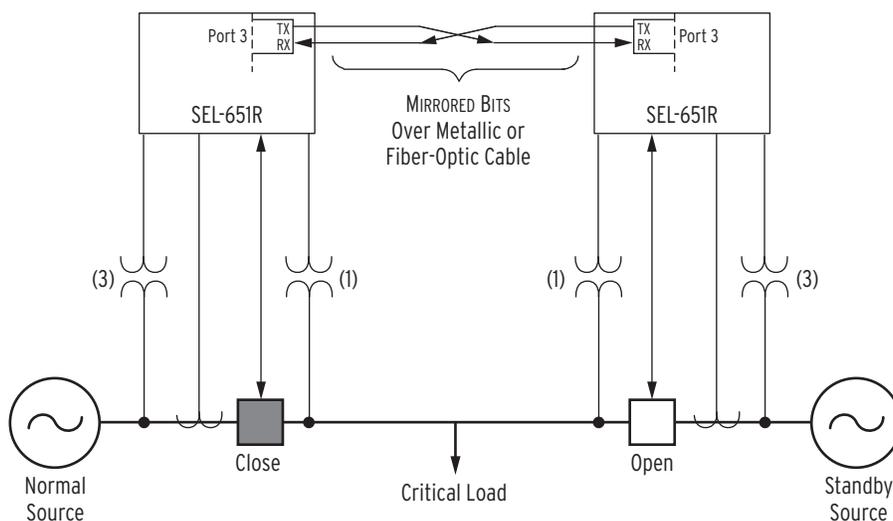
Figure D.1 shows this example with the SEL-651R-2.


Figure D.1   Automatic Source Transfer Application

D.2 | MIRRORED BITS Communications
Communications Channels and Logical Data Channels

Page 806 of 1080
Wolfe

Communications Channels and Logical Data Channels

The SEL-651R-2 supports two MIRRORED BITS communications channels, designated A and B. Use the port setting PROTO to assign one of the MIRRORED BITS communications channels to a serial port; PROTO := MBA for MIRRORED BITS communications Channel A or PROTO := MBB for MIRRORED BITS communications Channel B.

Transmitted bits include TMB1A–TMB8A and TMB1B–TMB8B. The last letter (A or B) designates with which channel the bits are associated. These bits are controlled by SELOGIC control equations. Received bits include RMB1A–RMB8A and RMB1B–RMB8B. You can use received bits as operands in SELOGIC control equations. The channel status bits are ROKA, RBADA, CBADA, LBOKA, ROKB, RBADB, CBADB, and LBOKB. You can also use these bits as operands in SELOGIC control equations. Use the **COM** command for additional channel status information.

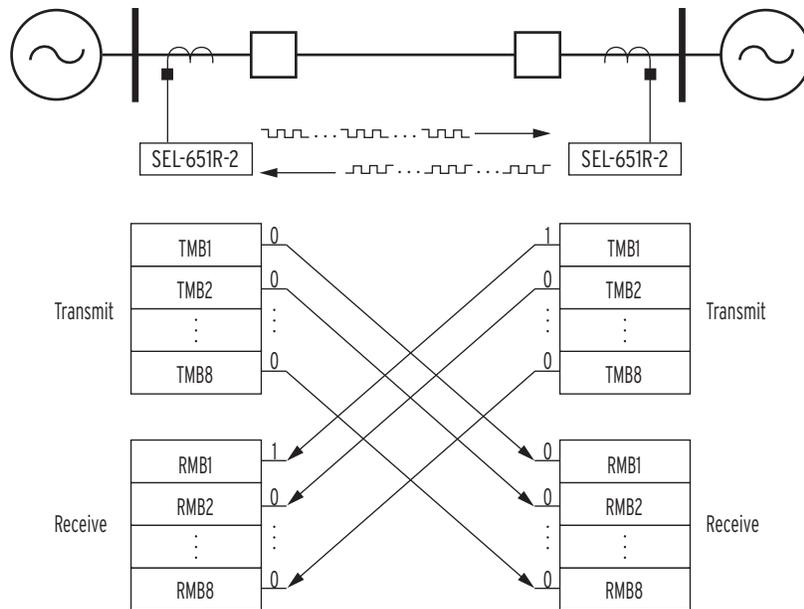
Within each MIRRORED BITS communications message for a given channel (A or B), there are eight logical data channels (1–8). In operation compatible with other SEL products, you can use the eight logical data channels for TMB1–TMB8, as shown in *Figure D.2*.


Figure D.2   Relay-to-Relay Logic Communication

Operation

Message Transmission

Depending on the settings, the SEL-651R-2 transmits a MIRRORED BITS communications message every 1/4 to 1/2 of an electrical cycle (see *Table D.2*). Each message contains the most recent values of the transmit bits. All messages are transmitted without idle bits between characters. Idle bits are allowed between messages.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 807 of 1080
MIRRORED BITS Communications D.3
operation
Wolfe

Message Reception

When the devices are synchronized and the MIRRORED BITS communications channel is in a normal state, the relay decodes and checks each received message. If the message is valid, the relay sends each received logic bit (RMBnc, where n = 1–8, c = A or B) to the corresponding pickup and dropout security counters, that in turn set or clear the RMBnc relay element bits.

Message Decoding and Integrity Checks

The relay provides indication of the status of each MIRRORED BITS communications channel, with element bits ROKA and ROKB. During normal operation, the relay sets the ROKc bit. The relay clears the bit upon detecting any of the following conditions:

➤ Parity, framing, or overrun errors.

➤ Receive data redundancy error.

➤ Receive message identification error.

➤ No message received in the time three messages have been sent.

The relay will assert ROKc only after successful synchronization as described below and two consecutive messages pass all of the data checks described above. After ROKc is reasserted, received data may be delayed while passing through the security counters described below.

While ROKc is not set, the relay does not transfer new RMB data to the pickup-dropout security counters described below. Instead, the relay sends one of the user-definable default values to the security counter inputs. For each RMBn, specify the default value with setting RXDFLT, as follows:

➤ 1

➤ 0

➤ X (to use the last valid value)

NOTE: When MIRRORED BITS serial port settings are changed, the received MIRRORED BITS reset to zero regardless of the RXDFLT setting.

Pickup/dropout security counters supervise the transfer of received data to RMB1c–RMB8c. Set these counters between 1 (allow every occurrence to pass) and at least 8 (require eight consecutive occurrences to pass). The pickup and dropout security count settings are separate.

The bit error rate of the MIRRORED BITS communications channel meets IEC-834-1 recommendations for direct tripping when the security counter (debounce) is set to 2 and can be further improved by increasing the message debounce.

A pickup/dropout security counter operates identically to a pickup/dropout timer, except that the counter uses units of "counted received messages," instead of time. An SEL-651R-2 communicating with another SEL-651R-2 sends and receives MIRRORED BITS messages four times per power system cycle. Therefore, a security counter set to two counts will delay a bit by about 1/2 power system cycle. You must consider the impact of the security counter settings in the receiving device to determine the channel timing performance.

Things become slightly more complicated when two relays of different processing rates are connected via MIRRORED BITS (for instance, an SEL-321 talking to an SEL-651R-2). The SEL-321 processes power system information each 1/8 power system cycle but processes the pickup/dropout security counters as messages are received. Because the SEL-321 is receiving messages from the SEL-651R-2, it will receive a message each 1/4 cycle processing interval. So, a counter set to two will again delay a bit by about 1/2 cycle. However, in that same example, a security counter set to two on the SEL-651R-2 will delay a bit by 1/4 cycle, because the SEL-651R-2 is receiving new MIRRORED BITS messages each 1/8 cycle from the SEL-321.

Wolfe

Channel Synchronization

When an SEL-651R-2 detects a communications error, it deasserts ROKA or ROKB. If a node detects two consecutive communications errors, it transmits an attention message, which includes its TXID setting.

When a node receives an attention message, it checks to see if its TXID is included.

If its own TXID is included and at least one other TXID is included, the node transmits data.

If its own TXID is not included, the node deasserts ROKc, includes its TXID in the attention message, and transmits the new attention message.

If its own TXID is the only TXID included, the relay assumes the message is corrupt unless the loopback mode has been enabled. If loopback is not enabled, the node deasserts ROKc and transmits the attention message with its TXID included. If loopback is enabled, the relay transmits data.

In summary, when a node detects two consecutive errors, it transmits attention until it receives an attention with its own TXID included. If three or four relays are connected in a ring topology, then the attention message will go all the way around the loop, and eventually will be received by the originating node. It will then be killed and data transmission will resume. This method of synchronization allows the relays to determine reliably which byte is the first byte of the message. It also forces mis-synchronized UARTs to become re-synchronized. On the down side, this method takes down the entire loop for a receive error at any node in the loop. This decreases availability. It also makes one-way communications impossible.

Loopback Testing

Use the **LOOP** command to enable loopback testing. While in loopback mode, ROKc is deasserted, and LBOKc asserts and deasserts based on the received data checks.

Channel Monitoring

Based on the results of data checks described above, the relay will collect information regarding the 255 most recent communications errors. Each record contains at least the following fields:

➤ Dropout Time/Date

➤ Pickup Time/Date

➤ Time elapsed during dropout

➤ Reason for dropout (see *Message Decoding and Integrity Checks*)

Use the **COM** command to generate a long or summary report of the communications errors.

There is a single record for each outage, but an outage can evolve. For example, the initial cause could be a data disagreement, but framing errors can extend the outage. If the channel is presently down, the **COM** record will only show the initial cause, but the **COM** summary will display the present cause of failure.

When the duration of an outage on Channel A or B exceeds a user-definable threshold, the relay will assert a user-accessible flag, RBADA or RBADB.

When channel unavailability exceeds a user-settable threshold, the relay will assert a user-accessible flag, hereafter called CBADc (where c = A or B).

MIRRORED BITS Communications   D.5
MIRRORED BITS Protocol for the Pulsar 9600 Bps Modem
Wolfe

MIRRORED BITS Protocol for the Pulsar 9600 Bps Modem

Setting RTSCTS := MBT indicates that a Pulsar MBT modem is connected. When the user selects MBT, the data rate setting must be set to 9600 bps.

The MIRRORED BITS protocol compatible with the Pulsar MBT-9600 modem is identical to the standard MIRRORED BITS protocol with the following exceptions:

➤ The relay injects a delay (idle time) between messages.

➤ The length of the delay is one relay processing interval.

➤ The relay resets RTS (to a negative voltage at the EIA-232 connector).

➤ The relay sets RTS (to a positive voltage at the EIA-232 connector) for MIRRORED BITS communications that use the R6 or original R version of MIRRORED BITS.

➤ The relay monitors the CTS signal of the EIA-232 connector, which the modem will deassert if the channel has too many errors.

Settings

The SEL-651R-2 port settings associated with MIRRORED BITS communications are shown in *Table D.1*. Set PROTO = MBA to enable the MIRRORED BITS communications protocol Channel A on this port. Set PROTO = MBB to enable the MIRRORED BITS communications protocol Channel B on this port.

Table D.1   MIRRORED BITS (Sheet 1 of 2)

Name	Description	Range	Default
PROTO	Protocol	SEL, DNP, MBA, MBB, MB8A, MB8B	SEL (Need to set to one of the MB_ values for MIRRORED BITS communications)
SPEED	Data Rate	300, 1200, 2400, 4800, 9600, 19200, 38400, 57600	9600 (see *Table D.2*)
RTSCTS	Enable Hardware Handshaking	Y, N, MBT	N
TXID	MIRRORED BITS Transmit Identifier	1–4	2
RXID	MIRRORED BITS Receive Identifier	1–4	1
RBADPU	MIRRORED BITS RX Bad Pickup Time	1–10000 s	60
CBADPU	PPM MIRRORED BITS Channel Bad Pickup	1–10000	1000
RXDFLT	MIRRORED BITS Receive Default State	8 character string of 1s, 0s, or Xs	XXXXXXXX
RMB1PU	MIRRORED BITS RMB_ Pickup Debounce Msgs	1–8	1
RMB1DO	MIRRORED BITS RMB_ Dropout Debounce Msgs	1–8	1
RMB2PU	MIRRORED BITS RMB_ Pickup Debounce Msgs	1–8	1
RMB2DO	MIRRORED BITS RMB_ Dropout Debounce Msgs	1–8	1
RMB3PU	MIRRORED BITS RMB_ Pickup Debounce Msgs	1–8	1
RMB3DO	MIRRORED BITS RMB_ Dropout Debounce Msgs	1–8	1

Table D.1 MIRRORED BITS (Sheet 2 of 2)

Name	Description	Range	Default
RMB4PU	MIRRORED BITS RMB_ Pickup Debounce Msgs	1–8	1
RMB4DO	MIRRORED BITS RMB_ Dropout Debounce Msgs	1–8	1
RMB5PU	MIRRORED BITS RMB_ Pickup Debounce Msgs	1–8	1
RMB5DO	MIRRORED BITS RMB_ Dropout Debounce Msgs	1–8	1
RMB6PU	MIRRORED BITS RMB_ Pickup Debounce Msgs	1–8	1
RMB6DO	MIRRORED BITS RMB_ Dropout Debounce Msgs	1–8	1
RMB7PU	MIRRORED BITS RMB_ Pickup Debounce Msgs	1–8	1
RMB7DO	MIRRORED BITS RMB_ Dropout Debounce Msgs	1–8	1
RMB8PU	MIRRORED BITS RMB_ Pickup Debounce Msgs	1–8	1
RMB8DO	MIRRORED BITS RMB_ Dropout Debounce Msgs	1–8	1

As a function of the settings for SPEED, the message transmission periods are shown in *Table D.2*.

Table D.2 Message Transmission Periods

SPEED	SEL-651R-2
57600	1 message per 1/4 cycle
38400	1 message per 1/4 cycle
19200	1 message per 1/4 cycle
9600	1 message per 1/4 cycle
4800	1 message per 1/2 cycle

Use the RBADPU setting to determine how long a channel error must last before the relay element RBADA is asserted. RBADA is deasserted when the channel error is corrected. RBADPU is accurate to ±1 second.

Use the CBADPU setting to determine the ratio of channel downtime to the total channel time before the relay element CBADA is asserted. The times used in the calculation are those that are available in the **COMM** records. See the *COM Command (Communication Data) on page 10.44* for a description of the **COMM** records.

Set the RXID of the local relay to match the TXID of the remote relay. For example, in the three-terminal case, where Relay X transmits to Relay Y, Relay Y transmits to Relay Z, and Relay Z transmits to Relay X:

	TXID	RXID
Relay X	1	3
Relay Y	2	1
Relay Z	3	2

NOTE: When MIRRORED BITS serial port settings are changed, the received MIRRORED BITS reset to zero regardless of the RXDFLT setting.

Use the RXDFLT setting to determine the default state the MIRRORED BITS should use in place of received data if an error condition is detected. The setting is a mask of 1s, 0s and/or *X*s, for RMB1A–RMB8A, where *X* represents the most recently received valid value.

Supervise the transfer of received data (or default data) to RMB1A–RMB8A with the MIRRORED BITS pickup and dropout security counters. Set the pickup and dropout counters individually for each bit.

Appendix E

DNP3 Communications

Overview

The SEL-651R-2 Recloser Control provides a DNP3 (Distributed Network Protocol) Level 2 Outstation interface for direct network connections to the relay. This section covers the following topics:

➤ *Introduction to DNP3 on page E.1*

➤ *DNP3 in the SEL-651R-2 on page E.6*

➤ *DNP3 Documentation on page E.23*

Introduction to DNP3

A supervisory control and data acquisition (SCADA) manufacturer developed DNP3 from the lower layers of IEC 60870-5. DNP3 was designed for use in telecontrol applications. The protocol has become popular for both local substation data collection and telecontrol. DNP is one of the protocols included in the IEEE Recommended Practice for Data Communication between remote terminal units and intelligent electronic devices in a substation.

The DNP User's Group maintains and publishes DNP standards. See the DNP User's Group website, www.dnp.org, for more information on DNP standards, implementers of DNP, and tools for working with DNP.

DNP3 Specifications DNP3 is a feature-rich protocol with many ways to accomplish tasks, defined in an eight-volume series of specifications. Volume 8 of the specification, called the Interoperability Specification, simplifies DNP3 implementation by providing four standard interoperable implementation levels. The levels are listed in *Table E.1*.

Table E.1   DNP3 Implementation Levels

Level	Description	Equipment Types
1	Simple: limited communication requirements	Meters, simple IEDs
2	Moderately complex: monitoring and metering devices and multifunction devices that contain more data	Protective relays, RTUs
3	Sophisticated: devices with great amounts of data or complex communication requirements	Large RTUs, SCADA masters
4	Enhanced: additional data types and functionality for more complex requirements	Large RTUs, SCADA masters

E.2 | DNP3 Communications
Introduction to DNP3

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 812 of 1080
Wolfe

Each level is a proper superset of the previous lower-numbered level. A higher-level device can act as a master to a lower-level device, but can only use the data types and functions implemented in the lower level device. For example, a typical SCADA master is a Level 3 device and can use Level 2 (or lower) functions to poll a Level 2 (or lower) device for Level 2 (or lower) data. Similarly, a lower-level device can poll a higher-level device, but the lower level device can only access the features and data available to its level.

In addition to the eight-volume DNP3 specification, the protocol is further refined by conformance requirements, optional features, and a series of technical bulletins. The technical bulletins supplement the specifications with discussion and examples of specific features of DNP3.

Data Handling

Objects

DNP3 uses a system of data references called objects, which the Basic 4 standard object library defines. Each subset level specification requires a minimum implementation of object types and also recommends several optional object types. Object types are commonly referred to as objects. DNP3 objects are specifications for the type of data the object carries. An object can include a single value or more complex data. Some objects serve as shorthand references for special operations, including collections of data, time synchronization, or even all data within the DNP3 device.

If there can be more than one instance of a type of object, then each instance of the object includes an index that makes it unique. For example, each binary status point (Object 1) has an index. If there are 16 binary status points, these points are Object 1, Index 0–Object 1, Index 15.

Each object also includes multiple versions called variations. For example, Object 1 has three variations: 0, 1, and 2. Use Variation 0 to request the default variation. Variation 1 is used to specify binary input values only and Variation 2 is used to specify binary input values with status information.

Each DNP3 device has both a list of objects and a map of object indices. The list of objects defines the available objects, variations, and qualifier codes. The map defines the indices for objects that have multiple instances and defines what data or control points correspond with each index.

A master initiates all DNP3 message exchanges except unsolicited data. DNP3 terminology describes all points from the perspective of the master. Binary points for control that move from the master to the remote are called binary outputs, while binary status points within the remote are called binary inputs.

Function Codes

Each DNP3 message includes a function code. Each object has a limited set of function codes that a master may use to manipulate the object. The object listing for the device shows the permitted function codes for each type of object. The most common DNP3 function codes are listed in *Table E.2*.

Table E.2   Selected DNP3 Function Codes

Function Code	Function	Description
1	Read	Request data from the remote
2	Write	Send data to the remote
3	Select	First part of a select-before-operate operation
4	Operate	Second part of a select-before-operate operation
5	Direct operate	One-step operation with reply
6	Direct operate, no reply	One-step operation with no reply

Qualifier Codes and Ranges

DNP3 masters use qualifier codes and ranges to make requests for specific objects by index. Qualifier codes specify the style of range, and the range specifies the indices of the objects of interest. DNP3 masters use qualifier codes to compose the shortest, most concise message possible when requesting points from a DNP3 remote.

For example, the qualifier code 01 specifies that the request for points will include a start address and a stop address. Each of these two addresses uses two bytes. An example request using qualifier code 01 might have the four-hexadecimal byte range field, 00h 04h 00h 10h, that specifies points in the range 4 to 16.

Access Methods

DNP3 has many features that help it obtain maximum possible message efficiency. Requests are sent with the least number of bytes by using special objects, variations, and qualifiers that reduce the message size. Other features eliminate the continual exchange of data values that are not changing. These features optimize use of bandwidth and maximize performance over any speed connection.

DNP3 event data collection eliminates the need to use bandwidth to transmit values that have not changed. Event data are records of when observed measurements changed. For binary points, the remote device (DNP3 outstation) logs changes from logical 1 to logical 0 and from logical 0 to logical 1. For analog points, the remote device logs changes that exceed a dead band. DNP3 remote devices collect event data in a buffer that the master can either request or the relay can send to the master without a request message. Data sent from the remote to the master without a polling request are called unsolicited data.

DNP3 data fit into one of four event classes: 0, 1, 2, or 3. Class 0 is reserved for reading the present value data (static data). Classes 1, 2, and 3 are event data classes. The meaning of Classes 1 to 3 is arbitrary and defined by the application at hand. With remotes that contain great amounts of data or in large systems, the three event classes provide a framework for prioritizing different types of data. For example, you can poll once a minute for Class 1 data, once an hour for Class 2 data, and once a day for Class 3 data.

DNP3 also supports static polling, simple polling of the present value of data points within the remote. By combining event data, unsolicited polling, and static polling, you can operate your system in one of the four access methods shown in *Table E.3*.

E.4 | DNP3 Communications
Introduction to DNP3

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 814 of 1080
Wolfe

The access methods listed in *Table E.3* are in order of increasing communication efficiency. With various tradeoffs, each method is less demanding of communication bandwidth than the previous one. For example, unsolicited report-by-exception consumes less communication bandwidth because of the elimination of polling messages from the master required by polled report-by-exception. You must also consider overall system size and the volume of data communication expected to properly evaluate which access method provides optimum performance for your application.

Table E.3   DNP3 Access Methods

Access Method	Description
Polled static	Master polls for present value (Class 0) data only
Polled report-by-exception	Master polls frequently for event data and occasionally for Class 0 data
Unsolicited report-by-exception	Remote devices send unsolicited event data to the master, and the master occasionally polls for Class 0 data
Quiescent	Master never polls and relies on unsolicited reports only

Binary Control Operations

DNP3 masters use Object 12 (control relay output block) to perform DNP3 binary control operations. The control relay output block has both a trip/close selection and a code selection. The trip/close selection allows a single DNP3 index to operate two related control points such as trip and close or raise and lower.

The control relay output block code selection specifies either a latch or pulse operation on the point. In many cases, DNP3 remotes have only a limited subset of the possible combinations of the code field. Sometimes, DNP3 remotes assign special operation characteristics to the latch and pulse selections. *Table E.8* describes control point operation for the SEL-651R-2.

Conformance Testing

In addition to the protocol specifications, the DNP User's Group has approved conformance testing requirements for Level 1 and Level 2 devices. Some implementers perform their own conformance specification testing, while some contract with independent companies to perform conformance testing.

Conformance testing does not always guarantee that a master and remote will be fully interoperable (work together properly for all implemented features). Conformance testing does help to standardize the testing procedure and move the DNP implementers toward a higher level of interoperability. The SEL-651R-2 is tested for conformance using third-party conformance test software and has passed DNP Level 2 Slave Conformance tests. The conformance certificate is on file at SEL and listed on the DNP User's Group website (www.dnp.org).

DNP3 Serial Network Issues

Data Link Layer Operation

DNP3 employs a three-layer version of the seven-layer Open Systems Interconnect (OSI) model called the enhanced performance architecture. The layer definition helps to categorize functions and duties of various software components that make up the protocol. The middle layer, the data link layer, includes several functions for error checking and media access control.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 815 of 1080
Wolfe
DNP3 Communications E.5
Introduction to DNP3

A feature called data link confirmation is a mechanism that provides positive confirmation of message receipt by the receiving DNP3 device. While this feature helps you recognize a failed device or failed communications link quickly, it also adds significant overhead to the DNP3 conversation. Consider for your individual application whether you require this link integrity function at the expense of overall system speed and performance.

The DNP technical bulletin (*DNP Confirmation and Retry Guidelines 9804-002*) on confirmation processes recommends against using data link confirmations because these processes can add to traffic in situations where communications are marginal. The increased traffic will reduce connection throughput further, possibly preventing the system from operating properly.

Network Medium Contention

When more than one device requires access to a single network medium, you must provide a mechanism to resolve the resulting network medium contention. For example, unsolicited reporting results in network medium contention if you do not design your network as a star topology of point-to-point connections or use carrier detection on a multidrop network.

To avoid collisions among devices trying to send messages, DNP3 includes a collision avoidance feature. Before sending a message, a DNP3 device listens for a carrier signal to verify that no other node is transmitting data. The device transmits if there is no carrier or waits for a random time before transmitting. However, if two nodes both detect a lack of carrier at the same instant, these two nodes could begin simultaneous transmission of data and cause a data collision. If your network allows for spontaneous data transmission including unsolicited event data transmissions, you also must use application confirmation to provide a retry mechanism for messages lost as a result of data collisions.

DNP3 LAN/WAN Overview

The main process for carrying DNP3 over an Ethernet Network (LAN/WAN) involves encapsulating the DNP3 data link layer data frames within the transport layer frames of the Internet Protocol (IP) suite. This allows the IP stack to deliver the DNP3 data link layer frames to the destination in place of the original DNP3 physical layer.

The DNP User Group Technical Committee has recommended the following guidelines for carrying DNP3 over a network:

NOTE: Link layer confirmations are explicitly disabled for DNP3 LAN/WAN. The IP suite already provides a reliable delivery mechanism, which is backed up at the application layer by confirmations when required.

> ➤ DNP3 shall use the IP suite to transport messages over a LAN/WAN

> ➤ Ethernet is the recommended physical link, though others may be used

> ➤ TCP must be used for WANs

> ➤ TCP is strongly recommended for LANs

> ➤ User Datagram Protocol (UDP) may be used for highly reliable single segment LANs

> ➤ UDP is necessary if broadcast messages are required

> ➤ The DNP3 protocol stack shall be retained in full

> ➤ Link layer confirmations shall be disabled

The Technical Committee has registered a standard port number, 20000, for DNP3 with the Internet Assigned Numbers Authority (IANA). This port is used for either TCP or UDP.

DNP3 in the SEL-651R-2

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 816 of 1080
Wolfe

TCP/UDP Selection

The Committee recommends the selection of TCP or UDP protocol as per the guidelines in *Table E.4*.

Table E.4   TCP/UDP Selection Guidelines

Use in the case of...	TCP	UDP
Most situations	X	
Nonbroadcast or multicast	X	
Mesh Topology WAN	X	
Broadcast		X
Multicast		X
High-reliability single-segment LAN		X
Pay-per-byte, nonmesh WAN, for example, Cellular Digital Packet Data (CDPD)		X
Low priority data, for example, data monitor or configuration information		X

DNP3 in the SEL-651R-2

The SEL-651R-2 is a DNP3 Level 2 remote (outstation) device. Additional implementation documentation describing DNP3 in the relay is in *DNP3 Communications on page E.1*.

Data Access

NOTE: Because unsolicited messaging only operates properly in some situations, for maximum performance and minimum risk of configuration problems, use the polled report-by-exception access method. Configure the master to perform at least 10 event polls for every integrity poll.

NOTE: In the settings below, the suffix n represents the DNP3 LAN/WAN session number from 1 to 6. This suffix is not present in Serial Port DNP3 settings. All settings with the same numerical suffix comprise the complete DNP3 session configuration.

You can use any of the data access methods listed in *Table E.5*. *Table E.5* also lists the SEL-651R-2 DNP3 settings. You must configure the DNP3 master for the data access method you select.

Table E.5   DNP3 Access Methods

Access Method	Master Polling	SEL-651R-2 Settings
Polled static	Class 0	Set ECLASSB, ECLASSC, ECLASSA, ECLASSV to 0; UNSOL to No
Polled report-by-exception	Class 0 occasionally, Class 1, 2, 3 frequently	Set ECLASSB, ECLASSC, ECLASSA, ECLASSV to the desired event class; UNSOL to No
Unsolicited report-by-exception	Class 0 occasionally, optional Class 1, 2, 3 less frequently; mainly relies on unsolicited messages	Set ECLASSB, ECLASSC, ECLASSA, ECLASSV to the desired event class; set UNSOL to Yes and PUNSOL to Yes or No
Quiescent	Class 0, 1, 2, 3 never; relies completely on unsolicited messages	Set ECLASSB, ECLASSC, ECLASSA, ECLASSV to the desired event class; set UNSOL and PUNSOL to Yes.

In both the unsolicited report-by-exception and quiescent polling methods shown in *Table E.5*, you must make a selection for the PUNSOL setting. This setting enables or disables unsolicited data reporting at power up. If your master can send the DNP3 message to enable unsolicited reporting from the SEL-651R-2, you should set PUNSOL to No.

While automatic unsolicited data transmission on power up is convenient, problems can result if your master is not prepared to start receiving data immediately on power up. If the master does not acknowledge the unsolicited data with an Application Confirm, the relay will resend the data until it is acknowledged. On a large system, or in systems where the processing power of the master is limited, you may have problems when several relays simultaneously begin sending data and waiting for acknowledgment messages.

The SEL-651R-2 allows you to set the conditions for transmitting unsolicited event data on a class-by-class basis. It also allows you to assign points to event classes on a point-by-point basis (see *Configurable Data Mapping on page E.14*). You can prioritize data transmission with these event class features. For example, you might place high-priority points in event class 1 and set it with low thresholds (NUM1EVE and AGE1EVE settings) so that changes to these points will be sent to the master quickly. You might then place low priority data in event class 2 with higher thresholds.

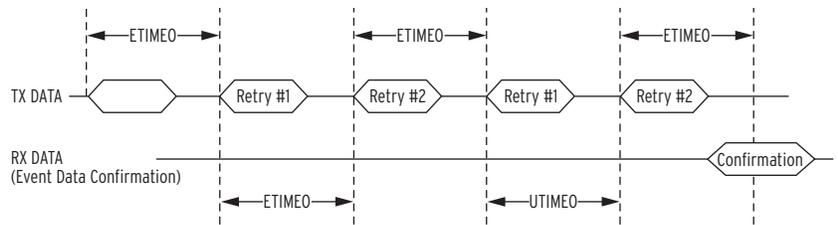
If the SEL-651R-2 does not receive an Application Confirm in response to unsolicited data, it will wait for ETIMEO seconds and then repeat the unsolicited message. If any message, other than an Application Confirm with a matching sequence number, is received from the master during the ETIMEO interval, the SEL-651R-2 will continue to retry to send the unsolicited message at the ETIMEO interval. To prevent excess traffic on the network with unsolicited data retries, the SEL-651R-2 uses the URETRY and UTIMEO settings to increase retry time when the number of retries set in URETRY is exceeded. After URETRY has been exceeded, the SEL-651R-2 pauses UTIMEO seconds and then transmits the unsolicited data again. *Figure E.1* provides an example with URETRY := 2.


Figure E.1   Application Confirmation Timing With URETRY := 2

If using a modem and UTIMEO is set to OFF, the SEL-651R-2 hangs up the phone and re-dials instead of extending the delay to UTIMEO seconds. If the SEL-651R-2 does not receive an Application Confirm in response to unsolicited data, it will wait for ETIMEO seconds and then repeat the unsolicited message. When the number of retries exceeds URETRY, the SEL-651R-2 will hang up the phone and wait 10 • ETIMEO seconds, then it will redial a phone number. When PH_NUM1 and PH_NUM2 are both populated, the SEL-651R-2 will alternate between the two phone numbers each time it redials, otherwise it will redial PH_NUM1.

Collision Avoidance

If your application uses unsolicited reporting, you must select a half-duplex medium or a medium that includes carrier detection to avoid data collisions. EIA-485 two-wire networks are half-duplex. EIA-485 four-wire networks do not provide carrier detection, while EIA-232 systems can support carrier detection.

NOTE: MINDLY and MAXDLY settings are only available for EIA-232 and EIA-485 serial port sessions.

The relay uses Application Confirmation messages to guarantee delivery of unsolicited event data before erasing the local event data buffer. Data collisions are typically resolved when messages are repeated until confirmed.

E.8 | DNP3 Communications
DNP3 in the SEL-651R-2

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 818 of 1080
Wolfe

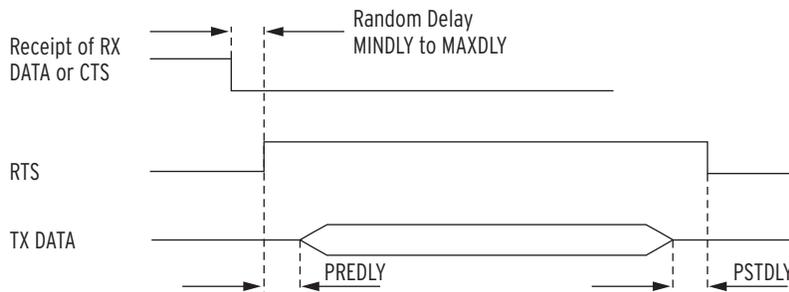
The SEL-651R-2 pauses for a random delay between the settings MAXDLY and MINDLY when it detects a carrier through data on the receive line or the CTS pin. If you use the settings of 0.10 seconds for MAXDLY and 0.05 seconds for MINDLY, the SEL-651R-2 will insert a random delay of 50 to 100 ms between the end of carrier detection and the start of data transmission (see *Figure E.2*).


Figure E.2   Message Transmission Timing

Transmission Control

If you use a media transceiver (for example, EIA-232 to EIA-485) or a radio system for your DNP3 network, you may need to adjust data transmission properties. Use the PREDLY and POSTDLY settings to provide a delay between RTS signal control and data transmission (see *Figure E.2*). For example, an EIA-485 transceiver typically requires 10 to 20 ms to change from receive to transmit. If you set the predelay to 30 ms, you will avoid data loss resulting from data transmission beginning at the same time as RTS signal assertion.

In applications where the radio system has a limited packet size capability, the RESPSZ can be set to send smaller DNP3 messages. The default RESPSZ specifies the maximum response size as 2411 octets. The message size of 2411 contains a Maximum Application Layer Fragment of 2048 octets plus the DNP3 Application Layer, Transport Function and Data Link Layer overhead. RESPSZ can be set from 200 to 2411 octets if the communications network limits the message size.

Binary Controls

The SEL-651R-2 provides more than one way to control individual points within the relay. The relay maps incoming control points either to remote bits within the relay or to internal command bits that cause circuit breaker operations. *Table E.8* lists control points and control methods available in the SEL-651R-2.

A DNP technical bulletin *(Control Relay Output Block Minimum Implementation 9701-002)* recommends that you use one point per Object 12 (control relay output block). You can use this method to perform Pulse On, Pulse Off, Latch On, and Latch Off operations on selected remote bits.

If your master does not support the single-point-per-index messages or single-operation database points, you can use the trip/close operation or use the code field in the DNP3 message to specify operation of the points as shown in *Control Point Operation on page E.22*.

Time Synchronization

The accuracy of DNP3 time synchronization is insufficient for most protection and oscillography needs. DNP3 time synchronization provides backup time synchronization in the event the relay loses primary synchronization through the IRIG-B input. Enable time synchronization with the TIMERQ setting and use Object 50, Variation 1 to set the time via the Session *n* DNP3 master

Case No. 2018-00295

Wolfe

(Object 50, Variation 3 for DNP3 LAN/WAN). Object 51, Variation 2 (Unsynchronized Time and Date CTO) is supported but only in conjunction with Object 2, Variation 3 (Binary Input Change With Relative Time).

By default, the SEL-651R-2 accepts and ignores time set requests (TIMERQ := I). (This mode allows the SEL-651R-2 to use a high-accuracy IRIG-B time source, but still interoperate with DNP3 masters that send time synchronization messages.) It can be set to request time synchronization periodically by setting the TIMERQ setting to the desired period. It can also be set to accept, but not request, time synchronization (TIMERQ = M).

If synchronization of relay time occurs only over DNP3, the relay time is synchronized for a period based on the TIMERQ Port setting. When the TIMERQ setting is less than 30 minutes, the relay is time-synchronized for twice the TIMERQ setting. When the TIMERQ setting is greater than 30 minutes, the relay is time synchronized for 30 minutes plus the TIMERQ setting. When TIMERQ is not set to a time (TIMERQ := M) for any port, the time is synchronized for 60 minutes. When the device is time-synchronized, an Object 2, Variation 3 (Binary Input Event with Relative Time) request will result in Object 51, Variation 1 (Time and Date Common Time-of-Occurrence—synchronized) response. When the device is no longer time-synchronized, an Object 2, Variation 3 (Binary Input Event with Relative Timer) request will result in Object 51, Variation 2 (Time and Date Common Time-of-Occurrence—unsynchronized) response.

Modem Support

The SEL-651R-2 DNP3 implementation includes modem support. Your DNP3 master can dial in to the SEL-651R-2 and establish a DNP3 connection. The SEL-651R-2 can automatically dial out and deliver unsolicited DNP3 event data. When the relay dials out, it waits for the "CONNECT" message from the local modem and for assertion of the relay CTS line before continuing the DNP3 transaction. This requires a connection from the modem DCD to the relay CTS line.

NOTE: Contact SEL for information on serial cable configurations and requirements for connecting your SEL-651R-2 to other devices.

NOTE: RTS/CTS hardware flow control is not available for a DNP3 modem connection. You must use either X-ON/X-OFF software flow control or set the port data speed slower than the effective data rate of the modem.

Either connect the modem to a computer and configure it before connecting it to the relay, or program the appropriate modem setup string in the modem startup string setting MSTR. Use the PH_NUM1 setting to set the phone number that you want the relay to call. The relay automatically will send the ATDT modem dial command and then the contents of the PH_NUM1 setting when dialing the modem. PH_NUM1 is a text setting that must conform to the AT modem command set dialing string standard. Use a comma (,) for a pause of four seconds. You may need to include a nine to reach an outside line or a one if the number requires long distance access. You can also insert other special codes your telephone service provider designates for block call waiting and other telephone line features.

The SEL-651R-2 supports the use of two phone numbers for its modem support. This can be extremely useful where a communications link is unreliable, or is likely to become very congested (i.e., many devices reporting to the same phone number). If the second phone number is enabled, the SEL-651R-2 will attempt to make a connection on the primary phone number (PH_NUM1). If the connection attempt is unsuccessful, the SEL-651R-2 will retry for a set number of times (RETRY1). If no connection is accomplished within the set number of retries, the control will then attempt to connect via the second phone number (PH_NUM2). Connection via the second phone number (PH_NUM2) will be attempted for a set number of retries (RETRY2). If, after the set number of retries, no connection has been made, the SEL-651R-2 will revert to the first phone number (PH_NUM1) and the process will repeat. When PH_NUM2 is set to OFF, the SEL-651R-2 will continue connection attempts using the first phone number (PH_NUM1).

DNP3 Settings

The DNP3 port configuration settings available on the SEL-651R-2 are shown in *Table E.6*. You can enable DNP3 on any of the Serial Ports 1, 2, 3, or F or on Ethernet Port 5, to a maximum of six concurrent DNP3 sessions.

The SEL-651R-2 allows as many as six simultaneous DNP3 sessions. All six DNP3 sessions can be on the Ethernet port or on a combination of the four separate serial ports and Ethernet sessions (see *Table 10.7* for DNP3 protocol session limitations).

Each session defines the connected DNP3 Master characteristics you assign to one of the three available custom maps. Some settings only apply to DNP3 LAN/WAN and are visible only when configuring the Ethernet port. For example, you only have the ability to define multiple sessions (as many as six) on the Ethernet Port 5. For this reason, DNP3 settings for Ethernet sessions have a suffix, n, that indicates the session number from one to six (e.g., DNPIP1, ETIMEO2, and AGE1EVE3). Serial DNP3 ports do not support multiple sessions, so they do not have the suffix, *n*.

Table E.6   SEL-651R-2 Port DNP3 Protocol Settings (Sheet 1 of 4)

Head/Name	Description	Range	Default Value
Serial Port 1–4 Settings			
DNPADR	Device DNP3 Address	0–65519	0
REPADR	DNP3 address of the Master to send messages to	0–65519	1
DNPMAP	DNP3 Session Custom Map	1–3	1
DVARAI	Analog Input Default Variation	1–6	4
ECLASSB	Class for binary event data, 0 disables	0–3	1
ECLASSC	Class for counter event data, 0 disables	0–3	0
ECLASSA	Class for analog event data, 0 disables	0–3	2
ECLASSV	Class for virtual terminal response data	0–3	3
DECPLA	Decimal places scaling for current data	0–3	1
DECPLV	Decimal places scaling for voltage data	0–3	1
DECPLM	Decimal places scaling for miscellaneous data	0–3	1
ANADBA	Analog reporting dead band for current; hidden if ECLASSA set to 0	0–32767	100
ANADBV	Analog reporting dead band for voltages; hidden if ECLASSA set to 0	0–32767	100
ANADBM	Analog reporting dead band for miscellaneous analogs; hidden if ECLASSA and ECLASSC set to 0	0–32767	100
TIMERQ	Time set request interval, minutes (M = Disables time synchronize requests, but still accepts and applies time synchronizes from Master; I = Ignores [does not apply] time synchronizes from Master)	I, M, 1–32767	I
STIMEO	Select/operate time out, seconds	0.0–30.0	1
DRETRY	Data link retries	0–15	0
DTIMEO	Data link time out, seconds; hidden if DRETRY set to 0	0–5	1
RESPSZ	Maximum Response Size	200–2411 bytes	2411
ETIMEO	Event message confirm time out, seconds	1–120	5
UNSOL	Enable unsolicited reporting; hidden and set to N if ECLASSB, ECLASSC, and ECLASSA set to 0	Y, N	N
PUNSOL[a]	Enable unsolicited reporting at power up; hidden and set to N if UNSOL set to N	Y, N	N
NUM1EVE[a]	Threshold to send unsolicited message on Class 1 data	1–200	10

[a] Hidden if UNSOLn set to N.
[b] DNP IP Address of each session (DNPIP1, DNPIP2, etc.) must be unique.
[c] Set DNPIPn = 0.0.0.0 to accept connections from any DNP master (on up to one DNP session, DNPTRn = TCP only). This will not allow connections with masters that have IP addresses that are included in the DNPIPn setting for another session.

The SEL-651R-2 allows one DNP3 session to be configured to accept an anonymous DNP3 master connection through use of the Port 5 setting DNPIPn = 0.0.0.0. For this session, the SEL-651R-2 will accept a DNP3 connection request from any DNP3 master whose address is not configured as DNPIPn in another session.

Be advised that once an anonymously connected DNP3 master disconnects from the session in which DNPIPn = 0.0.0.0, that session is again available, and any DNP3 master that requests a connection (whose address is not explicitly set as a DNPIPn setting elsewhere) will connect to the anonymous session.

DNP3 events and class polls are associated with the session, not with a particular DNP3 master. If a DNP3 master disconnects from the anonymous session and a different DNP3 master then connects, previously acknowledged DNP3 events will not be re-sent by the SEL-651R-2.

Because the SEL-651R-2 will accept *any* connection when a session is configured with DNPIPn = 0.0.0.0, ensure that you use secure network practices to avoid unintended or undesired access.

Configurable Data Mapping

One of the most powerful features of the SEL-651R-2 implementation is the ability to remap DNP3 data and, for analog values, specify per-point scaling, dead bands, and event class. Remapping is the process of selecting data from the reference map and organizing it into a data subset optimized for your application. The SEL-651R-2 uses object and point labels, rather than point indices, to streamline the remapping process. This enables you to quickly create a custom map without having to search for each point index in a large reference map.

You can use any of the three available DNP3 maps simultaneously with as many as six unique DNP3 masters. Each map is initially populated with default data points, as described in *Reference Data Map on page E.30*. You can remap the points in a default map to create a custom map with as many as:

> ➤ 200 Binary Inputs

> ➤ 71 Binary Outputs

> ➤ 200 Analog Inputs

> ➤ 8 Analog Outputs

> ➤ 16 Counters

You can use the **SHOW D** *x* **<Enter>** command to view the DNP3 data map settings, where *x* is the DNP3 map number from 1 to 3. See *Figure E.3* for an example display of Map 1.

E.15
DNP3 Communications
Page 1825 of 1080
SET D
Wolfe

You can use the command **SET D** *x*, where *x* is the map number, to edit or create custom DNP3 data maps. You can also use the ACSELERATOR QuickSet SEL-5030 Software, which is recommended for this purpose.

The following are valid entries if you choose to use the **SET D** command to create or edit custom maps:

> ➤ Binary Inputs—Any Relay Word bit label or additional DNP3 binary input (see *Binary Inputs on page E.20*) with class, e.g., RB01:2, the values 0 or 1, or NA

> ➤ Binary Outputs—Any Remote bit label or pair, Breaker bit label or pair, or additional DNP3 binary output (see *Binary Outputs on page E.20*), or NA

> ➤ Analog Inputs—Any analog input quantity (see *Analog Inputs on page E.22*) with scaling and/or dead band value, and/or class, e.g., IA:0, 1:50:2 (see below), the values 0 or 1, or NA

> ➤ Analog Outputs—Any analog output label (see *Table E.11*), NOOP, or NA

> ➤ Counter Inputs—Any counter label with dead band and/or class, e.g., ACTGRP:0:3 (see *Table E.11*)

For the above custom map settings, a label of 0 or 1 shall yield the label value when the point is polled. A NOOP can be used as a placeholder for analog outputs—control of a point with this label does not change any relay values nor respond with an error message. Any gaps left in the custom map between labels (NA) will be removed and the contents packed.

You can customize the DNP3 analog input map with per-point scaling, dead band, and event class settings. Scaling (DECPLA, DECPLV, and DECPLM), dead band (ANADBA, ANADBV, and ANADBM), and event class (ECLASSA) settings are applied to indices that do not have per-point entries. Per-point dead band settings override any class dead band settings. Per-point scaling overrides any class scaling and multiplies the analog input by the scaling value. Unlike per-point scaling, class-level scaling is specified by an integer in the range 0–3 (inclusive), which indicates the number of decimal place shifts. In other words, you should select 0 to multiply by 1, 1 for 10, 2 for 100, or 3 for 1000.

Per-point scaling factors allow you to overcome the limitations imposed, by default, of the integer nature of Objects 30 and 32. For example, DNP3 in the SEL-651R-2, by default, truncates a value of 11.4 A to 11 A. You may use per-point scaling to include decimal point values by multiplying by a power of 10. For example, if you use 10 as a scaling factor, 11.4 A will be transmitted as 114. You must divide the value by 10 in the master to see the original value including one decimal place.

You can also use per-point scaling to avoid overflowing the 16-bit maximum integer value of 32767. For example, if you have a value that can reach 157834, you cannot send it using DNP3 16-bit analog object variations. You could use a scaling factor of 0.1 so that the maximum value reported is 15783. You can then multiply the value by 10 in the master to see a value of 157830. You will lose some precision as the last digit is truncated off in the scaling process, but you can transmit the scaled value using the default variations for DNP3 Objects 30 and 32.

DNP3 in the SEL-651R-2

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 826 of 1080
Wolfe

Assign Class (Function Code 22) allows assigning and re-assigning of data objects to class 0, 1, 2, and 3 dynamically during run-time, with an Object 60 (FC 22) request. Per-point class assignments override the ECLASSB, ECLASSC, and ECLASSA settings for the binary inputs, counters, and analog inputs, respectively.

If your DNP3 master has the capability to request floating-point analog input variations, the SEL-651R-2 will support them. These floating point variations, 5 and 6 for Object 30 and 5–8 for Object 32, allow the transmission of 16- or 32-bit floating-point values to DNP3 masters. When implemented, these variations eliminate the need for scaling and still maintain the resolution of the relay analog values. Note that this support is greater than DNP3 Level 4 functionality, so you must confirm that your DNP3 master can work with these variations before you consider using unscaled analog values.

If it is important to maintain tight data coherency (that is, all data reads of a certain type were sampled or calculated at the same time), then you should group those data together within your custom map. For example, if you want all the currents to be coherent, you should group points IA, IB, IC, and IN together in the custom map. If points are not grouped together, they might not come from the same data sample.

The following example describes how to create a custom DNP3 map by point type. The example demonstrates the SEL ASCII command **SET D** for each point type, but the entire configuration may be completed without saving changes between point types. To do this, you simply continue entering data and save the entire map at the end. Alternatively, you can use QuickSet to simplify custom data map creation.

Consider a case where you want to set the AI points in a map as shown in *Table E.7*.

Table E.7   Sample Custom DNP3 AI Map

Desired Point Index	Description	Label	Scaling	Dead Band	Class
0	IA magnitude	IA	default	default	1
1	IB magnitude	IB	default	default	1
2	IC magnitude	IC	default	default	1
3	IN magnitude	IN	default	default	1
4	Three-Phase Real Power	MW3	5	default	default
5	Y-Terminal A-Phase-to-Neutral Voltage Magnitude	VAY	default	default	default
6	Y-Terminal A-Phase-to-Neutral Voltage Angle	VAYFA	1	15	default
7	Frequency	FREQ	0.01	1	default

To set these points as part of Custom Map 1, you can use the command **SET D 1 AI_000 TERSE <Enter>** as shown in *Figure E.4*.

The **SET D x CO_000 TERSE <Enter>** command allows you to populate the DNP3 counter map with per-point dead bands and class. Entering these settings is similar to defining the analog input map settings.

