Attention Mr. Harold Nasserden
 Director, Forecasts & Budgets

Pursuant to your request, we have conducted a depreciation study related to the electric distribution system of FortisAlberta, Inc. as of December 31, 2006. Our report presents a description of the methods used in the estimation of depreciation and net salvage, the statistical analyses of service life and the summary and detailed tabulations of annual and accrued depreciation.

The calculated annual depreciation accrual rates presented in the report are applicable to plant in service as of December 31, 2006. The depreciation rates are based on the straight-line whole life method using the equal life group procedure, with any accumulated depreciation variances in excess of 5% amortized over the greater of 5 years or the estimated remaining life of the assets.

Respectfully submitted,

GANNETT FLEMING, INC.

Calgary, Alberta

DEPRECIATION STUDY

PART I. INTRODUCTION

SCOPE

This report sets forth the results of the depreciation study conducted for the electric distribution assets of FortisAlberta, Inc. ("FortisAlberta") to determine the annual depreciation accrual rates and amounts for ratemaking purposes applicable to the original cost of plant at December 31, 2006.

The depreciation accrual rates presented herein are based on generally-accepted methods and procedures for calculating depreciation. The estimated survivor curves and estimated net salvage percents used in this report are based on studies incorporating data through 2006 for most accounts, and incorporate the results of an extensive internal FortisAlberta review of salvage policies, practices and accounting procedures.

Part I, Introduction, contains statements with respect to the scope of the report and the basis of the study. Part II, Methods Used in the Estimation of Depreciation, presents the methods used in the estimation of average service lives, survivor curves and net salvage and in the calculation of depreciation. Part III, Results of Study, presents a summary of annual depreciation, the statistical analyses of service lives, and the detailed tabulations of annual depreciation.

BASIS OF THE STUDY

Depreciation. The depreciation accrual rates and accrued depreciation were calculated using the straight-line method, the whole life basis and the equal life group (ELG) procedure. The calculation was based on the attained ages and estimated service life and net salvage characteristics for each depreciable group of assets.

Service Life and Net Salvage Estimates. The method of estimating service life consisted of compiling the service life history of the plant accounts and subaccounts, reducing this history to trends through the use of analytical techniques that have been generally accepted in various regulatory jurisdictions, and forecasting the trend of survivors for each depreciable group on the basis of interpretations of past trends and consideration of Company plans for the future. The combination of the historical trend and the estimated future trend yielded a complete pattern of life characteristics from which the average service life was derived. The service life estimates used in the depreciation calculation incorporated historical data compiled through December 31, 2006. Such data included plant additions, retirements, transfers and other plant activity.

Gannett Fleming has been engaged by FortisAlberta in a number of assignments since 2003 and has gained an understanding of the operational and accounting practices and policies. Additionally, Gannett Fleming was engaged to provide advice throughout the FortisAlberta internal review of net salvage policies and procedures. Through this review, a number of operational practices and procedures were reviewed. As such, Gannett Fleming undertook only a limited number of operational interviews specific to the life analysis.

The estimates of net salvage were based on the results of an internal study conducted by FortisAlberta. Gannett Fleming participated in the net salvage review in an

advisory role and supports the results of the study. The net salvage review resulted in an extensive review of all of the net salvage transactions over the last three-year period and developed net salvage indications based on a number of changes to accounting and operational tracking of expenditures related to the removal of plant. As such, Gannett Fleming did not perform an additional net salvage study of historic transactions.

RECOMMENDATIONS

The calculated annual depreciation accrual rates set forth herein apply specifically to plant in service as of December 31, 2006. Continued surveillance and periodic revisions are normally required to maintain continued use of appropriate depreciation rates.

The depreciation rates should be reviewed periodically to reflect the changes that result from plant and reserve account activity. A depreciation reserve deficiency or surplus will develop if future capital expenditures vary significantly from those anticipated in this study.

The survivor curves, net salvage percents, and amortization periods used in this study should be the basis for periodic recalculations. Complete depreciation studies, which re-evaluate these parameters, should be performed every three to five years.

