The EPA administers the Resource Conservation and Recovery Act (RCRA), which governs the disposal of solid and hazardous waste.[99] Solid waste is regulated under subtitle D. Subtitle D criteria are not directly enforced by the EPA. Subtitle C governs the disposal of hazardous waste. Hazardous waste is subject to direct regulatory control by the EPA from the time it is generated until its ultimate disposal.

On April 17 2015, the EPA published a rule under Subtitle D of RCRA, the Coal Combustion Residuals rule (2015 CCRR), which sets criteria for the disposal of coal combustion residues (CCRs), or coal ash, produced by electric utilities and independent power producers.[100] CCRs include fly ash (trapped by air filters), bottom ash (scooped out of boilers) and scrubber sludge (filtered using wet limestone scrubbers). These residues are typically stored on site in ponds (surface impoundments) or sent to landfills.

In 2016, RCRA was amended to establish a permitting scheme allowing states to apply to the EPA for approval to operate a permit program that implements the CCR rule. Such state programs could include alternative state standards, provided that the EPA determines that they are ''at least as protective as'' the EPA CCR regulations.[101]

Effective August 9, 2018, the EPA approved certain revisions to the 2015 CCRR ("2018 CCRR Revisions") partly in response to the 2016 amendments.[102]

The 2018 CCRR Revisions provide for two types of alternative performance standards. The first type of standards allows a state director (if a state has an EPA approved CCR permit program) or the EPA (if no state program) to suspend groundwater monitoring requirements if there is evidence that there is no potential for migration of hazardous constituents to the uppermost aquifer during the active life of the unit and during post closure care. The second type allows issuance of technical certifications by a state director in lieu of a professional engineer.

The 2018 CCRR Revisions revised the groundwater protection standards for health-based levels for four contaminants: cobalt at 6 mg/L; lithium at 40 mg/L; molybdenum at 100 mg/L and lead at 15 mg/L. Standards for other monitored contaminants follow the Maximum Contaminant Level (MCL) established under the Safe Water Drinking Act.

The 2018 CCRR Revisions extended the deadline for closing coal ash units in two situations: (i) detection of a statistically significant increase above a groundwater protection standard from an unlined surface impoundment; or (ii) inability to comply with the location restriction regarding placement above the uppermost aquifer. The exceptions in the 2018 CCRR to the standards in the 2015 CCRR and relaxation of the deadlines create a less stringent federal rule.

The U.S. Court of Appeals for the D.C. Circuit invalidated certain provisions of the 2015 CCRR and remanded it to the EPA.[103]

On July 29, 2020, the EPA finalized revisions to the CCR rule in compliance with the court orders ("Revised CCRR").[104] The Revised CCRR requires (i) unlined surface impoundments (ponds) and ponds failing restrictions on the minimum depth to or interaction with an aquifer to cease receiving waste as soon as technically feasible and no later than April 11, 2021; and (ii) removal of compacted soil lined and clay lined ponds from classification as lined and exempt from CCRR.[105]

In response to the RCRA amendments, the EPA proposed a new rule to implement a federal CCR permit program in nonparticipating states, noticed February 20, 2020.[106] This proposal includes requirements for federal CCR permit applications, content and modification, as well as procedural requirements. The EPA would implement this permit program at CCR units located in states that have not submitted their own CCR permit program for approval. No PJM state has yet applied for EPA approval of its own CCR permit program.

The new EPA Administrator has indicated plans to prioritize expeditious state permit reviews and update the CCR permit program.[107]

State Environmental Regulation

State Coal Ash Regulations

In Virginia, the Waste Management Board amended the Virginia Solid Waste Management Regulations in December 2015, to incorporate the EPA's 2015 CCRR, and did not adopt the less stringent 2018 CCRR Revisions. On July 1, 2019, Virginia enacted legislation directing the closure of coal ash ponds located in the Chesapeake Bay Watershed and owned by Dominion Energy.[108] Dominion is developing plans to remove coal ash ponds at power stations in the Chesapeake Bay Watershed. The removed coal ash must be recycled (at least 6.8 million cubic yards) or disposed of in a modern, lined landfill. The Virginia DEQ is addressing closing ash ponds under two types of environmental permits: wastewater discharge permits covering the removal of treated water from the ponds; or solid waste permits covering the permanent closure of the ponds.

Table 8-2 shows the compliance status of affected units with Virginia Solid Waste Management Regulations:[109]

108 Va. Code § 10.1-1402.03.
109 Virginia Department of Environmental Quality website: <https://www.deq.virginia.gov/permits/waste/coal-ash>.

Table 8-2 Compliance status of affected units with Virginia Solid Waste Management Regulations

Plant	CCR Compliance Status
Bremo Bluff Power Station	As of April 2020, ash has been removed from the East and West Ponds. Plans for closure by removal of ash from the remaining North Pond impoundment are under development and will be addressed by the Virginia DEQ in a separate future permitting action.
Chesapeake Energy Center	The facility is currently developing plans for closure by removal of ash from the landfill, historical area, and impoundment.
Chesterfield Power Station	Dominion Energy Virginia submitted the required solid waste permit application for closure by removal and groundwater monitoring of the Upper and Lower Ash Ponds in February 2020, and it is currently under review. The application outlines the removal of ash to either an offsite permitted landfill or offsite beneficial reuse. The application estimates that it will take approximately 13 years to complete closure by removal activities.
Clinch River Power Station	The ash pond was closed and capped prior to January 1, 2019. Clinch River Plant ceased burning coal in 2015 and no longer produces CCR material. The Plant now uses natural gas as fuel. All units are currently being monitored and maintained in post-closure care.
Clover Power Station	The station also has had a permitted CCR landfill since 1993. The permit is currently under revision to incorporate EPA CCR Rule requirements applicable to existing landfills.
Possum Point	The impoundments at this facility (coal ash ponds) are subject to the EPA CCR Rule and the requirements of Virginia Waste Management Act.

Effective April 21, 2021, in response to a statutory mandate,[110] the Illinois Environmental Protection Agency (Illinois EPA) promulgated rules for coal combustion residual surface impoundments with the Illinois Pollution Control Board.[111] The proposed rules contain standards for the storage and disposal of coal combustion residuals in surface impoundments. The rules include a permitting program intended to meet federal standards.[112] The Illinois EPA identified 73 coal combustion residuals surface impoundments at power stations, some lined with impermeable materials and some not.[113] The Illinois

110 Ill. Public Act 101-171 (a.k.a. SB 09).
111 The proposed rule amends the Illinois Administrative Code to create a new Part 845 in Title 35.
112 See *In the Matter of Standards for the Disposal of Coal Combustion Residuals in Surface Impoundments*, No. R 2020-019 (March 30, 2020) at 1 (Proposed New 35 Ill. Adm. Code 845).
113 In the Matter of Standards for the Disposal of Coal Combustion Residuals in Surface Impoundments, No. R 2020-019 (March 30, 2020) at 3 (Proposed New 35 Ill. Adm. Code 845z0.

EPA believes that as many as six lined surface impoundments may comply with the federal liner standards.[114]

State Emissions Regulations

States have in some cases enacted emissions regulations more stringent or potentially more stringent than federal requirements:[115]

- **Illinois Climate and Equitable Jobs Act (CEJA).** On September 16, 2021, the Climate and Equitable Jobs Act (CEJA) became law. CEJA created an expanded nuclear subsidy program. CEJA mandates that all fossil fuel plants close by 2045. CEJA established emissions caps for investor owned, gas-fired units with three years of operating history, effective October 1, 2021, on a rolling 12 month basis. The emissions caps are based on average emissions over a three year period from 2018 through 2020. The capped emissions are CO_2e and co-pollutants.[116] [117] New investor owned, gas fired units will have emissions caps after three years of operation. The resultant emissions caps are very low for some units and higher for others. More than 10,000 MW of capacity are currently affected, most of which have requested that the MMU calculate a unit specific opportunity cost. The MMU calculates opportunity costs for units that make requests and provide required data.

  CEJA includes provisions promoting the development of batteries and utility scale solar at the sites of up to five closed coal plants, two of which may be located in PJM. CEJA grants a subsidy of $110,000/MW for battery projects with at least 37 MW of capacity, capped at $28 million per year. A solar resource at a defined site may elect to receive either the battery subsidies or to sell premium RECs for $30 each.

- **New Jersey HEDD.** Units that run only during peak demand periods have relatively low annual emissions, and have less reason to make investments in emissions reductions under the EPA transport rules. New Jersey addressed the issue of NO_X emissions on peak energy demand days with a rule that defines peak energy usage days, referred to as high electric demand days or HEDD, and imposes operational restrictions and emissions control requirements on units responsible for significant NO_X emissions on such high energy demand days. New Jersey's HEDD rule, which became effective May 19, 2009, applies to HEDD units, which include units that have a NO_X emissions rate on HEDD equal to or exceeding 0.15 lbs/MMBtu and lack identified emission control technologies.

- **New Jersey Control and Prohibition of Carbon Dioxide Emissions.** On December 2, 2022, New Jersey implemented rules restricting new power plants to CO_2 emissions less than 860 pounds per megawatt hour, and banning sales of No. 4 and No. 6 fuel oil.[118] The rule limits existing electric generating units to no more than 1,700 lbs of CO_2 per megawatt hour of the gross energy input, by January 1, 2024, to no more than 1,300 pounds per megawatt hour by 2027, and to no more than 1,000 pounds per megawatt hour by 2035.

- **Climate Solutions Now Act of 2022.** One April 8, 2022, Maryland enacted a requirement for reduction of statewide greenhouse gas emissions by 60 percent from 2006 levels by 2031 and net-zero emissions by 2045.[119]

- **Illinois Air Quality Standards (NO_X, SO_2 and Hg).** The State of Illinois has promulgated its own standards for NO_X, SO_2 and Hg (mercury) known as Multi-Pollutant Standards (MPS) and Combined Pollutants Standards (CPS). MPS and CPS establish standards that are more stringent and take effect earlier than comparable Federal regulations, such as the EPA's MATS.

Some states proposed legislation in 2024 designed to reduce or eliminate greenhouse gas and other emissions. The proposed legislation is summarized in Table 8-3.

114 *Id.*
115 For more details, see the *2019 State of the Market Report for PJM*, Appendix H: "Environmental and Renewable Energy Regulations."
116 Carbon dioxide equivalent (CO2e) emissions means the total emissions of six greenhouse gases (carbon dioxide, nitrous oxide, methane, hydrofluorocarbons, perfluorocarbons and sulfur hexafluoride). Co-pollutants mean the six criteria pollutants identified by the US EPA pursuant to the Clean Air Act: Carbon Monoxide, Lead, Nitrogen Dioxide, Ozone, Particle Pollution, and Sulfur Dioxide.
117 See Energy Transition Act, Public Act 102-0662, Section 90-55, which amends section 9.15 (k-5) FOR the Illinois Environmental Protection Act.
118 See N.J.A.C. 7:27F.
119 See Maryland SB 528.

Table 8-3 Summary of proposed environmental regulatory activity affecting PJM resources by jurisdiction

Jurisdiction	Bill/Docket No.	Environmental Regulatory Activity
Delaware	SB 205	153rd Gen. Assembly: Would require any entity seeking to begin the business of using 30 megawatts (MW) of electricity or greater to first obtain a Certificate to Operate (COP) from the Public Service Commission.
	HB 233	153rd Gen. Assembly: Act requires regulated utilities to establish a separate rate for large energy-use facilities that mitigates the risk of costs associated with expanding infrastructure and maintaining reliability in the face of growing demand from being shifted to residential, small business, and other electric customers.
Illinois	HB 3758/SB 2497	2025-2026/104th General Assembly: Bill requiring energy storage procurement and reforms to the grid interconnection process.
Indiana		No current activity.
Kentucky		No current activity.
Maryland		No current activity.
Michigan		No current activity.
New Jersey	S 222	2024-2025 Reg. Sess.: Bill would authorize regulation of greenhouse gas emissions under "Air Pollution Control Act (1954)" and "Global Warming Response Act."
	S 220	2024-2025 Reg. Sess.: Bill would establish Nuclear Power Advisory Commission.
	S 2816	2024-2025 Reg. Sess.: Requires electric public utilities to submit to BPU and to implement electric infrastructure improvement plans.
	S 4143	2024-2025 Reg. Sess.: Requires submission of energy usage plan to BPU for proposed artificial intelligence data centers; requires all electricity for artificial intelligence data centers to be derived from new clean energy sources.
	S 237	2024-2025 Reg. Sess.: Establishes 100 percent clean electricity standard and directs BPU to establish clean electricity certificate program.
	A 5902/S 4693	2024-2025 Reg. Sess.: Requires BPU to work with neighboring states to research and recommend certain action concerning electric capacity and transmission.
	SJR 154/AJR 216	2024-2025 Reg. Sess.: Directs BPU to investigate RPM; directs State to promote affordable energy practices and to urge PJM to implement certain reforms.
	S 4143/ A 5564	2024-2025 Reg. Sess.: Requires submission of energy usage plan to BPU for proposed artificial intelligence data centers; requires all electricity for artificial intelligence data centers to be derived from new clean energy sources.
	S 4289/A 5267	2024-2025 Reg. Sess.: Requires BPU to procure and incentivize transmission scale energy storage.
	S 237	2024-2025 Reg. Sess.: The "New Jersey Clean Energy Act of 2024" establishes 100 percent clean electricity standard and directs BPU to establish clean electricity certificate program.
	S 4570	2024-2025 Reg. Sess.: Withdraws New Jersey's participation in RGGI.
North Carolina		No current activity.
Ohio		No current activity.
Pennsylvania	HB 782	2025-2026 Reg. Sess.: Requires public utilities to report lobbying and political activities expenses to exclude them from rates; requires electric distribution companies to be in an RTO and to report voting in PJM processes.
Tennessee		No current activity.
Virginia		No current activity.
Washington, D.C.		No current activity.
West Virginia		No current activity.

Clean Energy Standards

- In April 2020, Virginia enacted the Virginia Clean Economy Act, which orders the closure of most coal generation in state by 2024, most fossil fuel generation by 2045, and adopts a 100 percent clean energy standard by 2045.[120] The legislation mandates Chesterfield Power Station Units 5 & 6 and Yorktown Power Station Unit 3 to be retired by the end of 2024, Altavista, Southampton and Hopewell to be retired by the end of 2028 and Virginia Power's remaining fossil fuel units to be retired by the end of 2045, unless the retirement of such generating units will compromise grid reliability or security.[121] The legislation also imposes a temporary moratorium on Certificates of Public Convenience and Necessity for fossil fuel generation, unless the resources are needed for grid reliability.[122]

Opportunity Cost

PJM generators are subject to environmental constraints that limit generation. These constraints are specified in the operating permits issued by the jurisdictional environmental authority. Schedule 2 of the PJM Operating Agreement provides that the opportunity cost associated with the environmental constraints may be included in a generator's cost-based offer.[123] Opportunity cost associated with a physical equipment limitation or a fuel supply limitation, under certain circumstances, may also qualify for inclusion in the cost-based offer.[124]

More than 10,000 MW of capacity are currently affected by CEJA, most of which have requested that the MMU calculate a unit specific opportunity cost. The CEJA operating limits have resulted in significant opportunity cost adders to cost-based energy market offers for affected units. The CEJA opportunity cost adders were 3.1

120 Va. HB 1526/SB 851.
121 See Dominion Energy, Inc., et al., SEC Form 10-Q (Quarter ending June 30, 2020).
122 *Id.*
123 PJM Operating Agreement, Schedule 2,
124 Id. at 5(b).

times, on average, the opportunity cost adders associated with the operating permit constraints during the first nine months of 2025.

The MMU calculates opportunity costs for units that make requests and provide required data. The MMU calculated opportunity cost adders for 175 generators in the first nine months of 2025. The calculations are generally done one time per week and the resulting opportunity cost is effective for a seven day period. More frequent calculations are done in cases where the constraints are tight and the opportunity cost is expected to vary significantly from day to day.

RGGI

The Regional Greenhouse Gas Initiative (RGGI) is a cooperative effort by Connecticut, Delaware, Maine, Maryland, Massachusetts, New Hampshire, New Jersey (as of January 1, 2020), New York, Rhode Island, Vermont and Virginia (as of January 1, 2021) to cap CO_2 emissions from power generation facilities.[125] Virginia withdrew from RGGI effective January 1, 2024.

Delaware, Maryland and New Jersey are members of RGGI, and Virginia was a member from January 1, 2021 through 2023. New Jersey, a founding member of RGGI, opted out in 2011 but rejoined RGGI in 2020.[126] Virginia joined RGGI on January 1, 2021, and left RGGI on December 31, 2023. A decision issued November 18, 2024, by the Floyd County Circuit Court of Virginia determined that the Governor lacked the authority to remove Virginia from RGGI.[127] An appeal of the decision is pending in the Virginia Court of Appeals (Case No. 1494-23-4). Pennsylvania took action to join RGGI on April 23, 2022, but such action has been enjoined by court order on appeal.[128] [129] A decision on the merits of the appeal is pending at the Supreme Court of Pennsylvania.[130]

Table 8-4 shows the RGGI CO_2 auction clearing prices and quantities, in short tons and metric tonnes, for the 3rd control period through the 6th control period.[131] The clearing price for the auction held September 3, 2025, was \$22.25 per allowance (equal to one short ton of CO_2).[132] The Cost Containment Reserve (CCR) for 2025 was exhausted in the first auction of 2025 and all RGGI auctions held in 2025 have cleared above the CCR trigger price of \$17.03 per allowance.[133] All RGGI auctions in 2024 and the first two auctions of 2025 cleared above the CCR trigger price. The September 2025 auction clearing price increased11.6 percent from the last auction clearing price of \$19.93 in June 2025. The average RGGI auction price in the first nine months of 2025 was \$20.51 per allowance, a 1.5 percent increase over the average RGGI auction price in the first nine months of 2024.

125 RGGI provides a link on its website to state statutes and regulations authorizing its activities, which can be accessed at: <http://www.rggi.org/design/regulations>.

Commonwealth Leadership in Addressing Climate Change through Electric Sector Emissions Reductions, Tom Wolf, Governor, October 3, 2019, <https://www.governor.pa.gov/newsroom/executive-order-2019-07-commonwealth-leadership-in-addressing-climate-change-through-electric-sector-emissions-reductions/>.
129 See *Bowfin KeyCon Holdings, LLC v. Pennsylvania Department of Environmental Protection*, 347 M.D. 2022 (November 1, 2023) ("held that the Pennsylvania [DEP]'s CO2 Budget Trading Program Regulation is an unconstitutional tax, declared the rule to be void, and enjoined DEP from enforcing it"); *Ramez Ziadeh, et al. v. Pennsylvania Legislative Reference Bureau*, Memorandum Opinion, Commonwealth Court of Pennsylvania Case No. No. 41 M.D. 2022 (July 8, 2022); *Ramez Ziadeh, et al. v. Pennsylvania Legislative Reference Bureau*, Order Granting Application to Vacate, Commonwealth Court of Pennsylvania Case No. No. 41 M.D. 2022 (July 25, 2022).
130 See *Shirley v. Pennsylvania Legislative Reference Bureau* (No. 247 M.D. 2022); Supreme Court Docket Nos. 81 MAP 2022, 83 MAP 2022, or 85 MAP 2022.
131 Each control period is three years in duration. The 3rd control period covers 2015 through 2017. The 4th control period covers 2018 through 2020. The 5th control period covers 2021 through 2023. The 6th control period covers 2024 through 2026.
132 RGGI measures carbon in short tons (short ton equals 2,000 pounds) while world carbon markets measure carbon in metric tonnes (metric tonne equals 1,000 kilograms or 2,204.6 pounds).
133 RGGI auctions employ a price cap called the Cost Containment Reserve (CCR) trigger price. When demand for allowances exceeds the supply at the CCR trigger price, the auction is cleared by setting the price equal to the CCR trigger price and drawing on allowances that are held in reserve. In the March 2025 auction, the reserve allowances were not sufficient to meet the demand at the CCR trigger price and the auction cleared above the CCR trigger price. Since the CCR allowances for 2025 have been exhausted, the CCR trigger price of \$17.03 will not affect the remaining RGGI auctions in 2025.

Table 8-4 RGGI CO_2 allowance auction prices and quantities in short tons and metric tonnes: 3rd, 4th, 5th and 6th Control Periods[134]

	Short Tons				Metric Tonnes

134 See Regional Greenhouse Gas Initiative, "Auction Results," <https://www.rggi.org/auctions/auction-results>.

The RGGI auction held on September 3, 2025, generated $337.7 million in auction revenue. RGGI auctions have generated $9.7 billion in auction revenue since 2008.[135] RGGI auction revenue is returned to the states. RGGI reported that the RGGI states, cumulative through the 2022 reporting year, have invested $4.9 billion, 67.8 percent of auction revenues.[136] RGGI reports that 56 percent of the $4.9 billion was invested in energy efficiency, 12 percent on clean and renewable energy, seven percent on greenhouse gas abatement, 15 percent on direct bill assistance, five percent on beneficial electrification, six percent on administration and one percent on RGGI, Inc.[137]

If all PJM states joined RGGI, the total RGGI revenue to the PJM states would be significant. The estimated allowance revenue for PJM states based on 2024 CO_2 emission levels and the RGGI clearing price for the September 2025 auction ranges from $3.9 billion per year to $7.4 billion per year depending on associated reductions in carbon emission levels (Table 8-5).[138] Table 8-5 shows the estimated carbon allowance revenue for each PJM state based on the latest RGGI auction price and reductions below 2024 CO_2 emission levels ranging from five to 50 percent. A power plant owner must acquire an allowance for each ton of CO_2 emissions and the revenue values in Table 8-5 are computed by multiplying the carbon price by the emission cap level which is expressed as a reduction below the 2024 actual emissions level. States that

138 This assumes that the PJM states would implement their RGGI rules consistent with the current RGGI states where owners of fossil fuel generators are required to purchase emission allowances in a regional centralized auction or purchase allowances in a secondary market.

participate in RGGI choose their emission cap. For example, New Jersey chose an emission cap of 18,000,000 short tons for reentry into RGGI in 2020, 5.3 percent below New Jersey's 2018 CO_2 emissions level; the New Jersey emission cap will be reduced by 540,000 short tons each year through 2030.[139]

Table 8-5 Estimated CO_2 allowance revenue at June 2025 RGGI price level[140 141]

		Estimated CO_2 allowance revenue ($ millions), carbon price $22.25 per short ton						
Jurisdiction	2024 power generation CO_2 missions (million short tons)	5 percent reduction below 2024 emission levels	10 percent reduction below 2024 emission levels	15 percent reduction below 2024 emission levels	20 percent reduction below 2024 emission levels	25 percent reduction below 2024 emission levels	50 percent reduction below 2024 emission levels

West Virginia	48.2	$1,018.4	$964.8	$911.2	$857.6	$804.0	$536.0
Total	347.8	$7,350.8	$6,964.0	$6,577.1	$6,190.2	$5,803.3	$3,868.9

The RGGI emissions cap (carbon budget) is the sum of CO_2 allowances issued by each state. Table 8-6 shows the RGGI emission cap history. Compliance with the RGGI allowance obligation is evaluated at the end of each three year period which is called the control period. The first control period began in 2009. The 2025 compliance year is the second year of the sixth control period.

In 2021, RGGI announced a third adjustment to the RGGI emissions cap to account for banked allowances from previous control periods.[142] [143] The first adjustment removed 57.4 million allowances that were banked or unused from the first control period. The reduction to the RGGI emissions cap was spread over a seven year period beginning in 2014 and ending with 2020.[144] A second cap adjustment, corresponding to banked allowances for 2012 and 2013, began in 2015 with an adjustment of 13.7 million allowances per year and was in place through 2020.[145] The third adjustment of 95.5 million allowances will be spread over a five year period beginning in 2021.[146] The base emissions cap for each of the next five years will be reduced by 19.1 million allowances. The percent

139 "Governor Murphy Announces Adoption of Rules Returning New Jersey to Regional Greenhouse Gas Initiative," State of New Jersey, Governor Phil Murphy Press Release, June 17, 2019 <https://nj.gov/governor/news/news/562019/approved/20190617a.shtml>.
140 The 2024 CO_2 emissions data is from the EPA Continuous Emission Monitoring System (CEMS) from PJM generators.
141 Power generation companies subject to a RGGI emission cap can offset up to 3.3 percent of their allowance obligation by undertaking certain greenhouse gas emission reduction projects. The allowance revenue values in Table 8-5 do not reflect offset allowances.
142 "Third Adjustment for Banked Allowances Announcement," Regional Greenhouse Gas Initiative (March 15, 2021) <https://www.rggi.org/news-releases/rggi-releases>.
143 A banked allowance is an allowance acquired during a previous control period that was not used to fulfill a RGGI allowance obligation.
144 "Second Control Period Interim Adjustment for Banked Allowances Announcement," Regional Greenhouse Gas Initiative (March 17, 2014) at 2. Due to rounding, the adjustment is 8,207,664 allowances for years 2014 through 2018, and 8,207,663 allowances for the remaining two years <https://www.rggi.org/sites/default/files/Uploads/Design-Archive/2012-Review/Adjustments/2014_03_17_SCP_Adjustment.pdf>.

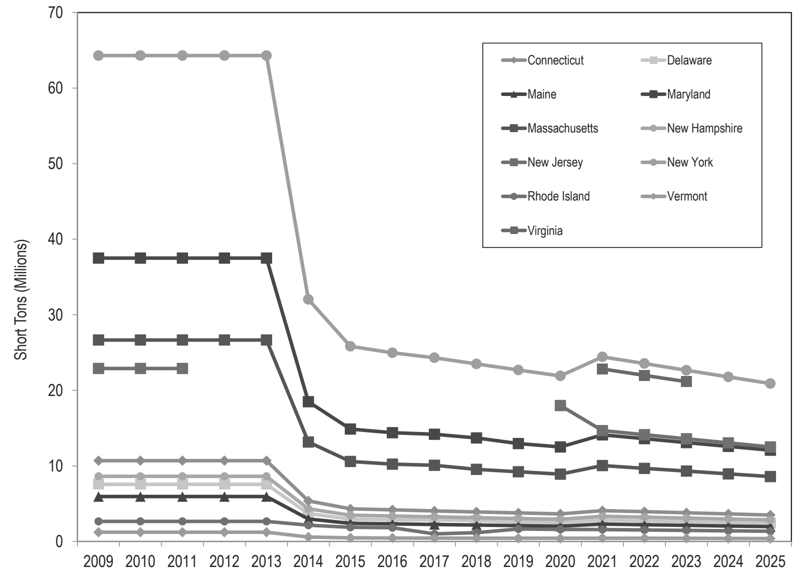
change columns in Table 8-6 show the year to year percent changes in the base RGGI cap and the adjusted RGGI cap.[147] The adjusted emissions cap for 2021 is the only year for which the adjusted carbon emissions cap increased.[148] Figure 8-2 shows the adjusted carbon budgets (CO_2 emissions caps) for the RGGI states.

Table 8-6 RGGI emissions cap history[149 150]

	Control Period	RGGI Average Clearing Price ($ per short ton)	RGGI Cap (short tons)	Percent Change in RGGI Cap	RGGI Adjusted Cap (short tons)	Percent Change in Adjusted Cap
2009	1st	$2.77	188,076,976		188,076,976	
2010		$1.93	188,076,976	0.0%	188,076,976	0.0%
2011		$1.89	188,076,976	0.0%	188,076,976	0.0%
2012	2nd	$1.93	165,184,246	0.0%	165,184,246	0.0%
2013		$2.92	165,184,246	0.0%	165,184,246	0.0%
2014		$4.72	91,000,000	(44.9%)	82,792,336	(49.9%)
2015	3rd	$6.10	88,725,000	(2.5%)	66,833,592	(19.3%)
2016		$4.47	86,506,875	(2.5%)	64,615,467	(3.3%)
2017		$3.42	84,344,203	(2.5%)	62,452,795	(3.3%)
2018	4th	$4.41	82,235,598	(2.5%)	60,344,190	(3.4%)
2019		$5.43	80,363,945	(2.3%)	58,472,538	(3.1%)
2020		$6.41	96,354,847	(2.5%)	74,463,439	(3.4%)
2021	5th	$9.61	119,767,784	(3.9%)	100,677,454	4.5%
2022		$13.46	116,112,784	(3.1%)	97,022,454	(3.6%)
2023		$13.58	112,457,784	(3.1%)	93,367,454	(3.8%)
2024	6th	$20.17	84,162,784	(3.2%)	69,401,609	(3.9%)
2025		$20.51	81,347,784	(3.3%)	66,586,609	(4.1%)

147 Percent changes for years with membership changes do not reflect the impacts of the change in membership. For example, the RGGI cap for 2020 reflects the impact of New Jersey rejoining RGGI in 2020 but the percent change from 2019 to 2020 does not include New Jersey's allowance budget. Virginia's adoption of RGGI in 2021 and Virginia's withdrawal at the end of 2023 are treated analogously.
148 The increase of 4.5 percent does not reflect the addition of Virginia as a RGGI state.
149 See Regional Greenhouse Gas Initiative, "Allowance Distribution" <https://www.rggi.org/allowance-tracking/allowance-distribution> (Accessed April 21, 2025).
150 The increase in the RGGI Cap and the RGGI Adjusted Cap in 2020 is due to the reentry of New Jersey. The new cap is 18 million short tons higher than the previously published 2020 caps.

Figure 8-2 RGGI adjusted carbon budgets by state[151]



Carbon Pricing, State Revenues and Energy Market Prices

Table 8-7 shows the estimated allowance revenue for PJM states for carbon prices ranging from $20 per short ton to $50 per short ton and for emissions reductions ranging from five percent to 50 percent. Allowance revenues to states would be $16.5 billion if the carbon price were $50 per short ton and emission levels were five percent below 2024 levels. Allowance revenues to states would be $3.5 billion if the carbon price were $20 per short ton and emission levels were 50 percent below 2024.

151 Data for the figure was collected from allowance distribution reports available on the RGGI website <https://www.rggi.org/allowance-tracking/allowance-distribution>

Table 8-7 Estimated CO_2 allowance revenue at various carbon prices

	Estimated CO_2 allowance revenue ($ millions)

Table 8-8 shows the estimated impact of five different carbon prices on PJM load-weighted LMP. For example, if the carbon price were $25.00 per tonne, the PJM load-weighted average LMP in the first nine months of 2025 would have increased by 0.7 percent.[152]

Table 8-8 Estimated impact of carbon price on LMP: January through September, 2024 and 2025

		2024 (Jan - Sep)			2025 (Jan - Sep)		
Scenario	Carbon Price ($/Metric Ton)	Actual LMP ($/MWh)	Estimated LMP ($/MWh)	Percent Change	Actual LMP ($/MWh)	Estimated LMP ($/MWh)	Percent Change
Scenario 1	$5.00	$34.31	$31.71	(7.6%)	$50.51	$48.88	(3.2%)
Scenario 2	$10.00	$34.31	$32.50	(5.3%)	$50.51	$49.38	(2.2%)
Scenario 3	$15.00	$34.31	$33.28	(3.0%)	$50.51	$49.87	(1.3%)
Scenario 4	$25.00	$34.31	$34.86	1.6%	$50.51	$50.87	0.7%
Scenario 5	$50.00	$34.31	$38.80	13.1%	$50.51	$53.36	5.7%

Table 8-9 shows the impact of a range of carbon prices on the cost per MWh of producing energy from three basic unit types.[153] [154] For example, if the price of carbon were $50.00 per tonne, the short run marginal costs would increase by $24.45 per MWh for a new combustion turbine (CT) unit, $16.85 per MWh for a new combined cycle (CC) unit and $43.12 per MWh for a new coal plant (CP). Table 8-11 and Table 8-12 show the carbon price impact ($ per MWh) for a range of heat rates and carbon prices for natural gas and coal fired generation.

Table 8-9 Carbon price per MWh by unit type

	Carbon Price per MWh						
Unit Type	Carbon $5/tonne	Carbon $10/tonne	Carbon $15/tonne	Carbon $50/tonne	Carbon $100/tonne	Carbon $200/tonne	Carbon $400/tonne
CT	$2.44	$4.89	$7.33	$24.45	$48.89	$97.79	$195.58
CC	$1.68	$3.37	$5.05	$16.85	$33.70	$67.40	$134.79
CP	$4.31	$8.62	$12.94	$43.12	$86.25	$172.49	$344.99

Table 8-9 also illustrates the effective cost of carbon included in the price of a REC or SREC. For example, the average price of an SREC in New Jersey was $187.50 per credit in the first nine months of 2025. The SREC price is paid in addition to the energy price paid at the time the solar energy is produced. The carbon price implied by the SREC price is slightly less than $400 per tonne. Table 8-9 shows that if the MWh produced by the solar resource resulted in avoiding the production of one MWh from a CT, the value of carbon reduction implied by an SREC price of $195.58 is a carbon price of $400 per tonne. This result also assumes that the entire value of the SREC was based on reduced carbon emissions. The SREC price consistent with a carbon price of $50.00 per tonne, assuming that a MWh from a CT is avoided, is $24.45 per MWh.

Applying this method to Tier I and Class I REC, and SREC price histories yields the implied carbon prices in Table 8-10. The carbon price implied by the average REC price for the first nine months of 2025 in Ohio is $10.24 per tonne which is less than half the average RGGI auction clearing price of $22.61 per tonne in the first nine months of 2025. The implied carbon prices for RECs in the other jurisdictions in Table 8-10 range from $49.24 per tonne to $65.23 per ton. The implied carbon price for Virginia RECs is $65.23, 2.9 times the average RGGI auction clearing price. The social cost of carbon is estimated to be in the range of $50 per tonne.[155] [156] The carbon prices implied by SREC prices have no apparent relationship to carbon prices implied by the REC clearing prices. The carbon prices implied by the SREC prices all exceed the carbon prices implied by the corresponding REC prices.

152 LMPs are recalculated to account for the defined cost of carbon emissions on marginal units' offer prices. The LMP calculation is not based on a counterfactual redispatch of the system to determine the marginal units and the marginal costs that would have occurred if all units had made all offers at short run marginal cost. See Technical Reference for PJM Markets, "Calculation and Use of Generator Sensitivity/Unit Participation Factors," <http://www.monitoringanalytics.com/reports/Technical_References/references.shtml>.
153 Heat rates from: *2024 Annual State of the Market Report for PJM*, Section 7: Net Revenue, Table 7-3.
154 Prices reflect carbon emissions rates from *Table A.3. Carbon Dioxide Uncontrolled Emission Factors*, EIA, <https://www.eia.gov/electricity/annual/html/epa_a_03.html> (Accessed May 7, 2024).
155 "Technical Update of the Social Cost of Carbon for Regulatory Impact Analysis – Under Executive Order 12899," Interagency Working Group on the Social Cost of Greenhouse Gases, United States Government, (Aug. 2016), <https://19january2017snapshot.epa.gov/sites/production/files/2016-12/documents/sc_co2_tsd_august_2016.pdf>.
156 A recent update by the EPA estimates the social cost of carbon emissions for 2030 to be between $140 and $380 per metric ton (2020 dollars). See Table ES.1 in Report on the Social Cost of Greenhouse Gases, U.S. Environmental Protection Agency (November 2023) <https://www.epa.gov/environmental-economics/scghg>.

State Renewable Portfolio Standards

Ten of 14 PJM jurisdictions have enacted legislation that requires that a defined percentage of retail load be served by renewable resources, for which there are many standards and definitions. These requirements are known as renewable portfolio standards, or RPS. In PJM jurisdictions that have adopted an RPS, load serving entities are required by law to meet defined shares of load using specific renewable and/or alternative energy sources commonly called eligible technologies. Load serving entities may generally fulfill these obligations in one of two ways: they may use their own generation resources classified as eligible technologies to produce power or they may purchase renewable energy credits (RECs) that represent a known quantity of power produced with eligible technologies by other market participants or in other geographical locations. Load serving entities that fail to meet the percent goals set in their jurisdiction's RPS must pay penalties (alternative compliance payments).

Renewable energy sources replenish naturally in a short period of time but are flow limited and include solar, geothermal, wind, biomass and hydropower from flowing water. Renewable energy sources are virtually inexhaustible in duration but limited in the amount of energy that is available per unit of time. Nonrenewable energy sources do not replenish in a short period of time and include crude oil, natural gas, coal and uranium (nuclear energy).[159] Some state rules allow nonrenewable energy sources as part of their Renewable Portfolio Standard.

As of September 30, 2025, Delaware, Illinois, Maryland, Michigan, New Jersey, North Carolina, Ohio, Pennsylvania, Virginia and Washington, DC had mandatory renewable portfolio standards that include penalties.

As of September 30, 2025, Indiana had voluntary renewable portfolio standards that do not require participation and do not include noncompliance penalties. Incentives are offered to load serving entities to develop renewable generation or, to a more limited extent, purchase RECs. The voluntary standard was enacted by the Indiana legislature in 2011, but no load serving entities have volunteered to participate in the program.[160]

As of September 30, 2025, Kentucky, Tennessee and West Virginia had no renewable portfolio standards.

How each state satisfies its renewable portfolio standard requirements should be more transparent. While some jurisdictions publish transparent information regarding total REC generation, how the standard is fulfilled and the total cost to the state, some jurisdictions do not provide the same level of detail and there can be a significant lag from the end of the compliance year to the publication of the information. Some states provide adequate information

158 Prices reflect carbon emission rates for refined coal in *Table A.3. Carbon Dioxide Uncontrolled Emission Factors*, EIA, <https://www.eia.gov/electricity/annual/html/epa_a_03.html> (Accessed May 7, 2024).

159 *Renewable Energy Explained*, U.S. Energy Information Administration, <https://www.eia.gov/energyexplained/index.php?page=renewable_home> (Accessed May 7, 2024).

160 See the Indiana Utility Regulatory Commission's "2021 Annual Report," at 37 (Oct. 2021) <https://www.in.gov/iurc/2981.htm>.

with respect to the total cost for the RPS, where the RECs originated that fulfill the RPS requirements, and if the state fulfilled the RPS goals. Pennsylvania and Maryland both provide more information than other states and serve as a model for other states. The MMU recommends that jurisdictions with a renewable portfolio standard make the compliance data and cost data available in a more complete and transparent manner.

Since a REC may be applied in years other than the year in which it was generated, each vintage of RECs for each state has a different price. For example, the Pennsylvania Alternative Energy Portfolio Standard allows an electric distribution company or generation supplier to retain RECs from the current reporting year for use toward satisfying their REC obligation in either of the two subsequent reporting years.[161]

Beginning in March 2023, RECs for GATS generators will be hourly time stamped certificates.[162] Prior to March 2023, PJM EIS issued RECs based on how much a generator produced in a month.

Table 8-13 shows the percent of retail electric load that must be served by renewable and/or alternative energy resources under each PJM jurisdictions' RPS by year.

Table 8-13 Renewable and alternative energy standards of PJM jurisdictions: 2024 to 2034[163 164 165]

Jurisdiction with RPS	2024	2025	2026	2027	2028	2029	2030	2031	2032	2033	2034

The Climate and Equitable Jobs Act (CEJA), which became effective on September 15, 2021 in Illinois, increased the RPS target percent from 25 percent by 2025 to 40 percent by 2030. CEJA also increased the quotas for RECs sourced from new wind and new photovoltaic resources, and made changes to eligible technologies and geographic restrictions. See Table 8-14 for details.

Updates to the Maryland RPS became effective on June 1, 2021. Maryland Senate Bill 65 changed the intermediate RPS target levels while maintaining the target of 50 percent renewable by 2030.[166] Part of the legislation was to eliminate resources fueled by black liquor as a Tier 1 eligible technology. Senate Bill 65 reduced the penalty for solar noncompliance from $100 per credit to $80 per credit, and extended the Tier 2 standard which was scheduled to expire with the 2020 compliance year.

161 Pennsylvania General Assembly, "Alternative Energy Portfolio Standards Act – Enactment Act of Nov. 30, 2004, P.L. 1672, No. 213," Section (e)(6).

163 This shows the total standard of alternative resources in all PJM jurisdictions, including Tier I and Tier II.
164 The table reflects calendar year standards for Maryland, Washington, DC, Ohio, and North Carolina. The standards for the remaining jurisdictions are for compliance years that begin on June 1, CCYY and end on May 31 of the following year.
165 New Jersey Administrative Code, Section 14:8-2.3 does not specify standards beyond compliance year 2032/2033.
166 *Senate Bill 65 Electricity – Renewable Energy Portfolio Standard – Tier 2 Renewable Sources, Qualifying Biomass, and Compliance Fees*, Maryland General Assemble (2021) <https://mgaleg.maryland.gov/mgawebsite/Legislation/Details/sb0065?ys=2021RS>.

The Delaware General Assembly passed new RPS legislation on February 10, 2021. The new law updates the Delaware RPS targets from 25 percent in 2025 to 40 percent in 2035.[167] Additional details are provided in Table 8-14.

On April 11, 2020, the Virginia legislature passed a new law that replaced Virginia's current voluntary RPS with a mandatory RPS.[168] The new law requires by 2050 that 100 percent of energy sold by phase I utilities must come from RPS eligible resources; and 100 percent of energy sold by phase II utilities must come from RPS eligible resources by 2045.[169] [170] Intermediate RPS targets begin in 2021 with a 6.0 percent standard for phase I utilities and a 14.0 percent standard for phase II utilities. Eligible RPS resources include wind, solar, hydroelectric, landfill gas and biomass resources.

In 2018, New Jersey passed legislation that included provisions promoting the development of solar power in the state.[171] The Board of Public Utilities is directed to develop and provide an orderly transition to a new or modified program to support distributed solar. The Board must also design a Community Solar Energy Pilot Program that would "permit customers of an electric public utility to participate in a solar energy project that is remotely located from their properties but is within their electric public utility service territory to allow for a credit to the customer's utility bill equal to the electricity generated that is attributed to the customer's participation in the solar energy project." The pilot program would convert into a permanent program within three years. The statute targets the development of 600 MW of electric storage by 2021 and 2,000 MW by 2030.

On May 18, 2021, Maryland enacted legislation doubling the limit on net metered capacity from 1,500 to 3,000 MW.[172] The legislation is expected to boost the installation of distribution level solar power.

On July 9, 2021, New Jersey enacted legislation establishing a new program for SRECs under the BPU.[173] Through the SREC-II program, the BPU distribute solar renewable certificates to qualifying solar power facilities. The legislation includes incentives for at least 1,500 MW of behind the meter solar facilities and 750 MW of community solar by 2026. It also includes a new competitive solicitation process to incentivize at least 1,500 MW of large-scale solar power facilities by 2026, and develops siting criteria for large-scale solar projects.

Table 8-14 summarizes recent rules changes in Ohio, Maryland, New Jersey, and Washington, DC.

Table 8-14 Recent changes in RPS rules[174 175 176 177 178 179 180]

Jurisdiction	Legislation	Effective Date	Summary of changes
Illinois	Climate and Equitable Jobs Act (Public Act 102-0662)	September 15, 2021	Updated the RPS target to 40.0 percent by 2030. The previous target of 25.0 percent by 2025 is still required. Updated the requirement for RECs from new wind generation from 2,000 GWH annually to 4,500 GWH beginning in the 2021/2022 delivery year; increasing to 20,250 GWH in 2030/2031. Updated the requirement for RECs from new photovoltaic generation from 2,000 GWH annually to 5,500 GWH beginning in the 2021/2022 delivery year; increasing to 24,750 GWH in 2030/2031. Removed tree waste as an energy source for eligible resources and added waste heat to power systems and qualified combined heat and power systems as eligible resources. Updated the geographic restrictions to allow RECs from utility scale wind or photovoltaic resources that are deliverable via high voltage direct current transmission.
Maryland	Senate Bill 65	June 1, 2021	Maintains theTier 1 target of 50.0 percent in 2030 with 14.5 percent solar carve out, but changes the intermediary target levels beginning in 2022. The alternatvie compliance payment for solar was reduced and the definition of Tier 1 resource now excludes generators fueled by black liquor. Extends indefinitely the Tier 2 target of 2.5 percent which was set to expire in 2020. Tier 2 resources are defined as hydroelectric power other than pumped storage.
Delaware	151st General Assembly Senate Bill 33	February 1, 2021	Increases the RPS target from 25.0 percent in 2025 to 40.0 percent in 2035. Sets the solar carve out requirement to 10.0 percent in 2035. Establishes intermediary target levels for total RPS and the solar carve out for compliance years 2026 through 2034. Lowered the solar alternative compliance payment (SACP) from $400 per credit to $150 per credit.
Virginia	Virginia Clean Economy Act	April 11, 2020	Replaces the voluntary RPS with a mandartory RPS beginning in January 2021. The legislation requires 100 percent clean energy by 2050 for phase I utilities and 100 percent clean energy by 2045 for phase II utilities. Intermediate target levels begin in 2021 with 6 percent for phase I utilities and 14 percent for phase II utilities.
Ohio	House Bill 6	October 22, 2019	Reduced the RPS percent for each year beginning in 2020. The 2020 standard was reduced from 6.5 percent to 5.5 percent; the 2026 standard was reduced from 12.5 percent to 8.5 percent. The legislation also removed language that had previously indicated that the standard would remain at the 2026 level for each year after 2026. The solar carve out was removed for compliance year 2020 and beyond. Prior to the recent legislation, the solar carve out was 0.26 percent for 2020, increased to 0.50 percent for 2026, and remained at 0.50 percent for subsequent years.
Maryland	Clean Energy Jobs Act	May 25, 2019	Established a new Tier I target of 50.0 percent in 2030; previously the 2030 Tier I standard was 25.0 percent. The 2019 Tier I standard increased from 20.4 percent to 20.7. The solar carve out percent for 2019 increased from 1.95 percent to 5.50 percent. The solar carve out percent for 2030 increased from 2.5 percent to 14.5 percent. The 2.5 percent Tier II standard, scheduled to end in 2018, was extended through 2020.
Washington, D.C.	CleanEnergy DC Omnibus Amendment Act of 2018	March 22, 2019	Established a 100 percent Tier I renewable standard by 2032. Previously, the 2032 target was 50.0 percent. Tier I increases start in 2020, going from 20.0 percent to 26.25 percent. The 2020 solar carve out will increase from 1.58 percent to 2.175 percent. The 2041 target for the solar carve out is 10.0 percent.

On January 20, 2025, the Trump Administration issued a Presidential Memorandum withdrawing "from disposition for wind energy leasing all areas within the Offshore Continental Shelf."[181] The withdrawal effectively puts on hold indefinitely the offshore wind projects in New Jersey and Maryland. On May 5, 2025, the Attorneys General of New Jersey and Maryland, along with the 16 other states, filed suit against the Trump Administration over the withdrawal of offshore leasing.[182 183]

New Jersey and Maryland have taken significant steps to promote offshore wind. Both states enacted legislation for offshore wind renewable energy credits (ORECs) in 2010.[184]

184 See Offshore Wind Economic Development Act of 2010, P.L. 2010, c. 57, as amended, N.J.S.A. 48:3-87 to -87.2.

On May 24, 2018, New Jersey enacted a statute directing the Board of Public Utilities (NJPBU) to create an OREC program targeting installation of at least 3,500 MW of offshore wind capacity by 2030 (plus 2,000 MW of energy storage capacity).[185] The New Jersey statute also reinstates certain tax incentives for offshore wind manufacturing activities. Governor Murphy has issued Executive Order No. 8, which calls for full implementation of the statute. The offshore wind target 3,500 MW by 2030 has since been replaced by a target of 7,500 MW by 2035.[186] The BPU opened a 100 day application window for qualified offshore wind projects on September 20, 2018, and on June, 21, 2019, the first award for a 1,100 MW offshore wind project was granted to Danish wind power developer Ørsted.[187] [188] Two more projects were approved on June 30, 2021. Ørsted was awarded a second project for offshore wind capacity of 1,148 MW and Atlantic Shores Offshore Wind was awarded a project for 1,510 MW.[189] On October 31, 2023, Ørsted announced that it was canceling two major offshore wind projects, Ocean Wind 1 (1,100 MW) and Ocean Wind 2 (1,148 MW), that were planned off the coast of New Jersey.[190] The Associated Press reported in May 2024 that the New Jersey and Ørsted reached a settlement that required Ørsted to pay New Jersey $125 million.[191]

On January 24, 2024, the NJBPU awarded 2,400 MW of offshore wind capacity to the Leading Light Wind project and 1,342 to Attentive Energy LLC.[192] The Leading Light Wind project is a partnership between Invenergy and energyRE.

On December 17, 2021, the Maryland Public Service Commission awarded ORECs in its Round 2 solicitation to the 846 MW Skipjack Wind 2 offshore project, owned by Skipjack Offshore Energy LLC, an Ørsted subsidiary, and to the 808.5 MW Momentum Wind offshore project, owned by US Wind Inc.[193] ORECs for Skipjack Wind 2 have a levelized price of $71.61; ORECs for Momentum Wind have a levelized price of $54.17.[194] Both projects are expected to become operational before the end of 2026.[195] In 2017, Round 1 ORECs were awarded to Deepwater Wind's 120-MW Skipjack Wind Farm, later acquired by Ørsted, and U.S. Wind's 248 MW project.[196] On January 25, 2024, Ørsted announced it "has withdrawn from the Maryland Public Service Commission Orders approving the Skipjack 1 and 2 projects," noting that the OREC prices in the orders "are no longer commercially viable."[197]

On July 1, 2019, Dominion Energy announced the beginning of construction on an offshore wind demonstration project. The project consists of two 6 MW offshore wind turbines.[198] In September 2019, Dominion filed an interconnection agreement with PJM associated with its proposal to develop a 2,600 MW offshore wind farm.[199]

Each PJM jurisdiction with an RPS identifies the type of generation resources that may be used for compliance. These resources are often called eligible technologies. Some PJM jurisdictions with RPS group different eligible technologies into tiers based on the magnitude of their environmental impact. Of the ten PJM jurisdictions with mandatory RPS, Maryland, New Jersey, Pennsylvania, and Washington, DC group the eligible technologies that must be used to comply with their RPS programs into Tier I and Tier II resources.[200] Although there are minor differences across these four jurisdictions' definitions of Tier I resources, technologies that use solar photovoltaic, solar thermal, wind, ocean, tidal, biomass, low-impact hydro, and geothermal sources to produce electricity are classified as Tier I resources. Table 8-15 shows the Tier

200 New Jersey separates technologies into Class I/Class II resources in a manner that is consistent with the other jurisdictions' Tier I/Tier II categorizations.

I standards for PJM states.[201] All eligible technologies for the RPS standards in Table 8-15 satisfy the EIA definition of renewable energy.[202]

Table 8-15 Tier I / Class I renewable standards of PJM jurisdictions: 2024 to 2034[203]

Jurisdiction with RPS	2024	2025	2026	2027	2028	2029	2030	2031	2032	2033	2034
Maryland	33.70%	35.50%	38.00%	41.50%	43.00%	49.50%	50.00%	50.00%	50.00%	50.00%	50.00%
New Jersey	35.00%	38.00%	41.00%	44.00%	47.00%	50.00%	50.00%	50.00%	50.00%		
Pennsylvania	8.00%	8.00%	8.00%	8.00%	8.00%	8.00%	8.00%	8.00%	8.00%	8.00%	8.00%
Washington, DC	45.00%	52.00%	59.00%	66.00%	73.00%	80.00%	87.00%	94.00%	100.00%	100.00%	100.00%

Delaware, Illinois, Michigan, North Carolina, Virginia and Ohio do not classify the resources eligible for their RPS standards by tiers. In these states eligible technologies are largely but not completely renewable resources.[204]

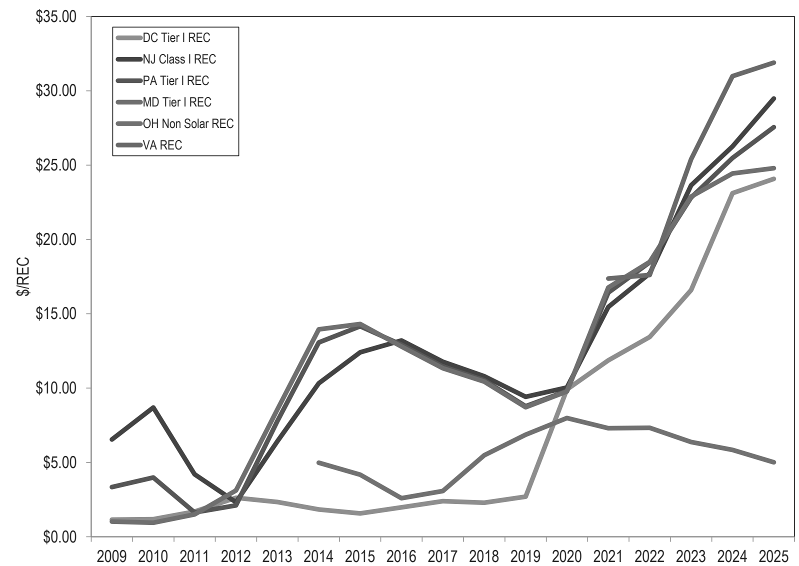
RECs do not need to be used during the year in which they are generated. The result is that there may be multiple prices for a REC based on the year in which it was generated. RECs typically have a shelf life of five years during which they can be used to satisfy a state's RPS requirement. For example if a load serving entity (LSE) owns renewable generation and the renewable generation exceeds the LSE's RECs purchase obligation for the current year, the LSE can either sell the REC to another LSE or hold the REC for use in a subsequent year.

PJM GATS makes data available for the amount of eligible RECs by jurisdiction. Eligible RECs are not the amount of actual RECs generated for that timeframe. A REC that is created may be eligible in multiple jurisdictions resulting in an over representation of generated RECs. This means if one REC is retired in Pennsylvania, the total amount of eligible RECs will reduce by more than one REC.

The REC prices are the average price for each vintage of REC, defined by the year in which the associated power was generated, regardless of when the REC is consumed. REC prices are required to be publicly disclosed in Maryland, Pennsylvania and Washington, DC, but in the other states REC prices are not publicly available.

Figure 8-3 shows the annual average Tier I REC price by jurisdiction from 2009 through September 2025. Tier I REC prices are lower than SREC prices. Several states have more stringent geographical restrictions for SRECs and higher alternative compliance payments (ACP) for SRECs than for RECs. For example, the average SREC price for the first nine months of 2025 in Washington, DC was $406.90 and the average Tier I REC price for the first nine months of 2025 in Washington, DC was $24.08. The DC RPS requires SRECs to be sourced from within DC while Tier I RECs may be sourced from anywhere within the PJM footprint. The DC solar ACP is $460 per SREC compared to $50 per REC for Tier I compliance.

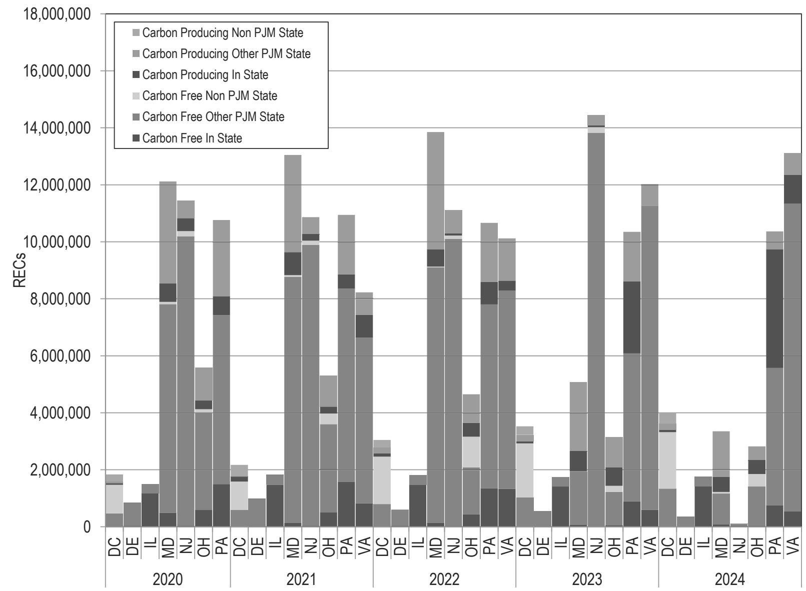
Figure 8-3 Average Tier I REC price by jurisdiction: 2009 through September 2025



201 This includes New Jersey's Class I renewable standard.
202 *Renewable Energy Explained*, U.S. Energy Information Administration, <https://www.eia.gov/energyexplained/index.php?page=renewable_home> (Accessed May 7, 2024).
203 New Jersey Administrative Code, Section 14:8-2.3 does not specify standards beyond compliance year 2032/2033.
204 Michigan's Public Act 342, effective April 20, 2017, removed nonrenewable technologies (e.g. coal gasification, industrial cogeneration, and coal with carbon capture) from the list of RPS eligible technologies.

Figure 8-4 and Table 8-16 shows the fulfillment of Tier I equivalent RPS requirement for 2019 through 2023 by state and by carbon producing and noncarbon producing RECs.[205] Depending on the state, the RPS requirement can be fulfilled by wind, solar, hydro ("Noncarbon REC") or with landfill gas, captured methane, wood, black liquor, and other fuels. ("Carbon Producing REC"). States' Tier I requirements are not all carbon free. The Illinois RPS, beginning in 2019, is fulfilled by noncarbon RECs, but all other state Tier I equivalent RPS requirements allow carbon producing RECs to fulfill the RPS requirements. Figure 8-4 shows the use of in state, other PJM state and out of state carbon producing RECs and in state, other PJM state and out of state noncarbon RECs by state to meet the RPS requirements. In Table 8-16 the retired RECs are summarized by in state, other PJM state and non PJM state, and carbon producing RECs and noncarbon RECs. For example, Virginia met its 2024 RPS target using 4.1 percent carbon free RECs from Virginia, 82.3 percent carbon free RECs from other PJM states and 13.5 percent carbon producing RECs from Virginia and other PJM states. Ohio met its 2024 RPS target using 1.0 percent carbon free RECs from Ohio, 49.0 percent carbon free RECs from other PJM states, 15.6 percent carbon free RECs from non PJM states and 34.5 percent carbon producing RECs from Ohio and other PJM states. Illinois met its 2024 RPS target using 80.3 percent carbon free RECs from Illinois and 19.7 percent carbon free RECs from other PJM states. Illinois met its RPS target using 100.0 percent carbon free RECs for the 2019 through 2024 compliance years.

Figure 8-4 State fulfillment of Tier I equivalent RPS: 2020 through 2024



205 Retired REC information obtained through PJM GATS <https://gats.pjm-eis.com/gats2/PublicReports/RPSRetiredCertificatesReportingYear>. The timing of the REC retirement reports varies by state and the 2023 reporting year data is incomplete for some states.

Table 8-17 shows the percent of retail electric load that must be served by Tier II or a specific type of resource under each PJM jurisdiction's RPS by year. Tier II resources are generally not renewable resources. Table 8-17 also shows specific technology requirements that PJM jurisdictions have added to their renewable portfolio standards. The standards shown in Table 8-17 are included in the total RPS requirements presented in Table 8-13. Maryland, New Jersey and Pennsylvania have Tier II or Class II standards, which allow specific nonrenewable technology types, such as waste coal units located in Pennsylvania, to qualify for renewable energy credits. Washington, DC previously had Tier II standards. The Washington, DC tier II standard was discontinued at the end of the 2019 compliance year. By 2024, North Carolina's RPS requires that 0.2 percent of power be generated using swine waste and that 900 GWh of power be produced by poultry waste in 2020. Maryland established a minimum standard for offshore wind in 2017 that took effect in 2021 with an original requirement that 1.37 percent of load be served by offshore wind.[206] The standard has been revised to 0.14 percent for 2024.[207] The offshore wind requirement is only applicable if the Maryland offshore wind projects are producing RECs.[208]

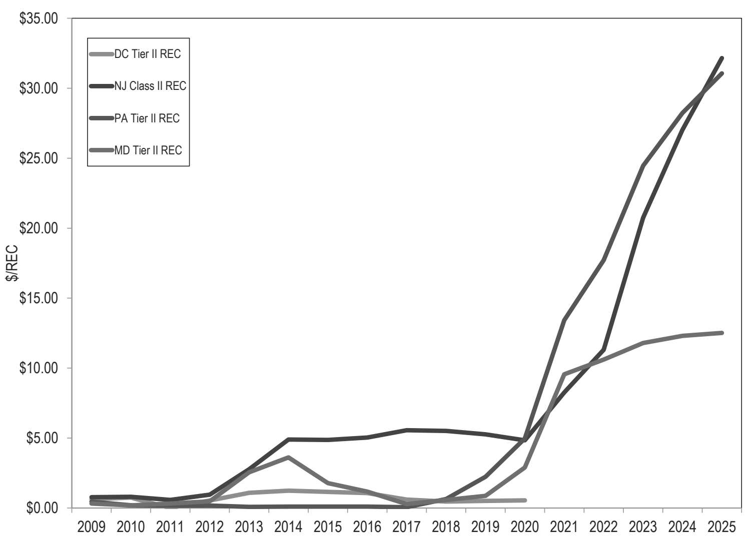
Figure 8-5 shows the annual average Tier II REC price by jurisdiction for 2009 through September 2025. Tier II prices have been lower than Tier I REC prices in the past, but Pennsylvania and New Jersey Tier II REC prices are higher than their corresponding Tier I REC prices over the first nine months of 2025. Maryland, New Jersey and Pennsylvania are the only states with a Tier II standard in 2025.[210] The average Pennsylvania Tier II REC price for the first nine months of 2025 was $31.06, 10.0 percent higher than the average price for 2024. The average New Jersey Class II REC price for the first nine months of 2025 was $32.15, 19.0 percent higher than the average price for 2024. The average Maryland Tier II REC price for the first nine months of 2025 was $12.51, 1.7 percent higher than the average price for the 2024.[211]

Figure 8-5 Average Tier II REC price by jurisdiction: 2009 through September 2025



209 New Jersey Administrative Code, Section 14:8-2.3 does not specify standards beyond compliance year 2032/2033.
210 The District of Columbia dropped Tier II RECs from their RPS in 2021.
211 Tier II REC price information obtained through Evolution Markets, Inc.