You can use the command **SET D *x* BO_000 TERSE <Enter>** to change the binary output Map *x* as shown in *Figure E.7*. You may populate the custom BO map with any of the 32 remote bits (RB01–RB32), breaker bits (OC3, CC3, OCA, CCA, OCB, CCB, OCC, CCC), reset bits (DRST_DEM, DRST_PDM, DRST_BK, DRST_HIS, DRST_ENE, DRST_MML, DRST_TAR, DRST_HAL, DRSTDNPE), NXTEVE, or SINGEVE bit. You can define bit pairs for remote bits or breaker bits in BO maps by including a colon (:) between the bit labels.

Binary Inputs

Binary Inputs (Objects 1 and 2) are supported as defined in *Table E.10*. The default variation for both static and event inputs is 2. Only the Read function code (1) is allowed with these objects. All variations are supported. Function Code 22 (Class Assign) is allowed on Object 1, variation 0 in conjunction with an Object 60 Assign Class function. Object 2, variation 3 will be responded to, but will contain no data.

Binary inputs are scanned approximately once per second to generate events. When time is reported with these event objects, it is the time at which the scanner observed the bit change. This may be significantly delayed from when the original source changed and should not be used for sequence-of-events determination. Binary inputs registered with SER are derived from the SER and carry the time stamp of actual occurrence.

Binary Outputs

Binary Outputs are supported as defined in *Table E.10* and *Table E.11*. Binary Output status (Object 10, variation 2) is supported. Static reads of points RB1–RB32 respond with the online bit set and the state of the requested bit. Reads of NXTEVE respond with the online bit set and a state of 1 if event summary data are being read in multiple-event FIFO mode and a state of 0 otherwise. Reads of SINGEVE respond with the online bit set and a state of 1 when event summary data are being read in single-event mode and a state of 0 when event summary data are being read in multiple-event mode. Reads from breaker control points (OC3, CC3, OCA, etc.) and control-only binary output points (such as the data reset controls DRST_DEM, DRST_ENE, etc.) respond with the online bit set and a state of 0 (or tripped) because of the pulse only control operation of these points.

Control Relay Output Block (CROB) objects (Object 12, variation 1) are also supported. The control relays correspond to the remote bits and other functions as shown below. The Trip/Close bits take precedence over the control field. The control field is interpreted as follows.

Table E.8 Object 12 Control Relay Operations (Sheet 1 of 2)

Label	Index	Close	Trip	Latch On (3)	Latch Off (4)	Pulse On (1)	Pulse Off (2)

NOTE: In Table E.8, index numbers are provided as a reference to aid in the conversion of settings from the SEL-651R-0, -1 to the SEL-651R-2.

If the Trip bit is set, a Latch Off operation is performed on the specified point. If the Close bit is set, a Latch On operation is performed. The Status field is used exactly as defined. All other fields are ignored. A pulse operation is asserted for a single processing interval. Note that the relay supports simultaneous pulse operations on multiple control points, but these may not occur on the same processing interval. You can perform a maximum of ten operations for a single command. For any attempt in excess of ten operations, the relay will respond with Control Status Code 08 (too many objects).

Wolfe

Control Point Operation

You can define any two RB points as a pair for Trip/Close or Code Selection operations with Object 12 (control relay output block) command messages. The SEL-651R-2 assigns some special operations to the code portion of the control relay output block command. Because the SEL-651R-2 allows only one control bit to be pulsed at a time, you should send consecutive control bits in consecutive messages. Pulse operations provide a pulse with duration of one processing interval.

Analog Inputs

NOTE: Dead band changes via Object 34 are stored in volatile memory. Make sure to reissue the Object 34 dead band changes you wish to retain after a change to DNP3 port settings, issuing a **STA C** command, or a relay cold start (power cycle).

Analog inputs (30) and analog change events (32) are supported as defined in *Table E.10* and *Table E.11*. Analog values are reported in primary units. See *Appendix G: Analog Quantities* for a list of all available analog inputs and the DNP3 reference map for default scaling and dead bands. A dead band check is done after any scaling has been applied. Event class messages are generated whenever an input changes beyond the value given by the appropriate dead band setting. The voltage and current phase angles will only generate an event if, in addition to their dead band check, the corresponding magnitude changes beyond its own dead band. Analog inputs are scanned at approximately a 1 second rate, except for the Fault analog inputs discussed in *Relay Event Data*. The ANADBA and DECPLA settings apply to the current values. The ANADBV and DECPLV settings apply to the voltage values. ANADBA, ANADBV, and ANADBM shall not be applied to the fault analog inputs. All values related to a fault shall be updated cohesively regardless of the dead bands. All events generated during a scan will use the time the scan was initiated.

Relay Event Data

The following fault analog inputs are derived from the history queue data for the most recently read event: FTYPE, FTYPE16, FLOC, FI, FIA, FIB, FIC, FIG, FIN, FIQ, FFREQ, FGRP, FSHO, FTIMEH, FTIMEM, FTIMEL, FTIMEH16, FTIMEM16, FTIMEL16, and FUNR. These quantities, also referred to as the event registers, generate DNP3 analog change events (Object 32). Because these event registers refer to the same event summary record, the relay creates analog change events for all of these event registers when any one of the registers exceeds its dead band. Events for these inputs will use the time the scan was initiated. Current quantities FI, FIA, FIB, FIC, FIG, FIN, and FIQ are populated with currents from the maximum fault row.

Analog input FLOC is the fault location value. If this field contains "$$$$$$" (undetermined location) or is blank (when EFLOC := N), the relay will set the internal value of FLOC to –999.9 for DNP3. As with most of the event register values, FLOC is subject to scaling by the DECPLM setting (1 by default). So by default, a DNP3 poll of this value under the above conditions would yield a value of –9999.0 at the master. This value was chosen to represent an undetermined or blank FLOC that would not create nuisance alarms by presenting an over-range value to a DNP3 master. Note that if DECPLM is changed, this will change the end value of this point at the DNP3 master. If DECPLM is changed, you should set per-point scaling to 1 for FLOC to override the DECPLM scaling and ensure that it is transmitted as expected.

Analog input FUNR is derived from the history queue. Analog input FTYPE is a 16-bit composite value, as defined in *Table E.12* and *Table E.13* and the accompanying language.

Settings Data

Analog inputs 51PJP, 51PKP, 51N1JP, 51N1KP, 51N2JP, 51N2KP, 51G1JP, 51G1KP, 51G2JP, 51G2KP, 51QJP, 51QKP, 51AJP, 51AKP, 51BJP, 51BKP, 51CJP, 51CKP, 51PJP_P, 51PKP_P, 51N1JP_P, 51N1KP_P, 51N2JP_P, 51N2KP_P, 51G1JP_P, 51G1KP_P, 51G2JP_P, 51G2KP_P, 51QJP_P, 51QKP_P, 51AJP_P, 51AKP_P, 51BJP_P, 51BKP_P, 51CJP_P, and 51CKP_P are derived from the present active Group settings. If the associated setting is set to off, the value will be reported as –1. Please note that these values are subject to scaling by the DECPLA setting (i.e., you will see a value of –10 for OFF with the default DECPLA setting.) You can override the default scaling by applying per-point scaling to these values in a custom DNP3 map.

Testing

Use the **TEST DB** command to temporarily force the relay to send fixed analog and/or digital values over communications interfaces for DNP3 testing (see *TEST DB Command on page 10.76*).

DNP3 Documentation

The DNP3 Device Profile XML document, available on the supplied CD or as a download from the SEL website, contains the standard device profile information for the SEL-651R-2. Please refer to this document for complete information on the DNP3 Protocol support in the SEL-651R-2.

Device Profile

Table E.9 contains the standard DNP3 device profile information. Rather than check boxes in the example Device Profile in the DNP3 Subset Definitions, only the relevant selections are shown.

Table E.9   SEL-651R-2 DNP3 Device Profile (Sheet 1 of 2)

Parameter	Value
Vendor name	Schweitzer Engineering Laboratories
Device name	SEL-651R-2 Recloser Control
Highest DNP3 request level	Level 2
Highest DNP3 response level	Level 2
Device function	Outstation
Notable objects, functions, and/or qualifiers supported	Virtual Terminal, Analog Dead Band Objects (Object 34)
Maximum data link frame size transmitted	292
Maximum data link frame size received (octets)	292
Maximum data link retries	Configurable, range 0–15
Requires data link layer confirmation	Configurable by setting
Maximum application fragment size transmitted/received (octets)	Configurable by setting
Maximum application layer retries	None
Requires application layer confirmation	When reporting Event Data
Data link confirm time-out	Configurable

Sends static data in unsolicited responses	Never
Default counter object/variation	Object 20, Variation 6
Counter roll-over	16 bits
Sends multifragment responses	Yes

In response to the delay measurement function code, the SEL-651R-2 will return a time delay accurate to within 25 milliseconds at 9600 bps. Accuracy improves with higher data rates.

Object List

Table E.10 lists the objects and variations with supported function codes and qualifier codes available in the SEL-651R-2. The list of supported objects conforms to the format laid out in the DNP3 specifications and includes both supported and unsupported objects. Those that are supported include the function and qualifier codes. The objects that are not supported are shown without any corresponding function and qualifier codes.

113	all	Virtual Terminal Event Data	1	6	129, 130	17, 28
N/A		No object required for the following function codes: 13 cold start 14 warm start 23 delay measurement	13, 14, 23			

[a] Supported in requests from master.
[b] May generate in response to master.
[c] Decimal.
[d] Hexadecimal.
[e] Default variation.
[f] The relay accepts function codes 7, 8, 9, and 10 and responds without an error, but no action is taken because frozen counters are not supported.
[g] DNP3 implementation Level 2 functionality, which the relay does not support.

Reference Data Map

Table E.11 shows the SEL-651R-2 reference data map. The reference map shows the data available to a DNP3 master. You can use the default map or the custom DNP3 mapping functions of the SEL-651R-2 to retrieve only the points required by your application.

To retrieve SER-quality binary inputs, SEL-651R-0, -1 models required mapping points within the range of indexes (800–999/1000–1199) dedicated to SER inputs. This is not necessary for the SEL-651R-2 recloser control. If a point is registered in the SER, it will automatically have an SER time stamp when included in the default or custom data map.

The relay scales analog values by the indicated settings or fixed scaling indicated in the description. Analog dead bands for event reporting use the indicated settings, or ANADBM if you have specified no setting.

Table E.11   DNP3 Reference Data Map (Sheet 1 of 8)

Object Type	Label	Description	SEL-651R-0/1 Index
01,02	Relay Word	Relay Word Bit label	000–799 (651R-0) 000–999 (651R-1)
01,02	Relay Word	SER indices derived from SER trigger settings SER1–SER4	800–999 (651R-0) 1000–1199 (651R-1)
01,02	TLED_01–TLED_16	Relay front-panel targets (01–16), product specific meaning	1600–1615
01,02	RLYDIS	Relay disabled	1616
01,02	STFAIL	Relay diagnostic failure	1617
01,02	STWARN	Relay diagnostic warning	1618
01,02	UNRDEV	An unread relay event is available	1619
01,02	STSET	Settings change or relay restart	1620
01,02	LDPFA	Power factor leading for A-phase	1632
01,02	LDPFB	Power factor leading for B-phase	1633
01,02	LDPFC	Power factor leading for C-phase	1634
01,02	LDPF3	Power factor leading for three-phase	1635
01,02	TLED_17–TLED_24	Relay front-panel targets (17–24), product specific meaning	1636–1643
01,02	NUNREV	A more recent unread relay event is available	1644
10,12	RB01–RB16	Remote bits RB01–RB16	00–15

Table E.11   DNP3 Reference Data Map (Sheet 8 of 8)

Object Type	Label	Description	SEL-651R-0/1 Index
80		Internal Indications	
112		Virtual Terminal Output Block	
113		Virtual Terminal Event Data	

ᵃ Default current scaling DECPLA on magnitudes and angles multiplied by 100. Dead band ANADBA on magnitudes and ANADBM on angles.
ᵇ Default voltage scaling DECPLV on magnitudes and angles multiplied by 100. Dead band ANADBV on magnitudes and ANADBM on angles.
ᶜ Default miscellaneous scaling DECPLM and dead band ANADBM.
ᵈ Default scaling = 100 and dead band ANADBM.
ᵉ Default scaling = 100 and dead band = 1.
ᶠ Default scaling = 1 and dead band ANADBM.
ᵍ ANADBA, ANADBV, and ANADBM are not applicable to fault Analog Inputs. See Relay Event Data on page E.22 for a detailed description of the labels.
ʰ Minimum values that have been reset report the largest positive value possible. Maximum values that have been reset report the largest negative value possible.

Fault summary information (fault type, targets, location, frequency, settings group, and recloser shot counter) are available through Object 30. Depending upon setting RPEVTYP, any new trip event (TRIPA, TRIPB, TRIPC, or TRIP3P, when RPEVTYP := TRIP) or any new event (rising edge of TRIP*x* Relay Word bits, rising edge of SELOGIC control equation setting ER, **TRI** command, pulsing an output when RPEVTYP := ALL) is latched into these event registers. The event registers will be locked (they will not update) for time EVELOCK. The event registers are cleared by an assertion of the TRGTR Relay Word bit.

Object 30, Fault Type, is a 16-bit composite value, where the upper byte value indicates an event cause as shown in *Table E.12* and the lower byte indicates a fault type as shown in *Table E.13*. The upper and lower byte will be the sum of the applicable event cause and fault types. For example, a Fault Type of 3079 decimal would translate to 0C07 hex, and indicate a Trip and an ER element Event Cause ($4 + 8 = 12$ or 0C hex) on A Phase, B Phase and C Phase ($1 + 2 + 4 = 07$). If input FTYPE is 0, fault information has not yet been read and the fault analog inputs do not contain valid event data.

Table E.12   Object 30, Fault Type Upper Byte–Event Cause

Byte Value	Description
1	Trigger command
2	Pulse command
4	Trip element
8	Event report element

Table E.13   Object 30, Fault Type Lower Byte–Fault Type

Byte Value	Description
0	Indeterminate
1	A-phase
2	B-phase
4	C-phase
8	Ground

In some instances, the values in the FTIME*x* registers and FTYPE register may contain a value greater than 32767, which can be read correctly using Object 30 variation 1 or 3 (32-bit value). However, some DNP masters cannot

E.38 | DNP3 Communications
DNP3 Documentation

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 848 of 1080
Wolfe

read a 32-bit value, so the 16-bit variations (2 and 4) clamp the value and variation 2 reports an over range flag. FTYPE16, FTIMEH16, FTIMEM16, and FTIMEL16 contain a 16-bit signed value that can be read using variation 2 or 4. The FIMEx16 and FTYPE16 registers contain the FTIMEx or FTYPE value minus 65536 if the value is greater than 32767. The value is reported as a negative number without an over range flag.

Use *Table E.14* to determine the charger mode (CMODE).

Table E.14   Object 30, CMODE

CMODE Value	Description
0	Shutdown
1	Startup
2	Constant Current Charge
3	Fast Charge
4	Float Charge
5	Discharge
6	Bad Battery
7	Capacitor Charging
8	Battery Test

Event Data

DNP event data objects contain change-of-state and time-stamp information that the SEL-651R-2 collects and stores in a buffer. You can configure the SEL-651R-2 to either report the data without a polling request from the master (unsolicited data) or hold the data until the master requests the information with an event poll message.

With the event class settings ECLASSBn, ECLASSCn, and ECLASSAn, you can set the event class for binary, counter, and analog inputs for Ethernet port session n (the suffix n is not present for serial port event class settings). ECLASSV sets the event class for virtual terminal in serial sessions only. You can use the classes as a simple priority system for collecting event data. The relay does not treat data of different classes differently with respect to message scanning, but the relay does allow the master to perform independent class polls.

NOTE: Most RTUs that act as substation DNP masters perform an event poll that collects event data of all classes simultaneously. Confirm that the polling configuration of your master allows independent polling for each class before implementing separate classes in the SEL-651R-2.

For event data collection you must also consider and enter appropriate settings for dead band and scaling operation on analog points shown in *Table E.11*. You can either set and use default dead band and scaling according to data type or use a custom data map to select dead bands on a point-by-point basis. See *Configurable Data Mapping on page E.14* for a discussion of how to set scaling and dead band operation on a point-by-point basis.

Dead bands for analog inputs can be modified at run-time by writing to Object 34. Dead band changes via Object 34 are stored in volatile memory. Make sure to reissue the Object 34 dead band changes you want to retain after a change to DNP port settings, after issuing an **STA C** command, or after a relay power cycle.

The settings ANADBAn, ANADBVn, and ANADBMn control default dead band operation for the specified data type.

The relay uses the NUMcEVEn and AGEcEVEn settings to decide when to send unsolicited data to the master. The relay sends an unsolicited report when the total number of class c (where c is 1, 2, or 3) events accumulated in the event buffer for master n reaches NUMcEVEn (where n is 1–6). The relay also

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 849 of 1080
DNP3 Communications E.39
DNP3 Documentation
Wolfe

sends an unsolicited report if the age of the oldest class *c* event in the master *n* buffer exceeds AGE*c*EVE*n*. The SEL-651R-2 has the buffer capacities listed in *Table E.15*. If event limits are exceeded, then some event data will be lost.

Table E.15   SEL-651R-2 Event Data Buffer Limits

Event Data Type	Maximum Number of Events
Binary Inputs (object 2)	1024
Counter (object 22)	16
Analog Inputs (object 32)	200
Virtual Terminal (object 113)	5

Reading Relay Events

The SEL-651R-2 provides protective relay event history information in one of two modes: single-event or multiple-event mode. The port setting EVEMODE determines which mode each DNP session will start up in after a relay cold start, DNP port settings change, DNP map change or SER settings change. The default setting for EVEMODE is SINGLE. The reporting method can also be changed by asserting a binary output control point. The relay changes to multiple-event mode on a per-session basis if the NXTEVE control point is pulsed. The relay changes to single-event mode on a per-session basis if the SINGEVE control point is pulsed. Multiple-event mode supports first-in, first-out (FIFO) and last-in, first-out (LIFO) data access. A relay power cycle, a DNP port settings change, a DNP map change, or a SER settings change returns the reporting method to the mode specified by EVEMODE.

Port setting RPEVTYP determines the types of event reports reported in the DNP event summary data. When RPEVTYP := TRIP, only TRIP events are reported in the DNP event summary data. When RPEVTYP := ALL, all events are reported in the DNP event summary data. Single-Event mode provides the most recent RPEVTYP type event to the event summary area. In Single-Event mode, any new RPEVTYP type event causes event data to be latched into the event registers and made available in the DNP event summary data. The relay shall ignore any subsequent events for EVELOCK (port setting) time. The event registers will be cleared on a rising edge of the TRGTR Relay Word bit. The relay element EVELOCK is set when an event is triggered and reset when EVELOCK time expires.

Multiple-Event mode shall be initiated if the NXTEVE control point is pulsed or after a relay cold start, DNP port settings change, DNP map change, or SER settings change when EVEMODE := MULTI. In multiple-event mode, an event is loaded into the event registers when a control point is pulsed. The order that events are loaded depends on the binary output point controlled— Load-Event LIFO Mode or Load-Event FIFO Mode. The user cannot traverse event summaries forward, then backwards. When switching from multi-event mode to single-event mode by operating SINGEVE, the event registers are set to zero, but the event buffer is not reset. For example, if the relay is in single-event mode, three events occur, and the relay is switched to multiple-event mode by latching on NXTEVE, a read of the analog event registers will show data for the oldest event and FUNR will be equal to 2. If the relay is switched to single-event mode by operating SINGEVE, a read of the analog event registers will show that they are all zero but the event buffer will still contain two unread events. This can be seen by latching on NXTEVE to switch back to multiple-event mode. Once in multiple-event mode, a read of the analog event registers will show data for the oldest event and FUNR will be equal to 1, indicating that there is still one unread event in the event buffer. Note that

the switching between modes is not normal behavior for a DNP master and is only discussed here to illustrate the event buffer functionality when switching modes.

To use Multiple-Event FIFO Mode, the master should monitor the UNRDEV binary input point (Unread Event Available, *Table E.11*), which will be asserted when there is an unread relay event summary. To read the oldest relay event summary, the master should latch on the NXTEVE binary output point (Load-Event FIFO Mode, see *Table E.8*). This will load the relay event summary analogs (fault type, location, current, frequency, settings group, shot country, and time, *Table E.11*) with information from the oldest relay event summary, discarding the values from the previous load.

After reading the analogs, the master should again check the UNRDEV binary input point, which will be asserted if another unread relay event summary is available. The master should continue to be asserted if another unread relay event summary is available. The master should continue this monitor-latch-on-read events process until the UNRDEV binary input point deasserts. If the master attempts to load values by latching on the NXTEVE binary output point with the UNRDEV binary input point deasserted, the relay event summary analogs will be filled with zeroes. With the FIFO method, the relay event summaries will always be collected in chronological order.

Similarly, to use Multiple-Event LIFO Mode, the master should also monitor the UNRDEV binary input point (Unread Event Available), which will be asserted when there is an unread relay summary. To read the newest relay event summary, the master should latch off the NXTEVE binary output point (Load-Event LIFO Mode, see *Table E.8*). This will load the relay event summary analogs with information from the newest relay event summary, discarding the values from the previous load. After reading the events, the master should check the UNRDEV binary input points and latch off the NXTEVE binary output point, if it is asserted, to read the next newest event. The master should continue this process until the UNRDEV binary input point deasserts. If the master attempts to load values by latching off the NXTEVE binary output point with the UNRDEV binary input point deasserted, the relay event summary analogs will be filled with zeroes. Note that events will be in chronological order if no new events have occurred, the most recent event will always be in the event registers if the load-event control point is latched after an event, and events will always be out of order if new events occur before all of the previous events have been read.

SELOGIC control equation RSTDNPE is used to clear the DNP event registers and the DNP event buffer for both single-event mode and multiple-event mode for all DNP sessions. When RSTDNPE is evaluated to one, the DNP event registers are set to zero and the DNP event buffer is cleared. The DNP binary output DRSTDNPE is similar in function to RSTDNPE, and can also be used to clear the DNP event registers and the DNP event buffer when the relay is in single-event mode or multiple-event mode on a per-session basis. Likewise, the SELOGIC control equation RSTTRGT can be used to clear the DNP event data in single-event mode.

Default Data Map

NOTE: Dead band changes via Object 34 are stored in volatile memory. Make sure to reissue the Object 34 dead bands after a warm (**HIS C**) or cold start (power cycle).

Table E.16 shows the SEL-651R-2 default data map. The default map is a subset of the reference map to reduce the response time. Use the custom DNP3 mapping functions to create the map required for your application.

Appendix F

Relay Word Bits

Relay Word bits show the status of functions within the relay. The bits are available via communications protocols and the front panel.

Any Relay Word bit can be used in SELOGIC control equations (see *Section 7: SELOGIC Control Equation Programming*) and the Sequential Events Recorder (SER) trigger list settings (see *Section 12: Analyzing Events*).

Use *Table F.1* for an overview of what bits are available and their row number. You can display the bits with either the row number (**TAR** *row_number*) or the bit name (**TAR** *bit_name*).

Table F.2 provides an alphabetical listing of the Relay Word bits that includes a description of each bit.

Table F.1 and *Table F.2* include cross-reference information for most Relay Word bits. *Table F.3* describes Relay Word bits that are not described elsewhere in the manual.

a An asterisk (*) denotes "reserved for future use."
b IN101–IN107 and OUT101–OUT108 are displayed only if the extra I/O is ordered.
c LINK5 is replaced by "*" when dual Ethernet connectors are present.
d Relay Word bits (for dual Ethernet ports) are replaced by "*" when a single Ethernet connector is present.
e Virtual bits VB001–VB128 are only present in relays ordered with IEC 61850 protocol.
f Relay Word bits for row 124–132 are only present in relays ordered with High-Impedance Fault Detection.
g Relay Word bits follows SELᴏɢɪᴄ Setting of same name.
h Relay Word bits are only present in relays ordered with Multi-Recloser Interface.

Table F.2 Alphabetic List of Relay Word Bits (Sheet 1 of 14)

Name	Definition	Usage	Relay Word Bit Row[a]
25A1, 25A2	Synchronism-check elements (see *Figure 4.31*)	Control	30
27B81	Undervoltage element for frequency element blocking (see *Figure 4.34* and *Figure 4.35*)	Control	32
27YA1, 27YA2	A-phase undervoltage elements, Y-terminal (see *Figure 4.26*)	Control	22
27YAB1	AB-phase-to-phase undervoltage element, Y-terminal (see *Figure 4.27*)	Control	23
27YB1, 27YB2	B-phase undervoltage elements, Y-terminal (see *Figure 4.26*)	Control	22
27YBC1	BC-phase-to-phase undervoltage element, Y-terminal (see *Figure 4.27*)	Control	23
27YC1, 27YC2	C-phase undervoltage elements, Y-terminal (see *Figure 4.26*)	Control	22
27YCA1	CA-phase-to-phase undervoltage, Y-terminal (see *Figure 4.27*)	Control	23
27ZA1, 27ZA2	A-phase undervoltage elements, Z-terminal (see *Figure 4.28*)	Control	26
27ZAB1	AB-phase-to-phase undervoltage element, Z-terminal (see *Figure 4.29*)	Control	27
27ZB1, 27ZB2	B-phase undervoltage elements, Z-terminal (see *Figure 4.28*)	Control	26
27ZBC1	BC-phase-to-phase undervoltage element, Z-terminal (see *Figure 4.29*)	Control	27
27ZC1, 27ZC2	C-phase undervoltage elements, Z-terminal (see *Figure 4.28*)	Control	26
27ZCA1	CA-phase-to-phase undervoltage element, Z-terminal (see *Figure 4.29*)	Control	27
32GF	Forward directional control for ground overcurrent elements (see *Figure 4.57*)	Testing, Special directional control schemes	73
32GR	Reverse directional control for ground overcurrent elements (see *Figure 4.57*)	Testing, Special directional control schemes	73
32PF	Forward directional control for phase overcurrent elements (see *Figure 4.61*)	Testing, Special directional control schemes	73
32PR	Reverse directional control for phase overcurrent elements (see *Figure 4.61*)	Testing, Special directional control schemes	73
32QE	Enable for negative-sequence voltage-polarized directional element (see *Figure 4.52*)	Testing	71
32QF	Forward directional control for negative-sequence overcurrent elements (see *Figure 4.61*)	Testing, Special directional control schemes	73

Table F.2   Alphabetic List of Relay Word Bits (Sheet 2 of 14)

Name	Definition	Usage	Relay Word Bit Row[a]
32QGE	Enable for negative-sequence voltage-polarized directional element for ground (see *Figure 4.52*)	Testing	71
32QR	Reverse directional control for negative-sequence overcurrent elements (see *Figure 4.61*)	Testing, Special directional control schemes	73
32VE	Enable for zero-sequence voltage-polarized directional element (see *Figure 4.53*)	Testing	71
3P27Y	Three-phase undervoltage element, Y-terminal = 27YA1 AND 27YB1 AND 27YC1 (see *Figure 4.26*)	Control	24
3P27Z	Three-phase undervoltage element, Z-terminal = 27ZA1 AND 27ZB1 AND 27ZC1 (see *Figure 4.28*)	Control	28
3P59Y	Three-phase overvoltage element, Y-terminal = 59YA1 AND 59YB1 AND 59YC1 (see *Figure 4.26*)	Control	24
3PH_EVE	Three-phase Event Detection in the Difference Current Quantity (see *High-Impedance Fault Detection (Arc Sense Technology) on page 4.111*)	Control	125
3P59Z	Three-phase overvoltage element, Z-terminal = 59ZA1 AND 59ZB1 AND 59ZC1 (see *Figure 4.28*)	Control	28
3PO	Three-pole open condition (see *Figure 5.5*)	Testing	19
3PWR1–3PWR4	Three-phase power elements, 1–4 (see *Figure 4.44*)	Tripping, Control	88, 89
50A	A-phase instantaneous overcurrent element = 50A1 OR 50A2 OR 50A3 OR 50A4 (see *Figure 4.7*)	Tripping, Control	7
50A1–50A4	Level 1–Level 4 A-phase instantaneous overcurrent elements (see *Figure 4.1*)	Tripping, Control	4, 5
50A1T–50A4T	Level 1–Level 4 A-phase definite time-overcurrent elements (see *Figure 4.4*)	Tripping, Control	14, 15
50B	B-phase instantaneous overcurrent element = 50B1 OR 50B2 OR 50B3 OR 50B4 (see *Figure 4.7*)	Tripping, Control	7
50B1–50B4	Level 1–Level 4 B-phase instantaneous overcurrent elements (see *Figure 4.1*)	Tripping, Control	4, 5
50B1T–50B4T	Level 1–Level 4 B-phase definite time-overcurrent elements (see *Figure 4.5*)	Tripping, Control	14, 15
50C	C-phase instantaneous overcurrent element = 50C1 OR 50C2 OR 50C3 OR 50C4 (see *Figure 4.7*)	Tripping, Control	7
50C1–50C4	Level 1–Level 4 C-phase instantaneous overcurrent elements (see *Figure 4.1*)	Tripping, Control	4, 5
50C1T–50C4T	Level 1–Level 4 C-phase definite time-overcurrent elements (see *Figure 4.6*)	Tripping, Control	14, 15
50G1–50G6	Level 1–Level 6 ground instantaneous overcurrent elements (see *Figure 4.12* and *Figure 4.13*)	Tripping, Testing, Control	6, 8
50G1T–50G4T	Level 1–Level 4 ground definite time-overcurrent elements (see *Figure 4.12*)	Tripping, Testing, Control	16
50GF	Forward direction ground overcurrent threshold exceeded (see *Figure 4.53*)	Testing	9
50GHIZ	Ground HIZ Instantaneous Overcurrent Pickup (see *Figure 4.77*)	Testing, Control	130
50GHIZA	50G HIZ Alarm (see *Figure 4.80*)	Indication, Control	132
50GR	Reverse direction ground overcurrent threshold exceeded (see *Figure 4.53*)	Testing	9

Table F.2   Alphabetic List of Relay Word Bits (Sheet 3 of 14)

Name	Definition	Usage	Relay Word Bit Row[a]
50L	Phase instantaneous overcurrent element for load detection = 50LA OR 50LB OR 50LC (see *Figure 5.5*)	Testing	9
50LA	A-phase instantaneous overcurrent element for load detection (see *Figure 5.6*)	Testing	9
50LB	B-phase instantaneous overcurrent element for load detection (see *Figure 5.6*)	Testing	9
50LC	C-phase instantaneous overcurrent element for load detection (see *Figure 5.6*)	Testing	9
50N1–50N6	Level 1–Level 6 neutral instantaneous overcurrent elements (see *Figure 4.10*)	Tripping, Testing, Control	7, 8
50N1T–50N4T	Level 1–Level 4 neutral definite time-overcurrent elements (see *Figure 4.10*)	Tripping, Testing, Control	17
50P1–50P6	Level 1–Level 6 phase instantaneous overcurrent elements (see *Figure 4.1* and *Figure 4.2*)	Tripping, Testing, Control	4, 5, 8
50P1T–50P4T	Level 1–Level 4 phase definite time-overcurrent elements (see *Figure 4.3*)	Tripping, Testing, Control	14, 15
50P32	Three-phase overcurrent threshold exceeded for phase directional element (see *Figure 4.60*)	Testing	7
50Q1–50Q6	Level 1–Level 6 negative-sequence instantaneous overcurrent elements (see *Figure 4.14* and *Figure 4.15*)	Testing, Control	6, 8
50Q1T–50Q4T	Level 1–Level 4 negative-sequence definite time-overcurrent elements (see *Figure 4.14*)	Testing, Control	16
50QF	Forward direction negative-sequence overcurrent threshold exceeded (see *Figure 4.52*)	Testing	9
50QR	Reverse direction negative-sequence overcurrent threshold exceeded (see *Figure 4.52*)	Testing	9
51A	A-phase time-overcurrent element picked up (see *Figure 4.17*)	Testing, Control	10
51AR	A-phase time-overcurrent element reset (see *Figure 4.17*)	Testing	10
51AS	A-phase time-overcurrent element, J/K setting indication[b] (see *Figure 4.17*)	Control	10
51AT	A-phase time-overcurrent element timed out (see *Figure 4.17*)	Tripping	10
51B	B-phase time-overcurrent element picked up (see *Figure 4.18*)	Testing, Control	10
51BR	B-phase time-overcurrent element reset (see *Figure 4.18*)	Testing	10
51BS	B-phase time-overcurrent element, J/K setting indication[b] (see *Figure 4.18*)	Control	10
51BT	B-phase time-overcurrent element timed out (see *Figure 4.18*)	Tripping	10
51C	C-phase time-overcurrent element picked up (see *Figure 4.19*)	Testing, Control	11
51CR	C-phase time-overcurrent element reset (see *Figure 4.19*)	Testing	11
51CS	C-phase time-overcurrent element, J/K setting indication[b] (see *Figure 4.19*)	Control	11
51CT	C-phase time-overcurrent element timed out (see *Figure 4.19*)	Tripping	11
51G1	#1 Ground time-overcurrent element picked up (see *Figure 4.22*)	Testing, Control	12
51G1R	#1 Ground time-overcurrent element reset (see *Figure 4.22*)	Testing	12
51G1S	#1 Ground time-overcurrent element, J/K setting indication[b] (see *Figure 4.22*)	Control	12
51G1T	#1 Ground time-overcurrent element timed out (see *Figure 4.22*)	Tripping	12

Table F.2   Alphabetic List of Relay Word Bits (Sheet 4 of 14)

Name	Definition	Usage	Relay Word Bit Row[a]
51G2	#2 Ground time-overcurrent element picked up (see *Figure 4.23*)	Testing, Control	12
51G2R	#2 Ground time-overcurrent element reset (see *Figure 4.23*)	Testing	12
51G2S	#2 Ground time-overcurrent element, J/K setting indication[b] (see *Figure 4.23*)	Control	12
51G2T	#2 Ground time-overcurrent element timed out (see *Figure 4.23*)	Tripping	12
51N1	#1 Neutral time-overcurrent element picked up (see *Figure 4.20*)	Testing, Control	13
51N1R	#1 Neutral time-overcurrent element reset (see *Figure 4.20*)	Testing	13
51N1S	#1 Neutral time-overcurrent element, J/K setting indication[b] (see *Figure 4.20*)	Control	13
51N1T	#1 Neutral time-overcurrent element timed out (see *Figure 4.20*)	Tripping	13
51N2	#2 Neutral time-overcurrent element picked up (see *Figure 4.21*)	Testing, Control	17
51N2R	#2 Neutral time-overcurrent element reset (see *Figure 4.21*)	Testing	17
51N2S	#2 Neutral time-overcurrent element, J/K setting indication[b] (see *Figure 4.21*)	Control	17
51N2T	#2 Neutral time-overcurrent element timed out (see *Figure 4.21*)	Tripping	17
51P	Maximum-phase time-overcurrent element picked up (see *Figure 4.16*)	Testing, Control	11
51PR	Maximum-phase time-overcurrent element reset (see *Figure 4.16*)	Testing	11
51PS	Maximum-phase time-overcurrent element, J/K setting indication[b] (see *Figure 4.16*)	Control	11
51PT	Maximum-phase time-overcurrent element timed out (see *Figure 4.16*)	Tripping	11
51Q	Negative-sequence time-overcurrent element picked up (see *Figure 4.24*)	Testing, Control	13
51QR	Negative-sequence time-overcurrent element reset (see *Figure 4.24*)	Testing	13
51QS	Negative-sequence time-overcurrent element, J/K setting indication[b] (see *Figure 4.24*)	Control	13
51QT	Negative-sequence time-overcurrent element timed out (see *Figure 4.24*)	Tripping	13
52A3P	Circuit breaker status (see *Figure 6.2*)	Indication	18
52AA, 52AB, 52AC	A-, B-, or C-phase circuit breaker status (available when setting BKTYP := 1) (see *Figure 6.2*)	Indication	18
59VP	Healthy voltage VP for synchronism check (see *Figure 4.30*)	Testing	30
59VS	Healthy voltage VS for synchronism check (see *Figure 4.30*)	Testing	30
59YA1, 59YA2	A-phase overvoltage elements, Y-terminal (see *Figure 4.26*)	Control	22, 23
59YAB1	AB-phase-to-phase overvoltage element, Y-terminal (see *Figure 4.27*)	Control	23
59YB1, 59YB2	B-phase overvoltage elements, Y-terminal (see *Figure 4.26*)	Control	22, 23
59YBC1	BC-phase-to-phase overvoltage element, Y-terminal (see *Figure 4.27*)	Control	24
59YC1, 59YC2	C-phase overvoltage elements, Y-terminal (see *Figure 4.26*)	Control	23
59YCA1	CA-phase-to-phase overvoltage element, Y-terminal (see *Figure 4.27*)	Control	24
59YN1, 59YN2	Zero-sequence overvoltage elements, Y-terminal (see *Figure 4.27*)	Control	24
59YQ1	Negative-sequence overvoltage element, Y-terminal (see *Figure 4.27*)	Control	24
59YV1	Positive-sequence overvoltage element, Y-terminal (see *Figure 4.27*)	Control	24
59ZA1, 59ZA2	A-phase overvoltage elements, Z-terminal (see *Figure 4.28*)	Control	26, 27

Table F.2 Alphabetic List of Relay Word Bits (Sheet 5 of 14)

Name	Definition	Usage	Relay Word Bit Row[a]
59ZAB1	AB-phase-to-phase overvoltage element, Z-terminal (see *Figure 4.29*)	Control	27
59ZB1, 59ZB2	B-phase overvoltage elements, Z-terminal (see *Figure 4.28*)	Control	26, 27
59ZBC1	BC-phase-to-phase overvoltage element, Z-terminal (see *Figure 4.29*)	Control	28
59ZC1, 59ZC2	C-phase overvoltage elements, Z-terminal (see *Figure 4.28*)	Control	27
59ZCA1	CA-phase-to-phase overvoltage element, Z-terminal (see *Figure 4.29*)	Control	28
59ZN1, 59ZN2	Zero-sequence overvoltage elements, Z-terminal (see *Figure 4.29*)	Control	28
59ZQ1	Negative-sequence overvoltage element, Z-terminal (see *Figure 4.29*)	Control	28
59ZV1	Positive-sequence overvoltage elements, Z-terminal (see *Figure 4.29*)	Control	28
69__YH	Yellow operating handle in lock-open position (Multi-Recloser Interface only; see *Figure 5.2* and *Figure 6.11*)	Tripping, Control	134
79CY3P	Reclosing relay in the Reclose Cycle State (available when setting ESPB := N) (see *Figure 6.1*)	Control	64
79CYA, 79CYB, 79CYC	A-, B-, or C-phase reclosing relay in the Reclose Cycle State (available when setting ESPB := Y) (see *Figure 6.1*)	Control	65–67
79LO3P	Reclosing relay in the Lockout State (available when setting ESPB := N) (see *Figure 6.1*)	Control	64
79LOA, 79LOB, 79LOC	A-, B-, or C-phase reclosing relay in the Lockout State (available when setting ESPB := Y) (see *Figure 6.1*)	Control	65–67
79RS3P	Reclosing relay in the Reset State (available when setting ESPB := N) (see *Figure 6.1*)	Control	64
79RSA, 79RSB, 79RSC	A-, B-, or C-phase reclosing relay in the Reset State (available when setting ESPB := Y) (see *Figure 6.1*)	Control	65–67
81D1–81D6	Level 1–Level 6 instantaneous frequency elements (for testing only) (see *Figure 4.38*)	Testing	31
81D1T–81D6T	Level 1–Level 6 definite-time frequency elements (see *Figure 4.38*)	Tripping, Control	32
81R1T–81R4T	Level 1–Level 4 rate-of-change-of-frequency elements (see *Figure 4.39*	Tripping, Control	35
81RT	81R1T OR 81R2T OR 81R3T OR 81R4T	Tripping, Control	35
A1_CFG	Global setting RECL_CFG := A1 (Multi-Recloser Interface only; see *Table 2.4*, *Figure 5.2*, and *Figure 6.11*)	Indication, Control	134
A2_CFG	Global setting RECL_CFG := A2 (Multi-Recloser Interface only; see *Table 2.4*, *Figure 5.2*, and *Figure 6.11*)	Indication, Control	134
A3_CFG	Global Setting RECL_CFG := A3 (Multi-Recloser Interface only; see *Table 2.4*, *Figure 5.2*, and *Figure 6.11*.	Indication, Control	134
ACCESS	Asserted while any user is logged in at Access Level B or higher (see *Port Access Levels on page 10.21*)	Indication	106
ACCESSP	Pulses for approximately 1 second when any user increases their access level to B or higher (see *Port Access Levels on page 10.21*)	Indication	107
BADPASS	Pulses for approximately 1 second whenever a user enters three successive bad passwords (see *Port Access Levels on page 10.21*)	Indication	107
BCW	Any contact wear has reached 100% wear level = BCWA OR BCWB OR BCWC (see *Breaker/Recloser Contact Wear Monitor on page 8.23*)	Indication	74
BCWA	A-phase breaker contact wear has reached 100% wear level (see *Breaker/Recloser Contact Wear Monitor on page 8.23*)	Indication	74

Table F.2 Alphabetic List of Relay Word Bits (Sheet 6 of 14)

Name	Definition	Usage	Relay Word Bit Row[a]
BCWB	B-phase breaker contact wear has reached 100% wear level (see *Breaker/Recloser Contact Wear Monitor on page 8.23*)	Indication	74
BCWC	C-phase breaker contact wear has reached 100% wear level (see *Breaker/Recloser Contact Wear Monitor on page 8.23*)	Indication	74
BTFAIL	Battery failure (see *Battery Status on page 8.43*)	Indication, Control	38
CBADA, CBADB	MIRRORED BITS channel unavailability over threshold, Channels A and B (see *Appendix D: MIRRORED BITS Communications*)	Indication	84
CC3	Asserts for one processing interval for CLOSE command execution (see *Figure 6.4*)	Testing, Control	42
CCA	Asserts for one processing interval for CLOSE A command execution	Testing, Control	42
CCB	Asserts for one processing interval for CLOSE B command execution	Testing, Control	42
CCC	Asserts for one processing interval for CLOSE C command execution	Testing, Control	42
CF3P	Close Failure condition (available when setting ESPB := N) (see *Figure 6.1*)	Indication	68
CFA, CFB, CFC	A-, B-, or C-phase Close Failure condition (available when setting ESPB := Y) (see *Figure 6.1*)	Indication	68
CHGPASS	Pulses for approximately one second whenever a password changes. (see *Port Access Levels on page 10.21*)	Indication	107
CHIZ0	HIZ Counts = 0 (see *50G High-Impedance (HIZ) Fault Detection on page 4.116*)	Control	129
CHRGG	Battery is charging (see *Battery Status on page 8.43*)	Indication	38
CLOSE3P	Close logic output asserted (available when setting ESPB := N) (see *Close Logic on page 6.5*)	Testing, Control	68
CLOSEA, CLOSEB, CLOSEC	A-, B-, or C-phase close logic output asserted (available when setting ESPB := Y) (see *Close Logic on page 6.5*)	Testing, Control	68
CPUDO0	50G HIZ Pickup/Dropout counts = 0 (see *50G High-Impedance (HIZ) Fault Detection on page 4.116*)	Control	129
DD	Disturbance Detector (see *Switch-Onto-Fault (SOTF) Trip Logic on page 5.11*)	Indication	19
DDNA, DDNB, DDNC	A-, B-, C-Phase Tuning Threshold Decrease (see *High-Impedance Fault Detection (Arc Sense Technology) on page 4.111*)	Control	130
DIA_DIS, DIB_DIS, DIC_DIS	A-, B-, C-Phase Large Difference Current Disturbance (see *High-Impedance Fault Detection (Arc Sense Technology) on page 4.111*)	Control	127
DISCHG	Battery is discharging (see *Battery Status on page 8.43*)	Indication	38
DISTST	Battery Discharge Test in Progress (see *Battery System Operation on page 8.40*)	Testing, Indication	38
DL2CLRA, DL2CLRB, DL2CLRC	A-, B-, C- Phase Decision Logic 2 Clear (see *High-Impedance Fault Detection (Arc Sense Technology) on page 4.111*)	Control	128
DST	Daylight Saving Time active	Indication	104
DSTP	Daylight Saving Time change Pending. Asserts up to a minute before daylight saving time change.	Indication	104
DTFAIL	Battery failed discharge test (see *Automatic Battery Load Test on page 8.42*).	Indication	38
DUPA, DUPB, DUPC	A-, B-, C- Phase Tuning Threshold Increase (see *High-Impedance Fault Detection (Arc Sense Technology) on page 4.111*)	Control	129

Table F.2   Alphabetic List of Relay Word Bits (Sheet 7 of 14)

Name	Definition	Usage	Relay Word Bit Row[a]
DVA_DIS, DVB_DIS, DVC_DIS	A-, B-, C- Phase Difference Voltage Disturbance (see *High-Imped-ance Fault Detection (Arc Sense Technology) on page 4.111*)	Control	127
EN	Enabled LED. Asserts when relay enabled. (see *Front-Panel Target LEDs ENABLED and TRIP on page 5.15*)	Indication	0
F32P	Forward positive-sequence voltage-polarized directional element (see *Figure 4.60*)	Testing, Special direc-tional control schemes	72
F32Q	Forward negative-sequence voltage-polarized directional element (see *Figure 4.59*)	Testing, Special direc-tional control schemes	71
F32QG	Forward negative-sequence voltage-polarized directional element (for ground) (see *Figure 4.55*)	Testing, Special direc-tional control schemes	71
F32V	Forward zero-sequence voltage-polarized directional element (see *Figure 4.56*)	Testing, Special direc-tional control schemes	72
FAULT	Output of SELOGIC control equation FAULT (see *SELOGIC Control Equation Setting FAULT on page 5.18*)	Indication	21
FREQOK	System frequency and tracking frequency valid (see *Analog Scaling and Frequency Indicators on page F.19*)	Indication, Testing	31
FRZCLRA, FRZ-CLRB, FRZCLRC	A-, B-, C- Phase Averager Freeze and Trending Clear Condition (see *High-Impedance Fault Detection (Arc Sense Technology) on page 4.111*)	Testing, Control	126
FSA, FSB, FSC	Fault identification logic outputs (used in targeting)	Control	19
GDEM	Ground demand current element (see *Figure 8.4*)	Indication	74
GNDSW	Ground Switch (Ground elements operating off of channel IN when asserted) (see *Table 4.23*)	Testing	19
GRPSW	Pulses for approximately 1 second whenever groups are switched (see *Section 9: Settings*)	Indication	107
HALARM	Hardware Alarm (diagnostic alarms) (see *Section 13: Testing and Troubleshooting*)	Indication	106
HALARMA	This bit pulses for approximately five seconds per minute when a hardware diagnostic warning occurs. It stops pulsing within approxi-mately one second of the rising edge of RST_HAL (see *Section 13: Testing and Troubleshooting*).	Indication	106
HALARML	Latches in for relay diagnostic failures (see *Section 13: Testing and Troubleshooting*)	Indication	106
HALARMP	Pulses for approximately five seconds when a warning diagnostic con-dition occurs (see *Section 13: Testing and Troubleshooting*)	Indication	106
HBL2AT, HBL2BT, HBL2CT	A-, B-, C- Phase Second-Harmonic Block Timed Out (see *Figure 4.25*)	Testing, Control	133
HBL2T	Combined-Phase Second-Harmonic Block Timed Out (see *Figure 4.25*)	Testing, Control	133
HIA2_A, HIA2_B, HIA2_C	A-, B-, C- Phase HIF Alarm from Algorithm 2 (see *Figure 4.75*)	Indication	126
HIF2_A, HIF2_B, HIF2_C	A-, B-, C- Phase HIF Detection by Algorithm 2 (see *Figure 4.75*)	Indication, Tripping, Con-trol	125
HIFER	HIF Event Report Setting (see *High-Impedance Fault Detection (Arc Sense Technology) on page 4.111*)	HIF Event Report duration	126
HIFFRZ	SELOGIC Control to Freeze HIF Detection (see *High-Impedance Fault Detection (Arc Sense Technology) on page 4.111*)	Testing, Control	126

Table F.2   Alphabetic List of Relay Word Bits (Sheet 8 of 14)