PART II. METHODS USED IN THE
ESTIMATION OF DEPRECIATION

PART II. METHODS USED IN THE ESTIMATION OF DEPRECIATION

DEPRECIATION

Depreciation, in public utility regulation, is the loss in service value not restored by current maintenance, incurred in connection with the consumption or prospective retirement of electric plant in the course of service from causes which are known to be in current operation and against which the utility is not protected by insurance. Among causes to be given consideration are wear and tear, deterioration, action of the elements, inadequacy, obsolescence, changes in the art, changes in demand, and the requirements of public authorities.

Depreciation, as used in accounting, is a method of distributing fixed capital costs, less net salvage, over a period of time by allocating annual amounts to expense. Each annual amount of such depreciation expense is part of that year's total cost of providing electric distribution service. Normally, the period of time over which the fixed capital cost is allocated to the cost of service is equal to the period of time over which an item renders service; that is, the item's service life. The most prevalent method of allocation is to distribute an equal amount of cost to each year of service life. This method is known as the straight-line method of depreciation.

The calculation of annual and accrued depreciation based on the straight-line method requires the estimation of survivor curves and the selection of group depreciation procedures. These subjects are discussed in the sections that follow.

ESTIMATION OF SURVIVOR CURVES

Survivor Curves. The use of an average service life for a property group implies that the various units within the group have different lives. The average life may be obtained by determining the separate lives of each of the units, or by constructing a survivor curve by plotting the number of units that survive at successive ages. Inasmuch as survivor curves were used in the estimation of service lives, a discussion of the general concept of survivor curves and their derivation is presented.

A survivor curve graphically depicts the amount of property existing at each age throughout the life of an original group. From the survivor curve, the average life of the group, as well as other functions, such as the remaining life expectancy, the probable life, and the frequency curve, can be calculated. Geometrically, the average life is obtained by calculating the area under the survivor curve, from age zero to the maximum age, and dividing this area by the ordinate at age zero, which is 100%. The average remaining life expectancy at any age can be calculated by obtaining the area under the curve, from the attained age to the maximum age, and dividing this area by the percent surviving at the attained age.

The range of survivor characteristics usually experienced by utility and industrial properties is encompassed by a system of generalized survivor curves known as the Iowa type curves. There are four families in the Iowa system, labeled in accordance with the location of the modes of retirement in relationship to the average life and the relative height of the modes. The left moded curves are those in which the greatest frequency of retirement occurs to the left of, or prior to, average service life. The symmetrical moded curves are those in which the greatest frequency of retirement occurs at average service life. The right moded curves are those in which the greatest frequency occurs to the right of, or after, average service life. The origin moded curves are those in which the greatest frequency of retirement occurs at the origin,

or immediately after age zero. The letter designation of each family of curves (L, S, R or O) represents the location of the mode of the associated frequency curve with respect to the average service life. The numerical subscripts represent the relative heights of the modes of the frequency curves within each family.

The Iowa curves were developed at the Iowa State College Engineering Experiment Station through an extensive process of observation and classification of the ages at which industrial property had been retired. A report of the study which resulted in the classification of property survivor characteristics into 18 type curves, which constitute three of the four families, was published in 1935 in the form of the Experiment Station's Bulletin 125.¹ These type curves have also been presented in subsequent Experiment Station bulletins and in the text, "Engineering Valuation and Depreciation."² In 1957, Frank V. B. Couch, Jr., an Iowa State College graduate student, submitted a thesis³ presenting his development of the fourth family consisting of the four O type survivor curves.

Retirement Rate Method of Analysis. The estimates of the appropriate survivor curves for most of the significant depreciable property groups were based in part upon calculated survivor curves that incorporated plant retirement experience through 2006. The retirement rate method was used for the analysis of the retirement activity related to the property groups of FortisAlberta, except for the six groups for which amortization accounting is proposed, as discussed later in this report. The retirement rate method is explained in several publications,

¹Winfrey, Robley. Statistical Analyses of Industrial Property Retirements. Iowa State College, Engineering Experiment Station, Bulletin 125. 1935.

²Marston, Anson, Robley Winfrey and Jean C. Hempstead. Engineering Valuation and Depreciation, 2nd Edition. New York, McGraw-Hill Book Company. 1953.

³Couch, Frank V. B., Jr. "Classification of Type O Retirement Characteristics of Industrial Property." Unpublished M.S. thesis (Engineering Valuation). Library, Iowa State College, Ames, Iowa. 1957.

including "Statistical Analyses of Industrial Property Retirements,"⁴ and "Engineering Valuation and Depreciation"⁵.