Some PJM jurisdictions have specific solar resource RPS requirements. These solar requirements are included in the total requirements shown in Table 8-13 and Table 8-15 but must be met by solar RECs (SRECs). Table 8-18 shows the percent of retail electric load that must be served by solar energy resources under each PJM jurisdiction's RPS by year. Delaware, Illinois, Maryland, New Jersey, North Carolina, Pennsylvania, and Washington, DC have requirements for the proportion of load to be served by solar. The Illinois RPS specifies the number of RECs that must be sourced from photovoltaic resources energized after June 1, 2017. Recent legislation increased the SREC requirement from 2,000,000 RECs to 5,500,000 RECs beginning with the 2021/2022 Delivery Year.[212] New Jersey closed registration for new SRECs on April 30, 2020, having met its milestone that solar power equal or exceed 5.1 percent of New Jersey electricity sales.[213] On December 6, 2019, the New Jersey Board of Public Utilities announced a transitional program for solar generators not eligible for New Jersey SRECs.[214] The new program establishes a 15 year fixed priced Transition REC (TREC). On July 28, 2021, New Jersey Board of Public Utilities approved the Successor Solar Incentive (SuSI) Program which will provide incentives for 3,750 MW of new solar generation by 2026.[215] Pennsylvania allows only solar photovoltaic resources to fulfill their solar requirements. Solar thermal units like solar hot water heaters that do not generate electricity are Tier I resources in Pennsylvania. Ohio, Michigan and Virginia have no specific solar standards. The New Jersey legislature in May 2018 increased the solar standard from 3.2 percent to 4.3 percent for 2018, 5.1 percent for 2020 through 2022 and the solar standard decreases to 1.1 percent for 2032.[216] Maryland legislation in 2019 increased the solar carve out percentages from 2.5 percent to 14.5 percent in 2030. Ohio HB 6 removed the solar carve out from the Ohio RPS.[217] The Delaware General Assembly passed new RPS legislation on February 10, 2021 that increased the solar carve out target from 3.5 percent in 2025 to 10.0 percent in 2035.[218]

Table 8-18 Solar renewable standards by percent of electric load for PJM jurisdictions: 2024 to 2034[219] [220]

Jurisdiction with RPS	2024	2025	2026	2027	2028	2029	2030	2031	2032	2033	2034
Delaware	3.25%	3.50%	3.75%	4.00%	4.25%	4.50%	5.00%	5.80%	6.60%	7.40%	8.40%

Washington, DC	3.15%	3.45%	3.75%	4.10%	4.50%	4.75%	5.00%	5.25%	5.50%	6.00%	6.50%

Figure 8-6 shows the annual average solar REC (SREC) price by jurisdiction for 2009 through the first nine months of 2025. The average NJ SREC price was $187.50 for the first nine months of 2025. The limited supply of solar facilities in Washington, DC compared to the RPS requirement results in higher SREC prices. The average Washington, DC SREC price was $406.90 for the first nine months of 2025, a 4.8 percent increase compared to the average DC SREC price for 2024.[221]

Figure 8-6 Average SREC price by jurisdiction: 2009 through September 2025

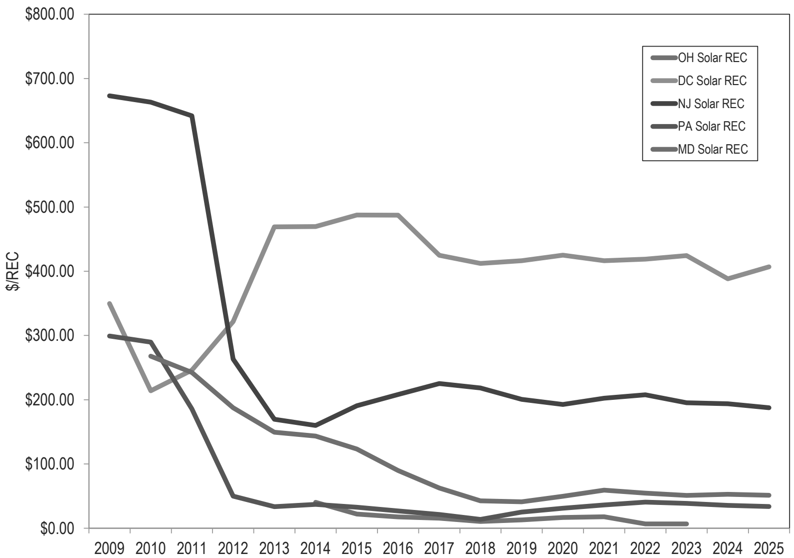

Figure 8-7 State fulfillment of Solar RPS: 2020 through 2024

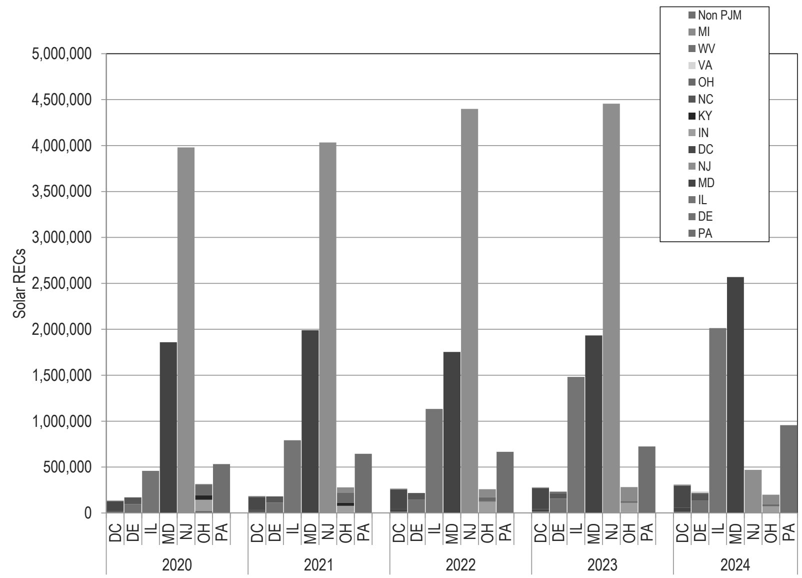

Figure 8-7 and Table 8-19 show where the SRECs originated that are used to satisfy the states' solar requirement for 2020 through 2024.[222] Depending on the state, the solar RPS requirement can be fulfilled by in state or out of state SRECs. The SRECs purchased in some states are imported from other PJM states and from non PJM states. Table 8-19 shows the percent of local SRECs, SRECs from other PJM states and SRECs from non PJM states used to meet the RPS requirements. Since 2020, all SRECs used for RPS compliance in Illinois, Maryland, Pennsylvania and New Jersey have been sourced from in state solar generators.

222 Retired REC information obtained through PJM GATS <https://gats.pjm-eis.com/gats2/PublicReportsRPSRetiredCertificates ReportingYear> (Accessed October 17, 2025). The timing of the REC retirement reports varies by state and the 2024 reporting year data is incomplete for some states.

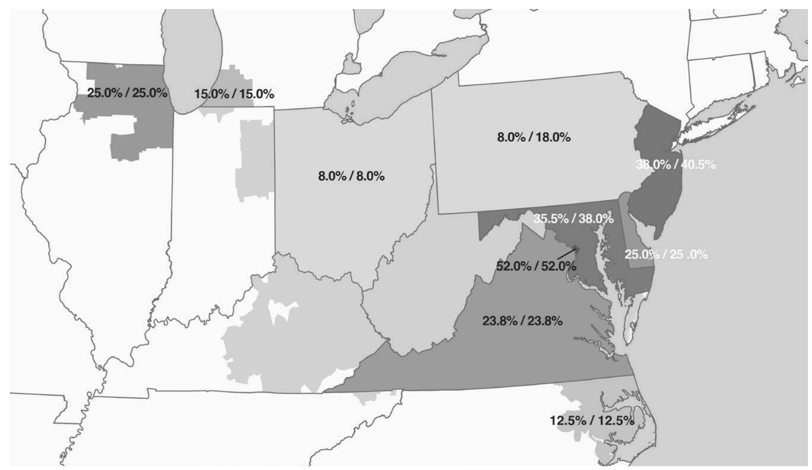
Figure 8-8 shows the percent of retail electric load that must be served by Tier I resources and Tier 2 resources in each PJM jurisdiction with a mandatory RPS. For each state in Figure 8-8, the first number represents the RPS percent for Tier I where defined, or renewable energy resources where tiers are not defined; the second number represents the RPS percent for all eligible technologies which includes both renewable and alternative energy resources. States with higher percent requirements for renewable energy resources are shaded darker. Jurisdictions with no standards or with only voluntary RPS are shaded gray. Pennsylvania's RPS illustrates the need to differentiate between percent requirements for renewable and alternative energy resources. The Pennsylvania RPS identifies solar photovoltaic, solar thermal, wind, geothermal, biomass, and low-impact hydropower as Tier I resources. The Pennsylvania RPS identifies waste coal, demand side management, large-scale hydropower, integrated gasification combined cycle, clean coal and municipal solid waste as eligible Tier II resources. As a result, the 18.0 percent number in Figure 8-8 overstates the percent of retail electric load in Pennsylvania that must be served by renewable energy resources. The 8.0 percent number in Figure 8-8 is a more accurate measure of the percent of retail electric load in Pennsylvania that must be served by renewable energy resources.

Figure 8-8 Map of retail electric load shares under RPS – Renewable / Alternative Energy resources: 2025[223]



223 The standards in this chart include the Tier I standards used by some states in the PJM footprint, as well as the total alternative energy standard for states that do not classify eligible technologies into tiers.

Under the existing state renewable portfolio standards, 19.8 percent of PJM load should have been served by Tier I and Tier II renewable and alternative energy resources in the first nine months of 2025. Tier I resources include landfill gas, run of river hydro, wind and solar resources. Tier II resources include pumped storage, large scale hydro, solid waste and waste coal resources. In the first nine months of 2025, only 9.5 percent of PJM generation was produced by renewable and alternative energy resources, including carbon producing and noncarbon producing Tier I and Tier II generation as shown in Table 8-20. If the proportion of load among states remains constant, 25.4 percent of PJM load must be served by Tier I and Tier II renewable and alternative energy resources in 2030 under currently defined RPS rules. Approximately 17.5 percent of PJM load should have been served by Tier I or renewable energy resources in the first nine months of 2025. In the first nine months of 2025, only 7.6 percent of PJM generation was Tier I or renewable energy. The current REC production from PJM generation resources was not enough to meet the state renewable requirements for the first nine months of 2025, and LSEs purchased RECs from non PJM resources (e.g. behind the meter rooftop solar) and RECs from resources outside the PJM footprint (Table 8-21). LSEs that are unable to meet the RPS with RECs may use alternative compliance payments for unmet goals based on each state's requirements. If the proportion of load among states remains constant, 23.1 percent of PJM load must be served by Tier I or renewable energy resources in 2030 under defined RPS rules.

In jurisdictions with an RPS, load serving entities must either generate power from eligible technologies identified in each jurisdiction's RPS or purchase RECs from resources classified as eligible technologies. Table 8-20 shows generation by jurisdiction and resource type for the first nine months of 2025. Wind generation accounted for 22,206.8 GWh of the 50,380.7 Tier I GWh, or 44.1 percent. As shown in Table 8-20, 62,956.0 GWh were generated by Tier I and Tier II resources, of which Tier I resources accounted for 80.0 percent. Wind and solar generation (noncarbon producing) was 6.5 percent of total generation in PJM in the first nine months of 2025. Tier I generation was 7.6 percent of total generation in PJM and Tier II was 1.9 percent of total generation in PJM in the first nine months of 2025. Biofuel, landfill gas, pumped storage hydro, solid waste and waste coal (carbon producing) accounted for 12,875.4 GWh, or 20.5 percent of the total Tier I and Tier II generation.

Table 8-20 Tier I and Tier II generation by jurisdiction and renewable resource type (GWh): January through September, 2025

	Tier I							Tier II

PJM states with RPS rely heavily on imports and generation from behind the meter resources for RPS compliance. In the first nine months of 2025, Tier I generation in PJM met only 46.8 percent of the Tier I RPS requirements. Table 8-21 compares each state's RPS requirement for the first nine months of 2025 with generation by RPS eligible PJM generators. Illinois had sufficient in state generation to cover 62.5 percent of the RPS requirement and Pennsylvania generation was sufficient to cover 84.4 percent of the Tier I RPS requirement and 64.4 percent of the Tier II RPS requirement. North Carolina generation was 7.1 times higher than the RPS requirement in the first nine months of 2025; but a relatively small portion of the North Carolina load is in PJM. Overall there was sufficient generation by PJM generators to meet 46.8 percent of the Tier I RPS requirement and 90.4 percent of the Tier II RPS requirement for the first nine months of 2025. RPS compliance reports indicate that almost all of the RPS requirement is met with the purchase or acquisition of RECs, with only a very small amount of the requirement fulfilled through alternative compliance payments. A large portion of the Tier I RPS requirement is satisfied by behind the meter generation in the PJM states and to a lesser extent, through the purchase of RECs from non PJM states.

Table 8-21 RPS Requirements and Generation by RPS Eligible Resources: January through September, 2025

	Tier I			Tier II

Table 8-22 shows the summer installed capacity rating of Tier I and Tier II wholesale capacity resources in PJM by jurisdiction, as defined by primary fuel type. This capacity includes coal, natural gas and oil units that qualify as Tier II because they have a secondary fuel capability that satisfies the alternative energy standards of a PJM state or jurisdiction. For example, a coal generator that can also burn waste coal to generate power could list the alternative fuel as waste coal. A REC is only generated when the unit is operating using the fuel listed as Tier I or Tier II. Ohio has the largest amount of solar capacity in PJM, 4,719.2 MW, or 28.8 percent of the total solar capacity. Wind resources located in western PJM, Illinois, Indiana and Ohio, account for 8,531.8 MW, or 72.7 percent of the total wind capacity.

Under the pre ELCC rules that were in effect up to the start of the 2023/2024 Delivery Year, a generator's capacity value was derated from the installed capacity level by multiplying the generator's net maximum capability by a derating factor. The derating factor was either based on the generator's historical performance during summer peak hours or a class average value calculated by PJM. The intent of the pre ELCC method was to obtain a MW value the generator can reliably produce during the summer peak hours.[224]

An average ELCC method was used to determine the capacity values for intermittent and storage resources for the 2023/2024 Delivery Year and the 2024/2025 Delivery Year.[225] Beginning with the 2025/2026 Delivery Year, PJM uses a marginal ELCC method to determine capacity values for all resources. As of September 30, 2025, the derated capacity for PJM capacity resources includes 2,265.7 MW of wind resources and 8,073.6 MW of solar resources. This compares to installed wind capacity of 11,862.8 MW in Table 8-33 and installed solar capacity of 13,515.3 MW in Table 8-37. Wind generators have higher derating factors during the winter months (November through April) because PJM rules make winter capacity interconnection rights (CIRs) available. The derated ICAP corresponding to wind capacity resources on March 31, 2025 was 3,594.8 MW. The decrease in the winter derated wind capacity from March 31, 2025 to September 30, 2025 is a result of winter CIRs that are provided

224 See Appendix B in "PJM Manual 21: Rules and Procedures for Determination of Generating Capability," <https://pjm.com/-/media/documents/manuals/m21.ashx>.
225 See Capacity Value of Intermittent Resources (ELCC) in *2024 Quarterly State of the Market Report for PJM: January through March*, Section 5: Capacity Market.

to wind without charge for the winter months. PJM's practice of giving away winter CIRs, that appear to be available because other resources paid for the supporting network upgrades, requires annual capacity resources to subsidize the interconnection costs of intermittent resources and artificially increases the capacity value of the winter resources. PJM should ensure that the winter capacity value of thermal resources is not inefficiently constrained by the failure to assign winter CIRs to thermal resources.

There were two pre ELCC classes of wind based on location with class average capacity factors of 14.7 percent and 17.6 percent. There were three pre ELCC classes of solar generators with capacity factors ranging from 38.0 percent to 60.0 percent.[227] For the 2023/2024 Delivery Year, the ELCC rating for solar generators with fixed panels was 50.0 percent, the ELCC rating for solar generators with tracking panels was 61.0 percent, and the ELCC rating for onshore wind generators was 15.0 percent.[228] For the 2024/2025 Delivery Year, the ELCC rating for solar generators with fixed panels was 33.0 percent, the ELCC rating for solar generators with tracking panels was 50.0 percent, and the ELCC rating for onshore wind generators was 21.0 percent. PJM implemented a new marginal ELCC approach for the 2025/2026 Delivery Year. For the 2025/2026 Delivery Year, the ELCC rating for solar generators with fixed panels is 10.0 percent, the ELCC rating for solar generators with tracking panels is 14.0 percent, and the ELCC rating for onshore wind generators is 38.0 percent.

Table 8-23 shows renewable capacity registered in the PJM generation attribute tracking system (GATS).[229] These resources are not PJM wholesale market resources even though most are located in PJM states. For example, roof top solar panels within the PJM footprint generate SRECs but are not PJM wholesale market units. These nonwholesale resources include solar capacity of 14,180.5 MW of which 4,135.9 MW are in New Jersey. These nonwholesale resources can

Renewable energy credits are related to the production and purchase of wholesale power, but are not, when they constitute a transaction separate from a wholesale sale of power, subject to FERC regulation.[231] RECs markets are, as an economic fact, integrated with PJM markets including energy and capacity markets, but are not formally recognized as part of PJM markets. Revenues from RECs markets are revenues for PJM resources earned in addition to revenues earned from the sale of the same MWh in PJM markets. RECs revenues are included in net revenues in unit offers in the capacity market and the treatment of RECs in unit cost-based offers is included in unit fuel cost policies.

Delaware, North Carolina, Michigan and Virginia allow various types of resources to earn multiple RECs per MWh, though typically one REC is equal to one MWh. For example, Delaware provided a three MWh REC for each MWh produced by in state customer sited photovoltaic generation and fuel cells using renewable fuels that are installed on or before December 31, 2014.[232] This is equivalent to providing a REC price equal to three times its stated value per MWh.

230 See PJM-EIS (Environmental Information Services), Generation Attribute Tracking System, "Renewable Generators Registered in GATS," <https://gats.pjm-eis.com/gats2/PublicReports/RenewableGeneratorsRegisteredinGATS>.
231 See *WSPP, Inc.*, 139 FERC ¶ 61,051 at P 18 (2012) ("we conclude that unbundled REC transactions fall outside of the Commission's jurisdiction under sections 201, 205 and 206 of the FPA. We further conclude that bundled REC transactions fall within the Commission's jurisdiction under sections 201, 205 and 206 of the FPA"); citing *American Ref-Fuel Company, et al.,* 105 FERC ¶ 61,004 at PP 23–24 (2003) ("American Ref-Fuel, 105 FERC ¶ 61,004 at PP 23-24 ("RECs are created by the States. They exist outside the confines of PURPA… And the contracts for sales of QF capacity and energy, entered into pursuant to PURPA, … do not control the ownership of RECs."); see also *Williams Solar LLC and Allco Finance Limited*, 156 FERC ¶ 61,042 (2016).
232 Delaware Code, Title 26, Chapter 1, Subchapter III-A, Section 356(a).

In addition to GATS, there are several other REC tracking systems used by states in the PJM footprint. Illinois, Indiana and Ohio use both GATS and M-RETS, the REC tracking system for resources located in the Midcontinent ISO, to track the sales of RECs used to fulfill their RPS requirements. Michigan and North Carolina have created their own state tracking systems, MIRECS and NC-RETS, through which all RECs used to satisfy these states' RPS requirements must ultimately be traded. Table 8-24 shows the REC tracking systems used by each state within the PJM footprint. To ensure a REC is only used one time, REC tracking systems must keep an account of a REC from its creation until its retirement. A REC is considered to be retired when it has been used to satisfy an obligation associated with an RPS.

Table 8-24 REC tracking systems in PJM states with renewable portfolio standards

Jurisdiction with RPS	REC Tracking System Used			
Delaware	PJM-GATS			
Illinois	PJM-GATS	M-RETS		
Maryland	PJM-GATS			
Michigan			MIRECS	
New Jersey	PJM-GATS			
North Carolina				NC-RETS
Ohio	PJM-GATS	M-RETS		
Pennsylvania	PJM-GATS			
Virginia	PJM-GATS			
Washington, D.C.	PJM-GATS			
Jurisdiction with Voluntary Standard				
Indiana	PJM-GATS	M-RETS		

All PJM states with renewable portfolio standards have established geographical restrictions governing the source of RECs to satisfy states' standards. Table 8-25 describes these restrictions. Indiana, Illinois, Michigan, and Ohio all have provisions in their renewables standards that require all or a portion of RECs used to comply with each state's standards to be generated by in state resources. Illinois recently relaxed the geographic restrictions to allow RECs sourced from wind or photovoltaic resources that are deliverable to Illinois or an adjacent state via high voltage direct current transmission. North Carolina has provisions that require RECs to be purchased from in state resources but Dominion, the only utility located in both North Carolina and PJM, is exempt from these provisions. Pennsylvania added a provision in 2017 that requires SRECs used to comply with Pennsylvania's solar photovoltaics carve out standard to be sourced from resources located in Pennsylvania.

In addition, Pennsylvania and Virginia require that RECs used for RPS compliance be produced from resources located within the PJM footprint. Delaware requires that RECs used for compliance with its RPS are produced from resources located within the PJM footprint or resources located elsewhere if these resources can demonstrate that the power they produce is directly deliverable to Delaware. The District of Columbia, Maryland and New Jersey allow RECs to be purchased from resources located within PJM in addition to large areas that adjoin PJM for compliance with their standards.

Table 8-25 Geographic restrictions on REC purchases for renewable portfolio standard compliance in PJM states

State with RPS	RPS Contains In-state Provision	Geographical Requirements for RPS Compliance
Delaware	No	RECs must be purchased from resources located either within PJM or from resources outside of PJM that are directly deliverable into Delaware.
Illinois	Yes	All RECs must be purchased from resources located within Illinois or from resources located in adjacent states that meet certain public interest criteria or from utility scale wind or photovoltaic resources that are deliverable to Illinois or an adjacent state via high voltage direct current transmission.
Maryland	No	RECs must come from within PJM, 10-30 miles offshore the coast of Maryland or from a control area adjacent to PJM that is capable of delivering power into PJM.
Michigan	Yes	RECs must either come from resources located within Michigan or anywhere in the service territory of retail electric provider in Michigan that is not an alternative electric supplier. There are many exceptions to these requirements (see Michigan S.B. 213).
New Jersey	No	RECs must either be purchased from resources located within PJM or from resources located outside of PJM for which the energy associated with the REC is delivered to PJM via dynamic scheduling.
North Carolina	Yes	Dominion, the only utility located in both the state of North Carolina and PJM, may purchase RECs from anywhere. Other utilities in North Carolina not located in PJM are subject to different REC requirements (see G.S. 62-113.8).
Ohio	Yes	All RECs must be generated from resources that are located in the state of Ohio or have the capability to deliver power directly into Ohio. Any renewable facility located in a state contiguous to Ohio has been deemed deliverable into the state of Ohio. For renewable resources in noncontiguous states, deliverabilty must be demonstarted to the Public Utilities Commission of Ohio.
Pennsylvania	Yes	RECs must be purchased from resources located within PJM. All SRECs used for compliance with the Solar PV standard must source from solar PV resources within the state of Pennsylvania.
Virginia	No	RECs must be purchased from resources located within PJM
Washington, D.C.	No	RECs must be purchased from either a PJM state or a state adjacent with PJM. A PJM state is defined as any state with a portion of their geographical boundary within the footprint of PJM. An adjacent state is defined as a state that lies next to a PJM state, i.e. SC, GA, AL, AR, IA, NY, MO, MS, and WI.

Alternative Compliance Payments

PJM jurisdictions have various methods for enforcing compliance with required renewable portfolio standards. If a retail supplier is unable to comply with the renewable portfolio standards required by the jurisdiction, suppliers may make alternative compliance payments (ACPs), with varying standards, to cover any shortfall between the RECs required by the state and those the retail supplier actually purchased. The ACPs, which are penalties, generally function as a cap on the market value of RECs, although in Pennsylvania the solar ACP is dependent upon the price of solar RECs retired during the year. In New Jersey, solar ACPs are currently $198 per MWh.[233] In Pennsylvania, the ACP for tier I and tier II RECs is $45 per MWh and the solar ACPs is 200 percent of the average credit price of Pennsylvania solar RECs sold during the reporting year plus the value of any solar rebates in other PJM states. The most recent ACP for Pennsylvania solar is $66.40.[234] Delaware recently reduced the solar ACP from $400 per credit to $150 per credit.[235] Maryland reduced the solar ACP from $100 per credit to $60 per credit effective June 1, 2021.[236] The Washington DC solar ACP was reduced from $480 per credit to $460 per credit for 2025.[237]

Figure 8-9 shows the historical relationship between SREC prices and ACP levels. The SREC price is represented by a solid line in the figure and the corresponding ACP level is represented by a dashed line. For each jurisdiction, the ACP is an upper bound for the price level. In Michigan and North Carolina, there are no defined values for ACPs. The public utility commissions in Michigan and North Carolina have discretionary power to assess what a load serving entity must pay for any RPS shortfalls.

237 DC Code: § 34-1434.

Table 8-26 shows the alternative compliance standards for RPS in PJM jurisdictions.

Table 8-26 Tier I, Tier II, and Solar alternative compliance payments in PJM jurisdictions for 2025[238] [239]

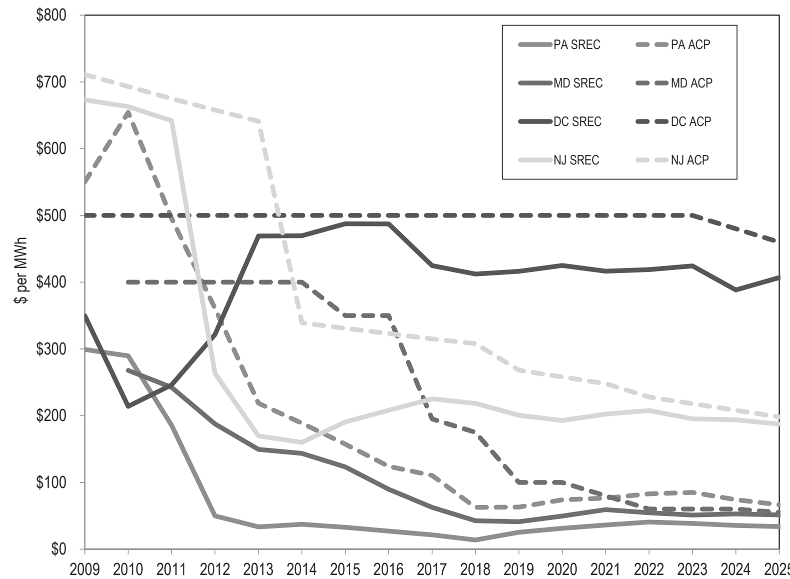
Jurisdiction with RPS	Standard Alternative Compliance ($/MWh)	Tier II Alternative Compliance ($/MWh)	Solar Alternative Compliance ($/MWh)
Delaware	$25.00		$150.00
Illinois	$0.35		
Maryland	$25.00	$15.00	$55.00
Michigan	No specific penalties		
New Jersey	$50.00	$50.00	$198.00
North Carolina	No specific penalties: At the discretion of the NC Utility Commission		
Ohio	$66.01		
Pennsylvania	$45.00	$45.00	$66.40
Washington, D.C.	$50.00	$10.00	$460.00
Jurisdiction with Voluntary Standard			
Indiana	Voluntary standard - No Penalties		
Jurisdiction with No Standard			
Kentucky	No standard		
Tennessee	No standard		
West Virginia	No standard		

Load serving entities participating in mandatory RPS programs in PJM jurisdictions must submit compliance reports to the relevant jurisdiction's public utility commission.

238 The Ohio standard alternative compliance payment (ACP) is updated annually <https://www.puco.ohio.gov/industry-information/industry-topics/acp-non-solar-alternative-compliance-payment-under-orc-492864/>. The Illinois Commerce Commission periodically publishes updates to the effective ACP amount <https://www.icc.illinois.gov/electricity/RPSCompliancePaymentNotices.aspx>. For updated Maryland ACPs, see Table 3 of the 2018 Renewable Energy Portfolio Standard Report <https://www.psc.state.md.us/commission-reports/>.

239 The entry for Pennsylvania reflects the solar ACP for 2023. See "Pricing," <https://www.pennaeps.com/reports/> (Accessed May 2, 2024).

Figure 8-9 Comparison of SREC price and solar ACP: 2009 through September 2025



In their submitted compliance reports, load serving entities must indicate the quantity of MWh that they have generated using eligible renewable or alternative energy resources. They must also identify the quantity of RECs they may have purchased to make up for renewable energy generation shortfalls or to comply with RPS provisions requiring that they purchase RECs. The public utility commissions then release RPS compliance reports to the public.

The Pennsylvania Public Utility Commission issued the 2023/2024 compliance report for the Pennsylvania Alternative Energy Standards Act of 2004 in June 2025.[240] Pennsylvania reported that the 670,435 SRECs, 10,403,173 Tier I RECs and 13,403,664 Tier II RECs were retired during the 2023/2024 reporting year

240 "Alternative Energy Portfolio Standards Act of 2004 Compliance for Reporting Year 2023-24," (June 2025), <https://www.puc.pa.gov/filing-resources/reports/alternative-energy-portfolio-standards-aeps-reports/>

(June 1, 2023 through May 31, 2024). Supplier obligations for 776 SRECs, 16,044 Tier I RECs and 20,625 Tier II RECs required ACPs.

The Public Service Commission of the District of Columbia reported that 307,793 SRECs and 34,005,495 Tier I RECs were retired during the 2024 compliance year. The average price for solar RECs was $421. ACPs increased from $1.8 million for 2023 to $3.9 million for 2024.[241]

The Public Service Commission of Maryland reported that Tier 1 RECs retired for 2023 compliance decreased by 8.7 million RECs, or 63.4 percent, compared with 2022.[242] The report notes that the "ACP prices were in many instances less expensive than REC prices, and as a result suppliers chose to pay the ACP."[243] The total cost of compliance for 2023 was $564.2 million, a 28.6 percent increase over 2022.

The Public Utilities Commission of Ohio reported that 7,532,762 RECs were retired in the 2023 compliance year, which is 4.6 percent higher than the number of RECs retired in 2023.[244] Compliance cost for 2023 were $79.8 million, 17.9 percent higher than 2022.

Delmarva Power is the only retail electric supplier that must file a compliance report with the Delaware Public Service Commission. The Delmarva report provides limited public information on RPS compliance cost.[245] Delmarva reports $13.0 million in ACPs but no other compliance cost information is available.

The Illinois Power Agency (IPA) reported delivery of ComEd RECs totaling 4,709,606 at an average price of $20.03 for the 2023/2024 RPS compliance year.[246]

246 "Annual Report Fiscal Year 2024" at 97, Illinois Power Agency (Feb. 18, 2025), <https://ipa.illinois.gov/about-ipa/ipa-publications.html>.

The North Carolina Utilities Commission reported that Dominion North Carolina Power submitted its 2020 compliance report on August 10, 2021. The compliance report stated that Dominion met its general RPS requirement by purchasing 427,657 credits that consisted of wind and biomass RECs and energy efficiency credits (EECs).[247] Dominion met its solar requirement of 8,562 RECs, poultry waste requirement of 22,311 RECs, and swine waste requirement of 2,997 RECs through REC purchases. Dominion North Carolina's total REC requirements for 2020 increased 4.9 percent over 2019.

The Michigan Public Service Commission reported that Indiana Michigan Power Company met the 2020 standard by generating or acquiring 315,384 RECs.[248]

New Jersey's Office of Clean Energy posted a summary of RPS compliance through the energy year ending May 31, 2024.[249] Electric power suppliers retired 14,449,269 class I RECs and 1,781,131 class II RECs. Suppliers submitted 298 class I ACPs and 54 class II ACPs at a cost of $50 per MWh. Electric power suppliers retired 3,156,170 solar RECs and 334,948 SACPs were submitted at a cost of $218 per MWh. Additionally, 958,816 transition RECs were retired and 341,632 SREC II were retired.[250] [251]

Table 8-27 shows the RPS compliance cost incurred by PJM jurisdictions as reported by the jurisdictions.[252] The compliance costs are the cost of acquiring RECs plus the cost of any alternative compliance payments. The cost of complying with RPS, as reported by the states, was $14.6 billion over the ten year period from 2014 through 2023 for the ten jurisdictions that had RPS and reported compliance costs.[253] The average RPS compliance cost per year based

252 RPS compliance cost totals for Illinois, Michigan, and North Carolina reflect the RPS compliance cost attributable to PJM load in each of the states.
253 The actual PJM RPS compliance cost exceeds the reported $14.6 billion due to incomplete data. The compliance cost data for Delaware, Michigan and North Carolina are not available for some years. Based on past data these states generally account for approximately 2 percent of the total RPS compliance cost of PJM states. The $14.6 billion cost also does not fully reflect the overhead and administrative costs associated with RPS programs.

on the reported compliance cost for the ten year period from 2014 through 2023 was $1.5 billion. The compliance cost for 2023, the most recent year with almost complete data, was $2.9 billion.

Table 8-27 RPS Compliance Cost[254 255 256 257 258 259 260 261 262 263 264]

Jurisdiction with RPS		2014	2015	2016	2017	2018	2019	2020	2021	2022	2023
Delaware	Total RPS		$16,013,421	$18,409,631	$18,772,855	$18,341,916	$19,401,476	$21,133,971	$25,550,239		
	Solar		$7,070,254	$7,748,073	$7,105,726	$6,565,240	$8,121,914	$9,096,298	$9,567,891		
	Non-Solar		$8,943,167	$10,661,557	$11,667,129	$11,776,676	$11,279,562	$12,037,673	$15,982,348		
Illinois	Total RPS	$19,900,679	$19,893,704	$23,538,303	$25,919,372	$25,775,523	$26,971,638	$34,726,109	$52,555,157	$73,185,068	$88,917,610

263 "Application of Dominion Energy North Carolina for Approval of Cost Recovery for Renewable Energy and Energy Efficiency Portfolio Standard Compliance and Related Costs," Docket No. E-22, Sub 557, Sub 558, August 30, 2018 <https://www.ncuc.net/>. The North Carolina compliance cost entries reflects the compliance cost of Dominion Energy North Carolina.
264 The reporting period for RPS compliance in Delaware, Illinois, New Jersey, and Pennsylvania corresponds to PJM capacity market delivery years, June 1 through May 31. The compliance cost amounts reported by these states were converted to calendar year by assuming the compliance cost was evenly spread across the months in the compliance year.

Transco Regional Energy Access Expansion Project

By order issued January 11, 2023, FERC authorized a request filed by Transco to modify its gas pipeline system to increase its capacity by 829,400 Dth/d (.8 BCF/day) from the north east on its Leidy line to points in Pennsylvania, New Jersey and Maryland. Transco planned to have service available at the end of the fourth quarter of 2023.[265] In order to increase the capacity on the pipeline for this project Transco installed about 36 miles of new pipe, a new electric compressor station and modified five existing compressor stations. By letter dated July 26, 2024, FERC authorized Transco to commence service with facilities associated with the Regional Energy Expansion Project.[266] The 829,400 Dth/Day would be enough to supply about five combined cycle power plants.[267] On March 13, 2023, the New Jersey Division of Rate Counsel and New Jersey Conservation Foundation, et al., sought review in the United States Court of Appeals for the District of Columbia Circuit.[268] The appeal primarily argues that FERC ignored evidence that "clearly demonstrated that the state of New Jersey does not need and will not benefit from the Project's capacity."[269] On July 30, 2024, the United States Court of Appeals for the District of Columbia Circuit vacated and remanded the Certificate Orders.[270] On September 6, 2024, Transco filed an Application for Temporary Emergency Certificate so they could continue to provide service while this matter is resolved on remand.[271] Both PJM and the MMU submitted comments supporting the application.[272] On January 24, 2025, FERC issued an order reinstating authorization for Transco's Regional Energy Access Expansion Project.[273]

265 See 182 FERC ¶ 61,006 (2023), *order on reh'g*, 182 FERC ¶ 61,148 (2023), *order on reh'g*, 183 FERC ¶ 61,071 (2023).

273 See FERC Docket No. CP21-94-004.

Mountain Valley Pipeline

"On October 23, 2015, Mountain Valley Pipeline (MVP) filed an application with FERC for approval to construct own and operate MVP."[274] On October 13, 2017, MVP received a certificate of convenience and necessity from FERC. The pipeline is approximately 303 miles long stretching from the Equitrans Transmission system in Wentzel County West Virginia to Transco Zone 5 station 165 in Pittsylvania County Virginia. The capacity of the pipeline is approximately 2 BCF per day. On June 14, 2024, MVP entered service.[275] The 2,000,000 Dth/Day would be enough to supply about eleven combined cycle power plants.[276]

Transco Southeast Supply Enhancement

On May 24, 2024, Transcontinental Gas Pipe Line Company, LLC (Transco) filed a general project description draft of the proposed Southeast Supply Enhancement Project. This project is an expansion of the Transco system in southern Virginia, North Carolina, South Carolina, Georgia and Alabama. The total capacity will be 1,591,900 Dth/day from Transco Station 165 Zone 5 and the interconnection with Mountain Valley and points south to North Carolina, South Carolina, Georgia and Alabama. The proposal includes about 55 miles of new pipe and the addition of seven new compressors at existing compressor stations. The expected completion of the project is June 2028.[277] The 1,591,900 Dth/Day would be enough to supply about eight combined cycle power plants.[278]

Transco Commonwealth Energy Connector Project

On August 24, 2022, Transcontinental Gas Pipe Line Company, LLC (Transco) filed a certificate of public convenience and necessity to construct the Commonwealth Energy Connector Project.[279] The new capacity will be 105,000 Dth/d which Virginia Natural Gas, Inc. (VNG) has contracted for. This project

276 See *2023 Annual State of the Market Report for PJM*, Volume 2: Section 7, Net Revenue, "Table 7-55 Gas pipeline capacity need to replace units at risk of retirement." New combined cycle unit ICAP 1,100 MW and fuel rate of 6.543 MMBtu/MWh.
277 See Transcontinental Gas Pipe Line Company, LLC Southeast Supply Enhancement Project, Docket No. PF24-2-000, Draft Resource Reports 1-12 (May 24, 2024).
278 See *2023 Annual State of the Market Report for PJM*, Volume 2: Section 7, Net Revenue: Table 7-55" New combined cycle unit ICAP 1,100 MW and fuel rate of 6.543 MMBtu/MWh.
279 See FERC Docket No. CP22-502.

is an expansion of the Transco system from Zone 5 Pooling point through Transco's South Virginia Lateral which interconnects between Transco and Columbia Gas Transmission, LLC. Additional compression, about 3.6 miles of additional pipe and modifications and installation of new facilities at the Emporia M&R station will be completed to increase the capacity. The project is expected to be completed by September 25, 2025. The 105,000 Dth per day would not be enough supply to run one combined cycle power plant [280]

Columbia Gas Transmission Virginia Reliability Project

On August 24, 2022, Columbia Gas Transmission LLC (Columbia) filed an abbreviated application for the authority necessary to construct and operate its Virginia Reliability project. The new capacity will be 100,000 Dth/d which Virginia Natural Gas, Inc. (VNG) has contracted for. This project will replace 49 miles of existing pipe, modifications at two compressor stations, modifications to one receipt point and delivery point increasing service to Market Area 34. This will allow VNG to receive gas at the Transco Columbia interconnection and deliver to VNG. This capacity is projected to be available by November 1, 2025.[281] The 100,000 Dth per day would not be enough supply to run one combined cycle power plant.[282]

Texas Eastern Transmission Appalachia to Market II Project

On July 7, 2022, Texas Eastern Transmission, LP (Texas Eastern) filed an abbreviated Application for a Certificate of Public Convenience and Necessity to develop the Appalachia to Market II Project. Prior to the filing, Texas Eastern conducted a binding open season for 55,000 Dth/d that will be made available based on improvements to the Texas Eastern system. The additional capacity will run from Appalachia supply basin in southwest Pennsylvania to New Jersey. Two compressor stations (reducing air emissions with upgraded compression equipment) will be replaced and two miles of looping of pipe will be added. PSEG Power LLC and Elizabethtown Gas signed up for the 55,000 Dth/d. The project is expected to be completed by November 1, 2025.[283] The 55,000 Dth per day would not be enough supply to run one combined cycle power plant.[284]

Eastern Gas Transmission and Storage Inc. Capital Area Project

On December 11, 2024 Eastern Gas Transmission and Storage (EGTS) filed an abbreviated Application for a Certificate of Public Convenience and Necessity to develop the Capital Area Project. The new capacity will be 67,500 Dth/d which Washington Gas Light Company (WGL) has contracted for. This project will increase EGTS capacity from the Leidy Area in Pennsylvania to points in Maryland and Virginia. Additional compression will be added at four compressor stations: Centre Compression Station, Chambersburg Compression Station, Leesburg Compression Station and Finnerfrock Compression Station. The expected completion date is November 1, 2027.[285] The 67,500 Dth/d would not be enough supply to run one combined cycle power plant.[286]

Emission Controlled Capacity and Emissions

Emission Controlled Capacity

Environmental regulations affect decisions about emission control investments in existing units, investment in new units and decisions to retire units lacking emission controls.[287] Most PJM units burning fossil fuels have installed emission control technology. All coal steam units in PJM are compliant with the state and federal emissions limits established by MATS.[288] [289]

280 See *2023 Annual State of the Market Report for PJM*, Volume 2: Section 7, Net Revenue, Table 7-55. New combined cycle unit ICAP 1,100 MW and fuel rate of 6.543 MMBtu/MWh.
281 See FERC Docket No. CP22-503.
282 See *2023 Annual State of the Market Report for PJM*, Volume 2: Section 7, Net Revenue, Table 7-55. New combined cycle unit ICAP 1,100 MW and fuel rate of 6.543 MMBtu/MWh.
283 See FERC Docket No. CP22-486-000.
284 See *2023 Annual State of the Market Report for PJM*, Volume 2: Section 7, Net Revenue, Table 7-55. New combined cycle unit ICAP 1,100 MW and fuel rate of 6.543 MMBtu/MWh.
285 See FERC Docket No. CP25-29-000.
286 See *2023 Annual State of the Market Report for PJM*, Volume 2: Section 7, Net Revenue, Table 7-55. New combined cycle unit ICAP 1,100 MW and fuel rate of 6.543 MMBtu/MWh.
287 See EPA, "National Ambient Air Quality Standards (NAAQS)," <https://www.epa.gov/criteria-air-pollutants/naaqs-table> (Accessed March 4, 2022).
288 On April 16, 2020, the EPA issued a revised final finding regarding the Mercury and Air Toxics Standards. See EPA. "Regulatory Actions," <https://www.epa.gov/mats/regulatory-actions-final-mercury-and-air-toxics-standards-mats-power-plants> (Accessed May 7, 2020).
289 On April 9, 2020, the EPA created a new subcategory of six coal refuse power plants in Pennsylvania and West Virginia with reduced limits of HCl and SO_2 emissions under MATS. These units were all compliant with the previous MATS rules. "Mercury and Air Toxics Standards,"<https://www.epa.gov/sites/production/files/2020-04/documents/frn_mats_coal_refuse_2060-au48_final_rule.pdf> (Accessed May 7, 2020)

Table 8-28 shows SO_2 emission controls by fossil fuel fired units in PJM.[290] [291] [292] Coal has the highest SO_2 emission rate, while natural gas and diesel oil have lower SO_2 emission rates.[293] Of the current 39,420.9 MW of coal capacity in PJM, 38,651.9 MW of capacity, 98.0 percent, has some form of FGD (flue-gas desulfurization) technology to reduce SO_2 emissions.

Table 8-28 SO_2 emission controls by fuel type (MW): September 30, 2025[294]

	SO_2 Controlled	No SO_2 Controls	Total	Percent Controlled
Coal	38,651.9	769.0	39,420.9	98.0%
Diesel Oil	0.0	3,448.4	3,448.4	0.0%
Natural Gas	0.0	78,255.3	78,255.3	0.0%
Other	325.0	1,850.0	2,175.0	14.9%
Total	38,976.9	84,322.7	123,299.6	31.6%

Table 8-29 shows NO_X emission controls by fossil fuel fired units in PJM. Coal has the highest NO_X emission rate, while natural gas and diesel oil have lower NO_X emission rates. Of the current 39,420.9 MW of coal capacity in PJM, 39,291.9 MW of capacity, 99.7 percent, has some form of emissions controls to reduce NO_X emissions. Most units in PJM have NO_X emission controls in order to meet each state's emission compliance standards, based on whether a state is part of CSAPR, Acid Rain Program (ARP) or a combination of the three. The NO_X compliance standards of MATS require the use of selective catalytic reduction (SCRs) or selective non-catalytic reduction (SCNRs) for coal steam units, as well as SCRs or water injection technology for peaking combustion turbine units.[295]

290 See EPA, "Air Market Programs Data," <http://ampd.epa.gov/ampd/> (Accessed March 4, 2022).
291 Air Markets Programs Data is submitted quarterly. Generators have 30 days after the end of the quarter to submit data, and all data is considered preliminary and subject to change until it is finalized in June of the following year. The most recent complete set of emissions data is from 2024.
292 The total MW are less than the 181,290.0 reported in Section 5: Capacity Market, because EPA data on controls could not be matched to some PJM units. "Air Markets Program Data," <http://ampd.epa.gov/ampd/QueryToolie.html> (Accessed January 1, 2025).
293 Diesel oil includes number 1, number 2, and ultra-low sulfur diesel. See EPA, "Electronic Code of Federal Regulations, Title 40, Chapter 1, Subchapter C, Part 72, Subpart A, Section 72.2," <http://www.ecfr.gov/cgi-bin/text-idx?SID=4f18612541a393473efb13acb879d470&mc=true&node=se40.18.72_12&rgn=div8> (Accessed May 7, 2020).
294 The "other" category includes petroleum coke, wood, process gas, residual oil, other gas, and other oil. The EPA's "other" category does not have strict definitions for inclusion.
295 See EPA. "Mercury and Air Toxics Standards, Cleaner Power Plants," <https://www.epa.gov/mats/cleaner-power-plants#controls> (Accessed May 7, 2020).

Table 8-29 NO_X emission controls by fuel type (MW): As of September 30, 2025

	NO_X Controlled	No NO_X Controls	Total	Percent Controlled
Coal	39,291.9	129.0	39,420.9	99.7%
Diesel Oil	1,020.3	2,428.1	3,448.4	29.6%
Natural Gas	77,288.3	967.0	78,255.3	98.8%
Other	775.0	1,400.0	2,175.0	35.6%
Total	118,375.5	4,924.1	123,299.6	96.0%

Table 8-30 shows particulate emission controls by fossil fuel units in PJM. Almost all coal units (99.8 percent) in PJM have particulate controls, as well as a few natural gas units (2.3 percent) and units with other fuel sources (53.9 percent). Typically, technologies such as electrostatic precipitators (ESP) or fabric filters (baghouses) are used to reduce particulate matter from coal steam units.[296] Fabric filters work by allowing the flue gas to pass through a tightly woven fabric which filters out the particulates. Of the current 39,420.9 MW of coal capacity in PJM, 39,335.9 MW of capacity, 99.8 percent, have some type of particulate emissions control technology.

Table 8-30 Particulate emission controls by fuel type (MW): As of September 30, 2025

	Particulate Controlled	No Particulate Controls	Total	Percent Controlled
Coal	39,335.9	85.0	39,420.9	99.8%
Diesel Oil	0.0	3,448.4	3,448.4	0.0%
Natural Gas	1,765.0	76,490.3	78,255.3	2.3%
Other	1,172.0	1,003.0	2,175.0	53.9%
Total	42,272.9	81,026.7	123,299.6	34.3%

In order to achieve compliance with MATS, most coal steam units in PJM have particulate emission controls in the form of ESPs, but many units have also installed baghouse technology, or a combination of an FGD and SCR. Currently, all of the 97 coal steam units have some combination of ESP, baghouse, or FGD and SCR technology installed to achieve MATS compliance for either SO_2 or particulate emissions control, representing all of the 39,420.9 MW total coal capacity.

296 See EPA, "Air Pollution Control Technology Fact Sheet," <https://www3.epa.gov/ttn/catc/dir1/ff-pulse.pdf> (Accessed May 4, 2022).

Emissions

Figure 8-10 shows the total CO_2 emissions in short tons, the CO_2 emission rate in short tons per MWh within PJM for all CO_2 emitting units, for each quarter from 1999 to the third quarter of 2025, and the CO_2 emission rate in short tons per MWh of total generation within PJM for each quarter from the third quarter of 2000 to the third quarter of 2025.[297]

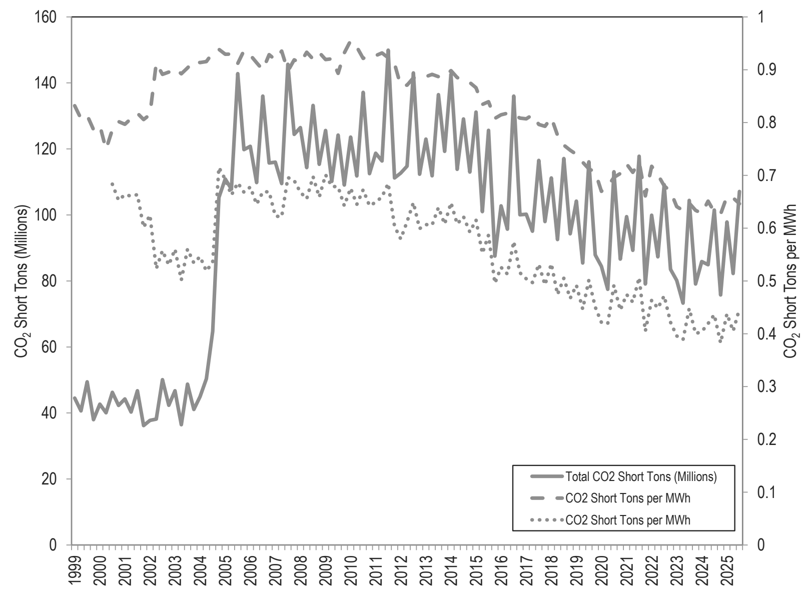
Figure 8-11 shows the total CO_2 emission in short tons on peak and off peak and the CO_2 emission rate in short tons per MWh for all CO_2 emitting units.

Table 8-31 shows the minimum and maximum CO_2 emission rates in short tons per MWh for all CO_2 emitting units, for all hours, as well as on and off peak hours, from the first quarter of 1999 through the third quarter of 2025.

Total PJM generation increased from 232,705.5 GWh in the third quarter of 2024 to 239,493.5 GWh in the third quarter of 2025, while CO_2 produced increased from 101.5 million short tons in the third quarter of 2024 to 107.1 million short tons in the third quarter of 2025.[298] The CO_2 emission rate averaged 0.64 short tons per MWh for all CO_2 emitting units in 2023, and 0.63 short tons per MWh for all CO_2 emitting units in 2024.

297 Unless otherwise noted, emissions are measured in short tons. A short ton is 2,000 pounds.
298 See the *2024 Annual State of the Market Report for PJM: Volume 2*, Section 3: Energy Market, Table 3-51.

Figure 8-10 CO_2 emissions by quarter (millions of short tons), by PJM units: January 1999 through September 2025[299 300]



In the third quarter of 2025, CO_2 emission rates were 0.64 short tons per MWh for all CO_2 emitting units for off peak hours, and 0.65 short tons per MWh for on peak hours. Of the top 10 largest CO_2 emitting units in the United States, three (Gavin, Prairie State, and Amos) are located in the PJM footprint.[301]

299 The emissions are calculated from the continuous emission monitoring system (CEMS) data from generators located within the PJM footprint.
300 In 2004 and 2005, PJM integrated the American Electric Power (AEP), ComEd, Dayton Power & Light Company (DAY), Dominion, and Duquesne Light Company (DLCO) Control Zones. The large increase in total emissions from 2004 to 2005 was a result of these integrations. In June 2011, PJM integrated the American Transmission Systems, Inc. (ATSI) Control Zone. In January 2012, PJM integrated the Duke Energy Ohio/Kentucky (DEOK) Control Zone. In June 2013, PJM integrated the Eastern Kentucky Power Cooperative (EKPC). In December 2018, PJM integrated the Ohio Valley Electric Corporation (OVEC).
301 "The top 10 emitting power plants in America," <https://www.eenews.net/articles/the-top-10-emitting-power-plants-in-america/> (Accessed November 4, 2022).

Figure 8-11 Total CO_2 emissions during on and off peak hours by quarter (millions of short tons), by PJM units: January 1999 through September 2025[302]

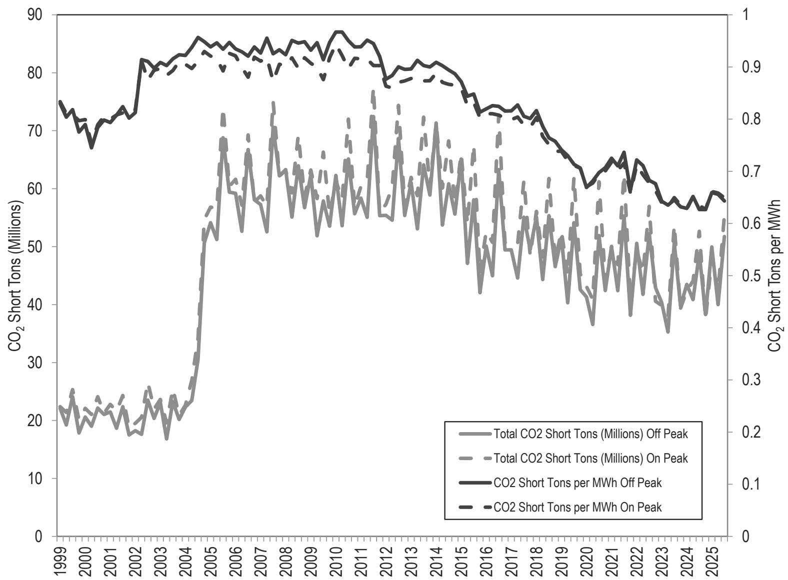


Table 8-31 Minimum and maximum CO_2 emissions per MWh: January 1999 through September 2025

		Short Tons per MWh	Year	Quarter
Minimum	All hours	0.63	2024	4
	On Peak	0.63	2024	4
	Off Peak	0.63	2024	4
Maximum	All hours	0.96	2010	1
	On Peak	0.94	2010	1
	Off Peak	0.97	2010	2

Figure 8-12 shows the total SO_2 and NO_X emissions and the emission rate in short tons per MWh for all SO_2 and NO_X emitting units, and the SO_2 and NO_X emission rate in short tons per MWh of total PJM generation. In the third quarter of 2025, the SO_2 emission rate was 0.000292 short tons per MWh for all SO_2 emitting units, and the NOx emission rate was 0.000198 short tons per MWh for all NO_X emitting units.

Figure 8-13 shows the total on peak hour and off peak hour SO_2 and NO_X emissions and the emission rate in short tons per MWh for all SO_2 and NO_X emitting units. In the third quarter of 2025, SO_2 emission rates were 0.000287 short tons per MWh and 0.000297 short tons per MWh for all SO_2 units, for off and on peak hours. In the third quarter of 2025, NO_X emission rates were 0.000186 short tons per MWh and 0.000209 short tons per MWh for all NO_X emitting units, for off and on peak hours.

Table 8-32 shows the minimum and maximum SO2 and NOx emission rate in short tons per MWh for all SO_2 and NO_X emitting units, for all hours, as well as on and off peak hours, from the first quarter of 1999 through the third quarter of 2025.

The consistent decline in SO_2 and NO_X emissions starting in 2006 is the result of a decline in the use of coal, an increase in the use of natural gas, and the installation of environmental controls from 2006 to 2025.[303] [304]

302 The emissions are calculated from the continuous emission monitoring system (CEMS) data from generators located within the PJM footprint.

303 See EIA, "Changes in coal sector led to less SO_2 and NO_x emissions from electric power industry,"<https://www.eia.gov/todayinenergy/detail.php?id=37752> (Accessed October 25, 2019).

304 See EIA, "Sulfur dioxide emissions from U.S. power plants have fallen faster than coal generation," <https://www.eia.gov/todayinenergy/detail.php?id=29812> (Accessed October 25, 2019).

Figure 8-12 SO_2 and NO_x emissions by quarter (thousands of short tons), by PJM units: January 1999 through September 2025[305]

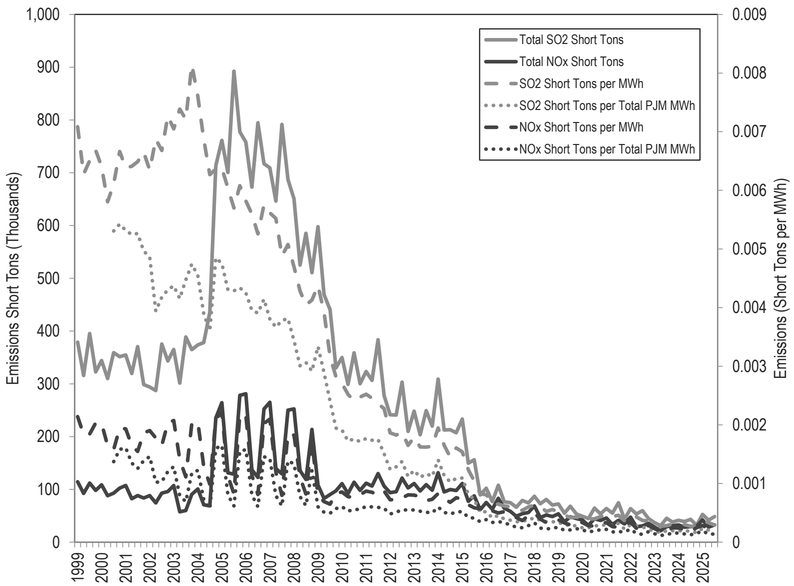

Figure 8-13 SO_2 and NO_x emissions during on and off peak hours by quarter (thousands of short tons), by PJM units: January 1999 through September 2025[306]

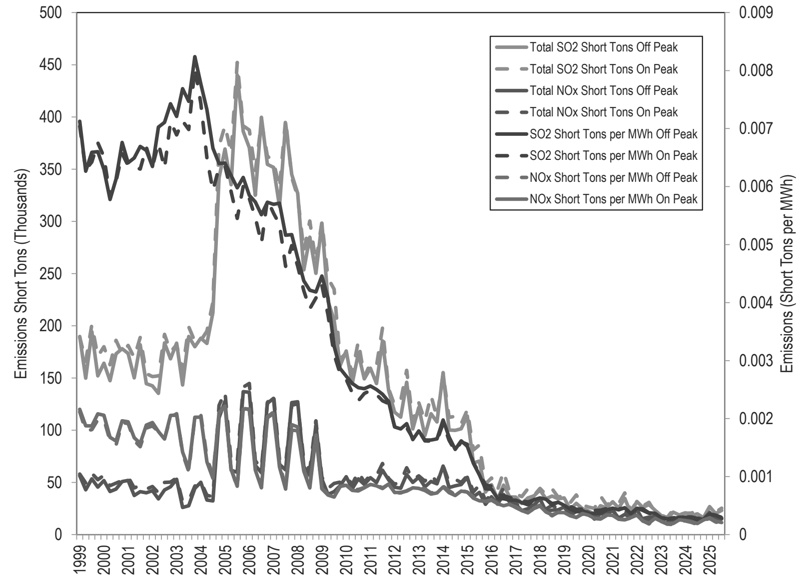

Table 8-32 Minimum and maximum SO_2 and NO_x emissions per MWh: January 1999 through September 2025

Emission Type			Short Tons per MWh	Year	Quarter
SO_2	Minimum	All hours	0.000	2024	4
		On Peak	0.000	2024	4
		Off Peak	0.000	2024	3
	Maximum	All hours	0.008	2003	4
		On Peak	0.008	2003	4
		Off Peak	0.008	2003	4
NO_x	Minimum	All hours	0.000	2023	3
		On Peak	0.000	2023	2
		Off Peak	0.000	2023	3
	Maximum	All hours	0.002	2005	1
		On Peak	0.002	2005	1
		Off Peak	0.002	2005	1

305 The emissions are calculated from the continuous emission monitoring system (CEMS) data from generators located within the PJM footprint.

306 The emissions are calculated from the continuous emission monitoring system (CEMS) data from generators located within the PJM footprint.

Renewable Energy Output

Wind and Solar Peak Hour Output

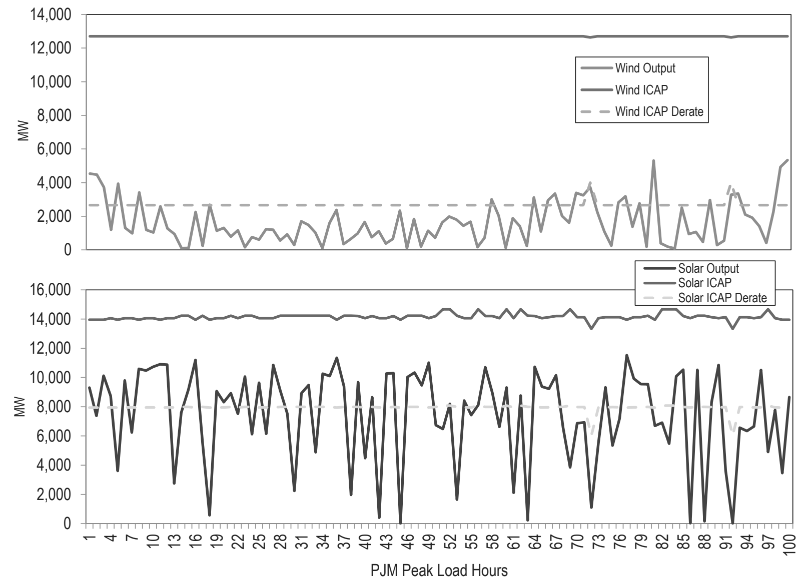
The capacity of solar and wind resources are derated from the nameplate or installed capacity value based on expected performance during hours with high risk of loss of load (unserved energy). Until June 1, 2023, PJM used average unit performance over 360 summer peak hours to determine the derating factors. For the 2023/2024 Delivery Year, which began on June 1, 2023, PJM used an average ELCC approach to determine the capacity derating factor.[307] The average ELCC approach was also used for the 2024/2025 Delivery Year. Beginning with the 2025/2026 Delivery Year, PJM changed to a marginal ELCC approach.[308] [309]

To illustrate the relationship between actual output and derating factors, Figure 8-14 shows wind and solar output during the top 100 load hours in PJM in the first nine months of 2025. Figure 8-15 shows wind and solar output for all hours in the first nine months of 2025. In the first nine months of 2025, 97 of the top 100 load hours in PJM are PJM defined peak load hours. The hours in Figure 8-14 are in descending order by load and the hours in Figure 8-15 are in chronological order. The solid lines represent the total ICAP and output of the wind or solar PJM resources. The dashed lines are the total capacity committed for each capacity resource, or the ICAP of wind and solar PJM resources derated by the applicable ELCC class rating if the unit is not a capacity resource.