Name	Definition	Usage	Relay Word Bit Row[a]
HIFITUNE	SELOGIC Control to Initiate Tuning Process for HIF (see *High-Impedance Fault Detection (Arc Sense Technology) on page 4.111*)	Testing, Control	128
HIFMODE	Sensitivity Mode of HIF Algorithms (see *High-Impedance Fault Detection (Arc Sense Technology) on page 4.111*)	Testing, Control	124
HIFREC	HIF Event Report being Captured by Device (see *High-Impedance Fault Detection (Arc Sense Technology) on page 4.111*)	Control	124
HIZ170–HIZ175	States 170 to 175 of HIZ Logic (see *50G High-Impedance (HIZ) Fault Detection on page 4.116*)	Status of HIZ logic states	131
HIZ180–HIZ181	States 180 to 181 of HIZ Logic (see *50G High-Impedance (HIZ) Fault Detection on page 4.116*)	Status of HIZ logic states	131
HIZ190–HIZ192	States 191 to 192 of HIZ Logic (see *50G High-Impedance (HIZ) Fault Detection on page 4.116*)	Status of HIZ logic states	132
HIZRST	Reset 50G HIZ Alarm (see *50G High-Impedance (HIZ) Fault Detection on page 4.116*)	Testing, Control	132
IAMET, IBMET, ICMET	Channel IA, IB, or IC operating from high-gain channel (see *Analog Scaling and Frequency Indicators on page F.19*)	Event Report	79
IN101–IN107	Optoisolated inputs IN101–IN107, asserted (optional inputs) (see *Figure 7.18*)	Status sensing or control via optoisolated inputs (only operable if optional I/O installed)	33
IN201–IN206	Status inputs IN201–IN206, asserted (see *Figure 7.17*)	Status sensing or control via optoisolated inputs	34
INI_HIF	Initiate Tuning Process for HIF (see *High-Impedance Fault Detection (Arc Sense Technology) on page 4.111*)	Testing, Control	128
INMET	Channel IN operating from high-gain channel (see *Analog Scaling and Frequency Indicators on page F.19*)	Event Report	79
INT3P	Three-phase voltage interruption element = INTA AND INTB AND INTC (see *Voltage Interruption Elements on page 4.60*)	Sag/Swell/Int reporting	87
INTA, INTB, INTC	A-, B-, or C-phase voltage interruption elements (see *Voltage Interruption Elements on page 4.60*)	Sag/Swell/Int reporting	87
IRIGOK	IRIG time-source signal detected (= TIRIG OR TSOK) (see *Configuring High-Accuracy Timekeeping on page J.21*)	Indication	79
ITUNE_A, ITUNE_B, ITUNE_C	A-, B-, C- Phase Initial Tuning (see *High-Impedance Fault Detection (Arc Sense Technology) on page 4.111*)	Control	128
LB01–LB16	Local bits 01–16, asserted (see *Control Menu on page 11.7*)	Control via front panel—replacing traditional panel-mounted control switches	40, 41
LBOKA, LBOKB	MIRRORED BITS channel looped back OK, Channels A and B (see *Table 12.4* and *Appendix D: MIRRORED BITS Communications*)	Indication	84
LINK5	Asserted when a valid Ethernet link is detected on port 5 (see *Section 10: Communications*) (only on relays with a single Ethernet connector)	Indication, Testing	99
LINK5A, LINK5B	Asserted when a valid Ethernet link is detected on port 5A or 5B (see *Section 10: Communications*) (only on relays with dual Ethernet connectors)	Indication, Testing	99
LNKFAIL	Asserted when a valid link is not detected on the active port(s) (see *Section 10: Communications*)	Indication, Testing	99

Table F.2   Alphabetic List of Relay Word Bits (Sheet 9 of 14)

Name	Definition	Usage	Relay Word Bit Row[a]
LOP	Loss-of-potential (see *Loss-of-Potential Logic on page 4.77*)	Testing, Special directional control schemes	19
LPSEC	Leap Second direction. Add second if deasserted, delete if asserted. Only available when Global setting IRIGC = C37.118 and a proper IRIG signal is decoded (see *Configuring High-Accuracy Timekeeping on page J.21*).	Indication	104
LPSECP	Leap Second Pending. Asserts up to a minute prior to leap second insertion (see *Configuring High-Accuracy Timekeeping on page J.21*).	Indication	104
LR3	Three-phase Load Reduction Event (see *High-Impedance Fault Detection (Arc Sense Technology) on page 4.111*)	Indication, Control	130
LRA, LRB, LRC	A-, B-, C- Phase Load Reduction (see *High-Impedance Fault Detection (Arc Sense Technology) on page 4.111*)	Indication	130
LT01–LT32	Latch bits 01–32, asserted (see *Latch Bits on page 7.9*)	Control—replacing traditional latching relays	44–47
NDEM	Neutral demand current element (available when EGNDSW := N) (see *Figure 8.4*)	Indication	74
NTUNE_A, NTUNE_B, NTUNE_C	A-, B-, C- Phase Normal Tuning (see *High-Impedance Fault Detection (Arc Sense Technology) on page 4.111*)	Control	129
OC3	Asserts for one processing interval for **OPEN** command execution (see *Figure 5.2*)	Testing, Control	42
OCA	Asserts for one processing interval for **OPEN A** command execution	Testing, Control	42
OCB	Asserts for one processing interval for **OPEN B** command execution	Testing, Control	42
OCC	Asserts for one processing interval for **OPEN C** command execution	Testing, Control	42
OPTMN3P	Reclosing relay open interval timer is timing (available when setting ESPB := N) (see *Figure 6.1*)	Testing	69
OPTMNA, OPTMNB, OPTMNC	A-, B-, or C-phase reclosing relay open interval timer is timing (available when setting ESPB := Y) (see *Figure 6.1*)	Testing	69
OREDHIF2	Asserts if high-impedance fault detected on A-, B-, or C-phase (see *High-Impedance Fault Detection (Arc Sense Technology) on page 4.111*)	Testing, Control	127
OUT101–OUT108	Output contacts OUT101–OUT108, asserted (optional outputs) (see *Output Contacts on page 7.34*)	Indication (only operable if optional I/O installed)	75
OUT201–OUT202	Output contact OUT201 or OUT202, asserted (see *Output Contacts on page 7.34*)	Indication	76
P5ASEL	Asserted when port 5A is active (see *Section 10: Communications*) (only on relays with dual Ethernet connectors)	Indication, Testing	99
P5BSEL	Asserted when port 5B is active (see *Section 10: Communications*) (only on relays with dual Ethernet connectors)	Indication, Testing	99
PASNVAL	Pulses for approximately one second when an incorrect password is entered when attempting to enter Access Level B or higher, or when changing passwords (see *Port Access Levels on page 10.21*)	Indication	107
PB01_LED–PB12_LED	Operator control pushbutton LEDs 01–12. Driven by associated SELOGIC front-panel settings PB01_LED-PB12_LED (see *Operator Controls on page 11.22*).	Indication	36, 37
PB01_PUL–PB12_PUL	Operator control pushbutton 01–12, momentarily pulsed (one processing interval assertion when button is first pressed) (see *Operator Controls on page 11.22*).	Indication	91, 93

Table F.2   Alphabetic List of Relay Word Bits (Sheet 10 of 14)

Name	Definition	Usage	Relay Word Bit Row[a]
PB01–PB12	Operator control pushbuttons 01–12 (asserted when button is being pressed) (see *Operator Controls on page 11.22*)	Indication	90, 92
PDEM	Maximum-phase demand current element (see *Figure 8.4*)	Indication	74
PHASE_A, PHASE_B, PHASE_C	A-, B-, or C-phase target logic output (see *Table 5.3*)	Indication	20
PMDOK	Phasor measurement data OK (see *Synchrophasor Relay Word Bits on page J.16*)	Synchrophasors	105
PMTRIG	Phasor Measurement Unit SELOGIC control equation trigger (see *Appendix J: Synchrophasors*). Sent with C37.118 synchrophasor message.	Indication, Synchrophasors	105
PWR_SRC1	Recloser control power supply is operating from external power source (e.g., 120 Vac) (see *Factory-Default 79CLS Settings Example on page 6.14*)	Indication	38
QDEM	Negative-sequence demand current element (see *Figure 8.4*)	Indication	74
R32P	Reverse positive-sequence voltage-polarized directional element (see *Figure 4.60*)	Testing, Special directional control schemes	72
R32Q	Reverse negative-sequence voltage-polarized directional element (see *Figure 4.59*)	Testing, Special directional control schemes	71
R32QG	Reverse negative-sequence voltage-polarized directional element (for ground) (see *Figure 4.55*)	Testing, Special directional control schemes	71
R32V	Reverse zero-sequence voltage-polarized directional element (see *Figure 4.56*)	Testing, Special directional control schemes	72
RB01–RB32	Remote bits 01–32, asserted (see *Remote Bits on page 7.22*)	Control via serial port	94–97
RBADA, RBADB	MIRRORED BITS outage duration over threshold, Channels A and B (see *Table 12.4* and *Appendix D: MIRRORED BITS Communications*)	Indication	84
RCCL1X	Pole 1 recloser close output asserted (see *Figure 7.26*)	Closing	76
RCCL2X	Pole 2 recloser close output asserted (only available for single-phase reclosers) (see *Figure 7.26*)	Closing	76
RCCL3X	Pole 3 recloser close output asserted (only available for single-phase reclosers) (see *Figure 7.26*)	Closing	76
RCSF3P	Reclose supervision failure, asserts for one processing interval (available when setting ESPB := N) (see *Figure 6.1*)	Indication	69
RCSFA, RCSFB, RCSFC	A-, B-, or C-phase reclose supervision failure, asserts for one processing interval (available when setting ESPB := Y) (see *Figure 6.1*)	Indication	69
RCTR1X	Pole 1 recloser trip output asserted (see *Figure 7.26*)	Tripping	76
RCTR2X	Pole 2 recloser trip output asserted (only available for single-phase reclosers) (see *Figure 7.26*)	Tripping	76
RCTR3X	Pole 3 recloser trip output asserted (only available for single-phase reclosers) (see *Figure 7.26*)	Tripping	76
RMB1A–RMB8A	Received MIRRORED BITS 1–8, channel A (see *Appendix D: MIRRORED BITS Communications*)	Control	80
RMB1B–RMB8B	Received MIRRORED BITS 1–8, channel B (see *Appendix D: MIRRORED BITS Communications*)	Control	82
ROKA, ROKB	MIRRORED BITS received data OK, Channels A and B (see *Appendix D: MIRRORED BITS Communications*)	Indication	84

Table F.2   Alphabetic List of Relay Word Bits (Sheet 11 of 14)

Name	Definition	Usage	Relay Word Bit Row[a]
RST_BK	Reset Breaker Monitor SELOGIC control equation (see *Section 8: Metering and Monitoring*). The relay resets the breaker monitor accumulators when a rising edge is detected on RST_BK.	Indication, Control	98
RST_DEM	Reset Demand Metering SELOGIC control equation (see *Section 8: Metering and Monitoring*). The relay resets the demand metering registers when a rising edge is detected on RST_DEM.	Indication, Control	98
RST_ENE	Reset Energy Metering SELOGIC control equation (see *Section 8: Metering and Monitoring*). The relay resets the energy metering registers when a rising edge is detected on RST_ENE.	Indication, Control	98
RST_HAL	Reset for HALARMA (see *Self-Tests on page 13.7*)	Indication, Control	98
RST_HIS	Reset Event History SELOGIC control equation (see *Section 8: Metering and Monitoring*). The relay clears the event history archive when a rising edge is detected on RST_HIS.	Indication, Control	98
RST_MML	Reset Max/Min Metering SELOGIC control equation (see *Section 8: Metering and Monitoring*). The relay resets the max/min metering registers when a rising edge is detected on RST_MML.	Indication, Control	98
RST_PDM	Reset Peak Demand Metering SELOGIC control equation (see *Section 8: Metering and Monitoring*). The relay resets the peak demand metering registers when a rising edge is detected on RST_PDM.	Indication, Control	98
RSTDNPE	Reset DNP event registers/buffers (see *Reading Relay Events on page E.39*)	Indication, Control	135
RSTMN3P	Reclosing relay reset timer is timing (available when setting ESPB := N) (see *Figure 6.1*)	Testing	70
RSTMNA, RSTMNB, RSTMNC	A-, B-, or C-phase reclosing relay reset timer is timing (available when setting ESPB := Y) (see *Figure 6.1*)	Testing	70
RSTTRGT	Reset Target SELOGIC control equation (see *Programmable Front-Panel Target LEDs on page 5.15*). The relay resets the latching-type front-panel target LEDs when a rising edge is detected on RSTTRGT. This will also reset DNP event data when in single-event mode (see *Reading Relay Events on page E.39* for details).	Indication, Control	98
SAG3P	Three-phase voltage sag element = SAGA AND SAGB AND SAGC (see *Voltage Sag Elements on page 4.60*)	Sag/Swell/Int reporting	85
SAGA, SAGB, SAGC	A-, B-, or C-phase voltage sag elements (see *Voltage Sag Elements on page 4.60*)	Sag/Swell/Int reporting	85
SALARM	Software Alarm (momentary assertion during group, active settings, password and access level changes) (see *Global Enable Settings on page SET.2*)	Indication	106
SC01QD–SC16QD	SELOGIC Counters 01–16, asserted when counter = 0 (see *Figure 7.15*)	Indication	61, 63
SC01QU–SC16QU	SELOGIC Counters 01–16, asserted when counter = Preset value (see *Figure 7.15*)	Indication	60, 62
SETCHG	Pulses for approximately one second whenever settings are changed (see SALARM in *Global Enable Settings on page SET.2*)	Indication	107
SF	Synchronism-check element, slip frequency less than setting 25SF (see *Figure 4.30*)	Testing	30
SFAST	Synchronism-check element, VP frequency greater than VS frequency (fP > fS) (see *Figure 4.30*)	Special control schemes	30
SG1–SG8	Setting group indication, group 1–8, asserted for active group (see *Active Settings Group Indication on page 7.23*)	Indication	78

Table F.2 Alphabetic List of Relay Word Bits (Sheet 12 of 14)

Name	Definition	Usage	Relay Word Bit Row[a]
SH03P	Reclosing relay shot counter = 0 (available when setting ESPB := N) (see *Figure 6.1*)	Control	64
SH0A, SH0B, SH0C	A-, B-, or C-phase reclosing relay shot counter = 0 (available when setting ESPB := Y) (see *Figure 6.1*)	Control	65–67
SH13P	Reclosing relay shot counter = 1 (available when setting ESPB := N) (see *Figure 6.1*)	Control	64
SH1A, SH1B, SH1C	A-, B-, or C-phase reclosing relay shot counter = 1 (available when setting ESPB := Y) (see *Figure 6.1*)	Control	65–67
SH23P	Reclosing relay shot counter = 2 (available when setting ESPB := N) (see *Figure 6.1*)	Control	64
SH2A, SH2B, SH2C	A-, B-, or C-phase reclosing relay shot counter = 2 (available when setting ESPB := Y) (see *Figure 6.1*)	Control	65-67
SH33P	Reclosing relay shot counter = 3 (available when setting ESPB := N) (see *Figure 6.1*)	Control	64
SH3A, SH3B, SH3C	A-, B-, or C-phase reclosing relay shot counter = 3 (available when setting ESPB := Y) (see *Figure 6.1*)	Control	65–67
SH43P	Reclosing relay shot counter = 4 (available when setting ESPB := N) (see *Figure 6.1*)	Control	64
SH4A, SH4B, SH4C	A-, B-, or C-phase reclosing relay shot counter = 4 (available when setting ESPB := Y) (see *Figure 6.1*)	Control	65–67
SOTFE	Switch-onto-fault enable logic output (see *SELOGIC Control Equation Functions on page 7.7*)	Testing	43
SOTFT	Switch-onto-fault trip (see *Figure 5.1*)	Testing, Indication	43
SPE	Single-phase mode enabled (asserted when setting ESPB := Y) (see *Overcurrent Element Torque-Control Setting Application on page 5.10*)	Indication	19
SPO	Single-pole/phase open condition (see *Figure 5.5*)	Indication	18
SPOA, SPOB, SPOC	Phase A, B, or C single-pole/phase open conditions (see *Figure 5.5*)	Indication	18
SSLOW	Synchronism-check element, VP frequency less than VS frequency (fP < fS) (see *Figure 4.30*)	Special control schemes	30
SV01–SV64	SELOGIC variables 01–64. Associated timers (below) are picked up when variable is asserted (see *SELOGIC Control Equation Functions on page 7.7*)	Testing, Seal-in functions, etc.	48–59, 100–103
SV01T–SV64T	SELOGIC timers 01–64, timed out when asserted (see *SELOGIC Control Equation Functions on page 7.7*)	Testing, Seal-in functions, etc.	48–59, 100–103
SW1	Recloser status "Switch 1" derived from inputs (only available for traditional retrofit reclosers, otherwise, it evaluates to logical 0) (see *Factory 52A Settings Example (Traditional Retrofit Recloser) on page 6.4*).	Indication	19
SW3P	Three-phase voltage swell element = SWA AND SWB AND SWC (see *Voltage Swell Elements on page 4.60*)	Sag/Swell/Int reporting	85
SWA, SWB, SWC	A-, B-, or C-phase voltage swell elements (see *Voltage Swell Elements on page 4.60*)	Sag/Swell/Int reporting	85
TCCAP	Recloser interface trip and close capacitor fully charged (see *Factory-Default 79CLS Settings Example on page 6.14*)	Indication, Control	39
TESTDB	Test DataBase command active. Asserts when analog and digital values reported via DNP, Modbus, IEC 61850, or Fast Meter protocol may be overridden (see *Section 10: Communications*).	Testing	87

Table F.2   Alphabetic List of Relay Word Bits (Sheet 13 of 14)

Name	Definition	Usage	Relay Word Bit Row[a]
TIRIG	Relay Time is based on IRIG-B time source (see *Synchrophasor Relay Word Bits on page J.16*)	Synchrophasors	105
TLED_01–TLED_24	Target LEDs 01–24. Asserted when LED illuminated (see *Front-Panel Target LEDs on page 5.13*)	Indication	1–3
TMB1A–TMB8A	Transmit MIRRORED BITS 1–8, channel A (see *Appendix D: MIRRORED BITS Communications*)	Control	81
TMB1B–TMB8B	Transmit MIRRORED BITS 1–8, channel B (see *Appendix D: MIRRORED BITS Communications*)	Control	83
TOSLP	To Sleep. Asserts for last minute of control operation on battery power (see *SEL-651R-2 Puts Itself to Sleep on page 8.40*)	Indication	38
TQUAL1–TQUAL4	Encoded IRIG time quality bits 1–4. Only available when Global setting IRIGC = C37.118 and a proper IRIG signal is decoded.	Indication	104
TREA1–TREA4	Trigger Reason bits 1–4 (follow SELOGIC control equations of same name (see *Appendix J: Synchrophasors*). Sent with C37.118 synchrophasor message.	Indication, Synchrophasors	105
TRGTR	Target Reset, button or command, asserts for one processing interval (see *Programmable Front-Panel Target LEDs on page 5.15*)	Control	43
TRIP3P	Trip logic output asserted (available when setting ESPB := N) (see *Figure 5.1*)	Indication	43
TRIPA, TRIPB, TRIPC	Phase A, B, or C trip logic output asserted (available when setting ESPB := Y) (see *Figure 5.1*)	Indication	43
TRIPLED	Trip target LED. Asserted when TRIP LED illuminated. (see *Front-Panel Target LEDs ENABLED and TRIP on page 5.15*)	Indication	0
TSNTPB	Asserts when relay time is based on Simple Network Time Protocol (SNTP) backup server (see *Simple Network Time Protocol (SNTP) on page 10.15*).	Indication	99
TSNTPP	Asserts when relay time is based on Simple Network Time Protocol (SNTP) primary server (see *Simple Network Time Protocol (SNTP) on page 10.15*).	Indication	99
TSOK	Time synchronization OK (see *Synchrophasor Relay Word Bits on page J.16*)	Synchrophasors	105
ULCL3P	Unlatch close condition. Driven by associated SELOGIC Group setting ULCL3P (see *Close Logic on page 6.5*)	Control	70
ULCLA, ULCLB, ULCLC	Phase A, B, or C unlatch close condition. Driven by associated SELOGIC Group settings ULCLA, ULCLB, or ULCLC (see *Close Logic on page 6.5*).	Control	70
V1GOOD	Positive-sequence voltage greater than setting VNOM • 0.85 (see *Loss-of-Potential Logic on page 4.77*)	Indication	19
VB001–VB128	Virtual bits 001–128. Virtual bit configuration is controlled by loaded CID file (IEC 61850 relay models only). Virtual bits can be configured to follow received GOOSE messages (see *Appendix L: IEC 61850*).	Control	108–123
VPOLV	Positive-sequence polarization voltage valid (see *Directional Elements on page 4.86*)	Testing	19
VSELY	VY voltage inputs selected (asserts when setting VSELECT := VY) (see *Figure 9.22*)	Indication	25
VSELZ	VZ voltage inputs selected (asserts when setting VSELECT := VZ) (see *Figure 9.22*)	Indication	29
XS_CLOS1, XS_CLOS2, XS_CLOS3	Pole 1, 2, or 3: excessive close operations detected (available for single-phase reclosers only)	Indication	39

Relay Word Bits F.19
Analog Scaling and Frequency Indicators
Wolfe

Table F.2 **Alphabetic List of Relay Word Bits** (Sheet 14 of 14)

Name	Definition	Usage	Relay Word Bit Row[a]
XS_TRIP1, XS_TRIP2, XS_TRIP3	Pole 1, 2, or 3: excessive trip operations detected (available for single-phase reclosers only)	Indication	39
ZLIN	Load encroachment "load in" element (see *Figure 4.48*)	Special phase overcurrent element control	21
ZLOAD	Load encroachment element = ZLIN OR ZLOUT (see *Figure 4.48*)	Special phase overcurrent element control	21
ZLOUT	Load encroachment "load out" element (see *Figure 4.48*)	Special phase overcurrent element control	21

[a] See Table F.1 for a list of the Relay Word bits by row number.

[b] Time-overcurrent (51) elements have two sets of settings called J and K, each of which includes pickup, curve, time dial, electromechanical reset, constant time adder, and minimum response time. Only one set can be operative for each 51 element. The 51_S Relay Word bit indicates which of these sets is operative for each element. It is deasserted when J settings are in use and asserted when K settings are in use. The relay uses the same output Relay Word bits (51_, 51_R, 51_T), regardless of the J/K selection.

Analog Scaling and Frequency Indicators

The SEL-651R-2 uses the Relay Word bits listed in *Table F.3* for internal operations, such as event report preparation and phasor measurement. the operating criteria for these elements are not exact, so they should not be included in commissioning tests.

Table F.3 **Analog Scaling and Frequency Indicators**

Relay Word Bit	Description	Asserts When:
INMET	Channel IN high-gain mode active	Channel IN current signal is less than the nominal current rating (0.2 A secondary)
ICMET	Channel IC high-gain mode active	Channel IC current signal is less than the nominal current rating (1 A secondary)
IBMET	Channel IB high-gain mode active	Channel IB current signal is less than the nominal current rating (1 A secondary)
IAMET	Channel IA high-gain mode active	Channel IA current signal is less than the nominal current rating (1 A secondary)
FREQOK	System frequency and tracking frequency valid	System frequency measurement source is healthy (see *Frequency Source Selection Setting (FSELECT) on page 9.33*), the frequency is between 40 Hz and 65 Hz, and the rate-of-change of frequency is less than 20 Hz/s.

This page intentionally left blank

Appendix G

Analog Quantities

The SEL-651R-2 Recloser Control contains several analog quantities that can be used for more than one function.

Analog quantities are typically generated and used by a primary function, such as metering, and selected quantities are made available for one or more supplemental functions, such as the load profile recorder.

SEL-651R-2 analog quantities are generated by the following:

> ➤ Metering functions (see *Section 8: Metering and Monitoring*)

> ➤ Recloser/breaker monitor (see *Section 8: Metering and Monitoring*)

> ➤ Self-Test diagnostics (see *Section 13: Testing and Troubleshooting*)

> ➤ DNP Communications Statistics (see *Appendix E: DNP3 Communications*)

> ➤ Relay settings (see *Section 9: Settings*)

> ➤ System date and time (see *Section 10: Communications*)

> ➤ SELOGIC counters (see *Section 7: SELOGIC Control Equation Programming*)

> ➤ Reclosing relay logic (see *Section 6: Close and Reclose Logic*)

Table G.1 provides a complete list of analog quantities that can be used in the following interfaces (when marked with an "x"):

> ➤ Display points (see *Rotating Display on page 11.13*)

> ➤ Load profile recorder (see *Load Profile Report on page 8.44*)

> ➤ DNP3 (see *Appendix E: DNP3 Communications*)

> ➤ Modbus (see *Appendix K: Modbus RTU and TCP Communications*)

> ➤ SEL Fast Meter protocol (see *Appendix I: Configuration, Fast Meter, and Fast Operate Commands*)

> ➤ IEC 61850 protocol (see *Appendix L: IEC 61850*)

See *Table 7.2* for a list of analog quantities that can be used in analog comparisons in SELOGIC control equations.

Table G.1 Analog Quantities (Sheet 1 of 11)

Label	Description	Units	Display Points	Load Profile	DNP3	Modbus	Fast Meter	IEC 61850
Fundamental Metering								
IA, IB, IC	Phase (A, B, C) current magnitudes	A pri	x	x	x	x	x	x
IAFA, IBFA, ICFA	Phase (A, B, C) current angles	degrees			x	x	x	x
IN	Neutral (channel IN) current magnitude	A pri	x	x	x	x	x	x
INFA	Neutral (channel IN) current angle	degrees			x	x	x	x
IG	Ground current magnitude[a]	A pri	x	x	x	x		x
IGFA	Ground current angle[a]	degrees			x	x		x
3I0, I1, 3I2	Sequence current magnitudes	A pri	x	x	x	x		x
3I0FA, I1FA, 3I2FA	Sequence current angles	degrees			x	x		x
VAY, VBY, VCY, VAZ, VBZ, VCZ	Phase (A, B, C) voltage magnitudes for Y- and Z-terminals	kV pri	x	x	x			x
VAY, VBY, VCY, VAZ, VBZ, VCZ	Phase (A, B, C) voltage magnitudes for Y- and Z-terminals	V pri				x	x	
VAYFA, VBYFA, VCYFA, VAZFA, VBZFA, VCZFA	Phase (A, B, C) voltage angles for Y- and Z-terminals	degrees			x	x	x	x
VABY, VBCY, VCAY, VABZ, VBCZ, VCAZ	Phase-to-phase (AB, BC, CA) voltage magnitudes for Y- and Z-terminals	kV pri	x	x	x			x
VABY, VBCY, VCAY, VABZ, VBCZ, VCAZ	Phase-to-phase (AB, BC, CA) voltage magnitudes for Y- and Z-terminals	V pri				x		
VABYFA, VBCYFA, VCAYFA, VABZFA, VBCZFA, VCAZFA	Phase-to-phase (AB, BC, CA) voltage angles for Y- and Z-terminals	degrees			x	x		x
V1Y, V2Y, 3V0Y, V1Z, V2Z, 3V0Z	Positive-, negative-, and zero-sequence voltage magnitudes for Y- and Z-terminals	kV pri	x	x	x			x
V1Y, V2Y, 3V0Y, V1Z, V2Z, 3V0Z	Positive-, negative-, and zero-sequence voltage magnitudes for Y- and Z-terminals	V pri				x		
V1YFA, V2YFA, 3V0YFA, V1ZFA, V2ZFA, 3V0ZFA	Positive-, negative-, and zero-sequence voltage angles for Y- and Z- terminals	degrees			x	x		x
MVAA, MVAB, MVAC	Phase (A, B, C) apparent power	MVA	x	x	x			
KVAA, KVAB, KVAC	Phase (A, B, C) apparent power	kVA				x		x
MVA3	Three-phase apparent power	MVA	x	x	x			
KVA3	Three-phase apparent power	kVA				x		x
MWA, MWB, MWC	Phase (A, B, C) real power	MW	x	x	x			
KWA, KWB, KWC	Phase (A, B, C) real power	kW				x		x
MW3	Three-phase real power	MW	x	x	x			
KW3	Three-phase real power	kW				x		x
MVARA, MVARB, MVARC	Phase (A, B, C) reactive power	MVAR	x	x	x			
KVARA, KVARB, KVARC	Phase (A, B, C) reactive power	kVAR				x		x
MVAR3	Three-phase reactive power	MVAR	x	x	x			
KVAR3	Three-phase reactive power	kVAR				x		x

Table G.1   Analog Quantities (Sheet 2 of 11)

Label	Description	Units	Display Points	Load Profile	DNP3	Modbus	Fast Meter	IEC 61850
PFA, PFB, PFC	Phase (A, B, C) power factor	per unit	x[b]	x	x	x		x
PF3	Three-phase power factor	per unit	x[b]	x	x	x		x
LDPFA, LDPFB, LDPFC	Phase (A, B, C) power factor leading	0 or 1	x	x	x	x		
LDPF3	Three-phase power factor leading	0 or 1	x	x	x	x		
FREQ	Frequency	Hz	x	x	x	x	x	x
Demand Metering								
IADEM, IBDEM, ICDEM	Phase (A, B, C) current magnitudes	A pri	x	x	x	x	x	x
INDEM	Neutral (channel IN) current magnitude	A pri	x	x	x	x	x	x
IGDEM	Ground current magnitude[a]	A pri	x	x	x	x	x	x
3I2DEM	Negative-sequence current magnitude	A pri	x	x	x	x	x	x
MVAAD, MVABD, MVACD	Phase (A, B, C) apparent power	MVA	x	x	x			
KVAAD, KVABD, KVACD	Phase (A, B, C) apparent power	kVA				x		
MVA3D	Three-phase apparent power	MVA	x	x	x			
KVA3D	Three-phase apparent power	kVA				x		
MWADI, MWBDI, MWCDI	Phase (A, B, C) real power in	MW	x	x	x		x	
KWADI, KWBDI, KWCDI	Phase (A, B, C) real power in	kW				x		
MW3DI	Three-phase real power in	MW	x	x	x		x	
KW3DI	Three-phase real power in	kW				x		
MWADO, MWBDO, MWCDO	Phase (A, B, C) real power out	MW	x	x	x		x	
KWADO, KWBDO, KWCDO	Phase (A, B, C) real power out	kW				x		
MW3DO	Three-phase real power out	MW	x	x	x		x	
KW3DO	Three-phase real power out	kW				x		
MVRADI, MVRBDI, MVRCDI	Phase (A, B, C) reactive power in	MVAR	x	x	x		x	
KVRADI, KVRBDI, KVRCDI	Phase (A, B, C) reactive power in	kVAR				x		
MVR3DI	Three-phase reactive power in	MVAR	x	x	x		x	
KVR3DI	Three-phase reactive power in	kVAR				x		
MVRADO, MVRBDO, MVRCDO	Phase (A, B, C) reactive power out	MVAR	x	x	x		x	
KVRADO, KVRBDO, KVRCDO	Phase (A, B, C) reactive power out	kVAR				x		
MVR3DO	Three-phase reactive power out	MVAR	x	x	x		x	
KVR3DO	Three-phase reactive power out	kVAR				x		

Table G.1 Analog Quantities (Sheet 3 of 11)

Label	Description	Units	Display Points	Load Profile	DNP3	Modbus	Fast Meter	IEC 61850
Peak (Demand) Metering								
IAPK, IBPK, ICPK	Phase (A, B, C) current magnitudes	A pri	x		x	x	x	x
INPK	Neutral (channel IN) current magnitude	A pri	x		x	x	x	x
IGPK	Ground current magnitude[a]	A pri	x		x	x	x	x
3I2PK	Negative-sequence current magnitude	A pri	x		x	x	x	x
MVAAP, MVABP, MVACP	Phase (A, B, C) apparent power	MVA	x		x			
KVAAP, KVABP, KVACP	Phase (A, B, C) apparent power	kVA				x		
MVA3P	Three-phase apparent power	MVA	x		x			
KVA3P	Three-phase apparent power	kVA				x		
MWAPI, MWBPI, MWCPI	Phase (A, B, C) real power in	MW	x		x		x	
KWAPI, KWBPI, KWCPI	Phase (A, B, C) real power in	kW				x		
MW3PI	Three-phase real power in	MW	x		x		x	
KW3PI	Three-phase real power in	kW				x		
MWAPO, MWBPO, MWCPO	Phase (A, B, C) real power out	MW	x		x		x	
KWAPO, KWBPO, KWCPO	Phase (A, B, C) real power out	kW				x		
MW3PO	Three-phase real power out	MW	x		x		x	
KW3PO	Three-phase real power out	kW				x		
MVRAPI, MVRBPI MVRCPI	Phase (A, B, C) reactive power in	MVAR	x		x		x	
KVRAPI, KVRBPI, KVRCPI	Phase (A, B, C) reactive power in	kVAR				x		
MVR3PI	Three-phase reactive power in	MVAR	x		x		x	
KVR3PI	Three-phase reactive power in	kVAR				x		
MVRAPO, MVRBPO, MVRCPO	Phase (A, B, C) reactive power out	MVAR	x		x		x	
KVRAPO, KVRBPO, KVRCPO	Phase (A, B, C) reactive power out	kVAR				x		
MVR3PO	Three-phase reactive power out	MVAR	x		x		x	
KVR3PO	Three-phase reactive power out	kVAR				x		
Energy Metering								
MWHAI, MWHBI, MWHCI	Phase (A, B, C) real energy in	MWh	x	x	x	x		
MWH3I	Three-phase real energy in	MWh	x	x	x	x		x
MWHAO, MWHBO, MWHCO	Phase (A, B, C) real energy out	MWh	x	x	x	x		
MWH3O	Three-phase real energy out	MWh	x	x	x	x		x

Table G.1   Analog Quantities (Sheet 4 of 11)

Label	Description	Units	Display Points	Load Profile	DNP3	Modbus	Fast Meter	IEC 61850
MVRHAI, MVRHBI, MVRHCI	Phase (A, B, C) reactive energy in	MVARh	x	x	x	x		
MVRH3I	Three-phase reactive energy in	MVARh	x	x	x	x		x
MVRHAO, MVRHBO, MVRHCO	Phase (A, B, C) reactive energy out	MVARh	x	x	x	x		
MVRH3O	Three-phase reactive energy out	MVARh	x	x	x	x		x
Max/Min Metering								
IAMAX, IBMAX, ICMAX	Maximum phase (A, B, C) current magnitude	A pri			x	x		x
IAMXD_[x][c], IBMXD_[x][c], ICMXD_[x][c]	Maximum phase (A, B, C) current magnitudes date	date				x		
IAMXT_[z][d], IBMXT_[z][d], ICMXT_[z][d]	Maximum phase (A, B, C) current magnitudes time	time				x		
INMAX	Maximum neutral (channel IN) current magnitude	A pri			x	x		x
INMXD_[x][c]	Maximum neutral (channel IN) current magnitude date	date				x		
INMXT_[z][d]	Maximum neutral (channel IN) current magnitude time	time				x		
IGMAX	Maximum ground current magnitude[a]	A pri			x	x		x
IGMXD_[x][c]	Maximum ground current magnitude date[a]	date				x		
IGMXT_[z][d]	Maximum ground current magnitude time[a]	time				x		
IAMIN, IBMIN, ICMIN	Minimum phase (A, B, C) current magnitude	A pri			x	x		x
IAMND_[x][c], IBMND_[x][c], ICMND_[x][c]	Minimum phase (A, B, C) current magnitude date	date				x		
IAMNT_[z][d], IBMNT_[z][d], ICMNT_[z][d]	Minimum phase (A, B, C) current magnitude time	time				x		
INMIN	Minimum neutral (channel IN) current magnitude	A pri			x	x		x
INMND_[x][c]	Minimum neutral (channel IN) current magnitude date	date				x		
INMNT_[z][d]	Minimum neutral (channel IN) current magnitude time	time				x		
IGMIN	Minimum ground current magnitude[a]	A pri			x	x		x
IGMND_[x][c]	Minimum ground current magnitude date[a]	date				x		
IGMNT_[z][d]	Minimum ground current magnitude time[a]	time				x		

Table G.1 Analog Quantities (Sheet 5 of 11)

Label	Description	Units	Display Points	Load Profile	DNP3	Modbus	Fast Meter	IEC 61850
VAYMAX, VBYMAX, VCYMAX, VAZMAX, VBZMAX, VCZMAX	Maximum phase (A, B, C) voltage magnitudes for Y- and Z-terminals	kV pri			x			x
VAYMAX, VBYMAX, VCYMAX, VAZMAX, VBZMAX, VCZMAX	Maximum phase (A, B, C) voltage magnitudes for Y- and Z-terminals	V pri				x		
VAYMXD_[x][c], VBYMXD_[x][c], VCYMXD_[x][c], VAZMXD_[x][c], VBZMXD_[x][c], VCZMXD_[x][c]	Maximum phase (A, B, C) voltage magnitudes for Y- and Z-terminals date	date				x		
VAYMXT_[z][d], VBYMXT_[z][d], VCYMXT_[z][d], VAZMXT_[z][d], VBZMXT_[z][d], VCZMXT_[z][d]	Maximum phase (A, B, C) voltage magnitudes for Y- and Z-terminals time	time				x		
VAYMIN, VBYMIN, VCYMIN, VAZMIN, VBZMIN, VCZMIN	Minimum phase (A, B, C) voltage magnitudes for Y- and Z-terminals	kV pri			x			x
VAYMIN, VBYMIN, VCYMIN, VAZMIN, VBZMIN, VCZMIN	Minimum phase (A, B, C) voltage magnitudes for Y- and Z-terminals	V pri				x		
VAYMND_[x][c], VBYMND_[x][c], VCYMND_[x][c], VAZMND_[x][c], VBZMND_[x][c], VCZMND_[x][c]	Minimum phase (A, B, C) voltage magnitudes for Y- and Z-terminals date	date				x		
VAYMNT_[z][d], VBYMNT_[z][d], VCYMNT_[z][d], VAZMNT_[z][d], VBZMNT_[z][d], VCZMNT_[z][d]	Minimum phase (A, B, C) voltage magnitudes for Y- and Z-terminals time	time				x		
MVA3MAX	Maximum three-phase apparent power	MVA			x			x
KVA3MAX	Maximum three-phase apparent power	kVA				x		
KVA3XD_[x][c]	Maximum three-phase apparent power date	date				x		
KVA3XT_[z][d]	Maximum three-phase apparent power time	time				x		
MW3MAX	Maximum three-phase real power	MW			x			x
KW3MAX	Maximum three-phase real power	kW				x		
KW3MND_[x][c]	Maximum three-phase real power date	date				x		
KW3MNT_[z][d]	Maximum three-phase real power time	time				x		
MVR3MAX	Maximum three-phase reactive power	MVAR			x			x
KVR3MAX	Maximum three-phase reactive power	kVAR				x		
KVR3XD_[x][c]	Maximum three-phase reactive power date	date				x		
KVR3XT_[z][d]	Maximum three-phase reactive power time	time				x		

Table G.1 Analog Quantities (Sheet 6 of 11)

Label	Description	Units	Display Points	Load Profile	DNP3	Modbus	Fast Meter	IEC 61850
MVA3MIN	Minimum three-phase apparent power	MVA			x			x
KVA3MIN	Minimum three-phase apparent power	kVA				x		
KVA3ND_[x][c]	Minimum three-phase apparent power date	date				x		
KVA3NT_[z][d]	Minimum three-phase apparent power time	time				x		
MW3MIN	Minimum three-phase real power	MW			x			x
KW3MIN	Minimum three-phase real power	kW				x		
KW3MXD_[x][c]	Minimum three-phase real power date	date				x		
KW3MXT_[z][d]	Minimum three-phase real power time	time				x		
MVR3MIN	Minimum three-phase reactive power	MVAR			x			x
KVR3MIN	Minimum three-phase reactive power	kVAR				x		
KVR3ND_[x][c]	Minimum three-phase reactive power date	date				x		
KVR3NT_[z][d]	Minimum three-phase reactive power time	time				x		
RMS Metering								
IAR, IBR, ICR	Phase (A, B, C) rms current	A pri	x	x	x	x		
INR	Neutral (channel IN) rms current	A pri	x	x	x	x		
VAYR, VBYR, VCYR, VAZR, VBZR, VCZR	Phase (A, B, C) rms voltage for Y- and Z-terminals	kV pri	x	x	x			
VAYR, VBYR, VCYR, VAZR, VBZR, VCZR	Phase (A, B, C) rms voltage for Y- and Z-terminals	V pri				x		
MWAR, MWBR, MWCR	Phase (A, B, C) average real power	MW	x	x	x			x
KWAR, KWBR, KWCR	Phase (A, B, C) average real power	kW				x		
MW3R	Three-phase average real power	MW	x	x	x			x
KW3R	Three-phase average real power	kW				x		
Harmonics Metering								
IAHT, IBHT, ICHT	Phase (A, B, C) current THD	%	x	x	x	x		
INHT	Neutral (channel IN) current THD	%	x	x	x	x		
IAH01, IBH01, ICH01[e]	Phase (A, B, C) current Fundamental Magnitude (harmonic metering)	A pri			x	x		
INH01[e]	Neutral (channel IN) current Fundamental Magnitude (harmonic metering)	A pri			x	x		
IAH*nn*, IBH*nn*, ICH*nn*	Phase (A, B, C) current Harmonic *nn* (*nn* = 02–16)	%			x	x		
INH*nn*	Neutral (channel IN) current Harmonic *nn* (*nn* = 02–16)	%			x	x		
VAYHT, VBYHT, VCYHT, VAZHT, VBZHT, VCZHT	Phase (A, B, C) voltage THD for Y- and Z-terminals	%	x	x	x	x		

Table G.1   Analog Quantities (Sheet 7 of 11)

Label	Description	Units	Display Points	Load Profile	DNP3	Modbus	Fast Meter	IEC 61850
VAYH01, VBYH01, VCYH01, VAZH01, VBZH01, VCZH01[e]	Phase (A, B, C) voltage Fundamental magnitudes for Y- and Z-terminals (harmonic metering)	kV			x			
VAYH01, VBYH01, VCYH01, VAZH01, VBZH01, VCZH01[e]	Phase (A, B, C) voltage Fundamental magnitudes for Y- and Z-terminals (harmonic metering)	V				x		
VAYH*nn*, VBYH*nn*, VCYH*nn*, VAZH*nn*, VBZH*nn*, VCZH*nn*	Phase (A, B, C) voltage Harmonics *nn* (*nn* = 02–16) for Y- and Z-terminals	%			x	x		
Breaker Monitor								
BRKDAT	Last Reset date and time	date/time	x					
INTTA, INTTB, INTTC	Phase (A, B, C) Internal Trip Counter	count	x		x[f]	x		
INTIA, INTIB, INTIC	Phase (A, B, C) Internal Trip Accumulated current	kA pri	x		x	x		
EXTTA, EXTTB, EXTTC	Phase (A, B, C) External Trip Counter	count	x		x[f]	x		
EXTIA, EXTIB, EXTIC	Phase (A, B, C) External Trip Accumulated current	kA pri	x		x	x		
OPSCTRA, OPSCTRB, OPSCTRC	Phase (A, B, C) Total Internal and External Trip Counter	count	x	x	x[f]	x		x
APHTR, BPHTR, CPHTR	Phase (A, B, C) Involvement Counter	count	x		x[f]	x		
GNDCTR	Ground Involvement Counter	count	x		x[f]	x		
WEARA, WEARB, WEARC	Phase (A, B, C) Breaker Wear Percentage	%	x	x	x	x		x
MAXWEAR	Greatest wear of WEARA, WEARB, or WEARC	%	x	x	x	x		x
BKTYP	Breaker Type, according to Global setting BKTYP		x		x	x		
Event History								
NUMEVE	Event History Number	count				x		
EVESEL	Selected History Number	count				x		
FDATE_Y	Fault date—Year portion	year				x		
FDATE_M	Fault date—Month portion	month				x		
FDATE_D	Fault date—Day portion	day				x		
FTIME_H	Fault time—Hour portion	hour				x		
FTIME_M	Fault time—Minute portion	minute				x		
FTIME_S	Fault time—Second portion	second				x		
FTIMEH	Fault date/time stamp—High word	binary			x			
FTIMEH16	Fault date/time stamp—High word formatted as a 16-bit signed value	binary			x			
FTIMEM	Fault date/time stamp—Middle word	binary			x			
FTIMEM16	Fault date/time stamp—Middle word formatted as a 16-bit signed value	binary			x			
FTIMEL	Fault date/time stamp—Low word	binary			x			

Table G.1 Analog Quantities (Sheet 8 of 11)

Label	Description	Units	Display Points	Load Profile	DNP3	Modbus	Fast Meter	IEC 61850
FTIMEL16	Fault date/time stamp—Low word formatted as a 16-bit signed value	binary			x			
FTYPE	Fault Type				x			
FTYPE16	Fault Type formatted as a 16-bit signed value				x			
EVE_TYPE	Event Type					x		
FLOC	Fault Location	LL units			x	x		
FI	Fault current Maximum of IA, IB, IC	A pri			x	x		
FIA, FIB, FIC	Fault current, A, B, or C-phase	A pri			x	x		
FIG	Fault current, residual ground (IG = 3I0)[a]	A pri			x	x		
FIQ	Fault current, negative-sequence (3I2)	A pri			x	x		
FTARHI	Fault targets - high word				x	x		
FTARLO	Fault targets - how word				x	x		
FFREQ	Event frequency	Hz			x	x		
FGRP	Setting group active at event trigger	count			x	x		
FSHO	Reclosing relay shot counter at event trigger	count			x	x		
FUNR	Number of unread faults	count			x			
FUNRC	Number of unread faults	count			x[f]			
FLRNUM	Unique Identification number of the latest event	unitless						x
FLREP	Event Report Present (shall be 1 when an event report is present and 0 otherwise)	0 or 1						x
HIFLRNUM	Unique Identification number of the latest HIF event	unitless						x
HIFLREP	Event Report Present (shall be 1 when an HIF event report is present, and 0 otherwise)	0 or 1						x
Diagnostics								
P5V_PS	+5 Volt power supply	Vdc			x	x		
P5V_REG	+5 Volt Regulated power supply	Vdc			x	x		
P15V_PS	+15 Volt power supply	Vdc			x	x		
N15V_PS	–15 Volt power supply	Vdc			x	x		
P12V_TC	+12 Volt trip/close capacitors control supply	Vdc			x	x		
P5VA_PS	+5 Volt analog power supply	Vdc			x	x		
N5VA_PS	–5 Volt analog power supply	Vdc			x	x		
TEMP	Temperature	Deg C	x		x	x		
CMODE	Battery or capacitor charger mode				x	x		
VBAT	Battery voltage	Vdc	x	x	x	x		x
IBAT	Battery current (negative indicates discharge)	A dc	x		x	x		

Table G.1   Analog Quantities (Sheet 9 of 11)

Label	Description	Units	Display Points	Load Profile	DNP3	Modbus	Fast Meter	IEC 61850
TBAT	Battery temperature	Deg C			x	x		
INPBV	Input power Bus voltage	Vdc			x	x		
12VAUX	+12 V auxiliary power supply	Vdc			x	x		
TCCAPV	Trip/close capacitor voltage	Vdc	x		x	x		
Settings Group, Date, and Time								
ACTGRP	Active settings group	count			x[g]	x		
DATE	Present date from relay clock	date	x				x	
TIME	Present time from relay clock	time	x				x	
DATE_Y	Present date—year portion	year				x		
DATE_M	Present date—month portion	month				x		
DATE_D	Present date—day portion	day				x		
TIME_H	Present time—hour portion	hour				x		
TIME_M	Present time—minute portion	minute				x		
TIME_S	Present time—second portion	second				x		
Relay Information								
FID	Relay firmware string							x
FWREV	Relay firmware revision				x	x		
FWVNUM	Relay firmware version number				x	x		
SNUMBL	Relay serial number, lowest 4 digits				x	x		
SNUMBM	Relay serial number, middle 4 digits				x	x		
SNUMBH	Relay serial number, highest 4 digits				x	x		
SERNUM	Relay serial number string							x
DNPADR	DNP slave address of relay				x			
REPADR	DNP master address				x			
Modbus Communications Counters								
MSGRCD	Number of messages received	count				x		
MSGOID	Number of messages to other devices (Other ID)	count				x		
ILLADDR	Illegal address count	count				x		
BADCRC	Bad CRC count	count				x		
UARTER	Uart error count	count				x		
ILLFUNC	Illegal function count	count				x		
ILLREG	Illegal register count	count				x		
ILLDATA	Illegal data count	count				x		
BADPF	Bad packet format count	count				x		
BADPL	Bad packet length count	count				x		
Math Variables								
MV01–MV64	Math variable		x		x	x		x

Table G.1   Analog Quantities (Sheet 10 of 11)

Label	Description	Units	Display Points	Load Profile	DNP3	Modbus	Fast Meter	IEC 61850
SELOGIC Counters								
SC01–SC16	SELOGIC counter *nn* present value (where *nn* = 01–16) count		x	x	x	x		x
Identifier Labels								
RID	Relay identifier		x					
TID	Terminal identifier		x					
Pickup Settings, 51h								
51PJP, 51PKP	Maximum-phase time-overcurrent element (J, K) pickup	A sec	x		x			
51AJP, 51BJP, 51CJP, 51AKP, 51BKP, 51CKP	Phase (A, B, C) time-overcurrent element (J, K) pickup	A sec	x		x			
51N1JP, 51N1KP	Neutral (#1) time-overcurrent element (J, K) pickup	A sec	x		x			
51N2JP, 51N2KP	Neutral (#2) time-overcurrent element (J, K) pickup	A sec	x		x			
51G1JP, 51G1KP	Ground (#1) time-overcurrent element (J, K) pickup	A sec	x		x			
51G2JP, 51G2KP	Ground (#2) time-overcurrent element (J, K) Pickup	A sec	x		x			
51QJP, 51QKP	Negative-Sequence time-overcurrent element (J, K) pickup	A sec	x		x			
51PJP_P, 51PKP_P	Maximum-phase time-overcurrent element (J, K) pickup	A pri	x		x			
51AJP_P, 51BJP_P, 51CJP_P, 51AKP_P, 51BKP_P, 51CKP_P,	Phase (A, B, C) time-overcurrent element (J, K) pickup	A pri	x		x			
51N1JP_P, 51N1KP_P	Neutral (#1) time-overcurrent element (J, K) pickup	A pri	x		x			
51N2JP_P, 51N2KP_P	Neutral (#2) time-overcurrent element (J, K) pickup	A pri	x		x			
51G1JP_P[i], 51G1KP_P[i]	Ground (#1) time-overcurrent element (J, K) pickup	A pri	x		x			
51G2JP_P[i], 51G2KP_P[i]	Ground (#2) time-overcurrent element (J, K) pickup	A pri	x		x			
51QJP_P, 51QKP_P	Negative-sequence time-overcurrent element (J, K) pickup	A pri	x		x			
Curve Settings 51h								
51PJC, 51PKC	Maximum-phase time-overcurrent element (J, K) curve	Curve	x					
51AJC, 51BJC, 51CJC, 51AKC, 51BKC, 51CKC	Phase (A, B, C) time-overcurrent element (J, K) curve	Curve	x					
51N1JC, 51N1KC	Neutral (#1) time-overcurrent element (J, K) curve	Curve	x					
51N2JC, 51N2KC	Neutral (#2) time-overcurrent element (J, K) curve	Curve	x

51G2JTD, 51G2KTD	Ground (#2) time-overcurrent element (J, K) time dial	Time Dial	x					
51QJTD, 51QKTD	Negative-Sequence time-overcurrent element (J, K) time dial	Time Dial	x					

[a]   When Global setting EGNDSW := Y, the metering ground current quantity IG automatically switches between 3I0 and IN, depending on the magnitude of the measured ground current. The metering IG quantity (A primary) is based on the IN channel for small signals and the 3I0 quantity for larger signals.
When Global setting EGNDSW := N, the ground current quantity IG is always based on 3I0 = IA + IB + IC (in A primary).
See Ground Switch Option on page 8.3 for more details.