Each retirement rate analysis resulted in a life table which, when plotted, formed an original survivor curve. Each original survivor curve as plotted from the life table represents the average survivor pattern experienced by the several vintage groups during the experience band considered. In the circumstances of three accounts, more than one experience band was studied. In these circumstances, the life table for each experience band is provided and plotted on the IOWA curves for each account. Inasmuch as this survivor pattern does not necessarily describe the life characteristics of the property group, interpretation of the original curves is required in order to use them as valid consideration in service life estimation. Iowa type curves were used in these interpretations.

Survivor Curve Judgments. The survivor curve estimates were based on judgment which considered a number of factors. The primary factors were the statistical analysis of data, current policies and outlook as determined through conversations with operations and management personnel over a number of years, and survivor curve estimates from previous studies of this company and other electric distribution companies.

Account 1650, Distribution-Poles, Towers and Fixtures, represents 31% of the depreciable plant studied. This account now includes all investment associated with distribution insulators. The retirements, additions and other plant transactions for the period 1929 through 2006 were analyzed by the retirement rate method. Additionally, a second experience band encompassing the retirement transactions that occurred from 1980 through 2006 was analyzed. The original survivor curves as plotted on page IV-10, indicate retirement ratios for both of the

⁴Winfrey, Robley, Supra Note 1.

⁵Marston, Anson, Robley Winfrey, and Jean C. Hempstead, Supra Note 2.

experience that begin relatively early in the assets' life and continue through to a maximum life of approximately 75 years. The retirement ratios are generally consistent through the entire life of the account, which leads to a low mode Iowa curve. Both experience bands produced similar results through the first 40 years of the group's life, which deals with the majority of plant exposed to retirement. The level of plant exposed to retirement in the shorter experience band is less than 4% at age 40. Therefore, the average service life for this account was selected based on the 1929-2006 (overall) experience band. The previously-approved estimate for this account was the Iowa 38-R1. The Iowa 45-R1.5, selected in this study, increases the average service life of investment in this account by 7 years, and provides a reasonable interpretation of the historical data, and is forecast to be representative of the future retirement activity.

Account 1675, Distribution-Line Transformers and Regulators represents 22% of the depreciable plant studied. This account consists primarily of the investment in various sizes of overhead and underground line transformers and regulators. Historical retirements, additions and other plant transactions for the period 1929 through 2006 were analyzed by the retirement rate method. Additionally, experience bands encompassing the last 26 (1980-2006) and 10-year (1996-2006) periods were analyzed. The original survivor curves, as plotted on page IV-27, show increasing retirement ratios beginning at an early age and continuing through to a maximum life of approximately 75 years, which will indicate a low moded Iowa curve. The previously-approved estimate for this account, was the Iowa 30-R0.5, continues to provide a reasonable fit to the historic retirement transactions and provides for a reasonable expectation of the future retirement trends.

Account 1660, Distribution-Overhead Conductor, represents 18% of the depreciable plant studied. This account consists of the material and installation costs associated with the overhead distribution conductor. Historical retirements, additions and other plant transactions for the period 1930 through 2006 were analyzed by the retirement rate method. Additionally,

experience bands encompassing the last 26 (1980-2006) and 10-year (1996-2006) periods were analyzed. The original survivor curves, as plotted on page IV-17, for all three experience bands, show increasing retirement ratios beginning at an early age and continuing through to a maximum life of approximately 75 years, which will indicate a low moded Iowa curve. The previously-approved estimate for this account, the Iowa 35-R1, has been modified in this study to the 39-R0 .5 to better represent the frequent occurrence of retirements at a young age. It is also considered that the 39-R0.5 Iowa curve provides for a reasonable expectation of the future retirement trends.

Account 1670, Distribution-Underground Conductor, represents approximately 14% of the depreciable plant studied. This account now consists of both the underground conductor and conduit. Historical retirements, additions and other plant transactions for the period 1950 through 2006 were analyzed by the retirement rate method. The original survivor curve, as plotted on page IV-24, shows a consistent level of retirement activity through the accounts early life. However, at approximately age 35, the account exhibits very large retirement ratios with a maximum life of approximately 70 years. The previously-approved estimate for this account, the Iowa 38-R2.5, has been modified to the 45-R3 to better represent the retirement pattern. It is also considered that the 45-R3 Iowa curve provides for a reasonable expectation of the future retirement trends.