The actual output of the wind and solar resources during the top 100 load hours varied both above and below the derated capacity values. Wind output was above the derated ICAP for 20 hours and below the derated ICAP for 80 hours of the top 100 load hours in the first nine months of 2025. The wind capacity factor for the top 100 load hours in the first nine months of 2025 was 12.9 percent. Wind output was above the derated ICAP for 2,921 hours and below the derated ICAP for 3,630 hours in the first nine months of 2025. The wind capacity factor in the first nine months of 2025 was 26.7 percent.

Solar output was above the derated ICAP for 55 hours and below the derated ICAP for 45 hours of the top 100 load hours in the first nine months of 2025. The solar capacity factor for the top 100 load hours in the first nine months of 2025 was 52.7 percent. Solar output was above the derated ICAP for 1,459 hours and below the derated ICAP for 5,092 hours in the first nine months of 2025. The solar capacity factor in the first nine months of 2025 was 22.5 percent.

Figure 8-14 Wind and solar output during the top 100 load hours: January through September, 2025



307 See Capacity Value of Intermittent Resources (ELCC) in *2024 Quarterly State of the Market Report for PJM: January through March*, Section 5: Capacity Market.
308 *Protest of the Independent Market Monitor for PJM*, ER24-99-000 (November 9, 2023).
309 Order 186 FERC ¶ 61,080 accepting PJM's marginal ELCC approach (January 30, 2024).

Figure 8-15 Wind and solar output: January through September, 2025

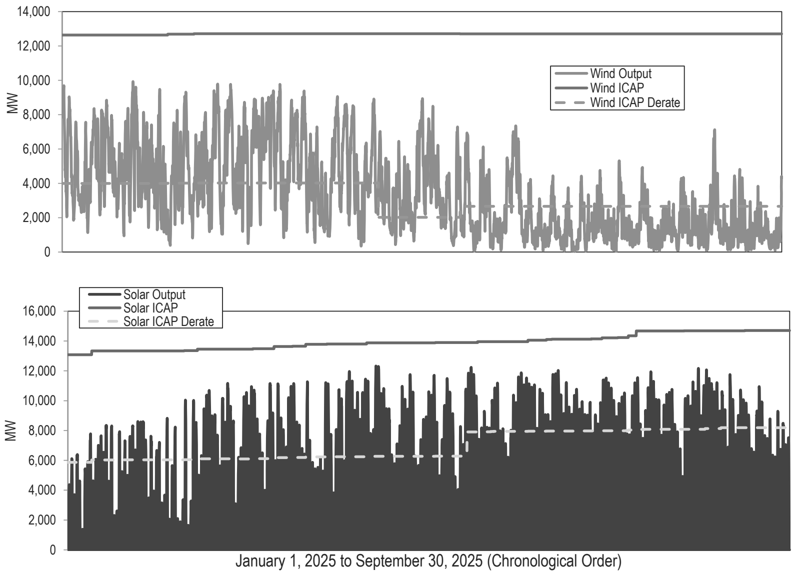


Figure 8-15 includes the impacts of the ELCC rules and winter CIR rules on the derated capacity values. The derated capacity for wind units reflects winter CIRs. On May 1, the CIRs for wind generators reverted from the winter ratings to the normal summer ratings which is reflected in Figure 8-15 as a step down of the wind ICAP derate line on May 1. On June 1, the ELCC ratings changed for the 2025/2026 capacity market delivery year.[310] This change is reflected in Figure 8-15 as a step up of the wind and solar ICAP derate lines on June 1. The increases in the solar ICAP line and the wind ICAP line reflect new generators coming online.

Wind Units

Table 8-33 shows the capacity factors of wind units in PJM. In the first nine months of 2025, the capacity factor of wind units in PJM was 26.7 percent. Wind units that were capacity resources had a capacity factor of 26.9 percent and an installed capacity of 11,862.8 MW. Wind units that were energy only had a capacity factor of 24.1 percent and an installed capacity of 832.7 MW. Wind capacity resources were derated to 14.7 or 17.6 percent of installed capacity for the capacity market prior to June 1, 2023, based on the wind farm terrain. Beginning June 1, 2023, wind capacity is derated to the ELCC accredited UCAP value.[311]

Table 8-33 Capacity factor of wind units: January through September, 2025

Type of Resource	Capacity Factor	Installed Capacity (MW)
Energy-Only Resource	24.1%	832.7
Capacity Resource	26.9%	11,862.8
All Units	26.7%	12,695.5

Wind units that are capacity resources are required, like all capacity resources except demand resources, to offer the energy associated with their cleared capacity in the day-ahead energy market and in the real-time energy market. Figure 8-16 shows the average hourly real-time generation and day-ahead commitment of wind units in PJM, by month and hour of the day for the first nine months of 2025. The hour with the highest average output in the first nine months of 2025 was hour 1 in March with an average of 6,010.6 MWh. The hour with the lowest average output in the first nine months of 2025 was hour 11 in June with an average of 771.4 MWh. Wind output in PJM is generally higher during off peak hours and lower during on peak hours. Wind output is generally highest during the months from November through March and lowest during the months from May through September.

Wind resources' day-ahead commitments are lower than real-time generation for most hours. Table 8-34 provides a summary of the deviations between wind resources' real-time generation and day-ahead commitments. In January 2025, hourly real-time generation exceeded day-ahead commitments by 1,572.6 MWh on average, the highest average monthly deviation for the first nine months of 2025. The lowest monthly average deviation occurred in July with hourly real-time generation exceeding day-ahead commitments by 332.7 MWh on average. Wind generation exceeded day-ahead commitments in 81.6 percent of hours in the first nine months of 2025. July had the highest

310 *ELCC Class Ratings for 2024-2025*, PJM Interconnection, L.L.C. (December 29, 2023) <https://www.pjm.com/planning/resource-adequacy-planning/effective-load-carrying-capability>.

311 ELCC rates and data are available on the PJM website <https://www.pjm.com/planning/resource-adequacy-planning/effective-load-carrying-capability>.

number of hours, 34.9 percent, with day-ahead commitments exceeding real time generation.

Figure 8-16 Average hourly real-time generation and day-ahead commitments of wind units: January through September, 2025

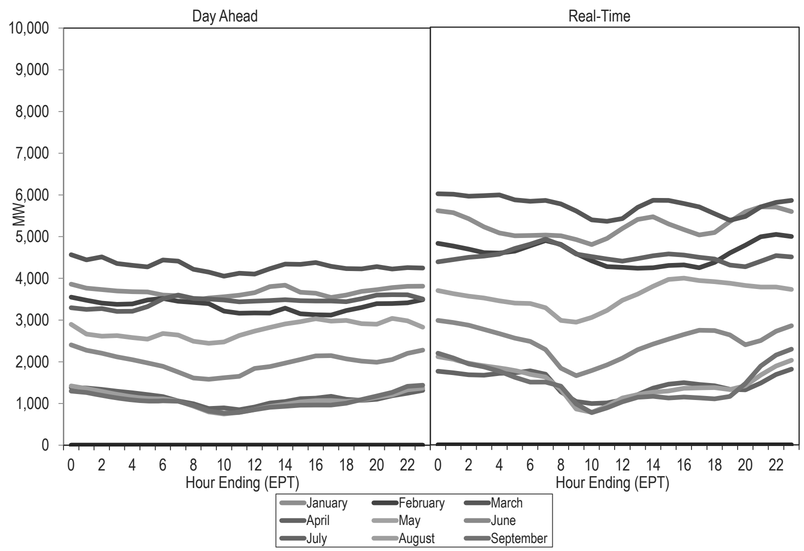

Table 8-34 Deviations between real-time wind generation and day-ahead commitments by month:[312] January through September, 2025

Month	Average Hourly Deviation	Minimum Hourly Deviation	Maximum Hourly Deviation	Hours with Negative Deviation
January	1,572.6	(1,957.7)	3,726.6	5.1%
February	1,251.2	(2,511.6)	3,900.0	9.8%
March	1,440.0	(799.6)	3,793.7	6.3%
April	1,078.5	(1,083.8)	3,684.1	16.0%
May	804.7	(1,171.5)	3,233.2	12.5%
June	476.4	(2,195.8)	3,048.9	31.0%
July	332.7	(1,060.2)	2,863.9	34.9%
August	416.3	(684.5)	2,115.7	22.6%
September	409.8	(893.7)	2,722.1	26.8%

312 Hourly deviations are equal to the real-time generation less day-ahead commitments.

Table 8-35 shows the generation and capacity factor of wind units by month for the first nine months in 2024 and 2025.

Table 8-35 Capacity factor of wind units in PJM by month: January through September, 2024 and 2025

	2024		2025	
Month	Generation (GWh)	Capacity Factor	Generation (GWh)	Capacity Factor
January	3,127.6	33.7%	3,907.9	41.6%
February	2,975.8	34.2%	3,084.0	36.2%
March	3,890.8	42.0%	4,261.9	45.1%
April	3,569.2	39.7%	3,259.4	35.6%
May	2,136.4	23.0%	2,660.4	28.1%
June	2,233.4	24.9%	1,780.2	19.5%
July	1,151.4	12.4%	1,090.0	11.5%
August	1,233.6	13.3%	1,123.5	11.9%
September	1,496.1	16.7%	1,062.3	11.6%
October	2,670.4	28.8%		
November	3,410.5	37.8%		
December	3,496.7	37.2%		

Output from wind turbines displaces output from other generation types because, in general, wind turbines generate power when the wind is blowing, regardless of the price. This displacement affects the output of marginal units in PJM. The magnitude and type of effect on marginal unit output depends on the level of wind turbine output, its location, time and duration. One measure of this displacement is based on the mix of marginal units when wind is producing output.[313] Figure 8-17 and Table 8-36 show the hourly average proportion of marginal units by fuel type mapped to the hourly average MW of real-time wind generation in the first nine months of 2025. This is not an exact measure of displacement because it is not based on a redispatch of the system without wind resources. In the first nine months of 2025, the SCED dispatch instruction for marginal wind resources was to reduce output for 67.5 percent of the marginal wind unit intervals. When wind appears as the displaced fuel at times when wind resources were on the margin this means that there was no displacement for those hours, if the dispatch instruction was to lower the generation. The level of wind displaced by wind is thus overstated by this metric.

313 The measure is based on the principle that any incremental change in the wind output is balanced by the change in the output of marginal generators, while holding everything else equal.

Figure 8-17 Marginal fuel at time of wind generation: January through September, 2025

Solar Units

Solar units in PJM may be in front of or behind the meter. The data reported include all and only PJM solar units that are in front of the meter. As shown in Table 8-22, there are 15,526.7 MW of solar capacity registered in GATS that are PJM units. As shown in Table 8-23, there are 14,180.5 MW capacity of solar registered in GATS that are not PJM units. Some behind the meter generation exists in clusters, such as community solar farms. The customers of these clusters may or may not be located at the same node on the transmission system as the solar farm. When behind the meter generation and its associated load are at separate nodes, loads should pay for the appropriate level of transmission service, and should not be permitted to avoid paying appropriate costs as a result of badly designed rules, such as rules for netting. The MMU recommends that load and generation located at separate nodes be treated as separate resources.

Table 8-37 shows the capacity factor of solar units in PJM. The capacity factor of solar units in PJM was 22.5 percent for the first nine months of 2025. Solar units that were capacity resources had a capacity factor of 22.8 percent and an installed capacity of 13,515.3 MW. Solar units that were energy only had a capacity factor of 12.2 percent and an installed capacity of 416.4 MW. Solar capacity resources were derated to 38.0, 42.0 or 60.0 percent of installed capacity for the capacity market, prior to June 1, 2023, based on the installation type. Beginning June 1, 2023, solar capacity is derated to the ELCC accredited UCAP value.

Table 8-37 Capacity factor of solar units: January through September, 2025

Type of Resource	Capacity Factor	Installed Capacity (MW)
Energy-Only Resource	12.2%	416.4
Capacity Resource	22.8%	13,515.3
All Units	22.5%	13,931.7

Solar units that are capacity resources are required, like all capacity resources except demand resources, to offer the energy associated with their cleared capacity in the day-ahead energy market and in the real-time energy market. Figure 8-18 shows the average real-time generation and day-ahead commitments of solar units in PJM, by month and hour of day.[314] The hour with the highest average output in the first nine months of 2025, was hour 13 in July with an average of 9,720.7 MW. January has the lowest solar output. The hour in January with the highest average output was hour 13 with an average of 5,847.4 MW. Solar output in PJM is generally higher during peak hours and lower during off peak hours. Solar output is generally highest during the months from May through August and lowest during the months from November through February.

Solar unit day-ahead commitments are lower than real-time generation for most hours. Table 8-38 provides a summary of the deviations between solar unit real-time generation and day-ahead commitments. In April 2025, hourly real-time solar unit generation exceeded day-ahead solar unit commitments by 636.6 MWh on average, the highest average monthly deviation. The lowest monthly average deviation occurred in September with hourly real-time solar unit generation exceeding day-ahead commitments by 209.8 MWh on average. Solar generation exceeded day-ahead commitments in 72.3 percent of hours in the first nine months of 2025. June had the highest number of hours, 42.4 percent, with day-ahead commitments exceeding real-time generation.

Figure 8-18 Average hourly real-time generation and day-ahead commitments of solar units: January through September, 2025

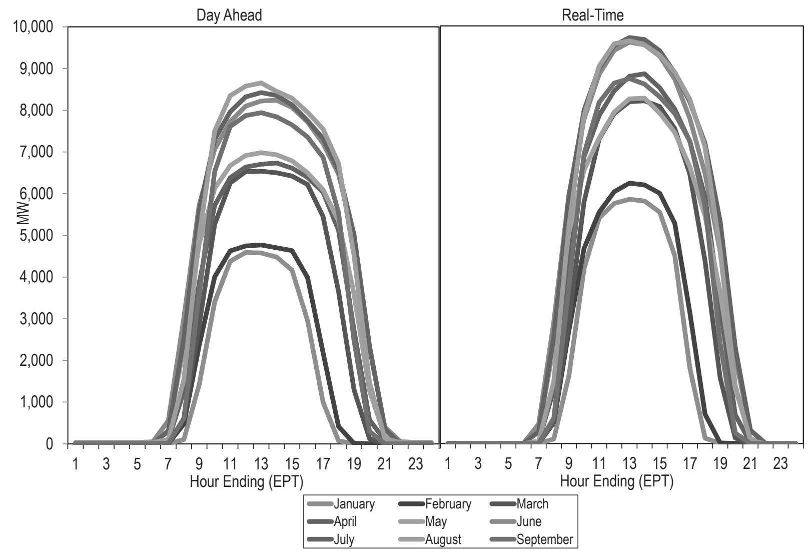

Table 8-38 Deviations between real-time solar generation and day-ahead commitments by month:[315] January through September, 2025

Month	Average Hourly Deviation	Minimum Hourly Deviation	Maximum Hourly Deviation	Hours with Negative Deviation
January	394.1	(1,507.9)	3,519.7	33.7%
February	428.1	(893.6)	4,028.3	18.3%
March	470.2	(1,571.7)	3,898.2	21.0%
April	636.6	(1,441.6)	5,237.1	23.8%
May	319.5	(2,424.0)	3,111.4	28.0%
June	319.2	(2,160.4)	2,789.2	42.4%
July	415.7	(1,909.4)	2,780.8	22.8%
August	286.7	(2,108.4)	2,943.5	35.2%
September	209.8	(1,416.3)	2,285.2	23.6%

314 The average day-ahead generation of solar units in PJM is greater than 0 for hours when the sun is down due to some solar units being paired with landfill units.

315 Hourly deviations are equal to the real-time generation less day-ahead commitments.

Table 8-39 shows the generation and capacity factor of solar units by month for the first nine months of 2024 and 2025.

Table 8-39 Capacity factor of solar units by month: January through September, 2024 and 2025

	2024		2025	
Month	Generation (MWh)	Capacity Factor	Generation (MWh)	Capacity Factor

September	1,526,641.4	18.6%	2,316,936.4	21.9%
October	1,759,610.5	19.7%		
November	1,028,502.6	11.5%		
December	905,724.9	9.6%		

Output from solar generators displaces output from other generation types because, in general, solar photovoltaic cells generate power when the sun is shining, regardless of the price. This displacement affects the output of marginal units in PJM. The magnitude and type of effect on marginal unit output depends on the level of solar photovoltaic cell output, its location, time and duration. One measure of this displacement is based on the mix of marginal units when a solar unit is producing output.[316] Figure 8-19 and Table 8-40 show the hourly average proportion of marginal units by fuel type mapped to the hourly average MW of real-time solar generation in the first nine months of 2025. This is not an exact measure of displacement because it is not based on a redispatch of the system without solar resources. In the first nine months of 2025, the SCED dispatch instruction for marginal solar resources was to reduce output for 97.6 percent of the marginal solar unit intervals. When solar appears as the displaced fuel at times when solar resources were on the margin this means that there was no displacement for those hours, if the dispatch instruction was to lower the generation. The level of solar displaced by solar is thus overstated by this metric.

316 The measure is based on the principle that any incremental change in the solar output is balanced by the change in the output of marginal generators, while holding everything else equal.

Interchange Transactions

PJM market participants import energy from, and export energy to, external regions continuously. The transactions involved may fulfill long-term or short-term bilateral contracts or respond to price differentials. The external regions include both market and nonmarket balancing authorities.

Overview

Interchange Transaction Activity

- **Aggregate Imports and Exports in the Real-Time Energy Market.** In the first nine months of 2025, PJM was a monthly net exporter of energy in the real-time energy market in all months.[1] In the first nine months of 2025, the real-time net interchange was -29,800.7 GWh. The real-time net interchange in the first nine months of 2024 was -27,542.0 GWh.
- **Aggregate Imports and Exports in the Day-Ahead Energy Market.** In the first nine months of 2025, PJM was a monthly net exporter of energy in the day-ahead energy market in all months. In the first nine months of 2025, the total day-ahead net interchange was -26,230.6 GWh. The day-ahead net interchange in the first nine months of 2024 was -24,393.4 GWh.
- **Aggregate Imports and Exports in the Day-Ahead and the Real-Time Energy Market.** In the first nine months of 2025, gross imports in the day-ahead energy market were 62.0 percent of gross imports in the real-time energy market (75.3 percent in the first nine months of 2024). In the first nine months of 2025, gross exports in the day-ahead energy market were 80.4 percent of the gross exports in the real-time energy market (84.8 percent in the first nine months of 2024).
- **Interface Imports and Exports in the Real-Time Energy Market.** In the first nine months of 2025, there were net scheduled exports at 14 of PJM's 19 interfaces in the real-time energy market.
- **Interface Pricing Point Imports and Exports in the Real-Time Energy Market.** In the first nine months of 2025, there were net scheduled exports at five of PJM's seven interface pricing points eligible for real-time transactions in the real-time energy market.
- **Interface Imports and Exports in the Day-Ahead Energy Market.** In the first nine months of 2025, there were net scheduled exports at 15 of PJM's 19 interfaces in the day-ahead energy market.
- **Interface Pricing Point Imports and Exports in the Day-Ahead Energy Market.** In the first nine months of 2025, there were net scheduled exports at six of PJM's seven interface pricing points eligible for day-ahead transactions in the day-ahead energy market.
- **Up To Congestion Interface Pricing Point Imports and Exports in the Day-Ahead Energy Market.** In the first nine months of 2025, up to congestion transactions were net exports at three of PJM's seven interface pricing points eligible for day-ahead transactions in the day-ahead energy market.
- **Inadvertent Interchange.** In the first nine months of 2025, net scheduled interchange was -29,800.7 GWh and net actual interchange was -29,592.4 GWh, a difference of 208.4 GWh. In the first nine months of 2024, the difference was 196.4 GWh. This difference is inadvertent interchange.
- **Loop Flows.** In the first nine months of 2025, the Northern Indiana Public Service (NIPS) Interface had the largest loop flows of any interface with -799.7 GWh of net scheduled interchange and -8,409.3 GWh of net actual interchange, a difference of 7,609.6 GWh. In the first nine months of 2025, the SOUTH interface pricing point had the largest loop flows of any interface pricing point with 2,746.0 GWh of net scheduled interchange and 6,535.3 GWh of net actual interchange, a difference of 3,789.3 GWh.

Interactions with Bordering Areas

PJM Interface Pricing with Organized Markets

- **PJM and MISO Interface Prices.** In the first nine months of 2025, the direction of the hourly flow was consistent with the real-time hourly price differences between the PJM/MISO Interface and the MISO/PJM Interface in 52.4 percent of the hours.

1 Calculated values shown in Section 9, "Interchange Transactions," are based on unrounded, underlying data and may differ from calculations based on the rounded values in the tables.

- **PJM and New York ISO Interface Prices.** In the first nine months of 2025, the direction of the hourly flow was consistent with the real-time hourly price differences between the PJM/NYIS Interface and the NYISO/PJM proxy bus in 59.2 percent of the hours.
- **Neptune Underwater Transmission Line to Long Island, New York.** In the first nine months of 2025, the hourly flow (PJM to NYISO) was consistent with the real-time hourly price differences between the PJM Neptune Interface and the NYISO Neptune bus in 81.5 percent of the hours.
- **Linden Variable Frequency Transformer (VFT) Facility.** In the first nine months of 2025, the hourly flow (PJM to NYISO) was consistent with the real-time hourly price differences between the PJM Linden Interface and the NYISO Linden bus in 80.3 percent of the hours.
- **Hudson DC Line.** In the first nine months of 2025, the hourly flow (PJM to NYISO) was consistent with the real-time hourly price differences between the PJM Hudson Interface and the NYISO Hudson bus in 80.7 percent of the hours.

Interchange Transaction Issues

- **PJM Transmission Loading Relief Procedures (TLRs).** PJM issued two TLRs of level 3a or higher in the first nine months of 2025, and zero such TLRs in the first nine months of 2024.
- **Up To Congestion.** The average number of up to congestion bids submitted in the day-ahead energy market increased by 57.7 percent, from 36,083 bids per day in the first nine months of 2024 to 48,979 bids per day in the first nine months of 2025. The average cleared volume of up to congestion bids submitted in the day-ahead energy market decreased by 10.1 percent, from 237,417 MWh per day in the first nine months of 2024, to 264,091 MWh per day in the first nine months of 2025.

Recommendations

- The MMU recommends that PJM implement rules to prevent sham scheduling. The MMU recommends that PJM apply after the fact market settlement adjustments to identified sham scheduling segments to ensure that market participants cannot benefit from sham scheduling. (Priority: High. First reported 2012. Status: Not adopted.)
- The MMU recommends that PJM implement a validation method for submitted transactions that would prohibit market participants from breaking transactions into smaller segments to defeat the interface pricing rule by concealing the true source or sink of the transaction. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM implement a validation method for submitted transactions that would require market participants to submit transactions on paths that reflect the expected actual power flow in order to reduce unscheduled loop flows. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that transactions sourcing in the Western Interconnection be priced at either the MISO interface pricing point or the SOUTH interface pricing point based on the locational price impact of flows between the DC tie line point of connection with the Eastern Interconnection and PJM. (Priority: High. First reported 2020. Status: Not adopted.)
- The MMU recommends that PJM eliminate the IMO interface pricing point, and assign the transactions that originate or sink in the IESO balancing authority to the MISO interface pricing point. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM review the mappings of external balancing authorities to individual interface pricing points to reflect changes to the impact of the external power source on PJM tie lines as a result of system topology changes. The MMU recommends that this review occur at least annually. (Priority: Low. First reported 2009. Status: Not adopted.)
- The MMU recommends that, in order to permit a complete analysis of loop flow, FERC and NERC ensure that the identified data are made available to market monitors as well as other industry entities determined appropriate by FERC. (Priority: Medium. First reported 2003. Status: Not adopted.)

- The MMU recommends that PJM explore an interchange optimization solution with its neighboring balancing authorities that would remove the need for market participants to schedule physical transactions across seams. Such a solution would include an optimized, but limited, joint dispatch approach that uses supply curves and treats seams between balancing authorities as constraints, similar to other constraints within an LMP market. (Priority: Medium. First reported 2014. Status: Not adopted.)
- The MMU recommends that PJM permit unlimited spot market imports as well as unlimited nonfirm point to point willing to pay congestion imports and exports at all PJM interfaces in order to improve the efficiency of the market. (Priority: Medium. First reported 2012. Status: Not adopted.)
- The MMU recommends that the emergency interchange cap be replaced with a market based solution. (Priority: Low. First reported 2015. Status: Not adopted.)
- The MMU recommends that the submission deadline for real-time dispatchable transactions be modified from 1800 on the day prior, to three hours prior to the requested start time, and that the minimum duration be modified from one hour to 15 minutes. These changes would give PJM a more flexible product that could be used to meet load in the most economic manner. (Priority: Medium. First reported 2014. Status: Partially adopted, 2015.)
- The MMU recommends eliminating the mechanism that defines FFE and M2M payments. These mechanisms are not consistent with markets and are not needed for efficient interface pricing. The MMU recommends that PJM file with the Commission to eliminate the FFE calculation and M2M payment of the PJM and MISO joint operating agreement. (Priority: Medium. First reported 2024. Status: Not adopted.)
- The MMU recommends clear, explicit and detailed rules that define the conditions under which PJM will and will not recall energy from PJM capacity resources and prohibit new energy exports from PJM capacity resources. The MMU recommends that those rules define the conditions under which PJM will purchase emergency energy while at the same time not recalling energy exports from PJM capacity resources. The MMU recommends clear rules governing when PJM may recall capacity backed exports. (Priority: Medium. First reported 2010. Status: Partially adopted.)

Conclusion

Transactions between PJM and multiple balancing authorities in the Eastern Interconnection are part of a single energy market. While some of these balancing authorities are termed market areas and some are termed nonmarket areas, all electricity transactions are part of a single energy market. Nonetheless, there are significant differences between market and nonmarket areas. Market areas, like PJM, include essential features of an energy market including locational marginal pricing, financial congestion offsets (FTRs and ARRs in PJM) and transparent, least cost, security constrained economic dispatch for all available generation. Nonmarket areas do not include these features. Pricing in the market areas is transparent and pricing in the nonmarket areas is not transparent.

The MMU's recommendations related to transactions with external balancing authorities all share the goal of improving the economic efficiency of interchange transactions. The standard of comparison is an LMP market. In an LMP market, redispatch based on LMP and competitive generator offers results in an efficient dispatch and efficient prices. The goal of designing interface transaction rules should be to match the outcomes that would exist in an LMP market across the interfaces.

It is not appropriate to have special pricing agreements between PJM and any external entity. The same market pricing should apply to all transactions. External entities wishing to receive the benefits of the PJM LMP market should join PJM.

In 2020, PJM terminated a number of interface pricing points, consistent with longstanding MMU recommendations. Following the termination of the Northwest pricing point on October 1, 2020, PJM failed to correctly map the pricing points to transactions that had been mapped to the Northwest pricing point to pricing points that are consistent with electrical impacts on the PJM system. The MMU recommends that transactions sourcing in the Western Interconnection be priced at either the MISO interface pricing point or the SOUTH interface pricing point based on the electrical impact of flows between the DC tie line point of connection with the Eastern Interconnection and PJM. The MMU continues to recommend the termination of the Ontario interface pricing point. The Ontario interface pricing point is noncontiguous to the PJM footprint that creates opportunities for market participants to engage in sham scheduling activities.

Interchange Transaction Activity

Charges and Credits Applied to Interchange Transactions

Interchange transactions are subject to various charges and credits. These charges and credits are dependent on whether the interchange transaction is submitted in the real-time or day-ahead energy market, the type of transaction, the transmission service used and whether the transaction is an import, export or wheel. Table 9-1 shows the billing line items that represent the charges and credits applied to real-time and day-ahead interchange transactions.[2]

Table 9-1 Charges and credits applied to interchange transactions

	Real-Time Transactions				Day-Ahead Transactions				
Billing Item	Import (Firm or Non Firm)	Import (Spot in)	Export	Wheel	Import (Firm or Non Firm)	Import (Spot in)	Export	Wheel	Up to Congestion
Firm or Non-Firm Point-to-Point Transmission Service	X		X[1]	X[1]	X		X[1]	X[1]

2 For an explanation and current rate for each billing line item, see "*Quick Reference Guide to Market Settlements By Type of Business*" (February 1, 2023) <https://www.pjm.com/-/media/DotCom/training/core-curriculum/ip-ms-301/ms-301-quick-reference-guide-to-markets-settlements-by-type-of-business.pdf>.

Aggregate Imports and Exports

Table 9-2 shows the real-time and day-ahead scheduled interchange totals for the first nine months of 2024 and 2025. In the first nine months of 2025, gross imports in the day-ahead energy market were 62.0 percent of gross imports in the real-time energy market (75.3 percent in the first nine months of 2024). In the first nine months of 2025, gross exports in the day-ahead energy market were 80.4 percent of gross exports in the real-time energy market (84.8 percent in the first nine months of 2024).

Table 9-2 Real-time and day-ahead scheduled interchange volumes (GWh): January through September, 2024 and 2025

Category	2024 (Jan-Sep)	2025 (Jan-Sep)	Percent Change
Real-Time Gross Imports	10,781.6	12,328.6	14.3%
Real-Time Gross Exports	38,323.6	42,129.3	9.9%
Real-Time Net Interchange	(27,542.0)	(29,800.7)	8.2%
Day-Ahead Gross Imports	8,115.1	7,646.1	(5.8%)
Day-Ahead Gross Exports	32,508.5	33,876.7	4.2%
Day-Ahead Net Interchange	(24,393.4)	(26,230.6)	7.5%
Monthly Average Real-Time Gross Exports	4,258.2	4,681.0	9.9%
Monthly Average Real-Time Gross Imports	1,198.0	1,369.8	14.3%
Monthly Average Day-Ahead Gross Exports	3,612.1	3,764.1	4.2%
Monthly Average Day-Ahead Gross Imports	901.7	849.6	(5.8%)

In the first nine months of 2025, PJM was a monthly net exporter of energy in the real-time energy market in all months. In the first nine months of 2025, PJM was a monthly net exporter of energy in the day-ahead energy market in all months (Figure 9-1).[3]

Figure 9-1 shows real-time and day-ahead import, export and net interchange volumes. The day-ahead totals include fixed, dispatchable and up to congestion transaction totals. The net interchange of up to congestion transactions are represented by the orange line.

Transactions in the day-ahead energy market create financial obligations to deliver in the real-time energy market and to pay operating reserve charges based on differences between the transaction MWh in the day-ahead and real-time energy markets times the applicable operating reserve rates. Up to congestion transactions also create financial obligations to deliver in real time, but did not pay operating reserve charges until November 1, 2020.

Figure 9-1 Scheduled imports and exports: January through September, 2025

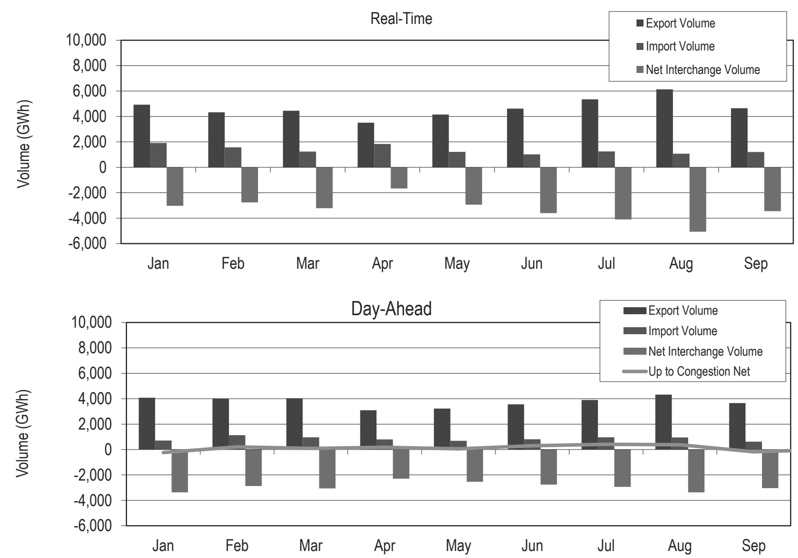

Figure 9-2 shows the real-time and day-ahead import and export volume for PJM from January 1999 through September 2025. PJM shifted from a consistent net importer of energy to relatively consistent net exporter of energy in 2004 in both the real-time and day-ahead energy markets, coincident with the expansion of the PJM footprint that included the integrations of Commonwealth Edison, American Electric Power and Dayton Power and Light into PJM. The net direction of power flows is generally expected to be a function of price differences net of transactions costs. Since the modification of the up to congestion product in September 2010, up to congestion transactions have played a significant role in power flows between PJM and external balancing authorities in the day-ahead energy market. On

3 Calculated values shown in Section 9, "Interchange Transactions," are based on unrounded, underlying data and may differ from calculations based on the rounded values in the tables.

November 1, 2012, PJM eliminated the requirement that every up to congestion transaction include an interface pricing point as either the source or sink. As a result, the volume of import and export up to congestion transactions decreased, and the volume of internal up to congestion transactions increased. While the gross import and export volumes in the day-ahead energy market decreased, PJM has remained primarily a net exporter in the day-ahead energy market. The requirement for external capacity resources to be pseudo tied into PJM has affected the real-time and day-ahead import volumes. Prior to June 1, 2016, these units were dynamically scheduled into PJM or were block scheduled into PJM and were part of scheduled interchange as imports. Pseudo tied units are treated as internal generation and therefore do not affect interchange volume. The reduction of the import volume based on the switch to pseudo tie status contributed to PJM remaining a net exporter in the real-time and day-ahead energy markets. On February 20, 2018, FERC issued an order limiting the eligible bidding points for up to congestion transactions to hubs, residual metered load and interfaces.[4] As a result, the volume of import and export up to congestion transactions increased, contributing to PJM becoming a net importer in the day-ahead energy market starting in March 2018. On July 16, 2020, FERC issued an order directing PJM to revise uplift allocation rules to allocate uplift to up to congestion transactions.[5] The Order requires PJM to treat an up to congestion transaction, for uplift allocation purposes, as if the up to congestion transaction were equivalent to a DEC at its sink point. On November 1, 2020, PJM began allocating uplift to up to congestion transactions. As a result, the volume of up to congestion transactions decreased, and PJM became a net exporter in the day-ahead energy market.

In February 2021, winter storms caused significant generation outages in Texas and resulted in power outages across the Electric Reliability Council of Texas (ERCOT) region. These outages occurred between February 10, 2021, and February 27, 2021. During this time, ERCOT imported generation from neighboring regions. While PJM did not have any scheduled exports directly to the ERCOT region, PJM exports during this time increased from an average hourly export of 4,772 MW per hour between February 1 and February 10, 2021, to 7,003 MW per hour between February 10 and February 27, 2021.

On June 13, 2022, PJM experienced several intervals of shortage pricing that resulted in high LMPs during the period from 1450 (EPT) through 1800 (EPT). PJM remained a net exporter of energy throughout the period despite the fact that PJM prices were much higher than MISO prices. PJM net exports averaged 4,431 MW during hours ending 1500 (EPT) through 1800 (EPT), a slight decrease from average net exports of 5,560 MW during the hours ending 1100 (EPT) through 1400 (EPT). Market participant response to the pricing signals in this period was affected by TLRs issued by MISO, SWPP and PJM, although the curtailments of scheduled imports to PJM were relatively small compared to the net exports. Export transactions to MISO continued to flow during this period primarily on firm and grandfathered transmission service. The lack of response to relative prices on the PJM/MISO interface was consistent with the ongoing pattern that there are net exports from PJM to MISO in almost every hour, regardless of relative prices. In the first nine months of 2025, flows were in the uneconomic direction on the PJM/MISO interface in 47.6 percent of all hours.

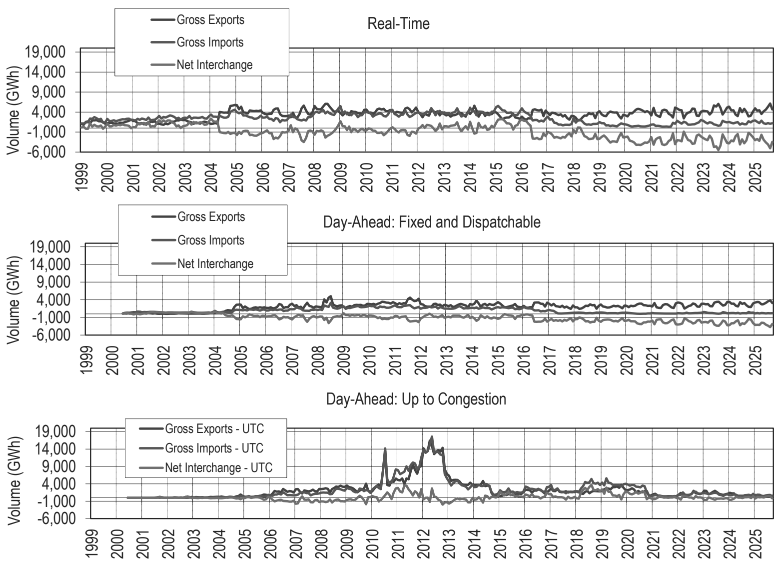
Figure 9-2 Scheduled import and export transaction volume history: January 1, 1999 through September 30, 2025



Real-Time Interface Imports and Exports

In the real-time energy market, scheduled imports and exports are defined by the scheduled path, which is the transmission path a market participant selects from the original source to the final sink. These scheduled flows are measured at each of PJM's interfaces with neighboring balancing authorities. Table 9-19 includes a list of active interfaces in the first nine months of 2025. Figure 9-3 shows the approximate geographic location of the interfaces. In the first nine months of 2025, PJM had 19 interfaces with neighboring balancing authorities. While the Linden (LIND) Interface, the Hudson (HUDS) Interface and the Neptune (NEPT) Interface are separate from the NYIS Interface, all four are interfaces between PJM and the NYISO. There are 10 separate interfaces that make up the MISO Interface between PJM and MISO. Table 9-3 through Table 9-5 show the real-time energy market scheduled interchange totals at the individual NYISO interfaces, as well as with the NYISO as a whole. Similarly, the scheduled interchange totals at the individual interfaces between PJM and MISO are shown, as well as with MISO as a whole. Net scheduled interchange in the real-time energy market is shown by interface for the first nine months of 2025 in Table 9-3, while gross scheduled imports and exports are shown in Table 9-4 and Table 9-5.

In the real-time energy market, in the first nine months of 2025, there were net scheduled exports at 14 of PJM's 19 interfaces. The top three net exporting interfaces in the real-time energy market accounted for 55.4 percent of the total net scheduled exports: PJM/NYISO (NYIS) with 21.1 percent, PJM/Cinergy (CIN) with 20.2 percent and PJM/MidAmerican Energy Company (MEC) with 14.2 percent of the net scheduled export volume. The four separate interfaces that connect PJM to the NYISO (PJM/NYIS, PJM/NEPT, PJM/HUDS and PJM/Linden (LIND)) together represented 48.1 percent of the total net PJM scheduled exports in the real-time energy market. There were net scheduled exports in the real-time energy market at seven of the 10 separate interfaces that connect PJM to MISO. Those seven exporting interfaces represented 49.3 percent of the total net PJM scheduled exports in the real-time energy market.

In the real-time energy market, in the first nine months of 2025, there were net scheduled imports at four of PJM's 19 interfaces. The top two importing interfaces in the real-time energy market accounted for 75.6 percent of the total net scheduled imports: PJM/Duke (DUK) with 42.3 percent and PJM/Ameren-Illinois (AMIL) with 33.4 percent of the total net scheduled import volume. The four separate interfaces that connect PJM to the NYISO (PJM/NYIS, PJM/NEPT, PJM/HUDS and PJM/Linden (LIND)) had net scheduled exports in the real-time energy market. There were net scheduled imports in the real-time energy market at two of the 10 separate interfaces that connect PJM to MISO (Ameren-Illinois (AMIL) and Indianapolis Power & Light (IPL). These importing interfaces represented 38.1 percent of the total net PJM scheduled imports in the real-time energy market.[6]

6 In the real-time energy market, one PJM interfaces had a net interchange of zero (PJM/City Water Light & Power (CWLP)). CWLP is a balancing authority on the western side of MISO.

Real-Time Interface Pricing Point Imports and Exports

Interfaces differ from interface pricing points. An interface is a point of interconnection between PJM and a neighboring balancing authority which market participants may designate as a path on which scheduled imports or exports will flow.[7] An interface pricing point defines the price at which transactions are priced, and is based on the path of the actual, physical transfer of energy. While a market participant designates a scheduled path from a generation control area (GCA) to a load control area (LCA), this path reflects the scheduled path as defined by the transmission reservations only, and may not reflect how the energy actually flows from the GCA to LCA. For example, the import transmission path from LG&E Energy, L.L.C. (LGEE), through MISO and into PJM would show the transfer of power into PJM at the PJM/MISO Interface based on the scheduled path of the transaction. However, the physical flow of energy does not enter the PJM footprint at the PJM/MISO Interface, but enters PJM at the southern boundary. For this reason, PJM prices an import with the GCA of LGEE at the SOUTH interface pricing point rather than the MISO pricing point.

Interfaces differ from interface pricing points. The challenge is to create interface prices, composed of external pricing points, which accurately represent the locational price impact of flows between PJM and external sources of energy and that reflect the underlying economic fundamentals across balancing authority borders.[8]

Transactions can be scheduled to an interface based on a contract transmission path, but pricing points are developed and applied based on the estimated electrical impact of the external power source on PJM tie lines, regardless of the contract transmission path.[9] PJM establishes prices for transactions with external balancing authorities by assigning interface pricing points to individual balancing authorities based on the generation control area and load control area as specified on the NERC Tag. Dynamic interface pricing calculations use actual system conditions to determine a set of weights for each external pricing point in an interface price definition. The weights are designed so that the interface price reflects actual system conditions. However, the weights are an approximation given the complexity of the transmission network outside PJM and the dynamic nature of power flows. Table 9-20 presents the interface pricing points used in the first nine months of 2025. On October 21, 2020, PJM updated the mappings of external balancing authorities to individual pricing points. Figure 9-4 shows a map of the default interface pricing point assignments for all external balancing authorities. Figure 9-4 shows that the balancing authorities in the Western Interconnection are mapped to either the MISO interface pricing point or the SOUTH interface pricing point. This determination was made by PJM based on geographic location rather than the electrical impact on the PJM system. When power is scheduled across a DC tie line, its effects on the PJM system are as if a generator is located at the point

7 There are multiple paths between any generation and load balancing authority. Market participants select the path based on transmission service availability and the transmission costs for moving energy from generation to load and interface prices.

8 See the *2007 Annual State of the Market Report for PJM*, Appendix D, "Interchange Transactions," for a more complete discussion of the development of pricing points.

9 See "Interface Pricing Point Assignment Methodology," (May 7, 2025) <https://www.pjm.com/-/media/DotCom/etools/exschedule/interface-pricing-point-assignment-methodology.pdf>. PJM periodically updates these definitions on its website.

in the Eastern Interconnection where the DC tie line connects. The electrical impact on PJM tie lines from sources in the Western Interconnection differ based on the relevant DC tie line and could vary from the MISO interface pricing point to the SOUTH interface pricing point. The MMU recommends that transactions sourcing in the Western Interconnection be priced at either the MISO interface pricing point or the SOUTH interface pricing point based on the locational price impact of flows between the DC tie line point of connection with the Eastern Interconnection and PJM rather than geographical location. The MMU recommends that PJM review the mappings of external balancing authority pricing points at least annually to reflect the fact that changes to the system topology can affect the electrical impact of external power sources on PJM.

The MMU has made multiple recommendations to either retire or consolidate interface pricing points used by PJM. The reasons for those recommendations include: pricing points that could no longer be used to price actual transactions; pricing points that were inappropriately used to support special agreements; pricing points that were treated as multiple pricing points when they were a single pricing point; and pricing points that were noncontiguous to the PJM footprint that created opportunities for sham scheduling. Table 9-6 shows the interface pricing points, the recommendation and the date the recommendation was adopted.

Table 9-6 MMU interface pricing point recommendations and dates adopted

OVEC	Retire Pricing Point - Obsolete (Integration into PJM)	1-Dec-2018

The interface pricing method implies that the weighting factors reflect the actual system flows in a dynamic manner. In fact, the weightings are static, and are modified by PJM only occasionally.[10] The MMU recommended that PJM monitor, and adjust as necessary, the weights applied to the components of the interfaces to ensure that the interface prices reflect ongoing changes in system conditions. At the March 20, 2024, meeting of the Markets and Reliability Committee, PJM stakeholders approved the implementation of a new annual review of interface pricing definitions.[11] [12] The annual review evaluates, and adjusts as necessary, the interface pricing definitions to ensure the buses and weightings used in the interface pricing definitions capture changes in system topology over time and reflect current system conditions.

The contract transmission path only reflects the path of energy into or out of PJM to one neighboring balancing authority. The NERC Tag requires the complete path to be specified from the generation control area (GCA) to the load control area (LCA), but participants do not always do so. The NERC Tag

10 On June 1, 2015, PJM began using a dynamic weighting factor in the calculation for the Ontario interface pricing point.
11 *See* "Manual 11 Revisions – Interface Pricing Points Review," Presented at the PJM Markets and Reliability Committee (MRC) meeting held on March 20, 2024 <https://www.pjm.com/-/media/committees-groups/committees/mrc/2024/20240320/20240320-consent-agenda-b---1-manual-11-revisions-interface-pricing-points---presentation.ashx>.
12 See PJM. "Manual 11: Energy & Ancillary Services Market Operations," Rev. 136 (October 1, 2025.

path is used by PJM to determine the interface pricing point that PJM assigns to the transaction. This approach will correctly identify the interface pricing point only if the market participant provides the complete path in the Tag.

In the real-time energy market, in the first nine months of 2025, there were net scheduled exports at five of PJM's seven interface pricing points eligible for real-time transactions. The top three net exporting interface pricing points in the real-time energy market accounted for 85.6 percent of the total net scheduled exports: PJM/MISO with 52.2 percent, PJM/NYIS with 20.9 percent and PJM/NEPTUNE with 12.5 percent of the net scheduled export volume. The four separate interface pricing points that connect PJM to the NYISO (PJM/NYIS, PJM/NEPTUNE, PJM/HUDSONTP and PJM/LINDENVFT) together represented 47.8 percent of the total net PJM scheduled exports in the real-time energy market.

In the real-time energy market, in the first nine months of 2025, there were net scheduled imports at two of PJM's seven interface pricing points eligible for real-time transactions. The top importing interface pricing point in the real-time energy market was the PJM/SOUTH interface pricing point, which accounted for 80.5 percent of the total net scheduled import volume. The four separate interface pricing points that connect PJM to the NYISO (PJM/NYIS, PJM/NEPTUNE, PJM/HUDSONTP and PJM/LINDENVFT) had net scheduled exports in the real-time energy market.

Day-Ahead Interface Imports and Exports

In the day-ahead energy market, as in the real-time energy market, scheduled imports and exports are determined by the scheduled path, which is the transmission path a market participant selects from the original source to the final sink. Entering external energy transactions in the day-ahead energy market requires fewer steps than in the real-time energy market. Market participants need to acquire a valid, willing to pay congestion (WPC) OASIS reservation to prove that their day-ahead schedule could be supported in the real-time energy market.[13] Day-ahead energy market schedules need to be cleared through the day-ahead energy market process in order to become an approved schedule. The day-ahead energy market transactions are financially binding, but will not physically flow unless they are also submitted in the real-time energy market. In the day-ahead energy market, a market participant is not required to acquire a ramp reservation, a NERC Tag, or to go through a neighboring balancing authority checkout process.

There are three types of day-ahead external energy transactions: fixed; up to congestion; and dispatchable.[14]

In the day-ahead energy market, transaction sources and sinks are determined solely by market participants. In Table 9-10, Table 9-11, and Table 9-12, the scheduled interface designation is determined by the transmission reservation that was acquired and associated with the day-ahead market transaction, and does not bear any necessary relationship to the pricing point designation selected at the time the transaction is submitted to PJM in real time. For example, if market participants want to import energy from the Southwest Power Pool (SPP) to PJM, they are likely to choose a scheduled path with the fewest transmission providers along the path and therefore the lowest transmission costs for the transaction, regardless of whether the resultant path is related to the physical flow of power. The lowest cost transmission path runs from SPP, through MISO, and into PJM, requiring only three transmission reservations, two of which are available at no cost (MISO transmission would be free based on the regional through and out rates, and the PJM transmission would be free, if using spot import transmission). Any other transmission path entering PJM, where the generating control area is to the south, would require the market participant to acquire transmission through nonmarket balancing authorities, and thus incur additional transmission costs. PJM's interface pricing method recognizes that transactions sourcing in SPP and sinking in PJM will create flows across the southern border and prices those transactions at the SOUTH interface price. As a result, a market participant who plans to submit a transaction from SPP to PJM may have a transmission reservation with a point of receipt of MISO and a point of delivery of PJM but may select SOUTH as the import pricing point when submitting the transaction in the day-ahead energy market. In the scheduled interface tables, the import transaction would appear as scheduled through the MISO Interface, and in the scheduled interface pricing point tables, the import transaction would appear as scheduled through the SOUTH interface pricing point, which reflects the expected power flow.

Table 9-10 through Table 9-12 show the day-ahead scheduled interchange totals at the individual interfaces. Net scheduled interchange in the day-ahead energy market is shown by interface for the first nine months of 2025 in Table 9-10, while gross scheduled imports and exports are shown in Table 9-11 and Table 9-12.

In the day-ahead energy market, in the first nine months of 2025, there were net scheduled exports at 15 of PJM's 19 interfaces. The top three net exporting

13 Effective September 17, 2010, up to congestion transactions no longer required a willing to pay congestion transmission reservation.
14 See the *2010 Annual State of the Market Report for PJM*, Volume 2, Section 4, "Interchange Transactions," for details.

interfaces in the day-ahead energy market accounted for 53.1 percent of the total net scheduled exports: PJM/NYISO (NYIS) with 21.9 percent, PJM/MidAmerican Energy Company (MEC) with 15.9 percent and PJM/Neptune (NEPT) with 15.3 percent of the net scheduled export volume. The four separate interfaces that connect PJM to the NYISO (PJM/NYIS, PJM/NEPT, PJM/HUDS and PJM/Linden (LIND)) together represented 50.2 percent of the total net PJM scheduled exports in the day-ahead energy market. In the first nine months of 2025, there were net exports in the day-ahead energy market at eight of the 10 separate interfaces that connect PJM to MISO. Those eight interfaces represented 39.3 percent of the total net PJM exports in the day-ahead energy market.

In the day-ahead energy market, in the first nine months of 2025, there were net scheduled imports at two of PJM's 19 interfaces. The top importing interface in the day-ahead energy market was the Duke (DUK) Interface, which accounted for 70.0 percent of the net scheduled import volume. The four separate interfaces that connect PJM to the NYISO (PJM/NYIS, PJM/NEPT, PJM/HUDS and PJM/Linden (LIND)) had net scheduled exports in the day-ahead energy market. In the first nine months of 2025, there were net imports in the day-ahead energy market at one of the 10 separate interfaces that connect PJM to MISO (Indianapolis Power & Light). That interface represented 30.0 percent of the total net PJM imports in the day-ahead energy market.[15]

Day-Ahead Interface Pricing Point Imports and Exports

Table 9-13 through Table 9-18 show the day-ahead scheduled interchange totals at the interface pricing points. In the first nine months of 2025, up to congestion transactions accounted for 77.9 percent of all scheduled import MW transactions and 14.1 percent of all scheduled export MW transactions in the day-ahead energy market. The day-ahead net scheduled interchange in the first nine months of 2025, including up to congestion transactions, is shown by interface pricing point in Table 9-13. Scheduled up to congestion transactions by interface pricing point in the first nine months of 2025 are shown in Table 9-14. Day-ahead gross scheduled imports and exports, including up to congestion transactions, are shown in Table 9-15 and Table 9-17, while gross scheduled import and export up to congestion transactions are shown in Table 9-16 and Table 9-18.

Maintaining outdated definitions of interface pricing points is unnecessary, inconsistent with the tariff and creates artificial opportunities for gaming by virtual transactions and FTRs. PJM should immediately eliminate interface pricing points when changes to the market mean that the pricing points can no longer be used to price actual transactions and do not reflect actual price formation.

In the day-ahead energy market, in the first nine months of 2025, there were net scheduled exports at six of PJM's seven interface pricing points eligible for day-ahead transactions. The top three net exporting interface pricing points in the day-ahead energy market accounted for 78.6 percent of the total net scheduled exports: PJM/MISO with 36.8 percent, PJM/NYIS with 26.0 percent and PJM/NEPTUNE (NEPT) with 15.8 percent of the net scheduled export volume. The four separate interface pricing points that connect PJM to the NYISO (PJM/NYIS, PJM/NEPTUNE, PJM/HUDSONTP and PJM/LINDENVFT) together represented 59.2 percent of the total net PJM scheduled exports in the day-ahead energy market.

In the day-ahead energy market, in the first nine months of 2025, there were net scheduled imports at one of PJM's seven interface pricing points eligible for day-ahead transactions, (Ontario Independent Electricity System Operator (IMO)), which accounted for 100.0 percent of the net scheduled import volume. The four separate interface pricing points that connect PJM to the NYISO (PJM/NYIS, PJM/NEPTUNE, PJM/HUDSONTP and PJM/LINDENVFT) had net scheduled exports in the day-ahead energy market.

In the day-ahead energy market, in the first nine months of 2025, up to congestion transactions had net scheduled exports at three of PJM's seven interface pricing points eligible for day-ahead transactions. The top two net exporting interface pricing points eligible for up to congestion transactions accounted for 87.9 percent of the total net up to congestion scheduled exports: PJM/NYIS with 44.6 percent and PJM/HUDSONTP with 43.3 percent of the net up to congestion scheduled export volume. The four separate interface pricing points that connect PJM to the NYISO (PJM/NYIS, PJM/NEPTUNE, PJM/HUDSONTP and PJM/LINDENVFT) together represented 100.0 percent of the total net scheduled up to congestion exports in the day-ahead energy market. However, the PJM/NEPTUNE interface pricing point had net up to congestion scheduled imports in the day-ahead energy market.

In the day-ahead energy market, in the first nine months of 2025, up to congestion transactions had net scheduled imports at four of PJM's seven interface pricing points eligible for day-ahead transactions. The top two importing interface pricing points eligible for up to congestion transactions accounted for 95.6 percent of the total up to congestion scheduled imports: PJM/SOUTH with 57.1 percent and PJM/MISO with 38.6 percent of the net up to congestion scheduled import volume. The four separate interface pricing points that connect PJM to the NYISO (PJM/NYIS, PJM/NEPTUNE, PJM/HUDSONTP and PJM/LINDENVFT) together represented 2.8 percent of the total net scheduled up to congestion imports in the day-ahead energy market. However, the PJM/HUDSONTP, PJM/LINDENVFT and PJM/NYIS interface pricing points had net up to congestion scheduled exports in the day-ahead energy market.

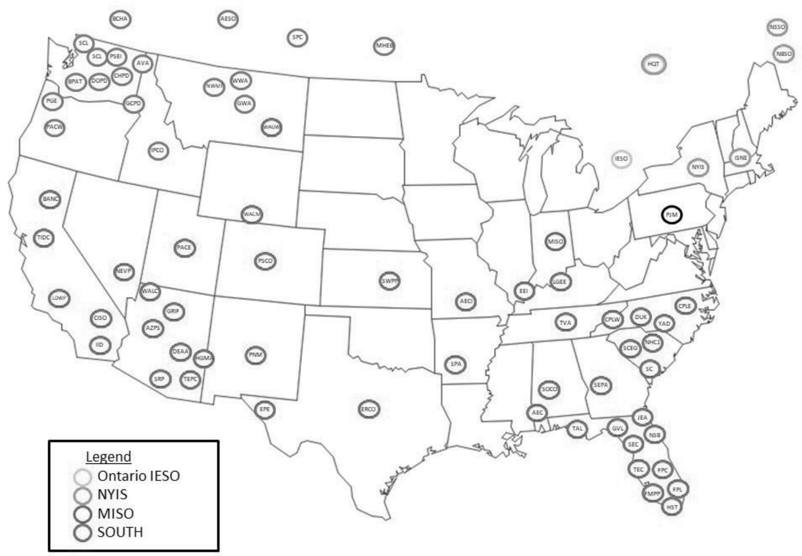
16 On July 2, 2012, Duke Energy Corp. (DUK) completed a merger with Progress Energy Inc. (CPLE and CPLW). As of September 30, 2025, DUK, CPLE and CPLW continued to operate as separate balancing authorities, and are still defined as distinct interfaces in the PJM energy market.

Figure 9-4 External balancing authority default interface pricing point assignments



Loop Flows

Actual energy flows are the real-time metered power flows at an interface for a defined period. The comparable scheduled flows are the real-time power flows scheduled at an interface for a defined period. Inadvertent interchange is the difference between the total actual flows for the PJM system (net actual interchange) and the total scheduled flows for the PJM system (net scheduled interchange) for a defined period. Loop flows are the difference between actual and scheduled power flows at a specific interface. Loop flows can exist at the same time that inadvertent interchange is zero. For example, actual imports could exceed scheduled imports at one interface and actual exports could exceed scheduled exports at another interface by the same amount. The result is loop flow, despite the fact that system actual and scheduled power flow net to a zero difference.[17]

17 See the *2012 Annual State of the Market Report for PJM*, Volume 2, Section 8, "Interchange Transactions," for a more detailed discussion.

Loop flows result, in part, from a mismatch between incentives to use a particular scheduled transmission path and the market-based price differentials at interface pricing points that result from the actual physical flows on the transmission system.

PJM's approach to interface pricing attempts to match prices with physical power flows and their impacts on the transmission system. For example, if market participants want to import energy from the Southwest Power Pool (SPP) to PJM, they are likely to choose a scheduled path with the fewest transmission providers along the path and therefore the lowest transmission costs for the transaction, regardless of whether the resultant path is related to the physical flow of power. The lowest cost transmission path runs from SPP, through MISO, and into PJM, requiring only three transmission reservations, two of which are available at no cost (MISO transmission would be free based on the regional through and out rates, and the PJM transmission would be free, if using spot import transmission). Any other transmission path entering PJM, where the generating control area is to the south, would require the market participant to acquire transmission through nonmarket balancing authorities, and thus incur additional transmission costs. PJM's interface pricing method recognizes that transactions sourcing in SPP and sinking in PJM will create flows across the southern border and prices those transactions at the SOUTH interface price. As a result, the transaction is priced appropriately, but a difference between scheduled and actual flows is created at PJM's borders. For example, if a 100 MW transaction were submitted, there would be 100 MW of scheduled flow at the PJM/MISO interface border, but there would be no actual flows on the interface. Correspondingly, there would be no scheduled flows at the PJM/SOUTH interface border, but there would be 100 MW of actual flows on the interface. In the first nine months of 2025, of the 2,746.0 GWh of net scheduled interchange that received the SOUTH interface pricing point, 1,622.6 GWh (59.1 percent) were scheduled through MISO. There were no net scheduled flows across the southern interface that received the MISO interface pricing point.

In the first nine months of 2025, net scheduled interchange was -29,800.7 GWh and net actual interchange was -29,592.4 GWh, a difference of 208.4 GWh. In the first nine months of 2024, net scheduled interchange was -27,542.0 GWh and net actual interchange was -27,738.4 GWh, a difference of 196.4 GWh. This difference is inadvertent interchange. PJM attempts to minimize the amount of accumulated inadvertent interchange by continually monitoring and correcting for inadvertent interchange. PJM can reduce the accumulation of inadvertent interchange by using unilateral or bilateral paybacks. Inadvertent interchange accumulations that are paid back unilaterally are paid by controlling to a non-zero area control error (ACE). For example, Table 9-21 shows that PJM had 208.4 GW of inadvertent interchange in the first nine months of 2025. To reduce this inadvertent interchange, PJM can control to an ACE less than zero, which would result in under generating. By way of the power balance equation, power would flow into PJM from its neighboring balancing authority areas. This would create decreased actual exports that were not scheduled, thus reducing the overall inadvertent. To maintain reliability, unilateral paybacks are accounted for in the control performance standard calculations. Bilateral paybacks are scheduled with other balancing authority areas by scheduling a correction and incorporating that amount as a bias in the energy management system.[18] [19]

Table 9-21 shows that in the first nine months of 2025, the Northern Indiana Public Service (NIPS) Interface had the largest loop flows of any interface with -799.7 GWh of net scheduled interchange and -8,409.3 GWh of net actual interchange, a difference of 7,609.6 GWh.

18 See PJM. "Manual 12: Balancing Operations," Rev. 56 (October 1, 2025).
19 PJM does not publish data on inadvertent payback.

Every external balancing authority is mapped to an import and export interface pricing point. The mapping is designed to reflect the physical flow of energy between PJM and each balancing authority. The net scheduled values for interface pricing points are defined as the MWh of scheduled transactions that will receive the interface pricing point based on the external balancing authority mapping.[20] For example, the MWh for a transaction whose transmission path is SPP through MISO and into PJM would be reflected in the SOUTH interface pricing point net schedule totals because SPP is mapped to the SOUTH interface pricing point. The actual flow on an interface pricing point is defined as the metered flow across the transmission lines that are included in the interface pricing point.

20 The terms balancing authority and control area are used interchangeably in this section. The NERC Tag applications maintained the terminology of generation control area (GCA) and load control area (LCA) after the implementation of the NERC functional model. The NERC functional model classifies the balancing authority as a reliability service function, with, among other things, the responsibility for balancing generation, demand and interchange balance.

The differences between the scheduled MWh mapped to a specific interface pricing point and actual power flows at the interface pricing points provide a better measure of loop flows than differences at the interfaces. The scheduled transactions are mapped to interface pricing points based on the expected flow from the generation balancing authority and load balancing authority, whereas scheduled transactions are assigned to interfaces based solely on the OASIS path that the market participants reflect the transmission path into or out of PJM to one neighboring balancing authority. Power flows at the interface pricing points provide a more accurate reflection of where scheduled power flows actually enter or leave the PJM footprint based on the complete transaction path. Table 9-22 shows the net scheduled and actual PJM flows by interface pricing point.