[b]   Lag or lead is automatically included in Display Points for power factor. For example, setting "DP02 = PFA" will display PF A = 0.76 LAG as display point 2.

[c]   Modbus date values are available as day, month, and year: [x] = D, M, Y.

[d]   Modbus time values are available as seconds, minutes, and hours; [z] = S, M, H.

[e]   The first harmonic (01) is also called the "fundamental" component and comes from the harmonic metering subsystem. This quantity may be different than the quantity from the fundamental metering subsystem because the relay calculates the two numbers by using different methods. For example, VBYH01 may not exactly match VBY (from Fundamental Metering).

[f]   Available in DNP as a counter input.

[g]   Available in DNP as both a counter input and analog output.

[h]   The time-overcurrent elements have two sets of settings, called J and K. Only one of these sets is operative at any time. J/K selection is controlled by the 51_SW SELogic Group setting for each of the 51_ elements.

[i]   When Global setting EGNDSW := Y, the primary ground pickup is calculated using CTRN. When Global setting EGNDSW := N, the primary ground pickup is calculated using CTR. See Ground Switch Option on page 8.3.

Appendix H

Fast SER Protocol

Introduction

This appendix describes special binary Fast Sequential Events Recorder (SER) messages that are not included in *Section 10: Communications* of this instruction manual. Devices with embedded processing capability can use these messages to enable and accept unsolicited binary Fast SER messages from the SEL-651R-2 Recloser Control.

SEL relays and communications processors have two separate data streams that share the same serial port. The normal serial interface consists of ASCII character commands and reports that are intelligible to people using a terminal or terminal emulation package. The binary data streams can interrupt the ASCII data stream to obtain information, and then allow the ASCII data stream to continue. This mechanism allows a single communications channel to be used for ASCII communications (e.g., transmission of a long event report) interleaved with short bursts of binary data to support fast acquisition of metering or SER data. To exploit this feature, the device connected to the other end of the link requires software that uses the separate data streams. The binary commands and ASCII commands can also be accessed by a device that does not interleave the data streams.

Make Sequential Events Recorder (SER) Settings With Care

The relay triggers a row in the Sequential Events Recorder (SER) event report for any change of state in any one of the elements listed in the SER1, SER2, SER3, or SER4 trigger settings. Nonvolatile memory is used to store the latest 1024 rows of the SER event report so they can be retained during power loss. The nonvolatile memory is rated for a finite number of "writes." Exceeding the limit can result in an EEPROM self-test failure. An average of one state change every three minutes can be made for a 25-year relay service life.

Page 886 of 1080
Wolfe

Recommended Message Usage

Use the following sequence of commands to enable unsolicited binary Fast SER messaging in the SEL-651R-2:

Step 1. On initial connection, send the **SNS** command to retrieve and store the ASCII names for the digital I/O points assigned to trigger SER records.

The order of the ASCII names matches the point indices in the unsolicited binary Fast SER messages. Send the "Enable Unsolicited Fast SER Data Transfer" message to enable the SEL-651R-2 to transmit unsolicited binary Fast SER messages.

Step 2. When SER records are triggered in the SEL-651R-2, the relay responds with an unsolicited binary Fast SER message. If this message has a valid checksum, it must be acknowledged by sending an acknowledge message with the same response number as contained in the original message. The relay will wait approximately 200–500 ms to receive an acknowledge message, at which time the relay will resend the same unsolicited Fast SER message with the same response number.

Step 3. Upon receiving an acknowledge message with a matching response number, the relay increments the response number and continues to send and seek acknowledgment for unsolicited Fast SER messages if additional SER records are available. When the response number reaches three, it wraps around to zero on the next increment.

Functions and Function Codes

In the messages shown below, all numbers are in hexadecimal unless otherwise noted.

01-Function Code: Enable Unsolicited Fast SER Data Transfer, Sent From Master to Relay

Upon being turned on, the SEL-651R-2 disables its own unsolicited transmissions. This function enables the SEL-651R-2 to begin sending unsolicited data to the device which sent the enable message, if the SEL-651R-2 has such data to transfer. The message format for function code 01 is shown in *Table H.1*.

Table H.1   Function Code 01 Message Format (Sheet 1 of 2)

Data	Description
A546	Message header
12	Message length in bytes (18 decimal)
0000000000	Five bytes reserved for future use as a routing address
YY	Status byte (LSB = 1 indicates an acknowledge is requested)
01	Function code
C0	Sequence byte (Always C0. Other values are reserved for future use in multiple frame messages.)
XX	Response number (XX = 00, 01, 02, 03, 00, 01...).
18	Function to enable (18 unsolicited SER messages)

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 887 of 1080
Fast SER Protocol   H.3
Functional and Function Codes
Wolfe

Table H.1   Function Code 01 Message Format (Sheet 2 of 2)

Data	Description
0000	Reserved for future use as function code data
nn	Maximum number of SER records per message, 01–20 hex
cccc	Two byte CRC-16 check code for message

The SEL-651R-2 verifies the message by checking the header, length, function code, and enabled function code against the expected values. It also checks the entire message against the CRC-16 field. If any of the checks fail, except the function code or the function to enable, the message is ignored.

If an acknowledge is requested as indicated by the least significant bit of the status byte, the relay transmits an acknowledge message with the same response number received in the enable message.

The *nn* field is used to set the maximum number of SER records per message. The relay checks for SER records approximately every 500 ms. If there are new records available, the relay immediately creates a new unsolicited Fast SER message and transmits it. If there are more than *nn* new records available, or if the first and last record are separated by more than 16 seconds, the relay will break the transmission into multiple messages so that no message contains more than *nn* records, and the first and last record of each message are separated by no more than 16 seconds.

If the function to enable is not 18 or the function code is not recognized, the relay responds with an acknowledge message containing response code 01 (function code unrecognized) and no functions are enabled. If the SER triggers are disabled (SER1, SER2, SER3, and SER4 are all set to NA), the unsolicited Fast SER messages are still enabled, but the only SER records generated are because of settings changes and power being applied to the relay. If the SER1, SER2, SER3, or SER4 settings are subsequently changed to any non-NA value and SER entries are triggered, unsolicited SER messages will be generated with the new SER records.

02-Function Code: Disable Unsolicited Fast SER Data Transfer, Sent From Master to Relay

This function disables the SEL-651R-2 from transferring unsolicited data. The message format for function code 02 is shown in *Table H.2*.

Table H.2   Function Code 02 Message Format

Data	Description
A546	Message header
10	Message length (16 decimal)
0000000000	Five bytes reserved for future use as a routing address.
YY	Status byte (LSB = 1 indicates an acknowledge is requested)
02	Function code
C0	Sequence byte (Always C0. Other values are reserved for future use in multiple frame messages.)
XX	Response number (XX = 00, 01, 02, 03, 01, 02...)
18	Function to disable (18 = Unsolicited SER)
00	Reserved for future use as function code data
cccc	Two byte CRC-16 check code for message

H.4 | Fast SER Protocol
Functions and Function Codes

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 888 of 1080
Wolfe

The SEL-651R-2 verifies the message by checking the header, length, function code, and disabled function code against the expected values. It also checks the entire message against the CRC-16 field. If any of the checks fail, except the function code or the function to disable, the message is ignored.

If an acknowledge is requested as indicated by the least significant bit of the status byte, the relay transmits an acknowledge message with the same response number received in the enable message.

If the function to disable is not 18 or the function code is not recognized, the relay responds with an acknowledge message containing response code 01 (function code unrecognized) and no functions are disabled.

18-Function: Unsolicited Fast SER Response, Sent From Relay to Master

The function 18 is used for the transmission of unsolicited Fast Sequential Events Recorder (SER) data from the SEL-651R-2. This function code is also passed as data in the "Enable Unsolicited Data Transfer" and the "Disable Unsolicited Data Transfer" messages to indicate which type of unsolicited data should be enabled or disabled. The message format for function code 18 is shown in *Table H.3*.

Table H.3   Function Code 18 Message Format (Sheet 1 of 2)

Data	Description
A546	Message header
ZZ	Message length (as long as 34 + 4 • *nn* decimal, where *nn* is the maximum number of SER records allowed per message as indicated in the "Enable Unsolicited Data Transfer" message)
0000000000	Five bytes reserved for future use as a routing address
YY	Status Byte (01 = need acknowledgment; 03 = settings changed and need acknowledgment. If YY = 03, the master should re-read the SNS data because the element index list may have changed)
18	Function code
C0	Sequence byte (Always C0. Other values are reserved for future use in multiple frame messages)
XX	Response number (XX = 00, 01, 02, 03, 01, 02...)
00000000	Four bytes reserved for future use as a return routing address
dddd	Two-byte day of year (1–366)
yyyy	Two-byte, four-digit year (e.g., 1999 or 07CF hex)
mmmmmmmm	Four-byte time of day in milliseconds since midnight
XX	1st element index (match with the response to the **SNS** command; 00 for 1st element, 01 for second element, and so on)
uuuuuu	Three-byte time tag offset of 1st element in microseconds since time indicated in the time of day field
XX	2nd element index
uuuuuu	Three-byte time tag offset of 2nd element in microseconds since time indicated in the time of day field
.	
.	
.	
xx	Last element index
uuuuuu	Three-byte time tag offset of last element in microseconds since time indicated in the time of day field

Fast SER Protocol
Functional Message and Function Codes
H.5

Table H.3   Function Code 18 Message Format (Sheet 2 of 2)

Data	Description
FFFFFFFE	Four-byte end-of-records flag
ssssssss	Packed four-byte element status for as many as 32 elements (LSB for the 1st element)
cccc	Two-byte CRC-16 check code for message

If the relay determines that SER records have been lost, it sends a message with the following format:

Data	Description
A546	Message header
22	Message length (34 decimal)
0000000000	Five bytes reserved for future use as a routing address.
YY	Status Byte (01 = need acknowledgment; 03 = settings changed and need acknowledgment)
18	Function code
C0	Sequence byte (Always C0. Other values are reserved for future use in multiple frame messages.)
XX	Response number (XX = 00, 01, 02, 03, 00, 01, ...)
00000000	Four bytes reserved for future use as a return routing address.
dddd	Two-byte day of year (1–366) of overflow message generation
yyyy	Two-byte, four-digit year (e.g., 1999 or 07CF hex) of overflow message generation.
mmmmmmmm	Four-byte time of day in milliseconds since midnight
FFFFFFFE	Four-byte end-of-records flag
00000000	Element status (unused)
cccc	Two byte CRC-16 check code for message

Acknowledge Message Sent from Master to Relay, and From Relay to Master

The acknowledge message is constructed and transmitted for every received message that contains a status byte with the LSB set (except another acknowledge message), and which passes all other checks, including the CRC. The acknowledge message format is shown in *Table H.4*.

Table H.4   Acknowledge Message Format

Data	Description
A546	Message header
0E	Message length (14 decimal)
0000000000	Five bytes reserved for future use as a routing address
00	Status byte (always 00)
XX	Function code, echo of acknowledged function code with MSB set
RR	Response code (see below)
XX	Response number (XX = 00, 01, 02, 03, 00, 01, ...) must match response number from message being acknowledged
cccc	Two byte CRC-16 check code for message

H.6 | Fast SER Protocol
Functions and Function Codes

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 890 of 1080
Wolfe

The SEL-651R-2 supports the following response codes:

Table H.5   SEL-651R-2 Response Codes

RR	Response
00	Success
01	Function code not recognized

Examples

1. Successful acknowledge for "Enable Unsolicited Fast SER Data Transfer" message from a relay with at least one of SER1, SER2, SER3, or SER4 not set to NA:

   A5 46 0E 00 00 00 00 00 00 81 00 XX cccc

   (XX is the same as the Response Number in the "Enable Unsolicited Data Transfer" message to which it responds)

2. Unsuccessful acknowledge for "Enable Unsolicited Fast SER Data Transfer" message from a relay with all of SER1, SER2, SER3, and SER4 set to NA:

   A5 46 0E 00 00 00 00 00 00 81 02 XX cccc

   (XX is the same as the response number in the "Enable Unsolicited Data Transfer" message to which it responds.)

3. Disable Unsolicited Fast SER Data Transfer message, acknowledge requested:

   A5 46 10 00 00 00 00 00 01 02 C0 XX 18 00 cccc

   (XX = 0, 1, 2, 3)

4. Successful acknowledge from the relay for the "Disable Unsolicited Fast SER Data Transfer" message:

   A5 46 0E 00 00 00 00 00 00 82 00 XX cccc

   (XX is the same as the response number in the "Disable Unsolicited Fast SER Data Transfer" message to which it responds.)

5. Successful acknowledge message from the master for an unsolicited Fast SER message:

   A5 46 0E 00 00 00 00 00 00 98 00 XX cccc

   (XX is the same as the response number in the unsolicited Fast SER message to which it responds.)

Notes:

Once the relay receives an acknowledge with response code 00 from the master, it will clear the Settings Changed bit (bit 1) in its status byte if that bit is asserted, and it will clear the Settings Changed bit in fast meter if that bit is asserted.

An element index of FE indicates that the SER record is a result of startup. An element index of FF indicates that the SER record is because of a setting change. An element index of FD indicates that the element identified in this SER record is no longer in the SER trigger settings.

When the relay sends an SER message packet, it will put a sequential number (0, 1, 2, 3, 0, 1, ...) into the response number. If the relay does not receive an acknowledge from the master before approximately 500 ms, the relay will resend the same message packet with the same response number until it

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 891 of 1080
Wolfe
Fast SER Protocol
Functions and Function Codes H.7

receives an acknowledge message with that response number. For the next SER message, the relay will increment the response number (it will wrap around to zero from three).

A single Fast SER message packet from the relay can have a maximum of 32 records and the data may span a time period of no more than 16 seconds. The master may limit the number records in a packet with the third byte of function code data in the "Enable Unsolicited Data Transfer" message (function code 01). The relay may generate an SER packet with less than the requested number of records, if the record time stamps span more than 16 seconds.

The relay always requests acknowledgment in unsolicited Fast SER messages (LSB of the status byte is set).

Unsolicited Fast SER messages can be enabled on multiple ports simultaneously.

Appendix I

Configuration, Fast Meter, and Fast Operate Commands

Overview

SEL relays have two separate data streams that share the same serial port. Data communications with the relay consist of ASCII character commands and reports that are intelligible using a terminal or terminal emulation package. The binary data streams can interrupt the ASCII data stream to obtain information and then allow the ASCII data stream to continue.

This mechanism allows a single communications channel to be used for ASCII communications (e.g., transmission of a long event report) interleaved with short bursts of binary data to support fast acquisition of metering data. The device connected to the other end of the link requires software that uses the separate data streams to exploit this feature. The binary commands and ASCII commands can also be accessed by a device that does not interleave the data streams.

SEL Application Guide AG95-10, *Configuration and Fast Meter Messages*, is a comprehensive description of the SEL binary messages. Below is a description of the messages provided in the SEL-651R-2.

Message Lists

Binary Message List

NOTE: The SEL-651R-2 is not compatible with Fast Meter requests when issued by an SEL-2020, an SEL-2030 with R124 firmware or earlier, or an SEL-2032 with R112 firmware or earlier.

494700000000	Analog channel name [IG] (IGDEM or IGPK)
02	Analog channel type
FF	Scale factor type
0000	Scale factor offset in Fast Meter message

NOTE: Analog channel names are transmitted by the relay as part of the A5C2 and A5C3 messages. To support legacy applications, some Fast Meter analog channel names differ from the analog labels used for DNP and Modbus protocols documented in Appendix G: Analog Quantities, Appendix E: DNP3 Communications, and Appendix K: Modbus RTU and TCP Communications. The analog channel names shown in brackets [] in Table I.6 are those contained in the Fast Meter message. The analog labels from Appendix G: Analog Quantities are shown in parentheses.

A5D2/A5D3 Demand/ Peak Demand Fast Meter Message

In response to the A5D2 or A5D3 request, the relay sends the following block.

Table I.7   A5D2/A5D3 Demand/Peak Demand Fast Meter Message

Data	Description
A5D2 or A5D3	Command
BE	Length
1 byte	1 Status Byte
176-bytes	IADEM/IAPK, IBDEM/IBPK, ICDEM/ICPK, INDEM/INPK, IGDEM/IGPK, 3I2DEM/3I2PK, MWADI/MWAPI, MWBDI/MWBPI, MWCDI/MWCPI, MW3DI/MW3PI, MVRADI/MVRAPI, MVRBDI/MVRBPI, MVRCDI/MVRCPI, MVR3DI/MVR3PI, MWADO/MWAPO, MWBDO/MWBPO, MWCDO/MWCPO, MW3DO/MW3PO, MVRADO/MVRAPO, MVRBDO/MVRBPO, MVRCDO/MVRCPO, MVR3DO/MVR3PO in 8-byte IEEE FPS
8 bytes	Time stamp
1 byte	Reserved
1 byte	1-byte checksum of all preceding bytes

A5B9 Fast Meter Status Acknowledge Message

In response to the A5B9 request, the relay clears the Fast Meter (message A5D1) Status Byte. The SEL-651R-2 Status Byte contains two active bits: STSET (bit 1) and PWRUP (bit 2); both bits are set on startup. The STSET bit is also set on settings changes. If the STSET bit is set, the external device should request the A5C1, A5C2, and A5C3 messages. The external device can then determine if the scale factors or line configuration parameters have been modified.

A5CE Fast Operate Configuration Block

In response to the A5CE request, the relay sends the following block.

Table I.8   A5CE Fast Operate Configuration Block (Sheet 1 of 4)

Data	Description
A5CE	Command
72	Length
04	Support 3 circuit breakers with individual phase operation
0020	Support 32 remote bit set/clear commands
0100	Allow remote bit pulse commands

5F	Operate code, pulse remote bit RB32
00	Reserved
checksum	1-byte checksum of all preceding bytes

A5E0 Fast Operate Remote Bit Control

The external device sends the following message to perform a remote bit operation.

Table I.9   A5E0 Fast Operate Remote Bit Control

Data	Description
A5E0	Command
06	Length
1 byte	Operate code: 00–1F clear remote bit RB01–RB32 20–3F set remote bit RB01–RB32 40–5F pulse remote bit for RB01–RB32 for one processing interval
1 byte	Operate validation: 4 • Operate code + 1
checksum	1-byte checksum of preceding bytes

The relay performs the specified remote bit operation if the following conditions are true:

➤ The Operate code is valid.

➤ The Operate validation = 4 • Operate code + 1.

➤ The message checksum is valid.

➤ The FASTOP port setting is set to Y.

➤ The relay is enabled.

Remote bit set and clear operations are latched by the relay. Remote bit pulse operations assert the remote bit for one processing interval (1/4 cycle).

It is common practice to route remote bits to output contacts to provide remote control of the relay outputs. If you wish to pulse an output contact closed for a specific duration, SEL recommends using the remote bit pulse command and SELOGIC control equations to provide secure and accurate contact control. The remote device sends the remote bit pulse command; the relay controls the timing of the output contact assertion. You can use any remote bit (RB01–RB32) and any SELOGIC control equation timer (SV01–SV64) to control any

Page 904 of 1080
Wolfe

of the output contacts. For example, to pulse output contact **OUT104** for 30 cycles with Remote Bit RB04 and SELOGIC control equation timer SV04, issue the following relay settings:

Via the **SET L** command:

ESV := **4** enable 4 SELOGIC control equations

SV04PU := **0** SV04 pickup time = 0

SV04DO := **30** SV04 dropout time is 30 cycles

SV4 := **RB04** SV04 input is RB04

OUT104 := **SV04T** route SV04 timer output to **OUT104**

To pulse the contact, send the **A5E006430DDB** command to the relay.

A5E3 Fast Operate Breaker Control

The external device sends the following message to perform a fast breaker open/close.

Table I.10   A5E3 Fast Operate Breaker Control

Data	Description
A5E3	Command
06	Length
1 byte	Operate code: 31—OPEN Breakers 1, 2, and 3 11—CLOSE Breakers 1, 2, and 3 32—OPEN Breaker 1 12—CLOSE Breaker 1 33—OPEN Breaker 2 13—CLOSE Breaker 2 34—OPEN Breaker 3 14—CLOSE Breaker 3
1 byte	Operate Validation: $4 \cdot$ Operate code $+ 1$
Checksum	1-byte checksum of preceding bytes

The relay performs the specified breaker operation if the following conditions are true:

➤ Conditions defined in the A5E0 message are true.

➤ The breaker jumper (JMP2B) is in place on the SEL-651R-2 main board.

A5CD Fast Operate Reset Definition Block

In response to an A5CD request, the relay sends the configuration block for the Fast Operate Reset message.

Table I.11   A5CD Fast Operate Reset Definition Block

Data	Description
A5CD	Command
0E	Message length
01	The number of Fast Operate reset codes supported
00	Reserved for future use
00	Fast Operate reset code ("00" for target reset)
54415220520D00	Fast Operate reset description string ("TAR R")
xx	Checksum

A5ED Fast Operate Reset Command

The Fast Operate Reset commands take the following form.

Table I.12 A5ED Fast Operate Reset Command

Data	Description
A5ED	Command
06	Message Length—always 6
00	Operate Code ("00" for target reset, "TAR R")
01	Operate Validation—(4 • Operate Code) + 1
xx	Checksum

ID Message

In response to the **ID** command, the relay sends the firmware ID (FID), boot firmware ID (BFID), firmware checksum (CID), relay TID setting (DEVID), Modbus device code (DEVCODE)—for use by an SEL Communications Processor, relay part number (PARTNO), relay serial number (SERIALNO), and configuration string (CONFIG)—for use by other IEDs or software.

A sample response is shown below; responses will differ depending on relay, settings, and firmware.

```
<STX>
"FID=SEL-651R-2-Rxxx-Vx-Zxxxxxx-Dxxxxxxxx","yyyy"<CR><LF>
"BFID=SLBT-3CF1-Rxxx-Vx-Zxxxxxx-Dxxxxxxxx","yyyy"<CR><LF>
"CID=xxxx","yyyy"<CR><LF>
"DEVID=STATION A","yyyy"<CR><LF>
"DEVCODE=56","yyyy"<CR><LF>
"PARTNO=0651R261XAA83A1113XXXX","yyyy"<CR><LF>
"SERIALNO=000000000000000","yyyy"<CR><LF>
"CONFIG=1124200","yyyy"<CR><LF>
"SPECIAL=01211","yyyy"<CR><LF>
"iedName=","0360"<CR><LF>
"type=","026F"<CR><LF>
"configVersion=","0609"<CR><LF>
<ETX>
```

where:

<STX>	is the STX character (02)
<ETX>	is the ETX character (03)
xxxx	is the 4-byte ASCII hex representation of the checksum of the relay firmware
yyyy	is the 4-byte ASCII hex representation of the checksum for each line

The ID message is available from Access Level 0 and higher.

DNA Message

In response to the **DNA T** or **DNA X** command, the relay sends names of the Relay Word bits transmitted in the A5D1 message. The first name is associated with the MSB, the last name with the LSB. These names are listed in the Relay Word in *Appendix F: Relay Word Bits*. The **DNA** command is available from Access Level 0 and higher.

In response to the **DNA** command (without T or X modifier), the relay sends the **DNA X** command with all Relay Word bit names replaced with *. This is necessary for compatibility with older communications processors.

BNA Message

In response to the **BNA** command, the relay sends names of the bits transmitted in the Status Byte in the A5D1 message. The first name is the MSB, the last name is the LSB. The BNA message is:

```
<STX>"*","*","*","*","*","PWRUP","STSET","*","yyyy"<CR><LF><ETX>
```

where:

yyyy   is the 4-byte ASCII representation of the checksum

"*"   indicates an unused bit location

The **BNA** command is available from Access Level 0 and higher.

SNS Message

In response to the **SNS** command, the relay sends the name string of the SER (SER1 SER2 SER3 SER4) settings. The **SNS** command is available at Access Level 1.

The relay responds to the **SNS** command with the name string in the SER settings. The name string starts with SER1, followed by SER2, SER3, and SER4.

For example, if

SER1 := 50A1 OUT101

SER2 := 50P1T 81D1T

SER3 := OUT102 52A3P

SER4 := TRIP3P OUT103

The name string will be

"50A1","OUT101","50P1T","81D1T","OUT102","52A3P","TRIP3P"," OUT103".

If there are more than eight settings in SER, the SNS message will have several rows. Each row will have eight strings, followed by the checksum and carriage return. The last row may have fewer than eight strings.

The SNS message for the SEL-651R-2 is shown below:

```
<STX>
"xxxx","xxxx","xxxx","xxxx","xxxx","xxxx","xxxx","xxxx","yyyy"<CR><LF>
"xxxx","xxxx","xxxx","xxxx","xxxx","xxxx","xxxx","xxxx","yyyy"<CR><LF>
"xxxx","xxxx","xxxx","xxxx","xxxx","xxxx","xxxx","xxxx","yyyy"<CR><LF>
"xxxx","yyyy"<CR><LF><ETX>
```

where:

xxxx   is a string from the settings in SER (SER1, SER2, SER3, and SER4)

yyyy   is the 4-byte ASCII representation of the checksum

Appendix J

Synchrophasors

Overview

The SEL-651R-2 provides phasor measurement unit (PMU) capabilities when connected to a suitable IRIG-B time source. Synchrophasor is used as a general term that can refer to data or protocol.

This section covers the following topics:

➤ *Introduction on page J.1*

➤ *Synchrophasor Measurement on page J.2*

➤ *Settings for IEEE C37.118 Protocol Synchrophasors on page J.4*

➤ *C37.118 Synchrophasor Protocol on page J.13*

➤ *Synchrophasor Relay Word Bits on page J.16*

➤ *View Synchrophasors by Using the MET PM Command on page J.17*

➤ *Configuring High-Accuracy Timekeeping on page J.21*

See *IRIG-B on page J.21* for the requirements of the IRIG-B time source. Synchrophasors are still measured if the high-accuracy time source is not connected, but the data are not time-synchronized to any external reference, as indicated by Relay Word bit TSOK = logical 0.

Introduction

The word synchrophasor is derived from two words: synchronized and phasor. Synchrophasor measurement refers to the concept of providing measurements taken on a synchronized schedule in multiple locations. A high-accuracy clock, commonly a global positioning system (GPS) receiver such as the SEL-2407 Satellite-Synchronized Clock, makes synchrophasor measurement possible.

The availability of an accurate time reference over a large geographic area allows multiple devices, such as a number of SEL-651R-2 recloser controls, to synchronize the gathering of power system data. The accurate clock allows precise event report triggering and other offline analysis functions.

The SEL-651R-2 Global settings contain the synchrophasor settings, including the choice of the synchrophasor data set the relay will transmit. The Port settings select which serial port(s) are reserved for synchrophasor protocol use and enables synchrophasors on Ethernet ports (see *Settings for IEEE C37.118 Protocol Synchrophasors on page J.4*).

Synchrophasor Measurement

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 910 of 1080
Wolfe

The SEL-651R-2 generates time status Relay Word bits and time-quality information that is important for synchrophasor measurement. Some protection SELOGIC control equation variables and programmable digital trigger information are also added to the Relay Word bits for synchrophasors (see *Synchrophasor Relay Word Bits on page J.16*).

The value of synchrophasor data increases greatly when the data can be shared over a communications network in real time. IEEE C37.118 synchrophasor protocol is available in the SEL-651R-2, which allows for a centralized device to collect data efficiently from several phasor measurement units (PMUs). Some possible uses of a system-wide synchrophasor system include the following:

➤ Power system state measurement

➤ Wide-area network protection and control schemes

➤ Small signal analysis

➤ Power system disturbance analysis

IEEE C37.118 compliant synchrophasor data are available on multiple serial ports when the port setting PROTO := PMU and on Ethernet Ports when port setting EPMIP := Y.

You can view synchrophasor data over a serial port set to PROTO = SEL, see *View Synchrophasors by Using the MET PM Command on page J.17*.

Synchrophasor Measurement

NOTE: The synchrophasor data stream is separate from the other protection and metering functions.

The phasor measurement unit in the SEL-651R-2 measures six voltages and four currents on a constant time basis. These samples are synchronized to the high-accuracy IRIG-B time source and occur at a fixed frequency of either 60 Hz or 50 Hz, depending on Global setting NFREQ. The relay then filters the measured samples according to Global setting PMAPP = F or N (see *PMAPP on page J.6*). The phase angle is measured relative to an absolute reference, which is represented by a cosine function in *Figure J.1*. The time of day is shown for the two time marks.

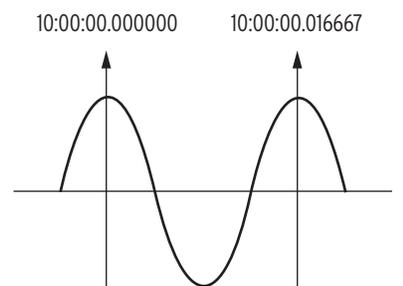
10:00:00.000000   10:00:00.016667


Figure J.1   High-Accuracy Clock Controls Reference Signal (60 Hz System)

NOTE: For SEL-651R-2 models with LEA inputs, the VnYPAC and VnZPAC settings (where n = 1, 2, or 3) are used to compensate for phase angle shifts in the measurement path (see Voltage Phase Angle Correction Settings for VY- and VZ-Terminal Voltage Inputs (Global Settings) on page 9.36). In this case, the VYCOMP and VZCOMP settings do not need to be used to compensate for such phase angle shifts.

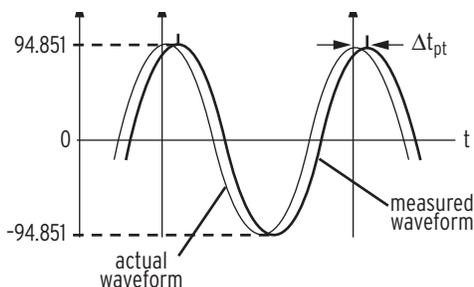
The instrument transformers (PTs or CTs) and the interconnecting cables may introduce a time shift in the measured signal. Global settings VYCOMP, VZCOMP, IPCOMP, and INCOMP, entered in degrees, are added to the measured phasor angles to create the corrected phasor angles, as shown in *Figure J.2*. The VYCOMP, VZCOMP, IPCOMP, and INCOMP settings may be positive or negative values. The corrected angles are displayed in the **MET PM** command and transmitted as part of synchrophasor messages.


Figure J.2   Waveform at Relay Terminals May Have Phase Shift

$$\text{Compensation Angle} = \frac{\Delta t_{pt}}{\left(\dfrac{1}{\text{freq}}\right)} \bullet 360°$$

$$= \Delta t_{pt} \bullet \text{freq} \bullet 360°$$

Equation J.1

If the time shift on the pt measurement path $\Delta t_{pt} = 0.784$ ms and the nominal frequency, $\text{freq}_{nominal} = 60 \text{Hz}$, use *Equation J.2* to obtain the correction angle:

$$0.784 \bullet 10^{-3} \text{s} \bullet 60 \text{s}^{-1} \bullet 360° = 16.934°$$

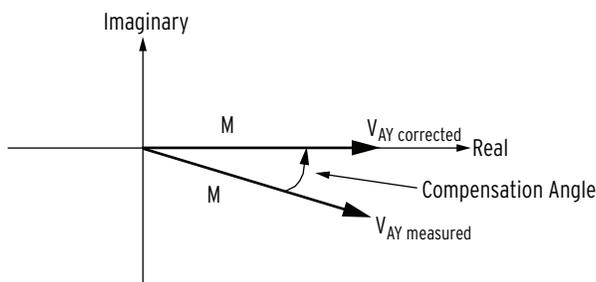
Equation J.2


Figure J.3   Correction of Measured Phase Angle

For a sinusoidal signal, the phasor magnitude is calculated as shown in *Equation J.3*. The phasors are rms values scaled in primary units, as determined by Group settings PTRY, PTRZ, CTR, and CTRN. The SEL-651R-2 then calculates the positive-sequence voltage and currents.

$$\text{Magnitude M} = \frac{V_{pk}}{\sqrt{2}} \bullet \text{PTR}_{setting}$$

Equation J.3

With PTRY = 2000 and the signal in *Figure J.2* (with peak voltage $V_{pk} = 94.851$ V), use *Equation J.4* to obtain the magnitude, VAY_MAG:

$$VAY\_MAG = \frac{94.851}{\sqrt{2}} \bullet 2000$$

$$= 134140 \text{ V}$$

$$= 134.140 \text{ kV}$$

Equation J.4

Finally, the magnitude and angle pair for each synchrophasor is converted to a real and imaginary pair by using *Equation J.5* and *Equation J.6*. For example, analog quantities VAY_MAG and VAY_ANG are converted to VAY_REAL and VAY_IMG. An example phasor with an angle measurement of 104.400° is shown in *Figure J.4*.

J.4 Synchrophasors
Settings for IEEE C37.118 Protocol Synchrophasors

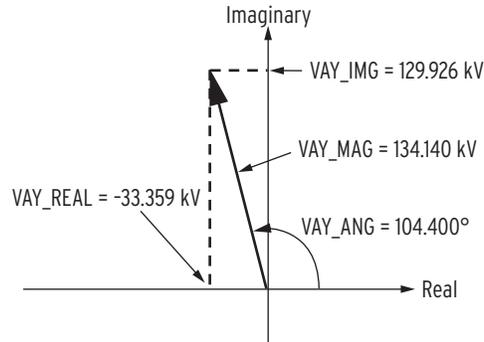
Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 912 of 1080
Wolfe


Figure J.4   Example Calculation of Real and Imaginary Components of Synchrophasor

$$\text{Real part } = \text{ M} \bullet \text{ cos (angle)} \qquad \textbf{Equation J.5}$$

$$\text{Imaginary part } = \text{ M} \bullet \text{ sin (angle)} \qquad \textbf{Equation J.6}$$

Using the magnitude M from *Equation J.5*, the real part is given in *Equation J.7*.

$$\text{VAY\_REAL } = \text{ 134.140 kV} \bullet \text{ cos 104.400°}$$
$$= -33.359 \text{ kV} \qquad \textbf{Equation J.7}$$

Similarly, the imaginary part is calculated in *Equation J.8*.

$$\text{VAY\_IMG } = \text{ 134.140 kV} \bullet \text{ sin 104.400°}$$
$$= 129.926 \text{ kV} \qquad \textbf{Equation J.8}$$

Because the sampling reference is based on the GPS clock (IRIG-B signal) and not synchronized to the power system, an examination of successive synchrophasor data sets will almost always show some angular change between samples of the same signal. This is not a malfunction of the relay or the power system, but is merely a result of viewing data from one system with an instrument with an independent time base. In other words, a power system has a nominal frequency of either 50 or 60 Hz, but on closer examination, it is usually running a little faster or slower than nominal.

Settings for IEEE C37.118 Protocol Synchrophasors

The phasor measurement unit (PMU) settings are listed in *Table J.1*. The SEL-651R-2 uses C37.118 message format for PMU applications because of increased settings flexibility and the availability of software and hardware for synchrophasor concentration, processing, and control.

The Global enable setting EPMU must be set to Y before the remaining SEL-651R-2 synchrophasor settings are available. No synchrophasor data collection can take place when EPMU := N.

You must make the port settings in *Table J.4* or *Table J.5* to transmit data with synchrophasor protocol. It is possible to set EPMU := Y without using any ports for synchrophasor protocols. For example, the serial port **MET PM** ASCII command can still be used.

Table J.1   PMU Settings in the SEL-651R-2 (Global Settings)

Global Settings	Description	Default
EPMU	Enable Synchronized Phasor Measurement (Y, N)	N[a]
MRATE	Messages per Second {1, 2, 5, 10, 25, or 50 when NFREQ := 50} {1, 2, 4, 5, 10, 12, 15, 20, 30, or 60 when NFREQ := 60}	2
PMAPP	PMU Application (F = Fast Response, N = Narrow Bandwidth)	N
PHCOMP	Frequency-Based Phasor Compensation (Y, N)	Y
PMSTN	Station Name (16 characters, mixed case)	STATION A
PMID	PMU Hardware ID (1–65534)	1
PHVOLT	Include Voltage Terminal (Y, Z, ALL)	Y
PHDATAV	Phasor Data Set, Voltages (V1, PH, ALL, NA)	V1
VYCOMP	Y Terminal Voltage Angle Compensation Factor (–179.99 to 180 degrees)	0.00
VZCOMP	Z Terminal Voltage Angle Compensation Factor (–179.99 to 180 degrees)	0.00
PHDATAI	Phasor Data Set, Currents (I1, PH, ALL, NA)	NA
IPCOMP	Phase Current Angle Compensation Factor (–179.99 to 180 degrees)	0.00
INCOMP	Neutral Current Angle Compensation Factor (–179.99 to 180 degrees)	0.00
PHNR[b]	Phasor Numeric Representation (I = Integer, F = Floating point)	I
PHFMT[b]	Phasor Format (R = Rectangular coordinates, P = Polar coordinates)	R
FNR	Frequency Numeric Representation (I = Integer, F = Float)	I
NUMDSW	Number of 16-bit Digital Status Words (0, 1, 2, 3, 4)	1

[a] Set EPMU := Y to access the remaining settings.
[b] Setting hidden when PHDATAV := NA and PHDATAI := NA.

Table J.2   PMU Settings in the SEL-651R-2 (Logic Settings)

Logic Settings	Description	Default
PMTRIG	Trigger (SELOGIC Equation)	0
TREA1	Trigger Reason Bit 1 (SELOGIC Equation)	0
TREA2	Trigger Reason Bit 2 (SELOGIC Equation)	0
TREA3	Trigger Reason Bit 3 (SELOGIC Equation)	0
TREA4	Trigger Reason Bit 4 (SELOGIC Equation)	0

Descriptions of Synchrophasor Settings

Definitions for the settings in *Table J.1* are as follows:

MRATE

Selects the message rate in messages per second for synchrophasor data streaming on serial ports.

Choose the MRATE setting that suits the needs of your PMU application. This setting is one of seven settings that determine the minimum port SPEED necessary to support the synchrophasor data packet rate and size. See *Communications Bandwidth for C37.118 Protocol on page J.14* for detailed information.

J.6 | Synchrophasors
Settings for IEEE C37.118 Protocol Synchrophasors

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 914 of 1080
Wolfe

PMAPP

Selects the type of digital filters used in the synchrophasor algorithm:

➤ The Narrow Bandwidth setting (N) represents filters with a cutoff frequency approximately ¼ of MRATE. The response in the frequency domain is narrower, and response in the time domain is slower. This method results in synchrophasor data that are free of aliasing signals and well suited for post-disturbance analysis.

➤ The Fast Response setting (F) represents filters with a higher cutoff frequency. The response in frequency domain is wider and the response in the time domain is faster. This method results in synchrophasor data that can be used in synchrophasor applications requiring more speed in tracking system parameters.

PHCOMP

Enables or disables frequency-based compensation for synchrophasors.

For most applications, set PHCOMP := Y to activate the algorithm that compensates for the magnitude and angle errors of synchrophasors for frequencies that are off nominal. Use PHCOMP := N if you are concentrating the SEL-651R-2 synchrophasor data with other PMU data that do not employ frequency compensation.

PMSTN and PMID

NOTE: The PMSTN setting is not the same as the SEL-651R-2 Group setting TID (Terminal Identifier), even though they share the same factory-default value.

Defines the name and number of the PMU.

The PMSTN setting is an ASCII string with as many as 16 characters. The PMID setting is a numeric value. Use your utility or synchrophasor data concentrator naming convention to determine these settings.

PHVOLT, PHDATAV, VYCOMP, and VZCOMP

PHVOLT selects which voltage terminal(s) data the Phasor Data Set setting (PHDATAV) applies to and can be set to Y, Z, or ALL. PHDATAV selects which voltage synchrophasors to include in the data packet. Consider the burden on your synchrophasor processor and offline storage requirements when deciding how much data to transmit. PHVOLT and PHDATAV are two of seven settings that determine the minimum port SPEED necessary to support the synchrophasor data packet rate and size. See *Communications Bandwidth for C37.118 Protocol on page J.14* for detailed information. The following examples are for PHVOLT set to ALL. If PHVOLT were set to Y or Z, only the VY or VZ terminal voltages would be included in the data packet.

NOTE: Global setting EPHANT has no effect on synchrophasors.

NOTE: For SEL-651R-2 models with LEA inputs, the VnYPAC and VnZPAC settings (where n = 1, 2, or 3) are used to compensate for phase angle shifts in the measurement path (see Voltage Phase Angle Correction Settings for VY- and VZ-Terminal Voltage Inputs (Global Settings) on page 9.36). In this case, the VYCOMP and VZCOMP settings do not need to be used to compensate for such phase angle shifts.

➤ PHDATAV := V1 will transmit only positive-sequence voltages, V1Y and V1Z.

➤ PHDATAV := PH will transmit VAY, VBY, VCY, VAZ, VBZ, and VCZ.

➤ PHDATAV := ALL will transmit V1Y, V1Z, VAY, VBY, VCY, VAZ, VBZ, and VCZ.

➤ PHDATAV := NA will not transmit any voltages.

Table J.3 describes the order of synchrophasors inside the data packet.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 915 of 1080

Synchrophasors J.7
Settings for IEEE C37.118 Protocol Synchrophasors
Wolfe

The VYCOMP and VZCOMP settings allow correction for any steady-state voltage phase errors (from the potential transformers or wiring characteristics). VYCOMP corrects the Y terminal voltages for phase angle error. VZCOMP corrects the Z terminal voltages for phase angle error. See *Synchrophasor Measurement on page J.2* for details on this setting.

PHDATAI, IPCOMP, and INCOMP

PHDATAI selects which current synchrophasors to include in the data packet. Consider the burden on your synchrophasor processor and offline storage requirements when deciding how much data to transmit. This setting is one of seven settings that determine the minimum port SPEED necessary to support the synchrophasor data packet rate and size. See *Communications Bandwidth for C37.118 Protocol on page J.14* for detailed information.

➤ PHDATAI := I1 will transmit only positive-sequence current, I1

➤ PHDATAI := PH will transmit IA, IB, and IC

➤ PHDATAI := ALL will transmit I1, IA, IB, IC, and IN

➤ PHDATAI := NA will not transmit any currents

The IPCOMP and INCOMP settings allow correction for any steady-state phase errors (from the current transformers or wiring characteristics). See *Synchrophasor Measurement on page J.2* for details on these settings.

Table J.3 describes the order of synchrophasors inside the data packet. Synchrophasors are transmitted in the order indicated from the top to the bottom of the table. When PHFMT := R, real values are transmitted first and imaginary values are transmitted second. When PHFMT := P, magnitude values are transmitted first and angle values are transmitted second. Synchrophasors are only transmitted if specified to be included by the PHVOLT, PHDATAV, and PHDATAI settings. For example, if PHVOLT := Y, PHDATAV := ALL, and PHDATAI := I1, Y-terminal phase voltages will be transmitted first, followed by positive-sequence current and Y-terminal positive-sequence voltage.

Table J.3   Synchrophasor Order in Data Stream (Voltages and Currents)

Synchrophasors[a]	Scaling[b]	When Enabled[c]
Phase A Current	CTR	PHDATAI := PH or ALL
Phase B Current	CTR	PHDATAI := PH or ALL
Phase C Current	CTR	PHDATAI := PH or ALL
Neutral Current	CTRN	PHDATAI := ALL
Phase A Voltage Y Terminal	PTRY	PHVOLT has Y and PHDATAV := PH or ALL
Phase B Voltage Y Terminal	PTRY	PHVOLT has Y and PHDATAV := PH or ALL
Phase C Voltage Y Terminal	PTRY	PHVOLT has Y and PHDATAV := PH or ALL
Phase A Voltage Z Terminal	PTRZ	PHVOLT has Z and PHDATAV := PH or ALL
Phase B Voltage Z Terminal	PTRZ	PHVOLT has Z and PHDATAV := PH or ALL
Phase C Voltage Z Terminal	PTRZ	PHVOLT has Z and PHDATAV := PH or ALL
Positive-Sequence Current	CTR	PHDATAI := I1 or ALL
Positive-Sequence Voltage Y Terminal	PTRY	PHVOLT has Y and PHDATAV := V1 or ALL
Positive-Sequence Voltage Z Terminal	PTRZ	PHVOLT has Z and PHDATAV := V1 or ALL

[a] Synchrophasors are included in the order shown (for example phase currents, if selected, will always precede phase voltage).

[b] Synchrophasors are transmitted as primary values. Relay settings CTR, CTRN, PTRY, PTRZ are used to scale the values as shown.

J.8 | Synchrophasors

c Settings conditions that enable the synchrophasor data.

PHNR

Selects the numeric representation of voltage and current phasor data in the synchrophasor data stream.

This setting is one of seven settings that determine the minimum port SPEED necessary to support the synchrophasor data packet rate and size. See *Communications Bandwidth for C37.118 Protocol on page J.14* for detailed information.

The choices for this setting depend on synchrophasor processor requirements.

Setting PHNR := I sends each voltage and/or current synchrophasor as 2 two-byte integer values.

Setting PHNR := F sends each voltage and/or current synchrophasor as 2 four-byte floating-point values.

PHFMT

Selects the phasor representation of voltage and current phasor data in the synchrophasor data stream.

The choices for this setting depend on synchrophasor processor requirements.

Setting PHFMT := R (rectangular) sends each voltage or current synchrophasor as a pair of signed real and imaginary values.

Setting PHFMT := P (polar) sends each voltage or current synchrophasor as a magnitude and angle pair. The angle is in radians when PHNR := F, and in radians • 10^4 when PHNR := I. The range is as follows:

$$-\pi < \text{angle} \leq \pi.$$

In both the rectangular and polar representations, the values are scaled in rms (root-mean-square) units. For example, a synchrophasor with a magnitude of 1.0 at an angle of –30 degrees will have a real component of 0.866 and an imaginary component of –0.500. See *Synchrophasor Measurement on page J.2* for an example of conversion between polar and rectangular coordinates.

FNR

Selects the numeric representation of the two frequency values in the synchrophasor data stream.

This setting is one of seven settings that determine the minimum port SPEED necessary to support the synchrophasor data packet rate and size. See *Communications Bandwidth for C37.118 Protocol on page J.14* for detailed information.

The choices for this setting depend on synchrophasor processor requirements.