Account 1800 – Distribution Meters contains the investment in metering equipment. The company is planning to replace older analog metering equipment with new digital metering equipment within the next few years. As such, old analog metering equipment will be replaced. Gannett Fleming recommends that the investment in the new digital metering equipment be held in a separate account. Additionally, Gannett Fleming recommends that the surviving investment in analog meters be depreciated in accordance with a square curve and over an amortization

period of 10 years. As such, all surviving investment in analog metering equipment will be recovered over the next 10-year period.

With the exception of Account 1800 all remaining accounts were based on similar considerations of historical analyses, management outlook and estimates for this company and other electric transmission utilities.

ESTIMATION OF NET SALVAGE

In response to prior Board directives and as required to comply with recent accounting directives, FortisAlberta undertook an extensive internal review of the policies, practices and procedures used in the treatment and recording of cost of retirement expenditures. The review has resulted in the development of clear guidelines regarding the allocation process relating to cost of removal versus replacement capital, revised processes to determine cost of removal labor, and a streamlined process for the handling of material returned from the field. Given that the revised policies, practices and accounting processes changed significantly as a result of the internal review, a review of all of the removal projects over the period 2004 through 2006 was undertaken. The purpose of the review of the last three-year period was to determine the reasonableness of the revised practices and procedures and to develop an historical database for use in the determination of the future net salvage expectation using the revised practices. The reviews of the net salvage indications for the past three year period when incorporating the revised practices are summarized in Table 3 at page III-6 in the Results of Study section of this report. As indicated in Table 3, the following represents the most recent three year average net salvage percentage requirements:

- Account 1650 - Poles, Towers and Fixtures- -66%
- Account 1660 - Overhead Conductor- -95%
- Account 1670 - Underground Conductors- -1%
- Account 1675 - Line Transformers/Regulators/OCR's- -5%
- Account 1685 - Street Lights/Controls- -59%
- Account 1800 – Meters and Equipment- -37%

Gannett Fleming recognizes that the three-year band of historic experience is relatively short. The results of the review indicated significantly more negative net salvage percentages than are currently approved -40% in the circumstances of Accounts 1650, 1660 and 1685. However in the circumstances of Account 1670, the indication of a net salvage percentage of -1% is significantly less negative than the currently-approved -40%. Gannett Fleming has reviewed the results of the internal FortisAlberta study in light of a number of other electric distribution utilities. Gannett Fleming found that the results of the FortisAlberta study generally corresponded with the electric distribution industry.

In considering the net salvage percentage for use in the depreciation rate calculations, Gannett Fleming considers that full implementation of the study may be premature until such time as a few more years of actual experience utilizing the revised practices can be reviewed. As such, the net salvage percentage has been limited to -50% in the circumstances of Accounts 1650, 1660, and 1685. Furthermore, given the recommendation in this report to amortize the remaining book value of the analog meters over the next 10-year period, a 0% net salvage percentage has been used for Account 1800 – Metering Equipment.

CALCULATION OF ANNUAL AND ACCRUED DEPRECIATION

Group Depreciation Procedures. When more than a single item of property is under consideration, a group procedure for depreciation is appropriate because normally all of the items within a group do not have identical service lives, but have lives that are dispersed over a range of time. There are two primary group procedures, namely, average service life and equal life group.

In the average service life procedure, the rate of annual depreciation is based on the average life or average service life of the group, and this rate is applied to the surviving balances of the group's cost. A characteristic of this procedure is that the cost of plant retired prior to

average life is not fully recouped at the time of retirement, whereas the cost of plant retired subsequent to average life is more than fully recouped. Over the entire life cycle, the portion of cost not recouped prior to average life is balanced by the cost recouped subsequent to average life. In this procedure, the accrued depreciation is based on the average service life of the group and the average remaining life of each vintage within the group derived from the area under the survivor curve between the attained age of the vintage and the maximum age.