The IMO interface pricing point with the Ontario IESO was created to reflect the fact that transactions that originate or sink in the Ontario Independent Electricity System Operator (IMO) balancing authority create physical flows that are split between the MISO and NYISO interface pricing points depending on transmission system conditions, so a mapping to a single interface pricing point does not reflect the actual flows. PJM created the IMO interface pricing point to reflect the actual power flows across both the MISO/PJM and NYISO/PJM Interfaces. The IMO does not have physical ties with PJM because it is not contiguous. Table 9-22 shows actual flows associated with the IMO interface pricing point as zero because there is no PJM/IMO Interface. The actual flows between IMO and PJM are included in the actual flows at the MISO and NYISO interface pricing points.

Table 9-22 shows that in the first nine months of 2025, the SOUTH interface pricing point had the largest loop flows of any interface pricing point with 2,746.0 GWh of net scheduled interchange and 6,535.3 GWh of net actual interchange, a difference of 3,789.3 GWh.

Table 9-22 PJM flows by interface pricing point (GWh): January through September, 2025

Interface Pricing Point	Actual	Net Scheduled	Difference (GWh)

NYIS	(6,807.4)	(6,941.4)	134.0
SOUTH	6,535.3	2,746.0	3,789.3
Total	(29,592.4)	(29,800.7)	208.4

The NERC Tag requires the complete path to be specified from the generation control area (GCA) to the load control area (LCA), but participants do not always do so. The NERC Tag path is used by PJM to determine the interface pricing point that PJM assigns to the transaction. This approach will correctly identify the interface pricing point only if the market participant provides the complete path in the Tag. This approach will not correctly identify the interface pricing point if the market participant breaks the transaction into portions, each with a separate Tag. The breaking of transactions into portions can be a way to manipulate markets and the result of such behavior can be incorrect and noncompetitive pricing of transactions.

PJM attempts to ensure that external energy transactions are priced appropriately through the assignment of interface prices based on the expected actual flow from the generation balancing authority (source) and load balancing authority (sink) as specified on the NERC Tag. Assigning prices in this manner is a reasonable approach to ensuring that transactions receive or pay the PJM market value of the transaction based on expected flows, but this method does not address loop flow issues.

Loop flows remain a significant concern for the efficiency of the PJM market. Loop flows can have negative impacts on the efficiency of markets with explicit locational pricing, including impacts on locational prices, on FTR revenue adequacy and on system operations, and can be evidence of attempts to game the markets.

The MMU recommends that PJM implement a validation method for submitted transactions that would prohibit market participants from breaking transactions into smaller segments to defeat the interface pricing rule and receive higher prices (for imports) or lower prices (for exports) from PJM resulting from the inability to identify the true source or sink of the transaction. If all of the Northeast ISOs and RTOs implemented validation to prohibit the breaking of transactions into smaller segments, the level of Lake Erie loop flow would be reduced.

The MMU also recommends that PJM implement a validation method for submitted transactions that would require market participants to submit transactions on paths that reflect the expected actual power flow in order to reduce unscheduled loop flows.

Table 9-24 shows the net scheduled and actual PJM flows by interface and interface pricing point. This table shows the interface pricing points that were assigned to energy transactions that had paths at each of PJM's interfaces. For example, Table 9-24 shows that in the first nine months of 2025, the majority of imports to the PJM energy market for which a market participant specified Michigan Electric Coordinated System (MECS) as the interface with PJM based on the scheduled transmission path, had a generation control area mapped to the IMO Interface, and thus actual flows were assigned the IMO interface pricing point (593.9 GWh). The majority of exports from the PJM energy market for which a market participant specified MECS as the interface with PJM based on the scheduled transmission path had a load control area for which the actual flows would leave the PJM energy market at the MISO Interface, and were assigned the MISO interface pricing point (-2,066.3 GWh).

Data Required for Full Loop Flow Analysis

Loop flows are defined as the difference between actual and scheduled power flows at one or more specific interfaces. The differences between actual and scheduled power flows can be the result of a number of underlying causes. To adequately investigate the causes of loop flows, complete data are required.

Loop flows exist because electricity flows on the path of least resistance regardless of the path specified by contractual agreement or regulatory prescription. Loop flows can arise from transactions scheduled into, out of or around a balancing authority on contract paths that do not correspond to the actual physical paths on which energy flows. Outside of LMP-based energy markets, energy is scheduled and paid for based on contract path, without regard to the path of the actual energy flows. Loop flows can also result from actions within balancing authorities.

Loop flows are a significant concern. Loop flows can have negative impacts on the efficiency of markets with explicit locational pricing, including impacts on locational prices, on FTR revenue adequacy and on system operations, and can be evidence of attempts to game such markets. Loop flows also have poorly understood impacts on nonmarket areas. In general, the detailed sources of the identified differences between scheduled and actual flows remain unclear as a result of incomplete or inadequate access to the required data.

A complete analysis of loop flow could provide additional insight that could lead to enhanced overall market efficiency and clarify the interactions among market and nonmarket areas. A complete analysis of loop flow would improve the overall transparency of electricity transactions. There are areas with transparent markets, and there are areas with less transparent markets (nonmarket areas), but these areas together comprise a market, and overall market efficiency would benefit from the increased transparency that would derive from a better understanding of loop flows.

For a complete loop flow analysis, several types of data are required from all balancing authorities in the Eastern Interconnection. The Commission required access to NERC Tag data. In addition to the Tag data, actual tie line data, dynamic schedule and pseudo tie data are required in order to analyze the differences between actual and scheduled transactions. ACE data, market flow impact data and generation and load data are required in order to understand the sources, within each balancing authority, of loop flows that do not result from differences between actual and scheduled transactions.[21]

NERC Tag Data

An analysis of loop flow requires knowledge of the scheduled path of energy transactions. NERC Tag data include the scheduled path and energy profile of the transactions, including the Generation Control Area (GCA), the intermediate Control Areas, the Load Control Area (LCA) and the energy profile of all transactions. Complete tag data include the identity of the specific market participants. FERC Order No. 771 required access to NERC Tag data for the Commission, regional transmission organizations, independent system operators and market monitoring units.[22]

Actual Tie Line Flow Data

An analysis of loop flow requires knowledge of the actual path of energy transactions. Currently, a very limited set of tie line data is made available via the NERC IDC and the Central Repository for Curtailments (CRC) website. The available tie line data, and the data within the IDC, are presented as information on a screen, which does not permit analysis of the underlying data.

Dynamic Schedule and Pseudo Tie Data

Dynamic schedule and pseudo ties represent another type of interchange transaction between balancing authorities. While dynamic schedules are required to be tagged, the tagged profile is only an estimate of what energy is expected to flow. Dynamic schedules are implemented within each balancing authority's Energy Management System (EMS), with the current values shared over Inter-Control Center Protocol (ICCP) links. By definition, the dynamic schedule scheduled and actual values will always be identical from a balancing authority standpoint, and the tagged profile should be removed

21 It is requested that all data be made available in downloadable format in order to make analysis possible. A data viewing tool alone is not adequate.
22 141 FERC ¶ 61,235 (2012).

from the calculation of loop flows to eliminate double counting of the energy profile. Dynamic schedule data from all balancing authorities are required in order to account for all scheduled and actual flows.

Pseudo ties are similar to dynamic schedules in that they represent a transaction between balancing authorities and are handled within the EMS systems and data are shared over the ICCP. Pseudo ties differ from dynamic schedules in how the generating resource is modeled within the balancing authorities' ACE equations. Dynamic schedules are modeled as resources located in one area serving load in another, while pseudo ties are modeled as resources in one area moved to another area. Unlike dynamic schedules, pseudo tie transactions are not required to be tagged. Pseudo tie data from all balancing authorities are required in order to account for all scheduled and actual flows.

Area Control Error (ACE) Data

Area control error (ACE) data provides information about how well each balancing authority is matching their generation with their load. This information, combined with the scheduled and actual interchange values will show whether an individual balancing authority is pushing on or leaning on the interconnection, contributing to loop flows.

NERC makes real-time ACE graphs available on their Reliability Coordinator Information System (RCIS) website. This information is presented only in graphical form, and the underlying data is not available for analysis.

Market Flow Impact Data

In addition to interchange transactions, internal dispatch can also affect flows on balancing authorities' tie lines. The impact of internal dispatch on tie lines is called market flow. Market flow data are imported in the IDC, but there is only limited historical data, as only market flow data related to TLR levels 3 or higher are required to be made available via a Congestion Management Report (CMR). The remaining data are deleted.

There is currently a project in development through the NERC Operating Reliability Subcommittee (ORS) called the Market Flow Impact Tool. The purpose of this tool is to make visible the impacts of dispatch on loop flows. The MMU supports the development of this tool, but, equally important, requests that FERC and NERC ensure that the underlying data are provided to market monitors and other approved entities.

Generation and Load Data

Generation data (both real-time scheduled generation and actual output) and load data would permit analysis of the extent to which balancing authorities are meeting their commitments to serve load. If a balancing authority is not meeting its load commitment with adequate generation, the result is unscheduled flows across the interconnections to establish power balance.

Market areas are transparent in providing real-time load while nonmarket areas are not. For example, PJM posts real-time load via its eDATA application. Most nonmarket balancing authorities provide only the expected peak load on their individual websites. Data on generation are not made publicly available, as this is considered market sensitive information.

The MMU recommends, that in order to permit a complete analysis of loop flow, FERC and NERC ensure that the identified data are made available to market monitors as well as other industry entities determined appropriate by FERC.

PJM and MISO Interface Prices

Both the PJM/MISO and MISO/PJM interface pricing points represent the value of power at the relevant border, as determined in each market. In both cases, the interface price is the price at which transactions are settled. For example, a transaction into PJM from MISO would receive the PJM/MISO interface price upon entering PJM, while a transaction into MISO from PJM would receive the MISO/PJM interface price. PJM and MISO use network models to determine these prices and to attempt to ensure that the prices are consistent with the underlying electrical flows.

Under the PJM/MISO Joint Operating Agreement, the two RTOs mutually determine a set of transmission facilities on which both RTOs have an impact, and therefore jointly operate to those constraints. These jointly controlled facilities are M2M (Market to Market) flowgates. When a M2M constraint binds, PJM's LMP calculations at the buses that make up PJM's MISO interface pricing point are based on the PJM model's distribution factors of the selected buses to the binding M2M constraint and PJM's shadow price of the binding M2M constraint. MISO's LMP calculations at the buses that make up MISO's PJM interface pricing point are based on the MISO model's distribution factors of the selected buses to the binding M2M constraint and MISO's shadow price of the binding M2M constraint.

Prior to June 1, 2014, the PJM interface definition for MISO consisted of nine buses located near the middle of the MISO system and not at the border between the RTOs.[23] The interface definitions led to questions about the level of congestion included in interchange pricing.

PJM modified the definition of the PJM/MISO interface price effective June 1, 2014. PJM's new MISO interface pricing point includes 10 equally weighted buses that are close to the PJM/MISO border. The 10 buses were selected based on PJM's analysis that showed that over 80 percent of the hourly tie line flows between PJM and MISO occurred on 10 ties composed of MISO and PJM monitored facilities. On June 1, 2017, MISO modified their MISO/PJM interface definition to match PJM's PJM/MISO interface definition.

Real-Time and Day-Ahead PJM/MISO Interface Prices

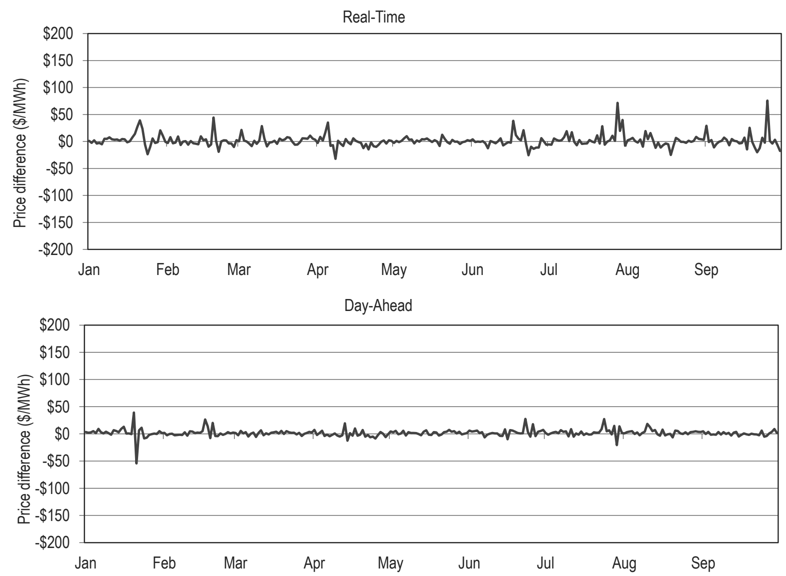
In the first nine months of 2025, the direction of flow was consistent with price differentials in 52.4 percent of the hours. Table 9-26 shows the number of hours and average hourly price differences between the PJM/MISO Interface and the MISO/PJM Interface based on LMP differences and flow direction. Table 9-26 shows that PJM was a net exporter of energy to MISO in all but 125 hours during the first nine months of 2025. The lack of response to relative prices on the PJM/MISO interface was consistent with the ongoing pattern that there are net exports from PJM to MISO in almost every hour, regardless of relative prices. In the first nine months of 2025, flows were in the uneconomic direction on the PJM/MISO interface in 47.6 percent of all hours. Figure 9-5 shows the underlying variability in prices calculated on a daily hourly average basis. There are a number of relevant measures of variability, including the number of times the price differential fluctuates between positive and negative, the standard deviation of individual prices and of price differences and the absolute value of the price differences (Table 9-30).

23 See "LMP Aggregate Definitions," (September 17, 2025) <https://www.pjm.com/-/media/DotCom/markets-ops/energy/lmp-model-info/lmp-aggregate-definitions.xlsx>. PJM periodically updates these definitions on its website. See <http://www.pjm.com>.

Table 9-26 PJM and MISO flow based hours and price differences: January through September, 2025

LMP Difference	Flow Direction	Number of Hours	Average Hourly Price Difference
MISO/PJM LMP > PJM/MISO LMP	Total Hours	3,418	$15.02
	Consistent Flow (PJM to MISO)	3,362	$14.96
	Inconsistent Flow (MISO to PJM)	56	$18.75
	No Flow	0	$0.00
PJM/MISO LMP > MISO/PJM LMP	Total Hours	3,133	$13.22
	Consistent Flow (MISO to PJM)	69	$13.27
	Inconsistent Flow (PJM to MISO)	3,064	$13.22
	No Flow	0	$0.00

Figure 9-5 Price differences (MISO/PJM Interface minus PJM/MISO Interface): January through September, 2025



Distribution and Prices of Hourly Flows at the PJM/MISO Interface

Almost without exception, power flows from PJM to MISO regardless of the direction of price differences. In the first nine months of 2025, the direction of hourly energy flows was consistent with PJM and MISO interface price differentials in 3,431 hours (52.4 percent of all hours), and was inconsistent with price differentials in 3,120 hours (47.6 percent of all hours). Table 9-27 shows the distribution of hourly energy flows between PJM and MISO based on the price differences between the PJM/MISO and MISO/PJM prices. Of the 3,120 hours where flows were in a direction inconsistent with price differences, 2,773 of those hours (88.9 percent) had a price difference greater than or equal to $1.00 and 1,745 of those hours (55.9 percent) had a price difference greater than or equal to $5.00. The largest price difference with such flows was $1,151.09. Of the 3,431 hours where flows were consistent with price differences, 3,022 of those hours (88.1 percent) had a price difference greater than or equal to $1.00 and 1,547 of all such hours (45.1 percent) had a price difference greater than or equal to $5.00. The largest price difference with such flows was $1,282.45.

Table 9-27 Distribution of hourly flows that are consistent and inconsistent with price differences between PJM and MISO: January through September, 2025

Price Difference Range (Greater Than or Equal To)	Inconsistent Hours	Percent of Inconsistent Hours	Consistent Hours	Percent of Consistent Hours
$0.00	3,120	100.0%	3,431	100.0%
$1.00	2,773	88.9%	3,022	88.1%
$5.00	1,745	55.9%	1,547	45.1%
$10.00	1,079	34.6%	871	25.4%
$15.00	724	23.2%	614	17.9%
$20.00	510	16.3%	452	13.2%
$25.00	373	12.0%	380	11.1%
$50.00	128	4.1%	187	5.5%
$75.00	64	2.1%	108	3.1%
$100.00	44	1.4%	74	2.2%
$200.00	9	0.3%	36	1.0%
$300.00	5	0.2%	17	0.5%
$400.00	4	0.1%	11	0.3%
$500.00	4	0.1%	10	0.3%

PJM and NYISO Interface Prices

If interface prices were defined in a comparable manner by PJM and the NYISO, if identical rules governed external transactions in PJM and the NYISO, if time lags were not built into the rules governing such transactions and if no risks were associated with such transactions, then prices at the interfaces would be expected to be very close and the level of transactions would be expected to be related to any price differentials. The fact that none of these conditions exists is important in explaining the observed relationship between interface prices and inter-RTO/ISO power flows, and those price differentials.[24]

PJM and NYISO each calculate an interface LMP using network models including distribution factor impacts. On May 1, 2017, PJM modified the PJM/NYIS interface price to be based on four buses within NYISO. The four buses were chosen based on a power flow analysis of transfers between PJM and the NYISO and the resultant distribution of flows across the free flowing A/C ties.

Prior to May 1, 2017, PJM's PJM/NYIS interface definition used two buses and included the impact of the ConEd wheeling agreement. The ConEd wheeling agreement ended on May 1, 2017. The end of the wheeling agreement meant that the expected actual power flows would change and therefore the definition of the interface price needed to change.

The NYISO uses proxy buses to calculate interface prices with neighboring balancing authorities. A proxy bus is a single bus, located outside the NYISO footprint, which represents generation and load in a neighboring balancing authority area. The NYISO models imports from PJM as generation at the Keystone proxy bus, delivered to the NYISO reference bus with the assumption that 32 percent of the flow will enter the NYISO across the free flowing A/C ties, 32 percent will enter the NYISO across the Ramapo PARs, 21 percent will enter the NYISO across the ABC PARs and 15 percent will enter the NYISO across the J/K PARs. The NYISO models exports to PJM as being delivered to load at the Keystone proxy bus, sourced from the NYISO reference bus with the assumption that 32 percent of the flow will enter PJM across the free flowing A/C ties, 32 percent will enter PJM across the Ramapo PARs, 21

24 See the *2012 Annual State of the Market Report for PJM*, Volume 2, Section 8, "Interchange Transactions," for a more detailed discussion.

percent will enter PJM across the ABC PARs and 15 percent will enter PJM across the J/K PARs.

Real-Time and Day-Ahead PJM/NYISO Interface Prices

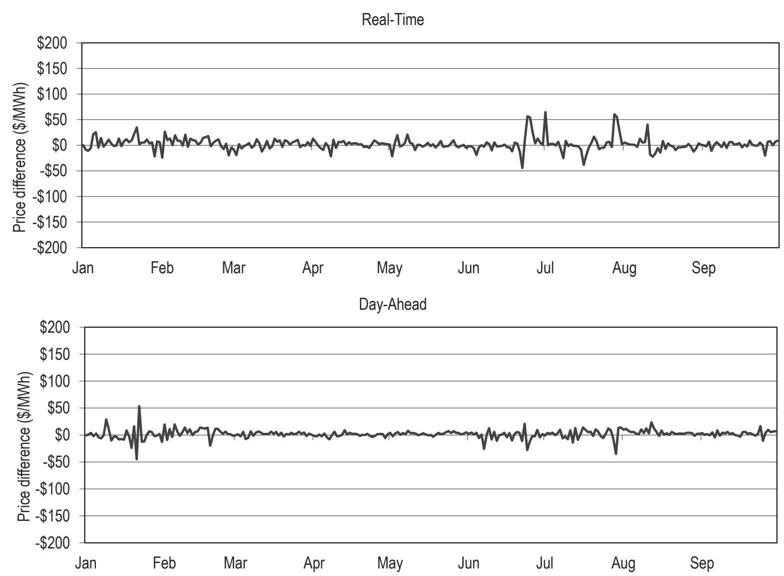
In the first nine months of 2025, the relationship between prices at the PJM/NYIS Interface and at the NYISO/PJM proxy bus and the relationship between interface price differentials and power flows continued to be affected by differences in institutional and operating practices between PJM and the NYISO. The direction of flow was consistent with price differentials in 59.2 percent of the hours in the first nine months of 2025. Table 9-28 shows the number of hours and average hourly price differences between the PJM/NYIS Interface and the NYIS/PJM proxy bus based on LMP differences and flow direction. Figure 9-6 shows the underlying variability in prices calculated on a daily hourly average basis. There are a number of relevant measures of variability, including the number of times the price differential fluctuates between positive and negative, the standard deviation of individual prices and of price differences and the absolute value of the price differences (Table 9-30).

Table 9-28 PJM and NYISO flow based hours and price differences: January through September, 2025[25]

LMP Difference	Flow Direction	Number of Hours	Average Hourly Price Difference
NYIS/PJM proxy bus LBMP > PJM/NYIS LMP	Total Hours	3,955	$16.45
	Consistent Flow (PJM to NYIS)	3,769	$14.47
	Inconsistent Flow (NYIS to PJM)	186	$56.49
	No Flow	0	$0.00
PJM/NYIS LMP > NYIS/PJM proxy bus LBMP	Total Hours	2,596	$19.13
	Consistent Flow (NYIS to PJM)	108	$45.06
	Inconsistent Flow (PJM to NYIS)	2,488	$18.01
	No Flow	0	$0.00

25 The NYISO Locational Based Marginal Price (LBMP) is the equivalent term to PJM's Locational Marginal Price (LMP).

Figure 9-6 Price differences (NY/PJM proxy - PJM/NYIS Interface): January through September, 2025



Distribution and Prices of Hourly Flows at the PJM/NYISO Interface

In the first nine months of 2025, the direction of hourly energy flows was consistent with PJM/NYISO and NYISO/PJM price differences in 3,877 hours (59.2 percent of all hours), and was inconsistent with price differences in 2,674 hours (40.8 percent of all hours). Table 9-29 shows the distribution of hourly energy flows between PJM and NYISO based on the price differences between the PJM/NYISO and NYISO/PJM prices. Of the 2,674 hours where flows were in a direction inconsistent with price differences, 2,456 of those hours (91.8 percent) had a price difference greater than or equal to $1.00 and 1,805 of all those hours (67.5 percent) had a price difference greater than or equal to $5.00. The largest price difference with such flows was $867.05. Of the 3,877 hours where flows were consistent with price differences, 3,646 of those hours (94.0 percent) had a price difference greater than or equal to $1.00 and 2,597 of all such hours (67.0 percent) had a price difference greater than or equal to $5.00. The largest price difference with such flows was $1,073.12.

Table 9-29 Distribution of hourly flows that are consistent and inconsistent with price differences between PJM and NYISO: January through September, 2025

Price Difference Range (Greater Than or Equal To)	Inconsistent Hours	Percent of Inconsistent Hours	Consistent Hours	Percent of Consistent Hours
$0.00	2,674	100.0%	3,877	100.0%
$1.00	2,456	91.8%	3,646	94.0%
$5.00	1,805	67.5%	2,597	67.0%
$10.00	1,245	46.6%	1,595	41.1%
$15.00	893	33.4%	1,016	26.2%
$20.00	678	25.4%	704	18.2%
$25.00	515	19.3%	553	14.3%
$50.00	209	7.8%	190	4.9%
$75.00	107	4.0%	87	2.2%
$100.00	70	2.6%	48	1.2%
$200.00	32	1.2%	14	0.4%
$300.00	20	0.7%	8	0.2%
$400.00	10	0.4%	6	0.2%
$500.00	5	0.2%	5	0.1%

Summary of Interface Prices between PJM and Organized Markets

Some measures of the real-time and day-ahead PJM interface pricing with MISO and with the NYISO are summarized and compared in Table 9-30, including average prices and measures of variability.

Table 9-30 PJM, NYISO and MISO border price averages: January through September, 2025[26]

		Real-Time		Day-Ahead	
	Description	NYISO	MISO	NYISO	MISO
Average Interval Price	PJM Price at ISO Border	$47.19	$38.04	$47.21	$38.54
	ISO Price at PJM Border	$49.61	$39.55	$49.15	$40.31
	Difference at Border (PJM-ISO)	($2.42)	($1.51)	($1.94)	($1.77)
	Average Absolute Value of Interval Difference at Border	$22.17	$18.68	$7.73	$6.21
	Sign Changes per Day	41.2	46.7	2.8	3.1
Standard Deviation	PJM Price at ISO Border	$68.54	$59.27	$34.66	$27.63
	ISO Price at PJM Border	$68.56	$80.39	$31.53	$26.65
	Difference at Border (PJM-ISO)	$69.40	$86.00	$12.64	$11.05

Neptune Underwater Transmission Line to Long Island, New York

The Neptune Line is a 65 mile direct current (DC) merchant 230 kV transmission line, with a capacity of 660 MW, providing a direct connection between PJM (Sayreville, New Jersey), and NYISO (Nassau County on Long Island). Schedule 14 of the PJM Open Access Transmission Tariff provides that power flows will only be from PJM to New York. The flows were consistent with price differentials in 81.5 percent of the hours in the first nine months of 2025. Table 9-31 shows the number of hours and average hourly price differences between the PJM/NEPT Interface and the NYIS/Neptune bus based on LMP differences and flow direction.

Table 9-31 PJM and NYISO flow based hours and price differences (Neptune): January through September, 2025

LMP Difference	Flow Direction	Number of Hours	Average Hourly Price Difference
NYIS/Neptune Bus LBMP > PJM/NEPT LMP	Total Hours	5,463	$31.17
	Consistent Flow (PJM to NYIS)	5,337	$31.54
	Inconsistent Flow (NYIS to PJM)	0	$0.00
	No Flow	126	$15.54
PJM/NEPT LMP > NYIS/Neptune Bus LBMP	Total Hours	1,088	$19.79
	Consistent Flow (NYIS to PJM)	0	$0.00
	Inconsistent Flow (PJM to NYIS)	1,065	$20.07
	No Flow	23	$6.81

26 Effective April 1, 2018, PJM implemented five minute LMP settlements in the real-time energy market. The sign changes per day represented in this table reflect the number of intervals where the sign changed per day. For the real-time energy market, there are 288 five minute intervals per day. For the day-ahead market there are 24 hourly intervals per day.

To move power from PJM to NYISO using the Neptune Line, two PJM transmission service reservations are required. A transmission service reservation is required from the PJM Transmission System to the Neptune HVDC Line (“Out Service”) and another transmission service reservation is required on the Neptune HVDC Line (“Neptune Service”).[27] The PJM Out Service is covered by normal PJM OASIS business operations.[28] The Neptune Service falls under the provisions for controllable merchant facilities, Schedule 14 of the PJM Tariff. The Neptune Service is also acquired on the PJM OASIS.

Neptune Service is owned by a primary rights holder, and any nonfirm service that is not used (as defined by a schedule on a NERC Tag) may be released either voluntarily by the primary rights holder or by default by PJM. The primary rights holder may elect to voluntarily release monthly, weekly, daily or hourly firm or nonfirm service. Voluntarily releasing the service allows for the primary rights holder to specify a rate to be charged for the released service. If the primary rights holder does not elect to voluntarily release nonfirm service, and does not use the service, the available transmission will be released by default at 12:00, one business day before the start of service. On September 30, 2025, the rate for the nonfirm service released by default was $10.00 per MWh. The primary rights holder remains obligated to pay for the released service unless a second transmission customer acquires the released service.

Table 9-32 shows the percent of scheduled interchange across the Neptune Line by the primary rights holder since commercial operations began in July 2007. Table 9-32 shows that in the first nine months of 2025, the primary rights holder was responsible for 100 percent of the scheduled interchange across the Neptune Line in January through May, and in July through September and the primary rights holder was responsible for less than 100 percent of the scheduled interchange across the Neptune Line in June. Figure 9-7 shows the hourly average flow across the Neptune Line for the first nine months of 2025.

Table 9-32 Percent of scheduled interchange across the Neptune Line by primary rights holder: July 2007 through September 2025

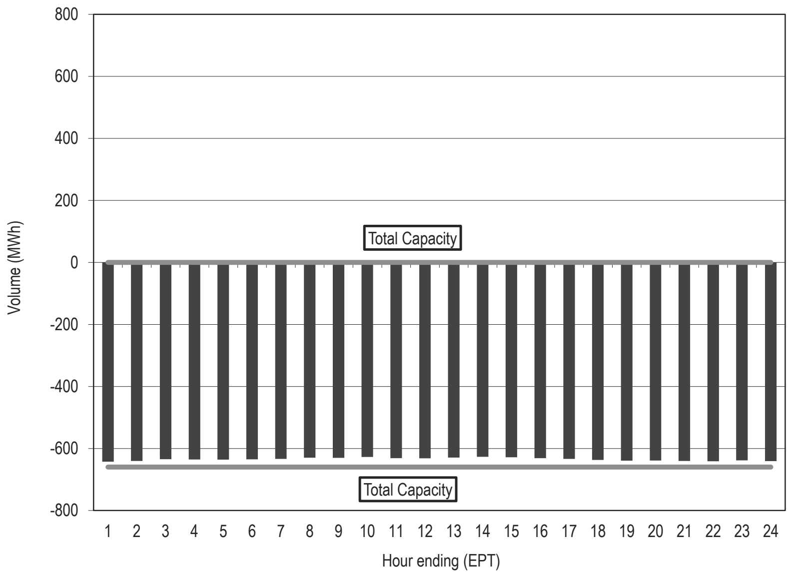
Figure 9-7 Neptune hourly average flow: January through September, 2025



Linden Variable Frequency Transformer (VFT) facility

The Linden VFT facility is a controllable AC merchant transmission facility, with a capacity of 315 MW, providing a direct connection between PJM (Linden, New Jersey) and NYISO (Staten Island, New York). The flows were consistent with price differentials in 80.3 percent of the hours in the first nine months of 2025. Table 9-33 shows the number of hours and average hourly price differences between the PJM/LIND Interface and the NYIS/Linden Bus based on LMP differences and flow direction.

Table 9-33 PJM and NYISO flow based hours and price differences (Linden): January through September, 2025

LMP Difference	Flow Direction	Number of Hours	Average Hourly Price Difference
NYIS/Linden Bus LBMP > PJM/LIND LMP	Total Hours	5,376	$26.86
	Consistent Flow (PJM to NYIS)	5,260	$26.92
	Inconsistent Flow (NYIS to PJM)	0	$0.00
	No Flow	116	$24.05
PJM/LIND LMP > NYIS/Linden Bus LBMP	Total Hours	1,175	$40.31
	Consistent Flow (NYIS to PJM)	0	$0.00
	Inconsistent Flow (PJM to NYIS)	1,166	$40.56
	No Flow	9	$7.82

To move power from PJM to NYISO on the Linden VFT Line, two PJM transmission service reservations are required. A transmission service reservation is required from the PJM Transmission System to the Linden VFT ("Out Service") and another transmission service reservation is required on the Linden VFT ("Linden VFT Service").[29] The PJM Out Service is covered by normal PJM OASIS business operations.[30] The Linden VFT Service falls under the provisions for controllable merchant facilities, Schedule 16 and Schedule 16-A of the PJM Tariff. The Linden VFT Service is also acquired on the PJM OASIS.

Linden VFT Service is owned by a primary rights holder, and any nonfirm service that is not used (as defined by a schedule on a NERC Tag) may be released either voluntarily by the primary rights holder or by default by PJM. The primary rights holder may elect to voluntarily release monthly, weekly, daily or hourly firm or nonfirm service. Voluntarily releasing the service allows for the primary rights holder to specify a rate to be charged for the released service. If the primary rights holder elects to not voluntarily release nonfirm service, and does not use the service, the available transmission will be released by default at 1200 (EPT), one business day before the start of service. On September 30, 2025, the rate for the nonfirm service released by default was $6.00 per MWh. The primary rights holder remains obligated to pay for the released service unless a second transmission customer acquires the released service.

29 See OASIS "PJM Business Practices for Linden VFT Transmission Service," (June 1, 2011) <https://www.pjm.com/-/media/DotCom/etools/oasis/merch-trans-facilities/linden-vft-oasis-business-practices-clean.pdf>.
30 See OASIS "Regional Transmission and Energy Scheduling Practices," Rev. 12 (July 26, 2023) <https://www.pjm.com/-/media/DotCom/etools/oasis/regional-practices-clean-pdf.pdf>.

Table 9-34 shows the percent of scheduled interchange across the Linden VFT Line by the primary rights holder since commercial operations began in November, 2009. Table 9-34 shows that in the first nine months of 2025, the primary rights holder was responsible for 100 percent of the scheduled interchange across the Linden VFT Line in all months. Figure 9-8 shows the hourly average flow across the Linden VFT Line for the first nine months of 2025.

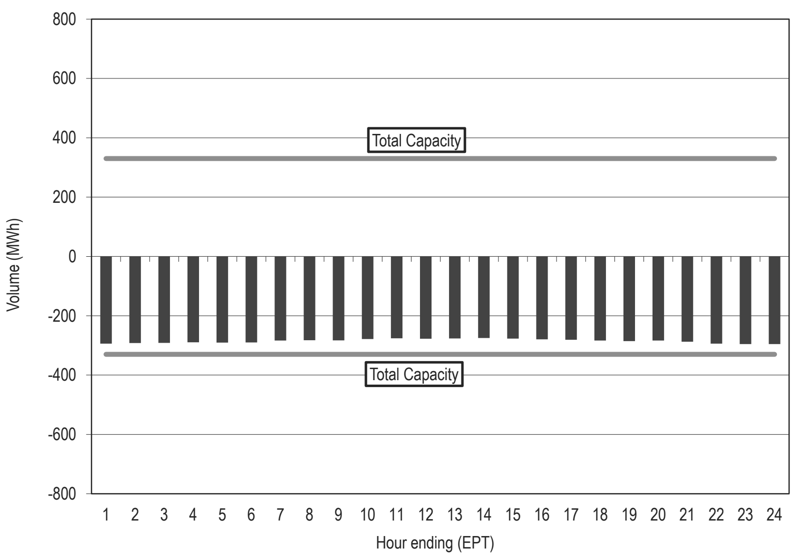
Figure 9-8 Linden hourly average flow: January through September, 2025[31]



31 The Linden VFT Line is a bidirectional facility. The "Total Capacity" lines represent the maximum amount of interchange possible in either direction. These lines were included to maintain a consistent scale, for comparison purposes, with the Neptune DC Tie Line.

Hudson Direct Current (DC) Merchant Transmission Line

The Hudson direct current (DC) Line is a bidirectional merchant 230 kV transmission line, with a capacity of 673 MW, providing a direct connection between PJM (Public Service Electric and Gas Company's (PSE&G) Bergen 230 kV Switching Station located in Ridgefield, New Jersey) and NYISO (Consolidated Edison's (Con Ed) W. 49th Street 345 kV Substation in New York City). The connection is a submarine cable system. While the Hudson DC Line is a bidirectional line, power flows are only from PJM to New York because the Hudson Transmission Partners, LLC had only requested withdrawal rights (320 MW of firm withdrawal rights, and 353 MW of nonfirm withdrawal rights). The flows were consistent with price differentials in 80.7 percent of the hours in the first nine months of 2025. Table 9-35 shows the number of hours and average hourly price differences between the PJM/HUDS Interface and the NYIS/Hudson bus based on LMP differences and flow direction.

Table 9-35 PJM and NYISO flow based hours and price differences (Hudson): January through September, 2025

LMP Difference	Flow Direction	Number of Hours	Average Hourly Price Difference
NYIS/Hudson Bus LBMP > PJM/HUDS LMP	Total Hours	5,490	$28.69
	Consistent Flow (PJM to NYIS)	5,289	$29.18
	Inconsistent Flow (NYIS to PJM)	0	$0.00
	No Flow	201	$15.89
PJM/HUDS LMP > NYIS/Hudson Bus LBMP	Total Hours	1,061	$22.32
	Consistent Flow (NYIS to PJM)	0	$0.00
	Inconsistent Flow (PJM to NYIS)	1,002	$23.09
	No Flow	59	$9.22

To move power from PJM to NYISO on the Hudson Line, two PJM transmission service reservations are required. A transmission service reservation is required from the PJM Transmission System to the Hudson Line ("Out Service") and another transmission service reservation is required on the Hudson Line ("Hudson Service").[32] The PJM Out Service is covered by normal PJM OASIS business operations.[33] The Hudson Service falls under the provisions for controllable merchant facilities, Schedule 17 of the PJM Tariff. The Hudson Service is also acquired on the PJM OASIS.

Hudson Service is owned by a primary rights holder, and any nonfirm service that is not used (as defined by scheduled on a NERC Tag) may be released either voluntarily by the primary rights holder or by default by PJM. The primary rights holder may elect to voluntarily release monthly, weekly, daily or hourly firm or nonfirm service. Voluntarily releasing the service allows for the primary rights holder to specify a rate to be charged for the released service. If the primary rights holder elects to not voluntarily release nonfirm service, and does not use the service, the available transmission will be released by default at 1200 (EPT), one business day before the start of service. On September 30, 2025, the rate for the nonfirm service released by default was $10.00 per MWh. The primary rights holder remains obligated to pay for the released service unless a second transmission customer acquires the released service.

32 See OASIS "PJM Business Practices for Hudson Transmission Service,"<https://www.pjm.com/-/media/DotCom/etools/oasis/merch-trans-facilities/hudson-oasis-business-practices-clean.pdf>.
33 See OASIS "Regional Transmission and Energy Scheduling Practices," Rev. 12 (July 26, 2023) <https://www.pjm.com/-/media/DotCom/etools/oasis/regional-practices-clean-pdf.pdf>.

Table 9-36 shows the percent of scheduled interchange across the Hudson Line by the primary rights holder since commercial operations began in May, 2013. Table 9-36 shows that in the first nine months of 2025, the primary rights holder was responsible for 100 percent of the scheduled interchange across the Hudson Line in all months. Figure 9-9 shows the hourly average flow across the Hudson Line for the first nine months of 2025.

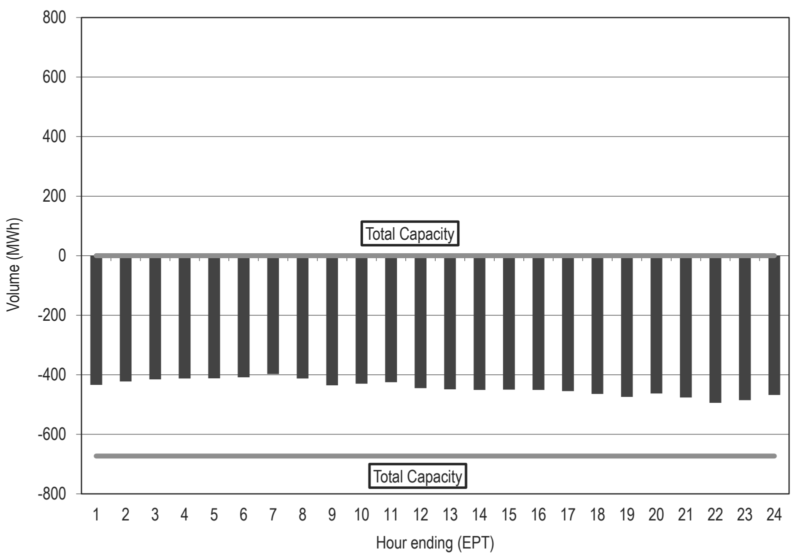
Figure 9-9 Hudson hourly average flow: January through September, 2025



34 The designation of "NA" means there was no flow on the Hudson Line during those months.

Interchange Activity During High Load Hours

The PJM metered system peak load during the first nine months of 2025 was 156,256 MW in the HE 1700 (EPT) on June 23, 2025. PJM was a net scheduled exporter of energy in all 24 hours on June 23, 2025, with average hourly scheduled exports of 3,360 MW. During HE 1700 on June 23, 2025, PJM had net scheduled exports of 2,296 MW and net metered actual exports of 2,158 MW. Net transaction exports during 1700 were consistent with price differences between the PJM/NEPT Interface and the NYIS/Neptune bus, the PJM/LIND Interface and the NYIS/Linden Bus and the PJM/HUDS Interface and the NYIS/Hudson Bus. Net transaction exports were inconsistent with price differences between PJM and MISO. Net transaction imports were consistent with price differences between PJM and the NYISO. During June 2025, PJM was a net scheduled exporter of energy in 718 of the 720 hours (99.7 percent of the hours). During June 2025, the average hourly scheduled interchange was -5,003 MW (representing 5.0 percent of the average hourly load of 99,752 MW in June 2025).

Operating Agreements with Bordering Areas

To improve reliability and reduce potential seams issues, PJM and its neighbors have developed operating agreements, including: operating agreements with MISO and the NYISO; a reliability agreement with TVA, LG&E and KU; an operating agreement with Duke Energy Progress, Inc.; a reliability coordination agreement with VACAR South; a balancing authority operations agreement with the Wisconsin Electric Power Company (WEC); and a Northeastern planning coordination protocol with NYISO and ISO New England.

Table 9-37 shows a summary of the elements included in each of the operating agreements PJM has with its bordering areas.

PJM and MISO Joint Operating Agreement[35]

The Joint Operating Agreement between MISO and PJM Interconnection, L.L.C. was executed on December 31, 2003. The PJM/MISO JOA includes provisions for congestion management that, for designated flowgates within MISO and PJM, allows for redispatch of units within the PJM and MISO regions to jointly manage congestion on these flowgates and to assign the costs of congestion management. This process was designed to address the impacts of market flows which are the loop flows on MISO's system created by PJM generators serving PJM load and vice versa. In 2012, MISO and PJM initiated a joint stakeholder process to address issues associated with the operation of the markets at the seam.[36]

Under the market to market rules, the organizations coordinate pricing at their borders. PJM and MISO each calculate an interface LMP using network models including distribution factor impacts. PJM uses 10 buses along the PJM/MISO border to calculate the PJM/MISO interface pricing point LMP. Prior to June

35 See "Joint Operating Agreement Between the Midwest Independent Transmission System Operator, Inc. and PJM Interconnection, L.L.C.," (December 11, 2008) <https://www.pjm.com/directory/merged-tariffs/miso-joa.pdf>.
36 See "PJM/MISO Joint and Common Market Initiative," <https://www.pjm.com/committees-and-groups/stakeholder-meetings/pjm-miso-joint-common>.

1, 2017, MISO used all of the PJM generator buses in its model of the PJM system in its calculation of the MISO/PJM interface pricing point.[37] On June 1, 2017, MISO modified their MISO/PJM interface definition to match PJM's PJM/MISO interface definition.

Coordinated flowgates are identified to determine which flowgates the market flows from PJM or MISO affect significantly. This set of flowgates may then be used in the congestion management process. PJM and MISO will conduct sensitivity studies to determine which flowgates are significantly affected by the market flows of the operating entity's control zones (historic control areas that existed in the IDC). There are five studies to determine which flowgates the operating entity will monitor and help control. These studies include generation to load distribution factor studies, transfer distribution factor analysis and an external asynchronous resource study. PJM or MISO may also specify additional flowgates that have not passed any of the five studies to be coordinated flowgates where the operating entity expects to use the TLR process to manage congestion. A reciprocal coordinated flowgate (RCF) is a CF that is monitored and controlled by PJM or MISO, on which both have significant impacts. Only RCFs are subject to the market to market congestion management process.[38]

As of January 1, 2025, PJM had 208 flowgates eligible for M2M (Market to Market) coordination. In the first nine months of 2025, PJM added 16 flowgates and deleted 93 flowgates, resulting in 131 flowgates eligible for M2M coordination as of September 30, 2025. As of January 1, 2025, MISO had 222 flowgates eligible for M2M coordination. In the first nine months of 2025, MISO added 30 flowgates and deleted 62 flowgates, resulting in 190 flowgates eligible for M2M coordination as of September 30, 2025.

The firm flow entitlement (FFE) represents the amount of historic 2004 market flows that each RTO had created on each RCF used in the market to market settlement process. The FFE establishes the amount of market flow that each RTO is permitted to create on the RCF before incurring redispatch costs during the market to market process. If the nonmonitoring RTO's real-time market flow is greater than their FFE plus the approved MW adjustment from day-ahead coordination, then the nonmonitoring RTO will pay the monitoring RTO the difference between their market flow and their FFE times the monitoring RTO's shadow price of the RCF. The shadow price is the incremental cost of dispatching marginal generation resources to relieve congestion on the RCF. If the nonmonitoring RTO's real-time market flow is less than their FFE plus the approved MW adjustment from day-ahead coordination, then the monitoring RTO will pay the nonmonitoring RTO for congestion relief provided by the nonmonitoring RTO. This payment is the difference between the nonmonitoring RTO's market flow and their FFE times the monitoring RTO's shadow price of the RCF.

April 1, 2004, known as the freeze date, is used to determine the firm rights on flowgates based on historic firm market flows that occurred prior to the implementation of M2M coordination. In the 21 years since 2004, significant topology and market changes have occurred, making the 2004 market flows irrelevant in 2025. The RTOs and stakeholders recognize that a modification to the definition of firm rights on flowgates is necessary. PJM and MISO stakeholders have spent years on the freeze date issues. No resolution to these issues appears imminent. The status quo results in significant payments by PJM customers to MISO customers. The final resolution should account for the investments made by each RTO in the transmission system. The final resolution should reflect current interchange patterns. In 2004, PJM was primarily an importer of energy from MISO. In 2025, as it has been since about 2010, PJM is primarily an exporter of energy to MISO.

The MMU recommends eliminating the mechanism that defines FFE and M2M payments. These mechanisms are not consistent with markets and are not needed for efficient interface pricing. PJM and MISO have demonstrated a longstanding failure to resolve the definition of firm rights on flowgates and related issues. The MMU recommends that PJM file with the Commission to eliminate the FFE calculation and M2M payment of the PJM and MISO joint operating agreement.

The original logic of FFEs was not clear, the calculation of FFEs was not clear, and the measurement of market flows was and is imprecise at best. It does not

37 See the *2012 Annual State of the Market Report for PJM*, Volume 2, Section 8, "Interchange Transactions," for a more detailed discussion.
38 See "Joint Operating Agreement Between the Midwest Independent Transmission System Operator, Inc. and PJM Interconnection, L.L.C.," (December 11, 2008) <https://www.pjm.com/directory/merged-tariffs/miso-joa.pdf>.

make sense to use outdated and meaningless FFEs from 2004. If current FFEs are used based on actual current power flows, the role of FFEs is not clear. Fully dynamic FFEs are equivalent to eliminating FFEs while continuing to price power flows at the correct shadow price.

The solution to the FFE and M2M issue is to eliminate FFEs. Elimination of FFEs, while maintaining the exchange of shadow price information and cooperative dispatch, would keep the benefits of efficient constraint resolution between PJM and MISO.

In the first nine months of 2025, market to market operations resulted in MISO and PJM redispatching units to control congestion on M2M flowgates and the exchange of payments for this redispatch. Table 9-38 shows credits for coordinated congestion management between PJM and MISO. In the first nine months of 2025, MISO payments to PJM were $7.6 million, and PJM payments to MISO were $63.8 million, for a net payment from PJM to MISO of $56.2 million. The large settlements in 2022 were due to the large amount of congestion and high LMPs observed in December during Winter Storm Elliott.

Table 9-38 PJM/MISO credits for coordinated congestion management: April 2005 through September 2025[39]

Year	Payments from PJM to MISO	Payments from MISO to PJM	Net Payment from PJM to MISO
2005	$25,068,903	$3,411,188	$21,657,715
2006	$18,664,630	$21,381,460	($2,716,830)
2007	$29,917,241	$17,774,637	$12,142,604
2008	$60,615,478	$15,417,040	$45,198,438
2009	$48,101,017	$10,632,885	$37,468,132
2010	$56,330,068	$20,558,982	$35,771,087
2011	$87,113,498	$9,445,949	$77,667,550
2012	$56,227,681	$7,602,112	$48,625,569
2013	$32,589,519	$14,733,770	$17,855,748
2014	$62,572,610	$19,263,896	$43,308,713
2015	$49,379,823	$11,266,866	$38,112,957
2016	$50,628,816	$9,826,347	$40,802,469
2017	$69,812,858	$16,698,276	$53,114,581
2018	$110,501,078	$10,400,122	$100,100,956
2019	$44,391,547	$7,886,392	$36,505,155
2020	$53,038,595	$7,985,027	$45,053,568
2021	$45,704,128	$18,792,183	$26,911,945
2022	$191,716,652	$8,560,992	$183,155,660
2023	$63,976,499	$5,467,435	$58,509,064
2024	$58,627,460	$17,671,566	$40,955,894
2025 (Jan)	$16,303,017	$0	$16,303,017
2025 (Feb)	$7,040,650	$272,322	$6,768,328
2025 (Mar)	$11,328,210	$149,429	$11,178,782
2025 (Apr)	$12,140,633	$385,758	$11,754,874
2025 (May)	$4,122,837	$69,789	$4,053,049
2025 (Jun)	$3,117,356	$2,614,125	$503,231
2025 (Jul)	$2,314,333	$1,332,336	$981,997
2025 (Aug)	$1,036,764	$2,428,997	($1,392,233)
2025 (Sep)	$6,406,708	$369,613	$6,037,094
2025	$63,810,508	$7,622,368	$56,188,140

39 The totals represented in this figure represent the settlements as of the time of this report and may not include adjustments or resettlements.

PJM and New York Independent System Operator Joint Operating Agreement (JOA)[40]

The Joint Operating Agreement between NYISO and PJM Interconnection, L.L.C. became effective on January 15, 2013. Under the market to market rules, the organizations coordinate pricing at their borders. Unlike the PJM/MISO JOA where firm flow entitlements are based on a freeze date, the PJM/NYISO JOA requires that each party calculates an M2M entitlement on each M2M flowgate and compare results at least once a year. This annual coordination of entitlements ensures that the impact of upgrades on both systems are incorporated into the M2M calculation. PJM and NYISO may mutually agree to not recalculate entitlements in a given year.

On June 28, 2019, NYISO and PJM submitted revisions to the NYISO-PJM Joint Operating Agreement (JOA). The revisions addressed RTO concerns identified in their joint request for limited waiver of the JOA to authorize redispatch of generation in PJM. The intent of the redispatch is to mitigate post-contingency overloads of transmission equipment on the New York side of the East Towanda-Hillside 230 kV Transmission Line. The agreement allows the RTOs to control for this contingency without the exchange of payments for redispatch.[41]

In the first nine months of 2025, market to market operations did not result in NYISO and PJM redispatching units to control congestion on M2M flowgates. Therefore, there was no exchange of payments for redispatch in the first nine months of 2025. Table 9-39 shows credits for coordinated congestion management between PJM and NYISO.

40 See "New York Independent System Operator, Inc., Joint Operating Agreement with PJM Interconnection, L.L.C.," (September 16, 2019) <https://www.pjm.com/~/media/DotCom/documents/agreements/nyiso-joa.ashx>.
41 See NYISO Filing, FERC Docket No. ER19-2282-000 (June 28, 2019).

Table 9-39 PJM/NYISO credits for coordinated congestion management (flowgates): January 2013 through September 2025[42]

Year	Payments from PJM to NYISO	Payments from NYISO to PJM	Net Payment from PJM to NYISO
2013	$119,121	$0	$119,121
2014	$58,631	$1,005	$57,626
2015	$242,488	$5,063	$237,425
2016	$632,768	$50,550	$582,219
2017	$422,304	$895	$421,409
2018	$0	$0	$0

2025 (Feb)	$0	$0	$0
2025 (Mar)	$0	$0	$0
2025 (Apr)	$0	$0	$0
2025 (May)	$0	$0	$0
2025 (Jun)	$0	$0	$0
2025 (Jul)	$0	$0	$0
2025 (Aug)	$0	$0	$0
2025 (Sep)	$0	$0	$0
2025	$0	$0	$0

The M2M coordination process focuses on real-time market coordination to manage transmission limitations that occur on M2M flowgates in a cost effective manner. Coordination between NYISO and PJM includes not only joint redispatch, but also incorporates coordinated operation of the PARs that are located at the PJM/NYIS border. This real-time coordination results in an efficient economic dispatch solution across both markets to manage the real-time transmission constraints that affect both markets, focusing on the actual flows in real time to manage constraints.[43] For each M2M flowgate, a PAR settlement will occur for each interval during coordinated operations. The PAR settlements are determined based on whether the measured real-time flow on each of the PARs is greater than or less than the calculated target value. If the actual flow is greater than the target flow, NYISO will make a payment to PJM.

42 The totals represented in this figure represent the settlements as of the time of this report and may not include adjustments or resettlements.
43 See "New York Independent System Operator, Inc., Joint Operating Agreement with PJM Interconnection, L.L.C.," (September 16, 2019) <https://www.pjm.com/~/media/DotCom/documents/agreements/nyiso-joa.ashx>.

This payment is calculated as the product of the M2M flowgate shadow price, the PAR shift factor and the difference between the actual and target PAR flow. If the actual flow is less than the target flow, PJM will make a payment to NYISO. This payment is calculated as the product of the M2M flowgate shadow price, the PAR shift factor and the difference between the target and actual PAR flow. Effective May 1, 2017, coincident with the termination of the ConEd wheel, PJM and NYISO began M2M coordination at all of the PARs along the PJM/NYISO seam. Prior to May 1, 2017, only the Ramapo PARs were included in the M2M process. In the first nine months of 2025, market to market operations resulted in NYISO and PJM adjusting PARs to control congestion and the exchange of payments for this coordination. In the first nine months of 2025, PJM payments to NYISO were $2.6 million, and NYISO payments to PJM were $3.2 million, for a net payment from NYISO to PJM of $565,570. Table 9-40 shows the PAR credits for coordinated congestion management between PJM and NYISO.

Table 9-40 PJM/NYISO credits for coordinated congestion management (PARs): January 2013 through September 2025[44]

Year	Payments from PJM to NYISO	Payments from NYISO to PJM	Net Payment from PJM to NYISO
2013	$7,403,255	$0	$7,403,255
2014	$5,723,571	$0	$5,723,571
2015	$4,691,302	$0	$4,691,302
2016	$617,733	$0	$617,733
2017	$2,328,763	$2,115,126	$213,637
2018	$3,327,747	$2,407,667	$920,081
2019	$3,341,615	$2,923,715	$417,900
2020	$3,004,543	$2,048,317	$956,226
2021	$8,911,160	$6,751,890	$2,159,270
2022	$21,128,605	$13,611,434	$7,517,171
2023	$1,755,207	$2,208,388	($453,181)
2024	$376,435	$1,227,033	($850,597)
2025 (Jan)	$1,057,106	$1,751,095	($693,989)
2025 (Feb)	$193,284	$427,199	($233,915)
2025 (Mar)	$178,336	$339,994	($161,657)
2025 (Apr)	$2,290	$1,203	$1,087
2025 (May)	$3,690	$985	$2,705
2025 (Jun)	$656,570	$344,867	$311,702
2025 (Jul)	$543,293	$149,277	$394,016
2025 (Aug)	$12,092	$148,239	($136,148)
2025 (Sep)	$28,036	$77,407	($49,371)
2025	$2,674,697	$3,240,267	($565,570)

44 The totals in this figure are from the settlements at the time of this report and may change based on later adjustments or resettlements.

PJM and TVA/LG&E and KU Joint Reliability Coordination Agreement (JRCA)[45]

The joint reliability coordination agreement (JRCA) executed on April 22, 2005, provides for the exchange of information and the implementation of reliability and efficiency protocols between TVA and PJM. The agreement also provides for the management of congestion and arrangements for both near-term and long-term system coordination. Under the JRCA, PJM and TVA honor constraints on the other's flowgates in their Available Transmission Capability (ATC) calculations. Market flows are calculated on reciprocal flowgates. When a constraint occurs on a reciprocal flowgate within TVA, PJM has the option to redispatch generation to reduce market flow, and therefore alleviate the constraint. Unlike the M2M procedure between MISO and PJM, this redispatch does not result in M2M payments. However, electing to redispatch generation within PJM can avoid potential market disruption by curtailing transactions under the Transmission Line Loading Relief (TLR) procedure to achieve the same relief. In 2022, PJM and TVA began discussions to add Louisville Gas and Electric Company (LG&E) and Kentucky Utilities (KU) as parties to the JRCA. The revisions to add LG&E and KU to the agreement were filed with the Commission on June 6, 2023.[46] On August 5, 2023, the Commission approved the filing.[47] The agreement remained in effect in the first nine months of 2025.

PJM and Duke Energy Progress, Inc. Joint Operating Agreement[48]

On September 9, 2005, FERC approved a JOA between PJM and Progress Energy Carolinas, Inc. (PEC), with an effective date of July 30, 2005. As part of this agreement, both parties agreed to develop a formal congestion management protocol (CMP). On February 2, 2010, PJM and PEC filed a revision to include a CMP under Article 14 of the JOA.[49] On January 20, 2011, the Commission conditionally accepted the compliance filing. On July 2, 2012, Duke Energy and Progress Energy Inc. completed a merger. At that time, Progress Energy

47 See *PJM Interconnection, L.L.C*, Docket No. ER23-2078-000 (August 5, 2023).
48 See "Amended and Restated Joint Operating Agreement Among and Between PJM Interconnection, L.L.C., and Duke Energy Progress Inc.," (July 22, 2019) <https://www.pjm.com/directory/merged-tariffs/progress-joa.pdf>.
49 See *PJM Interconnection, L.L.C and Progress Energy Carolinas, Inc.* Docket No. ER10-713-000 (February 2, 2010).

Carolinas Inc., now a subsidiary of Duke Energy, changed its name to Duke Energy Progress (DEP).

On May 20, 2019, PJM and DEP submitted revisions to the JOA to delete Article 14.[50] PJM and DEP requested an effective date of July 22, 2019, for the filed revisions. On July 2, 2019, the Commission issued a letter order accepting the revisions to the JOA to delete the congestion management agreement effective July 22, 2019.[51]

PJM and VACAR South Reliability Coordination Agreement[52]

On May 23, 2007, PJM and VACAR South (comprised of Duke Energy Carolinas, LLC (DUK), DEP, South Carolina Public Service Authority (SCPSA), Southeast Power Administration (SEPA), South Carolina Energy and Gas Company (SCE&G) and Yadkin Inc. (part of Alcoa)) entered into a reliability coordination agreement which provides for system and outage coordination, emergency procedures and the exchange of data. The parties meet on a yearly basis. The agreement remained in effect in the first nine months of 2025.

Balancing Authority Operations Coordination Agreement between Wisconsin Electric Power Company (WEC) and PJM Interconnection, LLC[53]

The Balancing Authority Operations Coordination Agreement executed on July 20, 2013, provides for the exchange of information between WEC and PJM. The purpose of the data exchange is to allow for the coordination of balancing authority actions to ensure the reliable operation of the systems. The agreement remained in effect in the first nine months of 2025.

50 See *PJM Interconnection, L.L.C*, Docket No. ER19-1905-000 (May 20, 2019).
51 FERC Docket No. ER19-1905-000.

53 See "Balancing Authority Operations Coordination Agreement between Wisconsin Electric Power Company and PJM Interconnection, L.L.C.," (July 20, 2013) <https://www.pjm.com/directory/merged-tariffs/rs43.pdf>.

Northeastern ISO-Regional Transmission Organization Planning Coordination Protocol[54]

The Northeastern ISO-RTO Planning Coordination Protocol executed on December 8, 2004, provides for the exchange of information among PJM, NYISO and ISO New England. The purpose of the data exchange is to allow for the long-term planning coordination among and between the ISOs and RTOs in the Northeast. The agreement remained in effect in the first nine months of 2025.

Interchange Transaction Issues

PJM Transmission Loading Relief Procedures (TLRs)

TLRs are called to control flows on electrical facilities when economic redispatch cannot solve overloads on those facilities. TLRs are called to control flows related to external balancing authorities, loop flows for example, as redispatch within an LMP market can generally resolve overloads on internal transmission facilities.

The number of PJM issued TLRs of level 3a or higher increased from zero in the first nine months of 2024 to two in the first nine months of 2025. The number of different flowgates for which PJM declared a TLR 3a was zero in the first nine months of 2024, and two in the first nine months of 2025. The total MWh of transaction curtailments was zero in the first nine months of 2024, and 5,646 MWh in the first nine months of 2025.[55]

The number of MISO issued TLRs of level 3a or higher increased from 17 in the first nine months of 2024 to 22 in the first nine months of 2025. The number of different flowgates for which MISO declared a TLR 3a was 13 in the first nine months of 2024, and 12 in the first nine months of 2025. The total MWh of transaction curtailments decreased by 4.5 percent from 13,048 MWh in the first nine months of 2024 to 12,462 MWh in the first nine months of 2025.

54 See "Northeastern ISO/RTO Planning Coordination Protocol," (December 8, 2004) <https://www.pjm.com/-/media/DotCom/documents/agreements/NE_Protocol.ashx>.
55 TLR Level 3a is the first level of TLR that results in the curtailment of transactions. See the *2020 Annual State of the Market Report for PJM*, Appendix E, "Interchange Transactions," for a more complete discussion of TLR levels.

The number of NYISO issued TLRs of level 3a or higher decreased from two in the first nine months of 2024 to zero in the first nine months of 2025. The number of different flowgates for which NYISO declared a TLR 3a or higher was one in the first nine months of 2024, and zero in the first nine months of 2025. The total MWh of transaction curtailments was from 11,597 MWh in the first nine months of 2024, and zero MWh in the first nine months of 2025.

Table 9-41 PJM, MISO, and NYISO TLR procedures: January through September, 2025[56]

	VACS	2	8	0	0	0	0	10
Total		185	264	0	18	26	0	493

56 The total row in the columns of the number of unique flowgates that experience TLRs are not a sum of the individual months. The total row represents the number of unique flowgates that have experienced TLRs for the year to date.
57 Southern Company Services, Inc. (SOCO) is the reliability coordinator covering a portion of Mississippi, Alabama, Florida and Georgia. Southwest Power Pool (SWPP) is the reliability coordinator for SPP. VACAR-South (VACS) is the reliability coordinator covering a portion of North Carolina and South Carolina.