Setting FNR := I sends the frequency data as a difference from nominal frequency, NFREQ, with the following formula:

$$(\text{FREQ}_{\text{measured}} - \text{NFREQ}) \cdot 1000,$$

represented as a signed, two-byte value.

Setting FNR := I also sends the rate-of-change-of-frequency data with scaling.

$$DFDT_{measured} \cdot 100,$$

represented as a signed, two-byte value.

Setting FNR := F sends the measured frequency data and rate-of-change of frequency as two four-byte, floating-point values.

NUMDSW

Selects the number of user-definable digital status words to be included in the synchrophasor data stream.

This setting is one of seven settings that determine the minimum port SPEED necessary to support the synchrophasor data packet rate and size. See *Communications Bandwidth for C37.118 Protocol on page J.14* for detailed information.

The choices for this setting depend on the synchrophasor system design. The inclusion of digital data can help indicate breaker status or other operational data to the synchrophasor processor. For example, because VZ terminal Phase A synchrophasors are IEEE C37.118 Level 1 compliant only when the frequency is the same as the VY terminal Phase A voltage, it may be desirable to monitor breaker position to indicate when there might be a frequency difference. See *IEEE C37.118 PMU Setting Example on page J.18* for a suggested use of the digital status word fields.

Setting NUMDSW := 0 sends no user-definable digital status words.

Setting NUMDSW := 1 sends the user-definable digital status words containing Relay Word bits SV49–SV64.

Setting NUMDSW := 2 sends the user-definable digital status words containing Relay Word bits SV33–SV64.

Setting NUMDSW := 3 sends the user-definable digital status words containing Relay Word bits SV17–SV64.

Setting NUMDSW := 4 sends the user-definable digital status words containing Relay Word bits SV1–SV64.

The digital status words are sent last in the synchrophasor data packet starting with SV49–SV64.

TREA1, TREA2, TREA3, TREA4, and PMTRIG

NOTE: The PM Trigger function is not associated with the SEL-651R-2 Event Report Trigger ER, a SELOGIC control equation in Report settings.

Defines the programmable trigger bits as allowed by IEEE C37.118.

Each of the four Trigger Reason settings, TREA1–TREA4, and the PMU Trigger setting, PMTRIG, are SELOGIC control equations in Logic settings. The SEL-651R-2 evaluates these equations and places the results in Relay Word bits with the same names: TREA1–TREA4 and PMTRIG.

The trigger reason equations represent the Trigger Reason bits in the STAT field of the data packet. After the trigger reason bits are set to convey a message, the PMTRIG Equation should be asserted for a reasonable amount of time, to allow the synchrophasor processor to read the TREA1–TREA4 fields.

The IEEE C37.118 standard defines the first eight of 16 binary combinations of these trigger reason bits (bits 0–3). The remaining eight binary combinations are available for user definition.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 918 of 1080
Wolfe

J.10 | Synchrophasors
Serial Port Settings for IEEE C37.118 Synchrophasors

The SEL-651R-2 does not automatically set the TREA1–TREA4 or PMTRIG Relay Word bits—these bits must be programmed even for the eight combinations defined by IEEE C37.118.

These bits may be used to send various messages at a low bandwidth via the synchrophasor message stream. Digital Status Words may also be used to send binary information directly, without the need to manage the coding of the trigger reason messages in SELOGIC.

Use these Trigger Reason bits if your synchrophasor system design requires these bits. The SEL-651R-2 synchrophasor processing and protocol transmission are not affected by the status of these bits.

Serial Port Settings for IEEE C37.118 Synchrophasors

IEEE C37.118 compliant synchrophasors are available via serial or Ethernet port. The associated serial port settings are shown in *Table J.4*.

Table J.4   SEL-651R-2 Serial Port Settings for Synchrophasors

Setting	Description	Default
EPORT	Enable Port (Y, N)	Y[a]
PROTO	Protocol (SEL, DNP, MOD, MBA, MBB, MB8A, MB8B, PMU)[b]	SEL[c]
SPEED	Data Speed (300 to 57600)	9600
STOP	Stop Bits (1, 2)	1
RTSCTS[d]	Enable Hardware Handshaking (Y, N)	N
FASTOP	Fast Operate Enabled (Y, N)[e]	N

[a] Set EPORT := Y to access the remaining settings.
[b] Some of the other PROTO setting choices may not be available.
[c] Set PROTO := PMU to enable C37.118 synchrophasor protocol on this port.
[d] The RTSCTS setting is not available on Port 1.
[e] See Synchrophasor Protocols and SEL Fast Operate Commands on page J.25.

The serial port settings for PROTO := PMU, shown in *Table J.4*, do not include the settings BITS and PARITY; these two settings are internally fixed as BITS = 8, PARITY = N.

Serial port setting PROTO cannot be set to PMU (see *Table J.4*) when Global setting EPMU := N. Synchrophasors must be enabled (EPMU := Y) before PROTO can be set to PMU. If the PROTO setting for any serial port is PMU, EMPU cannot be set to N.

If you use a computer terminal session or ACSELERATOR QuickSet SEL-5030 Software connected to a serial port, and then set that same serial port PROTO setting to PMU, you will lose the ability to communicate with the relay through ASCII commands. If this happens, either connect via another serial port (that has PROTO := SEL) or use the front-panel HMI SET/SHOW screen to change the port PROTO setting back to SEL.

Ethernet Port Settings for IEEE C37.118 Synchrophasors

IEEE C37.118 compliant synchrophasors are available via serial or Ethernet port. The associated Ethernet port settings are shown in *Table J.5*.

Two PMU Ethernet Output sessions are available, except when IEC 61850 is enabled. When Port 5 setting E61850 := Y, only one PMU Ethernet output can be used.

Table J.5   SEL-651R-2 Ethernet Port Settings for Synchrophasors

Setting	Description	Default
EPMIP[a]	Enable PMU Processing (Y,N)	N[b]
PMOTS1	PMU Output 1 Transport Scheme (OFF, TCP, UDP_S, UDP_T, UDP_U)	OFF
PMOIPA1	PMU Output 1 Client IP (Remote) Address (www.xxx.yyy.zzz)	192.168.1.3
PMOTCP1	PMU Output 1 TCP/IP (Local) Port Number (1–65534)	4712
PMOUDP1	PMU Output 1 UDP/IP Data (Remote) Port Number (1–65534)	4713
PMOTS2[c]	PMU Output 2 Transport Scheme (OFF, TCP, UDP_S, UDP_T, UDP_U)	OFF
PMOIPA2[c]	PMU Output 2 Client IP (Remote) Address (www.xxx.yyy.zzz)	192.168.1.4
PMOTCP2[c]	PMU Output 2 TCP/IP (Local) Port Number (1–65534)	4722
PMOUDP2[c]	PMU Output 2 UDP/IP Data (Remote) Port Number (1–65534)	4713

[a] Setting is hidden when EPMU := N.
[b] Set EPMIP := Y to access other settings and to enable IEEE C37.118 protocol synchrophasors on this port. Setting EPMIP is not available when Global setting EPMU is set to N. EPMU cannot be set to N if EPMIP := Y on any Ethernet port.
[c] PMU Output 2 settings are not available when IEC 61850 functions are enabled.

Descriptions for some of the settings in *Table J.5* are as follows.

EPMIP.   Setting this to Y enables synchrophasor data transmission over Ethernet port. Setting this to N disables the synchrophasor data transmission over Ethernet port.

Ethernet port setting EPMIP cannot be set to Y (see *Table J.5*) when Global setting EPMU := N. Synchrophasors must be enabled (EPMU := Y) before EPMIP can be set to Y. If EPMIP := Y for any Ethernet port, EPMU cannot be set to N.

PMOTS[1,2].   Selects the PMU Output transport scheme for Session 1 and 2, respectively.

> ➤ PMOTS[1,2] := TCP establishes a single, persistent TCP socket for transmitting and receiving synchrophasor messages (both commands and data), as illustrated in *Figure J.5*.

C37.118 Synchrophasor Protocol
Wolfe

C37.118 Synchrophasor Protocol

The SEL-651R-2 complies with *IEEE C37.118, Standard for Synchrophasors for Power Systems*.

The protocol is available on serial ports 1, 2, 3, and F by setting the corresponding Port setting PROTO := PMU. The protocol is available on any Ethernet port when EPMIP := Y.

This subsection does not cover the details of the protocol, but highlights some of the important features and options that are available.

Settings Affect Message Contents

The SEL-651R-2 allows several options for transmitting synchrophasor data. These are controlled by Global settings described in *Settings for IEEE C37.118 Protocol Synchrophasors on page J.4*. You can select how often to transmit the synchrophasor messages (MRATE), which synchrophasors to transmit (PHVOLT, PHDATAV and PHDATAI), which numeric representation to use (PHNR), and which coordinate system to use (PHFMT).

The SEL-651R-2 automatically includes the frequency and rate-of-change of frequency in the synchrophasor messages. Global setting FNR selects the numeric format to use for these two quantities.

The relay can include as many as 64 digital status values, as controlled by Global setting NUMDSW.

The SEL-651R-2 always includes the results of four synchrophasor Trigger Reason SELOGIC control equations TREA1, TREA2, TREA3, and TREA4, and the trigger SELOGIC control equation result PMTRIG, in the synchrophasor message. *Table J.6* shows the contents of the SEL-651R-2 Data Frame.

Table J.6   C37.118 Data Frame (Sheet 1 of 2)

Field	Size (Bytes)	Description

SYNC	2	Bits 15 to 8—0xAA
		Bit 7—Reserved Always set to 0
		Bits 6 to 4—Frame identifier
		  000 for data frames
		  001 for header frames
		  010 for configuration 1 frames
		  011 for configuration 2 frames
		  100 for command frames
		Bits 3 to 0—Version of synchrophasor spec, set to 001

FRAMESIZE	2	Number of bytes in frame, 16 bit unsigned integer
IDCODE	2	PMID setting, 16 bit unsigned integer
SOC	4	Time stamp, 32 bit unsigned second of century from January 1, 1970
FRACSEC	4	Bit 31—Reserved. Always set to 0 Bit 30—Leap second direction, 0 for add, 1 for delete Bit 29—Leap second occurred. Set on the falling edge of leap second pending bit (LPSECP) if TIRIG = 1. Once set, Bit 29 remains set for 24 hours. Bit 28—Leap second pending. Follows LPSECP Bits 27 to 24—Time quality flags. TQUAL1 through TQUAL4 Bits 23 to 0—Fractions of a second 16777215*Message index for current second/MRATE

DFREQ	2 or 4	Rate-of-change of frequency*100 if FNR=INT, Rate-of-change of frequency if FNR=FLOAT
ANALOG	0	No analog data are transmitted
DIGITAL	0 or 2	2 * NUMDSW
CHK	2	

Communications Bandwidth for C37.118 Protocol

A phasor measurement unit (PMU) that is configured to transmit a single synchrophasor (positive-sequence voltage, for example) at a message rate of once per second places little burden on the communications channel. As more synchrophasors or digital status words are added, or if the message rate is increased, some communications channel restrictions come into play.

If the SPEED setting on any serial port set with PROTO := PMU is insufficient for the PMU Global settings, the SEL-651R-2 or SEL-5030 software will display an error message and fail to save settings until the error is corrected.

The C37.118 synchrophasor message format always includes 18 bytes for the message header and terminal ID, time information, and status bits. The selection of synchrophasor data, numeric format, and programmable digital data will add to the byte requirements. *Table J.7* can be used to calculate the number of bytes in a synchrophasor message.

NOTE: There are no limitations placed on the number of bytes in the synchrophasor message and the message rate if only the Ethernet port is enabled for synchrophasors.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 923 of 1080
Synchrophasors J.15
C37.118 Synchrophasor Protocol
Wolfe

Table J.7   Size of a C37.118 Synchrophasor Message

Item	Possible Number of Quantities	Bytes per Quantity	Minimum Number of Bytes	Maximum Number of Bytes
Fixed			18	18
Synchrophasors	0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 11, 12, or 13	4 {PHNR := I} 8 {PHNR := F}	0	104
Frequency	2 (fixed)	2 {FNR := I} 4 {FNR := F}	4	8
Digital Status Words	0–4	2	0	8
Total (Minimum and Maximum)			22	138

Table J.8 lists the bps settings available on any SEL-651R-2 serial port (setting SPEED) and the maximum message size that can fit within the port bandwidth. Blank entries indicate bandwidths of less than 20 bytes.

Table J.8   Serial Port Bandwidth for Synchrophasors (in Bytes)

Global Setting MRATE	Port Setting SPEED							
	300	1200	2400	4800	9600	19200	38400	57600
1	25	103	207	414	829	1658	3316	4974
2		51	103	207	414	829	1658	2487
4 (60 Hz only)		25	51	103	207	414	829	1243
5		20	41	82	165	331	663	994
10			20	41	82	165	331	497
12 (60 Hz only)				34	69	138	276	414
15 (60 Hz only)				27	55	110	221	331
20 (60 Hz only)				20	41	82	165	248
25 (50 Hz only)					33	66	132	198
30 (60 Hz only)					27	55	110	165
50 (50 Hz only)						33	66	99
60 (60 Hz only)						27	55	82

Referring to *Table J.7* and *Table J.8*, it is clear that the lower SPEED settings are very restrictive.

The smallest practical synchrophasor message would be comprised of one synchrophasor and this message would consume between 26 and 34 bytes, depending on the numeric format settings. This type of message could be sent at any message rate (MRATE) when SPEED := 38400 or 57600, as high as MRATE := 50 or 30 when SPEED := 19200, and as high as MRATE := 25 or 20 when SPEED := 9600.

Another example application has messages comprised of 13 synchrophasors and four digital status words. This type of message would consume between 82 and 138 bytes, depending on the numeric format settings. The 82-byte version, using integer numeric representation, could be sent at as high as MRATE := 50 or 60 when SPEED := 57600. The 138-byte version, using floating-point numeric representation, could be sent at as high as MRATE := 25 or 30 when SPEED := 57600, as high as MRATE := 10 or 20 when SPEED := 38400, and as high as MRATE := 10 or 12 when SPEED := 19200.

Page 924 of 1080
Wolfe

Protocol Operation

The SEL-651R-2 will only transmit synchrophasor messages over serial ports that have setting PROTO := PMU. The connected device will typically be a synchrophasor processor, such as the SEL-3373. The synchrophasor processor controls the PMU functions of the SEL-651R-2 with IEEE C37.118 commands, including commands to start and stop synchrophasor data transmission, and commands to request a configuration block from the relay, so the synchrophasor processor can automatically build a database structure.

Transmit Mode Control

The SEL-651R-2 will not begin transmitting synchrophasors until an enable message is received from the synchrophasor processor. The relay will stop synchrophasor transmission when the appropriate command is received from the synchrophasor processor. The SEL-651R-2 can also indicate when a configuration change occurs, so the synchrophasor processor can request a new configuration block and keep its database up-to-date.

The SEL-651R-2 will only respond to configuration block request messages when it is in the nontransmitting mode.

Independent Ports

Each serial port with the PROTO := PMU setting is independently configured and enabled for synchrophasor commands. The ports are not required to have the same SPEED setting, although the slowest SPEED setting on a PROTO := PMU port will affect the maximum Global MRATE setting that can be used.

Synchrophasor Relay Word Bits

Table J.9 and *Table J.10* list the SEL-651R-2 Relay Word bits that are related to synchrophasor measurement.

The Synchrophasor Trigger Relay Word bits in *Table J.9* follow the state of the SELOGIC control equations of the same name, listed in *Table J.2*. These Relay Word bits are included in the IEEE C37.118 synchrophasor data frame STAT field. See *Table J.3* for standard definitions for these settings.

Table J.9   Synchrophasor Trigger Relay Word Bits

Name	Description
PMTRIG	Trigger (SELOGIC Equation)
TREA4	Trigger Reason Bit 4 (SELOGIC Equation)

Synchrophasors ➤ J.17
View Synchrophasors by Using the MET PM Command

Table J.10   Time-Synchronization Relay Word Bits

Name	Description
TIRIG	Asserts while relay time is based on IRIG-B time source.
TSOK	Time synchronization OK. Asserts while time is based on high-accuracy IRIG-B time source of sufficient accuracy for synchrophasor measurement.
IRIGOK	IRIG time source signal detected (= TIRIG OR TSOK).
PMDOK	Phasor measurement data OK. Asserts when the SEL-651R-2 is enabled, synchrophasors are enabled (Global setting EPMU := Y), the frequency calculated by the synchrophasor algorithm is within the frequency tracking range of the recloser control, and the positive-sequence voltage (for Y or Z Terminal, based on Global setting FSELECT) is greater than 10 V secondary. A few seconds may be required for PMDOK to assert when the relay is first powered, after any of the settings in *Table J.1* are changed, or when an IRIG-B time signal is first connected.

View Synchrophasors by Using the MET PM Command

The **MET PM** serial port ASCII command may be used to view the SEL-651R-2 synchrophasor measurements. See *MET Command (Metering Data) on page 10.57* for general information on the **MET** command.

There are multiple ways to use the **MET PM** command:

➤ As a test tool, to verify connections, phase rotation, and scaling.

➤ As an analytical tool, to capture synchrophasor data at an exact time to compare this information with similar data captured in other phasor measurement unit(s) at the same time.

➤ As a method of periodically gathering synchrophasor data through a communications processor.

The **MET PM** command displays the same set of analog synchrophasor information, regardless of the Global settings PHVOLT, PHDATAV and PHDATAI. The **MET PM** command can function even when no ports are sending synchrophasor data.

The **MET PM** command only displays data when the Relay Word bit TSOK = logical 1. *Figure J.8* shows a sample **MET PM** command response. The synchrophasor data are also available in the QuickSet HMI and have a similar format to *Figure J.8*.

The **MET PM** *time* command can be used to direct the SEL-651R-2 to display the synchrophasor for an exact specified time, in 24-hour format. For example, entering the command **MET PM 14:14:12** will result in a response similar to *Figure J.8* occurring just after 14:14:12, with the time stamp 14:14:12.000.

This method of data capture always reports from the exact second, even if the time parameter is entered with fractional seconds. For example, entering **MET PM 14:14:12.200** results in the same data capture as **MET PM 14:14:12**, because the relay ignored the fractional seconds.

Page 926 of 1080
Wolfe

See *MET PM (Synchrophasor Metering) on page 10.62* for complete command options and error messages.

MET PM HIS recalls the most recently triggered synchrophasor meter report. This is useful when synchrophasor data from multiple relays must be captured on a single PC. For example, connect to each relay and issue the **MET PM 14:14:00** command. At 14:14, each relay will issue a response similar to *Figure J.8*. After 14:14, connect to each relay, issue the **MET PM HIS** command, and capture the results. Because **MET PM HIS** recalls the last MET PM report, the data captured from every relay will be from the same time. Values displayed reflect present relay settings, not settings in effect at the time of the original **MET PM** command.

Figure J.8   Sample MET PM Command Response

IEEE C37.118 PMU Setting Example

A utility is upgrading its distribution system to use reclosers with the SEL-651R-2 recloser control. The utility also wants to install phasor measurement units (PMUs) at each recloser to collect data to monitor voltages and currents throughout the system.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Synchrophasors J.19
Page 927 of 1080
IEEE C37.118 Settings Example
Wolfe

The PMU data collection requirements call for the following data, collected at 10 messages per second:

➤ Frequency

➤ Positive-sequence voltage from the source side of the recloser

➤ Three-phase, positive-sequence, and neutral current

➤ Indication when the breaker is open

➤ Indication when the voltage or frequency information is unusable

The utility is able to meet the requirements with the SEL-651R-2 recloser controls, an SEL-2407 Satellite-Synchronized Clock, and an SEL-3373 Station Phasor Data Concentrator in each substation communicating to the recloser controls with SEL-3031 Serial Radio transceivers.

This example will cover the PMU settings in one of the SEL-651R-2 recloser controls.

Some system details:

➤ The nominal frequency is 60 Hz.

➤ The source PTs and wiring have a phase error of 1.20 degrees (lagging) at 60 Hz.

➤ The recloser CTs and wiring have a phase error of 1.50 degrees (lagging) at 60 Hz.

➤ The neutral CT of the recloser control is fed the summation of the phase CTs, so its phase error will be 1.50 degrees (lagging) at 60 Hz as well.

➤ The synchrophasor data will be using port 3, and the maximum bps allowed is 19200.

➤ The system designer specified floating-point numeric representation for the synchrophasor data, and rectangular coordinates.

➤ The system designer specified integer numeric representation for the frequency data.

➤ The system designer specified synchrophasor response, because the data are being used for system monitoring.

The protection settings will not be shown.

Determining Settings

The protection engineer performs a bandwidth check by using *Table J.7*, and determines the required message size. The system requirements, in order of appearance in *Table J.7*, are:

➤ 6 synchrophasors, in floating-point representation

➤ Integer representation for the frequency data

➤ 3 digital status bits, which require one status word

The message size is $18 + 6 \cdot 8 + 2 \cdot 2 + 1 \cdot 2 = 72$ bytes. Using *Table J.8*, the engineer verifies that the port bps of 19200 is adequate for the message, at 10 messages per second.

Setting	Description	Value
EPORT	Enable Port (Y, N)	Y
PROTO	Protocol (SEL, DNP, MBA, MBB, RTD, PMU)	PMU
SPEED	Data Speed (300 to 57600)	19200
STOP	Stop Bits (1, 2 bits)	1
RTSCTS	Enable Hardware Handshaking (Y, N)	N
FASTOP	Fast Operate Enabled (Y, N)	

Configuring High-Accuracy Timekeeping

The SEL-651R-2 features high-accuracy timekeeping when supplied with an IRIG-B signal. When the supplied clock signal is sufficiently accurate, the SEL-651R-2 can act as a phasor measurement unit (PMU) and transmit synchrophasor data representative of the power system at fixed time periods to an external data processor. The relay can also record event report data by using the high-accuracy time stamp (see *Synchrophasor-Level Accuracy in Event Reports on page 12.31*).

IRIG Standard 200-04 defines many different types of time code formats. IRIG-B002, or "standard IRIG-B" provides time data once per second. The time data are formatted as second of the minute, minute of the hour, hour of the day, and day of the year. IRIG-B000, or extended IRIG-B, adds control functions that are defined based on the application. In this manual, IRIG-B000 is used to identify a time signal containing the control functions defined by IEEE C37.118 Standard for Synchrophasors for Power Systems. These control functions include the year, leap second and daylight saving time information, UTC offset, time quality indicator codes, and a parity bit.

IRIG-B

The SEL-651R-2 has two input connectors that accept IRIG-B demodulated time-code format: the IRIG-B pins of Serial Port 2 and the IRIG-B BNC connector.

The IRIG-B connections can be used for high-accuracy timekeeping purposes, with as high as 1 μs accuracy with an appropriate time source. Either input can also be used for general-purpose timekeeping with as high as 5 ms accuracy. See *Table J.15* for SEL-651R-2 timekeeping mode details.

J.22 | Synchrophasors
Configuring High-Accuracy Timekeeping

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 930 of 1080
Wolfe

Table J.15   SEL-651R-2 Timekeeping Modes

Item	Internal Clock	Normal Accuracy IRIG	Holdover	High-Accuracy IRIG
Best accuracy (condition)	Depends on last method of setting, plus internal clock drift[a]	5 ms (when IRIG-B signal not meeting requirements for high-accuracy IRIG is connected)		1 μs (when time source jitter is less than 500 ns and time-error is less than 1 μs)[b]
IRIG-B Connection Required	None	BNC connector (preferred), or Serial Port 2		BNC connector (preferred) or Serial Port 2
Relay Word bits	TIRIG = logical 0 TSOK = logical 0 IRIGOK = logical 0	TIRIG = logical 1 TSOK = logical 0 IRIGOK = logical 1	TIRIG = logical 0 TSOK = logical 1 IRIGOK = logical 1	TIRIG = logical 1 TSOK = logical 1 IRIGOK = logical 1

[a] The SEL-651R-2 internal clock can be synchronized via SNTP, DNP3, SEL-2030 Communications Processor, SEL-3530 RTAC, or ASCII TIM command.

[b] The time-error check only applies when Global setting IRIGC := C37.118.

NOTE: If the time-code signal connected to the BNC connector degrades in quality, the SEL-651R-2 will not switch over to the IRIG-B pins of Serial Port 2. The SEL-651R-2 will only switch to Serial Port 2 if the signal on the BNC connector completely fails (e.g., the cable is un-plugged). Use the TIME Q command to determine which IRIG-B source is in use.

Only one IRIG-B time source can be used by the SEL-651R-2. The relay uses IRIG-B signals from the two sources with the following priority:

➤ BNC input

➤ Serial Port 2 IRIG-B pins

The SEL-651R-2 determines the suitability of the IRIG-B signal for Normal Accuracy IRIG by applying several tests:

➤ Seconds, minutes, and day field is in range

➤ Time from two consecutive messages differ by 1 second, except for leap second or daylight saving time transitions.

➤ When IRIGC=C37.118, the signal contains the correct parity bit.

The SEL-651R-2 determines the suitability of the IRIG-B signal for high-accuracy timekeeping by applying two additional tests:

➤ The jitter between positive transitions (rising edges) of the clock signal is less than 500 ns.

➤ The time-error information contained in the IRIG-B control field indicates time error is less than 10^{-6} seconds (1 μs).

NOTE: Set IRIGC = C37.118 only when an IRIG-B000 signal is connected to the relay. Set IRIGC = NONE when an IRIG-B002 (standard IRIG) signal is connected.

When IRIGC := C37.118, the SEL-651R-2 will assert Relay Word bit TSOK only when these two tests are met. When IRIGC := NONE, the relay will assert TSOK when only the first test is met.

The relay accepts C37.118 (IRIG-B000) signals with either odd or even parity. When an IRIG-B signal is connected, the relay detects whether the signal has odd or even parity and continues to check received IRIG-B messages for that parity. If a message is received with the opposite parity or no parity, the signal fails the parity test.

If your clock has programmable parity and the parity is changed, the relay disqualifies the IRIG-B signal for a few seconds until it detects that the parity change is not a result of corrupt messages.

If the relay is in high-accuracy mode and either of the two tests fails, the relay enters holdover mode. When in holdover, the relay asserts TSOK, deasserts TIRIG, and holds Relay Word bits TQUAL1, TQUAL2, TQUAL3, and TQUAL4 at their last state. The relay remains in holdover mode for as long as 15 seconds, and then reverts to high-accuracy IRIG, normal-accuracy IRIG, or internal clock, depending on conditions.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 931 of 1080
Synchrophasors J.23
Configuring High-Accuracy Timekeeping
Wolfe

If you connect two IRIG-B sources, they should be of the same format (IRIG-B000 with C37.118 control extensions or IRIG-B002) and match the IRIGC setting. SEL does not recommend connecting different types of signals to different inputs (for example, an IRIG-B000 signal to the BNC input and an IRIG-B002 signal to Port **1** or Port **2**) when IRIGC=C37.118. The IRIG-B002 signal provides neither the year nor the parity bit required for Normal Accuracy mode when IRIGC=C37.118. In this case, if the IRIG-B000 source fails, relay timekeeping reverts to the internal clock, but the relay year changes to 2000 and remain incorrect until the IRIG-B000 signal returns. The relay will update the time from the IRIG-B002 signal about once every 10 seconds, if the signal passes the remaining two tests for Normal Accuracy mode. Relay Word bit TIRIG asserts momentarily during the update.

Table J.16   Time and Date Management

Label	Prompt	Default Value
IRIGC[a]	IRIG-B Control Bits Definition (None, C37.118)	None

[a] When EPMU := Y, IRIGC is forced to C37.118.

A time quality value is determined based on the four-bit Time Quality indicator code defined in the IEEE C37.118 standard. When Global setting IRIGC := C37.118, the raw time quality information from the IRIG-B signal is placed into four Relay Word bits TQUAL1, TQUAL2, TQUAL3, and TQUAL4. For example, if TQAUL1 := 1, TQUAL2 := 0, TQUAL3 := 1, and TQUAL4 := 0, the binary time quality indicator code received from the clock via the IRIG signal is 0101, which corresponds to 10 microseconds time error. See *Table J.17* for time quality decoding. The time quality is shown in the MET PM report beside the label `Time Quality Maximum time synchronization error:` viewed with the **MET PM** command, and in the **TIM Q** command.

Table J.17   Time Quality Decoding

TQUAL	Time Quality	TQUAL	Time Quality
0000	Locked	1000	10 milliseconds
0001	1 nanosecond	1001	100 milliseconds
0010	10 nanoseconds	1010	1 second
0011	100 nanoseconds	1011	10 seconds
0100	1 microsecond	1100	100 seconds
0101	10 microseconds	1101	1000 seconds
0110	100 microseconds	1110	10,000 seconds
0111	1 millisecond	1111	Fault

When IRIGC := C37.118, the relay also decodes Leap Second Pending, Leap Second Direction, Daylight Savings Pending, and Daylight Saving control bits that are present in the IRIG-B signal. The status of these control bits is reflected in Relay Word bits LPSECP, LPSEC, DSTP, and DST, respectively.

When IRIGC := NONE, the TQUAL1, TQUAL2, TQUAL3, TQUAL4, LPSECP, LPSEC, DSTP, and DST Relay Word bits are not updated. When Global setting EPMU := Y, IRIGC is forced to C37.118.

Connecting High-Accuracy Timekeeping

The procedure in the following steps assumes that you have a modern high-accuracy GPS receiver with a BNC connector output for an IRIG-B signal. Use a communications terminal to send commands and receive data from the relay.

This example assumes that you have successfully established communication with the relay. In addition, you must be familiar with relay access levels and passwords.

Step 1. Confirm that the relay is operating.

Step 2. Prepare to control the relay at Access Level 2.

a. Using a communications terminal, type **ACC <Enter>**.

b. Type the Access Level 1 password and press **<Enter>**.

You will see the Access Level 1 => prompt.

Step 3. Connect the cable.

Attach the IRIG-B signal with a BNC-to-BNC coaxial jumper cable from the GPS receiver IRIG-B output to the SEL-651R-2 **IRIG-B** BNC connector.

Step 4. Confirm/Enable automatic detection of high-accuracy timekeeping.

a. Wait at least 20 seconds for the SEL-651R-2 to acquire the clock signal, and then, at a communications terminal, type **TAR TIRIG <Enter>**

The relay will return one row from the Relay Word, as shown in *Figure J.9*. Only the states of the TIRIG and TSOK Relay Word bits are discussed in the troubleshooting steps below.

```
=>TAR TIRIG <Enter>

TSOK     TIRIG    PMDOK    PMTRIG   TREA4    TREA3    TREA2    TREA1
1        1        1        0        0        0        0        0
=>
```

Figure J.9   Confirming the High-Accuracy Timekeeping Relay Word Bits

b. The TIRIG and TSOK Relay Word bits should be asserted (logical 1), indicating that the relay is in the high-accuracy IRIG timekeeping mode.

If TSOK is not asserted, but TIRIG is asserted, the relay is in regular IRIG timekeeping mode. The **TIME Q** command shows which IRIG-B source is in use and the time quality. Here is a list of possible reasons for not entering high-accuracy mode:

➢ Global setting IRIGC := C37.118, but the IRIG-B clock does not use the IEEE C37.118 Control Bit assignments.

➢ The IRIG-B signal jitter is too high.

➢ The termination resistor, required by some IRIG clocks, is not installed.

➢ Global setting IRIGC := C37.118, but the time-source clock is reporting that its time error is greater than 1 μs.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 933 of 1080
Synchrophasors J.25
Synchrophasor Protocols and SEL Fast Operate Commands
Wolfe

If neither TSOK nor TIRIG are asserted, the relay is not in an IRIG time-source mode. Here is a list of possible reasons for not entering IRIG mode:

➢ The IRIG-B clock signal is not of sufficient accuracy or is improperly configured.

➢ The termination resistor, required by some IRIG clocks, is not installed.

➢ The time source clock is not connected to an antenna.

Synchrophasor Protocols and SEL Fast Operate Commands

The SEL-651R-2 can be configured to process SEL Fast Operate commands received on serial ports that have Port setting PROTO := PMU, when the Port setting FASTOP := Y.

This functionality can allow a host device to initiate control actions in the PMU without the need for a separate communications interface.

If port setting FASTOP := Y on a serial port set to PROTO := PMU, the SEL-651R-2 will provide Fast Operate support. The host device can request a Fast Operate Configuration Block when the relay is in the nontransmitting mode, and the relay will respond with the message, which includes codes that define the circuit breaker and remote bit control points that are available via Fast Operate commands.

The SEL-651R-2 will process Fast Operate requests regardless of whether synchrophasors are being transmitted, as long as serial port setting FASTOP := Y. When FASTOP := N, the relay will ignore Fast Operate commands. Use the FASTOP := N option to lock out any control actions from that serial port if required by your company operating practices.

The SEL-651R-2 does not acknowledge received Fast Operate commands, but it is easy to program one or more Relay Word bits to observe the controlled function. For example, a Fast Operate Circuit Breaker close command could be confirmed by monitoring the breaker status bit 52A3P by assigning SELOGIC setting SV32 := 52A3P.

Note that only the Fast Operate function is available on ports set to PROTO := PMU. The protocols SEL Fast Meter and SEL Fast SER are unavailable on PROTO := PMU ports.

Appendix K

Modbus RTU and TCP Communications

Overview

This appendix describes Modbus RTU and TCP communications features supported by the SEL-651R-2 Recloser Control. Complete specifications for the Modbus protocol are available from the Modbus user's group website at www.modbus.org.

The SEL-651R-2 allows as many as three simultaneous Modbus sessions. The number of Ethernet Modbus sessions is limited by the number of enabled Ethernet DNP sessions (see *Session Limits on page 10.14*).

The SEL-651R-2 Modbus communication allows a Modbus master device to do the following:

➤ Acquire metering, monitoring, and event data from the relay.

➤ Control SEL-651R-2 output contacts and remote bits.

➤ Read and switch the Active Settings Group.

➤ Read and set the time and date.

➤ Reset targets, demand and peak data, energy data, breaker monitor, min/max, and event history data.

Enable Modbus TCP protocol with the Ethernet port setting EMODBUS. The master IP address for each session is selected with the Ethernet port settings MODIP1, MODIP2, and MODIP3. The Master IP address 0.0.0.0 is a valid entry and is used to accept a connection from any master. Use caution when using this address as any Modbus master may connect to the Ethernet port through this connection. When a Modbus TCP master attempts to connect, the relay will first search the valid master IP addresses. If no matching Modbus master IP address is found and one of the MODIP*x* addresses is 0.0.0.0, the master will be allowed to connect through that connection. The TCP port number is the Modbus TCP registered port 502. Modbus TCP uses the device IP address as the Modbus identifier and accesses the data in the relay through use of the same function codes and data maps as Modbus RTU.

Modbus RTU is a binary protocol that permits communication among a single master device and multiple slave devices. The communication is half duplex—only one device transmits at a time. The master transmits a binary command that includes the address of the desired slave device. All of the slave devices receive the message, but only the slave device with the matching address responds. Enable Modbus RTU protocol with the serial port PROTO = MOD setting.

K.2 | Modbus RTU and TCP Communications
Communications Protocol

Communications Protocol

Modbus RTU Queries

Modbus master devices initiate all exchanges by sending a query. The query format for Modbus RTU consists of the fields shown in *Table K.1*.

Table K.1 Modbus Query Fields

Field	Number of Bytes
Slave Device Address	1 byte
Function Code	1 byte
Data Region	0–251 bytes
Cyclic Redundancy Check (CRC)	2 bytes

The SEL-651R-2 serial port SLAVEID setting defines the device address. Set this value to a unique number for each device on the Modbus network. For Modbus RTU communication to operate properly, no two slave devices may have the same address.

The cyclic redundancy check detects errors in the received data. If an error is detected, the relay discards the packet.

Modbus TCP Queries

The Modbus request or response is encapsulated when carried on a Modbus TCP/IP network. A dedicated header used on TCP/IP identifies the Modbus Application Data Unit (ADU). The header, called the Modbus Application Protocol header (MBAP), contains the following fields:

Field	Number of Bytes
Transaction Identifier	2 Bytes
Protocol Identifier	2 Bytes (0 = MODBUS protocol)
Length	2 Bytes
Unit Identifier	1 Byte

The Modbus TCP Message consists of the MBAP Header, followed by the Modbus function code and the data supporting the function code. The Modbus TCP message does not contain the 2-byte CRC that is included in the RTU message, as the error checking is accomplished through TCP. Otherwise, the data following the MBAP header are identical to the Modbus RTU message.

The remainder of this section will cover the Modbus Function codes in terms of the Modbus RTU protocol.

Modbus Responses

The slave device sends a response message after it performs the action the query specifies. If the slave cannot execute the query command for any reason, it sends an error response. Otherwise, the slave device response is formatted similarly to the query and includes the slave address, function code, data (if applicable), and a cyclic redundancy check value.

Supported Modbus Function Codes

The SEL-651R-2 supports the Modbus function codes shown in *Table K.2*.

Modbus RTU and TCP Communications K.3
Communications Protocol

Table K.2   SEL-651R-2 Modbus Function Codes

Codes	Description
01h	Read Discrete Output Coil Status
02h	Read Discrete Input Status
03h	Read Holding Registers
04h	Read Input Registers
05h	Force Single Coil
06h	Preset Single Register
08h	Diagnostic Command
10h	Preset Multiple Registers

Modbus Exception Responses

The SEL-651R-2 sends an exception code under the conditions described in *Table K.3*.

Table K.3   SEL-651R-2 Modbus Exception Codes

Exception Code	Error Type	Description
1	Illegal Function Code	The received function code is either undefined or unsupported.
2	Illegal Data Address	The received command contains an unsupported address in the data field.
3	Illegal Data Value	The received command contains a value that is out of range.
4	Device Error	The SEL-651R-2 is in the wrong state for the function a query specifies.
		The relay is unable to perform the action specified by a query (i.e., cannot write to a read-only register, device is disabled, etc.).
6	Busy	The device is unable to process the command at this time because of a busy resource.

In the event that any of the errors listed in *Table K.3* occur, the relay assembles a response message that includes the exception code in the data field. The relay sets the most significant bit in the function code field to indicate to the master that the data field contains an error code, instead of the required data.

Cyclic Redundancy Check

The SEL-651R-2 calculates a 2-byte CRC value by using the device address, function code, and data region (see *Table K.1*). It appends this value to the end of every Modbus RTU response. When the master device receives the response, it recalculates the CRC. If the calculated CRC matches the CRC sent by the SEL-651R-2, the master device uses the data received. If there is no match, the check fails and the message is ignored. The devices use a similar process when the master sends queries.

01h Read Discrete Output Coil Status Command

Use function code 01h to read the On/Off status of the selected bits (coils) (see the Output Coils table shown in *Table K.14*). The SEL-651R-2 coil addresses start at 0. The coil status is packed one coil per bit of the data field. The least significant bit (LSB) of the first data byte contains the starting coil address in the query. The other coils follow towards the high order end of this byte and from low order to high order in subsequent bytes.

K.4 | Modbus RTU and TCP Communications
Communications Protocol

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 938 of 1080
Wolfe

Table K.4   01h Read Discrete Output Coil Status Command

Bytes	Field
Requests from the master must have the following format:	
1 byte	Slave Address
1 byte	Function Code (01h)
2 bytes	Address of the first bit
2 bytes	Number of bits to read
2 bytes	CRC-16
A successful response from the slave will have the following format:	
1 byte	Slave Address
1 byte	Function Code (01h)
1 byte	Bytes of data (*n*)
n bytes	Data
2 bytes	CRC-16

To build the response, the SEL-651R-2 calculates the number of bytes required to contain the number of bits requested. If the number of bits requested is not evenly divisible by eight, the device adds one more byte to maintain the balance of bits, padded by zeros to make an even byte. *Table K.14* includes the coil number and lists all possible coils (identified as Outputs and Remote bits) available in the device.

The relay responses to errors in the query are shown in *Table K.5*.

Table K.5   Responses to 01h Read Discrete Output Coil Query Errors

Error	Error Code Returned	Communication Counter Increments
Invalid bit to read	Illegal Data Address (02h)	Invalid Address
Invalid number of bits to read	Illegal Data Value (03h)	Illegal Register
Format error	Illegal Data Value (03h)	Bad Packet Format

02h Read Input Status Command

Use function code 02h to read the On/Off status of the selected bits (inputs), as shown in *Table K.7*. Input addresses start at 0. The input status is packed one input per bit of the data field. The LSB of the first data byte contains the starting input address in the query. The other inputs follow towards the high order end of this byte, and from low order to high order in subsequent bytes.

Table K.6   02h Read Input Status Command (Sheet 1 of 2)

Bytes	Field
Requests from the master must have the following format:	
1 byte	Slave Address
1 byte	Function Code (02h)
2 bytes	Address of the first bit
2 bytes	Number of bits to read
2 bytes	CRC-16

Modbus RTU and TCP Communications
Communications Protocol

K.5

Table K.6 02h Read Input Status Command (Sheet 2 of 2)

Bytes	Field
A successful response from the slave will have the following format:	
1 byte	Slave Address
1 byte	Function Code (02h)
1 byte	Bytes of data (*n*)
n bytes	Data
2 bytes	CRC-16

To build the response, the device calculates the number of bytes required to contain the number of bits requested. If the number of bits requested is not evenly divisible by eight, the device adds one more byte to maintain the balance of bits, padded by zeros to make an even byte.

In each row, the input numbers are assigned from the right-most input to the left-most input (i.e., input address 0 is TLED18 and input address 7 is TLED11). Input addresses start at 0000. *Table K.7* includes the input address in decimal and hexadecimal and lists all possible inputs (Relay Word bits) available in the device.

Table K.7 02h SEL-651R-2 Inputs[a] (Sheet 1 of 5)

[a] See Appendix F: Relay Word Bits for relay element row numbers and definitions.

The relay responses to errors in the query are shown in *Table K.8*.

Table K.8   Responses to 02h Read Input Query Errors

Error	Error Code Returned	Communication Counter Increments
Invalid bit to read	Illegal Data Address (02h)	Invalid Address
Invalid number of bits to read	Illegal Data Value (03h)	Illegal Register
Format error	Illegal Data Value (03h)	Bad Packet Format

03h Read Holding Register Command

Use function code 03h to read directly from the Modbus Register Map shown in *Table K.23*. Use the **SET M** command (see *User-Defined Modbus Data Region and SET M Command on page K.19*) to configure the map with the register label names shown in *Table K.22*. You can read a maximum of 125 registers at once with this function code.

Table K.9   03h Read Holding Register Command (Sheet 1 of 2)

Bytes	Field
Requests from the master must have the following format:	
1 byte	Slave Address
1 byte	Function Code (03h)
2 bytes	Starting Register Address
2 bytes	Number of Registers to Read
2 bytes	CRC-16
A successful response from the slave will have the following format:	
1 byte	Slave Address
1 byte	Function Code (03h)
1 byte	Bytes of data (*n*)

Illegal register to read	Illegal Data Address (02h)	Invalid Address
Illegal number of registers to read	Illegal Data Value (03h)	Illegal Register
Format error	Illegal Data Value (03h)	Bad Packet Format

04h Read Input Register Command

Use function code 04h to read directly from the Modbus Register Map shown in *Table K.23*. Use the **SET M** command (see *User-Defined Modbus Data Region and SET M Command on page K.19*) to configure the map with the register label names shown in *Table K.22*. You can read a maximum of 125 registers at once with this function code.

Table K.11   04h Read Input Register Command

Bytes	Field
Requests from the master must have the following format:	
1 byte	Slave Address
1 byte	Function Code (04h)
2 bytes	Starting Register Address
2 bytes	Number of Registers to Read
2 bytes	CRC-16
A successful response from the slave will have the following format:	
1 byte	Slave Address
1 byte	Function Code (04h)
1 byte	Bytes of data (*n*)
n bytes	Data (2–250)
2 bytes	CRC-16

The relay responses to errors in the query are shown in *Table K.12*.

Table K.12   Responses to 04h Read Input Register Query Errors

Error	Error Code Returned	Communication Counter Increments
Illegal register to read	Illegal Data Address (02h)	Invalid Address
Illegal number of registers to read	Illegal Data Value (03h)	Illegal Register
Format error	Illegal Data Value (03h)	Bad Packet Format

05h Force Single Coil Command

Use function code 05h to set or clear a coil. The command response is identical to the command request shown in *Table K.13*.

Table K.13   05h Force Single Coil Command

Bytes	Field
Requests from the master must have the following format:	
1 byte	Slave Address
1 byte	Function Code (05h)
2 bytes	Coil Reference
1 byte	Operation Code (FF for bit set, 00 for bit clear)
1 byte	Placeholder (00)
2 bytes	CRC-16

Table K.14 lists the coil numbers supported by the SEL-651R-2. The physical coils (coils 00–13) are self-resetting. Pulsing a Set remote bit (decimal address 80–111) causes the remote bit to be cleared at the end of the pulse.

Table K.14   01h, 05h SEL-651R-2 Output Coils (Sheet 1 of 7)

Coil Address in Decimal	Coil Address in Hex	Function Code Supported	Coil Description	Coil Function	Duration	Notes

Modbus RTU and TCP Communications K.17
Communications Protocol

Table K.14   01h, 05h SEL-651R-2 Output Coils (Sheet 7 of 7)

Coil Address in Decimal	Coil Address in Hex	Function Code Supported	Coil Description	Coil Function	Duration	Notes
134	86	1, 5	Reserved			
135	87	1, 5	Reserved			

ᵃ Output coil pulsing of physical coils is intended only for low-level testing when the recloser control is out of service. For permanent control, use a remote bit in the appropriate SELᴏɢɪᴄ control equation.

Coil addresses start at 0000. If a function code 05 operation to coils 116 (OC3), 117 (CC3), 118 (OCA), 119 (CCA), 120 (OCB), 121 (CCB), 122 (OCC), or 123 (CCC) is attempted and the breaker jumper is not installed, the device will respond with Error Code 6. If the device is disabled, a function code 05 to any coil will respond with Error Code 4 (Device Error). In addition to Error Code 4, the device responses to errors in the query are shown in *Table K.15*.

Table K.15   Responses to 05h Force Single Coil Query Errors

Error	Error Code Returned	Communication Counter Increments
Invalid bit (coil)	Illegal Data Address (02h)	Invalid Address
Invalid bit state requested	Illegal Data Value (03h)	Illegal Register
Format Error	Illegal Data Value (03h)	Bad Packet Format

06h Preset Single Register Command

The SEL-651R-2 uses this function to allow a Modbus master to write directly to a database register. Refer to the Modbus Quantities Table in *Table K.22* for a list of registers that can be written by using this function code.

The command response is identical to the command request shown in *Table K.16*.

Table K.16   06h Preset Single Register Command

Bytes	Field
Queries from the master must have the following format:	
1 byte	Slave Address
1 byte	Function Code (06h)
2 bytes	Register Address
2 bytes	Data
2 bytes	CRC-16

The relay responses to errors in the query are shown in *Table K.17*.

Table K.17   Responses to 06h Preset Single Register Query Errors

Error	Error Code Returned	Communication Counter Increments
Illegal register address	Illegal Data Address (02h)	Invalid Address Illegal Write
Illegal register value	Illegal Data Value (03h)	Illegal Write
Format error	Illegal Data Value (03h)	Bad Packet Format

08h Loopback Diagnostic Command

The SEL-651R-2 uses this function to allow a Modbus master to perform a diagnostic test on the Modbus communications channel and relay. When the subfunction field is 0000h, the relay returns a replica of the received message.

Table K.18   08h Loopback Diagnostic Command

Bytes	Field
Requests from the master must have the following format:	
1 byte	Slave Address
1 byte	Function Code (08h)
2 bytes	Subfunction (0000h)
2 bytes	Data Field
2 bytes	CRC-16
A successful response from the slave will have the following format:	
1 byte	Slave Address
1 byte	Function Code (08h)
2 bytes	Subfunction (0000h)
2 bytes	Data Field (identical to data in Master request)
2 bytes	CRC-16

The relay responses to errors in the query are shown in *Table K.19*.

Table K.19   Responses to 08h Loopback Diagnostic Query Errors

Error	Error Code Returned	Communication Counter Increments
Illegal subfunction code	Illegal Data Value (03h)	Illegal Function Code/Op Code
Format error	Illegal Data Value (03h)	Bad Packet Format

10h Preset Multiple Registers Command

This function code works much like code 06h, except that it allows you to write multiple registers at once.

Table K.20   10h Preset Multiple Registers Command (Sheet 1 of 2)

Bytes	Field
Queries from the master must have the following format:	
1 byte	Slave Address
1 byte	Function Code (10h)
2 bytes	Starting Address
2 bytes	Number of Registers to Write
1 byte	Number of Bytes of Data (*n*)
n bytes	Data
2 bytes	CRC-16
A successful response from the slave will have the following format:	
1 byte	Slave Address
1 byte	Function Code (10h)
2 bytes	Starting Address

K.19

Table K.20 10h Preset Multiple Registers Command (Sheet 2 of 2)

Bytes	Field
2 bytes	Number of Registers
2 bytes	CRC-16

The relay responses to errors in the query are shown below.