In the equal life group procedure, the property group is subdivided according to service life. That is, each equal life group includes that portion of the property which experiences the life of that specific group. The relative size of each equal life group is determined from the property's life dispersion curve. The calculated depreciation for the property group is the summation of the calculated depreciation based on the service life of each equal life group. The table on the following page presents an illustration of the calculation of equal life group depreciation using the Iowa 15-R3 survivor curve, 0 percent net salvage and a December 31, 2006 calculation date. In the table, each equal life group is defined by the age interval shown in columns 1 and 2. These are the ages at which the first and last retirement of each group occurs, and the group's equal life, shown in column 3, is the midpoint of the interval. For purposes of the calculation, each vintage is divided into equal life groups arranged so that the midpoint of each one-year age interval coincides with the calculation date, e.g., December 31 in this case. This enables the calculation of annual accruals for a twelve-month period centered on the date of calculation.

The retirement during the age interval, shown in column 4, is the size of each equal life group and is derived from the Iowa 15-R3 survivor curve and 0 percent net salvage. It is the difference between the percents surviving at the beginning and end of the age interval. Each equal life group's annual accrual, shown in column 5, equals the group's size (column 4) divided by its life (column 3).

Columns 6 through 10 show the derivation of the annual and accrued factors for each vintage based on the information developed in the first five columns. The year installed is shown in column 6. For all vintages other than 2006, the summation of annual accruals for each year installed, shown in column 7, is calculated by adding one-half of the group annual accrual (column 5) for that vintage's current age interval plus the group annual accruals for all succeeding age intervals. For example, the figure 7.53413204309 for 2005 equals one-half of 0.14669333333 plus all of the succeeding figures in column 5. Only one-half of the annual accrual for the vintage's current age interval group is included in the summation because the equal life group for that interval has reached the year during which it is expected to be retired.

The summation of annual accruals (column 7) for installations during 2006 is calculated on the basis of an in-service date at the midpoint of the year, i.e., June 30. Inasmuch as the overall calculation is centered on December 31, 2006, the first figure in column 7, for vintage

2006, equals all of the group annual accrual for the first equal life group plus the accruals for all of the subsequent equal life groups.

The average percent surviving, derived from the Iowa 15-R3 survivor curve and 0 percent net salvage, is shown in column 8 for each age interval. The annual factor, shown in column 9, is the result of dividing the summation of annual accruals (column 7) by the average percent surviving (column 8). The accrued factor, shown in column 10, equals the annual factor multiplied by the age of the group at December 31, 2006.

CALCULATION OF ANNUAL AND ACCRUED AMORTIZATION

Amortization is the gradual extinguishment of an amount in an account by distributing such amount over a fixed period, over the life of the asset or liability to which it applies, or over the period during which it is anticipated the benefit will be realized. Normally, the distribution of the amount is in equal amounts to each year of the amortization period.

The calculation of annual and accrued amortization requires the selection of an amortization period. The amortization periods used in this report were based on judgment which incorporated a consideration of the period during which the assets will render most of their service, the amortization period and service lives used by other utilities, and the service life estimates previously used for the asset under depreciation accounting.

Amortization accounting is proposed for certain general plant accounts that represent numerous units of property, but a very small portion of depreciable gas plant in service. The accounts and their amortization periods for the general plant accounts are as follows:

<u>Account</u>	<u>Amortization Period, Years</u>
2050 Office Furniture & Equipment	15
2200 Tools and Instruments	10
2250 Computer Hardware	5
2300 Computer Software – Other than SAP	5
2300 Computer Software - SAP	7
LHI Leasehold Improvements	10

For the purpose of calculating annual amortization amounts as of December 31, 2006, the book depreciation reserve for each plant account or subaccount is assigned or allocated to vintages. The book reserve assigned to vintages with an age greater than the amortization period is equal to the vintage's original cost. The remaining book reserve is allocated among vintages with an age less than the amortization period in proportion to the calculated accrued amortization. The calculated accrued amortization is equal to the original cost multiplied by the ratio of the vintage's age to its amortization period. The annual amortization amount is determined by dividing the future amortizations (original cost less allocated book reserve) by the remaining period of amortization for the vintage.