Up To Congestion Transactions

The original purpose, in 2000, of up to congestion transactions (UTC) was to allow market participants to submit a maximum congestion charge, up to $25 per MWh, they were willing to pay on an import, export or wheel through transaction in the day-ahead energy market. This product was offered as a tool for market participants to limit their congestion exposure on scheduled transactions in the real-time energy market.[58]

Up to congestion transactions affect the day-ahead dispatch and unit commitment. Despite that, up to congestion transactions were not required to pay uplift charges from their introduction in 2000 through October 31, 2020. On July 16, 2020, FERC issued an Order directing PJM to revise uplift allocation rules to allocate uplift to one side of up to congestion transactions.[59] The Order requires PJM to treat an up to congestion transaction, for uplift allocation purposes, as if the up to congestion transaction were equivalent to a DEC at its sink point. On November 1, 2020, PJM began allocating uplift to up to congestion transactions. Up to congestion transactions also negatively affect FTR funding.[60]

Figure 9-10 shows the monthly volume of cleared up to congestion transactions. Following an initial decline, UTC volumes had steadily increased following the allocation of uplift charges to UTCs effective November 1, 2020. However, the volume of cleared UTC transactions has declined again in the recent 12 month period to levels below what was seen prior to the allocation of uplift charges to UTCs. Table 9-43 shows the UTC volumes from the 12 month period prior to the allocation of uplift charges (November 1, 2019, through October 31, 2020), to the most recent 12 month period (October 1, 2024 through September 30, 2025). Table 9-44 shows the UTC volumes for the first nine months of 2024 and 2025.

58 See the *2012 Annual State of the Market Report for PJM*, Volume 2, Section 8, "Interchange Transactions," for a more detailed discussion.
59 172 FERC ¶ 61,046 (2020).
60 See the *2025 Quarterly State of the Market Report for PJM: January through September*, Section 13: FTRs and ARRs, "FTR Forfeitures" for more information on up to congestion transaction impacts on FTRs.

Table 9-44 Up to congestion volumes: January through September, 2024 and 2025

Category	2024 (Jan-Sep)	2025 (Jan-Sep)	Percent Change
Daily Average UTC Bids Submitted	36,083	48,979	35.7%
Daily Average UTC Bids Cleared	16,374	17,795	8.7%
Daily Average UTC Volume Submitted (MWh)	747,595	737,144	(1.4%)
Daily Average UTC Volume Cleared (MWh)	264,091	237,417	(10.1%)

Table 9-45 shows the monthly cleared submitted volume of UTC bids from January 2024 through September 2025. In the first nine months of 2025, the cleared MW volume of up to congestion transactions was comprised of 7.6 percent imports, 5.8 percent exports, 1.6 percent wheeling transactions and 85.0 percent internal transactions. Less than 0.1 percent of the up to congestion transactions had matching real-time energy market transactions.

Sham Scheduling

Sham scheduling refers to a scheduling method under which a market participant breaks a single transaction, from generation balancing authority (source) to load balancing authority (sink), into multiple segments. Sham scheduling hides the actual source of generation from the load balancing authority. When unable to identify the source of the energy, the load balancing authority cannot see how the power will flow to the load, which can create loop flows and result in inaccurate pricing for transactions.

For example, if the generation balancing authority (source) is NYISO, and the load balancing authority (sink) is PJM, the transaction would be priced, in the PJM energy market, at the PJM/NYIS Interface regardless of the submitted path. However, if a market participant were to break the transaction into multiple segments, one on the NYIS-ONT path, and a second segment on the ONT-MISO-PJM path, the market participant would conceal the true source (NYISO) from PJM, and PJM would price the transaction as if its source were Ontario (the ONT interface price).

Sham scheduling can also be achieved by submitting a transaction that is in the opposite direction of a portion of a larger transaction schedule.

For example, market participants can submit one transaction with multiple segments among balancing authorities and another transaction which offsets all or part of a segment of the first transaction. If a market participant submits two separate transactions, one on the ONT-MISO-PJM path, and a second on the PJM-MISO path, the result of these transactions would be a net scheduled transaction from ONT to MISO, as the MISO-PJM segment of the first transaction is offset by the PJM-MISO transaction. In this example, PJM is not required to raise or lower generation as a result of these transactions, as they would for an import or an export, and there are no associated power flows across PJM. Nonetheless, the market participant is paid the price difference between the PJM/ONT interface pricing point and the PJM/MISO interface pricing point. The market participant would be paid the PJM/ONT interface pricing point for the first transaction (ONT to PJM import) and the market participant would pay the PJM/MISO interface pricing point for the second transaction (PJM to MISO export). If the PJM/ONT interface price were higher than the PJM/MISO interface price, the market participant would be paid a net profit from the PJM market even though there was no impact on PJM operations.

At the April 10, 2013, PJM Market Implementation Committee (MIC), the MMU presented a problem statement and issue charge to address sham scheduling activities.[61] The expected deliverables from the stakeholder meetings were revisions to the Tariff and PJM business manuals. The topic was discussed at several MIC meetings. While there was stakeholder agreement that sham scheduling activity was inappropriate, consensus on revised tariff and manual language was not achieved. The topic was closed. The MMU clarified that it would continue to monitor transactions for sham scheduling activities and that the MMU could refer market participants for sham scheduling activities.

The MMU monitors for sham scheduling activities on a daily basis. Following the stakeholder discussions in 2013, the net profits obtained from sham scheduling activities fell by 104.9 percent, from net profits of $15.5 million in 2014, to a net loss of $761,012 in 2024. The total number of hours of sham scheduling segments where the MW profile matched exactly across all segments of the path combinations in the same hour fell by 86.6 percent, from 1,898 hours in 2014 to 254 hours in 2024.

The MMU recommends that PJM implement rules to prevent sham scheduling. The MMU recommends that PJM apply after the fact market settlement adjustments to identified sham scheduling segments to ensure that market participants cannot benefit from sham scheduling.

Elimination of Ontario Interface Pricing Point

The PJM/IMO interface pricing point (Ontario) was created to reflect the fact that transactions that originate or sink in the IESO balancing authority create actual energy flows that are split between the MISO and NYISO interface pricing points. PJM created the PJM/IMO interface pricing point to reflect the

61 *See* Market Path/Interface Pricing Point alignment Problem Statement, at: <http://www.monitoringanalytics.com/reports/Presentations/2013/IMM_MIC_Market_Path_Interface_Pricing_Point_Alignment_Problem_Statement_201304010.pdf>.

actual power flows across both the MISO/PJM and NYISO/PJM Interfaces. The IMO does not have physical ties with PJM because it is not contiguous.

Prior to June 1, 2015, the PJM/IMO interface pricing point was defined as the LMP at the IESO Bruce bus. The LMP at the Bruce bus includes a congestion and loss component across the MISO and NYISO balancing authorities.

The noncontiguous nature of the PJM/IMO interface pricing point creates opportunities for market participants to engage in sham scheduling activities.[62] For example, a market participant can use two separate transactions to create a flow from Ontario to MISO. In this example, the market participant uses the PJM energy market as a temporary generation and load point by first submitting a wheeling transaction from Ontario, through MISO and into PJM, then by submitting a second transaction from PJM to MISO. These two transactions, combined, create an actual flow along the Ontario/MISO Interface. Through sham scheduling, the market participant receives settlements from PJM when no changes in generation occur. This activity is similar to that observed when PJM had a Southwest and Southeast interface pricing point. During that time, market participants would use the PJM spot market as a temporary load and generation point to wheel transactions through the PJM energy market. This was done to take advantage of the price differences between the interfaces without providing the market benefits of congestion relief.

A new PJM/IMO interface price method was implemented on June 1, 2015. The new method uses a dynamic weighting of the PJM/MISO interface price and the PJM/NYIS interface price, based on the performance of the Michigan-Ontario PARs. When the absolute value of the actual flows on the PARs are greater than or equal to the absolute value of the scheduled flows on the PARs, and the scheduled and actual flows are in the same direction, the PJM/IMO interface price will be equal to the PJM/MISO interface price (i.e. 100 percent weighting on the PJM/MISO Interface). When actual flows on the PARs are in the opposite direction of the scheduled flows on the PARs, the PJM/IMO interface price will be equal to the PJM/NYIS interface price (i.e. 100 percent weighting on the PJM/NYIS Interface). When the absolute value of the actual flows on the PARs are less than or equal to the absolute value of the scheduled flows on the PARs, and the scheduled and actual flows are in the same direction, the PJM/IMO interface price will be a combination to the PJM/MISO interface price and the PJM/NYIS interface price. In this case the weightings of the PJM/MISO and PJM/NYIS interface prices are determined based on the scheduled and actual flows. For example, in a given interval, the scheduled flow on the Michigan-Ontario PARs is 1,000 MW, and the actual flow is 800 MW. If in that same interval, the PJM/MISO interface price is $45.00 and the PJM/NYIS interface price $30.00, the PJM/IMO interface price would be calculated with a weighting of 80 percent of the PJM/MISO interface price ($45.00 * 0.8, or $36.00) and 20 percent of the PJM/NYIS interface price ($30.00 * 0.2, or $6.00), for a PJM/IMO interface price of $42.00.

The MMU believes that the new PJM/IMO interface price method is a step in the right direction towards pricing energy that sources or sinks in Ontario based on the path of the actual, physical transfer of energy. The MMU remains concerned about the assumption of PAR operations, and will continue to evaluate the impact of PARs on the scheduled and actual flows and the impacts on the PJM/IMO interface price. The MMU remains concerned about the potential for market participants to continue to engage in sham scheduling activities after the new method is implemented.

The MMU recommends that if the PJM/IMO interface price remains and with PJM's new method in place, that PJM implement additional business rules to remove the incentive to engage in sham scheduling activities using the PJM/IMO interface price. Such rules would prohibit the same market participant from scheduling an export transaction from PJM to any balancing authority while at the same time an import transaction is scheduled to PJM that receives the PJM/IMO interface price. PJM should also prohibit the same market participant from scheduling an import transaction to PJM from any balancing authority while at the same time an export transaction is scheduled from PJM that receives the PJM/IMO interface price.

In the first nine months of 2025, there were 666.5 GWh of net scheduled transactions between PJM and IESO. The net scheduled transactions were made up of 676.5 GWh of imports wheeled through MISO, and 10.0 GWh of exports wheeled through the NYISO. (Table 9-25). The MMU recommends

62 *See* "Sham Scheduling," Presented at the PJM Market Monitoring Unit Advisory Committee (MMUAC) meeting held on December 6, 2013 <http://www.monitoringanalytics.com/reports/Presentations/2013/IMM_Sham_Scheduling_20131206.pdf>.

that PJM eliminate the PJM/IMO interface pricing point, and assign the transactions that originate or sink in the IESO balancing authority to the PJM/MISO interface pricing point.[63]

PJM and NYISO Coordinated Interchange Transactions

Coordinated transaction scheduling (CTS) provides the option for market participants to submit intra-hour transactions between the NYISO and PJM that include an interface spread bid on which transactions are evaluated.[64] The evaluation is based on the forward-looking prices as determined by PJM's intermediate term security constrained economic dispatch tool (IT SCED) and the NYISO's real-time commitment (RTC) tool. PJM shares its PJM/NYISO interface price IT SCED results with the NYISO. The NYISO compares the PJM/NYISO interface price with its RTC calculated NYISO/PJM interface price. If the PJM and NYISO interface price spread is greater than the market participant's CTS bid, the transaction is approved. If the PJM and NYISO interface price spread is less than the CTS bid, the transaction is denied.

The IT SCED application runs every five minutes and each run produces forecast LMPs for the intervals approximately 30 minutes, 45 minutes, 90 minutes and 135 minutes ahead. Therefore, for each 15 minute interval, the various IT SCED solutions will produce 12 forecasted PJM/NYIS interface prices. To evaluate the accuracy of IT SCED forecasts, the forecasted PJM/NYIS interface price for each 15 minute interval from IT SCED was compared to the actual real-time interface LMP for the first nine months of 2025. Table 9-46 shows that over all 12 forecast ranges, IT SCED predicted the real-time PJM/NYIS interface LMP within the range of $0.00 to $5.00 in 22.5 percent of the intervals. In those intervals, the average price difference between the IT SCED forecasted LMP and the actual real-time LMP was $2.22 per MWh. In 26.3 percent of all intervals, the absolute value of the average price difference between the IT SCED forecasted LMP and the actual real-time interface LMP was greater than $20.00. The average price differences were $94.53 when the price difference was greater than $20.00, and $67.32 when the price difference was greater than -$20.00.

63 On October 1, 2013, a sub-group of PJM's Market Implementation Committee started stakeholder discussions to address this inconsistency in market pricing.
64 PJM and the NYISO implemented CTS on November 4, 2014. 146 FERC ¶ 61,096 (2014).

Table 9-46 Differences between forecast and actual PJM/NYIS interface prices: January through September, 2025

Range of Price Differences	Percent of All Intervals	Average Price Difference
> $20	18.4%	$94.53
$10 to $20	10.3%	$14.29
$5 to $10	11.3%	$7.22
$0 to $5	22.5%	$2.22
$0 to -$5	17.4%	$2.04
-$5 to -$10	6.4%	$7.18
-$10 to -$20	5.7%	$14.33
< -$20	7.9%	$67.32

Table 9-47 shows how the accuracy of the IT SCED forecasted LMPs changes as the cases approach real-time. In the final IT SCED results prior to real time, in 35.5 percent of all intervals, the average price difference between the IT SCED forecasted LMP and the actual real-time interface LMP fell within +/- $5.00 of the actual PJM/NYIS interface real-time LMP, compared to 39.5 percent in the 135 minute ahead IT SCED results.

Table 9-47 Differences between forecast and actual PJM/NYIS interface prices: January through September, 2025

	~ 135 Minutes Prior to Real-Time		~ 90 Minutes Prior to Real-Time		~ 45 Minutes Prior to Real-Time		~ 30 Minutes Prior to Real-Time	
Range of Price Differences	Percent of Intervals	Average Price Difference	Percent of Intervals	Average Price Difference	Percent of Intervals	Average Price Difference	Percent of Intervals	Average Price Difference
> $20	23.2%	$99.14	15.6%	$77.12	17.8%	$90.62	20.1%	$106.99
$10 to $20	10.6%	$14.39	10.4%	$14.25	9.9%	$14.23	10.2%	$14.36
$5 to $10	11.1%	$7.24	11.5%	$7.23	11.5%	$7.21	10.2%	$7.26
$0 to $5	23.2%	$2.18	24.4%	$2.21	21.6%	$2.25	17.9%	$2.24
$0 to -$5	16.3%	$1.91	18.1%	$2.01	17.4%	$2.09	17.6%	$2.21
-$5 to -$10	5.1%	$7.08	6.3%	$7.23	6.9%	$7.14	7.7%	$7.16
-$10 to -$20	4.4%	$14.47	5.6%	$14.37	6.3%	$14.27	6.9%	$14.25
< -$20	6.1%	$70.36	8.0%	$66.57	8.6%	$68.01	9.4%	$64.41

In 29.5 percent of the intervals in the 30 minute ahead forecast, the absolute value of the average price difference between the IT SCED forecasted LMP and the actual real-time interface LMP was greater than $20.00. The average price difference was $106.99 when the price difference was greater than $20.00, and $64.41 when the price difference was greater than -$20.00.

Table 9-48 and Table 9-49 show the monthly differences between forecasted and actual PJM/NYIS interface prices. Analysis of the data on a monthly basis shows that there is a decline in the accuracy of the IT SCED forecast during periods of cold and hot weather.

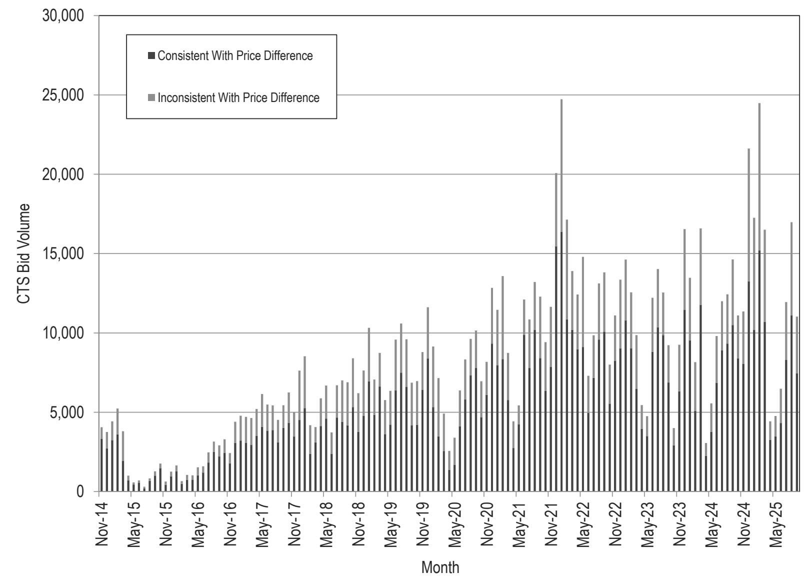
The NYISO uses PJM's IT SCED forecasted LMPs to compare against the NYISO Real-Time Commitment (RTC) results in its evaluation of CTS transactions. The NYISO approves CTS (spread bid) transactions when the offered spread is less than or equal to the spread between the IT SCED forecast PJM/NYIS interface LMP and the NYISO RTC forecast NYIS/PJM interface LMP. The large differences between forecast and actual LMPs in the intervals closest to real-time could cause CTS transactions to be approved that would contribute to transactions being scheduled counter to real-time economic signals, and contribute to inefficient scheduling across the PJM/NYIS border.

CTS transactions are evaluated based on the spread bid, which limits the amount of price convergence that can occur. As long as balancing operating reserve charges are applied and CTS transactions are optional, the CTS proposal represents a small incremental step toward better interface pricing. The NYISO has a 75 minute bid submission deadline. While market participants have the option to specify bid data on 15 minute intervals, market participants must submit their bids 75 minutes prior to the requested transaction start time. The 75 minute bid submission deadline associated with scheduling energy transactions in the NYISO should be shortened. Reducing this deadline could significantly improve pricing efficiency at the PJM/NYISO border for non-CTS transactions and for CTS transactions as market participants would be able to adjust their bids in response to real-time price signals.

CTS transactions were evaluated for each 15 minute interval. From November 4, 2014, through September 30, 2025, 1,060,261 15 minute CTS schedules were approved through the CTS process based on the forecast LMPs. When the forecast LMPs for the approved intervals were compared to the hourly integrated real-time LMPs, the direction of the flow in 330,293 (31.2 percent) of the intervals was inconsistent with the differences in real-time PJM/NYISO and NYISO/PJM prices. For example, if a market participant submits a CTS transaction from NYISO to PJM with a spread bid of $5.00, and NYISO's forecasted PJM interface price was at least $5.00 lower than PJM's forecasted NYISO interface price, the transaction would be approved. For 31.2 percent of the approved transactions, the actual, real-time price differentials were in the opposite direction of the forecast differential. The actual, real-time price differentials meant that the transactions would have been economic in the opposite direction. For 68.8 percent of the intervals, the forecast price differentials were consistent with real-time PJM/NYISO and NYISO/PJM price differences. Figure 9-11 shows the monthly volume of cleared PJM/NYIS CTS bids. Figure 9-11 also shows the percent of cleared bids that resulted in flows consistent and inconsistent with price differences.

Figure 9-11 Monthly cleared PJM/NYIS CTS bid volume: November 4, 2014 through September 30, 2025



The data reviewed show that IT SCED is not a highly accurate predictor of the real-time PJM/NYIS interface prices. This limits the effectiveness of CTS in improving interface pricing between PJM and NYISO.

Reserving Ramp on the PJM/NYISO Interface

Prior to the implementation of CTS, PJM held ramp space for all transactions submitted between PJM and the NYISO as soon as the NERC Tag was approved. At that time, once transactions were evaluated by the NYISO through their real-time market clearing process, any adjustments made to the submitted transactions would be reflected on the NERC Tags and the PJM ramp was adjusted accordingly.

As part of this process, PJM was often required to make adjustments to transactions on its other interfaces in order to bring total system ramp back to within its limit. The default ramp limit in PJM is +/- 1,000 MW. For example, the ramp in a given interval is currently -1,000 MW, consisting of 2,000 MW of imports from the NYISO to PJM and 3,000 MW of exports from PJM on its other interfaces. If, through the NYISO real-time market clearing process, the NYISO only approves 1,000 MW of the imports, the other 1,000 MW of import transactions from the NYISO would be curtailed. The ramp in this interval would then be -2,000 MW, consisting of the 1,000 MW of cleared imports from the NYISO to PJM and 3,000 MW of exports from PJM on its other interfaces. PJM would then be required to curtail an additional 1,000 MW of exports at its other interface to bring the limit back to within +/- 1,000. These curtailments were made on a last in first out basis as determined by the timestamp on the NERC Tag.

With the implementation of the CTS product with the NYISO, PJM modified how ramp is handled at the PJM/NYISO Interface. Effective November 4, 2014, PJM no longer holds ramp room for any transactions submitted between PJM and the NYISO at the time of submission. Only after the NYISO completes its real-time market clearing process, and communicates the results to PJM, does PJM perform a ramp evaluation on transactions scheduled with the NYISO. If, in the event the NYISO market clearing process would violate ramp, PJM would make additional adjustments based on a last-in first-out basis as determined by the timestamp on the NERC Tag. This process prevents the transactions scheduled at the PJM/NYISO Interface from holding (or creating) ramp until NYISO has completed its economic evaluation and the transactions are approved through the NYISO market clearing process.

PJM and MISO Coordinated Interchange Transaction Proposal

PJM and MISO proposed the implementation of coordinated interchange transactions, similar to the PJM/NYISO approach, through the Joint and Common Market Initiative. The PJM/MISO coordinated transaction scheduling (CTS) process provides the option for market participants to submit intra-hour transactions between the MISO and PJM that include an interface spread bid on which transactions are evaluated. Similar to the PJM/NYISO approach, the evaluation is based, in part, on the forward-looking prices as determined by PJM's intermediate term security constrained economic dispatch tool (IT SCED). Unlike the PJM/NYISO CTS process in which the NYISO performs the evaluation, the PJM/MISO CTS process uses a joint clearing process in which both RTOs share forward looking prices. On October 3, 2017, PJM and MISO implemented the CTS process.

The IT SCED application runs every five minutes and each run produces forecast LMPs for the intervals approximately 30 minutes, 45 minutes, 90 minutes and 135 minutes ahead. Therefore, for each 15 minute interval, the various IT SCED solutions will produce 12 forecasted PJM/MISO interface prices. To evaluate the accuracy of IT SCED forecasts, the forecasted PJM/MISO interface price for each 15 minute interval from IT SCED was compared to the actual real-time interface LMP for the first nine months of 2025. Table 9-50 shows that over all 12 forecast ranges, IT SCED predicted the real-time PJM/MISO interface LMP within the range of $0.00 to $5.00 in 23.2 percent of all intervals. In those intervals, the average price difference between the IT SCED forecasted LMP and the actual real-time LMP was $2.16. In 27.4 percent of all intervals, the absolute value of the average price difference between the IT SCED forecasted LMP and the actual real-time interface LMP was greater than $20.00. The average price differences were $90.19 when the price difference was greater than $20.00, and $76.35 when the price difference was greater than -$20.00.

Table 9-50 Differences between forecast and actual PJM/MISO interface prices: January through September, 2025

Range of Price Differences	Percent of All Intervals	Average Price Difference
> $20	22.3%	$90.19
$10 to $20	10.1%	$14.27
$5 to $10	10.9%	$7.22
$0 to $5	23.2%	$2.16
$0 to -$5	18.6%	$1.96
-$5 to -$10	5.7%	$7.09
-$10 to -$20	4.0%	$14.08
< -$20	5.1%	$76.35

Table 9-51 shows how the accuracy of the IT SCED forecasted LMPs change as the cases approach real-time. In the final IT SCED results prior to real-time, in 38.4 percent of all intervals, the average price difference between the IT SCED forecasted LMP and the actual real-time interface LMP fell within +/- $5.00 of the actual PJM/MISO interface real-time LMP, compared to 41.3 percent in the 135 minute ahead IT SCED results.

Table 9-51 Differences between forecast and actual PJM/MISO interface prices: January through September, 2025

	~ 135 Minutes Prior to Real-Time		~ 90 Minutes Prior to Real-Time		~ 45 Minutes Prior to Real-Time		~ 30 Minutes Prior to Real-Time

< -$20	3.9%	$82.85	5.0%	$76.54	5.4%	$77.01	5.8%	$72.45

In 30.7 percent of the intervals in the 30 minute ahead forecast, the absolute value of the average price difference between the IT SCED forecasted LMP and the actual real-time interface LMP was greater than $20.00, the average price differences were $101.29 when the price difference was greater than $20.00, and $72.45 when the price difference was greater than -$20.00.

Table 9-52 and Table 9-53 show the monthly differences between forecasted and actual PJM/MISO interface prices. Analysis of the data on a monthly basis shows that there is a decline in the accuracy of the IT SCED forecast during periods of cold and hot weather.

Table 9-52 Monthly differences between forecast and actual PJM/MISO interface prices (percent of intervals): January through September, 2025

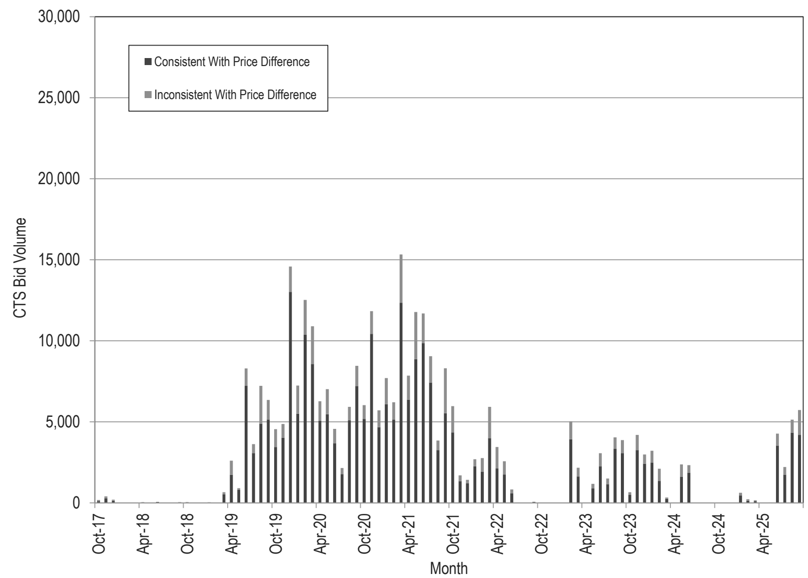
CTS transactions were evaluated for each interval. From October 3, 2017, through September 30, 2025, 309,913 CTS schedules were approved through the CTS process based on the forecast LMPs. When the forecast LMPs for the approved intervals were compared to the hourly integrated real-time LMPs, the direction of the flow in 63,324 (20.4 percent) of the intervals was inconsistent with the differences in real-time PJM/MISO and MISO/PJM prices. For example, if a market participant submits a CTS transaction from MISO to PJM with a spread bid of $5.00, and MISO's forecasted PJM interface price was at least $5.00 lower than PJM's forecasted MISO interface price, the transaction would be approved. For 20.4 percent of the approved transactions, the actual, real-time price differentials were in the opposite direction of the forecast differential. The actual, real-time price differentials meant that the transactions would have been economic in the opposite direction. For 79.6 percent of the intervals, the forecast price differentials were consistent with real-time PJM/MISO and MISO/PJM price differences. Figure 9-12 shows the monthly volume of cleared PJM/MISO CTS bids. Figure 9-12 also shows the percent of cleared bids that resulted in flows consistent and inconsistent with price differences. In June 2022, MISO experienced software issues that prevented the submission and clearing of CTS transactions. The issue was resolved in August 2022. It is unclear why market participants did not resume scheduling CTS transactions at the MISO interface until February 2023. Market participants did not use the MISO CTS transaction option between June 2024 and January 2025. While the forecast LMPs have not proven to be a good predictor of real time LMPs, that has not changed. It is not clear why market participants stopped using the MISO CTS transaction option during that time, or have not resumed using the option at volumes previously used.

Figure 9-12 Monthly cleared PJM/MISO CTS bid volume: October 3, 2017 through September 30, 2025



The data reviewed show that IT SCED is not a highly accurate predictor of the real-time PJM/MISO interface prices. This limits the effectiveness of CTS in improving interface pricing between PJM and MISO.

Willing to Pay Congestion and Not Willing to Pay Congestion

When reserving nonfirm transmission, market participants have the option to choose whether or not they are willing to pay congestion. When the market participant elects to pay congestion, PJM operators redispatch the system if necessary to allow the energy transaction to continue to flow. The system redispatch often creates price separation across buses on the PJM system. The difference in LMPs between two buses in PJM is the congestion cost (and losses) that the market participant pays in order for their transaction to continue to flow.

The MMU recommended that PJM modify the not willing to pay congestion product to address the issues of uncollected congestion charges. The MMU recommended charging market participants for any congestion incurred while the transaction is loaded, regardless of their election of transmission service, and restricting the use of not willing to pay congestion transactions (as well as all other real-time external energy transactions) to transactions at interfaces.

On April 12, 2011, the PJM Market Implementation Committee (MIC) endorsed the changes recommended by the MMU. The elimination of internal sources and sinks on transmission reservations addressed most of the MMU concerns, as there can no longer be uncollected congestion charges for imports to PJM or exports from PJM. There is still potential exposure to uncollected congestion charges in wheel through transactions, and the MMU will continue to evaluate if additional mitigation measures would be appropriate to address this exposure.

Table 9-54 shows that since the inception of the business rule change on April 12, 2013, there was uncollected congestion in only two months (January 2016 and February 2019). In both months, there was negative uncollected congestion. The negative congestion means that market participants who used the not willing to pay congestion transmission option for their wheel through transactions had transactions that flowed in the direction opposite to congestion. When market participants use the not willing to pay congestion product, it also means that they are not willing to receive congestion credits, which was the case in both January 2016 and February 2019.

Table 9-54 Monthly uncollected congestion charges: January 2010 through September 2025

Month	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025

Transmission Service Requests

Requests for transmission service are made on the PJM Open Access Same Time Information System (OASIS) on any of the posted paths. The products available on the OASIS include both firm and nonfirm service. Nonfirm service is available on an hourly, daily, weekly and monthly basis. Firm transmission service is defined as either short term or long term firm. Short term firm transmission is available on a daily, weekly or monthly basis, and long term firm is available for a period of one year or longer.

The total transfer capability (TTC) reflects the maximum amount of power that can be transferred over a transmission line or a group of transmission lines. In order to maintain reliability, transmission providers do not make the entire TTC available to be used. The available flowgate capability (AFC) is calculated for each path and product pair by taking the TTC and subtracting existing service requests, a capacity benefit margin[65], a transmission reliability margin[66] and taking postbacks and counterflows into consideration. The amount of transmission service that can be reserved is the Available Transfer Capability (ATC). The ATC is calculated for each path and product, and is determined by taking the AFC and adjusting it for all other committed transmission service requests that impact that path.

PJM calculates and posts ATC for all valid posted paths product pairs. The range of calculated ATCs depends on the duration of service. Hourly service is available up to seven days in advance, daily service is available 35 days in advance, weekly service is available five weeks in advance and monthly service is available 18 months in advance. Any transmission request that falls within the posted ATC period is evaluated based on the posted ATC. If there is sufficient capability, the transmission service request is accepted. If there is not sufficient capability, the transmission service request is denied.

Long term firm transmission service requests that extend beyond the ATC posting calculation are subject to system impact studies and must be submitted and evaluated in the new services queue. There is currently a backlog of projects in the new services queue. The backlog is being resolved through a transition to a new planning process, but new transmission service requests may not be evaluated or approved until 2027.[67]

65 The capacity benefit margin is defined by NERC as "the amount of firm transmission transfer capability preserved by the transmission provider for Load-Serving Entities (LSEs), whose loads are located on that Transmission Service Provider's system, to enable access by the LSEs to generation from interconnected systems to meet generation reliability requirements. Preservation of CBM for an LSE allows that entity to reduce its installed generating capacity below that which may otherwise have been necessary without interconnections to meet its generation reliability requirements. The transmission transfer capability preserved as CBM is intended to be used by the LSE only in times of emergency generation deficiencies."

66 The transmission reliability margin is defined by NERC as "the amount of TTC necessary to provide reasonable assurance that the interconnected transmission network will be secure".

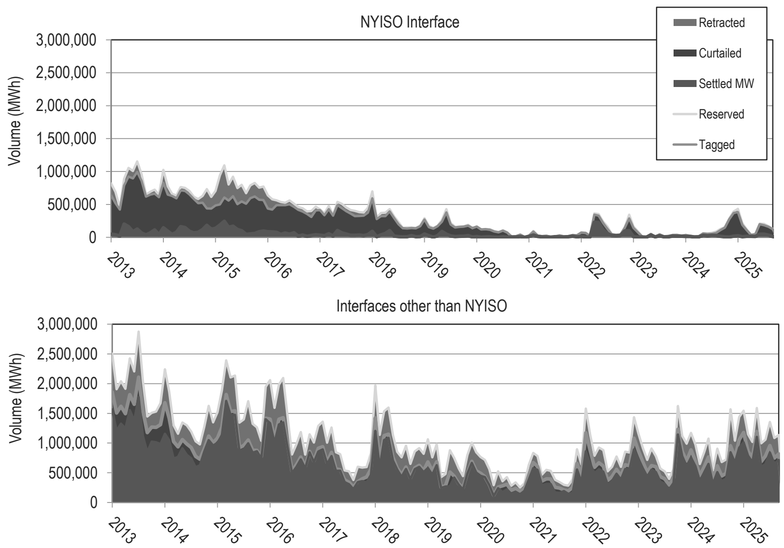
67 See the *2025 Quarterly State of the Market Report for PJM: January through September*, Section 12, "Generation and Transmission Planning," for additional details.

Spot Imports

Figure 9-13 shows the spot import service use for the NYISO Interface, and for all other interfaces, from January 1, 2013 through September 30, 2025. The yellow line shows the total monthly MWh of spot import service reserved and the orange line shows the total monthly MWh of tagged spot import service. The gray shaded area between the yellow and orange lines represents the MWh of retracted spot import service and may represent potential hoarding volumes. This ATC was initially reserved, but not tagged (used). It is possible that in some instances the reserved transmission consisted of the only available ATC which could have been used by another market participant had it not been reserved and not used. The blue shaded area between the orange line and green shaded area represents the MWh of curtailed transactions using spot import service. This area may also represent hoarding opportunities, particularly at the NYISO Interface. In this instance, it is possible that while the market participant reserved and scheduled the transmission, they may have submitted purposely uneconomic bids in the NYISO market so that their transaction would be curtailed, yet their transmission would not be retracted. The NYISO allows for market participants to modify their bids on an hourly basis, so these market participants can hold their transmission service and evaluate their bids hourly, while withholding the transmission from other market participants that may wish to use it. The green shaded area represents the total settled MWh of spot import service. Figure 9-13 shows that while there are proportionally fewer retracted MWh on the NYISO Interface than on all other interfaces, the NYISO has proportionally more curtailed MWh. This is a result of the NYISO market clearing process.[68]

68 See the *2018 Annual State of the Market Report for PJM*, Volume 2, Section 9, "Interchange Transactions," for a more complete discussion of the history of spot import transmission service.

Figure 9-13 Spot import service use: January 2013 through September 2025



The MMU continues to recommend that PJM permit unlimited spot market imports (as well as all nonfirm point to point willing to pay congestion imports and exports) at all PJM interfaces.

Interchange Optimization

When PJM prices are higher than prices in surrounding balancing authorities, imports will flow into PJM until the prices are approximately equal. This is an appropriate market response to price differentials. Given the nature of interface pricing and the treatment of interface transactions, it is not possible for PJM system operators to reliably predict the quantity or sustainability of such imports. The inability to predict interchange volumes creates additional challenges for PJM dispatch in trying to meet loads, especially on high load days. If all external transactions were submitted as real-time dispatchable transactions during emergency conditions, PJM would be able to include interchange transactions in its supply stack, and dispatch only enough interchange to meet the demand.

The MMU recommends that the submission deadline for real-time dispatchable transactions be modified from 1800 (EPT) on the prior day to three hours prior to the requested start time, and that the minimum duration be modified from one hour to 15 minutes.[69] These changes would give PJM a more flexible product that could be used to meet load based on economic dispatch rather than guessing the sensitivity of the transactions to price changes.

In addition to changing prices, transmission line loading relief procedures (TLRs), market participants' curtailments for economic reasons, and external balancing authority curtailments affect the duration of interchange transactions.

The MMU recommends that PJM explore an interchange optimization solution with its neighboring balancing authorities that would remove the need for market participants to schedule physical transactions across seams. Such a solution would include an optimized, but limited, joint dispatch approach that uses supply curves and treats seams between balancing authorities as constraints, similar to other constraints within an LMP market.

Interchange Cap During Emergency Conditions

An interchange cap is a limit on the level of interchange permitted for nondispatchable energy using spot import or hourly point to point transmission. An interchange cap is a nonmarket intervention which should be a temporary solution and should be replaced with a market based solution as soon as possible. Since the approval of this process on October 30, 2014, PJM has not yet needed to implement an interchange cap.

The purpose of the interchange cap is to help ensure that actual interchange more closely meets operators' expectations of interchange levels when internal PJM resources, e.g. CTs or demand response, are dispatched to meet the peak load. Once these resources have been called on, PJM must honor their minimum operating constraints regardless of whether additional interchange

69 The minimum duration for a real-time dispatchable transaction was modified to 15 minutes. See *Integration of Variable Energy Resources*, Order No. 764, 139 FERC ¶ 61,246, order on reh'g, Order No. 764-A, 141 FERC ¶ 61231 (2012).

then materializes. Therefore any interchange received in excess of what was expected can have a suppressive effect on energy and reserve pricing and result in increased uplift.

PJM will notify market participants of the possible use of the interchange cap the day before. The interchange cap will be implemented for the forecasted peak and surrounding hours during emergency conditions.

The interchange cap will limit the acceptance of spot import and hourly nonfirm point to point interchange (imports and exports) not submitted as real time with price transactions once net interchange has reached the interchange cap value. Spot imports and hourly nonfirm point to point transactions submitted prior to the implementation of the interchange cap will not be limited. In addition, schedules with firm or network designated transmission service will not be limited either, regardless of whether net interchange is at or above the cap.

The calculation of the interchange cap is based on the operator expectation of interchange at the time the cap is calculated plus an additional margin. The margin is set at 700 MW, which is half of the largest contingency on the system. The additional margin also allows interchange to adjust to the loss of a unit or deviation between actual load and forecasted load. The interchange cap is based on the maximum sustainable interchange from PJM reliability studies.

45 Minute Schedule Duration Rule

PJM limits the change in interchange volumes on 15 minute intervals. These changes are referred to as ramp. The PJM ramp limit is designed to limit the change in the amount of imports or exports in each 15 minute interval to account for the physical characteristics of the generation to respond to changes in the level of imports and exports. The purpose of imposing a ramp limit is to help ensure the reliable operation of the PJM system. The 1,000 MW ramp limit per 15 minute interval was based on the availability of ramping capability by generators in the PJM system. The limit is based on the assumption that the available generation in the PJM system can only move 1,000 MW over any 15 minute period, although there is no supporting analysis. As an example of how the ramp limit works, if at 0800 (EPT) the sum of all external transactions were -3,000 MW (negative sign indicates net exporting), the limit for 0815 would be -2,000 MW to -4,000 MW. In other words, the starting or ending of transactions would be limited so that the overall change from the previous 15 minute period would not exceed 1,000 MW in either direction.

In 2008, there was an increase in 15 minute external energy transactions that caused swings in imports and exports submitted in response to intrahour LMP changes. This activity was due to market participants' ability to observe price differences between RTOs in the first third of the hour, and predict the direction of the price difference on an hourly integrated basis. Large quantities of MW would then be scheduled between the RTOs for the last 15 minute interval to capture those hourly integrated price differences with relatively little risk of prices changing. This increase in interchange on 15 minute intervals created operational control issues, and in some cases led to an increase in uplift charges due to calling on resources with minimum run times greater than 15 minutes needed to support the interchange transactions. As a result, a new business rule was proposed and approved that required all transactions to be at least 45 minutes in duration.

On June 22, 2012, FERC issued Order No. 764, which required transmission providers to give transmission customers the option to schedule transmission service at 15 minute intervals to reflect more accurate power production forecasts, load and system conditions.[70] On April 17, 2014, FERC issued its order which found that PJM's 45 minute duration rule was inconsistent with Order No. 764.[71]

PJM and the MMU issued a statement indicating ongoing concern about market participants' scheduling behavior, and a commitment to address any scheduling behavior that raises operational or market manipulation concerns.[72]

MISO Multi-Value Project Usage Rate (MUR)

MISO defines a multi-value project (MVP) to be a project which, according to MISO, enables the reliable and economic delivery of energy in support of

70 *Id.* at P 51.
71 See *Id.* at P 12.
72 See joint statement of PJM and the MMU re Interchange Scheduling issued July 29, 2014 <http://www.monitoringanalytics.com/reports/Market_Messages/Messages/PJM_IMM_Statement_on_Interchange_Scheduling_20140729.pdf>.

public policy needs, provides multiple types of regional economic value or provides a combination of regional reliability and economic value. On July 15, 2010, MISO submitted revisions to the MISO Tariff to implement criteria for identifying and allocating the costs of MVPs.[73] On December 16, 2010, the Commission accepted the proposed MVP charge for export and wheel-through transactions, except for transactions that sink in PJM.[74] The Commission stated that MISO had not shown that their proposal did not constitute a resumption of rate pancaking along the MISO-PJM seam. Following the December 16, 2010, Order, MISO began applying a multi-value usage rate (MUR) to monthly net actual energy withdrawals, export schedules and through schedules with the exception of transactions sinking in PJM. The MUR charge was applied to the relevant transactions in addition to the applicable transmission, ancillary service and network upgrade charges.

On June 7, 2014, the U.S. Court of Appeals for the Seventh Circuit granted a petition for review regarding the Commission's determination in the MVP Order and MVP Rehearing Order.[75] The Court ordered the Commission to consider on remand whether, in light of current conditions, what if any limitations on export pricing to PJM by MISO are justified.[76] The Seventh Circuit highlighted the fact that at the time of the Commission's decision to prohibit rate pancaking on transactions between MISO and PJM, all of MISO's transmission projects were local and provided only local benefits.[77]

On July 13, 2016, FERC issued an order permitting MISO to collect charges associated with MVPs for all transactions sinking in PJM, effective immediately.[78] The July 13th Order noted that in light of "the development of large scale wind generation capable of serving both MISO's and its neighbors' energy policy requirements in the western areas of MISO; the reported need of PJM entities to access those resources; and the reported need for MISO to build new transmission facilities to deliver the output of those resources within MISO for export… it is appropriate to allow MISO to assess the MVP usage charge for transmission service used to export to PJM just as MISO assesses the MVP usage charge for transmission service used to export energy to other regions."[79]

The policy rationale for permitting MISO to impose transmission costs on PJM market participants without clear criteria is weak and results in pancaking of rates. The impact is expected to increase.

Table 9-55 shows the projected usage rate to be collected for all wheels through and exports from MISO, including those that sink in PJM, for 2024 through 2045.[80] As shown in Table 9-4, there were 4,672.1 GWh of imports from MISO in the first nine months of 2025. At the 2025 MUR of $1.57 per MWh, PJM market participants paid $7.3 million towards the costs of MISO's multi value projects. It is not clear whether the MUR charge has affected interchange volumes from MISO into PJM.

Table 9-55 MISO projected multi value project usage rate: 2025 through 2045

Year	Total Indicative MVP Usage Rate ($/MWh)
2025	$1.57
2026	$1.58
2027	$1.56
2028	$1.53
2029	$1.50
2030	$1.47
2031	$1.44
2032	$1.41
2033	$1.39
2034	$1.36
2035	$1.33
2036	$1.31
2037	$1.28
2038	$1.26
2039	$1.23
2040	$1.21
2041	$1.18
2042	$1.16
2043	$1.13
2044	$1.11
2045	$1.09

Ancillary Service Markets

FERC defined six ancillary services in Order No. 888: scheduling, system control and dispatch; reactive supply and voltage control from generation service; regulation and frequency response service; energy imbalance service; operating reserve - spinning reserve service; and operating reserve - supplemental reserve service.[1] PJM provides scheduling, system control and dispatch as part of the PJM administrative function. PJM provides reactive on what is asserted to be a cost of service basis. PJM provides regulation, energy imbalance, synchronized reserve, and supplemental reserve services through market mechanisms.[2] The PJM ancillary service markets are regulation, synchronized reserve, primary reserve, and 30-minute reserve. Although not defined by FERC as an ancillary service, black start service plays a comparable role. Black start service is provided on the basis of formula rates and cost of service rates.

The MMU analyzed measures of market structure, conduct and performance for the PJM Synchronized Reserve Market for the first nine months of 2025.

Table 10-1 The synchronized reserve market results were not competitive

Market Element	Evaluation	Market Design
Market Structure: Regional Markets	Not Competitive	
Participant Behavior	Competitive	
Market Performance	**Not Competitive**	**Flawed**

- The synchronized reserve market structure was evaluated as not competitive due to supplier concentration. The RTO Reserve Zone was unconcentrated in the day-ahead market and unconcentrated in the real-time market. The MAD Reserve Subzone was moderately concentrated in the day-ahead market and moderately concentrated in the real-time market.
- Participant behavior was evaluated as competitive because the market rules require all available reserves to offer at cost-based offers.
- Market performance was evaluated as not competitive because the interaction of participant behavior with the market design does not result in competitive prices as a result of PJM's changes to the operating reserve demand curve (ORDC). In an attempt to counter poor unit specific synchronized reserve performance, PJM unilaterally and inappropriately extended the first step of the ORDC for synchronized reserve, known as the synchronized reserve reliability requirement, in May 2023, raising prices for synchronized reserves, nonsynchronized reserves and energy.
- Market design was evaluated as flawed based on PJM's modifications to the ORDC. PJM previously adopted reforms, including several based on MMU recommendations, removing both physical and economic withholding from the market.
- Significant communications technology issues when calling resources during synchronized reserve events have resulted in slow response from resources. On December 17, 2024, PJM implemented an electronic deployment of reserves via an augmented dispatch signal, but PJM does not require that resources be able to receive this signal.

The MMU analyzed measures of market structure, conduct and performance for the PJM Nonsynchronized Reserve Market for the first nine months of 2025.

Table 10-2 The nonsynchronized reserve market results were not competitive

Market Element	Evaluation	Market Design
Market Structure: Regional Markets	Not Competitive	
Participant Behavior	Competitive	
Market Performance	**Not Competitive**	**Flawed**

- The nonsynchronized reserve market structure was evaluated as not competitive due to supplier concentration for primary reserve. The RTO Reserve Zone was unconcentrated in the day-ahead market and unconcentrated in the real-time market. The MAD Reserve Subzone was moderately concentrated in the day-ahead market and moderately concentrated in the real-time market.

1 See 75 FERC ¶ 61,080 (1996). PJM renamed spinning reserve as synchronized reserve based on PJM's inclusion of demand side resources in the product.
2 Energy imbalance service refers to the real-time energy market.

- Participant behavior was evaluated as competitive because all available reserves are included by the PJM markets software, so withholding is not possible.
- Market performance was evaluated as not competitive because the interaction of participant behavior with the market design does not result in competitive prices as a result of PJM's changes to the operating reserve demand curve (ORDC). In an attempt to counter poor unit specific synchronized reserve performance, PJM unilaterally and inappropriately extended the first step of the ORDC for synchronized reserve, known as the synchronized reserve reliability requirement, in May 2023. Because the first step of the ORDC for primary reserve, known as the primary reserve reliability requirement, is based on the synchronized reserve reliability requirement, the primary reserve reliability requirement was consequently also extended, raising prices for synchronized reserves, nonsynchronized reserves, and energy.
- Market design was evaluated as flawed based on PJM's modifications to the first step of the ORDC.

The MMU analyzed measures of market structure, conduct and performance for the PJM Secondary Reserve Market for the first nine months of 2025.

Table 10-3 The secondary reserve market results were competitive

Market Element	Evaluation	Market Design
Market Structure	Competitive	
Participant Behavior	Competitive	
Market Performance	**Competitive**	**Effective**

- The secondary reserve market structure was evaluated as competitive due to the lack of supplier concentration for 30-minute reserve. The RTO Reserve Zone was unconcentrated in the day-ahead market and unconcentrated in the real-time market.
- Participant behavior was evaluated as competitive because all available reserves are included by the PJM software, so withholding is not possible.
- Market performance was evaluated as competitive because the combination of a competitive market structure and competitive participation resulted in competitive market outcomes.
- The market design was evaluated as effective because the market rules ensure competitive market offers and require repayment of offline cleared secondary reserves that are not available when called on to provide energy in 30 minutes.

The MMU analyzed measures of market structure, conduct and performance for the PJM Regulation Market for the first nine months of 2025.

Table 10-4 The regulation market results were not competitive

Market Element	Evaluation	Market Design
Market Structure	Not Competitive	
Participant Behavior	Competitive	
Market Performance	**Not Competitive**	**Flawed**

- The regulation market structure was evaluated as not competitive because the PJM Regulation Market failed the three pivotal supplier (TPS) test in 94.2 percent of the hours in the first nine months of 2025.
- Participant behavior in the PJM Regulation Market was evaluated as competitive in the first nine months of 2025 because market power mitigation requires competitive offers when the three pivotal supplier test is failed, although the inclusion of a positive margin is not consistent with competitive offers.
- Market performance was evaluated as not competitive, because all units are not paid the same price on an equivalent MW basis.
- Market design was evaluated as flawed. The market design has failed to correctly incorporate a consistent implementation of the marginal benefit factor in optimization, pricing and settlement. The market results continue to include the incorrect definition of opportunity cost. The result is significantly flawed market signals to existing and prospective suppliers of regulation.

Overview

Primary Reserve

Primary reserves consist of both synchronized and nonsynchronized reserves that can provide energy within 10 minutes and sustain that output for at least 30 minutes during a contingency event. PJM made several changes to the primary reserve market, effective October 1, 2022. These included a must offer requirement and correction of misspecified cost-based offers. By removing opportunities for physical and economic withholding, the changes resulted in clearing increased quantities of available synchronized reserves at competitive prices. Starting in May 2023, to compensate for poor unit specific resource performance, PJM unilaterally increased the synchronized reserve reliability requirement, which in turn increased the primary reserve reliability requirement.

Market Structure

- **Supply.** Primary reserve is provided by both synchronized reserve (generation or demand response currently synchronized to the grid and available within 10 minutes) and nonsynchronized reserve (generation currently offline but available to start and provide energy within 10 minutes).
- **Demand.** The primary reserve reliability requirement is equal to 150 percent of the synchronized reserve reliability requirement. The primary reserve requirement is equal to the primary reserve reliability requirement, with a shortage penalty price of $850 per MWh, plus the extended reserve requirement (190 MW), with a shortage penalty price of $300 per MWh. The synchronized reserve requirement is equal to the synchronized reserve reliability requirement plus the extended reserve requirement, with a default level of 190 MW. The synchronized reserve reliability requirement is normally equal to the most severe single contingency (MSSC). Starting in May 2023, PJM increased the size of the synchronized reserve reliability requirement in the RTO Reserve Zone by 30 percentage points to 130 percent of the most severe single contingency (MSSC), in effect increasing the primary reserve reliability requirement to 195 percent of the MSSC. In the first nine months of 2025, the real-time average primary reserve requirement was 3,401.4 MW in the RTO Reserve Zone and 2,584.7 MW in the Mid-Atlantic Dominion Reserve Subzone. In the first nine months of 2025, the day-ahead average primary reserve requirement was 3,384.4 MW in the RTO Reserve Zone and 2,559.0 MW in the Mid-Atlantic Dominion Reserve Subzone.
- **Market Concentration.** Both the Mid-Atlantic Dominion (MAD) Reserve Subzone Market and the RTO Reserve Zone Market for primary reserve were characterized by structural market power in the first nine months of 2025. The average HHI for real-time primary reserve in the RTO Reserve Zone was 980, which is classified as unconcentrated. The average HHI for day-ahead primary reserve in the RTO Zone was 915, which is classified as unconcentrated. The average HHI for real-time primary reserve in the MAD Reserve Subzone was 1563, which is classified as moderately concentrated. The average HHI for day-ahead primary reserve in the MAD Reserve Subzone was 1401, which is classified as moderately concentrated.

Synchronized Reserve Market

Synchronized reserves include all capacity synchronized to the grid and available to satisfy PJM's power balance requirements within 10 minutes. This includes online resources loaded below their full output, storage or condensing resources synchronized to the grid but consuming energy, and 10-minute demand response capability. As of October 1, 2022, all generation capacity resources must offer their entire synchronized reserve capability to the PJM market at all times. PJM jointly optimizes energy, synchronized reserve, primary reserve, and 30-minute reserve needs in both the day-ahead and real-time markets. Synchronized reserve prices are based on opportunity costs calculated by PJM in the market optimization and the anticipated cost of a performance penalty. All real-time cleared synchronized reserves are obligated to perform when PJM initiates a synchronized reserve event based on a loss of supply.

Market Structure

- **Supply.** In the first nine months of 2025, the real-time average supply of available synchronized reserve was 5,763.4 MW in the RTO Reserve Zone, of which 2,814.0 MW on average was located in the Mid-Atlantic Dominion Reserve Subzone. In the first nine months of 2025, the day-ahead average supply of available synchronized reserve was 6,664.6 MW in the RTO Reserve Zone, of which 3,392.5 MW on average was located in the Mid-Atlantic Dominion Reserve Subzone.
- **Demand.** The synchronized reserve requirement is equal to the synchronized reserve reliability requirement, with a shortage penalty price of $850 per MWh, plus the extended reserve requirement, with a shortage penalty price of $300 per MWh and a default value of 190 MW. The synchronized reserve reliability requirement is normally equal to the most severe single contingency (MSSC). Since May 19, 2023, PJM has inappropriately set the synchronized reserve reliability requirement to 130 percent of the MSSC for the RTO Reserve Zone. The real-time average synchronized reserve requirement in the first nine months of 2025 was 2,330.9 MW in the RTO Reserve Zone and 1,786.4 MW in the Mid-Atlantic Dominion Reserve Subzone. The day-ahead average synchronized reserve requirement in the first nine months of 2025 was 2,319.6 MW in the RTO Reserve Zone and 1,769.4 MW in the Mid-Atlantic Dominion Reserve Subzone.
- **Market Concentration.** The Mid-Atlantic Dominion (MAD) Reserve Subzone Market for synchronized reserve was characterized by structural market power in the first nine months of 2025. The average HHI for real-time synchronized reserve in the RTO Reserve Zone was 911, which is classified as unconcentrated. The average HHI for day-ahead synchronized reserve in the RTO Zone was 799, which is classified as unconcentrated. The average HHI for real-time synchronized reserve in the MAD Reserve Subzone was 1721, which is classified as moderately concentrated. The average HHI for day-ahead synchronized reserve in the MAD Reserve Subzone was 1341, which is classified as moderately concentrated.

Market Conduct

- **Offers.** There is a must offer requirement for synchronized reserve. All nonemergency generation capacity resources are required to offer their entire synchronized reserve capability. PJM calculates the available synchronized reserve for all conventional resources based on the energy offer ramp rate, energy dispatch point, and the lesser of the synchronized reserve maximum or economic maximum output. Hydro resources, energy storage resources, and demand response resources submit their available synchronized reserve MW. Wind, solar, and nuclear resources are by default considered incapable of providing synchronized reserve, but may offer with an exception approved by PJM. Synchronized reserve offers are capped at cost plus the expected value of performance penalties. PJM calculates opportunity costs based on LMP.

  Significant communications technology and modelling issues when calling resources during spinning events continue to result in slow response from a significant share of resources.

Market Performance

- **Price.** In the first nine months of 2025, for the Mid-Atlantic Dominion Reserve Subzone, the weighted average real-time price for synchronized reserve was $3.94 per MWh and the weighted average day-ahead price was $6.26 per MWh. In the first nine months of 2025, for the RTO Reserve Zone, the weighted average real-time price for synchronized reserve was $4.55 per MWh and the weighted average day-ahead price was $6.23 per MWh.

Nonsynchronized Reserve

Nonsynchronized reserve is comprised of nonemergency energy resources not currently synchronized to the grid that can provide energy within 10 minutes. Nonsynchronized reserve is available to meet the portions of the primary reserve requirement and the 30-minute reserve requirement not already satisfied by reserve cleared for the synchronized reserve requirement.

Market Structure

- **Supply.** In the first nine months of 2025, the real-time average supply of eligible and available nonsynchronized reserve was 1,006.5 MW in the RTO Reserve Zone, of which 614.1 MW on average was available in the Mid-Atlantic Dominion Reserve Subzone. In the first nine months of 2025, the real-time average supply of eligible and available nonsynchronized reserve was 1,039.6 MW in the RTO Reserve Zone, of which 476.9 MW on average was available in the Mid-Atlantic Dominion Reserve Subzone.
- **Demand.** Demand for nonsynchronized reserve is the primary reserve requirement less the amount of synchronized reserves cleared by PJM.[3] Although nonsynchronized reserve can be used to meet the 30-minute reserve requirement, any 30-minute reserve beyond the primary reserve requirement is usually provided by secondary reserve due to its lower cost and greater availability.

Market Conduct

- **Offers.** Generation owners do not submit supply offers for nonsynchronized reserve from non-hydroelectric units. Nonemergency generation resources that are available to provide energy and can start in 10 minutes or less are defined to be available for nonsynchronized reserves. For non-hydroelectric units, PJM calculates the MW available from a unit based on the unit's energy offer. Hydroelectric units set their own offered reserve amount. For all units, the offer price of nonsynchronized reserve is $0 per MWh.[4] Hybrid units and energy storage resources are not eligible to provide nonsynchronized reserves.

Market Performance

- **Price.** The nonsynchronized reserve price is determined by the marginal primary reserve resource. In the first nine months of 2025, the nonsynchronized reserve weighted average real-time price for all intervals in the RTO Reserve Zone was $1.87 per MWh and the weighted average day-ahead price was $2.42 per MWh. In the first nine months of 2025, the nonsynchronized reserve weighted average real-time price for all intervals in the MAD Reserve Subzone was $2.22 per MWh and the weighted average day-ahead price was $3.43 per MWh.

30-Minute Reserve Market

The supply of 30-minute reserves consists of resources, online or offline, which can respond within 30 minutes. This includes primary reserves and secondary reserves. There is no reserve subzone for 30-minute reserves.

Market Structure

- **Supply.** The supply of 30-minute reserve is provided by both primary reserve (synchronized and nonsynchronized resources that can provide energy within 10 minutes) and secondary reserve (synchronized and nonsynchronized resources that can provide energy within 30 minutes but that take more than 10 minutes). In the first nine months of 2025, the real-time average supply of available 30-minute reserve was 27,655.6 MW in the RTO Zone.
- **Demand.** The 30-minute reserve requirement is equal to the 30-minute reserve reliability requirement, with a shortage penalty price of $850 per MWh, plus the extended reserve requirement (190 MW), with a shortage penalty price of $300 per MWh. The 30-minute reserve reliability requirement is equal to the maximum of: the primary reserve reliability requirement; the largest active gas contingency; and 3,000 MW. Since PJM increased the synchronized reserve reliability requirement, the 30-minute reserve reliability requirement is frequently equal to the primary reserve reliability requirement. In the first nine months of 2025, the average 30-minute reserve requirement was 3,519.5 MW in the real-time market and 3,508.8 MW in the day-ahead market.
- **Market Concentration.** The RTO Reserve Zone Market for 30-minute reserves was characterized by moderate structural market power in the first nine months of 2025. In the first nine months of 2025, the average HHI for real-time 30-minute reserves was 869, which is classified as

3 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations," § 4.1 Overview of the PJM Reserve Markets, Rev. 134 (Apr. 23, 2025).
4 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations," § 4.2.3 Reserve Market Resource Offer Structure, Rev. 134 (Apr. 23, 2025).

unconcentrated. In the first nine months of 2025, the average HHI for day-ahead 30-minute reserves was 857, which is classified as unconcentrated.

Secondary Reserve

Secondary reserves are reserves that take more than 10 minutes to convert to energy, but less than 30 minutes. This includes the unloaded capacity of online generation that can be achieved according to the resource ramp rates in 10 to 30 minutes, and offline resources with a start time of less than 30 minutes. Secondary reserves can only be used to satisfy the 30-minute reserve requirement.

Market Structure

- **Supply.** In the first nine months of 2025, in the RTO Reserve Zone, the real-time average supply of available secondary reserve was 21,163.8 MW and the day-ahead average supply of available secondary reserve was 12,402.1 MW. As with the 30-minute reserve service, there is no defined reserve subzone for secondary reserves.
- **Demand.** Demand for secondary reserve is the 30-minute reserve requirement less the amount of primary reserves cleared by PJM.[5]

Market Conduct

- **Offers.** Energy storage resources, hydroelectric resources, hybrid resources, and demand-side response resources submit their available secondary reserve MW. For all other resource types, PJM calculates the MW available from a resource based on the resource's energy offer. For all resources, the offer price of secondary reserve is $0 per MWh.[6] In both the day-ahead and real-time secondary reserves markets, PJM uses lost opportunity costs as the offers and not offers submitted by market participants. For online secondary reserves, PJM calculates an opportunity cost based on LMP.

5 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations," § 4.1 Overview of the PJM Reserve Markets, Rev. 134 (Apr. 23, 2025).
6 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations," § 4.2.3 Reserve Market Resource Offer Structure, Rev. 134 (Apr. 23, 2025).

Market Performance

- **Price.** The secondary reserve price is determined by the marginal 30-minute reserve resource. In the first nine months of 2025, the secondary reserve real-time price for all intervals was $0.01 per MWh. In the first nine months of 2025, the secondary reserve day-ahead price for all intervals was $0.00 per MWh.

Regulation Market

The PJM Regulation Market is a real-time market. Regulation is provided by generation resources and demand response resources that qualify to follow one of two regulation signals, RegA or RegD. PJM jointly optimizes regulation with synchronized reserve and energy to provide all three products at least cost. The PJM regulation market design includes three clearing price components: capability; performance; and opportunity cost. The RegA signal is designed for energy unlimited resources with physically constrained ramp rates. The RegD signal is designed for energy limited resources with fast ramp rates. In the regulation market RegD MW are converted to effective MW using a marginal rate of technical substitution (MRTS), called a marginal benefit factor (MBF). Correctly implemented, the MBF would be the marginal rate of technical substitution (MRTS) between RegA and RegD, holding the level of regulation service constant. The current market design is critically flawed as it has not properly implemented the MBF as an MRTS between RegA and RegD resource MW and the MBF has not been consistently applied in the optimization, clearing and settlement of the regulation market.

PJM filed significant changes to the regulation market design on April 16, 2024, that were accepted as filed by order of June 17, 2024.[7] PJM will implement the changes to the regulation market in two phases. Phase 1, implemented on October 1, 2025, is a single product, single signal market with one clearing price. Phase 2, to be implemented on October 1, 2026, will include separate regulation up and regulation down markets. The proposed Phase 1 changes will eliminate many of the significant issues identified by the MMU that have resulted from a two product, two signal market design including the incorrect and inconsistent use and application of the MBF/MRTS.