Table K.21 10h Preset Multiple Registers Query Error Messages

Error	Error Code Returned	Communication Counter Increments
Illegal register to set	Illegal Data Address (02h)	Invalid Address Illegal Write
Illegal number of registers to set	Illegal Data Value (03h)	Illegal Register Illegal Write
Incorrect number of bytes in query data region	Illegal Data Value (03h)	Bad Packet Format Illegal Write
Invalid register data value	Illegal Data Value (03h)	Illegal Write

Bit Operations Using Function Codes 06h and 10h

The SEL-651R-2 includes registers for controlling some of the outputs. See LOG_CMD and RSTDAT in *Table K.22*. Use Modbus function codes 06h or 10h to write appropriate flags. Remember that when writing to the Logic command register with output contacts, it is not a bit operation. All the bits in that register need to be written together to reflect the state you want for each of the outputs.

User-Defined Modbus Data Region and SET M Command

The SEL-651R-2 Modbus Register Map defines an area of 250 contiguous addresses whose contents are defined by user-settable labels. This feature allows you to take 250 discrete values from anywhere in the Modbus Quantities Table (see *Table K.22*) and place them in contiguous registers that you can then read in a single command. Use the SEL ASCII command **SET M** (or the Modbus User Map settings in ACSELERATOR QuickSet SEL-5030 software) to define the user map addresses. A default map is provided with the relay. If the default Modbus map is not appropriate or more data are desired, edit the map as required for your application.

To use the user-defined data region, follow the steps listed below.

Step 1. Define the list of desired quantities (as many as 250). Arrange the quantities in any order that is convenient for you to use.

Step 2. Refer to *Table K.22* for a list of the Modbus labels for each quantity.

Step 3. Use the **SET M** command from the command line or QuickSet Modbus User Map to map user registers 001 to 250 (MOD_001 to MOD_250) using the labels in *Table K.22*.

Step 4. Use Modbus function code 03h or 04h to read the desired quantities from addresses 0–249 (decimal).

Note that the Modbus addresses begin with zero, which corresponds to Set M setting MOD_001.

As each label is entered in a register via the **SET M** command, the relay will increment to the next valid register.

K.20 | Modbus RTU and TCP Communications
Communications Protocol

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 954 of 1080
Wolfe

If a label is entered for a 32-bit quantity register (e.g., VAY, VBY, VCY, KW3), the relay will automatically skip a register in the sequence because two registers are required for the 32-bit quantity. The register with the lower index is the most significant word and the register with the higher index is the least significant word in the 32-bit quantity. In the following example, MOD_015 was previously set to 3I2, which is a 16-bit value and consumes one register. By changing the register label to KW3, a 32-bit value, the next register shown available for setting is MOD_017.

```
=>>SET M MOD_015 <Enter>

Modbus Map, Section 1:
USER REG#015
MOD_015 := 3I2
       ? KW3

USER REG#017
MOD_017 := VAY
      ?

USER REG#019
MOD_019 := VAYFA
       ?
=>>
```

Similarly, in this example, MOD_017 was previously set to VAY, which is a 32-bit value and consumes two registers. By changing the register label to IA, a 16-bit value, the next register shown available for setting is MOD_018. Because MOD_018 was previously not available, as it was the second register used for MOD_017 (VAY), there is no label assigned to it and it shows NA.

```
=>>SET M MOD_017 <Enter>

Modbus Map, Section 1:
USER REG#017
MOD_017 := VAY
      ? IA

USER REG#018
MOD_018 := NA
      ? IAFA

USER REG#019
MOD_019 := VAYFA
      ? IB
=>>
```

5- or 6-Digit Master Addresses

If your master uses 5- or 6-digit address references, add the appropriate number to the Modbus data register address, provided in *Table K.23*, when configuring your master. For example, if your master uses 5-digit addressing, add 40001 for holding register operations. For input register functions, add 30001. If your master uses 6-digit addressing, add 400001 for holding register operations or 300001 for input register functions. The actual address that appears in the address field of the message will be the address shown in *Table K.23*. For example, MOD_001 is address 0000 (see *Table K.23* for Modbus register addresses). A master using 6-digit addresses to read a holding register may be configured for address 400001. However, the data address field of the message from the master will contain address 0000.

Table K.22   Modbus Quantities Table (Sheet 18 of 18)

Description	Valid Function Codes	SET_M Point Label/ Enums[a]	Number of 16-Bit Registers[b]	Min Value	Max Value	Scaling (X1 unless specified)
ROW 133	03, 04	ROW_133	1	0	255	
ROW 134	03, 04	ROW_134	1	0	255	
ROW 135	03, 04	ROW_135	1	0	255	

[a] Point names appearing in bold may only be assigned to a single register in the User Map. If an attempt is made to assign one of these points to multiple registers, the relay will respond with the error message, `Value may only appear in the map once`.

[b] For quantities using two 16-bit registers, the register with the lower index is the most significant word and the register with the higher index is the least significant word in the 32-bit quantity.

[c] If the fault location is undefined, Modbus will report the value as 32767.

[d] FTARLO represents the status of the Target LEDs T01LED–T16LED. The lower 8 bits of FTARHI represent the status of Target LEDs T17LED–T24LED. The upper 8 bits of FTARHI are unused.

[e] Breaker Close and Breaker Open are mutually exclusive and the relay asserts neither bit and returns the Exception Response if an attempt is made to write both bits.

[f] Minimum values that have been reset report the largest positive value possible. Maximum values that have been reset report the largest negative value possible.

[g] Where nn represents the 2nd through the 16th harmonics.

[h] See Battery Status on page 8.43 for Battery Charger Mode definitions.

[i] The active settings group can be modified by writing the desired settings group number to ACTGRP. If a logic setting has been programmed to control the active settings group, the write will be accepted but the active group will not change.

Table K.23   Default Modbus Map (Sheet 1 of 2)

1017–1032		TID	Value of setting TID, two characters per register[a]
1033–65535		Reserved	

[a] Register labels appearing in bold are 32-bit quantities and consume two registers.

[b] Modbus Addresses 1001–1032 contain string data. Strings are packed 2 characters per register, with the most significant bit containing the character closest to the beginning of the string.

Reading Event Data Via Modbus

The SEL-651R-2 provides a feature that allows relay event history data to be retrieved via Modbus. The Event History registers are listed in *Table K.22* under the Historical Data description heading. To read the history data, set the Modbus Map to contain the EVESEL label, along with the other Fault History related labels. The following example shows some of the available history data labels in the Modbus Map:

```
=>> SHO M <Enter>

MOD_001 = NUMEVE
MOD_002 = EVESEL
MOD_003 = FTIME_S
MOD_004 = FTIME_M
MOD_005 = FTIME_H
MOD_006 = FDATE_D
MOD_007 = FDATE_M
MOD_008 = FDATE_Y
MOD_009 = FLOC
MOD_010 = FI
MOD_011 = FIA
MOD_012 = FIB
MOD_013 = FIC
MOD_014 = FIG
MOD_015 = FIQ
MOD_016 = FFREQ
MOD_017 = FGRP
MOD_018 = FSHO
MOD_019 = EVE_TYPE
```

K.40 | Modbus RTU and TCP Communications
Communications Protocol

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 974 of 1080
Wolfe

Use Modbus function code 03 or 04 to read the Modbus registers. The NUMEVE label will contain the number of events listed in the event history, **HIS** command, and response. To read event history data via Modbus, use function code 06 to write the event number to the Modbus register containing the EVESEL label. The SEL-651R-2 will populate the other event related registers with the data relayed to the event number specified in the EVESEL label address. Issue a Modbus function code 03 or 04 command to read the registers containing the history data.

For example, consider the following **HIS** command:

```
=>> HIS <Enter>

SEL-651R-2                          Date: 10/30/2015  Time: 23:17:03.346
FEEDER 1                            Time Source: internal

#    DATE       TIME       EVENT LOCAT  CURR FREQ GST          TARGETS
                                                  RHR    COLUMN 1      COLUMN 2
1  10/25/2015 12:52:44.876 CA     2.26 3024 60.0 131 111000001000 001000000000
2  10/25/2015 11:12:16.812 AB T   0.10 4168 60.0 131 111100001000 001100000000
3  10/25/2015 11:05:26.805 AB T   0.10 4078 60.0 131 111100001000 001100000000
```

To retrieve the history data for Event number 2 in this example, set register address 0001 to the value of 2 by using a function code 06 command. (Note that the Modbus Map is indexed beginning with 1, which corresponds to register address 0 in Modbus.) If a value is written to the EVESEL register for an event that does not currently exist in the history data, the SEL-651R-2 will respond with an exception code 03.

Following the function code 06 command, issue a function code 03 or 04 command to read registers that follow (e.g., MOD_003 = FTIME_S through MOD_019 = EVE_TYPE in the preceding example map). The data returned contain the event time, event date, fault location, maximum fault current, fault current per phase, ground fault current, negative-sequence fault current, frequency, settings group, number of shots, and event type associated with Event number 2.

The relay can report the EVE_TYPE value as a composite of the numbers listed in Event Type under *Historical Data* in *Table K.22*. For example, a CAG T event type shall have an EVE_TYPE analog value of 77 (CAG + Trip). Likewise, a CAG event triggered by a Relay Word bit in the ER equation shall have an EVE_TYPE analog value of 141 (CAG + ER).

The **HIS E** command returns the same history data, but uses a unique event number in the range of 10000–65535. The SEL-651R-2 will also return the history data if the unique event number (e.g., 10008) is written to the EVESEL register as long as that event is currently in the history data.

```
=>> HIS E <Enter>

SEL-651R-2                           Date: 10/30/2015  Time: 23:17:03.346
FEEDER 1                             Time Source: internal

#        DATE       TIME       EVENT LOCAT  CURR FREQ GST          TARGETS
                                                      RHR    COLUMN 1      COLUMN 2
10007  10/25/2015 12:52:44.876 CA     2.26 3024 60.0 131 111000001000 001000000000
10008  10/25/2015 11:12:16.812 AB T   0.10 4168 60.0 131 111100001000 001100000000
10009  10/25/2015 11:05:26.805 AB T   0.10 4078 60.0 131 111100001000 001100000000
```

If the history data are cleared (either from the **HIS C** command or a remote control point), the value in the NUMEVE register is changed to 0. This indicates that there are no events listed in the event history. The Modbus fault data registers may still contain data from a past event until a new valid event number is written to the EVESEL register.

Appendix L

IEC 61850

Features

The SEL-651R-2 supports the following features using Ethernet and IEC 61850:

➤ **SCADA**—Connect as many as seven simultaneous IEC 61850 MMS client sessions. The SEL-651R-2 also supports as many as seven buffered and seven unbuffered report control blocks. See the CON Logical Device Table for Logical Node mapping that enables SCADA control via a Manufacturing Messaging Specification (MMS) browser. Controls support the direct control, select before operate control (SBO), and SBO with enhanced security control models.

➤ **Peer-to-Peer Real-Time Status and Control**—Use GOOSE with as many as 24 incoming (receive) and 8 outgoing (transmit) messages. Virtual bits (VB001–VB128) can be mapped from incoming GOOSE messages.

➤ **Configuration**—Use FTP client software or ACSELERATOR Architect SEL-5032 Software to transfer the Substation Configuration Language (SCL) Configured IED Description (CID) file to the relay.

➤ **Commissioning and Troubleshooting**—Use software such as MMS Object Explorer and AX-S4 MMS from Sisco, Inc., to browse the relay logical nodes and verify functionality.

This section presents the information you need to use the IEC 61850 features of the SEL-651R-2:

➤ *Introduction to IEC 61850 on page L.1*

➤ *IEC 61850 Operation on page L.3*

➤ *IEC 61850 Configuration on page L.21*

➤ *Logical Nodes on page L.26*

➤ *ACSI Conformance Statements on page L.58*

Introduction to IEC 61850

In the early 1990s, the Electric Power Research Institute (EPRI) and the Institute of Electrical and Electronics Engineers, Inc. (IEEE) began to define a Utility Communications Architecture (UCA). They initially focused on inter-control center and substation-to-control center communications and produced

Wolfe

the Inter-Control Center Communications Protocol (ICCP) specification. This specification, later adopted by the IEC as 60870-6 TASE.2, became the standard protocol for real-time exchange of data between databases.

In 1994, EPRI and IEEE began work on UCA 2.0 for Field Devices (simply referred to as UCA2). In 1997, they combined efforts with Technical Committee 57 of the IEC to create a common international standard. Their joint efforts created the current IEC 61850 standard.

The IEC 61850 standard, a superset of UCA2, contains most of the UCA2 specification, plus additional functionality. The standard describes client/ server and peer-to-peer communications, substation design and configuration, testing, and project standards.

The IEC 61850 standard consists of the parts listed in *Table L.1*.

Table L.1   IEC 61850 Document Set

IEC 61850 Sections	Definitions
IEC 61850-1	Introduction and overview
IEC 61850-2	Glossary
IEC 61850-3	General requirements
IEC 61850-4	System and project management
IEC 61850-5	Communication requirements
IEC 61850-6	Configuration description language for substation IEDs
IEC 61850-7-1	Basic communication structure for substations and feeder equipment—Principles and models
IEC 61850-7-2	Basic communication structure for substations and feeder equipment—Abstract communication service interface (ACSI)
IEC 61850-7-3	Basic communication structure for substations and feeder equipment—Common data classes
IEC 61850-7-4	Basic communication structure for substations and feeder equipment— Compatible logical node (LN) classes and data classes
IEC 61850-8-1	SCSM—Mapping to Manufacturing Messaging Specification (MMS) (ISO/IEC 9506-1 and ISO/IEC 9506-2 over ISO/IEC 8802-3)
IEC 61850-9-1	SCSM—Sampled values over serial multidrop point-to-point link
IEC 61850-9-2	SCSM—Sampled values over ISO/IEC 8802-3
IEC 61850-10	Conformance testing

The IEC 61850 document set, available directly from the IEC at www.iec.ch, contains information necessary for successful implementation of this protocol. SEL strongly recommends that anyone involved with the design, installation, configuration, or maintenance of IEC 61850 systems be familiar with the appropriate sections of this standard.

IEC 61850 Operation

Ethernet Networking

IEC 61850 and Ethernet networking model options are available when ordering a new SEL-651R-2 and may also be available as field upgrades to relays equipped with dual copper and dual or single fiber-optic Ethernet. In addition to IEC 61850, the relay provides support protocols and data exchange, including FTP and Telnet. Access the SEL-651R-2 Port 5 settings to configure all of the Ethernet settings, including IEC 61850 enable settings.

The SEL-651R-2 supports IEC 61850 services, including transport of Logical Node objects, over TCP/IP. The relay can coordinate a maximum of seven concurrent IEC 61850 sessions.

Object Models

The IEC 61850 standard relies heavily on the Abstract Communication Service Interface (ACSI) models to define a set of services and the responses to those services. In terms of network behavior, abstract modeling enables all IEDs to act identically. These abstract models are used to create objects (data items) and services that exist independently of any underlying protocols. These objects are in conformance with the common data class (CDC) specification IEC 61850-7-3, which describes the type and structure of each element within a logical node. CDCs for status, measurements, controllable analogs and statuses, and settings all have unique CDC attributes. Each CDC attribute belongs to a set of functional constraints that groups the attributes into specific categories such as status (ST), description (DC), and substituted value (SV). Functional constraints, CDCs, and CDC attributes are used as building blocks for defining Logical Nodes.

UCA2 used GOMSFE (Generic Object Models for Substation and Feeder Equipment) to present data from station IEDs as a series of objects called models or bricks. The IEC working group has incorporated GOMSFE concepts into the standard, with some modifications to terminology; one change was the renaming of bricks to logical nodes. Each logical node represents a group of data (controls, status, measurements, etc.) associated with a particular function. For example, the MMXU logical node (polyphase measurement unit) contains measurement data and other points associated with three-phase metering including voltages and currents. Each IED may contain many functions such as protection, metering, and control. Multiple logical nodes represent the functions in multifunction devices.

Logical nodes can be organized into logical devices that are similar to directories on a computer disk. As represented in the IEC 61850 network, each physical device can contain many logical devices and each logical device can contain many logical nodes. Many relays, meters, and other IEC 61850 devices contain one primary logical device where all models are organized.

IEC 61850 devices are capable of self-description. You do not need to refer to the specifications for the logical nodes, measurements, and other components to request data from another IEC 61850 device. IEC 61850 clients can request and display a list and description of the data available in an IEC 61850 server device. This process is similar to the autoconfiguration process used within SEL communications processors (SEL-2032 and SEL-2030). Simply run an MMS browser to query devices on an IEC 61850 network and discover what data are available. Self-description also permits extensions to both standard and custom data models. Instead of having to look up data in a profile stored in its database, an IEC 61850 client can simply query an IEC 61850 device and receive a description of all logical devices, logical nodes, and available data.

L.4 | IEC 61850
IEC 61850 Operation

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 986 of 1080
Wolfe

Unlike other Supervisory Control and Data Acquisition (SCADA) protocols that present data as a list of addresses or indices, IEC 61850 presents data with descriptors in a composite notation made up of components. *Table L.2* shows how the A-phase current expressed as METMMXU1AphsA$cVal is broken down into its component parts. The Data Attribute is characterized (filtered) by a functional constraint (FC) property. The supported FCs are listed in *Table L.3*. The FC for the given example above is MX.

Table L.2   Example IEC 61850 Descriptor Components

Component		Description
METMMXU1	Logical Node	Polyphase measurement unit
A	Data Object	Phase-to-ground amperes
phsA	Sub-Data Object	Phase A
cVal	Data Attribute	Complex value

Table L.3   Functional Constraints

FC	Description
ST	Status information
MX	Measurements (analog values)
CO	Control
CF	Configuration
DC	Description
EX	Extended definition

Data Mapping

Device data are mapped to IEC 61850 Logical Nodes (LN) according to rules defined by SEL. Refer to IEC 61850-5:2003(E) and IEC 61850-7-4:2003(E) for the mandatory content and usage of these LNs. The SEL-651R-2 logical nodes are grouped under Logical Devices for organization based on function. See *Table L.4* for descriptions of the Logical Devices in an SEL-651R-2. See *Logical Nodes on page L.26* for a description of the LNs that make up these Logical Devices.

Table L.4   SEL-651R-2 Logical Devices

Logical Device	Description
ANN	Annunciator elements—alarms, status values
CFG	Configuration elements—datasets and report control blocks
CON	Control elements—remote bits
MET	Metering or Measurement elements—currents, voltages, power, etc.
PRO	Protection elements—protection functions and breaker control

MMS

Manufacturing Messaging Specification (MMS) provides services for the application-layer transfer of real-time data within a substation LAN. MMS was developed as a network independent data exchange protocol for industrial networks in the 1980s and standardized as ISO 9506.

In theory, you can map IEC 61850 to any protocol. However, it can become unwieldy and quite complicated to map objects and services to a protocol that only provides access to simple data points via registers or index numbers. MMS supports complex named objects and flexible services that enable

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 1987 of 1080
IEC 61850 Operation
IEC 61850   L.5
Wolfe

mapping to IEC 61850 in a straightforward manner. This was why the UCA users group used MMS for UCA from the start, and why the IEC chose to keep it for IEC 61850.

Event files are also available through MMS. See *File Transfer Protocol (FTP) and MMS File Transfer on page 10.17* and *Retrieving COMTRADE Event Files on page 12.15*. If MMS authentication is enabled, the device will authenticate each MMS association by requiring the client to provide the password authentication parameter with a value that is equal to the 2AC password of the SEL-651R-2.

> ➤ If the correct password authentication parameter value is not received, the device will return a `not authenticated` error code.

> ➤ If the correct password authentication parameter value is received, the device will give a successful association response. The device will allow access to all supported MMS services for that association.

GOOSE

The Generic Object Oriented Substation Event (GOOSE) object within IEC 61850 is for high-speed control messaging. IEC 61850 GOOSE automatically broadcasts messages containing status, controls, and measured values onto the network for use by other devices. IEC 61850 GOOSE sends the message several times, increasing the likelihood that other devices receive the messages. GOOSE message publication is a persistent function. Once GOOSE is enabled, the IED will continuously publish GOOSE messages until they are disabled regardless of the contents. The publication process description indicates when and why the publication rate changes.

IEC 61850 GOOSE objects can quickly and conveniently transfer status, controls, and measured values between peers on an IEC 61850 network. Configure SEL devices to respond to GOOSE messages from other network devices with Architect. Also, configure outgoing GOOSE messages for SEL devices in Architect. See the Architect instruction manual or online help for more information.

Each IEC 61850 GOOSE sender includes a text identification string (GOOSE Control Block Reference), APP ID field, and an Ethernet multicast group address, in each outgoing message. Some devices that receive GOOSE messages use the text identification and multicast group to identify and filter incoming GOOSE messages. The SEL-651R-2 uses only the APP ID and multicast group to identify and filter incoming GOOSE messages.

Virtual bits (VB001–VB128) are control inputs that you can map to GOOSE receive messages by using Architect. If you intend to use any SEL-651R-2 virtual bits for controls, you must create SELOGIC control equations to define these operations.

File Services

The Ethernet File System allows reading or writing data as files. The File System supports FTP and MMS File Transfer. The File System provides:

> ➤ A means for the device to transfer data as files.

> ➤ A hierarchal file structure for the device data.

The SEL-651R-2 supports MMS File transfer with or without authentication. The service is intended to support:

> ➤ CID file download and upload

> ➤ Event report retrieval (from the COMTRADE directory)

L.6 | IEC 61850
| **IEC 61850 Operation**

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 988 of 1080
Wolfe

MMS File Services are enabled or disabled via Port 5 setting EMMSFS. Permissions for the 2AC level apply to MMS File Services requests. All files and directories that are available at Access Level 2 via any supported file transfer mechanism (FTP, file read/write, etc.) are also available for transfer via MMS File Services.

SCL Files

Substation Configuration Language (SCL) is an XML-based configuration language used to support the exchange of database configuration data between different tools, which may come from different manufacturers. There are four types of SCL files:

➤ Intelligent Electronic Device (IED) Capability Description file (.ICD)

➤ System Specification Description (.SSD) file

➤ Substation Configuration Description file (.SCD)

➤ Configured IED Description file (.CID)

The ICD file describes the capabilities of an IED, including information on LN and GOOSE support. The SSD file describes the single-line diagram of the substation and the required LNs. The SCD file contains information on all IEDs, communications configuration data, and a substation description. The CID file, of which there may be several, describes a single instantiated IED within the project, and includes address information.

Datasets

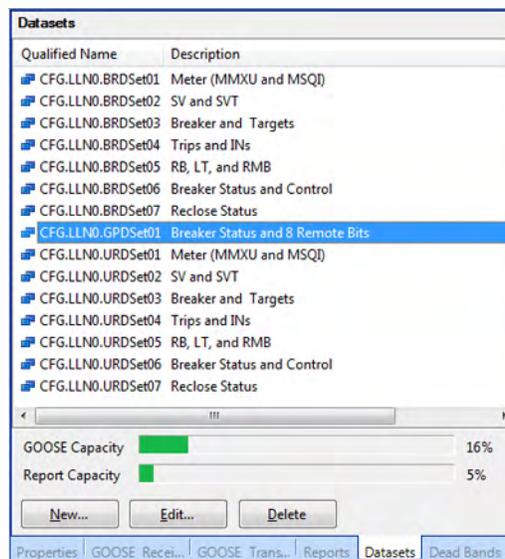
Datasets are configured using Architect and contain data attributes which represent real data values within the SEL-651R-2 device. See *Logical Nodes* for the logical node tables that list the available data attributes for each logical node and the Relay Word bit mapping for these data attributes. The list of datasets in *Figure L.1* are the defaults for a SEL-651R-2 device. Fourteen datasets are preconfigured with common FCDAs to be used for reporting. One dataset is preconfigured for GOOSE. These datasets can be configured to represent the desired data to be monitored.


Figure L.1   SEL-651R-2 Datasets

Case No. 2018-00295

Page 980 of 1080
IEC 61850 Operation
Wolfe

Within Architect, IEC 61850 datasets have the following purposes:

➤ GOOSE: You can use the predefined dataset (GPDSet01), edit existing datasets, or create new datasets for outgoing GOOSE transmission.

➤ Reports: Fourteen predefined datasets (BRDSet01–BRDSet07 and URDSet01–URDSet07) correspond to the default seven buffered and seven unbuffered reports. Note that you cannot change the number (14) or type of reports (buffered or unbuffered) within Architect. However, you can alter the data attributes that a dataset contains and so define what data an IEC 61850 client receives with a report.

➤ MMS: You can use predefined or edited datasets, or you can create new datasets to be monitored by MMS clients.

NOTE: Do not edit the dataset names used in reports. Changing or deleting any of those dataset names will cause a failure in generating the corresponding report.

Reports

The SEL-651R-2 implements the IEC 61850 reporting service as part of its server functionality. The reporting service includes the functionality necessary to configure, manage, and send IEC 61850 buffered and unbuffered reports as unsolicited reports, periodic integrity reports, or as the result of a general interrogation. See the IEC 61850 Standard, Part 7-1, Section 6.4.3.3, Part 7-2, Section 14, and Part 8-1, Section 17 for more details on the IEC 61850 reporting service.

A total of 14 predefined reports (7 buffered and 7 unbuffered) are supported. The predefined reports and the datasets assigned to each report are shown in *Figure L.2* and are available by default via IEC 61850. The number of reports (14), the dataset assigned to each report, and the type of reports (buffered or unbuffered) cannot be changed. However, by using Architect, you can reallocate data within each report dataset to present different data attributes for each report beyond the predefined datasets.

ID	Name	Description	Dataset
URep07	URep07	Predefined Unbuffered Report 07	URDSet07
URep06	URep06	Predefined Unbuffered Report 06	URDSet06

Figure L.2   SEL-651R-2 Predefined Reports

For each buffered report control block (BRCB), there can be just one client association (i.e., only one client can be associated to a BRCB at any given time). The client association occurs when the client enables the RptEna attribute of the BRCB. Once enabled, the associated client has exclusive access to the BRCB until the connection is closed or the client disables the

L.8 | IEC 61850
| **IEC 61850 Operation**

Attachment to Response to AG-2 Question No. 68(g)
Page 990 of 1080
Wolfe

RptEna attribute. Once enabled, all unassociated clients have read only access to the BRCB and the associated client will be the only client that receives buffered report data. The BRCB parameters are shown in *Table L.5*.

Table L.5   Buffered Report Control Block Client Access

RCB Attribute	User Changeable (Report Disabled)	User Changeable (Report Enabled)	Default Values
RptId	YES		BRDSet01–BRDSet07
RptEna	YES	YES	FALSE
OptFlds	YES		seqNum
			timeStamp
			dataSet
			reasonCode
			entryID
BufTm	YES		500
TrgOps	YES		dchg
			qchg
			period
IntgPd	YES		0
GI	YES[a,b]	YES[a]	FALSE
PurgeBuf	YES[a]		FALSE
EntryId	YES		0

[a] Exhibits a pulse behavior. Write a one to issue the command. Once command is accepted will return to zero. Always read as zero.

[b] When disabled, a GI will be processed and the report buffered if a buffer has been previously established. A buffer is established when the report is enabled for the first time.

Once a BRCB has been enabled, a report buffer is established. The buffer is sized to contain 10 complete reports with a size hard coded in the SEL-651R-2 ICD file. However, in cases where the report dataset is smaller than the allowed maximum size, or when the encoded report does not include the entire dataset, as many as 200 reports may appear in the buffer. Reports are maintained in the buffer regardless of having been sent. This allows the client to retrieve reports that have already been sent by writing an EntryID prior to the current EntryID.

When a client sets the RptEna attribute of a BRCB to true, all new reports contained in the report buffer, starting from the buffer entry following the EntryID attribute specified in the BRCB until the most current buffered report, are sent. At this time, new reports will be sent as required by normal report processing. This behavior allows the client to write the last received EntryID to the BRCB before enabling the report in an attempt to retrieve all report entries that were lost during a lapse in the client association.

When insertion of a new report into a report buffer would cause the buffer size to be exceeded, the oldest entries in the buffer are discarded until the buffer size has been reduced sufficiently to allow the new report to be added to the buffer. If the reports removed from the buffer have not yet been sent to the client, a buffer overflow indication is set in the next report queued for transmission to indicate that reports have been lost. The buffer overflow indication is reported in the BufOvfl field of the report if the buffer overflow OptFld has been enabled in the BRCB.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 990 of 1080
Wolfe

IEC 61850
Access and operation
L.9

The contents of a report buffer are deleted when a PurgeBuf is commanded by a client. As noted in the requirements for the BRCB, the PurgeBuf can only be commanded when the report is disabled. The buffer overflow indication shall be cleared when the client commands a PurgeBuf. Additionally, the buffered reports will be purged if any of the BRCB attributes RptID, DatSet, BufTm, TrgOps, or IntgPd are modified by the client while the report is disabled.

For each unbuffered control block (URCB), there can be as many as seven client associations. The client association occurs when the client enables the RptEna attribute of the URCB. Once enabled, each client has independent access to its instance of the URCB and all associated clients receive unbuffered report data. The URCB parameters are shown in *Table L.6*.

Although the URCB Resv attribute is writable, the SEL-651R-2 does not support reservations. Writing any field of the URCB causes the client to obtain their own instance of the URCB—in essence, acquiring a reservation.

Table L.6   Unbuffered Report Control Block Client Access

RCB Attribute	User Changeable (Report Disabled)	User Changeable (Report Enabled)	Default Values
RptId	YES		URDSet01–URDSet07
RptEna	YES	YES	FALSE
Resv	YES		FALSE
OptFlds	YES		seqNum
			timeStamp
			dataSet
			reasonCode
BufTm	YES		250
TrgOps	YES		dchg
			qchg
			period
IntgPd	YES		0
GI		YES[a]	0

[a] Exhibits a pulse behavior. Write a one to issue the command. Once command is accepted will return to zero. Always read as zero.

NOTE: The TrgOp data update is not supported by the SEL-651R-2 device.

The IEC 61850 standard defines the trigger options (TrgOp) of data change, quality change, and data update. These TrgOps allow reports to be filtered to report only changes associated with the selected TrgOps. Additionally, each of these TrgOps is only associated with or valid for certain data attributes. The valid TrgOps for any given data attribute is described in the Common Data Class (CDC) Descriptions contained within the IEC standard, Part 7-3.

When a client has enabled the RptEna attribute of a BRCB or URCB and any of the data change or quality change TrgOps are enabled within the same BRCB or URCB, the SEL-651R-2 sends an unsolicited report to that client upon detecting a change on an FCDA with a reason corresponding to one of the enabled TrgOps. The unsolicited report contains only those FCDAs that have been detected to have changed for a reason corresponding to one of the enabled TrgOps.

When a client has enabled the RptEna attribute of a BRCB or URCB and that same client writes a non-zero value to the GI attribute of the BRCB or URCB, a report is sent to that client containing the current data for all FCDA within the report dataset.

L.10 | IEC 61850
IEC 61850 Operation

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 992 of 1080
Wolfe

When a client has enabled the RptEna attribute and the IntgPd attribute of the BRCB or URCB is set to a non-zero value, and the TrgOps period attribute is enabled, a report is sent to that client containing the current data for all FCDAs within the report dataset upon detecting an expiration of the IntgPd.

FCDA updates are serviced every 500 ms. The client can set the report control block (BRCB or URCB) IntgPd to any value greater than 500 ms with a resolution of 1 ms. However, the integrity report is only sent when the period has been detected as having expired. The new IntgPd will begin at the time that the current report is serviced.

BufTm timers are part of the report control block (BRCB and URCB). The purpose of the BufTm timers is to buffer mutually exclusive data change events over a period of time and send these changes out as one report. Each client that enables an unbuffered report may have a BufTm value independent of other clients that enable the same unbuffered report. This does not apply to buffered reports because only one client can enable a buffered report.

Report data are updated every 500 ms. Setting BufTm less than 500 ms does not result in data changes from multiple scans being buffered into a single report. For a BRCB with a non-zero BufTm attribute, a BufTm timer is started upon receiving notification of the change of a member of a dataset, and all changes received during BufTm are combined into a single report to be buffered and sent at the expiration of BufTm. If a second internal notification of the same member of a dataset has occurred prior to the expiration of BufTm, a report is immediately buffered and sent.

Reports are formatted as specified in the IEC 61850 standard, Part 7-2, Table 24. The report EntryID attribute is incremented each time a report is built.

Supplemental Software

Examine the data structure and values of the supported IEC 61850 LNs with an MMS browser such as MMS Object Explorer and AX-S4 61850 from Sisco, Inc.

The settings needed to browse an SEL-651R-2 with an MMS browser are shown below.

OSI-PSEL (Presentation Selector)	00000001
OSI-SSEL (Session Selector)	0001
OSI-TSEL (Transport Selector)	0001

Time Stamps and Quality

In addition to the various data values, the two attributes q (quality) and t (time stamp) are available at any time. The time stamp is determined when a data or quality change is detected and is UTC reported as the Second of Century since January 1, 1970, plus fractional seconds.

The time stamp is applied to all data and quality attributes (Boolean, Bstrings, Analogs, etc.) in the same fashion when a data or quality change is detected.

Functionally constrained data attributes (FCDA) mapped to points assigned to the SER report have SER-accuracy time stamps for data change events. To ensure that you will get SER-quality timestamps for changes to certain points, you must include those points in the SER report. All other FCDAs are scanned for data changes on a 1/2-second interval and have 1/2-second time-stamp accuracy. See *SET Command (Change Settings) on page 10.67* for information on programming the SER report.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 993 of 1080
Wolfe

IEC 61850 L.11
GOOSE Processing and Performance

The SEL-651R-2 uses GOOSE quality attributes to indicate the quality of the data in its transmitted GOOSE messages. Under normal conditions, all attributes are zero, indicating good quality data. Internal status indicators provide the information necessary for the device to set these attributes. If the device becomes disabled, as shown via status indications (e.g., an internal self-test failure), the SEL-651R-2 will stop transmitting GOOSE messages.

GOOSE Processing and Performance

SEL devices support GOOSE processing as defined by IEC 61850-7-1:2003(E), IEC 61850-7-2:2003(E), and IEC 61850-8-1:2004(E).

Four times per power system cycle, the relay reads inputs, processes protection algorithms, and controls outputs. Each of these quarter-cycle periods is called a processing interval. GOOSE messages are considered inputs and outputs and are processed with the same priority as contact inputs, contact outputs, and protection algorithms. The relay processes incoming GOOSE messages near the beginning of every processing interval just after it reads the contact inputs, and processes outgoing GOOSE messages near the end of every processing interval after it controls the contact outputs.

GOOSE Construction Tips

➤ Quality bit strings published from SEL relays are not generally useful in determining the quality of associated data because the SEL IEDs suspend publication of GOOSE messages if any quality attribute fails. Therefore, receipt of the message indicates that all quality attributes are normal. Do not include quality bit strings in published GOOSE messages unless required by some other type of IED.

➤ Make GOOSE publications as small as possible. Include in the GOOSE publication only the information required by subscribing relays.

➤ Give higher VLAN priority tags to more important GOOSE. This allows the network to preferentially forward those GOOSE to the subscribers, and also gives a subscribing SEL-651R-2 an indication that the more important GOOSE should be decoded before lower priority GOOSE.

➤ The relay supports no more than 128 unique Boolean elements mapped between all GOOSE publications.

GOOSE Construction Example

The dataset shown in *Figure L.3* is used in a GOOSE publication from an SEL-651R. It contains information that is not necessary to a subscribing relay. For example, the dataset contains the Mod, Beh, and Health fields (ANN.OUT1GGIO3.Mod.*, ANN.OUT1GGIO3.Beh.*, and ANN.OUT1GGIO3.Health.*) from the OUT1 logical node. In this case, the information in those fields is of no use to a subscribing relay. Also, each of the two OUT1 statuses contained in the dataset are accompanied by their corresponding quality bit strings and time stamps (ANN.OUTGGIO3.Ind01.q, ANN.OUT1GGIO3.Ind01.t, etc.). If the quality field is included in a GOOSE, then the subscribing device must spend additional processing time decoding that quality bit string and applying it to the associated data.

L.12 IEC 61850
GOOSE Processing and Performance

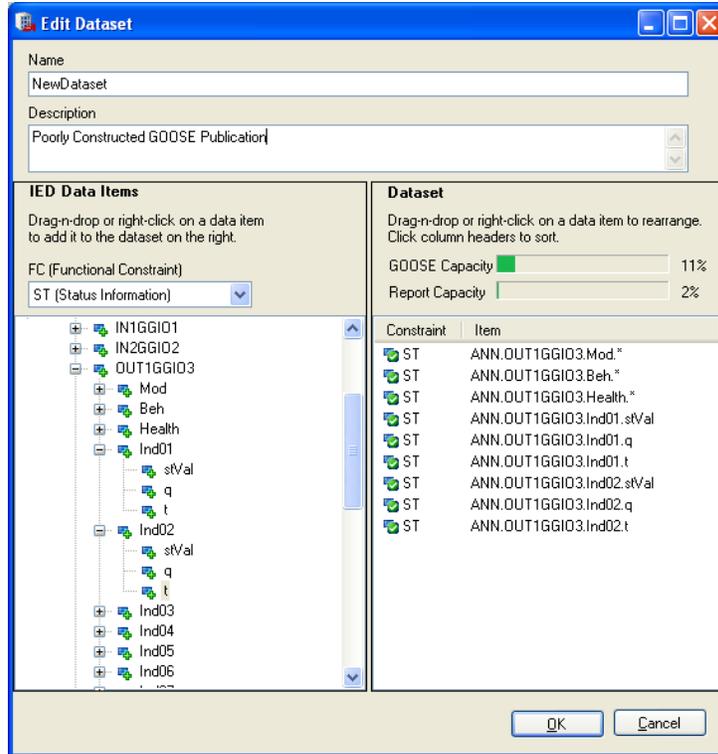
Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 994 of 1080
Wolfe


Figure L.3   Example of a Poorly Constructed GOOSE Dataset

Figure L.4 shows an example of a GOOSE publication from an SEL-651R with better construction. This dataset contains only the information required by the subscribing relay(s) to decode the OUT1 status from the publishing SEL-651R (ANN.OUT1GGIO3.Ind01.stVal and ANN.OUT1GGIO3.Ind02.stVal) and does not include quality bit strings or time stamps.

Page 995 of 1080
Wolfe

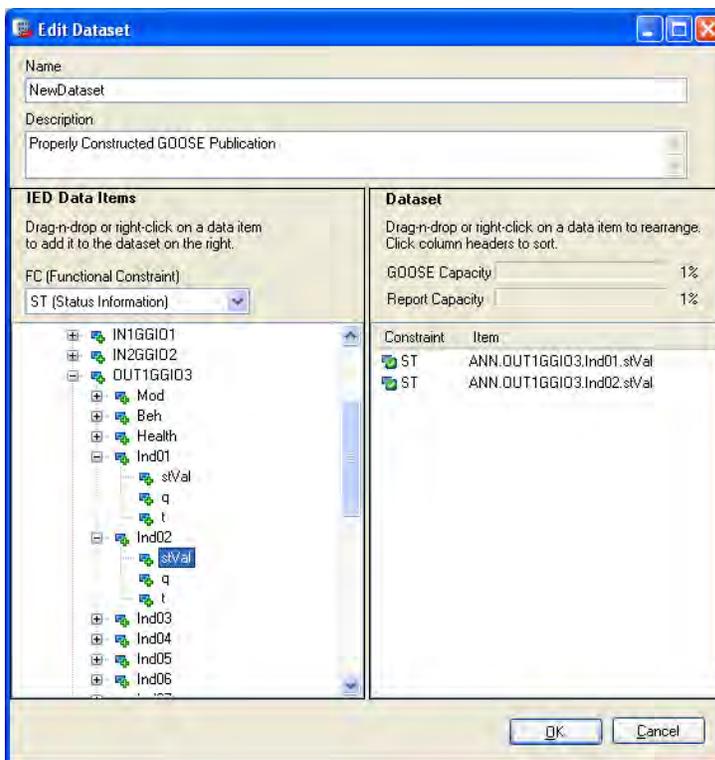
IEC 61850 L.13
GOOSE Processing and Performance


Figure L.4   Example of a Properly Constructed GOOSE Dataset

GOOSE Receive and Transmit Capacity

Each processing interval, the relay processes received and transmitted GOOSE messages. The relay assigns each received and transmitted message a point value at configuration time (when the relay receives and parses the CID file). The point values for various messages are calculated as described in *GOOSE Subscription (Receive) Processing on page L.13* and *GOOSE Publication (Transmit) Processing on page L.18*. The number of points that can be received per processing interval is 80 and that can be transmitted per processing interval is 40.

A single GOOSE receive subscription shall not be allowed to exceed 112 points, and a single GOOSE transmit publication shall not be allowed to exceed 64 points. If a receive subscription exceeds 80 points or a transmit publication exceeds 40 points, 2 processing intervals are necessary to process the message.

GOOSE Subscription (Receive) Processing

The relay supports as many as 24 GOOSE subscriptions. GOOSE messages which arrive at the relay are subjected to the following processing steps when port setting EGSE is set to Y.

Filter

Each message is inspected for proper multicast MAC address and GOOSE App ID. If those parameters match values expected by the relay for one of as many as 24 GOOSE subscriptions, then the message is passed on to the next level of processing. Otherwise the message is discarded. Each message on the LAN must have a unique combination of multicast MAC address and GOOSE App ID.

L.14 | IEC 61850
GOOSE Processing and Performance

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 996 of 1080
Wolfe

Buffer

The relay retains the most recent arrival for each of as many as 24 subscriptions. If a subsequent GOOSE arrives for a subscription that already has a message buffered, then the earlier arrival is discarded.

Decode

The decoding process consists of several stages. Each decoding stage has an associated processing cost, and the relay limits the total cost of all received GOOSE decoding to reserve enough time to process protection algorithms, programmable logic, outputs, outgoing GOOSE messages, etc. Some messages will be decoded during subsequent processing intervals if they are in the receive buffers at the beginning of the processing interval and cost more than 80 points to decode when synchrophasors are disabled (Global setting EPMU := N) or more than 40 points to decode when synchrophasors are enabled (Global setting EMPU := Y). The sections below describe how the relay scores each message as it is decoded and assume that synchrophasors are not enabled (Global setting EPMU := N).

Header Decoding

Each message contains a header that indicates the status of the message. The relay ignores the remainder of the message if any of four indicators in the message header are true:

➤ Configuration Mismatch. The configuration number of the incoming GOOSE changes.

➤ Needs Commissioning. This Boolean parameter of the incoming GOOSE message is true.

➤ Test Mode. This Boolean parameter of the incoming GOOSE message is true.

➤ State Number. This parameter is the same as the last time the message was decoded. State Number increments when the contents of the message change, so if the State Number is unchanged, there is no reason to decode the rest of the message.

Whether the header indicates the message should be subjected to further decoding or ignored, decoding the header always costs eight points.

Message Body Decoding

The cost of decoding the message body depends on the structure of the message. *Table L.7* shows the cost of each type of data in the message body and the cost of decoding the message header.

Table L.7   Point Cost of Decoding GOOSE Messages (Sheet 1 of 2)

Data Type	Description	Point Value	Comments
	Message header	8	Each message counts for at least eight points, regardless of the content of the message.
Message Quality Bit	A Boolean value created in the receiving relay indicating the status of the received message	0	This bit can always be mapped to local virtual bits for zero cost.
Boolean	A Boolean value mapped to a virtual bit	1	Boolean values not mapped to local virtual bits count as zero points.

Table L.7   Point Cost of Decoding GOOSE Messages (Sheet 2 of 2)

Data Type	Description	Point Value	Comments
Quality Bit String	A quality field associated with a data item, where the data item contains data mapped to a virtual bit	1	Quality fields not associated with a data item containing data that are mapped to a virtual bit count as zero points.
Time	Data item time stamp	0	Some data items are accompanied by a time stamp. The time stamp is never used or decoded by the SEL-651R-2. It counts as zero points.
Bit String (other than Quality)	Several bits packed together in the same data item, where at least one of the bits is mapped to a virtual bit	1 for the bit string, plus 1 per bit in the bit string mapped to a virtual bit	Bit strings are often used for breaker position. A bit string that contains no bits mapped to a virtual bit counts as zero points.
Floating Point	Either single or double precision floating point values	0	Floating point values always count as zero points.
Other types of data	Any data type other than those shown above		The relay will correctly process any valid GOOSE message to which it subscribes. However, some data types are costly for the relay to process even if the data are not used by the receiving relay. Contact the SEL factory if you must configure the SEL-651R-2 to subscribe to GOOSE messages with data types other than those listed above.

Message Point Value Calculation Example

Assume the relay subscribes to a message with 10 Boolean values, five of which are mapped to local virtual bits. Each of the 10 Boolean values is accompanied by a quality indicator. The message also contains one breaker position (a two-bit string) with accompanying quality indicator and time stamp. The two bits of breaker position are mapped to two virtual bits in the SEL-651R-2. The message also contains two single precision floating point numbers. In addition, the message quality bit is mapped to a local virtual bit.

The dataset for such a message is shown in *Figure L.5*. As described above, not all items from the dataset are mapped to local resources within the receive SEL-651R-2. Similar to the example GOOSE shown in *Figure L.3*, the GOOSE message shown in *Figure L.5* is poorly constructed and is shown only as an example of a GOOSE message containing several types of data.

Attachment to Response to AG-2 Question No. 68(g)
Page 998 of 1080
Wolfe

Figure L.5   Example Receive GOOSE Dataset

The score for this message is as follows:

➤ 8 points for the message

➤ 0 points for the message quality bit

➤ 5 points for 5 mapped Booleans

➤ 5 points for 5 quality fields associated with data items that have data mapped to local virtual bits

➤ 3 points total for the breaker position indication (one for the bit string and one each for the two bits in the string)

➤ 1 point for the quality bit string associated with the breaker position bit string

➤ 0 points for the breaker position bit string time stamp

➤ 0 points for the single precision floating-point numbers

   22 total points in this message

Examples of GOOSE Subscription (Receive) Processing

The following examples assume that synchrophasors are not enabled (EPMU := N), so the relay is guaranteed to process as many as 80 points in a processing interval. For example, assume the relay subscribes to messages as shown in *Table L.8*.

Table L.8   Scores for Subscribed Messages Used in Example (Sheet 1 of 2)

Subscription Number	Message Score
1	10
2	10
3	9

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 999 of 1080

IEC 61850 L.17
GOOSE Processing and Performance
Wolfe

Table L.8   Scores for Subscribed Messages Used in Example (Sheet 2 of 2)

Subscription Number	Message Score
4	12
5	10
6	10
7	9
8	10
Total	**80**

The total score for all of the subscribed messages is 80 points. Even if every message in *Table L.8* arrives every processing interval, and even if the header information from every message indicates that the message must be decoded, the relay is guaranteed to process every message, update the local virtual bits, and use those updated values in programmable logic during that processing interval.

Next, assume that the relay subscribes to messages as shown in *Table L.9*.

Table L.9   Scores for Subscribed Messages Used in Example

Subscription Number	Message Score
1	16
2	20
3	10
4	28
5	16
6	24
7	12
8	10
9	10
Total	**146**

The total score for all of the subscribed messages is 146 points. Notice that if all of the message points are because of message headers and mapped Boolean values, then these nine messages represent 74 Boolean values mapped to local virtual bits. Assume every message arrives during the same processing interval, but messages 1–6 are repeats of messages processed earlier (i.e., those messages do not have changed state numbers). Those six repeated messages count as 8 points each, or 48 points total. Assume messages 7, 8, and 9 each contain changed data, so the state number has incremented since the last time the message was processed. The combined score for messages 7, 8, and 9 is 32 points. So, the total score for all messages is 80 points. In this case the relay will process all messages in a single processing interval.

Finally, assume that the relay subscribes to messages as shown in *Table L.10*.

Table L.10   Scores for Subscribed Messages Used in Example (Sheet 1 of 2)

Subscription Number	Message Score
1	16
2	20
3	10

GOOSE Processing and Performance

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 1000 of 1080
Wolfe

Table L.10   Scores for Subscribed Messages Used in Example (Sheet 2 of 2)

Subscription Number	Message Score
4	16
5	16
6	10
7	12
8	28
9	16
10	20
11	10
12	16
13	10
14	10
15	12
16	16
17	20
18	10
19	16
20	16
21	10
22	12
23	28
24	16
Total	**366**

The total combined score for all of the subscribed messages is 366 points. As long as messages totaling 80 or fewer points arrive each processing interval, the relay will process all received messages every processing interval. If messages totaling more than 80 points arrive in any processing interval, then the relay will process messages totaling 80 or fewer points, and will continue processing during the next quarter-cycle processing interval.