MONITORING OF BOOK ACCUMULATED DEPRECIATION

The calculated accrued depreciation or amortization represents that portion of the depreciable cost which will not be allocated to expense through future depreciation accruals, if current forecasts of service life characteristics and net salvage materialize and are used as a basis for depreciation accounting. Thus, the calculated accrued depreciation provides a measure of the book accumulated depreciation. The use of this measure is recommended in the amortization of book accumulated depreciation variances to insure complete recovery of capital over the life of the property.

In accordance with the policy of the Alberta Energy and Utilities Board⁶, the recommended amortization of the variance between the book accumulated depreciation and the calculated accrued depreciation is based on an amortization period equal to the composite remaining life for each property group where the variance exceeds five percent of the calculated accrued depreciation. In order to reduce large fluctuations of the true-up provision from report to report, a minimal 5-year remaining life period has been incorporated into the true-up calculations.

In order to comply with a prior Board directive to reallocate the historic net salvage transactions that have all been recorded to Account 1650 to the appropriate accounts, the true-up calculations have been based on re-allocated accumulated depreciation amounts. In total, the accumulated depreciation amounts reconcile to the Company's financial records; however, the individual accounts do not match due to the re-allocation of the historic transactions. Gannett Fleming understands that FortisAlberta will book the entry to re-allocate the accumulated depreciation account upon Board approval of the net salvage study.

The composite remaining life for use in the reducing accumulated depreciation variances is derived by compositing the individual equal life group remaining lives in accordance with the following equation:

$$\text{Composite Remaining Life} = \frac{\sum (\frac{\text{Book Cost}}{\text{Life}} \times \text{Remaining Life})}{\sum \frac{\text{Book Cost}}{\text{Life}}}.$$

The book costs and lives of the several equal life groups, which are summed in the foregoing equation, are defined by the estimated future survivor curve.

⁶ Pages 31 through 37 of Decision No. E82131 of the Public Utilities Board for the Province of Alberta, dated June 21, 1982, in the matter of an application by TransAlta Utilities Corporation.

Inasmuch as book cost divided by life equals the whole life annual accrual, the foregoing equation reduces to the following form:

$$\text{Composite Remaining Life} = \frac{\sum \text{Whole Life Future Accruals}}{\sum \text{Whole Life Annual Accruals}}$$

or

$$\text{Composite Remaining Life} = \frac{\sum \text{Book Cost - Calc. Reserve}}{\sum \text{Whole Life Annual Accrual}}.$$

PART III. RESULTS OF STUDY

PART III. RESULTS OF STUDY

QUALIFICATION OF RESULTS

The calculated annual and accrued depreciation and the annual provision for true-up (amortization of the accumulated depreciation variance) are the principal results of the study. Continued surveillance and periodic revisions are normally required to maintain continued use of appropriate annual depreciation accrual rates. An assumption that accrual rates can remain unchanged over a long period of time implies a disregard for the inherent variability in service lives and salvage and for the change of the composition of property in service. The annual accrual rates and the accrued depreciation were calculated in accordance with the straight-line method, using the equal life group procedure based on estimates which reflect considerations of current historical evidence and expected future conditions.

DESCRIPTION OF DETAILED TABULATIONS

The service life estimates were based on judgment that incorporated statistical analysis of retirement data, discussions with management, and consideration of estimates made for other electric utilities. The results of the statistical analysis of service life are presented in the section beginning on pages IV-2.

For each depreciable group analyzed by the retirement rate method, a chart depicting the original and estimated survivor curves is followed by a tabular presentation of the original life table(s) plotted on the chart. The survivor curves estimated for the depreciable groups are shown as dark smooth curves on the charts. Each smooth survivor curve is denoted by a numeral followed by the curve type designation. The numeral used is the average life derived from the entire curve from 100 percent to zero percent surviving.

The titles of the chart indicate the group, the symbol used to plot the points of the original life table, and the experience and placement bands of the life tables which where plotted.

The experience band indicates the range of years for which retirements were used to develop the stub survivor curve. The placements indicate, for the related experience band, the range of years of installations which appear in the experience.

The tables of the calculated annual depreciation applicable to plant as of December 31, 2006 are presented in account sequence starting at page V-2. The tables indicate the estimated average survivor curves and net salvage percents used in the calculations. The tables set forth, for each installation year, the original cost, calculated accrued depreciation, and the calculated annual accrual.