7 PJM, "Regulation Market Design Filing," Docket No. ER24-1772-000 (April 16, 2024).

This report analyzes the current (as of the third quarter of 2025) regulation market design and results during the first nine months of 2025.

Market Structure

- **Supply.** In the first nine months of 2025, the average hourly offered supply of regulation for nonramp hours was 788.7 performance adjusted MW (787.2 effective MW). This was an increase of 93.2 performance adjusted MW (an increase of 78.9 effective MW) from the first nine months of 2024, when the average hourly offered supply of regulation was 695.5 actual MW (708.3 effective MW). In the first nine months of 2025, the average hourly offered supply of regulation for ramp hours was 1,063.0 performance adjusted MW (1,119.1 effective MW). This was an increase of 68.6 performance adjusted MW (an increase of 72.1 effective MW) from the first nine months of 2024, when the average hourly offered supply of regulation was 994.4 performance adjusted MW (1,047.0 effective MW).
- **Demand.** The hourly regulation demand is 525.0 effective MW for nonramp hours and 800.0 effective MW for ramp hours.
- **Supply and Demand.** The nonramp regulation requirement of 525.0 effective MW was provided by a combination of cleared RegA and RegD resources equal to 486.9 hourly average performance adjusted actual MW in the first nine months of 2025. This is an increase of 8.3 performance adjusted actual MW from the first nine months of 2024, when the average hourly total regulation cleared performance adjusted actual MW for nonramp hours were 478.5 performance adjusted actual MW. The ramp regulation requirement of 800.0 effective MW was provided by a combination of cleared RegA and RegD resources equal to 690.8 hourly average performance adjusted actual MW in the first nine months of 2025. This is a decrease of 6.6 performance adjusted actual MW from the first nine months of 2024, where the average hourly regulation cleared MW for ramp hours were 697.5 performance adjusted actual MW.

  The ratio of the average hourly offered supply of regulation to average hourly regulation demand (performance adjusted cleared MW) for nonramp hours was 1.62 in the first nine months of 2025 (1.45 in the first nine months of 2024). The ratio of the average hourly offered supply of regulation to average hourly regulation demand (performance adjusted cleared MW) for ramp hours was 1.54 in the first nine months of 2025 (1.42 in the first nine months of 2024).
- **Market Concentration.** In the first nine months of 2025, the three pivotal supplier test was failed in 94.2 percent of hours. In the first nine months of 2025, the effective MW weighted average HHI of RegA resources was 2632 which is highly concentrated and the effective MW weighted average HHI of RegD resources was 2015 which is also highly concentrated. The effective MW weighted average HHI of all resources was 1315, which is moderately concentrated.

Market Conduct

- **Offers.** Daily regulation offer prices are submitted for each unit by the unit owner. Owners are required to submit a cost-based offer and may submit a price-based offer. Offers include both a capability offer and a performance offer. Owners must specify which signal type the unit will be following, RegA or RegD.[8] In the first nine months of 2025, there were 193 resources following the RegA signal and 60 resources following the RegD signal.

Market Performance

- **Price and Cost.** The weighted average clearing price for regulation was $42.42 per MW of regulation in the first nine months of 2025, an increase of $11.12 per MW, or 35.5 percent, from the weighted average clearing price of $31.30 per MW in the first nine months of 2024. The weighted average cost of regulation in the first nine months of 2025 was $52.35 per MW of regulation, an increase of 33.2 percent, from the weighted average cost of $39.31 per MW in the first nine months of 2024.
- **Prices.** RegD resources continue to be incorrectly compensated relative to RegA resources due to an inconsistent application of the marginal benefit factor in the optimization, assignment and settlement processes. If the

8 See the *2024 Annual State of the Market Report for PJM*, Appendix F "Ancillary Services Markets."

regulation market were functioning efficiently and competitively, RegD and RegA resources would be paid the same price per effective MW.

- **Marginal Benefit Factor.** The marginal benefit factor (MBF) is intended to measure the operational substitutability of RegD resources for RegA resources. The marginal benefit factor is incorrectly defined and applied in the PJM market clearing. The current incorrect and inconsistent implementation of the MBF has resulted in the PJM Regulation Market over procuring RegD relative to RegA in most hours and in an inefficient market signal about the value of RegD in every hour.

Black Start Service

Black start service is required for the reliable restoration of the grid following a blackout. Black start service is the ability of a generating unit to start without an outside electrical supply, or is the demonstrated ability of a generating unit to automatically remain operating at reduced levels when disconnected from the grid (automatic load rejection or ALR).[9]

In the first nine months of 2025, total black start charges were $39.6 million, a decrease of $15.6 million (28.3 percent) from 2024. In the first nine months of 2025, total revenue requirement charges were $39.2 million, a decrease of $15.7 million (28.6 percent) from 2024. In the first nine months of 2025, total black start uplift charges were $0.4 million, a increase of $.01 million (30.4 percent) from 2024. Black start revenue requirements consist of fixed black start service costs, variable black start service costs, training costs, fuel storage costs, and an incentive payment. Black start uplift charges are paid to units scheduled in the day-ahead energy market or committed in real time to provide black start service under the ALR option or for black start testing. Black start zonal charges in the first nine months of 2025 ranged from $0 in the OVEC and REC Zones to $6.6 million in the AEP Zone.

CRF values are a key determinant of total payments to black start units. The CRF values in PJM tariff tables should have been changed for both black start and the capacity market when the tax laws changed effective January 1, 2018. As a result of the failure to reduce the CRF values, black start units have been and continue to be significantly overcompensated since the changes to the tax code. In March 2023, FERC issued an order establishing hearing and settlement judge procedures.[10] By order issued September 23, 2025, the Commission approved a settlement over the MMU's objection that continued to allow overcompensation.[11] On July 4, 2025, enactment of the One Big Beautiful Bill Act (OBBBA) changed the rules for bonus depreciation again, allowing 100 percent bonus depreciation for assets constructed between January 20, 2025 and December 31, 2028, and placed in service before January 1, 2031.[12] The CRF values for affected units should incorporate 100 percent bonus depreciation. It is essential that PJM not repeat its earlier mistake when it ignored the tax law changes in 2017.

Reactive

Reactive service, reactive supply and voltage control are provided by generation and other sources of reactive power (measured in MVAr). Reactive power helps maintain appropriate voltage levels on the transmission system and is essential to the flow of real power (measured in MW). The same equipment provides both MVAr and MW. Generation resources are required to meet defined reactive capability requirements as a condition to receive interconnection service in PJM.[13] RTOs and their customers are not required to separately compensate generation resources for such reactive capability.[14] In the first nine months of 2025, PJM customers paid $273.1 million for reactive capability based on archaic, nonmarket and unsupported assertions about cost allocation and a regulatory review process of filings by individual units that results in unsupported black box settlements. The current rules have permitted over recovery of reactive costs through reactive capability charges. All costs of generators should be incorporated in the market.

9 OATT Schedule 1 § 1.3BB. There are no ALR units currently providing black start service.

10 See 182 FERC ¶ 61,194.
11 See 193 FERC ¶ 61,059.
12 OBBA § 70301(b)(3).
13 OATT Attachment O.
14 See 182 FERC ¶ 61,033 at P 52 (2023); *see also Standardization of Generator Interconnection Agreements & Procedures*, Order No. 2003, 104 FERC ¶ 61,103 at P 546 (2003), *order on reh'g*, Order No. 2003-A, 106 FERC ¶ 61,220 at P 28, *order on reh'g*, Order No. 2003-B, 109 FERC ¶ 61,287 (2004), *order on reh'g*, Order No. 2003-C, 111 FERC ¶ 61,401 (2005), *aff'd sub nom. National Association of Regulatory Utility Commissioners v. FERC*, 475 F.3d 1277 (D.C. Cir. 2007); *California ISO*, 160 FERC ¶ 61,035 at P 19 (2017); 119 FERC ¶ 61,199 at P 28 (2007), *order on reh'g*, 121 FERC ¶ 61,196 (2007); *see also* 178 FERC ¶ 61,088, at PP 29–31 (2022); 179 FERC ¶ 61,103, at PP 20-21 (2022).

The nonmarket approach to reactive capability payments will be eliminated effective June 1, 2026, based on FERC's Order No. 904 and the order approving PJM's compliance filing.[15]

Reactive service charges based on opportunity costs are appropriately paid to units that operate in real time outside of their normal range at the direction of PJM for the purpose of providing real-time reactive power.

In the first nine months of 2025, total reactive charges were $273.7 million, a decrease of $12.1 million (4.24 percent) from 2024. In the first nine months of 2025, total reactive capability charges were $273.1 million, a decrease of $11.7 million (4.1 percent) from 2024. In the first nine months of 2025, total reactive service charges were $0.59 million, a decrease of $0.41 million (41.4 percent) from 2024.

Total zonal reactive service charges ranged from $0 in the REC and OVEC Zones, to $28.6 million in the AEP Zone in the first nine months of 2025.

Primary Frequency Response

On February 15, 2018, the Commission issued Order No. 842, which modified the pro forma large and small generator interconnection agreements and procedures to require all newly interconnecting non-nuclear generating facilities, both synchronous and nonsynchronous, to include equipment for primary frequency response capability as a condition to receive interconnection service.[16]

Primary frequency response begins within a few seconds and extends up to a minute. The purpose of primary frequency response is to arrest and stabilize the system until other measures (secondary and tertiary frequency response) become active. This includes a governor or equivalent controls capable of operating with a maximum five percent droop and a +/- 0.036 Hz deadband.[17] In addition to resource capability, resource owners must comply by setting control systems to autonomously adjust real power output in a direction to correct for frequency deviations.

The response of generators within PJM to NERC identified frequency events occurs two to three times per month. A frequency event is declared whenever the system frequency stays outside ±0.040 Hz deadband for at least one minute, and the minimum/maximum frequency reaches ±0.053 Hz. Exclusions to PJM monitoring include nuclear plants, offline units, units with no available headroom, units assigned to regulation, and units with a current outage ticket in eDART. Effective June 2024 through June 2025, the NERC BAL-003-2 requirement for balancing authorities (PJM is a balancing authority) uses a threshold value (L_{10}) equal to +/- 258.3 MW/0.1 Hz.[18]

The MMU has identified several issues with PJM's enforcement and evaluation of generation PFR performance.

Market Procurement of Real-Time Ancillary Services

PJM uses market mechanisms to varying degrees in the procurement of ancillary services including synchronized reserves, primary reserves and 30-minute reserves, and regulation. Ideally, all ancillary services would be procured taking full account of the interactions with the energy market. When a resource is used for an ancillary service instead of providing energy in real time, the cost of removing the resource, either fully or partially, from the energy market should be included in the offer for the ancillary service. The degree to which PJM markets account for these interactions depends on the timing of the product clearing, software limitations, and the accuracy of resource parameters and offers.

All reserve products are jointly cleared with energy in every real-time market solution. The synchronized reserve market clearing is more integrated with the energy market clearing than the other ancillary services because dispatched energy and synchronized reserve are outputs of the same optimization problem for each market interval. Given the joint clearing of energy and flexible synchronized reserves, the synchronized reserve market clearing price should

15 See *Compensation for Reactive Power within the Standard Power Factor Range*, Order No. 904, 189 FERC ¶ 61,034 (2024); PJM compliance filing, Docket No. ER24-1073 (January 28, 2025); 192 FERC ¶ 61,113 (2025).
16 Nuclear Regulatory Commission (NRC) regulated facilities are exempt from this provision. Behind the meter generation that is sized to load is also exempt.
17 OATT Attachment O § 4.7.2 (Primary Frequency Response).
18 See NERC. "2024 Frequency Bias Settings," June 11, 2024. <https://www.nerc.com/comm/OC/Documents/OY_2024_Frequency_Bias_Annual_Calculations_correction_06112024.pdf>.

always cover the opportunity cost of providing flexible synchronized reserves. Inflexible synchronized reserves, provided by resources that require hourly commitments due to run-time or staffing constraints, are not cleared with energy in the real-time market solution.[19] Instead, inflexible synchronized reserves are cleared hourly by the Ancillary Service Optimizer (ASO) or the day-ahead energy market. The ASO considers energy market price forecasts, availability of resources for flexible synchronized reserves, and regulation requirements to estimate the costs and benefits of using a resource for inflexible synchronized reserves. The ASO selected inflexible reserves are a fixed input to RT SCED, which clears the balance of the requirement with flexible synchronized reserves.

Nonsynchronized reserves and offline secondary reserves are cleared with every real-time energy market solution. The energy commitment decisions to keep the resources offline have already been made when the RT SCED clears the five-minute reserves markets. Therefore, offline reserves have no lost opportunity cost. They will not be called on for energy during the market interval for which they are assigned as offline resources.

Prices for the regulation and reserve markets are set by the pricing calculator (LPC), which uses the RT SCED solution as an input. The LPC includes fast start pricing logic and system marginal price caps, so the final prices can be inconsistent with the marginal cost of the resources that clear regulation and reserves.

Recommendations

Reserve Markets

- The MMU recommends that to minimize lag and improve performance, PJM use an electronic synchronized reserve event notification process for all resources and that all resources be required to have the ability to receive and automatically respond to the notifications. (Priority: Medium. First reported 2023. Status: Partially adopted 2024.)
- The MMU recommends that PJM replace the Mid-Atlantic Dominion Reserve Subzone with a reserve zone structure consistent with the actual deliverability of reserves based on current transmission constraints. (Priority: High. First reported 2019. Status: Partially adopted 2022.)
- The MMU recommends that the components of the cost-based offers for providing regulation and synchronous condensing be defined in Schedule 2 of the Operating Agreement. (Priority: Low. First reported 2019. Status: Not adopted.)
- The MMU recommends that, for calculating the penalty for a synchronized reserve resource failing to meet its scheduled obligation during a spinning event, the unit repay all credits back to the last time that the unit successfully responded to an event 10 minutes or longer. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that, for calculating the penalty for a synchronized reserve resource failing to meet its scheduled obligation during a spinning event, the synchronized reserve shortfall penalty should include LOC payments as well as SRMCP and MW of shortfall. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that aggregation not be permitted to offset unit specific penalties for failure to respond to a synchronized reserve event. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that PJM immediately remove the 30 percent increase to the synchronized reserve reliability requirement. (Priority: High. First reported 2024. Status: Not adopted.)

Regulation Market

- The MMU recommends that the two signal regulation market design be replaced with a one signal regulation market design. (Priority: Medium. First reported 2023. Status: Not adopted.)[20]
- The MMU recommends that the ability to make dual offers (to make offers as both a RegA and a RegD resource in the same market hour) be removed

19 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations," § 4.4.3 Reserve Market Clearing, Rev. 134 (Apr. 23, 2025).

20 PJM filed proposed changes to the regulation market with the FERC on April 16, 2024, (Regulation Market Design Filing," Docket No. ER24-1772-000). The Commission Order on June 17, 2024 accepted the PJM Proposal as filed. PJM will implement the changes to the regulation market in two phases. Phase 1, scheduled to be implemented on October 1, 2025, will result in a single signal, bidirectional market with one clearing price that eliminates the need for an MBF. Phase 1 will eliminate RegA and RegD dual offers. Phase 1 will reduce the regulation commitment period from a 60-minute commitment to a 30-minute commitment. In Phase 1 the lost opportunity cost calculation used in the regulation market will be based on the resource's dispatched energy offer schedule, not the lower of its price or cost offer schedule.

from the regulation market. (Priority: High. First reported 2019. Status: Not adopted.)[21]

- The MMU recommends that the regulation market be modified to incorporate a consistent application of the marginal benefit factor (MBF) throughout the optimization, assignment and settlement process. The MBF should be defined as the Marginal Rate of Technical Substitution (MRTS) between RegA and RegD. (Priority: High. First reported 2012. Status: Not adopted. FERC rejected.)[22]
- The MMU recommends that the current calculation of the performance score (based on precision, delay and correlation metrics) be replaced with the current calculation of the precision score. (Priority: Medium. First reported 2023. Status: Not adopted.).
- The MMU recommends that the regulation market commitment period be reduced from a 60-minute commitment to a 30-minute commitment. (Priority: Medium. First reported 2023. Status: Not adopted.).[23]
- The MMU recommends that the lost opportunity cost in the ancillary services markets be calculated using the schedule on which the unit was scheduled to run in the energy market. (Priority: High. First reported 2010. Status: Not adopted.[24] FERC rejected.)[25]
- The MMU recommends that the lost opportunity cost calculation used in the regulation market be based on the resource's dispatched energy offer schedule, not the lower of its price or cost offer schedule. (Priority: Medium. First reported 2010. Status: Not adopted. FERC rejected.)[26]
- The MMU recommends that the $12.00 margin adder be eliminated from the definition of the cost based regulation offer because it is a markup and not a cost. (Priority: Medium. First reported 2021. Status: Not adopted.)
- The MMU recommends that the ramp rate limited desired MW output be used in the regulation uplift calculation, to reflect the physical limits of the unit's ability to ramp and to eliminate overpayment for opportunity costs when the payment uses an unachievable MW. (Priority: Medium. First reported 2022. Status: Not adopted.)[27]
- The MMU recommends enhanced documentation of the implementation of the regulation market design. (Priority: Medium. First reported 2010. Status: Not adopted. FERC rejected.)[28]
- The MMU recommends that PJM be required to save data elements necessary for verifying the performance of the regulation market. (Priority: Medium. First reported 2010. Status: Not adopted.)
- The MMU recommends that all data necessary to perform the regulation market three pivotal supplier test be saved by PJM so that the test can be replicated. (Priority: Medium. First reported 2016. Status: Not adopted.)
- The MMU recommends that the total regulation (TReg) signal sent on a fleet wide basis be eliminated and replaced with individual regulation signals for each unit. (Priority: Low. First reported 2019. Status: Not adopted.)
- The MMU recommends that, to prevent gaming, there be a penalty enforced in the regulation market as a reduction in performance score and/or a forfeiture of revenues when resource owners elect to deassign assigned regulation resources within the hour. (Priority: Medium. First reported 2016. Status: Not adopted. FERC rejected.)[29]

Frequency Response, Reactive, and Black Start

- The MMU recommends that all resources, new and existing, have a requirement to include and maintain equipment for primary frequency response capability as a condition of interconnection service. The PJM markets already compensate resources for frequency response capability and any marginal costs. (Priority: Medium. First reported 2018. Status: Partially adopted.)

21 See *id.*
22 See 162 FERC ¶ 61,295 (2018), *reh'g denied*, 170 FERC ¶ 61,259 (2020).
23 See *id.*
24 This recommendation was adopted by PJM for the energy market. Lost opportunity costs in the energy market are calculated using the schedule on which the unit was scheduled to run. In the regulation market, this recommendation has not been adopted, as the LOC continues to be calculated based on the lower of price or cost in the energy market offer.
25 See 162 FERC ¶ 61,295 (2018), *reh'g denied*, 170 FERC ¶ 61,259 (2020).
26 See *id.*
27 In Phase 1 the ramp rate limited desired MW output will be used in the regulation uplift calculation. The MMU does not agree with how this change will be implemented and will be reviewing the market results in Phase 1.
28 See *id.*
29 See *id.*

- The MMU recommends that all data necessary to perform the generator primary frequency response evaluation be saved by PJM so that the test can be replicated. (Priority: Medium. First reported 2023. Status: Not adopted.)
- The MMU recommends that PJM maintain a full list of all units subject to the Primary Frequency Response generator requirements. (Priority: Medium. First reported Q1, 2025. Status: Not adopted.)
- The MMU recommends that PJM develop the metric(s) necessary to objectively evaluate each unit's performance during primary frequency response events. (Priority: Medium. First reported Q2, 2025. Status: Not adopted.)
- The MMU recommends that PJM create the necessary tariff/manual language to properly enforce compliance with the NERC mandated Primary Frequency Response generator requirements. (Priority: Medium. First reported Q1, 2025. Status: Not adopted.)
- The MMU recommends that separate cost of service payments for reactive capability be eliminated and the cost of reactive capability be recovered in PJM markets. (Priority: Medium. First reported 2016. Status: Adopted 2024.)[30]
- The MMU recommends that payments for reactive capability, if continued, be based on the 0.95 power factor included in the voltage schedule in Interconnection Service Agreements. (Priority: Medium. First reported 2018. Status: Not adopted.)[31]
- The MMU recommends that, if payments for reactive are continued, fleet wide cost of service rates used to compensate resources for reactive capability be eliminated and replaced with compensation based on unit specific costs. (Priority: Low. First reported 2019. Status: Not adopted.)[32]
- The MMU recommends that, if payments for reactive are continued, Schedule 2 to OATT be revised to state explicitly that only generators that provide reactive capability to the transmission system that PJM operates and has responsibility for are eligible for reactive capability compensation. (Priority: Medium. First reported 2020. Status: Not adopted.)[33]
- The MMU recommends that new CRF rates for black start units, incorporating current tax code changes, be implemented immediately. The new CRF rates should apply to all black start units. Black start units should be required to commit to providing black start service for the life of the unit. CRF rates effective January 20, 2025, should reflect 100 percent bonus depreciation.[34] (Priority: High. First reported 2020. Status: Not adopted.)
- The MMU recommends that black start planning and coordination be on a regional basis recognizing cross zonal cranking paths and not on a narrowly or purely zonal basis and that the costs of black start service be shared on an equal per MWh basis across the region. (Priority: Medium. First reported 2023. Status: Not adopted.)
- The MMU recommends that the fuel assurance rules be modified to recognize actual fuel assured resources within and across zones. (Priority: High. First reported Q2, 2025. Status: Not adopted.)
- The MMU recommends that the Reliability Backstop for black start service be eliminated. There is no reason that PJM cannot acquire black start resources if the TOs can acquire black start resources. (Priority: High. First reported Q2, 2025. Status: Not adopted.)

Conclusion

The October 1, 2022, changes to the reserve markets included a synchronized reserve must offer requirement applicable to all generation capacity resources. This resulted in an increase in available supply. Combined with the removal of the $7.50 per MWh margin and the invalid variable operations and maintenance cost, supply and demand logic predicts lower prices, which occurred in 2022, except during Winter Storm Elliott. This is evidence of market efficiency. With the elimination of tier 1 reserves, the total reserve market clearing price credits, while based on lower prices, are paid to a larger

30 On October 17, 2024, the Commission issued a final rule, Order No. 904, eliminating separate payments for reactive in all jurisdictional markets, including PJM. On January 28, 2025, PJM submitted a compliance filing to implement Order No. 904 ("Compliance Filing") that proposed a transition mechanism lasting through May 31, 2026. See Docket No. ER25-1073. This recommendation will be implemented effective June 1, 2026.
31 *Id.* FERC Order No. 904 eliminates payments for reactive capability. When Order 904 is in effect, which is planned for June 1, 2026, this recommendation will be withdrawn as no longer relevant.

MW quantity. Prices have been higher since PJM increased the demand for reserves in May 2023.

The new reserve market design has been called into question by PJM based on a slow response during synchronized reserve events. In all cases, other than during Winter Storm Elliott, the ACE recovered within the required time frame. No reliability problems have occurred. While the total response met the needs of the system, PJM responded to the poor performance of individual units by unilaterally and inappropriately increasing reserve requirements. This increase shifts the burden of poor resource performance from the resources themselves to customers, clearing more reserves instead of directly dealing with the causes of poor performance. These increases in reserve requirements were the primary cause of higher reserve prices in 2023, 2024, and the first nine months of 2025, including 35 intervals of shortage pricing in May 2023 and several intervals of shortage pricing during spin events in 2024 and the first nine months of 2025, even while reserve markets cleared over 1,000 MW more than what was normally cleared in the months and years prior.

The data on synchronized reserve event recovery do not support the conclusion that there was or is a need to increase the demand for reserves. The focus should be on correcting issues related to the responses of individual units rather than increasing demand.

Significant communications technology and modelling issues when calling resources during spinning events result in slow response. While PJM now calculates reserve offer MW for the majority of resource types, a resource's cleared reserve MW are based on a resource's energy output at the end of a scheduling interval. If a unit is still moving when an event is called, such as near the beginning of a scheduling interval, it may or may not be able to achieve its scheduled output. Likewise, a unit that is decreasing output to create more headroom might not be able to immediately increase output when an event is called.

Although PJM now augments a resource's economic basepoint with its dispatched reserve MW during a spin event, PJM does not require resources to be able to receive this signal. Many resources are still dispatched using phone calls, either from markets operation centers waiting for the PJM ALL-CALL or from MOCs themselves manually calling plant personnel.

Even if a unit is on AGC and receiving the augmented basepoint, depending on where that unit finds itself on its ramp rate curve, it might have to spend time coming off AGC or decreasing output in order to start ramping using power augmentation. Having a synchronized reserve maximum that is less than the unit's economic maximum can address this case, but it is the responsibility of that unit to request the exception.

The immediate solution is to improve the deployment of reserves in synchronized reserve events by requiring the capability to use an electronic signal for all synchronized reserves and the actual use of the signal. The archaic telephone communications technology has been a source of slow response times, such as markets operation centers waiting for the PJM ALL-CALL or manually calling unit personnel to deploy reserves. Phone calls are not an effective or efficient method for deploying resources for immediate response. The MMU recommends that to minimize lag and improve performance, PJM use an electronic synchronized reserve event notification process for all resources and that all resources be required to have the ability to receive and automatically respond to the notifications. On December 17, 2024, PJM partially adopted this recommendation by implementing an electronic deployment of reserves via an augmented dispatch signal, but PJM does not require that resources be able to receive this signal nor that the receiving units be able to follow the signal for deploying reserves. Further improvements in communications technology and requirements are necessary and PJM should pursue them immediately.

Along with changes to the communications and deployment process, PJM and the MMU have worked with generators to identify circumstances where reserves were not accurately measured based on the energy and reserve offer parameters. More broadly, the MMU's proposal is to buy the correct amount of reserves. No increase in demand is required. There has been no change in the need/demand for reserves. PJM ignored the supply side. The issue is that resources have not provided the reserves that were offered and paid for. With improved communications technology, instead of buying more MW of poorly performing reserves, PJM will be able to accurately recognize the actual supply of reserves and to more efficiently deploy them in synchronized reserve events. PJM should immediately remove the 30 percent increase to the synchronized reserve reliability requirement in place from May 2023 through September 2025.

The design of the current PJM Regulation Market is significantly flawed.[35] The market design does not correctly incorporate the marginal rate of technical substitution (MRTS) in market clearing and settlement. The market design uses the marginal benefit factor (MBF) to incorrectly represent the MRTS and uses a mileage ratio instead of the MBF in settlement. The current market design allows regulation units that have the capability to provide both RegA and RegD MW to submit an offer for both signal types in the same market hour. However, the method of clearing the regulation market for an hour in which one or more units has a dual offer incorrectly accounts for the amount of RegD and the effective MW of the RegD that it clears. The result of the flaw is that the MBF in the clearing phase is incorrectly low compared to the MBF in the solution phase and the actual amount of effective MW procured is higher than the regulation requirement. This failure to correctly and consistently incorporate the MRTS into the regulation market design has resulted in both underpayment and overpayment of RegD resources and in the over procurement of RegD resources in all hours. Under the current design, slower response RegA resources (generating units) must provide additional regulation to offset the negative impact of RegD resources (largely batteries) that are charging in the middle of a regulation hour. The ability of some resources to submit offers for both RegA and RegD (dual offers) results in inefficient high prices. The market results continue to include the incorrect definition of opportunity cost. These issues are the basis for the MMU's conclusion that the regulation market design is flawed.

PJM filed significant changes to the regulation market design on April 16, 2024, that were accepted as filed by order of June 17, 2024.[36] PJM will implement the changes to the regulation market in two phases. Phase 1, implemented on October 1, 2025, is a single product, single signal market with one clearing price. Phase 2, to be implemented on October 1, 2026, will include separate regulation up and regulation down markets. The proposed Phase 1 changes will eliminate many of the significant issues identified by the MMU that have resulted from a two product, two signal market design including the incorrect and inconsistent use and application of the MBF/MRTS.

The benefits of markets can be realized under the current approach to ancillary service markets. Even in the presence of structurally noncompetitive markets, there can be transparent, market clearing prices based on competitive offers that account explicitly and accurately for opportunity cost. This is consistent with the market design goal of ensuring competitive outcomes that provide appropriate incentives without reliance on the exercise of market power and with explicit mechanisms to prevent the exercise of market power. However, there are significant issues with the PJM ancillary services markets.

The MMU concludes that the synchronized reserve market results were not competitive. The MMU concludes that the nonsynchronized reserve market results were not competitive. The MMU concludes that the secondary reserve market results were competitive. The MMU concludes that the regulation market results were not competitive, and the market design is significantly flawed.

35 The current PJM regulation market design that incorporates two signals using two resource types was a result of FERC Order No. 755 and subsequent orders. Order No. 755, 137 FERC ¶ 61,064 at PP 197–200 (2011).

36 PJM, "Regulation Market Design Filing," Docket No. ER24-1772-000 (April 16, 2024).

PJM Reserve Markets

Reserves resources are scheduled and paid for the availability to respond to a loss of supply on the system by increasing their energy output within defined time limits. When a resource clears in a reserve market, it is assigned scheduled reserve MW by that reserve market. Most reserve MW are cleared by the reserve markets, but PJM has the ability to schedule resources outside of the markets when needed.

PJM clears reserves to satisfy defined reserve service requirements. There are three reserve services: the synchronized reserve service (SR), the primary reserve service (PR), and the 30-minute reserve service (TMR). Each reserve service is defined by its response time requirement and by whether the service can be provided by offline resources (Table 10-5). Only the synchronized reserve service requires that all providers be online and synchronized to the grid. The other two services, primary reserve and 30-minute reserve, can be provided by both online and offline resources.

Table 10-5 Reserve services and their definitions

Service	Response Requirement (minutes)	Provided by Online Resources	Provided by Offline Resources
Synchronized Reserve	10 or less	Yes	No
Primary Reserve	10 or less	Yes	Yes
30-Minute Reserve	30 or less	Yes	Yes

Each reserve service requires a specified number of MW to be available in order to cover a potential loss of supply event, known as that service's reserve requirement. The size of a service's requirement depends on the contingencies that the service is designed to address (determining the service's reliability requirement), plus the option to add a requirement to account for potential demand increases due to temporary conditions like emergencies and weather alerts (determining the extended requirement). A service's total requirement is equal to the sum of its reliability requirement, which is unique to each service, plus the extended reserve requirement, which is the same for all services and has a base value of 190 MW.[37] [38] The default extended reserve requirement of 190 MW was designed to phase in the price impacts of shortage pricing in real time.

The reserve services are nested, such that the satisfaction of the synchronized reserve requirement counts towards the satisfaction of the primary reserve requirement, which counts towards the satisfaction of the 30-minute reserve requirement. The principal contingency for which reserves are cleared is the loss, in a single event, of the largest generator or group of generators, known as the "most severe single contingency," or the MSSC. Therefore, the reliability requirement of each service, in whole or in part, depends upon the size of the MSSC. Table 10-6 shows the default definitions of the reliability requirements and the full requirements. For calculating the 30-minute reserve requirement, PJM uses a pre-defined set of additional contingencies to simulate the effects of gas infrastructure failures on gas generators.[39] The use of these special contingencies is communicated to generators via PJM Emergency Procedures under "Gas Pipeline Emergencies".[40]

PJM selectively calls upon reserve services to respond to events. For example, to engage synchronized reserves, PJM initiates a synchronized reserve event, also called a spinning event.[41] In the first nine months of 2025, PJM did not call on nonsynchronized reserves to collectively respond to a reserve event. PJM calls on some nonsynchronized resources to individually respond during synchronized reserve events.

The deployment of 10-minute reserves can also be in response to dispatches from the New York Independent System Operator (NYISO), which serves as the dispatcher for shared reserve activation.[42] [43] Members of the PJM Mid-Atlantic Control Zone have agreed to activate a portion of 10-minute reserve

37 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations," § 4.3 Reserve Requirement Determination, Rev. 134 (Apr. 23, 2025).
38 PJM has proposed creating individual extended requirements for each reserve service. This proposal was approved by the Reserve Certainty Senior Task Force on June 6, 2024, but was rejected by the Markets & Reliability Committee on July 24, 2024.

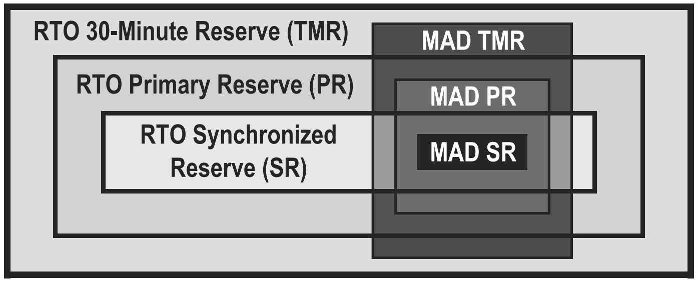
in coordination with members of the Northeast Power Coordinating Council when directed in order to relieve stress on the interconnected grid.

During an event, reserves respond either by increasing their energy output to the grid or by decreasing their energy consumption from the grid. The delivery of this energy is constrained by transmission limits, such that there are also limited locational requirements for each of the reserve services, except for the 30-minute reserve service.[44] PJM uses these constraints to define a reserve subzone with its own smaller requirements for synchronized reserve and primary reserve. Reserves in the subzone count towards the satisfaction of the requirements for the entire RTO Reserve Zone.[45] For example, satisfaction of the synchronized reserve requirement in the Mid-Atlantic Dominion (MAD) Reserve Subzone also counts towards the primary reserve requirement in the MAD Subzone and the synchronized reserve requirement in the RTO Zone, which in turn counts towards the satisfaction of the primary reserve requirement in the RTO Zone. There is only one active reserve subzone at a time. Figure 10-1 shows how reserve requirements for the MAD Reserve Subzone are nested inside the RTO Reserve Zone when the MAD Subzone is the active subzone.

Table 10-6 Service requirement definitions[46]

Service	Service Reliability Requirement	Service Extended Requirement
Synchronized Reserve (SR)	Most Severe Single Contingency	SR Reliability Requirement + Extended Reserve Requirement
Primary Reserve (PR)	1.5 × SR Reliability Requirement	PR Reliability Requirement + Extended Reserve Requirement
30-Minute Reserve (TMR)	Max(Largest Active Gas Contingency, PR Reliability Requirement, 3,000 MW)	TMR Reliability Requirement + Extended Reserve Requirement

Figure 10-1 Service nesting in the RTO Reserve Zone and the Mid-Atlantic Dominion (MAD) Reserve Subzone



In May 2023, PJM made two unilateral changes in succession to the reserve requirements to compensate for the asserted lack of performance during spin events. Table 10-21 shows the average performance for events 10 or more minutes long. The average response to the two events of 10 minutes or more that occurred in the first four months of 2023, both in January, was 56.9 percent, compared to 50.3 percent in the last three months of 2022. On May 12, 2023, PJM inappropriately increased the extended reserve requirement by 1,588 MW and on May 15, 2023, PJM reversed the increase. On May 19, 2023, PJM inappropriately increased the synchronized reserve reliability requirement by 30 percentage points to 130 percent of the MSSC. Figure 10-17 compares the changes in demand. PJM will decrease or increase the adder based on the average performance across non-overlapping sets of three 10-minute events.[47]

The reserve requirements effective for a scheduling interval can change from interval to interval depending on the contingencies and needs of the grid. When maintenance work at a power station risks tripping multiple generators whose total output is larger than the MSSC, PJM can increase the requirement for synchronized reserve to include that total output. PJM can increase the reserve requirement due to emergencies and weather alerts. In May 2023, PJM unilaterally modified *PJM Manual 11: Energy & Ancillary Services*

44 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations," § 4.3.1 Locational Aspect of Reserves, Rev. 134 (Apr. 23, 2025).
45 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations," § 4.4.1 Product and Locational Substitution, Rev. 134 (Apr. 23, 2025).
46 From mid-May 2023 through September 2025, PJM has set the synchronized reserve reliability requirement to be 130 percent of the MSSC. See "Synchronized Reserve Requirement for Reliability – Update," (March 6, 2025). <https://www.pjm.com/-/media/DotCom/committees-groups/committees/oc/2025/20250306/20250306-item-08b---synchronized-reserve-adder.pdf>.
47 See "Synchronized Reserve Requirement for Reliability – Update," PJM presentation to the Operating Committee. (March 6, 2025) <https://www.pjm.com/-/media/DotCom/committees-groups/committees/oc/2025/20250306/20250306-item-08b---synchronized-reserve-adder.pdf>.

Market Operations to allow PJM to temporarily increase the requirements to compensate for poor resource performance in order to continue compliance with ReliabilityFirst's regional criteria.[48] [49] Table 10-7 shows the instances identified by the MMU when PJM temporarily increased the reserve requirements in the first nine months of 2025.

Table 10-7 Temporary adjustments to 30-minute, primary, and synchronized reserve requirements: January through September, 2025[50]

From	To	Number of Hours	Amount of Adjustment
19-May-23	Ongoing	18,576+	30 percent increase to synchronized reserve reliability requirement
8-Jan-25	10-Jan-25	72	30-Minute Reserve (127 MW), Primary Reserve (245 MW), Synchronized Reserve (163 MW)
14-Jan-25	16-Jan-25	52	30-Minute Reserve (0 MW), Primary Reserve (0 MW), Synchronized Reserve (0 MW)
20-Jan-25	24-Jan-25	95	30-Minute Reserve (246 MW), Primary Reserve (420 MW), Synchronized Reserve (280 MW)
17-Feb-25	20-Feb-25	72	30-Minute Reserve (0 MW), Primary Reserve (28 MW), Synchronized Reserve (18 MW)
16-Mar-25	20-Mar-25	101	30-Minute Reserve (0 MW), Primary Reserve (0 MW), Synchronized Reserve (0 MW)

PJM must comply with the reserve requirements imposed by NERC, but PJM uses requirements that are more restrictive than NERC requirements. NERC Performance Standard BAL-002-3, which describes NERC's Disturbance Control Standard (DCS), defines a requirement for contingency reserve, which PJM implements as primary reserve.[51] [52] NERC BAL-002-3 does not define requirements specifically for synchronized reserve or for 30-minute reserve. NERC requires that contingency reserves respond within 15 minutes, while PJM requires that primary reserves respond within 10 minutes. NERC requires that PJM have contingency reserves greater than or equal to the MSSC, while PJM has historically targeted procuring primary reserve equal to at least 150 percent of the MSSC and procuring synchronized reserve equal to at least 100 percent of the MSSC. With PJM's 30-percent increase to the synchronized reserve reliability requirement (Table 10-7), PJM currently targets procuring primary reserve in excess of 195 percent of the MSSC and procuring synchronized reserve in excess of 130 percent of the MSSC.

A NERC DCS event is defined as the loss of supply, in a single event, of 80 percent or more of the MSSC. The event begins as soon as the Reporting ACE (a version of the area control error) starts to drop and ends when the Reporting ACE returns to the lesser of zero and its value at the start of the event. Although PJM uses synchronized reserve events to recover from DCS events, synchronized reserve events are generally longer than their corresponding DCS events (Table 10-23).

There are three kinds of resources that can provide reserves: online generators that can increase their energy output, offline generators that can start and provide their energy output, and demand response resources that can decrease their energy use. From these resources, there are three reserve products: synchronized reserves (SR), nonsynchronized reserves (NSR), and secondary reserves (SecR).[53] A reserve product is defined by its response-time requirement and by the types of resources that can provide it (Table 10-8).

Table 10-8 Reserve products and definitions

Reserve Product	Response Requirement (minutes)	Provided by Online Generators	Provided by Offline Generators	Provided by Demand-Side Response
Synchronized Reserve	10 or less	Yes	No	Yes
Nonsynchronized Reserve	10 or less	No	Yes	No
Secondary Reserve	10 exclusive to 30 exclusive	Yes	Yes	Yes

A reserve product can only be used to satisfy a reserve service's scheduling requirement if it also satisfies that service's response-time requirement and synchronization requirement, which are listed in Table 10-5. Table 10-9 shows which reserve products can be used to satisfy which reserve services.

48 RFC_Criteria_BAL-002-02. "Operating Reserves," August 29, 2012. <https://rfirst.org/ProgramAreas/Standards/Criteria/Regional%20Criteria%20Library/RFC_Criteria_BAL-002-02.pdf>.
49 See *id*, which describes the document as a "ReliabilityFirst Board of Directors approved good utility practice document which are not reliability standards" and notes that "ReliabilityFirst Regional Criteria are not NERC reliability standards, regional reliability standards, or regional variances, and therefore are not enforceable under authority delegated by NERC pursuant to delegation agreements and do not require NERC approval."
50 PJM does not make public the exact increases in reserves nor the exact times increases are used. This table shows the differences between the average reserve values inside times that have been identified for possible increases in reserves with the average values before and after those times. The ranges given can include several overlapping timespans of possible increases.
51 NERC BAL-002-3. "Disturbance Control Standard – Contingency Reserve for Recovery from a Balancing Contingency Event," April 1, 2019. <https://www.nerc.com/pa/Stand/Reliability%20Standards/BAL-002-3.pdf>.
52 See PJM. "PJM Manual 10: Pre-Scheduling Operations," § 3.1.1 Day-ahead and Real-Time Reserves, Rev. 45 (Nov. 21, 2024).
53 OATT, Attachment K - Appendix § 1.7.19 (Ramping).

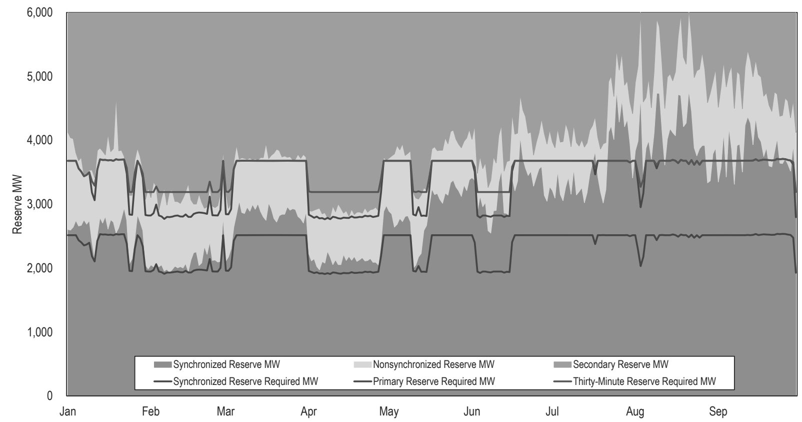
Table 10-9 Reserve products and the services they can provide

Reserve Product	Can Provide Synchronized Reserve	Can Provide Primary Reserve	Can Provide 30-Minute Reserve
Synchronized Reserve	Yes	Yes	Yes
Nonsynchronized Reserve	No	Yes	Yes
Secondary Reserve	No	No	Yes

Figure 10-2 shows how reserve products were cleared in real time to meet the reserve service requirements in the first nine months of 2025. In the figure, each line represents the extended requirement of a reserve service, which is the service's reliability requirement plus the generic extended requirement. The colored areas represent how the cleared MW of the three reserve products combine to satisfy the reserve requirements. As can be seen in the figure, the cleared reserve products providing the services do not exactly equal the service requirements. In the first nine months of 2025, the total amounts of cleared synchronized reserve and 30-minute reserve were frequently greater than their requirements. This can result from cleared resources providing more reserves than needed to satisfy the remainder of a requirement and can result from PJM clearing reserve products to help satisfy the requirements of the next broader reserve service. For example, in January, PJM cleared synchronized reserves in excess of the synchronized reserve requirement in order to, along with the cleared nonsynchronized reserve, more economically satisfy the primary reserve requirement.

Although not seen in Figure 10-2, PJM does not always clear enough reserves to satisfy a reserve requirement. When a service's requirement is not met, the result is shortage pricing.

Figure 10-2 Daily average real-time reserve products cleared and daily average real-time reserve service requirements used by RT SCED: January through September, 2025



PJM uses market mechanisms to clear resources. In general, products that meet shorter response time requirements and that can be used to satisfy multiple reserve requirements have higher prices. The objective is to minimize total cost when purchasing reserves and energy.

Implementation of PJM Reserve Markets

While the primary reserve requirement and 30-minute reserve requirement can be satisfied using multiple products, the products are purchased separately. There are separate markets for synchronized reserves, nonsynchronized reserves, and secondary reserves.[54] MW that are selected as reserve are said to have cleared the market. Effective October 1, 2022, each product's reserve market has a day-ahead component and a real-time component. The obligations of a reserve resource depend on its real-time assignment, which in turn depends on how the resource clears the day-ahead and real-time markets. A resource that cleared one market is not guaranteed to have cleared the other market, and a resource that cleared both markets need not clear the

54 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations," § 4.4.1 Product and Locational Substitution, Rev. 134 (Apr. 23, 2025).

same amount in real time as it did day ahead. Although multiple reserve products can be used to satisfy the same reserve service requirements, the reserve products are not necessarily paid the same market clearing prices. Each market for a reserve product has a single market clearing price that is applied to all reserve MW cleared in that market, regardless of the service that required the clearing of those MW.

In general, the reserve MW available from a resource are calculated by PJM based on the parameters in the resource's energy offer and reserve parameters. Some resource types, such as hydroelectric resources, energy storage resources, and demand response resources, can specify reserve offer amounts.[55] Generation capacity resources are required to participate in the reserve markets. However, nuclear, solar, and wind resources are excluded by default and must request inclusion in the reserve markets. PJM can automatically deselect a resource from participating in the reserve market for performance reasons.[56] [57] PJM can temporarily deselect a resource from providing reserves for, among other reasons, failing to reliably follow PJM's dispatch signal. A resource that is deselected for failing to follow PJM's dispatch signal is in violation of its must-offer requirement.[58]

A generation resource can request a maximum MW value for its reserve offer (synchronized, secondary, or both individually) that is lower than its economic maximum if that generator's reserve offer is subject to a physical limitation that cannot be modeled by a segmented hourly ramp rate.[59] Such a request must include documentation and data demonstrating the limitation. Both PJM and the MMU review the request. PJM must respond within 30 days after data supporting the request is submitted, telling the generation owner whether the request was accepted or denied, and if denied, for what reason.

The clearing of resources to meet PJM's operational requirements includes multiple steps to commit resources, dispatch resources, and calculate clearing prices.[60] [61] Each program in the commitment and dispatching process estimates future needs. The day-ahead market solution software schedules resources in one-hour blocks.[62] The real-time software schedules resources in five-minute intervals.

Due to their start and notification times, some resources can only be cleared in the earlier steps of PJM's commitment and dispatching process. Depending on their physical run-time requirements, resources are described as either flexible or inflexible. Inflexible resources are those that must run for at least one hour and are only committed in real-time by the hour-ahead real-time software or by a PJM operator, and can include demand response resources, offline CTs and hydro resources that can operate in condensing mode, and resources whose economic minimum output equals their economic maximum output. Flexible resources are those that can be cleared for reserves by RT SCED later in the process. Such resources are already online for energy, require no notification time, and can be automatically dispatched.

In general, resources do not have to clear the same amounts in the real-time and day-ahead markets, and a resource that cleared one of the markets is not guaranteed to have cleared the other. However, if an inflexible condenser or an inflexible economic load response resource has a day-ahead assignment, that assignment is also applied to the operating day.[63]

Not all resources that provide reserves necessarily clear the reserve market. When needed, PJM is able to manually schedule a resource for reserves if that resource would not have otherwise run.[64] Similarly, not all inflexible reserve resources cleared by the ASO and IT SCED are necessarily used for reserves. When needed, PJM can manually switch inflexible resources from providing reserves to providing energy.

Figure 10-4 compares the daily average requirements of the day-ahead clearing engine, the ASO, and RT SCED. Figure 10-4 shows that the reserve requirements used by the ASO and RT SCED do not differ significantly. Until May 12, 2023, the daily average 30-minute reserve requirement was almost always 3,190 MW in the day-ahead, ASO, and RT SCED (Figure 10-4).

Figure 10-3 compares the daily average cleared MW of the day-ahead clearing engine, the ASO, and RT SCED. In addition to the increase in cleared secondary reserve resulting from PJM correcting its software error, Figure 10-3 shows that the day-ahead market also tended to clear the most nonsynchronized reserve. For satisfying the primary reserve requirement, the ASO uses more synchronized reserves, clearing less nonsynchronized reserves than RT SCED due to differences in the available MW that result from differences in the applied unit schedules. This difference is also seen in Figure 10-23.

Figure 10-3 MW cleared by the day-ahead engine, the ASO, and RT SCED: January through September, 2025

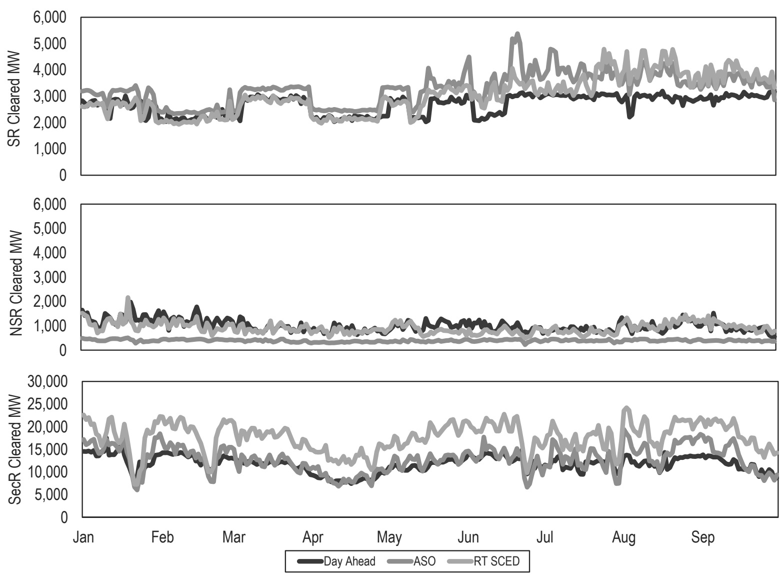

Figure 10-4 Requirements used in the day-ahead engine, the ASO, and RT SCED: January through September, 2025

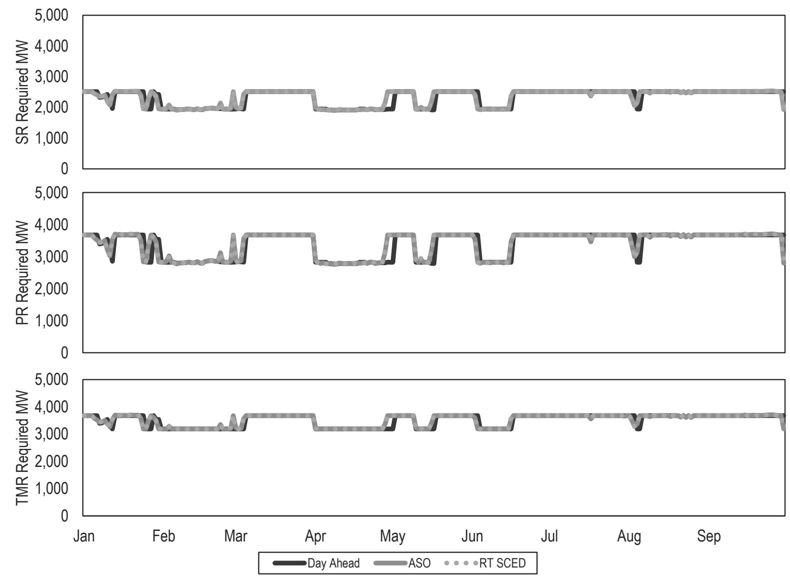
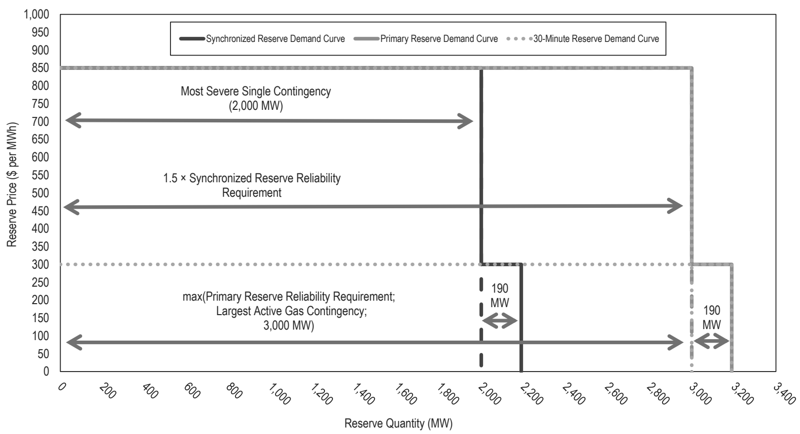


There is a defined MW demand only for synchronized reserves, primary reserves, and 30-minute reserves. The demand for nonsynchronized reserves and for secondary reserves is derived from those defined MW demand levels and cleared supply. PJM's administratively defined demand curve for reserves is called the Operating Reserve Demand Curve (ORDC) and has two steps. The first step of each reserve product's ORDC is set at that product's reliability requirement and is priced at $850 per MWh. The second step is the extended reserve requirement and is priced at $300 per MWh. Figure 10-5 shows example ORDCs for the three reserve products using an example MSSC of 1,000 MW with no increases in the extended reserve requirement.

In 2014, PJM added an optional second step to the ORDC, which could be increased from its default value of 0 MW to account for increased uncertainty identified by PJM. In 2017, PJM proposed a minimum value of 190 MW for the then optional second step, bringing it to its current form.[65] [66]

Figure 10-5 shows an example of the three operating reserve demand curves for each reserve product for an example MSSC at 1,000 MW with no increases in the extended reserve requirement. The adjusted ORDCs resulting from PJM's increase to the synchronized reserve reliability requirement are shown in Figure 10-18.

Figure 10-5 An example of the reserve product real-time operating reserve demand curves, including the permanent second steps



During periods of shortage pricing, the reserve market clearing prices can be higher than the limits shown in Figure 10-5. Offer prices for synchronized reserve are cost based and are capped at the expected value of the synchronized reserve penalty. The product substitution cost is a function of LMPs, the marginal cost of energy for the resources providing reserves, and the minimized cost of substituted MW providing energy. At the margin, the price is the sum of the offer price and the product substitution cost of the marginal unit(s).[67]

Like the markets, credits and charges for reserves have day-ahead and real-time components. Day-ahead credits depend only on a resource's day-ahead assignment and the day-ahead market clearing price. There are no lost opportunity cost (LOC) credits in the day-ahead market, nor are there any shortfall charges applied to day-ahead assignments when evaluating resource performance. These concepts apply only to the real-time reserve markets.

The real-time component, known as the balancing credit, is added to day-ahead credits based on the difference between the real-time and day-ahead assignments. This balancing credit for a resource is the sum of a resource's balancing MCP credit and LOC credit, less any shortfall charge for failing to provide the service. If a resource clears less MW in real-time than in the day-ahead market, and if it is found to be at fault for this reduction, then the balancing MCP credit is negative and so the resource buys back this difference at real-time prices. If the resource clears more in real time, then it is positive. If a resource's real-time assignment is the same as its day-ahead assignment, then the balancing MCP credit is $0 and the resource's total MCP credit uses only the day-ahead MCP.

For the synchronized reserve product and the secondary reserve product, the MW for which a resource receives real-time credit can be capped at a value less than the cleared real-time amount. Without capping, a reserve resource producing energy above its directed amount would be paid for reserve MW that it did not actually make available.

Reserve Subzones

Reserve subzones address transmission limits that may prevent the lowest cost reserves from being deliverable throughout the RTO. A reserve subzone has its own reserve requirements, which can only be satisfied by resources within the subzone. The RTO Reserve Zone has only one active subzone at any time. In practice, PJM has maintained only one subzone, the Mid-Atlantic

65 See the transmittal letter to Revisions to OA Schedule 1 and OATT Att K-Appx RE Operating Reserve Demand Curve, Docket No. ER17-1590-000 (May 12, 2017) at 8.
66 For background data, see "Shortage Pricing ORDC - Order 825," PJM presentation to the Market Implementation Committee. (October 26, 2016) <https://www.pjm.com/-/media/committees-groups/committees/mic/20161026-special/20161026-item-03-shortage-ordc.ashx>
67 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations," § 4.2.9 Synchronized Reserve Market Clearing Price (SRMCP) Calculation, Rev. 121 (July 7, 2022). This version of the manual has a clearer definition than later versions.

Dominion Reserve Subzone (MAD), and in every market solution, the most limiting constraining path sets the transfer limit between the RTO and in MAD. The price in MAD may exceed the price in the rest of the RTO when the constraints are binding.

While PJM generally triggers synchronized reserve events for the entire RTO, PJM has the option to only load reserves in the defined subzone. For example, on February 24, 2024, PJM initiated a synchronized reserve event only for MAD.

The choice of MAD was a result of historical congestion patterns. Transmission limits at times required maintaining out of merit reserves in the MAD area. On most days, the MAD Subzone is no longer binding. As of October 1, 2022, PJM has a process to revise the definition of the subzone. The subzone definition may change as often as daily based on system conditions, and new subzones can be defined as needed.[68] In 2024 and the first nine months of 2025, PJM did not change the subzone.

Figure 10-6 is a map of constraints and major generation sources, showing how the constraints separating the RTO Reserve Zone and MAD Reserve Subzone are defined by the underlying grid topology. The most frequently binding constraints in the first nine months of 2025 were Bedington-Black Oak, Brighton-Conastone, and Cloverdale-Lexington.

Figure 10-7 shows the reserve service requirements and cleared reserve product in the MAD Reserve Subzone in the first nine months of 2025. As there is no 30-minute reserve requirement for the MAD Reserve Subzone, secondary reserve is excluded. The increase in reserve requirements in effect since mid-May 2023 does not apply to the MAD Reserve Subzone, only to the RTO Reserve Zone.

68 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations," § 4.3.2 Creation of New Reserve Subzones, Rev. 134 (Apr. 23, 2025).

Figure 10-6 PJM RTO Zone and MAD Subzone map of constraints and generation sources

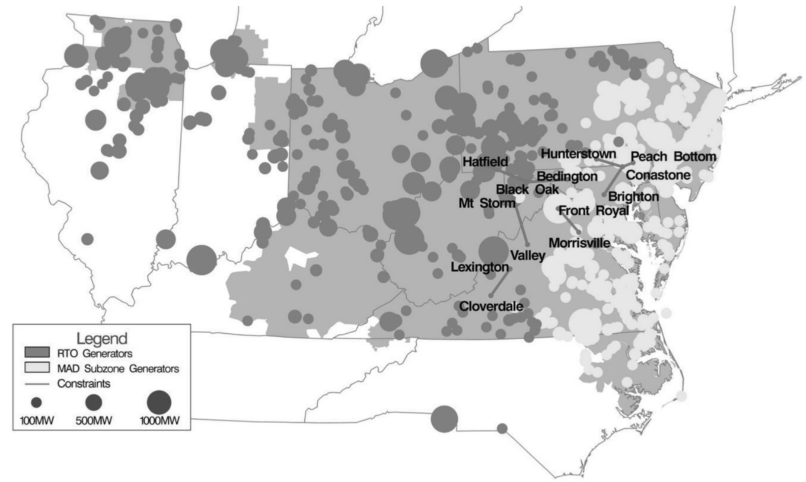


Figure 10-7 Daily average real-time MAD reserve products and daily average real-time MAD reserve service requirements: January through September, 2025

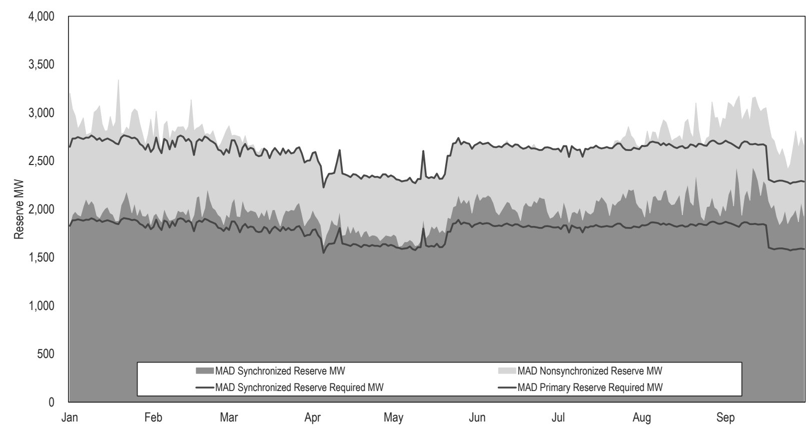


Primary Reserve

NERC Performance Standard BAL-002-3, Disturbance Control Standard – Contingency Reserve for Recovery from a Balancing Contingency Event, requires PJM to carry sufficient contingency reserve to recover from a sudden balancing contingency (usually a loss of generation). The Contingency Event Recovery Period is the time required to return the Reporting ACE to the lesser of zero and its pre-event level. The Contingency Reserve Restoration period is the time required to restore contingency (primary) reserves to a level greater than or equal to the largest single contingency after the end of the Contingency Event Recovery Period. NERC standards set the Contingency Event Recovery Period as 15 minutes and the Contingency Reserve Restoration Period as 90 minutes.[69] The NERC requirement is 100 percent compliance and status must be reported quarterly. PJM implements this contingency reserve recovery period requirement using primary reserves.[70] PJM maintains 10-minute reserves (primary reserves) which is more conservative than the NERC requirement. PJM's primary reserves are made up of resources, both synchronized and nonsynchronized, that can provide energy within 10 minutes. PJM does not have a Contingency Reserve Restoration Period standard.