GOOSE Publication (Transmit) Processing

The relay supports as many as eight GOOSE publications. Each publication can contain data from any logical node in the relay. The relay supports no more than 128 unique Boolean elements mapped between all GOOSE publications. The relay transmits a message from each publication soon after initialization (e.g., after startup). Near the end of each processing interval, the relay transmits one message from as many publications as possible in which the state numbers have incremented. The relay then transmits one message from as many publications as possible in which the transmit interval timers have expired.

State Number

The relay maintains a count of the number of times the contents of a publication have changed. The count is called the state number. If the state number increments, then the relay transmits a message from that publication, as discussed below.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 1001 of 1080
IEC 61850   L.19
GOOSE Processing and Performance
Wolfe

Transmit Interval

If the data contained in the messages do not change (i.e., if the state number does not increase), then the relay retransmits the message based on the configured MinTime and MaxTime settings from the CID file. The first transmission occurs immediately upon the trigger occurring. The second occurs approximately MinTime later. The third occurs approximately MinTime after the second. The fourth occurs twice MinTime after the third. All subsequent transmissions occur at the MaxTime interval. For example, if MinTime is 4 ms and MaxTime is 100 ms, the intervals between transmissions will be 4 ms, 4 ms, 8 ms, and then 100 ms. If MaxTime is not greater than twice MinTime, the third and all subsequent transmissions will occur at the MaxTime interval. The MinTime and MaxTime intervals can be configured for each GOOSE transmit message by using Architect. The time-to-live reported in the first two messages is three times MinTime. The time-to-live in all subsequent messages is two times MaxTime.

The total number of message transmissions possible during each processing interval because of either state number changes or transmit interval timeout depends on the structure of the messages to be transmitted and whether synchrophasors are enabled. The relay assigns each message a point value at configuration time (when the relay receives and parses the CID file). At each processing interval, the relay processes and transmits messages totaling as many as 40 points if synchrophasors are not enabled (Global setting EPMU := N) or 20 points if synchrophasors are enabled (Global setting EMPU := Y). Some messages available for transmission because their transmit intervals have timed out or because there state numbers have incremented will be transmitted on subsequent processing intervals. These messages either total more than 40 points for disabled synchrophasors (Global setting EPMU := N) or 20 points if synchrophasors are enabled (Global setting EMPU := Y). *Table L.11* shows the point value for different parts of the GOOSE message.

Table L.11   Score For Data Types Contained in Published Messages

Data Type	Description	Point Value	Comments
	Message	8	Each message counts at least 8 points every time it is transmitted, regardless of the content of the message. A message that is not transmitted counts as zero points.
Quality Bit String	A quality field associated with a data item.	0	Transmit quality is always zero.
Boolean, Time, Bit Strings (Other than Quality), Integer (INT8), Floating Point, Enumerations		1	Each of these data types costs one point to process and transmit.
Other Types of Data	Types of data other than those mentioned above.		The relay will correctly process and transmit any valid GOOSE message. However, some data types are costly for the relay to process. Contact the SEL factory if you must configure the SEL-651R-2 to publish GOOSE messages with data types other than those listed above.

Message Point Value Calculation Example

Assume the relay publishes a message with 10 Boolean values. Each of the 10 Boolean values is accompanied by a quality indicator and a time stamp. The message also contains two single precision floating-point numbers with associated time stamps.

L.20 | IEC 61850
GOOSE Processing and Performance

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 1002 of 1080
Wolfe

The dataset for such a message is shown in *Figure L.6*. Similar to the example GOOSE shown in *Figure L.3*, the GOOSE message shown in *Figure L.6* is poorly constructed and is shown only as an example of a GOOSE message containing several types of data.

Figure L.6   Example Transmit GOOSE Dataset

The score for this message is as follows:

➤ 8 points for the message

➤ 10 points for 10 Boolean values

➤ 0 points for 10 quality bit strings associated with the Boolean values

➤ 10 points for 10 time stamps associated with the Boolean values

➤ 2 points for 2 single precision floating-point numbers

➤ 2 points for 2 time stamps associated with the single precision floating-point numbers

32 total points in this message

Message Transmission Example

Assume the relay publishes four GOOSE messages as shown in *Table L.12*.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 1003 of 1080
Wolfe

IEC 61850 L.21
IEC 61850 Configuration

Table L.12 Scores for Published Messages Used In Example

Publication Number	Message Score
1	10
2	11
3	9
4	10
Total	**40**

The total score for all publications in this example is 40 points. The relay can process and transmit all messages every processing interval if required, assuming that synchrophasors are not enabled in the device.

Next assume the relay publishes messages as shown in *Table L.13*.

Table L.13 Scores for Published Messages Used In Example

Publication Number	Message Score
1	32
2	40
3	20
4	32
5	32
6	20
7	14
8	10
Total	**200**

The total score for all publications in this example is 200 points. If messages totaling more than 40 points are due to be transmitted in any single processing interval, then the relay will transmit messages until the next message transmitted would cause the total score for that processing interval to exceed 40 points. The relay will then continue transmitting during the next quarter-cycle processing interval.

IEC 61850 Configuration

Settings

Table L.14 lists IEC 61850 settings. These settings are only available if your device includes the optional IEC 61850 protocol.

Table L.14 IEC 61850 Settings

Label	Description	Range	Default
E61850	IEC 61850 interface enable	Y, N	N
EGSE[a]	IEC 61850 GSE message enable	Y, N	N
EMMSFS[a]	Enable MMS File Services	Y, N	N

[a] Settings EGSE and EMMSFS are hidden when E61850 is set to N.

L.22 | IEC 61850
| **IEC 61850 Configuration**

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 1004 of 1080
Wolfe

Devices ordered with the optional IEC 61850 protocol are delivered with a default CID file loaded on the device. The file is named SET_61850.CID. To make the device communicate with other devices over IEC 61850, the device must be configured.

Configure all other IEC 61850 settings, including subscriptions to incoming GOOSE messages, with Architect.

When IEC 61850 is enabled (E61850 = Y), the device parses the CID file to determine the device IEC 61850 configuration. When EGSE = Y, the device begins transmitting GOOSE messages and receiving GOOSE subscriptions configured in the CID file. Issuing the ASCII **GOO** command provides GOOSE status information. See *GOOSE Command on page 10.51* for a detailed description of the **GOO** Command.

NOTE: Firmware versions previous to R404 will display `PARSE FAILURE` in the iedName, type, and configVersion fields of the ID Command if the CID file is invalid. No GOOSE messages will be transmitted and MMS will be unavailable if `PARSE FAILURE` is displayed in these fields.

If the device does not have a valid IEC 61850 configuration, it will not send or receive any IEC 61850 communications. Issuing the ASCII **ID** command provides information on the status of the CID file. If there is a problem with the CID file, the iedName, type, and configVersion fields of the **ID** command response will display "PARSE FAILURE" as shown below.

```
=>>ID <Enter>

"FID=SEL-651R-2-Rxxx-Vx-Zxxxxxx-Dxxxxxxxx","0957"
"BFID=SLBT-3CF1-Rxxx-Vx-Zxxxxxx-Dxxxxxxxx","097A"
"CID=B0F0","0265"
"DEVID=STATION A","049C"
"DEVCODE=56","0312"
"PARTNO=0651R221XBAXAC2123B4XX","07D9"
"SERIALNO=000000000000000","05DA"
"CONFIG=11242200","03EF"
"SPECIAL=11000","03A0"
"iedName=PARSE FAILURE","0703"
"type=PARSE FAILURE","0612"
"configVersion=PARSE FAILURE","09AC"

=>>
```

NOTE: MMS File Services can be used to load a new CID file only if EMMSFS := Y and a valid CID file is currently loaded into the device. If no CID file is currently loaded, only FTP or Architect can load a valid CID file.

You will need to load a valid CID file into the device by using FTP, Architect, or MMS File Services. When loading a new CID file, Architect returns an error message if the file is not accepted. If using FTP or MMS File Services to load a new CID file, follow the write operation with a read of the ERR.TXT file from the device to verify successful transmission and configuration of the new CID file. If the file transfer fails or the device detects an invalid CID file, the ERR.TXT file will contain an error message. If the file is blank (length is zero), then the new CID file was accepted by the device. If a failure occurs, the CID file that you previously loaded in the device will be retained. The new CID file will replace the current CID file only if the transfer and configuration of the new CID file is successful.

Once a valid CID file is loaded into the device, the ID command response should look like that shown below with the iedName, type, and configVersion fields revealing the proper configured information. The iedName displays the configured IED name which can be modified by using Architect. The type and configVersion fields cannot be modified and represent the relay type and the ICD file version used for the configured CID file.

Architect

The Architect software enables protection and integration engineers to design and commission IEC 61850 substations containing SEL IEDs.

Engineers can use Architect to:

- ➤ Organize and configure all SEL IEDs in a substation project.

- ➤ Configure incoming and outgoing GOOSE messages.

- ➤ Edit and create GOOSE datasets.

- ➤ Read non-SEL IED Capability Description (ICD) and Configured IED Description (CID) files and determine the available IEC 61850 messaging options.

- ➤ Use or edit preconfigured datasets for reports.

- ➤ Enable/disable MMS authentication.

- ➤ Configure MMS inactivity timeout.

- ➤ Load IEC 61850 CID files into SEL IEDs.

- ➤ Generate ICD and CID files that will provide SEL IED descriptions to other manufacturers' tools so they can use SEL GOOSE messages and reporting features.

Architect provides a Graphical User Interface (GUI) for engineers to select, edit, and create IEC 61850 GOOSE messages important for substation protection, coordination, and control schemes. Typically, the user first places icons representing IEDs in a substation container, then edits the outgoing GOOSE messages or creates new ones for each IED. The user can also select incoming GOOSE messages for each IED to receive from any other IEDs in the domain.

Some measured values are reported to IEC 61850 only when the value changes beyond a defined dead-band value. Architect allows a dead band to be changed during the CID file configuration. Check and set the dead-band values for your particular application when configuring the CID file for a device.

Architect has the capability to read other manufacturers' ICD and CID files, enabling the user to map the data seamlessly into SEL IED logic. See the Architect online help for more information.

Logical Node Extensions

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 1006 of 1080
Wolfe

SEL ICD File Versions

Architect version R.1.1.69.0 and later supports multiple ICD file versions for each type of IED in a project. Because relays with different firmware versions may require different CID file versions, users can manage the CID files of all IEDs within a single project.

Please ensure that you work with the appropriate version of Architect relative to your current configuration, existing project files, and ultimate goals. If you want the best available IEC 61850 functionality for your SEL relay, obtain the latest version of Architect and select the appropriate ICD version(s) for your needs.

Architect generates CID files from ICD files so the ICD file version Architect uses also determines the CID file version generated. As of this writing, Architect comes with several versions of the SEL-651R-2 ICD file. Two versions are compatible with the SEL-651R-2 for use on new or existing projects. These versions are listed below.

SEL-651R2 File Version 005 (651R2 Firmware R404 or higher): File supports MMS Authentication, MMS file transfer, including COMTRADE events and CID files. It supports seven client connections.

SEL-651R2 File Version 004 (651R2 Firmware R400 or higher): This file supports six client connections and does not support MMS Authentication. Ensure that you use the appropriate version for your IEC 61850 project requirements.

Logical Node Extensions

The following Logical Nodes and Data Classes were created in this device as extensions to the IEC 61850 standard, in accordance with IEC 61850 guidelines.

Table L.15   New Logical Node Extension

METMSTA1	MinW.instMag.f	MW3MIN[b]	Three-phase real power, minimum magnitude
METMSTA1	MaxVAr.instMag.f	MVR3MAX[b]	Three-phase reactive power, maximum magnitude
METMSTA1	MinVAr.instMag.f	MVR3MIN[b]	Three-phase reactive power, minimum magnitude

[a] MX values contain instantaneous attributes (instMag and instCVal), which are updated whenever the source updates and other attributes that are only updated when the source goes outside the points dead band (mag and cVal). Only the instantaneous values are shown in the table.

[b] Minimum values that have been reset report the largest positive value possible.
Maximum values that have been reset report the largest negative value possible.

Table L.21 shows the LNs associated with control elements, defined as Logical Device CON. See *Appendix F: Relay Word Bits* for descriptions.

Table L.21   Logical Device: CON (Remote Control) (Sheet 1 of 2)

Logical Node	Status	Control	Relay Word Bit	Comment
RBGGIO1	SPCSO01.stVal–SPCSO08.stVal	SPCSO01.Oper.ctlVal–SPCSO08.Oper.ctlVal	RB01–RB08	Remote Bits (RB01–RB08)

Table L.22 shows the LNs associated with the annunciation element, defined as Logical Device ANN. See *Appendix F: Relay Word Bits* and *Appendix G: Analog Quantities* for descriptions.

Table L.22 Logical Device: ANN (Annunciation) (Sheet 1 of 5)

Logical Node	Attribute	Data Source	Comment
Functional Constraint = ST			
ALMGGIO8	Ind01.stVal	HALARM	Indication of a diagnostic failure or warning that warrants an ALARM
ALMGGIO8	Ind02.stVal	HALARML	Latches in for relay diagnostic failures
ALMGGIO8	Ind03.stVal	HALARMP	Pulses for five seconds when a warning diagnostic condition occurs
ALMGGIO8	Ind04.stVal	HALARMA	Pulses for five seconds per minute until reset when a hardware diagnostic warning occurs
ALMGGIO8	Ind07.stVal	ACCESS	Asserted while any user is logged in at Access Level B or higher
ALMGGIO8	Ind08.stVal	SALARM	Indication of software or user activity that warrants an ALARM
ALMGGIO8	Ind09.stVal	BADPASS	Pulses for approximately one second whenever a user enters three successive bad passwords in an SEL ASCII terminal session or web session
ALMGGIO8	Ind10.stVal	CHGPASS	Pulses for approximately one second whenever a password changes
ALMGGIO8	Ind11.stVal	SETCHG	Pulses for approximately one second whenever settings are changed
ALMGGIO8	Ind13.stVal	ACCESSP	Pulses for approximately one second when any user increases their access level to B or higher
ALMGGIO8	Ind14.stVal	PASNVAL	Pulses for approximately one second when an incorrect password is entered when attempting to enter Access Level B or higher, or when changing passwords
BATGGIO24	Ind01.stVal	CHRGG	Battery is charging
BATGGIO24	Ind02.stVal	DISCHG	Battery is discharging
BATGGIO24	Ind03.stVal	DTFAIL	Battery failed discharge test
BATGGIO24	Ind04.stVal	BTFAIL	Battery failure
BATGGIO24	Ind05.stVal	TOSLP	To Sleep—asserts for last minute of control operation on battery power
BATGGIO24	Ind06.stVal	PWR_SRC1	Recloser control power supply is operating from external power source
BATGGIO24	Ind07.stVal	TCCAP	Recloser interface trip and close capacitor fully charged
BATGGIO24	Ind08.stVal	DISTST	Asserted when battery discharge test is in progress
BKGGIO26	Ind01.stVal	52AA	A-phase breaker status
BKGGIO26	Ind02.stVal	52AB	B-phase breaker status
BKGGIO26	Ind03.stVal	52AC	C-phase breaker status
BKGGIO26	Ind04.stVal	52A3P	Three-phase breaker status

WEARB	PRO	BSBSCBR2	AbrPrt.instMag.f	B-phase breaker wear percentage
WEARC	PRO	BSCSCBR3	AbrPrt.instMag.f	C-phase breaker wear percentage

[a] Virtual bits retain state until overwritten or device is restarted.

Protocol Implementation Conformance Statement: SEL-651R-2

Table L.25 and *Table L.26* are as shown in the IEC 61850 standard, Part 8-1, Section 24. Note that because the standard explicitly dictates which services and functions must be implemented to achieve conformance, only the optional services and functions are listed.

Table L.25   PICS for A-Profile Support

	Profile	Client	Server	Value/Comment
A1	Client/Server	N	Y	
A2	GOOSE/GSE management	Y	Y	Only GOOSE, not GSSE
A3	GSSE	N	N	
A4	Time Sync	N	Y	

Table L.26   PICS for T-Profile Support

	Profile	Client	Server	Value/Comment
T1	TCP/IP	N	Y	
T2	OSI	N	N	
T3	GOOSE/GSE	Y	Y	Only GOOSE, not GSSE
T4	GSSE	N	N	
T5	Time Sync	N	Y	

Refer to the *ACSI Conformance Statements on page L.58* for information on the supported services.

MMS Conformance

The Manufacturing Message Specification (MMS) stack provides the basis for many IEC 61850 protocol services. *Table L.27* defines the service support requirement and restrictions of the MMS services in SEL-651R-2 devices. Generally, only those services whose implementation is not mandatory are shown. Refer to the IEC 61850 standard Part 8-1 for more information.

[f] c9 shall declare support if TP association is available.
[g] c10 shall declare support for at least one (SendMSVMessage or SendUSVMessage).

Appendix M

Cybersecurity Features

The SEL-651R-2 provides a number of features to help meet cybersecurity design requirements.

Access Control

The SEL-651R-2 has a number of mechanisms for managing electronic access. These include ways to limit access, provide user authentication, and monitor electronic and physical access.

Physical Port Controls

Each physical serial port and the Ethernet port can be individually disabled by using the EPORT setting. By default, all of the ports are enabled. It is good security practice to disable unused ports.

IP Ports

When using Ethernet, there are a number of IP ports available within the SEL-651R-2. Many of these IP port numbers are configurable. All IP ports can be disabled and are disabled by default. *Table M.1* describes each of these.

Table M.1   IP Port Numbers

IP Port Default	Port Selection Setting	Network Protocol	Default Port State	Port Enable Setting	Purpose
21	—	TCP	Disabled	EFTPSERV	FTP protocol access for file transfer of settings and reports
23	TPORT	TCP	Disabled	ETELNET	Telnet access for general engineering terminal access
80	HTTPPORT	TCP	Disabled	EHTTP	Web server access to read various relay information
102	—	TCP	Disabled	E61850	IEC 61850 MMS for SCADA functionality
123	SNTPPORT	UDP	Disabled	ESNTP	SNTP time synchronization
4712/ 4713	PMOTCP1/ PMOUDP1	TCP/UDP	Disabled	PMOTS1	Synchrophasor data output, session 1
4722/ 4713	PMOTCP2/ PMOUDP2	TCP/UDP	Disabled	PMOTS2	Synchrophasor data output, session 2
20000	DNPNUM	TCP/UDP	Disabled	EDNP	DNP for SCADA functionality
502	—	TCP	Disabled	EMODBUS	Modbus for SCADA functionality

See *Port 5 Settings on page SET.70* for more information on these settings.

Authentication and Authorization

The SEL-651R-2 supports four levels of access, as described in *Port Access Levels on page 10.21*. Refer to this section to learn how each level is accessed and how to change passwords. It is good security practice to change the default passwords of each access level and to use a unique password for each level.

M.2 | Cybersecurity Features
Access Control

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 1046 of 1080
Wolfe

The MAXACC setting limits the level of access for each port. This permits you to operate under the principle of "least privilege", restricting ports to the levels necessary for the functions performed on those ports.

The SEL-651R-2 supports strong passwords with as many as 12 characters, using any printable character, allowing users to select complex passwords if they so choose. SEL recommends that passwords have a minimum of eight characters and include at least one of each of the following: lowercase letter, uppercase letter, number, and special character.

Monitoring and Logging

The SEL-651R-2 provides Relay Word bits that are useful for monitoring relay access:

➤ BADPASS—Pulses for approximately one second if a user enters three successive incorrect passwords in an SEL ASCII terminal session or web session.

➤ ACCESS—Asserted while any user is logged in to Access Level B or higher.

➤ ACCESSP—Pulses for approximately one second whenever a user gains access to Access Level B or higher.

➤ PASNVAL—Pulses for approximately one second when an incorrect password is entered when attempting to enter Access Level B or higher, or when an incorrect password is entered when attempting to change passwords.

➤ LINK5, LINK5A, LINK5B—Asserted while the link is active on the Ethernet port(s). Loss of link can be an indication that an Ethernet cable has been disconnected.

➤ LNKFAIL—Asserted if link is lost on the active IP port (Ports 5, 5A, or 5B).

These bits can be mapped for SCADA monitoring via DNP3, IEC 61850, Modbus, or SEL Fast Message. They also may be added to the SER for later analysis or assigned to output contacts for alarm purposes.

The SEL-651R-2 SER is a useful tool for capturing a variety of relay events. In addition to capturing state changes of user-selected Relay Word bits, it captures all startups, settings changes, and group switches. See *Sequential Events Recorder (SER) Report on page 12.39* for more information about SER.

Physical Access Security

Physical security of cybersecurity assets is a common concern. SEL-651R-2 recloser controls can be installed within a control house that provides physical security. Other times, relays are installed in breakers or enclosures within the switchyard. The SEL-651R-2 provides tools to help manage physical security, especially when the unit is installed in the switch yard.

You can monitor physical ingress by wiring a door sensor to one of the SEL-651R-2 contact inputs. This input can then be mapped for SCADA monitoring or added to the SER log so that you can monitor when physical access to the relay occurs.

It is also possible to wire an electronic latch to an SEL-651R-2 contact output. You could then map this output for SCADA control.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 1047 of 1080
Cybersecurity Features M.3
Configuration Management
Wolfe

Configuration Management

Many users are concerned about managing the configuration of their relays. The SEL-651R-2 provides mechanisms to help users manage relay configuration.

All settings changes are logged to the SER log. Analysis of this log indicates if any unauthorized settings changes occurred.

The following Relay Word bits also indicate changes in relay configuration:

➤ SETCHG—Pulses for approximately one second when settings are changed or saved

➤ CHGPASS—Pulses for approximately one second when a password changes

➤ GRPSW—Pulses for approximately one second when the relay switches settings groups

The SEL-651R-2 also stores a hash code for each settings class in the CFG.TXT file. After configuring the device, read the CFG.TXT file and store it for future reference. Periodically read this file from the relay and compare it to the stored reference. If any of the hash codes have changed, then that settings class has been modified.

Firmware Hash Verification

This device supports digitally signed firmware upgrades. SEL uses the SHA-1 secure hash algorithm to compress and digitally sign firmware upgrade files. The signature ensures that the file has been provided by SEL and that its contents have not been altered. When the file is uploaded to the relay, the signature is verified using a public key stored on the relay. If the relay cannot verify the signature, it rejects the file. See *Appendix B: Firmware Upgrade Instructions* for more information on firmware upgrades.

Malware Protection

The SEL-651R-2 has inherent and continuous monitoring for malware. For a full description of this, see selinc.com/mitigating_malware/.

Security Vulnerabilities

If SEL finds a security vulnerability with the SEL-651R-2, it will be disclosed using our standard security notification process. For a full description of this process, see selinc.com/support/security-notifications/.

M.4 | Cybersecurity Features
Settings Erasure

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 1048 of 1080
Wolfe

Settings Erasure

It is often desirable to erase the settings from the relay when it is removed from service. You can completely erase all the configuration settings from the SEL-651R-2 by using this procedure:

Step 1.   Go to Access Level C (see *ACC, BAC, 2AC, and CAL Commands (Go to Access Level 1, B, 2, or C) on page 10.38*).

Step 2.   Execute the **R_S** command.

Step 3.   Allow the relay to restart.

NOTE: Do not erase settings when sending the relay for service at the factory. SEL needs to be able to see how the relay was configured to properly diagnose any problems.

Once this procedure is complete, all internal instances of user settings and passwords will be erased. Do not do this when sending in the relay for service at the factory. SEL needs to see how the relay was configured to properly diagnose many problems.

Glossary

AC Ripple	The peak-to-peak ac component of a signal or waveform. In the station dc battery system, monitoring ac ripple provides an indication of whether the substation battery charger has failed.
ACSELERATOR QuickSet SEL-5030 Software	A Windows-based program that simplifies settings and provides analysis support.
ACSELERATOR Architect SEL-5032 Software	Architect is an add-on to the QuickSet suite that uses the IEC 61850 Substation Configuration Language to configure SEL IEDs.
ACSI	Abstract communications service interface for the IEC 61850 protocol. Defines a set of objects, a set of services to manipulate and access those objects, and a base set of data types describing objects.
Active Settings Group	The settings group that the SEL-651R-2 is presently using from among eight settings groups available in the relay.
Analog Quantities	Variables represented by such fluctuating measurable quantities as temperature, frequency, current, and voltage.
AND Operator	Logical AND. An operator in Boolean SELOGIC control equations that requires fulfillment of conditions on both sides of the operator before the equation is true.
ANSI Standard Device Numbers	A list of standard numbers used to represent electrical protection and control relays. The standard device numbers used in this instruction manual include the following:

25	Synchronism-Check Element
27	Undervoltage Element
50	Overcurrent Element
51	Inverse Time-Overcurrent Element
52	AC Circuit Breaker
59	Overvoltage Element
69	Permissive Control Device (e.g., permit/block circuit breaker closing)
79	Reclosing Relay
81	Frequency Element

These numbers are frequently used within a suffix letter to further designate their application. The suffix letters used in this instruction manual include the following:

P	Phase Element
G	Ground Element
N	Neutral Element
Q	Negative-Sequence (3I2) Element

Apparent Power, S	Complex power expressed in units of volt-amps (VA), kilovolt-amperes (kVA), or megavolt-amperes (MVA). Accounts for both real (P) and reactive (Q) power dissipated in a circuit: $S = P + jQ$. This is power at the fundamental frequency only; no harmonics are included in this quantity.

GL.2 | Glossary
| ASCII–Contact Output

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 1050 of 1080
Wolfe

ASCII	Abbreviation for American Standard Code for Information Interchange. Defines a standard set of text characters. The SEL-651R-2 uses ASCII text characters to communicate, by using front- and rear-panel EIA-232 serial ports on the relay and through virtual serial ports.
ASCII Terminal	A terminal without built-in logic or local processing capability that can only send and receive information.
Assert	To activate. To fulfill the logic or electrical requirements needed to operate a device. To set a logic condition to the true state (logical 1) of that condition. To apply a closed contact to an SEL-651R-2 input. To close a normally open output contact. To open a normally closed output contact.
AT Modem Command Set Dialing String Standard	The command language standard that Hayes Microcomputer Products, Inc. developed to control auto-dial modems from an ASCII terminal (usually EIA-232 connected) or a PC (personal computer) containing software allowing emulation of such a terminal.
Autoconfiguration	The ability to determine relay type, model number, metering capability, port ID, data rate, passwords, relay elements, and other information that an IED (e.g., SEL-2020/2030/2032 Communications Processor) needs to automatically communicate with relays.
Automatic Messages	Messages including status failure and status warning messages that the relay generates at the serial ports and displays automatically on the front-panel LCD.
Automatic Reclose	Automatic closing of a circuit breaker after a breaker trip by a protective relay.
Boolean Logic Statements	Statements consisting of variables that behave according to Boolean logic operators, such as AND, NOT, and OR.
Breaker Auxiliary Contact	An electrical contact associated with a circuit breaker that opens or closes to indicate the breaker position. A Form A breaker auxiliary contact (ANSI Standard Device Number 52A) closes when the breaker is closed and opens when the breaker is open. A Form B breaker auxiliary contact (ANSI Standard Device Number 52B) opens when the breaker is closed and closes when the breaker is open.
Buffered Report	IEC 61850 IEDs can issue buffered reports of internal events (caused by trigger options data-change, quality-change, and data-update). These event reports can be sent immediately or buffered (to some practical limit) for transmission, such that values of data are not lost because of transport flow control constraints or loss of connection. Buffered reporting provides sequence-of-events (SOE) functionality.
C37.118	IEEE C37.118, Standard for Synchrophasors for Power Systems.
CID File	IEC 61850 Configured IED Description file. XML file that contains the configuration for a specific IED.
Common Data Class	IEC 61850 grouping of data objects that model substation functions. Common data classes include status information, controllable status, controllable analog, status settings, analog settings, and description information.
Contact Input	See Control Input.
Contact Output	See Control Output.

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 1051 of 1080
Wolfe
Glossary GL.3
Control Input–Event History

Control Input	Relay input for monitoring the state of external circuits. Connects auxiliary relay and circuit breaker contacts to the control inputs.
Control Output	Relay output that affects the state of other equipment. Connects control outputs to circuit breaker trip and close coils, breaker failure auxiliary relays, communications-assisted tripping circuits, and SCADA systems.
Coordination Timer	A timer that delays an overreaching element so that a downstream device has time to operate.
Counter	Variable or device such as a register or storage location that either records or represents the number of times an event occurs.
Data Class	In the IEC 61850 protocol, an aggregation of classes or data attributes.
Data Object	In the IEC 61850 protocol, part of a logical node representing specific information (status or measurement, for example). From an object-oriented point of view, a data object is an instance of a data class.
Dead Band	The range of variation an analog quantity can traverse before causing a response.
Deassert	To deactivate. To remove the logic or electrical requirements needed to operate a device. To clear a logic condition to its false state (logical 0). To open the circuit or open the contacts across an SEL-651R-2 input. To open a normally open output contact. To close a normally closed output contact.
Debounce Time	The time that masks the period when relay contacts continue to move after closing; debounce time covers this indeterminate state.
Default Data Map	The default map of objects and indices that the SEL-651R-2 uses in DNP protocol.
Demand Meter	A measuring function that calculates a rolling average or thermal average of instantaneous measurements over time.
DNP (Distributed Network Protocol)	Manufacturer-developed, hardware-independent communications protocol.
Dropout Time	The time measured from the removal of an input signal until the output signal deasserts. You can set the time, in the case of a logic variable timer, or the dropout time can be a result of the characteristics of an element algorithm, as in the case of an overcurrent element dropout time.
DTE Devices	Data terminal equipment (computers, terminals, printers, relays, etc.).
EIA-232	Electrical definition for point-to-point serial data communications interfaces, based on the standard EIA/TIA-232. Formerly known as RS-232.
ESD (Electrostatic Discharge)	The sudden transfer of charge between objects at different potentials caused by direct contact or induced by an electrostatic field.
Ethernet	A network physical and data link layer defined by IEE 802.2 and IEEE 802.3.
Event History	A quick look at recent relay activity that includes a standard report header; event number, date, time, and type; fault location; maximum fault phase current; active group at the trigger instant; and targets.

GL.4 | Glossary
Event Report–IP Address

Event Report	A text-based collection of data stored by the relay in response to a triggering condition, such as a fault or ASCII **TRI** command. The data show relay measurements before and after the trigger, in addition to the states of protection elements, relay inputs, and relay outputs each processing interval. After an electrical system fault, use event reports to analyze relay and system performance.
Event Summary	A shortened version of stored event reports. An event summary includes items such as event date and time, event type, fault location, time source, recloser shot counter, currents, and sequence currents. The relay sends an event report summary (if auto messaging is enabled) to the relay serial port a few seconds after an event.
Fast Meter	SEL binary serial port command used to collect metering data with SEL relays.
Fast Operate	SEL binary serial port command used to perform control with SEL relays.
FET	Field Effect Transistor.
Firmware	The nonvolatile program stored in the relay that defines relay operation.
Flash Memory	A type of nonvolatile relay memory used for storing large blocks of nonvolatile data.
FTP	File Transfer Protocol.
Function Code	A code that defines how you manipulate an object in DNP3 protocol.
Fundamental Frequency	The component of the measured electrical signal with a frequency equal to the normal electrical system frequency, usually 50 Hz or 60 Hz. Generally used to differentiate between the normal system frequency and any harmonic frequencies present.
Global Settings	General settings including those for breaker type, date format, phase rotation, nominal system frequency, enables, control inputs, settings group selection, and current and voltage source selection.
GOOSE	IEC 61850 Generic Object Oriented Substation Event. GOOSE objects can quickly and conveniently transfer status, controls, and measured values among peers on an IEC 61850 network.
GPS	Global Positioning System. Source of position and high-accuracy time information.
GUI	Graphical user interface.
HMI	Human-machine interface.
ICD File	IEC 61850 IED Capability Description file. XML file that describes IED capabilities, including information on logical node and GOOSE support.
IEC 61850	Internationally standard method of communications and integration conceived with the goal of supporting systems of multivendor IEDs networked together to perform protection, monitoring, automation, metering, and control.
IP Address	An identifier for a computer or a device on a TCP/IP network. Networks using the TCP/IP protocol route messages based on the IP address of the destination.

Glossary GL.5
Local Bits – Peak Demand Metering
Wolfe

The format of an IP address is a 32-bit numeric address written as four numbers separated by periods. For example, 1.160.10.240 could be an IP address.

Local Bits The Relay Word bit outputs of local control switches that you access through the SEL-651R-2 front panel. Local control switches replace traditional panel mounted control switches.

Lockout Relay An auxiliary relay that prevents operation of associated devices until it is reset either electrically or manually.

Logical 0 A false logic condition, dropped out element, or deasserted control input or control output.

Logical 1 A true logic condition, picked up element, or asserted control input or control output.

Logical Node In IEC 61850, the smallest part of a function that exchanges data. A logical node (LN) is an object defined by its data and methods. Each logical node represents a group of data (controls, status, measurements, etc.) associated with a particular function.

MAC Address The Media Access Control (hardware) address of a device connected to a shared network medium, most often used with Ethernet networks.

Maximum/Minimum Meter Type of meter data presented by the SEL-651R-2 that includes a record of the maximum and minimum of each value, along with the date and time that each maximum and minimum occurred.

Mechanical Operating Time Time between trip initiation or close initiation and the change in status of an associated circuit breaker auxiliary 52A normally open contacts.

MIRRORED BITS Communications Patented relay-to-relay communications protocol that sends internal logic status, encoded in a digital message, from one relay to the other. Eliminates the need for some communications hardware.

MMS Manufacturing Messaging Specification, a data exchange protocol used by UCA.

Nonvolatile Memory Relay memory that persists over time to maintain the contained data even when the relay is de-energized.

NOT Operator A logical operator that produces the inverse value.

OR Operator Logical OR. A Boolean SELOGIC control equation operator that compares two Boolean values and yields either a logical 1 if either compared Boolean value is logical 1 or a logical 0 if both compared Boolean values are logical 0.

Parentheses Operator Math operator. Use paired parentheses to control the execution of operations in a SELOGIC control equation.

PC Personal computer.

Peak Demand Metering Maximum demand and a time stamp for phase currents, negative-sequence and zero-sequence currents, and powers. The SEL-651R-2 stores peak demand values and the date and time these occurred to nonvolatile storage once per day, overwriting the previously stored value if the new value is larger.

GL.6 | Glossary
Phase Rotation–Shot Counter

Case No. 2018-00295
Attachment to Response to AG-2 Question No. 68(g)
Page 1054 of 1080
Wolfe

Should the relay lose control power, the relay restores the peak demand information saved at 23:50 hours on the previous day.

Phase Rotation

The sequence of voltage or current phasors in a multiphase electrical system. In an ABC phase rotation system, the B-phase voltage lags the A-phase voltage by 120°, and the C-phase voltage lags B-phase voltage by 120°. In an ACB phase rotation system, the C-phase voltage lags the A-phase voltage by 120°, and the B-phase voltage lags the C-phase voltage by 120°.

Phase Selection

Ability of the relay to determine the faulted phase or phases.

R_TRIG

Rising-edge trigger. Boolean SELOGIC control equation operator that triggers an operation upon logic detection of a rising edge.

Relay Word Bit

A single relay element or logic result. A Relay Word bit can equal either logical 1 or logical 0. Logical 1 represents a true logic condition, picked up element, or asserted control input or control output. Logical 0 represents a false logic condition, dropped out element, or deasserted control input or control output. Use Relay Word bits in SELOGIC control equations.

RTU

Remote Terminal Unit.

RXD

Received data.

SCADA

Supervisory control and data acquisition.

SCD File

IEC 61850 Substation Configuration Description file. XML file that contains information on all IEDs within a substation, communications configuration data, and a substation description.

SCL

IEC 61850 Substation Configuration Language. An XML-based configuration language that supports the exchange of database configuration data among different software tools that can be from different manufacturers. There are four types of SCL files used within IEC 61850: CID, ICD, SCD, and SSD.

Self-Test

A function that verifies the correct operation of a critical device subsystem and indicates detection of an out-of-tolerance condition. The SEL-651R-2 has self-tests that validate the relay power supply, microprocessor, memory, and other critical systems.

SELOGIC Control Equation

A relay setting that allows you to control a relay function (such as a control output) using a logical combination of relay element outputs and fixed logic outputs.

SELOGIC Expression Builder

A rules-based editor within the QuickSet software for programming SELOGIC control equations.

Sequential Events Recorder (SER)

A relay function that stores a record of the date and time of each assertion and deassertion of every Relay Word bit in a list that you set in the relay. SER provides a useful way to determine the order and timing of events of a relay operation.

SER

The relay serial port command to request a report of the latest 1000 sequential events.

Shot Counter

A counter that records the number of times a reclosing relay (dev. 79) attempts to close a circuit breaker.

Glossary GL.7
Single-Phase Trip–Unbuffered Report

Single-Phase Trip	A circuit breaker trip operation that occurs when one pole of the three poles of a circuit breaker opens independently of the other poles.
SSD File	IEC 61850 System Specification Description file. XML file that describes the single-line diagram of the substation and the required logical nodes.
Status Failure	A severe out-of-tolerance internal operating condition. The relay issues a status failure message and enters a protection-disabled state.
Status Warning	Out-of-tolerance internal operating conditions that do not compromise relay protection, yet are beyond expected limits. The relay issues a status warning message and continues to operate.
Subnet Mask	The subnet mask divides the local node IP address into two parts, a network number and a node address on that network. A subnet mask is four bytes of information and is expressed in the same format as an IP address.
Synchronized Phasor	A phasor calculated from data samples using an absolute time signal as the reference for the sampling process. The phasors from remote sites have a defined common phase relationship. Also known as synchrophasor.
Telnet	An Internet protocol for exchanging terminal data that connects a computer to a network server and allows control of that server and communication with other servers on the network.
Three-Phase Trip	A circuit breaker operation that occurs when the circuit breaker opens all three poles at the same time.
Torque Control	A method of using one relay element to supervise the operation of another.
Total Clearing Time	The time interval from the beginning of a fault condition to final interruption of the circuit.
Unbuffered Report	IEC 61850 IEDs can issue immediate unbuffered reports of internal events (caused by trigger options data-change, quality-change, and data-update) on a "best effort" basis. If no association exists, or if the transport data flow is not fast enough to support it, events can be lost.

SEL-651R-2 Recloser Control
Command Summary

Command	Access Level	Prompt	Command Description
2AC	1	=>	Enter Access Level 2.
ACC	0	=	Enter Access Level 1.
BAC	1	=>	Enter Breaker Access Level (Access Level B).
BNA	0	=	Display names of status bits in the A5D1 Fast Meter Message.
BRE	1	=>	Display breaker/recloser contact wear report.
BRE R	B	==>	Reset breaker/recloser contact wear monitor.
BRE W	B	==>	Preload breaker/recloser contact wear monitor data.
BTT	B	==>	Display latest battery load test results and time remaining until next discharge test.
BTT NOW	B	==>	Force a battery test and view the results.
CAL	2	=>>	Enter Access Level C. Reserved for SEL use only.
CAS	0	=	Display Compressed ASCII configuration message.
CEV *n*	1	=>	Display event report *n* in Compressed ASCII format. Parameter *n* can correspond to the number from the **HIS** command or the unique event number from the **HIS E** command.
CEV HIF *n*	1	=>	Display HIF event report *n* in Compressed ASCII format. Parameter *n* corresponds to the event number from the **HIS HIF** command.
CHI	1	=>	Display history data in Compressed ASCII format.
CHI HIF	1	=>	Display HIF history data in Compressed ASCII format.
CLO, CLO A, CLO B, CLO C	B	==>	Momentarily assert Relay Word bit CC3, CCA, CCB, or CCC).
COM *c*	1	=>	Show communications summary report (COM report) on MIRRORED BITS Channel *c* (*c* = A or B) using all failure records in the channel calculations.
COM *c row1*	1	=>	Show COM report for MIRRORED BITS Channel *c* using the latest *row1* failure records (*row1* = 1–255, where 1 is the most recent entry).
COM *c row1 row2*	1	=>	Show COM report for MIRRORED BITS Channel *c* using failure records *row1*–*row2* ([*row1* and *row2*] = 1–255).
COM *c date1*	1	=>	Show COM report for MIRRORED BITS Channel *c* using failures recorded on date *date1* (see **DAT** command for date format).
COM *c date1 date2*	1	=>	Show COM report for MIRRORED BITS Channel *c* using failures recorded between dates *date1* and *date2*, inclusive.
COM *c* C	1	=>	Clears communications records for MIRRORED BITS Channel *c* (or both channels if *c* is not specified).
COM *c*… L	1	=>	For all **COM** commands (except **COM *c* C**), **L** causes the specified COM report records to be listed after the summary.
CON *n*	B	==>	Set, clear, or pulse internal Remote Bit *n* (*n* is the Remote Bit number from 01–32). The control will respond with `CONTROL RBn:`. Reply with the following: `SRB` n (to set Remote Bit *n* (assert RB*n*)) `CRB` n (to clear Remote Bit *n* (deassert RB*n*)) `PRB` n (to pulse Remote Bit *n* (assert RB*n* for 1/4 cycle))
COP *m n*	2	=>>	Copy settings from Group *m* to Group *n*.

Command	Access Level	Prompt	Command Description
COP D *m n*	2	=>>	Copy DNP Map *m* to Map *n*.
COU *k*	1	=>	Show the SELOGIC counter values. Enter *k* for repeat count.
CST	1	=>	Display the recloser control status in Compressed ASCII format.
CSU *n*	1	=>	Display the event summary for event report *n* (with label lines) in Compressed ASCII format. If *n* is omitted, the default is 1 (most recent). Parameter *n* can correspond to the number from the **HIS** command or the unique event number from the **HIS E** command.
CSU HIF *n*	1	=>	Display the HIF event summary for event report *n* in Compressed ASCII format. If *n* is omitted, the default is 1 (most recent). Parameter *n* corresponds to the event number from the **HIS HIF** command.
DAT	1	=>	Display the internal clock date.
DAT *date*	1	=>	Set the internal clock date to *date* (Date Format setting DATE_F = MDY, YMD, or DMY).
DNA X or T	0	=	Display ASCII names of all Relay Word bits digital I/O. Either X or T is mandatory and results are identical.
ETH	1	=>	Displays information about Ethernet port(s).
ETH C	1	=>	Clears Ethernet port sent and received packets, bytes, and error statistics.
EVE *n*	1	=>	Show event report *n* with 4 samples per cycle (*n* = 1 to highest numbered event report, where 1 is the most recent report: see **HIS** command). If *n* is omitted (**EVE** command), the most recent report is displayed.
EVE *n* **A**	1	=>	Show event report *n* with analog section only.
EVE *n* **C**	1	=>	Show event report *n* in Compressed ASCII format with 16 samples-per-cycle analog resolution and 4 samples-per-cycle digital resolution.
EVE *n* **D**	1	=>	Show event report *n* with digital section only.
EVE *n* **L**	1	=>	Show event report *n* with 32 samples per cycle (similar to **EVE** *n* **S32**).
EVE *n* **L***y*	1	=>	Show first *y* cycles of event report *n* (*y* = 1 to Global setting LER).
EVE *n* **M**	1	=>	Show event report *n* with communications section only.
EVE *n* **P**	1	=>	Show event report *n* with synchrophasor-level accuracy time adjustment.
EVE *n* **R**	1	=>	Show event report *n* in raw (unfiltered) format with 32 samples-per-cycle resolution.
EVE *n* **S***x*	1	=>	Show event report *n* with *x* samples per cycle (*x* = 4, 16, 32, or 128). Must append R parameter for S128 (**EVE S128 R**)
EVE *n* **V**	1	=>	Show event report *n* with variable scaling for analog values.
EXI	0	=	Exit active Telnet session.
FIL DIR	1	=>	Display a list of available files.
FIL READ *filename*	1	=>	Transfer settings file or event file *filename* from the relay to the PC.
FIL SHOW *filename*	1	=>	Display contents of the ASCII file *filename*.
FIL WRITE *filename*	2	=>>	Transfer settings file *filename* from the PC to the relay.
GOO	1	=>	Display GOOSE information.
GOO *k*	1	=>	Display GOOSE information *k* times.
GOO S	1	=>	Display a list of GOOSE subscriptions with their ID.
GOO S *n*	1	=>	Display GOOSE statistics for subscription ID *n*.
GOO S *n* **C**	1	=>	Clear GOOSE statistics for subscription ID *n*.
GOO S *n* **L**	1	=>	Display GOOSE statistics for subscription ID *n* including error history.
GOO S ALL	1	=>	Display GOOSE statistics for all subscriptions.

Command	Access Level	Prompt	Command Description
GOO S ALL C	1	=>	Clear GOOSE statistics for all subscriptions.
GOO S ALL L	1	=>	Display GOOSE statistics for all subscriptions including error history.
GRO	1	=>	Display active group number.
GRO *n*	B	==>	Change active group to Group *n* (*n* = 1–8).
HIS	1	=>	Display event histories with the oldest at the bottom of the list and the most recent at the top of the list.
HIS *n*	1	=>	Display event histories with the oldest at the bottom of the list and the most recent at the top of the list beginning at event *n*.
HIS C	1	=>	Clear/reset the event history and all corresponding event reports from nonvolatile memory.
HIS E	1	=>	Same as **HIS**, but events are identified with a unique number in the range 10000–65535.
HIS HIF	1	=>	Display HIF event histories with the oldest at the bottom of the list and the most recent at the top of the list.
HIS HIF *n*	1	=>	Display *n* HIF event histories with the oldest at the bottom of the list and the most recent at the top of the list.
HIS HIF C	1	=>	Clear/reset the HIF event history and all corresponding event reports from nonvolatile memory.
HIZ	1	=>	Display HIZ event reports with the oldest at the bottom of the list and the most recent at the top of the list.
HIZ *n*	1	=>	Display *n* HIZ event reports with the oldest at the bottom of the list and the most recent at the top of the list.
HIZ C	1	=>	Clear/reset the HIZ event reports from nonvolatile memory.
ID	0	=	Display the firmware id, user id, device code, part number, and configuration information.
INI HIF	2	=>>	Force HIF algorithm into initial tuning mode.
L_D	2	=>>	Prepares the relay to receive new firmware.
LDP	1	=>	Show entire Load Profile (LDP) report.
LDP *n*	1	=>	Show latest *n* rows in the LDP report (*n* = 1 to several thousand, where 1 is the most recent entry).
LDP *row1 row2*	1	=>	Show rows *row1*–*row2* in the LDP report ([*row1* and *row2*] = 1 to several thousand).
LDP *date1*	1	=>	Show all rows in the LDP report recorded on the specified date *date1* (see **DAT** command for date format).
LDP *date1 date2*	1	=>	Show all rows in the LDP report recorded between dates *date1* and *date2*, inclusive.
LDP C	1	=>	Clears the Load Profile data from memory.
LDP D	1	=>	Display the number of days of Load Profile memory capacity remaining before data over-write occurs.
LOG HIF	1	=>	Display the HIF alarm and fault calculations as a percentage of their final value.
LOG HIF *n*	1	=>	Display the *n* most recent **LOG HIF** entries.
LOG HIF C	1	=>	Clear all **LOG HIF** data from memory.
LOO *c t*	2	=>>	Set MIRRORED BITS Channel *c* to loopback (*c* = A or B). The received MIRRORED BITS elements are forced to default values during the loopback test; *t* specifies the loopback duration in minutes (*t* = 1–5000, default is 5).
LOO *c t* **DATA**	2	=>>	Set MIRRORED BITS Channel *c* to loopback for duration *t* minutes. **DATA** allows the received MIRRORED BITS elements to change during the loopback test.
LOO *c* **R**	2	=>>	Cease loopback on MIRRORED BITS Channel *c* and return the channel to normal operation.
MAC	1	=>	Display Ethernet port MAC address.
MET *k*	1	=>	Display instantaneous metering data *k* times.
MET D	1	=>	Display demand and peak demand metering data.

Command	Access Level	Prompt	Command Description
MET E	1	=>	Display energy metering data.
MET H	1	=>	Display fundamental magnitudes, root-mean-square (rms) magnitudes, Total Harmonic Distortion, and harmonic magnitudes for the first 16 harmonics.
MET HIF *k*	1	=>	Display the HIF alarm and fault calculations as a percentage of their final value. Enter *k* for repeat count ($k = 1$–32767; if not specified, default is 1).
MET M	1	=>	Display maximum and minimum metering data.
MET PM *k*	1	=>	Display synchrophasor measurements (available when TSOK = logical 1). Enter *k* for repeat count.
MET PM *time*	1	=>	Display synchrophasor measurements (available when TSOK = logical 1). Enter *time* to display the synchrophasor for an exact specified time, in 24-hour format.
MET PM HIS	1	=>	Display the most recent MET PM synchrophasor report.
MET RD	1	=>	Reset demand metering data.
MET RE	1	=>	Reset energy metering data.
MET RM	1	=>	Reset maximum metering data. All values will display RESET until new maximum/minimum values are recorded.
MET RMS	1	=>	Display root-mean-square (rms) metering data.
MET RP	1	=>	Reset peak demand metering data.
OPE, OPE A, OPE B, OPE C	B	==>	Momentarily assert Relay Word bit OC3, OCA, OCB, or OCC).
PAR	2	=>>	Change the device part number. Use only under the direction of SEL.
PAS 1	2	=>>	Change the Access Level 1 password.
PAS B	2	=>>	Change the Access Level B password.
PAS 2	2	=>>	Change the Access Level 2 password.
PAS C	C	==>>	Change the Access Level C password.
PUL *n s*	B	==>	Pulse output contact OUT*n* (*n* = 201, 202 [all models]; 101–108 [models with extra I/O]) for *s* (1–30) seconds. Parameter OUT*n* must be specified; *s* defaults to 1 if not specified.
QUI	0	=	Reduce access level to Access Level 0 (exit relay control).
R_S	2	=>>	Restore factory-default settings and passwords. Use only under the direction of SEL. Only available after a settings or critical RAM failure.
SER	1	=>	Show entire Sequential Events Recorder (SER) report.
SER *n*	1	=>	Show latest *n* rows in the SER report (*n* = 1–1024, where 1 is the most recent entry).
SER *row1 row2*	1	=>	Show rows *row1*–*row2* in the SER report.
SER *date1*	1	=>	Show all rows in the SER report recorded on the specified date *date1* (see **DAT** command for date format).
SER *date1 date2*	1	=>	Show all rows in the SER report recorded between dates *date1* and *date2*, inclusive.
SER C	1	=>	Clears SER report from nonvolatile memory.
SET *n*	2	=>>	Change relay settings (overcurrent, reclosing, timers, etc.) for Group *n* (*n* = 1–8; if not specified, default is the active settings group).
SET D *n*	2	=>>	Change DNP Map *n* settings (*n* = 1, 2, or 3).
SET F	2	=>>	Change Front-Panel settings.
SET G	2	=>>	Change Global settings.
SET L *n*	2	=>>	Change SELOGIC control equation settings for Group *n* (*n* = 1–8; if not specified, default is the active settings group).
SET M	2	=>>	Change Modbus settings.

Command	Access Level	Prompt	Command Description
SET P *p*	2	=>>	Change Port settings for Serial Port *p* (*p* = 1, 2, 3, F, or 5; if not specified, default is the active port).
SET R	2	=>>	Change SER and LDP Recorder settings.
SET … *name*	2	=>>	For all **SET** commands, jump ahead to specific setting by entering setting name.
SET … TERSE	2	=>>	For all **SET** commands, the **TERSE** command disables the automatic **SHO** command after settings entry.
SHO *n*	1	=>	Show relay settings (overcurrent, reclosing, timers, etc.) for Group *n* (*n* = 1–8; if not specified, default is the active settings group).
SHO D *n*	1	=>	Show DNP Map *n* settings (*n* = 1, 2, or 3).
SHO F	1	=>	Show Front-Panel settings.
SHO G	1	=>	Show Global settings.
SHO L *n*	1	=>	Show SELOGIC control equation settings for Group *n* (*n* = 1–8; if not specified, default is the active settings group).
SHO M	1	=>	Show Modbus settings.
SHO P *p*	1	=>	Show Port settings for Serial Port *p* (*p* = 1, 2, 3, F, or 5; if not specified, default is the active port).
SHO R	1	=>	Show SER and LDP Recorder settings.
SHO … *name*	1	=>	For all **SHO** commands, jump ahead to specific setting by entering setting name.
SNS	0	=	Display the Fast Message name string of the SER settings.
SSI	1	=>	Show entire Voltage Sag/Swell/Interruption (SSI) report.
SSI *n*	1	=>	Show latest *n* rows in SSI report (*n* = 1 to several thousand, where 1 is the most recent entry).
SSI *row1 row2*	1	=>	Show rows *row1*–*row2* in SSI report.
SSI *date1*	1	=>	Show all rows in SSI report recorded on the specified date *date1* (see **DAT** command for date format).
SSI *date1 date2*	1	=>	Show all rows in SSI report recorded between dates *date1* and *date2*, inclusive.
SSI C	1	=>	Clears SSI report from nonvolatile memory.
SSI R	1	=>	Reset the VSSI recorder logic and clear the Vbase value.
SSI T	1	=>	Trigger the SSI recorder.
STA *k*	1	=>	Display the recloser control self-test information *k* times (*k* = 1–32767; if not specified, default is 1).
STA C	2	=>>	Clear status warning or failure and reboot the recloser control.
STA S	1	=>	Display the memory and execution utilization for the SELOGIC control equations.
SUM HIF *n*	1	=>	Display the HIF summary message for event *n*.
TAR	1	=>	Display Relay Word 0 or last displayed target row.
TAR *n k*	1	=>	Display Relay Word row number *n*. Enter *k* for repeat count (*k* = 1–32767; if not specified, default is 1).
TAR *name k*	1	=>	Display Relay Word row containing *name*. Enter *k* for repeat count (*k* = 1–32767; if not specified, default is 1).
TAR LIST	1	=>	Shows all the Relay Word bits in all of the rows.
TAR R	1	=>	Reset front-panel tripping targets.
TAR ROW …	1	=>	Shows the Relay Word row number at the start of each line, with other selected **TAR** commands as described above, such as *n*, **name**, *k*, and **LIST**.
TES DB	B	==>	Display the present status of digital and analog overrides.

Command	Access Level	Prompt	Command Description
TES DB A *name value*	B	==>	Override analog label *name* with *value* in communications interface.
TES DB A *row_x value*	B	==>	Override all Relay Word bits in Relay Word row number *row_x* with *value*.
TES DB D *name value*	B	==>	Override Relay Word bit *name* with *value* in communications interface, where *value* = 0 or 1.
TES DB *name* **OFF**	B	==>	Clear (analog or digital) override for element *name*.
TES DB OFF	B	==>	Clear all analog and digital overrides.
TIM	1	=>	Display the present internal clock time.
TIM *hh:mm*	1	=>	Set the internal clock to *hh:mm*.
TIM *hh:mm:ss*	1	=>	Set the internal clock to *hh:mm:ss*.
TIM Q	1	=>	Display time statistics.
TIM DST	1	=>	Display daylight-saving time information.
TRI	1	=>	Trigger event report data capture.
TRI *time*	1	=>	Trigger an event report data capture at specified *time*.
TRI HIF	1	=>	Trigger an HIF event report data capture. Only available in recloser controls that support Arc Sense technology.
TRI STA	1	=>	Display the status of a previous **TRI** *time* command.
VEC D	2	=>>	Display the standard Vector Report.
VEC E	2	=>>	Display the Extended Vector Report.
VER	1	=>	Display information about the configuration of the recloser control.

Keystroke Commands

Keystroke	Description	Keystroke When Using SET Command	Description
<Ctrl+Q>	Sends **XON** command to restart communications port output previously halted by XOFF.	**<Enter>**	Retains setting and moves on to next setting.
<Ctrl+S>	Sends **XOFF** command to pause communications port output.	**^ <Enter>**	Returns to previous setting.
<Ctrl+X>	Sends **CANCEL** command to abort current command and return to current access level prompt.	**< <Enter>**	Returns to previous setting section.
		> <Enter>	Skips to next setting section.
		END <Enter>	Exits setting editing session, then prompts user to save settings.
		<Ctrl+X>	Aborts setting editing session without saving changes.

SEL-651R-2 Recloser Control
Command Summary

Command	Access Level	Prompt	Command Description
2AC	1	=>	Enter Access Level 2.
ACC	0	=	Enter Access Level 1.
BAC	1	=>	Enter Breaker Access Level (Access Level B).
BNA	0	=	Display names of status bits in the A5D1 Fast Meter Message.
BRE	1	=>	Display breaker/recloser contact wear report.
BRE R	B	==>	Reset breaker/recloser contact wear monitor.
BRE W	B	==>	Preload breaker/recloser contact wear monitor data.
BTT	B	==>	Display latest battery load test results and time remaining until next discharge test.
BTT NOW	B	==>	Force a battery test and view the results.
CAL	2	=>>	Enter Access Level C. Reserved for SEL use only.
CAS	0	=	Display Compressed ASCII configuration message.
CEV n	1	=>	Display event report n in Compressed ASCII format. Parameter n can correspond to the number from the **HIS** command or the unique event number from the **HIS E** command.
CEV HIF n	1	=>	Display HIF event report n in Compressed ASCII format. Parameter n corresponds to the event number from the **HIS HIF** command.
CHI	1	=>	Display history data in Compressed ASCII format.
CHI HIF	1	=>	Display HIF history data in Compressed ASCII format.
CLO, CLO A, CLO B, CLO C	B	==>	Momentarily assert Relay Word bit CC3, CCA, CCB, or CCC).
COM c	1	=>	Show communications summary report (COM report) on MIRRORED BITS Channel c (c = A or B) using all failure records in the channel calculations.
COM c $row1$	1	=>	Show COM report for MIRRORED BITS Channel c using the latest $row1$ failure records ($row1$ = 1–255, where 1 is the most recent entry).
COM c $row1$ $row2$	1	=>	Show COM report for MIRRORED BITS Channel c using failure records $row1$–$row2$ ([$row1$ and $row2$] = 1–255).
COM c $date1$	1	=>	Show COM report for MIRRORED BITS Channel c using failures recorded on date $date1$ (see **DAT** command for date format).
COM c $date1$ $date2$	1	=>	Show COM report for MIRRORED BITS Channel c using failures recorded between dates $date1$ and $date2$, inclusive.
COM c **C**	1	=>	Clears communications records for MIRRORED BITS Channel c (or both channels if c is not specified).
COM c… **L**	1	=>	For all **COM** commands (except **COM** c **C**), **L** causes the specified COM report records to be listed after the summary.
CON n	B	==>	Set, clear, or pulse internal Remote Bit n (n is the Remote Bit number from 01–32). The control will respond with `CONTROL RBn:`. Reply with the following: `SRB  n` (to set Remote Bit n (assert RBn)) `CRB  n` (to clear Remote Bit n (deassert RBn)) `PRB  n` (to pulse Remote Bit n (assert RBn for 1/4 cycle))
COP m n	2	=>>	Copy settings from Group m to Group n.

Command	Access Level	Prompt	Command Description
COP D *m n*	2	=>>	Copy DNP Map *m* to Map *n*.
COU *k*	1	=>	Show the SELOGIC counter values. Enter *k* for repeat count.
CST	1	=>	Display the recloser control status in Compressed ASCII format.
CSU *n*	1	=>	Display the event summary for event report *n* (with label lines) in Compressed ASCII format. If *n* is omitted, the default is 1 (most recent). Parameter *n* can correspond to the number from the **HIS** command or the unique event number from the **HIS E** command.
CSU HIF *n*	1	=>	Display the HIF event summary for event report *n* in Compressed ASCII format. If *n* is omitted, the default is 1 (most recent). Parameter *n* corresponds to the event number from the **HIS HIF** command.
DAT	1	=>	Display the internal clock date.
DAT *date*	1	=>	Set the internal clock date to *date* (Date Format setting DATE_F = MDY, YMD, or DMY).
DNA X or T	0	=	Display ASCII names of all Relay Word bits digital I/O. Either X or T is mandatory and results are identical.
ETH	1	=>	Displays information about Ethernet port(s).
ETH C	1	=>	Clears Ethernet port sent and received packets, bytes, and error statistics.
EVE *n*	1	=>	Show event report *n* with 4 samples per cycle (*n* = 1 to highest numbered event report, where 1 is the most recent report: see **HIS** command). If *n* is omitted (**EVE** command), the most recent report is displayed.
EVE *n* **A**	1	=>	Show event report *n* with analog section only.
EVE *n* **C**	1	=>	Show event report *n* in Compressed ASCII format with 16 samples-per-cycle analog resolution and 4 samples-per-cycle digital resolution.
EVE *n* **D**	1	=>	Show event report *n* with digital section only.
EVE *n* **L**	1	=>	Show event report *n* with 32 samples per cycle (similar to **EVE** *n* **S32**).
EVE *n* **L***y*	1	=>	Show first *y* cycles of event report *n* (*y* = 1 to Global setting LER).
EVE *n* **M**	1	=>	Show event report *n* with communications section only.
EVE *n* **P**	1	=>	Show event report *n* with synchrophasor-level accuracy time adjustment.
EVE *n* **R**	1	=>	Show event report *n* in raw (unfiltered) format with 32 samples-per-cycle resolution.
EVE *n* **S***x*	1	=>	Show event report *n* with *x* samples per cycle (*x* = 4, 16, 32, or 128). Must append R parameter for S128 (**EVE S128 R**)
EVE *n* **V**	1	=>	Show event report *n* with variable scaling for analog values.
EXI	0	=	Exit active Telnet session.
FIL DIR	1	=>	Display a list of available files.
FIL READ *filename*	1	=>	Transfer settings file or event file *filename* from the relay to the PC.
FIL SHOW *filename*	1	=>	Display contents of the ASCII file *filename*.
FIL WRITE *filename*	2	=>>	Transfer settings file *filename* from the PC to the relay.
GOO	1	=>	Display GOOSE information.
GOO *k*	1	=>	Display GOOSE information *k* times.
GOO S	1	=>	Display a list of GOOSE subscriptions with their ID.
GOO S *n*	1	=>	Display GOOSE statistics for subscription ID *n*.
GOO S *n* **C**	1	=>	Clear GOOSE statistics for subscription ID *n*.
GOO S *n* **L**	1	=>	Display GOOSE statistics for subscription ID *n* including error history.
GOO S ALL	1	=>	Display GOOSE statistics for all subscriptions.

Command	Access Level	Prompt	Command Description
GOO S ALL C	1	=>	Clear GOOSE statistics for all subscriptions.
GOO S ALL L	1	=>	Display GOOSE statistics for all subscriptions including error history.
GRO	1	=>	Display active group number.
GRO *n*	B	==>	Change active group to Group *n* (*n* = 1–8).
HIS	1	=>	Display event histories with the oldest at the bottom of the list and the most recent at the top of the list.
HIS *n*	1	=>	Display event histories with the oldest at the bottom of the list and the most recent at the top of the list beginning at event *n*.
HIS C	1	=>	Clear/reset the event history and all corresponding event reports from nonvolatile memory.
HIS E	1	=>	Same as **HIS**, but events are identified with a unique number in the range 10000–65535.
HIS HIF	1	=>	Display HIF event histories with the oldest at the bottom of the list and the most recent at the top of the list.
HIS HIF *n*	1	=>	Display *n* HIF event histories with the oldest at the bottom of the list and the most recent at the top of the list.
HIS HIF C	1	=>	Clear/reset the HIF event history and all corresponding event reports from nonvolatile memory.
HIZ	1	=>	Display HIZ event reports with the oldest at the bottom of the list and the most recent at the top of the list.
HIZ *n*	1	=>	Display *n* HIZ event reports with the oldest at the bottom of the list and the most recent at the top of the list.
HIZ C	1	=>	Clear/reset the HIZ event reports from nonvolatile memory.
ID	0	=	Display the firmware id, user id, device code, part number, and configuration information.
INI HIF	2	=>>	Force HIF algorithm into initial tuning mode.
L_D	2	=>>	Prepares the relay to receive new firmware.
LDP	1	=>	Show entire Load Profile (LDP) report.
LDP *n*	1	=>	Show latest *n* rows in the LDP report (*n* = 1 to several thousand, where 1 is the most recent entry).
LDP *row1 row2*	1	=>	Show rows *row1*–*row2* in the LDP report ([*row1* and *row2*] = 1 to several thousand).
LDP *date1*	1	=>	Show all rows in the LDP report recorded on the specified date *date1* (see **DAT** command for date format).
LDP *date1 date2*	1	=>	Show all rows in the LDP report recorded between dates *date1* and *date2*, inclusive.
LDP C	1	=>	Clears the Load Profile data from memory.
LDP D	1	=>	Display the number of days of Load Profile memory capacity remaining before data over-write occurs.
LOG HIF	1	=>	Display the HIF alarm and fault calculations as a percentage of their final value.
LOG HIF *n*	1	=>	Display the *n* most recent **LOG HIF** entries.
LOG HIF C	1	=>	Clear all **LOG HIF** data from memory.
LOO *c t*	2	=>>	Set MIRRORED BITS Channel *c* to loopback (*c* = A or B). The received MIRRORED BITS elements are forced to default values during the loopback test; *t* specifies the loopback duration in minutes (*t* = 1–5000, default is 5).
LOO *c t* **DATA**	2	=>>	Set MIRRORED BITS Channel *c* to loopback for duration *t* minutes. **DATA** allows the received MIRRORED BITS elements to change during the loopback test.
LOO *c* **R**	2	=>>	Cease loopback on MIRRORED BITS Channel *c* and return the channel to normal operation.
MAC	1	=>	Display Ethernet port MAC address.
MET *k*	1	=>	Display instantaneous metering data *k* times.
MET D	1	=>	Display demand and peak demand metering data.

4

Command	Access Level	Prompt	Command Description
MET E	1	=>	Display energy metering data.
MET H	1	=>	Display fundamental magnitudes, root-mean-square (rms) magnitudes, Total Harmonic Distortion, and harmonic magnitudes for the first 16 harmonics.
MET HIF k	1	=>	Display the HIF alarm and fault calculations as a percentage of their final value. Enter k for repeat count (k = 1–32767; if not specified, default is 1).
MET M	1	=>	Display maximum and minimum metering data.
MET PM k	1	=>	Display synchrophasor measurements (available when TSOK = logical 1). Enter k for repeat count.
MET PM $time$	1	=>	Display synchrophasor measurements (available when TSOK = logical 1). Enter $time$ to display the synchrophasor for an exact specified time, in 24-hour format.
MET PM HIS	1	=>	Display the most recent MET PM synchrophasor report.
MET RD	1	=>	Reset demand metering data.
MET RE	1	=>	Reset energy metering data.
MET RM	1	=>	Reset maximum metering data. All values will display RESET until new maximum/minimum values are recorded.
MET RMS	1	=>	Display root-mean-square (rms) metering data.
MET RP	1	=>	Reset peak demand metering data.
OPE, OPE A, OPE B, OPE C	B	==>	Momentarily assert Relay Word bit OC3, OCA, OCB, or OCC).
PAR	2	=>>	Change the device part number. Use only under the direction of SEL.
PAS 1	2	=>>	Change the Access Level 1 password.
PAS B	2	=>>	Change the Access Level B password.
PAS 2	2	=>>	Change the Access Level 2 password.
PAS C	C	==>>	Change the Access Level C password.
PUL n s	B	==>	Pulse output contact OUTn (n = 201, 202 [all models]; 101–108 [models with extra I/O]) for s (1–30) seconds. Parameter OUTn must be specified; s defaults to 1 if not specified.
QUI	0	=	Reduce access level to Access Level 0 (exit relay control).
R_S	2	=>>	Restore factory-default settings and passwords. Use only under the direction of SEL. Only available after a settings or critical RAM failure.
SER	1	=>	Show entire Sequential Events Recorder (SER) report.
SER n	1	=>	Show latest n rows in the SER report (n = 1–1024, where 1 is the most recent entry).
SER $row1$ $row2$	1	=>	Show rows $row1$–$row2$ in the SER report.
SER $date1$	1	=>	Show all rows in the SER report recorded on the specified date $date1$ (see **DAT** command for date format).
SER $date1$ $date2$	1	=>	Show all rows in the SER report recorded between dates $date1$ and $date2$, inclusive.
SER C	1	=>	Clears SER report from nonvolatile memory.
SET n	2	=>>	Change relay settings (overcurrent, reclosing, timers, etc.) for Group n (n = 1–8; if not specified, default is the active settings group).
SET D n	2	=>>	Change DNP Map n settings (n = 1, 2, or 3).
SET F	2	=>>	Change Front-Panel settings.
SET G	2	=>>	Change Global settings.
SET L n	2	=>>	Change SELOGIC control equation settings for Group n (n = 1–8; if not specified, default is the active settings group).
SET M	2	=>>	Change Modbus settings.

Command	Access Level	Prompt	Command Description
SET P *p*	2	=>>	Change Port settings for Serial Port *p* (*p* = 1, 2, 3, F, or 5; if not specified, default is the active port).
SET R	2	=>>	Change SER and LDP Recorder settings.
SET … *name*	2	=>>	For all **SET** commands, jump ahead to specific setting by entering setting name.
SET … TERSE	2	=>>	For all **SET** commands, the **TERSE** command disables the automatic **SHO** command after settings entry.
SHO *n*	1	=>	Show relay settings (overcurrent, reclosing, timers, etc.) for Group *n* (*n* = 1–8; if not specified, default is the active settings group).
SHO D *n*	1	=>	Show DNP Map *n* settings (*n* = 1, 2, or 3).
SHO F	1	=>	Show Front-Panel settings.
SHO G	1	=>	Show Global settings.
SHO L *n*	1	=>	Show SELOGIC control equation settings for Group *n* (*n* = 1–8; if not specified, default is the active settings group).
SHO M	1	=>	Show Modbus settings.
SHO P *p*	1	=>	Show Port settings for Serial Port *p* (*p* = 1, 2, 3, F, or 5; if not specified, default is the active port).
SHO R	1	=>	Show SER and LDP Recorder settings.
SHO … *name*	1	=>	For all **SHO** commands, jump ahead to specific setting by entering setting name.
SNS	0	=	Display the Fast Message name string of the SER settings.
SSI	1	=>	Show entire Voltage Sag/Swell/Interruption (SSI) report.
SSI *n*	1	=>	Show latest *n* rows in SSI report (*n* = 1 to several thousand, where 1 is the most recent entry).
SSI *row1 row2*	1	=>	Show rows *row1–row2* in SSI report.
SSI *date1*	1	=>	Show all rows in SSI report recorded on the specified date *date1* (see **DAT** command for date format).
SSI *date1 date2*	1	=>	Show all rows in SSI report recorded between dates *date1* and *date2*, inclusive.
SSI C	1	=>	Clears SSI report from nonvolatile memory.
SSI R	1	=>	Reset the VSSI recorder logic and clear the Vbase value.
SSI T	1	=>	Trigger the SSI recorder.
STA *k*	1	=>	Display the recloser control self-test information *k* times (*k* = 1–32767; if not specified, default is 1).
STA C	2	=>>	Clear status warning or failure and reboot the recloser control.
STA S	1	=>	Display the memory and execution utilization for the SELOGIC control equations.
SUM HIF *n*	1	=>	Display the HIF summary message for event *n*.
TAR	1	=>	Display Relay Word 0 or last displayed target row.
TAR *n k*	1	=>	Display Relay Word row number *n*. Enter *k* for repeat count (*k* = 1–32767; if not specified, default is 1).
TAR *name k*	1	=>	Display Relay Word row containing *name*. Enter *k* for repeat count (*k* = 1–32767; if not specified, default is 1).
TAR LIST	1	=>	Shows all the Relay Word bits in all of the rows.
TAR R	1	=>	Reset front-panel tripping targets.
TAR ROW …	1	=>	Shows the Relay Word row number at the start of each line, with other selected **TAR** commands as described above, such as *n*, *name*, *k*, and **LIST**.
TES DB	B	==>	Display the present status of digital and analog overrides.

Command	Access Level	Prompt	Command Description
TES DB A *name value*	B	==>	Override analog label *name* with *value* in communications interface.
TES DB A *row_x value*	B	==>	Override all Relay Word bits in Relay Word row number *row_x* with *value*.
TES DB D *name value*	B	==>	Override Relay Word bit *name* with *value* in communications interface, where *value* = 0 or 1.
TES DB *name* **OFF**	B	==>	Clear (analog or digital) override for element *name*.
TES DB OFF	B	==>	Clear all analog and digital overrides.
TIM	1	=>	Display the present internal clock time.
TIM *hh:mm*	1	=>	Set the internal clock to *hh:mm*.
TIM *hh:mm:ss*	1	=>	Set the internal clock to *hh:mm:ss*.
TIM Q	1	=>	Display time statistics.
TIM DST	1	=>	Display daylight-saving time information.
TRI	1	=>	Trigger event report data capture.
TRI *time*	1	=>	Trigger an event report data capture at specified *time*.
TRI HIF	1	=>	Trigger an HIF event report data capture. Only available in recloser controls that support Arc Sense technology.
TRI STA	1	=>	Display the status of a previous **TRI** *time* command.
VEC D	2	=>>	Display the standard Vector Report.
VEC E	2	=>>	Display the Extended Vector Report.
VER	1	=>	Display information about the configuration of the recloser control.

Keystroke Commands

Keystroke	Description	Keystroke When Using SET Command	Description
<Ctrl+Q>	Sends **XON** command to restart communications port output previously halted by XOFF.	**<Enter>**	Retains setting and moves on to next setting.
<Ctrl+S>	Sends **XOFF** command to pause communications port output.	**^ <Enter>**	Returns to previous setting.
<Ctrl+X>	Sends **CANCEL** command to abort current command and return to current access level prompt.	**< <Enter>**	Returns to previous setting section.
		> <Enter>	Skips to next setting section.
		END <Enter>	Exits setting editing session, then prompts user to save settings.
		<Ctrl+X>	Aborts setting editing session without saving changes.

LOUISVILLE GAS AND ELECTRIC COMPANY

**Response to Attorney General's Supplemental Data Requests for Information
Dated December 13, 2018**

Case No. 2018-00295

Question No. 69

Responding Witness: John K. Wolfe

Q-69.   Explain how real-time information gained from SCADA, DSCADA, and ADMS
will be analyzed and centrally managed.

A-69.   ADMS is a common industry term that includes the Outage Management System
(OMS), Distribution Management System (DMS) and distribution SCADA. The
OMS and DMS modules are contained in a single information system, which is
then integrated with the distribution SCADA system. This allows all data to be
analyzed and managed centrally.

The distribution SCADA system will gather and provide data from field devices
such as reclosers and substation devices to the DMS allowing the Distribution
Systems Operator (DSO) to remotely monitor and operate these devices. The DMS
combines the distribution SCADA and outage call data from the OMS and provides
isolation and restoration plans to the DSO. These plans can be automatically
performed to isolate and restore the distribution SCADA devices or can be
manually performed by the DSO. The DMS will also recommend manual steps for
isolation and restoration on manually operated devices when requested by the DSO.

Additionally, the DMS provides real-time operational status of the system to the
DSO who can then coordinate work in the field. The DMS documents and tracks
switch plans and field safety work procedures such as Cautions and Hold cards.

LOUISVILLE GAS AND ELECTRIC COMPANY

**Response to Attorney General's Supplemental Data Requests for Information
Dated December 13, 2018**

Case No. 2018-00295

Question No. 70

Responding Witness: Lonnie E. Bellar / John K. Wolfe

Q-70. Provide projected spending levels for the next five (5) years for each of the
following items:

    a. overhead line replacements;

    b. underground line replacements;

    c. breaker replacements;

    d. switch replacements;

    e. substation insulator replacements;

    f. substation arrester replacements;

    g. coupling capacitor replacements

A-70. a-g. The tables below show the costs for each item for distribution and
transmission.

	Electric Distribution				
	2019	2020	2021	2022	2023
Overhead Line Replacements	$4,040,332	$4,212,459	$5,216,000	$4,104,000	$4,312,000
Underground Line Replacements	$17,687,854	$16,238,955	$14,922,027	$3,026,000	$3,117,000
Breaker Replacements	$1,764,900	$1,585,776	$1,711,833	$1,485,000	$1,634,000
Switch Replacements	Not specifically budgeted for in electric distribution				
Substation Insulator Replacements	$163,876	$167,898	$171,926	$177,000	$181,000
Substation Arrester Replacements	$64,999	$67,000	$68,000	$70,000	$72,000
Coupling Capacitor Replacements	Not a device used in electric distribution				

	Transmission				
	2019	2020	2021	2022	2023
Overhead Line Replacements	$10,130,316	$12,741,920	$18,022,162	$11,708,765	$9,739,584
Underground Line Replacements	$0	$0	$0	$0	$0
Breaker Replacements	**	**	**	**	**
Lines Switch Replacements	$155,988	$507,496	$0	$0	$0
Substation Insulator Replacements	**	**	**	**	**
Substation Arrester Replacements	**	**	**	**	**
Coupling Capacitor Replacements	**	**	**	**	**

** This information is not available as the replacement of these items is not planned or budgeted at a specific asset level. Transmission substation asset replacement programs are budgeted at a substation level where multiple asset replacement programs are often bundled into a single substation project. Taking this holistic approach is a more efficient means to replacing targeted assets outlined in the Transmission System Improvement Plan.

LOUISVILLE GAS AND ELECTRIC COMPANY

**Response to Attorney General's Supplemental Data Requests for Information
Dated December 13, 2018**

Case No. 2018-00295

Question No. 71

Responding Witness: Lonnie E. Bellar

Q-71.   Describe the efforts the Companies are making to engage customers and other potential stakeholders in distribution grid enhancements.

A-71.   LG&E and KU are promoting grid enhancements in a number of owned, earned and paid communications channels, including an animated video, television segments, native content, and digital and social advertising. The Companies have also responded to media inquiries, and promoted grid enhancements in customer newsletters, and on our website and social channels. Internal communications have focused on educating personnel and key contractors on overall and specific grid enhancement efforts to support direct customer and key stakeholder engagements.

LOUISVILLE GAS AND ELECTRIC COMPANY

**Response to Attorney General's Supplemental Data Requests for Information
Dated December 13, 2018**

Case No. 2018-00295

Question No. 72

Responding Witness: John K. Wolfe

Q-72.   To the extent not already provided, provide all cost benefit analyses performed
since the 2016 rate cases associated with Distribution Automation, preferably in
Excel electronic format, with active cells.

A-72.   See page 13 of the attachment to AG 1-193. Also, see attachments being provided
in Excel format.

The attachments are being provided in separate files in Excel format.

LOUISVILLE GAS AND ELECTRIC COMPANY

Response to Attorney General's Supplemental Data Requests for Information
Dated December 13, 2018

Case No. 2018-00295

Question No. 73

Responding Witness: Christopher M. Garrett

Q-73.   The Companies' response to AG DR 1-136(b) states, "See response to PSC 2-62(c)." The response to PSC 2-62(c) provides detail on the composition of the deferred tax balances for the base test year. It does not address the book-tax timing differences that underlie the deferred tax balances in rate base for the forecasted test year. Answer the question as restated below:

   a.   For each line item in Att_[LG&E]_PSC_1-65_Depreciation_Exp_Wkpr_Electric, provide the monthly gross book-tax timing differences through April 30, 2020.

   b.   For each line item in Att_[LG&E]_PSC_1-65_Depreciation_Exp_Wkpr_Gas, provide the monthly gross book-tax timing differences through April 30, 2020.

   c.   For each line item in Att_[LG&E]_PSC_1-65_Depreciation_Exp_Wkpr_Electric, provide the monthly deferred income tax activity through April 30, 2020.

   d.   For each line item in Att_[LG&E]_PSC_1-65_Depreciation_Exp_Wkpr_Gas, provide the monthly deferred income tax activity through April 30, 2020.

   e.   For each line item in Att_[LG&E]_PSC_1-65_Depreciation_Exp_Wkpr_Electric, provide the monthly accumulated deferred income tax (ADIT) balances through April 30, 2020.

   f.   For each line item in Att_[LG&E]_PSC_1-65_Depreciation_Exp_Wkpr_Gas, provide the monthly accumulated deferred income tax (ADIT) balances through April 30, 2020.

   g.   Demonstrate that the aggregate ADIT balances in response to subparts c) and d), above, reconciles to the amount reflected in rate base for test period ending April 30, 2020.

h. Provide the data requested in subparts a) through g), above, in electronic format with formulas intact.

A-73.

a-h.

The information requested is not available. Gross book-tax timing differences are not tracked by book depreciation groups, they are tracked by tax depreciation groups for each year's vintage. It is also not possible to derive that amount by simply applying a tax depreciation rate to the ending depreciable book basis amounts on each line item in Att_[LG&E]_PSC_1-65_Depreciation_Exp_Wkpr. MACRS tax depreciation rates are dependent on an asset's vintage and tax class; therefore the Company calculates forecasted tax depreciation by (1) calculating prior years' vintage tax depreciation on existing assets and (2) calculating tax depreciation on additions during the budget years by applying the appropriate MACRS rate. In the attached excel workbook, the Company has provided a reconciliation of its total tax depreciation calculation for years 2018-2020 to its income tax provision amounts for those same years. For prior years' vintage tax depreciation, the Company provided a report generated from its tax depreciation system by tax class with all vintages combined given the voluminous nature of the data.

The attachment is being provided in a separate file in Excel format.

LOUISVILLE GAS AND ELECTRIC COMPANY

**Response to Attorney General's Supplemental Data Requests for Information
Dated December 13, 2018**

Case No. 2018-00295

Question No. 74

Responding Witness: Daniel K. Arbough

Q-74.   Reference the Company's response to Staff DR 2-75 and Attachment Q75d
Schedule A. Explain why short-term debt shown on Schedule J-1 in the Company
calculation of the impact of slippage on LG&E revenue requirements for the
forecasted test year ($87,630,999) is different from the amount included in the
Company's application Schedule J-1 ($97,017,186).

A-74.   The short-term debt shown on Schedule J-1 in response to PSC 2-75 is lower than
the filed Schedule J-1 due to the application of the capital slippage factor and the
resulting reduction of capital spend for the forecasted test period. The reduction
of capital spend in the forecasted period reduces the Company's need to issue
short-term debt to finance the capital expenditures.

LOUISVILLE GAS AND ELECTRIC COMPANY

**Response to Attorney General's Supplemental Data Requests for Information
Dated December 13, 2018**

Case No. 2018-00295

Question No. 75

Responding Witness: Daniel K. Arbough

Q-75.   Reference the response to AG DR 1-34 (b), attachment. Provide details, including the amount to be spent during the test period, as to the following proposed capital spending projects. If a description for the projects is already included in the application or elsewhere in the record of this case, identify precisely where in the record it can be found:

a. 00066FACL BOC DCC SPACE CONVERSION LGE

b. 00076FACL Building Façade Repairs

c. 119902 Clear 12/04 A&G

d. 134898 PE Vehicle Purchases

e. 138032 IMPROVE PIPELINES

f. 141004 ST HELEN FACILITY

g. 144531 CR7 Misc Project (multi-year)

h. 144869 PRESTON CITY GATE STAT

i. 147831 Corporate Contingency-LGE

j. 152224 Clifty Creek DL1/DL2 Brkr Rpl

k. 152778 LGE FACILITY IMPROVEMENTS-2019

l. 156485 CANAL DEMOLITION

m. 157552 Adams Street Redevelopment

n. 157892 Smart Cities LG&E 2019

o. 157894 EE Business Dvlp LG&E 2019

p. 157897 EE Business Dvlp LG&E 2020

q. 448000011 Magnolia Paving

r. CEMTR134 LGE Electric Meters – 001340

s. CGMTR134 LGE Gas Meters – 001340

t. CRELD340 Capital Reliability – 003400

u. IT0528L LifeIns&Retire Frms/Prtl-LGE19

A-75.   See response to AG 1-34(b) for test year amounts. See attached for a-u.

	Project	Description	Detailed Description	Prior Reference in Case
a	00066FACL	BOC DCC SPACE CONVERSION LGE	Convert vacated Distribution Control Center space in Broadway Office Complex to swing space	
b	00076FACL	Building Façade Repairs	Façade repairs Broadway Office Complex	
c	119902	Clear 12/04 A&G	Capitalized Pension True-up	
d	134898	PE Vehicle Purchases	Purchase of off-road vehicles to be used by Project Engineering while supervising the field work associated with construction and demolition projects.	
e	138032	IMPROVE PIPELINES	General project for budgeting; funding source for improvements to defects discovered during in line inspections of gas transmission lines	
f	141004	ST HELEN FACILITY	Complete upgrades to St. Helen's gas regulating station	
g	144531	CR7 Misc Project (multi-year)	Aggregation of smaller capital expenditures that become necessary due to emergent equipment, operations, and maintenance activities associated with the Cane Run 7 NGCC (Natural Gas Combined Cycle) plant. These expected but unidentified costs are budgeted via miscellaneous projects that are then tracked through a year to fund these types of expected but unidentified needs as they occur.	
h	144869	PRESTON CITY GATE STAT	Rebuild city gate station on Preston Highway	
i	147831	Corporate Contingency-LGE	KY Tax Reform Sales Tax Estimates	AG DR 2-80
j	152224	Clifty Creek DL1/DL2 Brkr Rpl	Replace the existing 345kV DL1 and DL2 circuit breakers	
k	152778	LGE FACILITY IMPROVEMENTS-2019	General project for budgeting; funding source for specific Facilities projects identified throughout the year	
l	156485	CANAL DEMOLITION	This project is for demolition of the Canal generating facility retired in 1966. This amount includes engineering and commercial activities associated with the demolition	KIUC DR 1 LGE 35a
m	157552	Adams Street Redevelopment	New business redevelopment of east downtown Louisville along Adams Street.	
n	157892	Smart Cities LG&E 2019	Lighting and other projects requested as part of the City of Louisville Challenge Grant workshops in support of "Smart City" projects.	
o	157894	EE Business Dvlp LG&E 2019	Distributed Energy Resource (DER) projects	
p	157897	EE Business Dvlp LG&E 2020	Distributed Energy Resource (DER) projects	
q	448000011	Magnolia Paving	Paving work at the Magnolia gas storage facility	
r	CEMTR134	LGE Electric Meters - 001340	Electric meters, transformers, and labor associated with installation of electric meters and transformers, including maintaining adequate stock for the sample meter program.	
s	CGMTR134	LGE Gas Meters - 001340	Gas meters and labor associated with installation of gas meters, including maintaining adequate stock for the sample meter program.	
t	CRELD340	Capital Reliability - 003400	Capital blanket for reliability projects throughout the LGE Electric Distribution Territory	
u	IT0528L	LifeIns&Retire Frms/Prtl-LGE19	Convert hardcopy forms to PeopleSoft system forms	

LOUISVILLE GAS AND ELECTRIC COMPANY

**Response to Attorney General's Supplemental Data Requests for Information
Dated December 13, 2018**

Case No. 2018-00295

Question No. 76

Responding Witness: Lonnie E. Bellar

Q-76.   If not already provided, provide the most recent LG&E annual gas system plan.

A-76.   See attachment to Filing Requirements 807 KAR 5:001 Section 16(7)(c) – Attachment to Tab 16 – Item I, page 50 – 73.

LOUISVILLE GAS AND ELECTRIC COMPANY

Response to Attorney General's Supplemental Data Requests for Information
Dated December 13, 2018

Case No. 2018-00295

Question No. 77

Responding Witness: Lonnie E. Bellar / Robert M. Conroy

Q-77.   Reference the responses to AG DR 1-198 and AG DR 1-55.

a. Describe how frequently the Enhanced ILI inspections will be mandated under the new proposed regulation.

b. Confirm that Enhanced ILI inspections could still be conducted even without replacing the 13.2 miles of the Western Kentucky A and B transmission lines.

c. With regard to the Company's response to subpart (b) of AG DR 1-198:

(i) Describe the Enhanced ILI tools that can only collect data for a single diameter size.

(ii) Describe the temporary facilities that would have to be constructed. Provide also a cost estimate for such construction.

(iii) Could the temporary facilities be used again for any other mandated inspections? If not, explain fully why not.

d. Are all of the 13.2 miles of pipeline segments LG&E proposes to replace contiguous?

e. Provide a cost estimate for an Enhanced ILI inspection based on: (i) the pipelines in their current state; and (ii) the assumption that the proposed replacements will be made.

f. State whether there are any other transportation or distribution lines in the LG&E system that require a similar Enhanced ILI inspection, and which are composed of differently-sized pipe diameters. If so, provide a complete description.

(i) Is the Company aware of any other LDCs facing the same issues with regard to pipelines composed of segments having different diameters?

Discuss in detail, and provide any AGA guidance, recommendations or studies regarding this issue.

g. If the Commission should approve this project, state whether it would be more cost-effective to ratepayers if the project's costs were to be recovered via the Gas Line Tracking mechanism, or in base rates.

A-77.

a. Existing regulations (§192.939) require pipeline operators to conduct a form of assessment once every seven years. The proposed regulation does not establish a defined interval to repeat the Enhanced ILIs. However, the proposed regulation establishes a new standard for evaluating pipelines which the Enhanced ILI inspections will be a part of satisfying and LG&E expects to follow the new standard during the required reoccurring seven year assessments.

b. LG&E believes the Enhanced ILI inspections could still be performed, but at a much higher cost and as previously stated in AG 1-55.

c.

(i) Both the Circumferential Magnetic Flux Leakage (MFL-C) tool and Electro Magnetic Acoustic Transducer (EMAT) tool are unable to collect data on the entire length of a pipeline which has both 16-inch and 20-inch pipe in it. The Axial Magnetic Flux Leakage (MFL-A) tool, pipe grade sensors, MFL-C tool, and EMAT tool are unable to collect data the entire length of a pipeline which has 16-inch, 20-inch and 22-inch pipe in it.

(ii) The temporary facilities would be constructed of elbows, tees, valves, pipe, and ILI tool traps. It would cost $5.8M to fabricate, install, and remove the temporary facilities at over 20 locations. This assumes the temporary piping fabrications and ILI tool traps are reused at various sites. It also includes $937K to replace 507-feet of pipe spread across three locations to eliminate six sets of tool runs. The eliminated tool runs would cost more than the replacements. In addition to these construction costs for temporary piping, the cost to run the tools would be much higher as discussed in the response to question Q-77(e) below.

(iii) The majority of the cost is installing and removing the temporary facilities. About $508K in fabricated components and ILI tool traps could possibly be reused in other locations if a need arose. LG&E has not identified any such projects which would require the use of those facilities.

d. No. They are not contiguous sections.

e. In their current state, it would cost $72M to perform Enhanced ILIs of the Western Kentucky A and Western Kentucky B pipelines if no replacements were completed. If the 507-feet of pipe were replaced as discussed in the response to question Q-77 c(ii) above, it would cost $58M to perform the Enhanced ILIs. If the proposed 13.2 miles of replacements are made, it would cost $8.8M to perform the Enhanced ILIs the first time and $5M ($2.5M per pipeline) for the subsequent times. It will cost more the first time because the MFL-A tools are due to be run in the Western Kentucky A pipeline in 2019 and in the Western Kentucky B pipeline in 2020 seven calendar years after each pipeline's last integrity assessment and prior to the pipeline replacements being completed. The EMAT and MFL-C tools would be run after the pipeline replacements are completed. Findings from the Enhanced ILIs may result in the replacement of pipe. Therefore all replacement costs may not be avoided by leaving the pipelines in their current state and spending more money up front to perform Enhanced ILIs on shorter segments.

f. In addition to the pipelines discussed in AG DR 1-198 and AG DR 1-55, the Blanton to Paddy's pipeline is composed of differently sized pipe diameters and will require a similar Enhanced ILI inspection. The Blanton to Paddy's pipeline is 7.3 miles long and made of a 2.7 mile contiguous 20-inch section connected to a 4.6 mile contiguous 16-inch section.
    (i)   LG&E is not familiar with the systems of other LDCs. LG&E is not aware of any AGA guidance, recommendations or studies regarding the issue.

g. The criterion of cost-effectiveness does not apply to the method of recovery. For a summary of how LG&E determines whether costs for a particular project should be recovered through the GLT mechanism or in base rates, see the response to Question No. 78.

LOUISVILLE GAS AND ELECTRIC COMPANY

**Response to Attorney General's Supplemental Data Requests for Information
Dated December 13, 2018**

Case No. 2018-00295

Question No. 78

Responding Witness: Lonnie E. Bellar

Q-78.   Reference the Company's response to Louisville Metro- 1-90. What makes the $120 million in gas capital expenditures different from what is allowed recovery through the GLT?

A-78.   The $120 million figure referenced in response to Louisville Metro 1-90 is the total non-mechanism gas capital expenditure for the period from January 1, 2018 through October 31, 2019. As summarized on pp. 66 and 67 of Mr. Bellar's testimony, this amount includes capital costs to connect new gas customers, capital investment required to maintain and repair the gas network, and capital cost of certain projects that are not included in the Gas Line Tracker ("GLT") mechanism, including installation of new gas pipeline in Bullitt County and an East End Reinforcement project. These non-GLT capital projects are described in Mr. Bellar's testimony. LG&E seeks recover the costs for these capital investment through base rates.

Conversely, capital expenditures for projects included in the GLT are recovered through a separate line item on customer bills and are not included in base rates. Projects with an established GLT mechanism include replacement of customer gas service lines and gas risers, replacements to modernize gas transmission lines, and a program to replacing aging gas mains. Each of these projects has been approved by the PSC for inclusion in the GLT mechanism.

The decision on whether to include a specific project in a GLT mechanism or to seek recovery in base rates depends on the nature of each project. In general, recovery through the GLT allows LG&E to act more nimbly in response to high priority safety concerns and regulatory changes, without seeking significant upfront capital recovery for these projects through base rates. The inclusion of the gas riser replacement program in the GLT mechanism is one such example.[11]

_____

[11] *See* Case No. 2012-00222, *In the Matter of: Application Of Louisville Gas And Electric Company For An Adjustment Of Its Electric And Gas Rates, A Certificate Of Public Convenience And Necessity, Approval Of Ownership Of Gas Service Lines And Risers, And A Gas Line Surcharge.*

LOUISVILLE GAS AND ELECTRIC COMPANY

Response to Attorney General's Supplemental Data Requests for Information
Dated December 13, 2018

Case No. 2018-00295

Question No. 79

Responding Witness: Christopher M. Garrett

Q-79.   Reference the Company's response to AG DR 1-85.

a. If the actual history of bad debt is different as shown on PSC-LGE 1-49, explain why the LG&E gas (0.18%) and electric (0.18%) bad debt expense used on Schedule H-1 is the same.

b. Provide the Retail Revenues and Net Charge Offs and Net Charge Off's percent broken down between electric and gas for 2013–2017.

A-79.

a. The difference between the electric and gas net charge-off percentage in PSC 1-49 is the result of the removal of the Gas Supply Clause (GSC) bad debt expense. For example, the GSC bad debt provision for 2017 is $225K which increases the gas bad debt percentage by 0.07% to align with the electric net charge-off percentage.

The Company does not maintain a separate account balance for electric and gas uncollectible accounts, because LG&E customers receive one bill regardless of whether or not they receive gas service. Therefore, the Company used the same net charge-off percentage for electric and gas when developing the revenue requirements.

b. For purposes of responding to this question, the Company has performed an allocation similar to the one used in PSC 1-49 to derive the electric and gas net charge-off percentage split based on revenues.

LG&E Total Company Summary

Year	Retail Revenues	Net Charge Offs	Net Charge Off %
2013	1,314,194,010	1,863,407	0.142%
2014	1,403,783,006	3,623,462	0.258%
2015	1,395,053,719	2,698,427	0.193%
2016	1,373,169,377	2,083,763	0.152%
2017	1,377,548,223	2,271,999	0.165%
5-YR Avg			0.182%

LG&E Electric Summary

Year	Retail Revenues	Net Charge Offs	Net Charge Off %
2013	1,003,167,539	1,640,284	0.164%
2014	1,047,607,991	3,197,686	0.305%
2015	1,079,677,731	2,452,508	0.227%

LOUISVILLE GAS AND ELECTRIC COMPANY

**Response to Attorney General's Supplemental Data Requests for Information
Dated December 13, 2018**

Case No. 2018-00295

Question No. 80

Responding Witness: Daniel K. Arbough

Q-80.   Reference the Companies' response to Staff DR 1-17 and Attachment 1. Why are the following considered Construction projects?
a.

i)   April 30, 2020

(1) Line 7—Project number 151231 (page 1 of 11) EDO Contingency $1,000

(2) Line 115—Project number IT0000L IT Contingency-LGE (page 2 of 11) $1,649,734.89

(3) Line 187—Project number 147831 Corporate Contingency-LGE (page 3 of 11) $2,745,049.99

ii) December 31, 2018

(1) Line 1—Project number 122457 EDO ADJUSTMENTS (page 4 of 11) $131,000.00

(2) Line 7—Project number 151231 EDO Contingency (page 4 of 11) $1,000.00

(3) Line 91—Project IT0000L IT Contingency-LGE (page 5 of 11) $1,649,734.89

 b. Gas:

i)   April 30, 2020

(1) Line 118 - Project number 147831 Corporate Contingency-LGE (page 2 of 7) $1,233,283.33

ii) December 31, 2018

(1) Line 38 - Project number 147831 Corporate Contingency-LGE (page 3 of 7) $336,350.00

A-80.   The projects shown on this list, with 147831 as the only exception, reflect capital expenditures solely during the base period. Throughout each month in 2018 when the monthly forecast is completed, the lines of business hold funds in these projects to fund projects still under review, which still need to be fully vetted before being entered into the system as a capital project. The description on these projects would be more accurately depicted as "funding for projects under review".

Project 147831 was used this budget season for a last minute change due to Kentucky sales tax reform. This amount will be appropriately allocated across other capital projects through the burden process during the year.