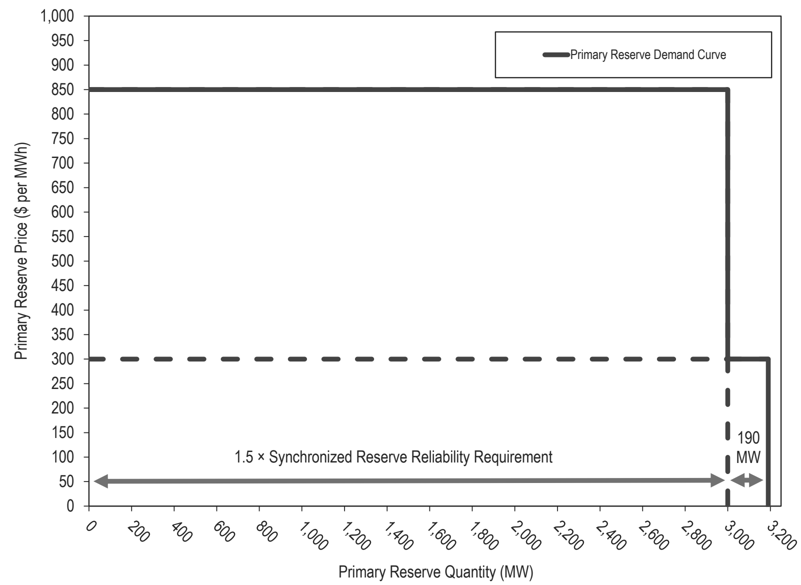
Market Structure

Demand

Demand for primary reserves is based on the primary reserve requirement. The primary reserve requirement is equal to the sum of the primary reserve reliability requirement, unique to the primary reserve service, plus the extended reserve requirement, which is the same for all services. The primary reserve reliability requirement is equal to 150 percent of the synchronized reserve reliability requirement. Figure 10-8 shows an example operating reserve demand curve for primary reserve for an example synchronized reserve reliability requirement of 2,000 MW plus the default 190 MW extension.

69 See PJM. "PJM Manual 12: Balancing Operations," Rev. 55 (Jun. 18, 2025) Attachment D, "the Disturbance Recovery Period is 15 minutes after the start of a Reportable Disturbance. Subsequently, PJM must fully restore the Synchronized Reserve within 90 minutes." While this cited attachment only references restoring synchronized reserves, PJM Manuals 10 & 13 make it clear that primary reserves serve as PJM's contingency reserves, although PJM generally uses synchronized reserves to recover from contingency events.
70 See PJM. "PJM Manual 10: Pre-Scheduling Operations," § 3.1 Reserve Definitions, Rev. 45 (Nov. 21, 2024).

Figure 10-8 An example of a primary reserve real-time operating reserve demand curve, including the permanent second step



In the first nine months of 2025, the average primary reserve requirement for the RTO Zone was 3,401.4 MW in the real-time market and 3,384.4 MW in the day-ahead market. The average primary reserve requirement in the MAD Subzone was 2,584.7 MW in the real-time market and 2,559.0 MW in the day-ahead market.

In an attempt to offset poor unit specific synchronized reserve performance, PJM unilaterally and inappropriately made changes to the reserve requirements in May 2023. On May 12, 2023, PJM inappropriately increased the extended reserve requirement by 1,588 MW and on May 15, 2023, PJM reversed the increase. On May 19, 2023, PJM inappropriately increased the synchronized reserve reliability requirement by 30 percentage points to 130 percent of the MSSC. In effect, this increased the primary reserve reliability requirement by

45 percentage points to 195 percent of the MSSC. PJM has announced criteria to decrease or increase the adder based on average performance across non-overlapping sets of three 10-minute events.[71]

Supply

In the first nine months of 2025, the demand for primary reserve was satisfied by synchronized reserves and nonsynchronized reserves. The primary reserve requirement is met from the least expensive combination of synchronized and nonsynchronized reserves that satisfies the requirements of the primary reserve service and the synchronized reserve service. Table 10-10 shows the real-time average available MW from synchronized and nonsynchronized resources in the first nine months of 2025.

Table 10-10 Average available MW for clearing: January through September, 2025

Location	Synchronized Reserve MW	Nonsynchronized Reserve MW
RTO	5,763.4	1,006.5
MAD	2,814.0	614.1

Table 10-11 provides the average dispatched reserves, by reserve product, used by the RT SCED market solution to satisfy the primary reserve requirement in the MAD Subzone from January 2024 through September 2025. Table 10-12 shows the average dispatched reserves, by reserve product, used by the RT SCED market solution to satisfy the primary reserve requirement in the RTO Zone from January 2024 through September 2025.

Table 10-11 Average monthly reserves used to satisfy the primary reserve requirement, MAD Subzone: January 2024 through September 2025

Year	Month	Synchronized Reserve MW	Nonsynchronized Reserve MW	Total Primary Reserve MW
2024	Jan	2,007.8	754.0	2,761.8

2025	Aug	4,068.4	1,096.1	5,164.6
2025	Sep	3,814.6	980.6	4,795.2
2025	Average	3,038.4	913.4	3,951.7

Market Concentration

In the first nine months of 2025, the RTO primary reserve market was unconcentrated in day ahead and unconcentrated in real time. In the first nine months of 2025, the MAD primary reserve market was moderately concentrated in day ahead and moderately concentrated in real time. Table 10-13 shows the average of the HHI values of each interval for primary reserves in the first nine months of 2025.

Table 10-13 Average primary reserve HHI: January through September, 2025

Location	Market	Average HHI	Percent of Intervals Max Market Share Above 20%	Description
RTO	RT	980	41.2%	Unconcentrated
RTO	DA	915	41.1%	Unconcentrated
MAD	RT	1563	81.4%	Moderately Concentrated
MAD	DA	1401	78.2%	Moderately Concentrated

Market Performance

Figure 10-9 shows daily weighted average synchronized and nonsynchronized market clearing prices in the first nine months of 2025. The synchronized reserve market clearing prices for the RTO Reserve Zone and the MAD Reserve Subzone diverged in 174 intervals, 0.2 percent of the total 78,612 five-minute intervals in the first nine months of 2025. The nonsynchronized reserve market clearing prices for the RTO Reserve Zone and the MAD Reserve Subzone diverged in 172 intervals, 0.2 percent of the total 78,612 five-minute intervals in the first nine months of 2025.

The prices of synchronized reserve and nonsynchronized reserve spiked on January 23, 2025, during the 2025 polar vortex, for which conservative operations were declared and a cold weather alert was issued. Shortage pricing for primary reserve in the RTO was used on February 11, March 12, March 18, and March 19, 2025. Shortage pricing for synchronized reserve for the RTO the MAD Reserve Subzone was used on February 5, 2025. The shortages on February 5 and February 11 occurred during synchronized reserve events. Cold weather alerts were issued for February 17 through February 19. Conservative operations were issued for February 14 and February 16 through February 19. Higher prices in March were due to a decrease in the available nonsynchronized reserve MW, leading PJM to increase the amount of cleared synchronized reserve MW used to satisfy the primary reserve requirement. The prices of synchronized reserve and nonsynchronized spiked on hot weather days in late June, for which conservative operations were declared and hot weather alerts, maximum emergency generation alerts, and a maintenance outage recall were issued. Shortage pricing for primary reserves in the RTO was used on June 22 through June 25, 2025. Shortage pricing for primary reserves in the MAD Reserve Subzone was on June 22 and June 24, 2025.

Shortage pricing for synchronized reserve in the RTO was used on June 22, June 23, June 24, and June 30. Shortage pricing for synchronized reserve in the MAD Reserve Subzone was used on June 24. In July, PJM declared hot weather alerts, maximum emergency generation alerts, and a maintenance outage recall during a second period of hot weather. This second period of hot weather saw 15 intervals of RTO primary reserve shortage pricing. The RTO also used shortage pricing for primary reserves on August 14, August 15, September 1, September 4, and September 25. The MAD Reserve Subzone used shortage pricing for primary reserve on September 4. Shortage pricing for synchronized reserve was used on September 4 in the RTO.

Table 10-14 shows the number of intervals with shortage pricing in which the amount cleared by RT SCED was greater than the reserve requirement absent the increase to the synchronized reserve reliability requirement. In the first nine months of 2025, in the majority of intervals with shortage pricing, RT SCED cleared enough reserve MW to satisfy the original reserve service requirements. These intervals were not short in the sense of failing to clear a sufficient amount of reserves. These intervals were short because of PJM's unilateral increase to the synchronized reserve reliability requirement.

Figure 10-9 Daily average market clearing prices for synchronized reserve and nonsynchronized reserve: January through September, 2025

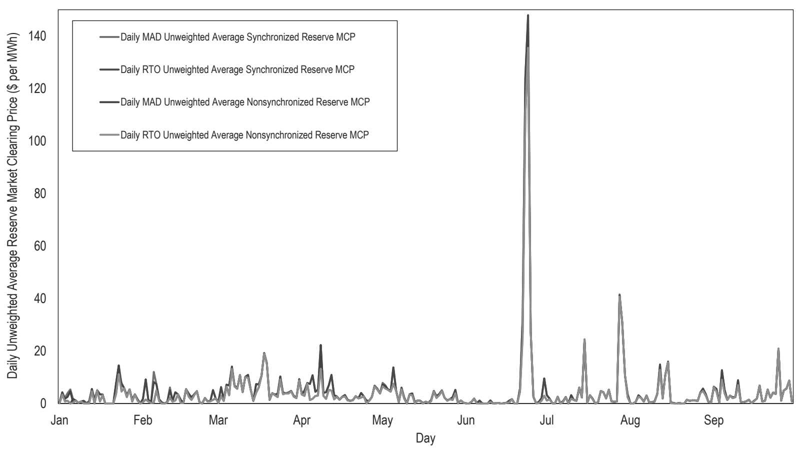

Table 10-14 Number of shortage pricing intervals which satisfied the unmodified reserve service requirement: January through September, 2025

	Intervals with Shortage Pricing			Intervals where RT SCED Satisfied Original Requirement			Percentage of Intervals where RT SCED Satisfied Original Requirement			Intervals where RT SCED Did Not Satisfy Original Requirement		
Location	SR	PR	TMR	SR	PR	TMR	SR	PR	TMR	SR	PR	TMR
RTO	17	111	22	17	79	16	100.0%	71.2%	72.7%	0	32	6
MAD	6	6	0	4	2	0	66.7%	33.3%	NA	2	4	0

Synchronized Reserve

All eligible generation capacity resources capable of providing synchronized reserves have a must offer requirement, and all cleared synchronized reserves have an obligation to perform and receive payment based on the synchronized reserve market clearing price. PJM Manual 11: Energy & Ancillary Services Market Operations states, "Any generator that is a PJM generation capacity resource that has a Reliability Pricing Model (RPM) or Fixed Resource Requirement (FRR) Resource commitment that is eligible to provide Reserves must offer their 10-minute and 30-min reserve capability, unless the unit is unavailable due to an approved planned outage, maintenance outage or forced outage."[72]

Since October 1, 2022, the reserve market design for synchronized reserve includes both day-ahead and real-time markets. Prior to that date, synchronized reserve was only a real-time product.

PJM uses synchronized reserve when PJM calls synchronized reserve events, also called spin events or spinning events.

Market Structure

For most resources, synchronized reserves consist of any online capacity not being used for energy that can be achieved within 10 minutes from the current dispatch point according to the resource's ramp rate. The PJM market solves an economic dispatch to determine which, if any, of these resources should be backed down to provide reserves. Some nondispatchable resources can provide synchronized reserves, including storage resources, hydro resources

72 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations," § 4.2.2 Reserve Resource Offer Requirements, Rev. 134 (Apr. 23, 2025).

with storage, synchronous condensers, and demand response resources. For both the RTO and the reserve subzone, the day-ahead market clears hourly synchronized reserve assignments and the real-time market clears five-minute synchronized reserve assignments.

Demand

Demand for the synchronized reserve product comes from the reserve requirement for the synchronized reserve service. The synchronized reserve requirement is equal to the synchronized reserve reliability requirement plus the extended reserve requirement. The synchronized reserve reliability requirement is normally equal to the most severe single contingency (MSSC). Figure 10-5 shows an example operating reserve demand curve for synchronized reserve.

In the first four months of 2023, the synchronized reserve reliability requirement was equal to the MSSC. PJM unilaterally increased the extended reserve requirement by 1,588 MW from May 12, 2023, through May 15, 2023. PJM then unilaterally increased the synchronized reserve reliability requirement to 130 percent of the MSSC on May 19, 2023, which increased the effective primary reserve reliability requirement from 150 percent of the MSSC to 195 percent of the MSSC. Since May 19, 2023, the demand portion has been equal to 130 percent of the MSSC. PJM did not increase demand in the MAD Reserve Subzone, only in the RTO Reserve Zone. Figure 10-17 compares the old and new RTO ORDCs with an example MSSC of 1,000 MW.

Figure 10-2 shows a plot of the daily average real-time requirement for synchronized reserve. In the first nine months of 2025, the average real-time synchronized requirement in the RTO Reserve Zone was 2,330.9 MW and the average day-ahead requirement was 2,319.6 MW. In the MAD Reserve Subzone, the average real-time synchronized requirement was 1,786.4 MW and the average day-ahead requirement was 1,769.4 MW.

Figure 10-16 compares the total amount of cleared synchronized reserve with the subset of cleared synchronized reserve that is provided by DSR. Prior to October 1, 2022, DSR resources were limited by PJM to being no more than 33 percent of cleared synchronized reserves in each interval, but that limitation was removed on October 1, 2022, as part of the changes to the reserve markets.

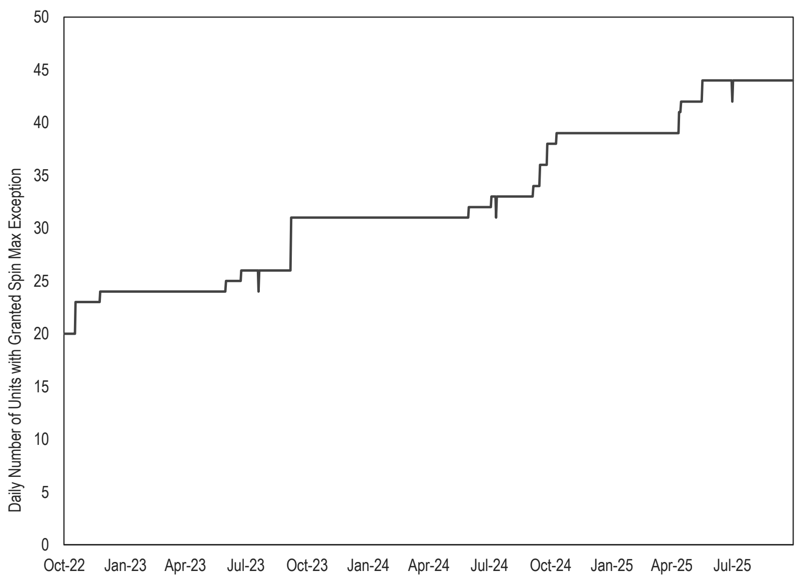
Supply

The supply of synchronized reserves consists of all unloaded capacity that can convert to energy in 10 minutes from eligible online generators and offers from eligible economic load response that can curtail in 10 minutes.[73] Any of this capacity that is not offered as dispatchable in the energy market does not have a lost opportunity cost in the security constrained economic dispatch (SCED). This includes synchronous condensers, storage resources, and demand response. Synchronous condensers and demand response are also considered inflexible in the reserve market and require an hourly commitment, which is made by the Ancillary Services Optimizer (ASO) in real time. This means that these resources enter the SCED reserves supply curve with a marginal cost of zero because PJM is effectively committing them as must run, block loaded reserves.

In general, a resource's reserve MW are the lesser of a resource's 10-minute ramp, and the difference between its energy output and its economic maximum output. A generation resource can request a maximum MW value for its synchronized reserve offer that is lower than its economic maximum if that generator's reserve offer is subject to a physical limitation that cannot be modeled by a segmented hourly ramp rate.[74] Figure 10-10 shows how the number of units that can use a lower synchronized reserve maximum MW has increased. If generators in need of the exception request it, PJM should see improved reserve performance due to a more accurate calculation of the available reserve MW.

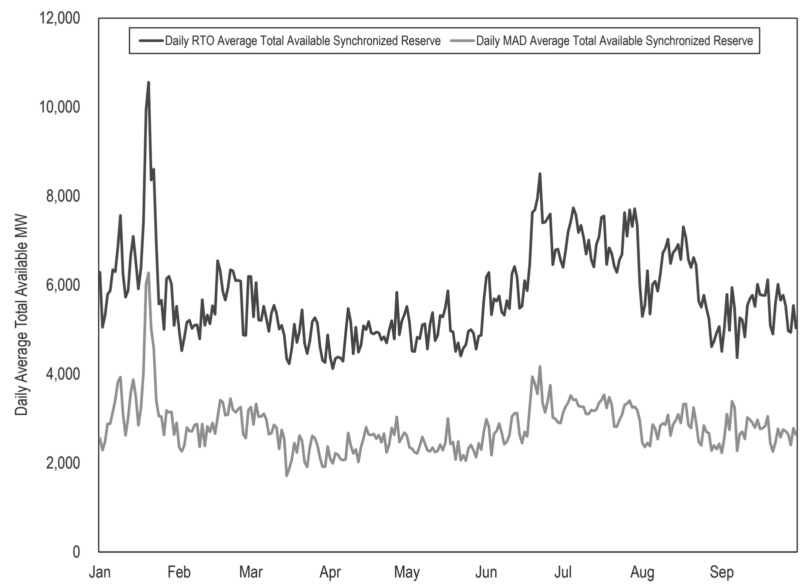
73 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations," § 4.2.1 Reserve Market Eligibility, Rev. 134 (Apr. 23, 2025).
74 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations," § 4.2.2.1 Communication for Reserve Capability Limitation, Rev. 134 (Apr. 23, 2025).

Figure 10-10 Number of units per day allowed to use a spin max less than eco max:[75] October 2022 through September 2025



In the first nine months of 2025, the average supply of offered and eligible synchronized reserve was 5,763.4 MW in the RTO Reserve Zone, of which 2,814.0 MW was located in the MAD Reserve Subzone. Figure 10-11 shows the daily average available synchronized reserve MW in the first nine months of 2025. The daily average total available synchronized reserve MW increased in late January due to PJM committing more resources to be online during the 2025 polar vortex. The daily average total available synchronized reserve MW increased in late June due to PJM committing more resources to be online on hot weather days.

Figure 10-11 Daily Average Available Synchronized Reserve: January through September, 2025



Market Concentration

Table 10-15 provides the average HHI and the percent of intervals during which the maximum market share was above 20 percent for the day-ahead and real-time synchronized reserve markets for the first nine months of 2025. In the first nine months of 2025, the MAD synchronized reserve market was moderately concentrated in day ahead and moderately concentrated in real time. In the first nine months of 2025, the RTO synchronized reserve market was unconcentrated in day ahead and unconcentrated in real time.

75 That a unit is able to use a spin maximum less than its economic maximum does not mean that it is required to do so. The count of units that used the exception on a given day can be less than what is shown.

Table 10-15 Day-ahead and real-time synchronized reserve average HHI: January through September, 2025

Location	Market	Average HHI	Percent of Intervals Max Market Share Above 20%	Description
RTO	RT	911	34.6%	Unconcentrated
RTO	DA	799	17.9%	Unconcentrated
MAD	RT	1721	88.5%	Moderately Concentrated
MAD	DA	1341	72.7%	Moderately Concentrated

In the first nine months of 2025, the Ancillary Service Optimizer, which schedules economic inflexible resources while considering all resources against forecasted LMPs, failed the three pivotal supplier test in 1,612 hours, 62.0 percent of the 2,602 hours to which the test applied.

Market Behavior

The synchronized reserve offer price must be cost based and is capped at the expected value of the synchronized reserve penalty, which equals the average penalty multiplied by the average rate of nonperformance multiplied by the probability that an event will occur.[76] These values are listed in Figure 10-12. For resources that do not provide an offer price, the offer price is treated as $0 per MWh. In the first nine months of 2025, the weighted average offer price for generators that set their offer MW was $0.001 per MWh. In the first nine months of 2025, the weighted average offer price for DSR resources that set their offer MW was $0.006 per MWh.

Figure 10-12 Expected values of the synchronized reserve penalty: October 2022 through September 2025[77]

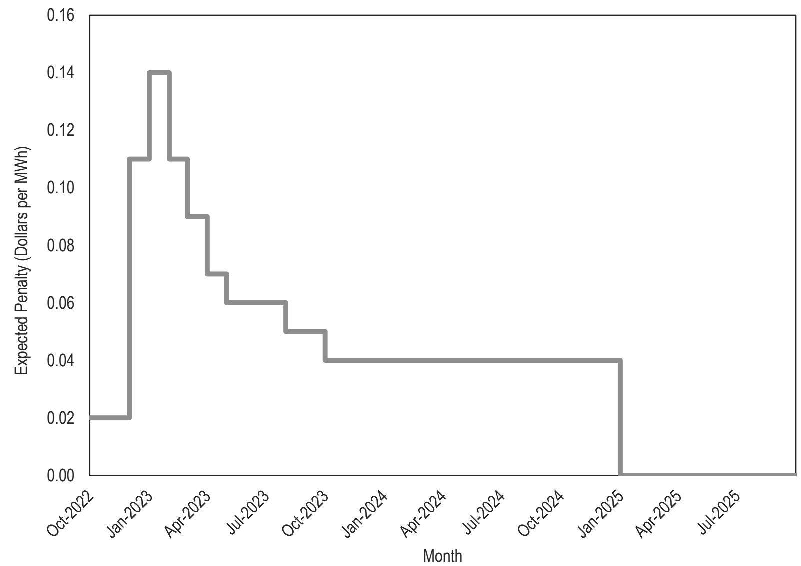


Figure 10-13 shows the average supply of synchronized reserve MW seen by the ASO based on the effective offers for the interval. A generator's effective offer is the sum of the generator's offer price, energy use cost, and the absolute value of the product substitution cost. A DSR resource's effective offer is equal to the offer price. Figure 10-13 also shows the average synchronized reserve requirement across all intervals used by the ASO and the maximum average supply of synchronized reserve MW using all effective offers. As seen in Figure 10-12, the expected value of the synchronized reserve penalty is $0 per MWh, resulting in the shape of the supply curve of the average total synchronized reserve MW.

76 See PJM. "PJM Manual 15: Cost Development Guidelines," § 4.7 Synchronized Reserve, Rev. 46 (Nov. 25, 2024).

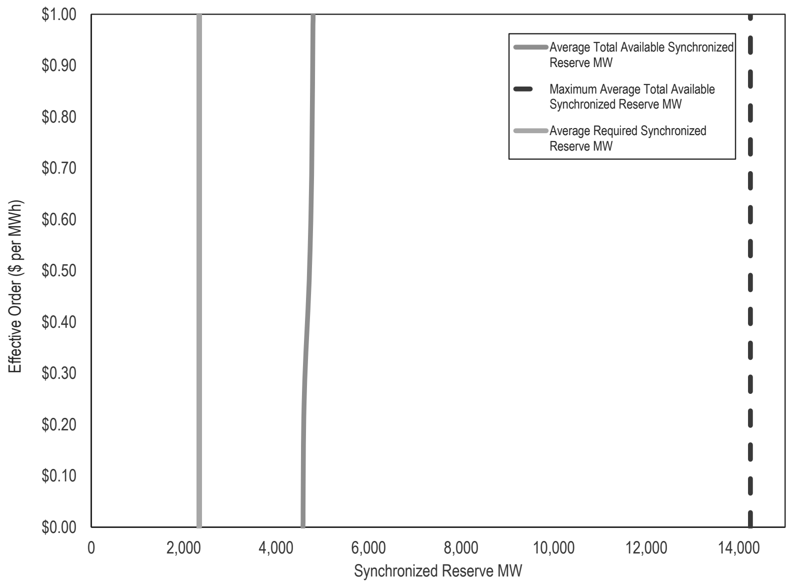
Figure 10-13 Average total available MW by effective offer: January through September, 2025



Market Performance

In the first nine months of 2025, the real-time RTO weighted average synchronized reserve market clearing price (SRMCP) was $4.55 per MWh and the day-ahead RTO weighted average SRMCP was $6.23 per MWh. The real-time MAD weighted average SRMCP was $3.94 per MWh and the day-ahead MAD weighted average SRMCP was $6.26 per MWh. In the first nine months of 2025, there were 78,612 five-minute intervals in the real-time market and there were 6,551 hours in the day-ahead market. The real-time RTO SRMCP was $0 per MWh in 67,847 intervals (86.3 percent of all intervals). The real-time MAD SRMCP was $0 per MWh in 67,714 intervals (86.1 percent of all intervals). The day-ahead RTO SRMCP was $0 per MWh in 3,571 hours (54.5 percent of all hours). The day-ahead MAD SRMCP was $0 per MWh in 3,474 hours (53.0 percent of all hours).

Figure 10-14 shows the daily unweighted average prices for synchronized reserve in the real-time and day-ahead markets. Higher day-ahead prices in January occurred during the 2025 polar vortex, for which conservative operations were declared and a cold weather alert was issued. In February, shortage pricing was used on February 5 for the RTO and MAD, and cold weather alerts were issued for February 17 through February 19. Conservative operations were issued for February 14 and February 16 through February 19. Higher average prices in March are due to, as seen in Figure 10-2, a return to a larger synchronized reserve reliability requirement paired with a decrease in the fraction of nonsynchronized reserve cleared. As shown by Figure 10-22, the available nonsynchronized reserve MW decreased in March due to several larger units having planned outages, which necessitated clearing more expensive synchronized reserve resources to satisfy the primary reserve requirement. Real-time prices in late June spiked on hot weather days, for which conservative operations were declared and hot weather alerts, maximum emergency generation alerts, and a maintenance outage recall were issued. On hot weather days in June 2025, the RTO Reserve Zone and the MAD Reserve Subzone used shortage pricing for 79 intervals for one or more of synchronized reserve, primary reserve, and 30-minute reserve. During this hot weather event, two intervals of synchronized reserve shortage pricing were concurrent with a spinning event on June 22, 2025. Higher day-ahead prices for July 27 and July 28 correspond with hot weather alerts and maximum emergency generation alerts. There was no shortage pricing for synchronized reserve on the July hot weather days.

Figure 10-14 Day-ahead and real-time synchronized reserve average market clearing prices: January through September, 2025

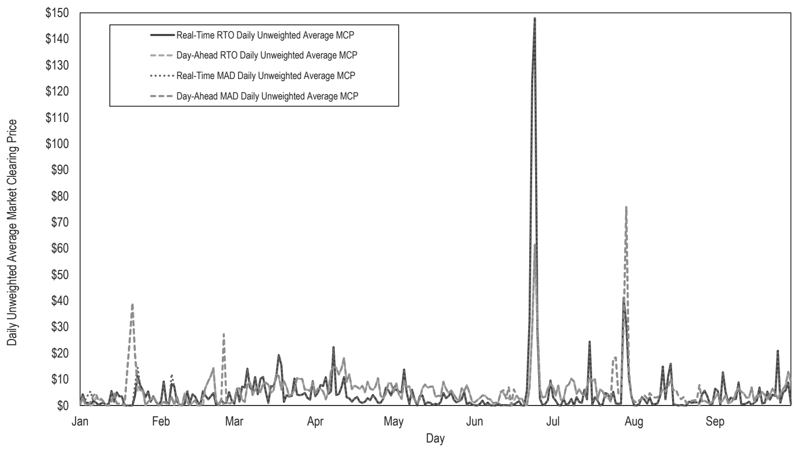


Table 10-16 and Table 10-17 compare the dispatch run and pricing run weighted average prices for the day-ahead and real-time markets. Fast start pricing increases LMP in the pricing run relative to the dispatch run, which increases reserve prices. Fast start pricing also reduces the amount of reserves available in the pricing run compared to the dispatch run, by pretending that fast start units can be dispatched for energy below their economic minimum output limit but not counting MW below the eco min as reserves. For the real-time values, these are the LPC prices weighted using the RT SCED MW. For the day-ahead values, these are the DA prices weighted using the DA dispatch MW. PJM dispatchers can update assignments after RT SCED has run, so these weights differ from the weighted average value reported elsewhere in this section.[78] In the first nine months of 2025, the real-time RTO weighted average price from the pricing run was 37.7 percent higher than the real-time RTO weighted average price from the dispatch run. In the first nine months of 2025, the day-ahead RTO weighted average price from the pricing run was 6.1 percent lower than the day-ahead RTO weighted average price from the dispatch run. In the first nine months of 2025, the real-time MAD weighted average price from the pricing run was 35.8 percent higher than the real-time MAD weighted average price from the dispatch run. In the first nine months of 2025, the day-ahead MAD weighted average price from the pricing run was 5.4 percent lower than the day-ahead MAD weighted average price from the dispatch run.

78 See PJM. "PJM Manual 01: Control Center and Data Exchange Requirements," § 1.7 Dispatch Management Tool (DMT), Rev. 50 (May 21, 2025).

Figure 10-15 shows the dispatch-run synchronized reserve RTO market clearing prices of the day-ahead software (DA), the hour-ahead software (ASO), and the real-time software (RT SCED). The pricing-run market clearing prices, calculated by the LPC, are in Figure 10-14. As seen in Figure 10-15, there can be significant differences in the dispatch-run clearing prices. The ASO schedules units by forecasting least-cost outcomes for the operating hour, and any inflexible resources cleared by the ASO are automatically cleared by RT SCED. Because it is possible for real time to differ from the ASO's forecasts, it is possible for an inflexible resource to be scheduled during real-time conditions in which, had it not been inflexible and already cleared by the ASO, RT SCED would not have scheduled it. For example, it is possible for an inflexible resource to be scheduled in real time even when its bid price is higher than the clearing prices used by RT SCED and the LPC. The opposite can also happen, in which an inflexible resource is not cleared by the ASO while its offer parameters, had it not been inflexible, would have led to it having been cleared by RT SCED.

Figure 10-15 Dispatch run synchronized reserve market clearing prices from the day-ahead software, the ASO, and RT SCED: January through September, 2025

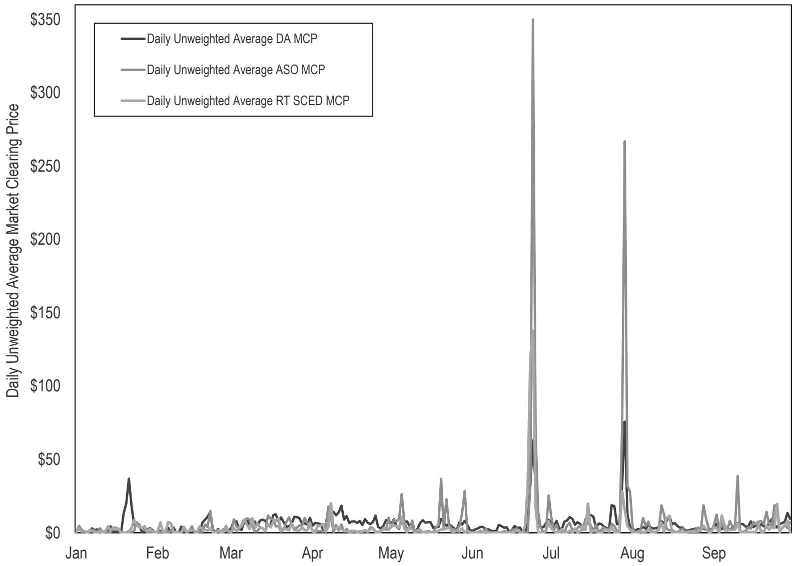

Table 10-18 shows total synchronized reserve payments by month for January 2023 through September 2025. Balancing credits for all but three months are negative, because, on average, resources buy back their day-ahead positions at higher real-time prices. LOC credits are paid to cover negative balancing credits if PJM converted a resource's day-ahead reserve position to energy in the real-time market. LOC credits are also paid to inflexible reserves when prices do not cover their opportunity costs. Shortfall charges are incurred by resources that do not provide their cleared reserve positions in real time. In Table 10-18, the only months with synchronized reserve events that lasted for 10 or more minutes were February 2024, July 2024, August 2024, November 2024, and February 2025, so there are no shortfall charges possible outside of those months. Day-ahead credits were larger in April 2024 and May 2024, corresponding with higher requirements in April and lower supply in May.

Total credits were larger in March 2025 due to a decrease in the available nonsynchronized reserve MW from units on planned outages, necessitating an increase in cleared synchronized reserve MW to meet the primary reserve requirement. Total credits in June 2025 were larger due to price spikes during a hot weather event in which shortage pricing was used for synchronized reserve in the RTO Reserve Zone and the MAD Reserve Subzone. Total credits in July 2025 were larger due to price spikes during a second set hot weather event in which PJM declared hot weather alerts, emergency maximum generation alerts, and a maintenance outage recall. Shortage pricing was not used for synchronized reserve during the July hot weather event.

Table 10-18 Total payments and charges by month: January 2024 through September 2025

Year	Month	Total Day-Ahead Credits	Total Balancing MCP Credits	Total LOC Credits	Total Shortfall Charges	Total Credits
2024	Jan	$4,327,646	($426,107)	$1,136,492	$0	$5,038,031
2024	Feb	$2,894,089	($98)	$535,213	$19,515	$3,409,689
2024	Mar	$5,930,989	($297,375)	$1,078,487	$0	$6,712,102
2024	Apr	$9,018,149	($907,004)	$594,268	$0	$8,705,412
2024	May	$9,477,497	($169,439)	$1,260,078	$0	$10,568,136
2024	Jun	$4,594,840	($602,073)	$788,610	$0	$4,781,377

2025	Jun	$15,012,782	($4,327,200)	$4,657,608	$0	$15,343,190
2025	Jul	$22,507,389	($310,371)	$2,567,031	$76,684	$24,687,365
2025	Aug	$7,390,714	$20,554	$1,016,281	$0	$8,427,550
2025	Sep	$10,131,551	($840,026)	$1,576,176	$159,581	$10,708,120
2025	All	$109,369,148	($7,501,228)	$15,786,067	$354,411	$117,299,575

Table 10-19 provides the day-ahead and real-time synchronized reserve by resource type and fuel type for the first nine months of 2025. For synchronized reserve, the MW for which a resource is credited at the market clearing price is capped at the lesser of its real-time assignment and the difference between its real-time output and the lesser of its economic maximum and its real-time reserve maximum. During spin events, this capped value is equal to the cleared MW. As it is this capped value for which a resource is credited, Table 10-19 only shows the capped value, excluding the additional cleared MW.

Table 10-19 Day-ahead and real-time synchronized reserve by resource type and fuel type: January through September, 2025

Resource / Fuel Type	Day-Ahead MWh	Real-Time Capped MWh	Day-Ahead Credits	Balancing MCP Credits	LOC Credits	Shortfall Charges	Total Credits
Combined Cycle	8,562,223	7,982,011	$45,202,817	($12,642,911)	$5,716,502	$96,711	$38,179,697

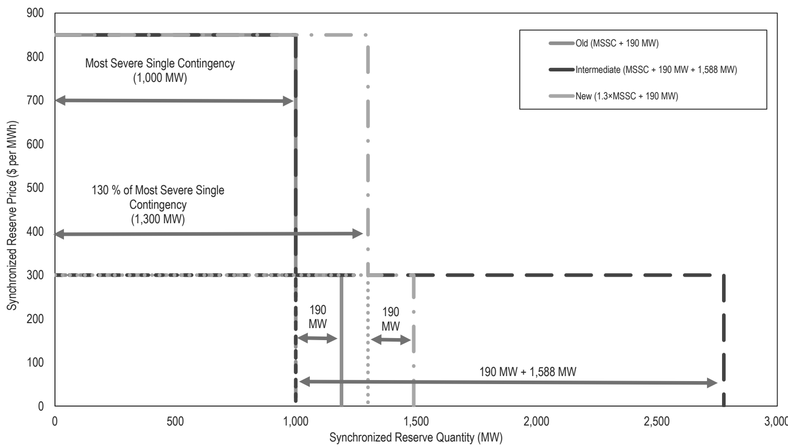
Other	34,112	37,468	$262,343	($29,176)	$58,708	$0	$291,876

The October 1, 2022, changes, removed the prior cap that limited DSR to 33 percent of the cleared synchronized reserves. In the first nine months of 2025, real-time DSR was more than 33 percent of the cleared real-time synchronized reserves in 578 five-minute intervals, 0.7 percent of the total 78,612 five-minute intervals. In the first nine months of 2025, day-ahead DSR was more than 33 percent of the cleared day-ahead synchronized reserves in zero hours. During these 578 five-minute intervals, on average, DSR made up 38.7 percent of the synchronized reserve MW. Figure 10-16 shows the portion of synchronized reserve provided by DSR. Since September 2023, there has been an increase in the use of DSR, but not enough to frequently exceed the former limit.

Figure 10-16 Daily average synchronized reserve from DSR and non-DSR: January 2024 through September 2025



Synchronized Reserve Performance

Resources providing synchronized reserves are paid for being available to respond to a synchronized reserve event and not for the actual response. Synchronized reserve resources are paid for their output in the energy market when they respond to an event.

Actual synchronized reserve event response is determined by final output minus initial output where final output is the largest output between 9 and 11 minutes after the start of the event, and initial output is the lowest output between one minute before the event and one minute after the event.[79]

Cleared synchronized reserve resources are obligated to sustain their final output for the shorter of the length of the event or 30 minutes. The owner of a cleared resource is penalized if it fails to perform during any synchronized reserve event lasting 10 minutes or longer, although the resource owner can use overperformance from another resource to offset those losses. As synchronized reserve resources are allowed 10 minutes to ramp up to their cleared output, performance penalties are not assessed for events lasting less than 10 minutes.

Table 10-20 shows synchronized reserve event response compliance for events that lasted 10 minutes or longer, using only the response from cleared synchronized reserves. In 2024, five events were 10 minutes or longer. Of those five reserve events, only one was associated with a DCS event. In the first nine months of 2025, four events lasted for at least 10 minutes. One event was due to the loss of a unit and corresponded with a DCS event. In the first nine months of 2025, PJM triggered three events explicitly due to low ACE. For all other DCS events, any associated reserve event lasted less than 10 minutes. PJM has the option, but not the obligation, to trigger a reserve event in response to a DCS event. In some circumstances, PJM system operators will opt to recover the system via regulation and the normal dispatching process.

Actual synchronized reserve response is the total increase in MW from all resources from the moment the spinning event is called to 10 minutes after. The overall response to spinning events was adequate or more than adequate to meet NERC requirements, in which the Reporting ACE must return to the lesser of zero and the value of the Reporting ACE before the disturbance that caused the event.[80] PJM, in practice, not only corrects the Reporting ACE disturbance that led to the event but over corrects. In the four spinning event lasting 10 or more minutes in the first nine months of 2025, the Reporting ACE recovered not just to the NERC required level of zero but overshot by over approximately 1,000 MW.

79 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations," § 4.2.10 Settlements, Rev. 134 (Apr. 23, 2025).

80 See PJM. "PJM Manual 12: Balancing Operations," Rev. 55 (Jun. 18, 2025) Attachment D.

81 Results for identified technologies shown only if they are consistent with PJM confidentiality rules.

In the first nine months of 2025, compliance with calls to respond to the single synchronized reserve event was significantly less than 100 percent. Table 10-21 shows the average amount of cleared synchronized reserve MW that responded to events 10 minutes or longer from January 2019 through September 2025. PJM experienced four events longer than 10 minutes in the first nine months of 2025.

Table 10-21 Average synchronized reserve response from scheduled resources for events longer than 10 minutes, excluding over response: January 2019 through September 2025

Year	No. of Events Longer than 10 Minutes	Average Percent of Scheduled Synchronized Reserve MW that Responded
2017	6	87.6%
2018	8	74.2%
2019	3	86.8%
2020	5	59.5%
2021	5	83.1%
2022 (Jan - Sep)	3	71.2%
2022 (Oct - Dec)	7	50.3%
2023	3	55.6%
2024	5	58.2%
2025 (Jan - Sep)	4	78.0%

In Table 10-21, from January 2017 through September 2022, cleared synchronized reserve was provided by tier 2 synchronized reserves, which were cleared when the estimated response from tier 1 resources was insufficient to cover the requirement. Since October 1, 2022, the requirement is fully met by cleared resources that offer the new synchronized reserve product. In the new reserve market, most resources capable of providing reserves were required to offer their full capability as calculated by PJM, whereas previously resources had set their own offer MW. Additionally, while units still set their prices in the new market, the maximum allowed offer price was reduced. Under these new market rules, there was a much larger pool of resources offering synchronized reserves, but the resources clearing the reserve market changed. In the months immediately following the change, PJM was clearing less DSR and fewer natural gas CTs and more combined cycles and steam coal units, a portion of which had not cleared in the months leading up to the change. This, in part, lead to the drop in synchronized reserve performance seen in Table 10-21.

In 2024, when PJM and the MMU inquired about poorly performing resources, responses pointed towards shortcomings in how resources were deployed. Although resources are required to fully respond within 10 minutes, resources do not necessarily have a full 10 minutes to respond. PJM schedules reserve MW with the expectation that resources will start responding as soon as an event begins, but this expectation fails to consider communication delays that result from how a resource's market operation center (MOC) notifies the resource of events. When a MOC receives PJM's ALL-CALL, it can take several minutes for the MOC to acknowledge the call and to contact the appropriate resources, which then can take minutes more to start responding.

The MMU recommends that, to minimize lag, PJM use an electronic synchronized reserve event notification process for all resources and that all resources be required to have the ability to receive and to have the ability to automatically respond to the notifications. PJM currently has an optional inter-control room connection protocol (ICCP) signal that some control rooms use, but PJM does not track who is actually using it. This or another form of electronic signal should be required for all resources. Stakeholders approved a joint PJM/MMU proposal to implement an electronic communications and reserve deployment process on July 24, 2024. On December 17, 2024, PJM implemented changes to augment the SCED dispatch signal to include reserve response during reserve events. However, this new process is not required for all synchronized reserve resources and does not replace the ALL-CALL. The new process mainly benefits units that automatically respond to the dispatch signal, such as by following AGC. Between December 17, 2024, and the end of September 2025, there were only four events lasting 10 or more minutes with which to sufficiently test the augmented dispatch signal. For the event on February 5, 2025, PJM took explicit action to make the event last long enough for testing.

The penalty structure when a resource fails to respond fully to a spinning event has two components. The first component is, for each interval during the day on which the event occurred, the forfeiture of awarded SRMCP credits in the amount of the lesser of the resource's capped synchronized reserve assignment during that interval and the resource's maximum shortfall MW during that day. The second component is a required return of SRMCP credits paid in the Immediate Past Interval (IPI), equal to the sum of, for each scheduled interval within the IPI, the SRMCP multiplied by the lesser of a resource's capped MW assignment during the penalized interval and the resource's penalty obligation for the day of the event. The IPI is defined as the average time, in number of days, since the start of the previous event over the previous two years or, if less, the number of days since the resource last failed to fully respond. For example, the maximum IPI for 2025 is 20 days and was calculated using the events from November 1, 2022 through October 31, 2024.[82]

There are several problems with this penalty structure.[83] First, resource owners are permitted to aggregate the response of multiple cleared reserve resources within the same portfolio, allowing owners to reduce the penalty obligation of a resource's underresponse by offsetting it with another scheduled resource's overresponse.[84] Second, the maximum IPI is calculated using events of any length, even though a resource is automatically considered compliant for events less than 10 minutes in length, artificially and significantly shortening the applied IPI. Third, the historical component of the penalty only applies to a resource's SRMCP credits, but not to LOC credits, even though a large portion of credits is awarded for LOC. For the four events that lasted for 10 or more minutes in the first nine months of 2025, for each resource interval in which the resource's penalty obligation MW was greater than or equal to the resource's capped MW during the penalized interval, the total historical penalty was $233,142 and the total LOC credit was $44,598.

The penalty structure for synchronized reserve nonperformance does not provide appropriate or reasonable performance incentives. Under the current penalty structure and due to the low frequency of sufficiently long events, it is possible for a resource to not respond to any spin events and yet still receive net revenues for providing synchronized reserve. The MMU continues to recommend that the penalty's repayment include the LOC credits in addition to the SRMCP credits. The MMU also recommends that a unit that fails to respond to a synchronized reserve event 10 minutes or longer repay all credits back to the last time that the unit successfully responded to an event 10 minutes or longer. A resource should not be paid for reserves that it does not provide.

The MMU also continues to recommend that aggregation not be permitted to offset resource specific penalties for failure to respond to a synchronized reserve event. Including aggregate responses from all cleared resources weakens the incentive to perform and creates an incentive to withhold reserves from other resources. Synchronized reserve commitment is resource specific, so the obligation to respond should also be resource specific.

Table 10-22 shows the possible total historical penalty if the historical penalty had been defined differently in a single aspect for the first nine months of 2025 for the one event that was 10 or more minutes in length. It compares the status quo, the amount if the IPI were defined using only events of 10 or more minutes, the amount if LOC credits were penalized in an amount proportionate to the shortfall, and if aggregate response were not allowed. As can be seen in the table, the values are similar for the status quo, for penalizing LOC credits, and for disallowing aggregate response. The larger effect of only using 10-minute events to calculate the IPI is due to using a 50-day IPI compared to PJM's current 20-day IPI. The 150 percent increase to the IPI is a consequence of PJM's increase to the synchronized reserve reliability requirement. As shown by Table 10-21, that change decreased the number of events of 10 or more minutes, increasing the time between such events.

82 See "2024 Third Quarter Synchronized Reserve Performance," PJM presentation to the Operations Committee. (December 5, 2024) <https://www.pjm.com/-/media/DotCom/committees-groups/committees/oc/2024/20241205/20241205-item-12---synchronous-reserve-update.pdf>.

Table 10-22 Comparison of historical/retroactive penalties using possible different definitions: January through September, 2025

Description	Total Retroactive Penalty
Status Quo	$2,345,747
Using only 10-minute events for IPI	$5,496,255
Including LOC credits in retroactive penalty	$2,586,050
Disallowing aggregate response	$2,589,936
All three changes	$7,030,601

Resources should not be paid for reserves that they do not provide. The MMU recommends reclaiming credits back to the last known fully compliant performance, while providing the opportunity to demonstrate performance between events. Resources do not control when PJM calls 10-minute events, nor do they control whether they are scheduled during the few 10-minute events that PJM calls. While actual performance is the key to not being penalized, those factors contribute to defining penalties for many resources. The solution is not to arbitrarily limit the penalized period, as PJM does with its IPI, but to instead provide opportunities, between events, for resources to demonstrate that they are capable of providing reserves.

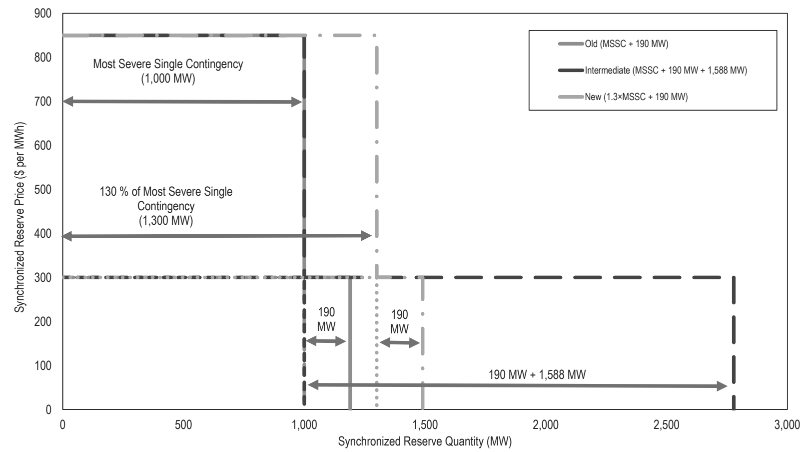
PJM's 2023 Response to Poor Unit Specific Performance

On October 1, 2022, PJM implemented substantial changes to the reserves markets, called Reserve Pricing Formation, meant to improve reserve reliability and improve accuracy when calculating reserve supply. Winter Storm Elliot occurred in December 2022. In the nine synchronized reserve events from October 2022 through April 2022, the average reserve performance was 53.7 percent. Excluding the events of Winter Storm Elliot, it was 49.4 percent.

In May 2023, in response to poor unit specific reserve performance since the market changes made on October 1, 2022, PJM made two unilateral decisions without approval from stakeholders or FERC. On May 12, 2023, PJM inappropriately increased the extended reserve requirement by 1,588 MW and on May 15, 2023, PJM reversed the increase. On May 19, 2023, PJM inappropriately increased the synchronized reserve reliability requirement by 30 percentage points to 130 percent of the MSSC.

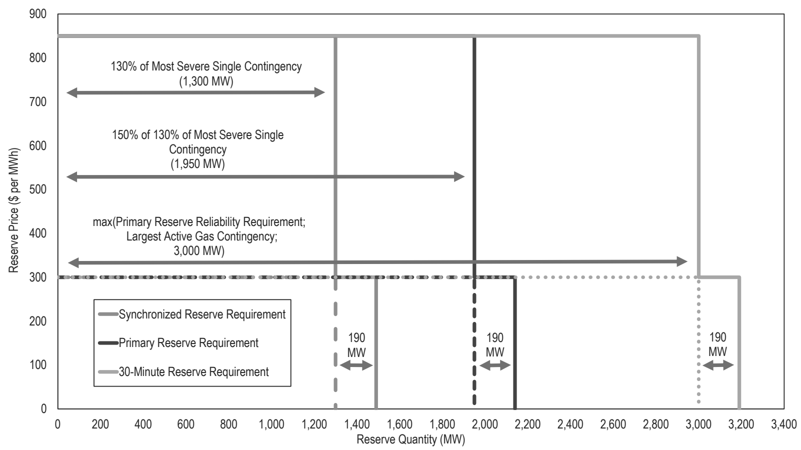
Figure 10-17 compares, for an example MSSC of 1,000 MW, the initial synchronized reserve ORDC from before these changes, the intermediate ORDC with the extension to the second step, and the new ORDC with the increase in the first step.

Figure 10-17 An example comparison of the old, intermediate, and new real-time synchronized reserve ORDCs



Because the definitions of the reserve reliability requirements are nested, PJM's increase to the synchronized reserve reliability requirement also increased the primary reserve reliability requirement, which in turn increased the 30-minute reserve reliability requirement. Figure 10-18 shows the new ORDCs of the three reserve services using an example MSSC of 1,000 MW and the default 190 MW for the extended requirements. Figure 10-5 shows the original ORDCs for the same example MSSC. As seen in Figure 10-2, although not shown in Figure 10-18, as a result of the increase, the 30-minute reserve requirement is now usually equal to the primary reserve requirement.

Figure 10-18 An example of the reserve services' new real-time operating reserve demand curves, including the permanent second steps



PJM did not have the authority to increase the extended reserve requirements without a hot or cold weather alert or an emergency condition. The most common cause of doubled synchronized reserve requirement in the first four months of 2023 and in prior years was the possibility of large units tripping or being disconnected while undergoing maintenance work, which is a clear increase in the size of the most severe single contingency.

The doubling of the requirement for May 12 to May 16, 2023, lead to 31 intervals of shortage pricing for synchronized reserve and primary reserve in the RTO, even though, based on the actual contingencies, both services cleared well in excess of what was actually needed. In addition, because there was no spin event on either May 12 or May 15, it is unknown whether the response that could have been gained by this increase in demand justified these higher prices.

After making these changes, PJM later modified Manual 11 to allow "temporarily" increasing contingency reserve requirements "as necessary to account for resource performance."[85] Neither temporary nor resource performance criteria are specified or defined in the manual. PJM announced criteria for reducing the increase to the synchronized reserve reliability requirement in the PJM Operating Committee on March 6, 2025.[86]

PJM already clears additional 10-minute reserve in the form of nonsynchronized reserve. PJM had and continues to have the option to use all 10-minute reserve that it clears for recovering within 10 minutes, but instead chooses to increase the amount of all 10-minute reserve that PJM clears, even though it only uses a subset.[87] Despite PJM's unexplained reluctance to call a nonsynchronized reserve event, PJM does use NSR resources to respond to synchronized reserve events. That PJM occasionally uses certain nonsynchronized resources to respond to synchronized reserve events while wishing to avoid the general use of NSR suggests a mismatch between NSR's definition, its actual characteristics, and PJM's definition of its operational needs.

PJM gave several reasons to support the changes to the reserve ORDCs, including that resource response to spin events has been poor and that the average length of spin events greater than 10 minutes has increased. In addition, PJM was concerned that it might be less able to avoid Disturbance Control Standard (DCS) violations, in which PJM would exceed the NERC-imposed 15-minute limit for recovering Reporting ACE from changes due to Reportable Disturbances.[88] The MMU agrees about the underlying facts, with caveats, but does not agree with PJM's assertions about the reasons for poor performance, or with the assumption about DCS events or that any of these reasons support PJM's actions.

The MMU agrees that the average length of reserve events has increased, but notes that recent DCS event lengths have remained well below requirements, except in one case. On December 26, 2022, during Winter Storm Elliott, PJM recovered from a DCS event in 15 minutes and 52 seconds, longer than NERC's

85 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations," § 6.3 Charges for Synchronized Reserve, Rev. 134 (Apr. 23, 2025). "In order to meet Reliability First (RF) Regional Criteria, PJM may schedule additional Contingency Reserves on a temporary basis in order to meet the Largest Single Contingency, as necessary to account for resource performance. PJM shall post details regarding additional scheduling of reserves in Markets Gateway."
86 See "Synchronized Reserve Requirement for Reliability – Update," PJM presentation to the Operating Committee. (March 6, 2025) <https://www.pjm.com/-/media/DotCom/committees-groups/committees/oc/2025/20250306/20250306-item-08b---synchronized-reserve-adder.pdf>.
87 See PJM. "PJM Manual 12: Balancing Operations," § 4.1.2 Loading Reserves, Rev. 55 (Jun. 18, 2025).
88 See PJM. "PJM Manual 12: Balancing Operations," Rev. 55 (Jun. 18, 2025) Attachment D.

requirement of recovery within 15 minutes. Due to possible extenuating circumstances, NERC has yet to determine whether that recovery was actually a DCS violation. Regardless, the data do not support the assertion that PJM is at risk of violating NERC standards during nonemergency conditions and the data do not support the assertion that there has been a change in PJM's DCS event response times. In general, PJM's recovery times are clearly and significantly shorter than NERC's 15-minute requirement and PJM's self-imposed 10-minute requirement. In many cases, PJM recovers Reporting ACE within five minutes. Table 10-23 compares the lengths of recent DCS events with the lengths of their corresponding spin events. As can be seen, many spin events are minutes longer than the DCS event for which they were triggered. In the cases where a spin event continues for more than 10 minutes, this can mean that resource performance becomes subject to evaluation for spin events whose purpose had already been achieved minutes ago (that is, the recovery of the Reporting ACE and the end of the DCS event). While there are reasons for PJM dispatchers to continue a spin event even after ACE recovers, Table 10-23 shows that the lengths of spin events do not suggest that PJM has become closer to having a DCS violation. Table 10-23 also shows that the lengths of DCS events with corresponding spin events from before the changes to the reserve markets were implemented on October 1, 2022, are not significantly different from the lengths of such events since then.

Table 10-23 A comparison of the lengths of recent DCS events with that of their corresponding spin events: January 2022 through September 2025

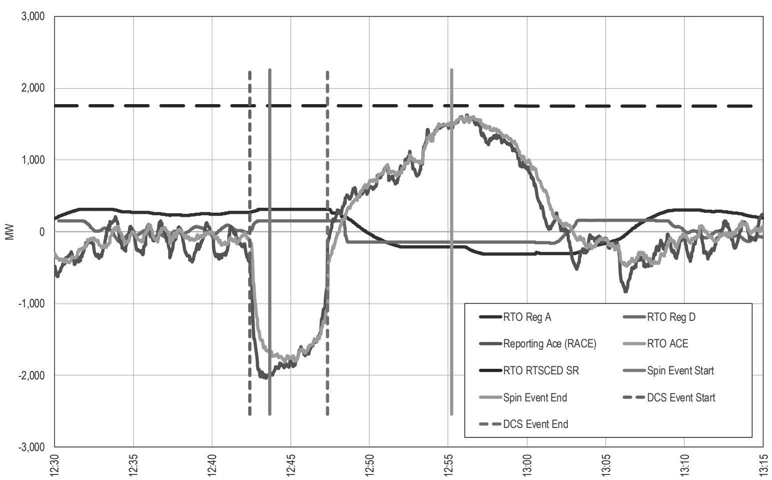
As an example of the differences between the lengths of spin events and the lengths of DCS events, Figure 10-19 shows PJM ACE during a DCS event and its corresponding spin event on January 5, 2023. The DCS event lasted 4 minutes and 56 seconds, while the spin event lasted 11 minutes and 33 seconds, more than twice as long. The DCS event ended when Reporting ACE (RACE) recovered to its level at the time of the loss of supply, while the spin event ended based on PJM discretion.

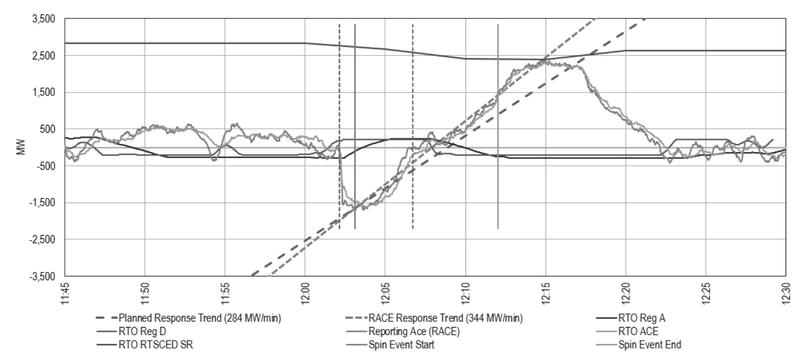
Figure 10-19 DCS Event vs. Spin Event: January 5, 2023



If the basis of the original definition of the synchronized reserve reliability requirement was an amount of MW needed to recover within 10 minutes, then an increase in the amount of cleared reserves can shorten the length of synchronized reserve events to be less than 10 minutes. In the remainder of 2023 after the increase in the reliability requirement in May 2023, there were eight spin events, of which seven were less than 10 minutes. Similarly, of the 19 spin events in 2024, 13 were less than 10 minutes. Of the 19 events in the first nine months of 2025, PJM triggered only four events of 10 or more minutes. That one event was allowed to reach the 10-minute mark so that PJM could fully test the new deployment method implemented in December 2024. If not for that, it also would have been less than 10 minutes. Because these shorter events lasted less than 10 minutes, only a small portion of the events since the increase qualify for performance assessment under the PJM Market Rules. PJM has stated that they monitor performance for events less than 10 minutes. If the PJM analysis fails to consider the lags that the ALL-CALL system introduces, different for each contacted resource, then it will continue to show underperformance.

In 35 of the 45 spin events for the RTO Reserve Zone that have occurred since the reserve requirement increase in May 2023 through the first nine months of 2025, ACE response is consistent with the rate of recovery that would be expected if reserves had performed adequately. Figure 10-20 shows one such event on January 29, 2024. However, some resources are responding to PJM's event notifications when they did not clear the reserve market, so they do not have reserve assignments during those events and so do not count towards reserve performance. PJM has defined the problem as one not of poor overall system response nor of poor ACE recovery, but one of poor performance from the assigned reserves. At the Operating Committee on March 6, 2025, PJM announced that they would decrease the adder to the synchronized reserve reliability requirement if average event performance were greater than 75 percent for qualifying events. Under these announced criteria, qualifying events would be any 10-minute event and any shorter event in which event performance was at least 75 percent. Even with these criteria, the fact that performance remains unsatisfactory for multiple events in the months with the increased requirements is evidence that the increase is not the correct solution to the asserted problem.

Figure 10-20 ACE response during a synchronized reserve event: January 29, 2024 from 12:03 to 12:12 EPT



The MMU disagrees with PJM that increasing the reserve requirement is the correct solution for accounting for poor reserve performance.[89] The MMU's position is that these problems with the supply of reserves should not be solved by changing the demand for reserves. The situation is a problem on the supply side, and it should be dealt with and solved on the supply side. The repeated lack of response means that resource personnel are insufficiently trained or that resource data inputs, such as ramp rates, the times needed for condensers to start, and economic maximums, are incorrect. It is the responsibility of market participants to correct their offer parameters and operating parameters. It is their obligation to submit correct data.

The data on synchronized reserve event recovery do not support the conclusion that there is an immediate need to change how reserves clear. If PJM insists on an immediate change, the focus should be on correcting the supply of reserves rather than increasing demand.

PJM's logic is that because reserves are responding at an average rate of about 50 percent during spin events, the solution is to buy twice as many MW of reserves. The result is that PJM is overpaying for reserve MW. PJM is paying for 1.0 MW but receiving 0.5 MW. PJM's solution is to pay for 2.0 MW in order to receive 1.0 MW.

Instead of increasing the demand requirement, the MMU proposes to purchase reserve MW from resources only in the amounts for which they can actually perform. If an underperforming resource's behavior shows that they can only reliably provide five MW of reserve, then PJM should only be purchasing five MW of reserve from them. PJM should not be paying MCP credit for MW that are not reliably provided, especially when it only recovers a portion of that money later via penalties and charges.

The MMU proposal is to pay for 0.5 MW from the underperforming unit. The MMU proposal is to pay for actual unit specific MW. The MMU proposal is to pay for 0.5 MW from each of two underperforming units. The result is to pay for 1.0 MW and to receive 1.0 MW of reserves. The MMU proposal is to buy the correct amount of reserves. No increase in demand is required.

89 See "Market Monitor Report," MMU presentation to the Members Committee Webinar. (May 22, 2023) <https://pjm.com/-/media/committees-groups/committees/mc/2023/20230522-webinar/item-04---imm-report.ashx>.

The solution is not to buy more MW of poorly performing reserves. The solution is to accurately recognize the actual supply of reserves. The solution is to buy the correct amount of reserves, accounting for the actual performance of supply.

A focus on the supply side issues should be implemented immediately: ensure correct and timely signals; provide education on requirements; buy required reliable MW, based on actual performance; pay only for reliable MW based on actual performance; and do not pay for MW not provided. Detailed, unit by unit analysis of the reasons for poor performance is needed. Potential unit specific issues include: ensuring the ability to receive and respond to signals; discontinuities in offer curves; the accuracy of ramp rates; ambient derates; fuel availability; demand side resource response; failure to follow dispatch; incorrect eco max or spin max; and incorrect parameters.

One result of PJM's changes to the reserve requirements is that the total cost of the synchronized reserve market has increased. For May 2023 through December 2023, total credits paid for synchronized reserve were $66.7 million in eight months or $8.3 million per month, compared to $6.4 million in four months or $1.6 million per month for January 2023 through April 2023. In 2024, the total credits paid for synchronized reserve were $74.1 million or $6.2 million per month. In the first nine months of 2025, the total credits paid for synchronized reserve were $117.3 million or $13.0 million per month. Table 10-18 shows the total payments and charges for synchronized reserve by month. The cost of underperformance by reserve suppliers is paid by PJM customers, while it should be incurred by the suppliers who fail to meet their responsibilities. If reserve suppliers cannot provide the energy that they offer and clear during synchronized reserve events, they should not be paid from the last time they successfully responded to a spin event. These suppliers are not accurately representing their true capability to the PJM market and/or have failed to establish processes to ensure that they follow PJM's instructions.

On March 6, 2025, PJM presented to the PJM Operating Committee its criteria for decreasing (or increasing) the adder to the synchronized reserve reliability requirement by reviewing the average performance of non-overlapping sets of three qualifying events.[90] [91] A qualifying event is an event lasting at least 10 minutes or an event whose performance was at least 75 percent of the total reserve assignment. This performance is based on a resource's scheduled MW, not the MW amount that PJM uses its tools to deploy. The adder is defined as a percentage of the most severe single contingency. Table 10-24 shows the average performance required for each level of adjustment, with the adder not to exceed 30 percent of the most severe single contingency. Since the increase to the requirement, the number of 10-minute events has decreased. In the first nine months of 2025, there have been only four events lasting 10 or more minutes. For the event on February 5, 2025, PJM acknowledged that operators let the event run long enough to fully test the new deployment mechanism. If it had been handled in the usual manner, that event too would have been less than 10 minutes. Therefore, under PJM's criteria, the effect of the adder means that it will take longer to remove the adder, even though shorter events are, by definition, successful events. That a shorter event does not achieve 75 percent performance in less than, for example, five minutes, is not necessarily indicative of a problem, because the only defining performance requirement for the synchronized reserve product is that it should achieve full performance by the tenth minute. Only events lasting 10 or more minutes can be true measures of under-performance. If PJM receives so great a response that it is difficult to allow an event to last at least 10 minutes, that is another indication that the adder should be removed immediately.

As shown by Table 10-20, poor performance is not an across the board problem, yet PJM's current criteria and approach treat it as if it were. Reserve supply issues are resource specific and should be addressed at the resource level, such as by requiring support for an electronic deployment signal. Increasing the requirement does not change resource behavior. Engaging with poorly performing resources, as the MMU and PJM have been doing, does change behavior. Reserve testing would allow PJM to identify underperforming resources that would benefit from unit specific engagement. Such identification would be proactive instead of reactive, improving event performance.

90 See "Synchronized Reserve Requirement for Reliability – Update," PJM presentation to the Operating Committee. (March 6, 2025) <https://www.pjm.com/-/media/DotCom/committees-groups/committees/oc/2025/20250306/20250306-item-08b---synchronized-reserve-adder.pdf>.

91 See "Synchronized Reserve Requirement for Reliability – Update," PJM presentation to the Operating Committee. (May 8, 2025) <https://www.pjm.com/-/media/DotCom/committees-groups/committees/oc/2025/20250508/20250508-item-20---synchronized-reserve-for-reliability-update.pdf>.

Table 10-24 PJM criteria for adjusting the adder in the synchronized reserve reliability requirement

Average Performance	Adder Adjustment
Below 70%	Increase by 10 percentage points
Above 75%	Decrease by 10 percentage points
Above 85%	Decrease by 20 percentage points
Above 95%	Decrease by 30 percentage points

History of Synchronized Reserve Events

Synchronized reserve is designed to provide relief for disturbances.[92] [93] A disturbance is defined as loss of the lesser of 900 MW and 80 percent of the largest single contingency within 60 seconds. In the absence of a disturbance, PJM operators have used synchronized reserve as a source of energy to provide relief from low ACE. Of the 12 spin events that occurred in 2023, three were explicitly due to low ACE, of which all were shorter than 10 minutes. Of the 19 events that occurred in 2024, two were explicitly due to low ACE, of which one was longer than 10 minutes. In the first nine months of 2025, PJM triggered three events explicitly due to low ACE, with all three events being less than 10 minutes long.

The risk of using synchronized reserves for energy or any other nondisturbance reason is that it reduces the amount of synchronized reserve available for a disturbance. Disturbances are unpredictable. Synchronized reserve has a requirement to sustain its output for 30 minutes at the most. When reserve output is still needed after 30 minutes, that output should come from secondary reserves, not synchronized reserves.

From January 2020 through September 2025, PJM experienced 108 synchronized reserve events, approximately 1.6 events per month, with an average duration of 10.8 minutes. Table 10-25 shows these events with their region and their duration rounded to the nearest tenth of a minute.

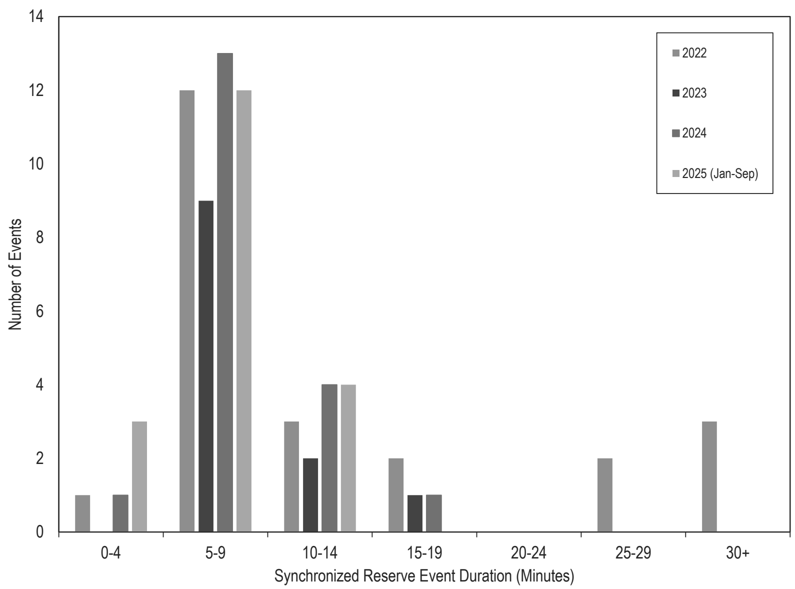
Figure 10-21 shows spin event durations over the past 4 years. Some events last longer than 30 minutes. Beyond 30 minutes, reserves no longer have an obligation to perform. It is not clear what resources are instructed or expected to do after the 30-minute performance obligation. This ambiguity applies to three synchronized reserve events during Winter Storm Elliott in December 2022, which all lasted longer than 30 minutes.

Figure 10-21 Synchronized reserve events duration distribution curve: January 2022 through September 2025



Nonsynchronized Reserve

Nonsynchronized reserve consists of MW available within 10 minutes but not synchronized to the grid. Startup time for nonsynchronized reserve resources is not subject to testing and is based on the parameters in the energy offers submitted by resource owners. There is no defined requirement for nonsynchronized reserve; it is available to economically meet the primary reserve requirement. Generation resources that have designated their entire output as emergency are not eligible to provide nonsynchronized reserves. Generation resources that are not available to provide energy are not eligible to provide nonsynchronized reserves.

The nonsynchronized reserve market has a day-ahead and a real-time component. There are no lost opportunity costs for nonsynchronized reserve. Offline units cannot be dispatched to provide energy, because PJM has not called them to come online, so they do not have a lost opportunity to provide energy. As a result, the supply curve for nonsynchronized reserve has a price of zero and there are no uplift credits paid when LMP is higher than the incremental cost of nonsynchronized reserve units.

PJM defines the demand curve for nonsynchronized reserve, and PJM defines the supply curve based on nonemergency generation resources that are available to provide energy and can start in 10 minutes or less. Since nonsynchronized reserve is considered a lower quality product than synchronized reserve, its clearing price is less than or equal to the synchronized reserve market clearing price. In most market intervals, under usual circumstances, the nonsynchronized reserve market clearing price (NSRMCP) is $0 per MWh. However, due to PJM's increase of the synchronized reserve reliability requirement, there has been an increase in the number of intervals with non-zero NSRMCPs. For example, in 2024, over 60 percent of intervals had a non-zero NSRMCP. Table 10-26 shows the number of intervals with non-zero NSRMCPs in the first nine months of 2025.

PJM uses nonsynchronized reserve when PJM calls nonsynchronized reserve events and when PJM calls specific nonsynchronized reserve resources to respond to synchronized reserve events. There were no nonsynchronized reserve events in the first nine months of 2025.

Market Structure

Demand

There is no explicit demand for nonsynchronized reserve beyond a more general demand for primary reserve, which can be satisfied by the synchronized and nonsynchronized reserve products, and for 30-minute reserve, which can be satisfied by all three reserve products. Beyond the synchronized reserve requirement, the balance of primary reserve can be made up by the economic combination of synchronized and nonsynchronized reserve. While it can be used to satisfy the 30-minute reserve requirement, as seen in Figure 10-2, nonsynchronized reserve is mainly used for satisfying the primary reserve requirement.

In the RTO Reserve Zone, in the first nine months of 2025, the average amount of real-time cleared nonsynchronized reserve was 909.9 MW and the average day-ahead cleared nonsynchronized reserve was 998.6 MW. In the MAD Reserve Subzone, in the first nine months of 2025, the average real-time cleared nonsynchronized reserve was 595.8 MW and the average day-ahead cleared nonsynchronized reserve was 477.0 MW.

Supply

The market solution considers the available supply of nonsynchronized reserve to be all generation resources currently not synchronized to the grid but available and capable of providing energy within 10 minutes. Generators that have made themselves unavailable or have defined themselves to be emergency only are not considered. Resources that generally qualify as nonsynchronized reserve include run of river hydro, pumped hydro, and combustion turbines and RICE generators that can start in 10 minutes or less.

The available reserve MW for nonsynchronized reserve units is the lesser of the economic maximum or the ramp rate times 10 minutes minus the startup and notification time. Hydroelectric resources must separately specify their availability and offer MW.

In the first nine months of 2025, an average of 909.9 MW of nonsynchronized reserve were cleared per five-minute interval out of an average eligible and available 1,039.6 MW as part of the primary reserve requirement in the RTO Reserve Zone. Figure 10-22 shows daily average total nonsynchronized reserve MW available in the first nine months of 2025. Available MW decreased in March due to several larger units having planned outages. Daily average available MW increased in May due to greater availability of hydro and RICE generators. Daily average available MW decreased in late June on hot weather days, for which PJM issued 78 intervals with shortage pricing for primary reserve in the RTO and 23 intervals with shortage pricing for 30-minute reserve in the RTO.

Figure 10-22 Daily Average Available Nonsynchronized Reserve: January through September, 2025

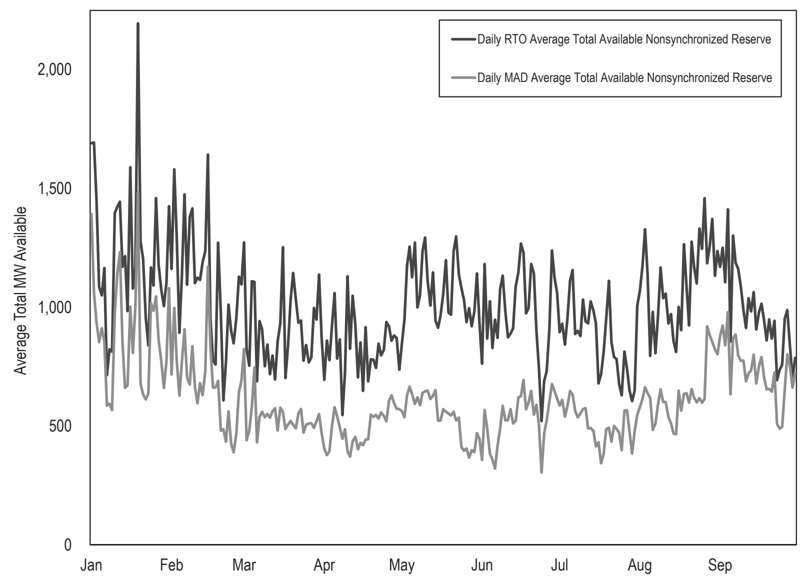


Figure 10-23 shows the daily average total available NSR MW in the ASO, RT SCED, and day-ahead solutions. The available MW in the ASO are consistently lower due to differences in the available MW from flexible units based on the goal of the ASO. For example, a unit could be projected to be online by the ASO but actually be offline in real time.

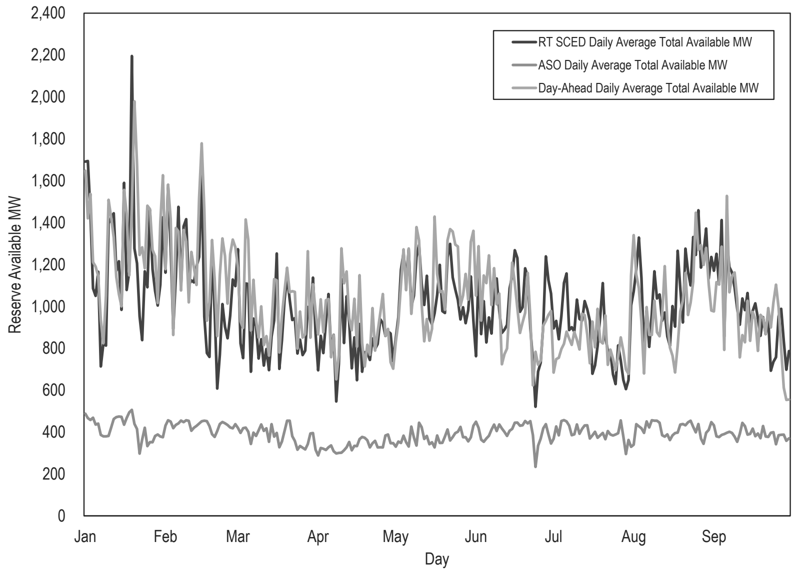
Figure 10-23 Daily average total available MW in the day-ahead, ASO, and RT SCED solutions: January through September, 2025



Market Behavior

The offer price for nonsynchronized reserve for all resources is cost based, which is $0 per MWh for all resources.

Market Performance

The settled price of nonsynchronized reserve is calculated in real time every five minutes for the RTO Reserve Zone and the MAD Reserve Subzone. Figure 10-24 shows the daily average nonsynchronized reserve market clearing price (NSRMCP) and average credited MW for the RTO Reserve Zone. In the first nine months of 2025, the real-time weighted average NSRMCP for all intervals in the RTO Reserve Zone was $1.87 per MWh and the real-time average nonsynchronized reserve cleared was 909.9 MW. The day-ahead weighted average NSRMCP for all intervals in the RTO Reserve Zone was $2.42 per MWh and the day-ahead average nonsynchronized reserve cleared MW was 998.6 MW. The real-time weighted average NSRMCP for all intervals in the MAD Reserve Subzone was $2.22 per MWh and the real-time average nonsynchronized reserve cleared was 595.8 MW. The day-ahead weighted average NSRMCP for all intervals in the MAD Reserve Subzone was $3.43 per MWh and the day-ahead average nonsynchronized reserve cleared MW was 477.0 MW.

Shortage pricing was used in the RTO Reserve Zone for primary reserve on February 11, March 12, March 18, March 19, April 8, May 8, June 22 through June 25, July 8, July 15, July 28, August 14, August 14, September 1, September 4, and September 25, 2025. Shortage pricing was used in the MAD Reserve Subzone for primary reserve on April 8, June 22, and June 24, 2025. The shortage pricing on February 11, June 22, August 14, September 4, and September 15, 2025 overlapped with synchronized reserve events. Conservative operations due to cold weather were in place from January 20 through January 23 and from February 16 through February 19, 2025. Cold weather alerts were issued for January 8 through January 10, January 14 through January 16, January 20 through January 23, February 17 through February 18, and February 19, 2025. Hot weather alerts were issued for May 1, June 22, June 26, July 6, July 7, July 17, July 23 through July 26, and July 28 through July 30, 2025. During most of these short intervals, there was not a true shortage, as PJM still cleared above the average reserve requirements used before PJM's mid-May 2023 increase.

Figure 10-24 Daily weighted average RTO Zone nonsynchronized reserve market clearing price, average MW purchased, and average percent of PR that is NSR: January 2024 through September 2025

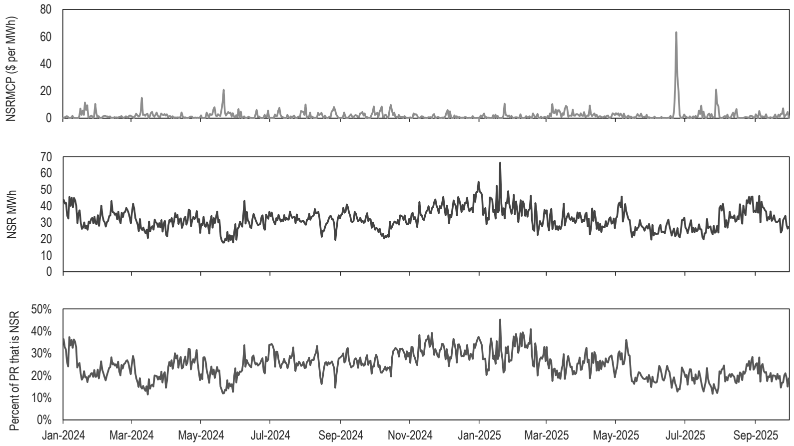


Table 10-26 shows the number of five-minute intervals with an NSRMCP above $0 per MWh. The NSRMCP is equal to the cost of the marginal primary reserve resource.[94] While the offer price of NSR resources is cost based and therefore $0 per MWh, if the marginal resource of primary reserve in an interval is an SR resource with a nonzero cost, then the NSRMCP in that interval will also be nonzero. While the real-time market clears resources in five-minute intervals, the day-ahead market clears by hour, equivalent to blocks of 12 five-minute intervals. Table 10-26 compares the two markets using five-minute intervals. There were 78,612 five-minute intervals in the first nine months of 2025.

Table 10-26 Number of five minute intervals with NSRMCP above $0 per MWh: January through September, 2025

Location	Market	Number of Intervals Where NSRMCP Above $0 per MWh	Percent of Intervals Where NSRMCP Above $0 per MWh
RTO	RT	8,551	10.9%
RTO	DA	23,328	29.7%
MAD	RT	8,680	11.0%
MAD	DA	24,252	30.9%

Figure 10-25 shows the number of intervals per day for which a nonzero NSRMCP equaled the SRMCP. Since the increase to the reserve requirement on May 12, 2023, the average number of such intervals per day has increased, with the maximum number and given number of such intervals per day both trending upwards. In January 2025 and February 2025, the number of such intervals per day decreased, because the number of intervals with a nonzero SRMCP decreased due to the expected value of the SR penalty decreasing to $0 per MWh (Figure 10-12), resulting in lower SR offer prices. However, in March 2025, PJM cleared more SR MW due to a decrease in available NSR MW (Figure 10-2), raising SRMCPs. In the first nine months of 2025, the number of such intervals differed for the RTO Reserve Zone and the MAD Reserve Subzone from January 4 through January 5. Table 10-27 shows a summary of the intervals for which a nonzero NSRMCP did not equal the SRMCP.

94 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations," § 4.4.5.2 Determination of Non-Synchronized Reserve Clearing Prices, Rev. 134 (Apr. 23, 2025).

Figure 10-25 Number of intervals per day for which a nonzero NSRMCP equaled the SRMCP: January 2024 through September 2025

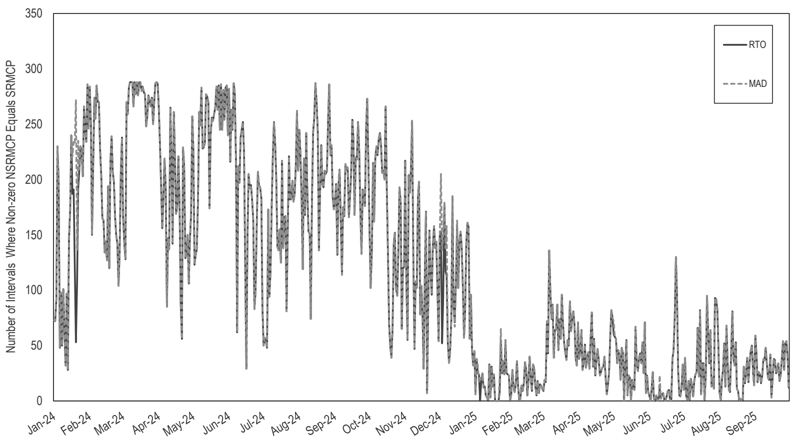

Table 10-27 Intervals with a nonzero NSRMCP in which the NSRMCP did not equal the SRMCP: January through September, 2025

	Intervals where NSRMCP differs from SRMCP		Average Absolute MCP Difference	
Day	RTO	MAD	RTO	MAD
3-Jan-2025	0	4	NA	$6.43

4-Sep-2025	1	1	$850.00	$550.00

Table 10-28 shows the effect of fast start pricing on the nonsynchronized reserve market's monthly weighted average market clearing price since October 2022. Fast start pricing increases LMP in the pricing run relative to the dispatch run, which increases reserve prices. Fast start pricing also reduces the amount of reserves available in the pricing run compared to the dispatch run, by pretending that fast start units can be dispatched for energy below their economic minimum output limit but not counting MW below the eco min as reserves. For the real-time market, these are the LPC prices weighted by the RT SCED MW. For the day-ahead values, these are the DA prices weighted by the DA dispatch MW. The weighted average market clearing price for each month tends to be higher in the pricing run than in the dispatch run. In the first nine months of 2025, the real-time RTO weighted average price of the pricing run was 42.3 percent higher than that of the dispatch run. In the first nine months of 2025, the day-ahead RTO weighted average price of the pricing run was 8.5 percent lower than that of the dispatch run. In the first nine months of 2025, the real-time MAD weighted average price of the pricing run was 37.9 percent higher than that of the dispatch run. In the first nine months of 2025, the day-ahead MAD weighted average price of the pricing run was 7.5 percent lower than that of the dispatch run.

Table 10-28 Comparison of fast start and dispatch RTO pricing: January 2024 through September 2025

		Day-Ahead				Real-Time

2025	Jun	$7.22	$6.76	($0.46)	(6.4%)	$4.28	$4.91	$0.62	14.5%
2025	Jul	$10.23	$9.40	($0.83)	(8.1%)	$1.88	$2.80	$0.92	49.2%
2025	Aug	$3.34	$2.82	($0.52)	(15.5%)	$0.82	$1.25	$0.44	53.3%
2025	Sep	$2.74	$2.22	($0.52)	(19.0%)	$1.60	$1.96	$0.36	22.5%
2025	All	$3.71	$3.43	($0.28)	(7.5%)	$1.63	$2.25	$0.62	37.9%

In the first nine months of 2025, in the RTO Reserve Zone, the real-time weighted average price of nonsynchronized reserve was $1.87 per MWh and the real-time weighted average sum of the MCP credits and LOC credits for nonsynchronized reserve was $1.86 per MWh. In the first nine months of 2025, in the MAD Reserve Subzone, the real-time weighted average price of nonsynchronized reserve was $2.22 per MWh and the real-time weighted average sum of the MCP credits and LOC credits for nonsynchronized reserve was $2.39 per MWh.

Table 10-30 shows the total nonsynchronized reserve payments by month from January 2024 through September 2025. In June 2025, shortage pricing for primary reserve in the RTO was used for 78 intervals during a hot weather event. In July 2025, shortage pricing for primary reserve in the RTO was used for 16 intervals during a second hot weather event. Figure 10-24 shows the resulting spike in prices. Due to units buying back portions of their day-ahead schedule at these high real-time prices, the sum of the real-time and balancing MCP credits seen in Table 10-30 for June 2025 is significantly negative.

Table 10-30 Total nonsynchronized reserve payments and charges by month: January 2024 through September 2025

Year	Month	Day-Ahead Credits	Real-Time and Balancing MCP Credits	LOC Credits	Shortfall Charges	Total Credits
2024	Jan	$549,761	($805,570)	$246,452	NA	($9,357)
2024	Feb	$406,207	($224,893)	$144,292	NA	$325,606

Hydro	3,770,151	3,371,307	$3,960,369	($3,720,750)	$1,043,923	$1,283,541
Other	47,087	28,830	$170,472	($31,613)	$3,060	$141,919

30-Minute Reserve

The 30-minute reserve service is provided by resources that can respond in 30 minutes. The requirement for the 30-minute reserve service can be satisfied by the primary reserve product and the secondary reserve product. There is no NERC standard for 30-minute reserve.

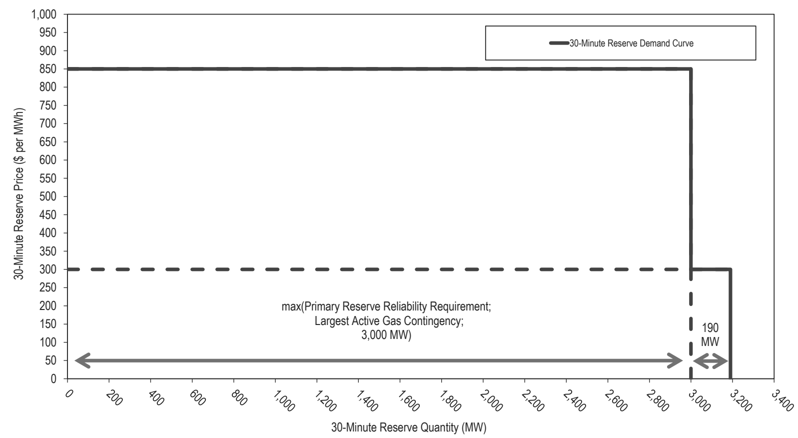
Market Structure

Demand

Demand for the 30-minute reserve service comes from the 30-minute reserve requirement. By default, the 30-minute reserve requirement is equal to the extended reserve requirement plus the 30-minute reserve reliability requirement. The 30-minute reserve reliability requirement is equal to the maximum of: the primary reserve reliability requirement; the largest active gas contingency; and 3,000 MW.[95] Unlike with synchronized reserve and primary reserve, PJM does not model a 30-minute reserve requirement for the defined reserve subzone.[96] However, PJM has the option to define a subzone natural gas contingency reserve requirement using 30-minute reserves. PJM did not exercise this option in the first nine months of 2025.

Figure 10-26 shows an example ORDC for 30-minute reserve for when the primary reserve reliability requirement and the largest active gas contingency are both less than 3,000 MW, and when the extended reserve requirement is equal to its base value of 190 MW. Since the increase to the synchronized reserve reliability requirement in May 2023, the 30-minute reserve requirement has frequently equaled the primary reserve requirement.

Figure 10-26 An example of a 30-minute reserve real-time operating reserve demand curve, including the permanent second step



In the first nine months of 2025, the real-time average 30-minute requirement was 3,519.5 MW and the day-ahead average 30-minute requirement was 3,508.8 MW (Figure 10-4).

Supply

The supply of 30-minute reserves includes all reserves that can convert to energy in 30 minutes. All reserve products can participate in the 30-minute reserve service. In the first nine months of 2025, the demand for 30-minute

95 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations" § 4.3 Reserve Requirement Determination, Rev. 134 (Apr. 23, 2025).
96 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations" § 4.3.1 Locational Aspect of Reserves, Rev. 134 (Apr. 23, 2025).

reserve was satisfied by primary reserves (made of synchronized reserves and nonsynchronized reserves) and secondary reserves. The 30-minute reserve requirement is met from the least expensive combination of synchronized, nonsynchronized, and secondary reserves that satisfies the requirements of the synchronized, primary, and 30-minute reserve services (Table 10-9).

Market Concentration

Table 10-32 shows the average HHI of the 30-minute reserve market, including synchronized, nonsynchronized, and secondary reserves, and the percent of intervals for which the maximum market share is above 20 percent. In the first nine months of 2025, the RTO Reserve Zone was unconcentrated in the day-ahead market and unconcentrated in the real-time market.

Table 10-32 PJM 30-minute reserve market HHI: January through September, 2025

Location	Market	Average HHI	Percent of Intervals Max Market Share Above 20%	Description
RTO	RT	869	46.2%	Unconcentrated
RTO	DA	857	54.4%	Unconcentrated

Market Performance

Due to the large amount of available secondary reserve, most 30-minute reserve is procured at low cost, with the amount of cleared secondary reserve far exceeding what is strictly needed to satisfy the 30-minute reserve requirement (Figure 10-2). In the 2025 polar vortex, at the point of lowest amount of cleared 30-minute reserve (January 22 at 8:50, see Figure 10-27), there were still thousands of MW available above the requirement (Figure 10-28).

Figure 10-27 Cleared reserves during the 2025 polar vortex: January 17 through January 26, 2025

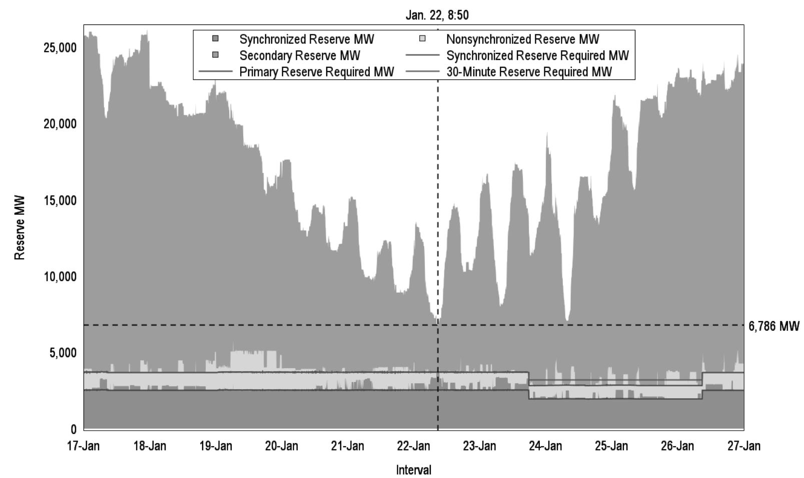


Figure 10-28 Available reserves during the 2025 polar vortex: January 17 through January 26, 2025

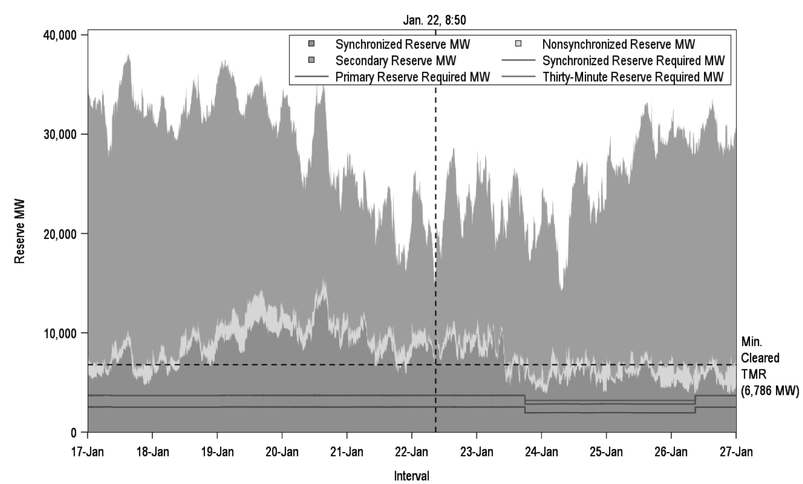
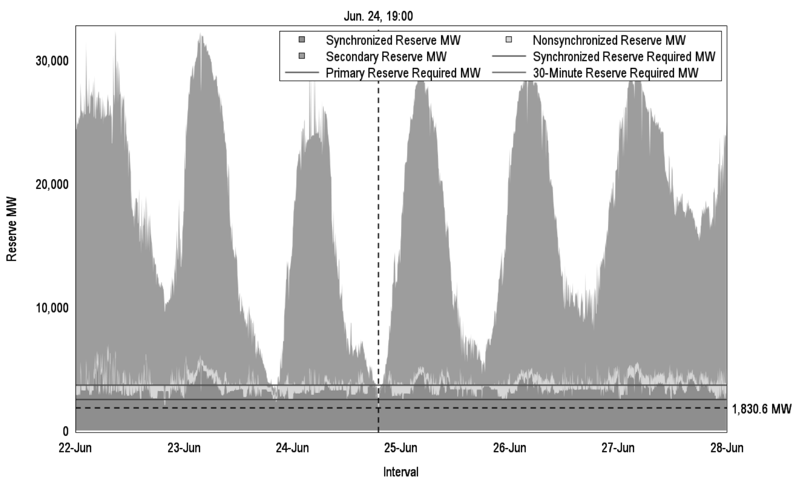


However, 30-minute reserves were short in 23 intervals from June 23, 2025, through June 24, 2025, during a hot weather event. Figure 10-29 shows the point during the hot weather event when cleared 30-minute reserves were at their lowest. For that interval, the amount of secondary reserve offered was 5,954.9 MW. This was larger than the 30-minute requirement of 3,677.6 MW.

Figure 10-29 Cleared reserves during the June 2025 hot weather event: June 22 through June 27, 2025



Secondary Reserve

PJM defines secondary reserve as reserves (online or offline available for dispatch) that can be converted to energy in 10 to 30 minutes. There is no NERC standard for secondary reserve. The secondary reserve product can only be used to satisfy the 30-minute reserve requirement, and is cleared for five-minute intervals in the real–time market and hourly intervals in the day–ahead market. Failure to convert offline secondary reserves to energy at PJM's request results in a shortfall charge.

Unlike synchronized reserves and nonsynchronized reserves, there is no "event" process to deploy secondary reserves. Instead, PJM uses secondary reserve via the normal energy commitment and dispatch process.

Market Structure

Demand

There is no explicit demand for secondary reserve beyond a more general demand for 30-minute reserve, which can be satisfied by the synchronized, nonsynchronized, and secondary reserve products. Beyond the primary reserve requirement, the balance of 30-minute reserve can be made up by the economic combination of synchronized, nonsynchronized, and secondary reserve.

When the secondary reserve market clearing price is $0 per MWh, PJM's clearing engines clear all available secondary reserve MW. Because of the large amount of secondary reserve cleared, most 30-minute reserve is secondary reserve and most cleared secondary reserve is cleared well in excess of the 30-minute reserve requirement (Figure 10-2).

Supply

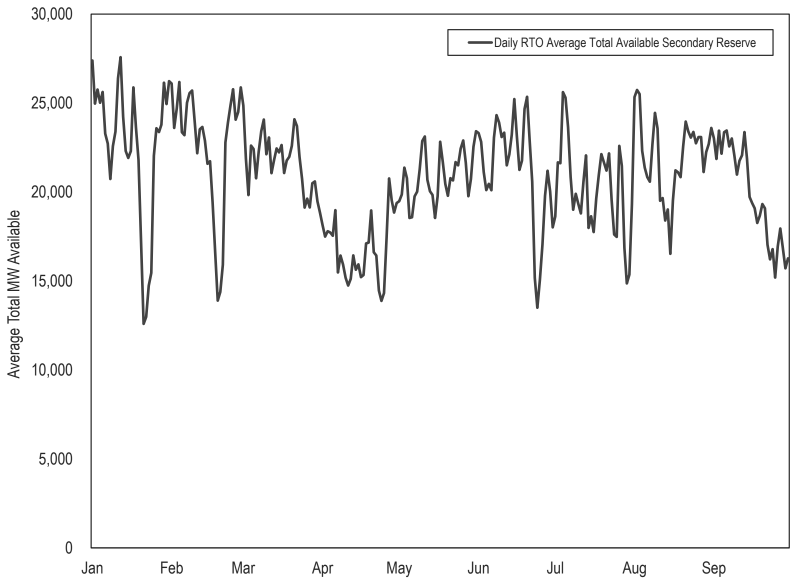
Secondary reserves are reserves that can convert to energy within 10 to 30 minutes. This includes the unloaded capacity of online generation that can be achieved according to the resource ramp rates in 10 to 30 minutes. It also includes offline resources that offer a time to start of less than 30 minutes but more than 10 minutes. Secondary reserves do not include pre-emergency or emergency demand response resources, even if they offer to start in less than 30 minutes. Secondary reserves do not include exports that can be recalled in less than 30 minutes.

As with the other reserve products, for most resources, PJM determines the MW available for secondary reserve based on energy offer parameters.[97] Energy storage resources, hydroelectric resources, and demand response resources must specify their availability and MW separately. Online resources' secondary reserves are based on ramp rates and the lesser of the secondary reserve maximum or economic maximum parameters, as well as any cleared synchronized reserve.[98] The use of the secondary reserve maximum output limit requires prior approval by PJM.[99] Offline resources' secondary reserves are based on the time to start, which is the start-up time plus notification time, and any cleared nonsynchronized reserve.[100] Certain resource types, including nuclear, wind, and solar units, are by default excluded from providing secondary reserves.

Figure 10-30 shows the daily average total available secondary reserve in the first nine months of 2025. In the first nine months of 2025, the real-time average supply of secondary reserve was 21,163.8 MW and the day-ahead average supply was 12,402.1 MW. The available secondary reserve decreased in January during the 2025 polar vortex (Figure 10-28) as PJM brought on more units for energy. The available secondary reserve decreased in February during conservative operations. Secondary reserve decreased in late June during a hot weather event as PJM brought on more units for energy and in late July during a second hot weather event on July 28 through July 30, for which PJM issued hot weather alerts and maximum emergency generation alerts.

97 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations" § 4.2.3 Reserve Market Resource Offer Structure, Rev. 134 (Apr. 23, 2025).
98 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations" § 4.2.5.1 Reserve Market Capability for Online Generation Resources, Rev. 134 (Apr. 23, 2025).
99 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations" § 4.2.2.1 Communication for Reserve Capability Limitation, Rev. 134 (Apr. 23, 2025).
100 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations" § 4.2.5.2 Reserve Market Capability for Offline Generation Resources, Rev. 134 (Apr. 23, 2025).

Figure 10-30 Daily Average Available Secondary Reserve: January through September, 2025



Market Behavior

For all resources, the secondary reserve offer price is $0 per MWh.[101] For online resources, the energy market opportunity cost is calculated by PJM based on market prices.

101 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations" § 4.2.3 Reserve Market Resource Offer Structure, Rev. 134 (Apr. 23, 2025).

Market Performance

Figure 10-31 shows the unweighted average market clearing prices for secondary reserves in the first nine months of 2025. Due to the product's low cost and ample supply, the secondary reserve market clearing price is almost always $0 per MWh. In the first nine months of 2025, the real-time SecRMCP was nonzero for 32 five-minute intervals and the day-ahead SecRMCP was nonzero for zero hours. These nonzero real-time intervals were the result of shortage pricing on June 23 and June 24, during a hot weather event. For June 23 and June 24, PJM issued Maximum Generation alerts. Maximum generation alerts in July during a second hot weather event did not happen similar price spikes.

Figure 10-31 Secondary reserve prices: January through September, 2025

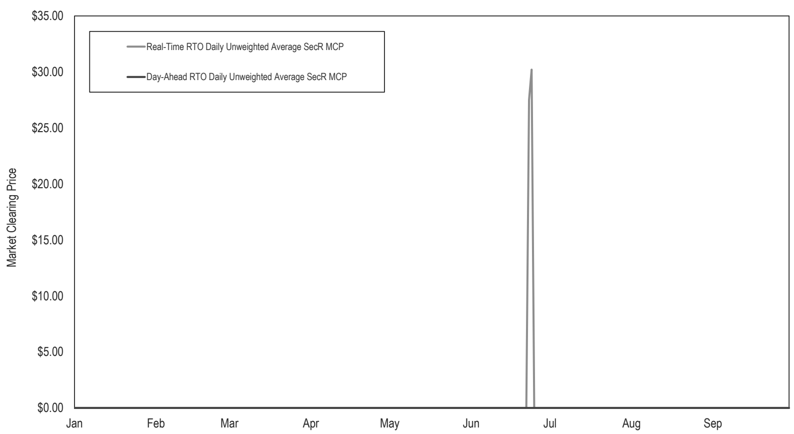


Table 10-33 compares the dispatch run and pricing run market clearing prices for the day-ahead and real-time secondary reserve markets. For both the dispatch run and the pricing run, the real-time values are the LPC prices for each run weighted by the RT SCED MW. For the day-ahead values, these are the DA prices weighted by the DA dispatch MW. In the first nine months of 2025, the day-ahead prices of secondary reserve were always $0 per MWh in both the pricing run and the dispatch run. In real time, the pricing run and dispatch run were nonzero for 32 five-minute intervals from June 23 through June 24, in which shortage pricing was used for 30-minute reserve.

Table 10-34 shows the day-ahead credits, balancing market credits, LOC credits, and effective shortfall charges for secondary reserves from January 2024 through September 2025.[102] In the first nine months of 2025, the real-time weighted average secondary reserve market clearing price was $0.01 per MWh and the day-ahead weighted average secondary reserve market clearing price was $0.00 per MWh. In the first nine months of 2025, the real-time weighted average credit per MWh, considering the total credits paid and the capped MWh, was $0.05 per MWh and the day-ahead weighted average credit was $0.00 per MWh.

Table 10-34 Monthly secondary reserve settlements: January 2024 through September 2025

Among other reasons, a secondary reserve resource is paid an LOC credit when PJM determines that the resource was backed down in order to clear more secondary reserve. Because the supply of secondary reserves greatly exceeds the amount needed to meet the 30-minute reserve requirement, PJM does not actually back down resources to clear more secondary reserve. However, because of the method used by PJM to determine whether a resource was backed down, PJM at times pays resources for an incorrectly determined real-time opportunity cost. For example, PJM erroneously treated resources coming online to provide energy as having been backed down to provide secondary reserves. PJM does not back down resources below their economic minimum to provide secondary reserves, but in the first nine months of 2025, for secondary reserve resources that did not clear day-ahead and were generating below their economic minimum points, PJM paid $2,095,647 in LOC credits.

102 Unlike synchronized reserve, for secondary reserve, shortfall is accounted for in the balancing MCP credits and is not a separate item. The effective shortfall charge is the real-time SecR MCP multiplied by the shortfall MW, a value used when calculating the balancing MCP credits.

Regulation Market

Regulation matches generation with short term changes in load by moving the output of selected resources up and down via an automatic control signal. Regulation is provided by generators with a short-term response capability (less than five minutes) or by demand response (DR). The PJM Regulation Market is operated as a single real-time market.

PJM filed proposed significant changes to the regulation market design with FERC on April 16, 2024.[103] The Commission Order of June 14, 2024, accepted the PJM proposal as filed. PJM will implement the changes to the regulation market in two phases.[104] Phase 1, implemented on October 1, 2025, is a single product, single signal market with one clearing price. Phase 2, to be implemented on October 1, 2026, will include separate regulation up and regulation down markets. The proposed Phase 1 changes will eliminate many of the significant issues identified by the MMU that have resulted from a two product, two signal market design including the incorrect and inconsistent use and application of the MBF/MRTS.

This report analyzes the current (as of the third quarter of 2025) regulation market design and results during the first nine months of 2025.

Market Design

PJM's regulation market design is a result of Order No. 755.[105] The objective of PJM's regulation market design should be to minimize the cost to provide regulation using two resource types in a single market.

The regulation market includes resources following two signals: RegA and RegD. Resources responding to either signal help control ACE (area control error). RegA is PJM's slow oscillation regulation signal and is designed for resources with the ability to sustain energy output for long periods of time, with slower ramp rates. RegD is PJM's fast oscillation regulation signal and is designed for resources with limited ability to sustain energy output and with faster ramp rates. Resources must qualify to follow one or both of the RegA and RegD signals, but will be assigned by the market clearing engine to follow only one signal in a given market hour.

The PJM regulation market design includes three clearing price components: capability ($/MW, based on the MW offered); performance ($/mile, based on the total MW movement requested by the control signal, known as mileage); and lost opportunity cost ($/MW of lost revenue from the energy market as a result of providing regulation). The marginal benefit factor (MBF) and performance score translate a RegD resource's capability (actual) MW into marginal effective MW and offers into $/effective MW.

The goal of the regulation market solution should be to meet the regulation requirement with the least cost combination of RegA and RegD. When solving for the least cost combination of RegA and RegD MW to meet the regulation requirement, the regulation market will substitute RegD MW for RegA MW when RegD is cheaper. Performance adjusted RegA MW are used as the common unit of measure, called effective MW, of regulation service. All resource MW (RegA and RegD) are converted into effective MW. RegA MW are converted into effective MW by multiplying the RegA MW offered by their performance score. RegD MW are converted into effective MW by multiplying the RegD offered by their performance score and by the MBF. The regulation requirement is defined as the total effective MW required to provide a defined amount of area control error (ACE) control.

The regulation market converts performance adjusted RegD MW into effective MW using the MBF in the PJM design. The MBF is used to convert incremental additions of RegD MW into incremental effective MW. The total effective MW for a given amount of RegD MW equal the area under the MBF curve (the sum of the incremental effective MW contributions). RegA and RegD resources should be paid the same price per effective MW.

The marginal rate of technical substitution (MRTS) is the marginal measure of substitutability of RegD resources for RegA resources in satisfying a defined regulation requirement at feasible combinations of RegA and RegD MW. While resources following RegA and RegD can both provide regulation service in PJM's Regulation Market, PJM's joint optimization is intended to

103 PJM, "Regulation Market Design Filing," Docket No. ER24-1772-000.
104 See 187 FERC ¶ 61,173.
105 See Order No. 755, 137 FERC ¶ 61,064 at P 2 (2011).

determine and assign the optimal mix of RegA and RegD MW to meet the hourly regulation requirement. The optimal mix is a function of the relative effectiveness and cost of available RegA and RegD resources.

At any valid combination of RegA and RegD, regulation offers are converted to dollars per effective MW using the RegD offer and the MBF associated with that combination of RegA and RegD. The marginal contribution of a RegD MW to effective MW is equal to the MRTS associated with that RegA/RegD combination.

For example, a 1.0 MW RegD resource with a total offer price of $2 per MW with a MBF of 0.5 and a performance score of 100 percent would be calculated as offering 0.5 effective MW (0.5 MBF times 1.00 performance score times 1 MW). The total offer price would be $4 per effective MW ($2 per MW offer divided by the 0.5 effective MW).

Regulation performance scores (0.0 to 1.0) measure the response of a regulating resource to its assigned regulation signal (RegA or RegD) every 10 seconds by measuring: delay, the time delay of the regulation response to a change in the regulation signal; correlation, the correlation between the regulating resource output and the regulation signal; and precision, the difference between the regulation response and the regulation requested.[106] Performance scores are reported on an hourly basis for each resource.

Table 10-36 and Figure 10-32 show the average performance score by resource type and the signal followed in the first nine months of 2025. In these figures, the MW used are actual MW and the performance score is the hourly performance score of the regulation resource.[107] Each category (color bar) is based on the percentage of the full performance score distribution for each resource (or signal) type. As Figure 10-32 shows, 91.5 percent of RegD resources had average performance scores within the 0.91-1.00 range, and 30.6 percent of RegA resources had average performance scores within that range in the first nine months of 2025. In the first nine months of 2024, 73.9 percent of RegD resources had average performance scores within the 0.91-1.00 range, and 22.0 percent of RegA resources had average performance scores within that range.

106 PJM "Manual 12: Balancing Operations," § 4.5.6 Performance Score Calculation, Rev. 54 (July Dec. 17, 2024).
107 Except where explicitly referred to as effective MW or effective regulation MW, MW means actual MW unadjusted for either MBF or performance factor.

Table 10-36 Hourly average performance score by unit type: January through September, 2025

		Performance Score Range			
		61-70	71-80	81-90	91-100
RegA	Battery	0.0%	0.0%	62.7%	37.3%
	CT	0.0%	6.3%	67.8%	25.9%
	Diesel	0.0%	0.0%	1.8%	98.2%
	DSR	0.0%	71.8%	26.5%	1.7%
	Hydro	0.0%	0.1%	51.4%	48.5%
	Steam	4.3%	20.6%	55.3%	19.8%
RegD	Battery	1.1%	0.3%	4.2%	94.2%
	CT	36.6%	34.2%	0.0%	29.2%
	Diesel	0.0%	0.0%	34.5%	65.5%
	DSR	0.2%	8.7%	10.6%	80.5%

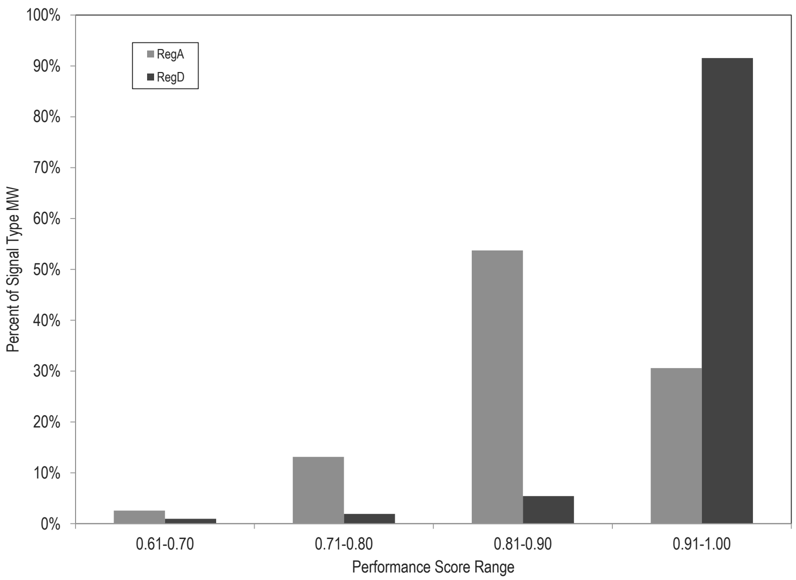
Figure 10-32 Hourly average performance score by regulation signal type: January through September, 2025



Each cleared resource in a class (RegA or RegD) is allocated a portion of the class signal (RegA or RegD). This portion of the class signal is based on the cleared regulation MW of the resource relative to the cleared MW for that class. This signal is called the Total Regulation Signal (TREG) for the resource. A resource that cleared 10 MW of capability (AREG) will be provided a percentage TREG signal asking for a positive or negative regulation movement between negative and positive 100 percent (10 MW) around its regulation set point.

The MMU identified an issue with the current method of calculating the regulation performance score of a resource. The issue is that the delay and correlation components of the performance score do not accurately reflect how well a unit is responding to the regulation signal. These delay and correlation components can remain high, even when a unit is responding poorly to the regulation signal, and artificially inflate the overall performance score of the unit. For example, during the Winter Storm Elliott event, several units were not able to maintain their response to the regulation signal. These units received a precision score of zero, however, their delay and accuracy scores were near perfect (>0.95). This resulted in several units receiving regulation credits because their overall performance score was approximately 0.65 (each component of the performance score has an equal 1/3 weighting) despite not actually providing regulation. To address this issue, the MMU has proposed to evaluate regulation performance using a precision based performance score, which would only depend on the difference between the regulation signal and the unit's response to that signal.

$$Performance\ Score_{10Sec} = 1 - ABS\left(\frac{RegOutputMW - SignalMW}{AReg}\right)$$

With the total performance score for the clearing interval being the average of each 10 second performance score. This means that, in a simplified 10 second interval, a unit that cleared 10 MW (AREG = 10 MW) responding with a steady 7.5 MW (75 percent of their total capability) to a positive pegged signal (Signal MW = 10; TREG = 100 percent) would logically receive a performance score of 0.75. The MMU presented this recommendation to the regulation market senior task force.

PJM's proposed solution evaluates the 10 second error in a unit's output based on the average regulation signal MW during the entire clearing interval.[108]

$$Performance\ Score_{10Sec} = 1 - ABS\left[\frac{(RegOutputMW - SignalMW)}{\left(\frac{ClearingIntervalAvgSignal + AReg}{2}\right)}\right]$$

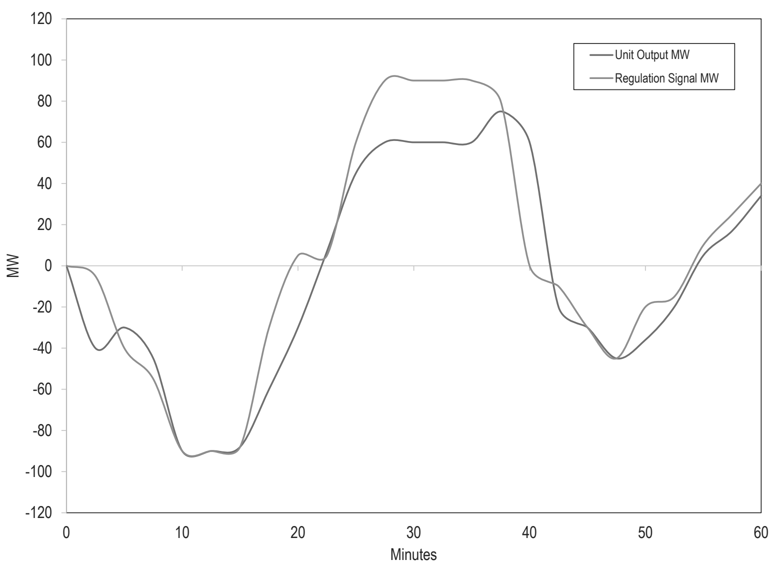
This has the effect of scaling each 10 second performance score based on the clearing interval average of the overall regulation signal. Using this equation in the simplified case above would yield a performance score equal to 0.75

108 The current regulation clearing interval is one hour. The proposed change is to move to a 30 minute clearing interval.

only if the clearing interval average signal is pegged, and less than 0.75 when the clearing interval average signal is close to zero.

Figure 10-33 illustrates an example unit that cleared 100 MW of regulation, following the regulation signal for one hour. Based on the MMU's proposed performance score calculation, the unit would have a performance score of 0.8450 for the hour. Using PJM's proposed calculation, that same unit would have a performance score of only 0.6981 for the hour because the clearing interval average signal is small (2.7 MW). If both the regulation signal and the unit's response in this example were shifted up (or down) by 10 MW, the MMU's result would remain the same, because it only depends on the response of the unit to the signal it is supposed to follow. The PJM result however, would change to 0.7249 because the clearing interval average signal would increase to 12.7 MW. PJM's calculation would lead to different results, based solely on the overall clearing interval average of the regulation signal; identical unit performance would yield different performance score results.

Figure 10-33 A example unit providing 100 MW of regulation while following an almost neutral regulation signal



Resources are paid Regulation Market Clearing Price (RMCP) credits and lost opportunity cost credits, which are uplift payments. If a resource's lost opportunity costs for an hour are greater than its RMCP credits, that resource receives lost opportunity cost credits equal to the difference. PJM posts clearing prices for the regulation market (RMCCP, RMPCP and RMCP) in dollars per effective MW. The regulation market clearing price (RMCP in $/effective MW) for the hour is the simple average of the 12 five minute RMCPs within the hour. The RMCP is set in each five minute interval based on the marginal offer in each interval. The performance clearing price (RMPCP in $/effective MW) is based on the marginal performance offer (RMPCP) for the hour. The capability clearing price (RMCCP in $/effective MW) is equal to the difference between the RMCP for the hour and the RMPCP for the hour. This is done so the total of RMPCP plus RMCCP equals the total clearing price (RMCP) but the RMPCP is maximized.

Market solution software relevant to regulation consists of the Ancillary Services Optimizer (ASO) solving hourly; the intermediate term security constrained economic dispatch market solution (IT SCED) solving every 15 minutes; and the real-time security constrained economic dispatch market solution (RT SCED) solving approximately every five minutes. The market clearing price is determined by pricing software (LPC) that looks at the units cleared in the most recently approved RT SCED case, approximately 10 minutes ahead of the target solution time. The marginal prices assigned by the LPC to five minute intervals are averaged over the hour for an hourly regulation market clearing price.

Market Design Issues

PJM's current regulation market design is severely flawed and is not efficient or competitive. The market results do not represent the least cost solution for the defined level of regulation service.

In a well functioning market, every resource should be paid the same clearing price per unit produced. That is not true in the PJM Regulation Market. RegA and RegD resources are not paid the same clearing price in dollars per effective MW. RegD resources are being paid more than the market clearing price. This flaw in the market design has caused operational issues, has caused over investment in RegD resources.

If all MW of regulation were treated the same in both the clearing of the market and in settlements, many of the issues in the PJM Regulation Market would be resolved. However, the current PJM rules result in the payment to RegD resources being up to 1,000 times the correct price.

RegA and RegD have different physical capabilities. In order to permit RegA and RegD to compete in the single PJM Regulation Market, RegD must be translated into the same units as RegA. One MW of RegA is one effective MW. The translation is done using the marginal benefit factor (MBF). As more RegD is added to the market, the relative value of RegD declines, based on its actual performance attributes. For example, if the MBF is 0.001, a MW of RegD is worth 0.001 MW of RegA (or 1/1,000 of a MW of RegA). This is the same thing as saying that 1.0 MW of RegD is equal to 0.001 effective MW when the MBF is 0.001.

Almost all of the issues in PJM's Regulation Market are caused by the inconsistent application of the MBF. Because the MBF is not included in settlements, when the MBF is less than 1.0, RegD resources are paid too much. When the MBF is less than 1.0, each MW of RegD is worth less than 1.0 MW of RegA. The market design buys the correct amount of RegD, but pays RegD as if the MBF were 1.0. In an extreme case, when the MBF is 0.001, RegD MW are paid 1,000 times too much. If the market clearing price is $1.00 per MW of RegA, RegD is paid $1,000 per effective MW. Resolution of this problem requires that PJM pay RegD for the same effective MW it provides in regulation, 0.001 MW.

To address the identified market flaws, the MMU and PJM developed a joint proposal which was approved by the PJM Members Committee on July 27, 2017, and filed with FERC on October 17, 2017. The PJM/MMU joint proposal addresses issues with the inconsistent application of the marginal benefit factor throughout the optimization and settlement process in the PJM Regulation Market. FERC rejected the proposal finding it inconsistent with Order No. 755.

The MBF related issues with the regulation market have been raised in the PJM stakeholder process. In 2015, PJM stakeholders approved an interim, partial solution to the RegD over procurement problem which was implemented on December 14, 2015. The interim solution was designed to reduce the relative value of RegD MW in all hours and to cap purchases of RegD MW during critical performance hours. But the interim solution did not address the fundamental issues in the optimization or the lack of consistency in the application of the MBF.

Additional changes were implemented on January 9, 2017. These modifications included changing the definition of off peak and on peak hours, adjusting the currently independent RegA and RegD signals to be interdependent, and changing the 15 minute neutrality requirement of the RegD signal to a 30 minute neutrality requirement.

The January 9, 2017, design changes appear to have been intended to make RegD more valuable. That is not a reasonable design goal. The design goal should be to determine the least cost way to provide needed regulation. The RegA signal is now slower than it was previously, which may make RegA following resources less useful as ACE control. RegA is now explicitly used to support the conditional energy neutrality of RegD. The RegD signal is now the difference between ACE and RegA. RegA is required to offset RegD when RegD moves in the opposite direction of that required by ACE control in order to permit RegD to recharge. These changes in the signal design will allow PJM to accommodate more RegD in its market solutions. The new signal design is not making the most efficient use of RegA and RegD resources. The explicit reliance on RegA to offset issues with RegD is a significant conceptual change to the design that is inconsistent with the long term design goal for regulation. PJM increased the regulation requirement as part of these changes.

The January 9, 2017, design changes replaced off peak and on peak hours with nonramp and ramp hours with definitions that vary by season. The regulation requirement for ramp hours was increased from 700 MW to 800 MW (Table 10-37). These market changes did not address the fundamental issues in the optimization or the lack of consistency in the application of the MBF.

Table 10-37 Seasonal regulation requirement definitions[109]

Season	Dates	Nonramp Hours	Ramp Hours
Winter	Dec 1 - Feb 28(29)	00:00 - 03:59 09:00 - 15:59	04:00 - 08:59 16:00 - 23:59
Spring	Mar 1 - May 31	00:00 - 04:59 08:00 - 16:59	05:00 - 07:59 17:00 - 23:59
Summer	Jun 1 - Aug 31	00:00 - 04:59 14:00 - 17:59	05:00 - 13:59 18:00 - 23:59
Fall	Sep 1 - Nov 30	00:00 - 04:59 08:00 - 16:59	05:00 - 07:59 17:00 - 23:59

Performance Scores

Performance scores, by class and unit, are not an indicator of how well resources contribute to ACE control. Performance scores are an indicator only of how well the resources follow their TREG signal. High performance scores with poor signal design are not a meaningful measure of performance. For example, if ACE indicates the need for more regulation but RegD resources have provided all their available energy, the RegD regulation signal will be in the opposite direction of what is needed to control ACE. So, despite moving in the wrong direction for ACE control, RegD resources would get a good performance score for following the RegD signal and will be paid for moving in the wrong direction.

The RegD signal prior to January 9, 2017, is an example of a signal that resulted in high performance scores, but due to 15 minute energy neutrality built into the signal, ran counter to ACE control at times. Energy neutrality means that energy produced equals energy used within a defined timeframe. With 15 minute energy neutrality, if a battery were following the regulation signal to provide MWh for 7.5 minutes, it would have to consume the same amount of MWh for the next 7.5 minutes. When neutrality correction of the RegD signal is triggered, it overrides ACE control in favor of achieving zero net energy over the 15 minute period. When this occurs, the RegD signal runs counter to the control of ACE and hurts rather than helps ACE. In that situation, the control of ACE, which must also offset the negative impacts of RegD, depends entirely on RegA resources following the RegA signal. High performance scores under the signal design prior to January 9, 2017, was not an indication of good ACE control.

The January 9, 2017, design changes did not address the fundamental issues with the definition of performance or the nature of payments for performance in the regulation market design. The regulation signal should not be designed to favor a particular technology. The signal should be designed to result in the lowest cost of regulation to the market. Only with a performance score based on full substitutability among resource types should payments be based on following the signal. The MRTS must be redesigned to reflect the actual capabilities of technologies to provide regulation. The PJM regulation market design remains fundamentally flawed.

In addition, the absence of a performance penalty, imposed as a reduction in performance score and/or as a forfeiture of revenues, for deselection initiated by the resource owner within the hour, creates a possible gaming opportunity for resources which may overstate their capability to follow the regulation signal. The MMU recommends that there be a penalty enforced as a reduction in performance score and/or a forfeiture of revenues when resource owners elect to deassign assigned regulation resources within the hour, to prevent gaming.

Battery Settlement

The change from 15 to 30 minute signal neutrality, implemented in the January 9, 2017, design changes, resulted in the reduction of performance scores for short duration batteries. In April 2017, several participants filed a complaint against PJM, asserting that these changes discriminated against their battery units.[110] The MMU objected to the complaints. Despite the unsupported assertions in the complaint, PJM settled with the participants. The settlement was approved by FERC on April 7, 2020.[111] Table 10-38 shows the battery units that are part of the settlement. Starting July 1, 2020, the affected battery units began receiving compensation based on the greater of

their current performance score, or their rolling average actual hourly performance score for the last 100 hours the resource operated prior to the January 9, 2017, implementation of the 30-minute conditional neutrality.

In addition to paying uneconomic regulation credits based on inflated performance scores, the settlement also required that the affected battery units be cleared in the regulation market regardless of whether their offer was economic. As long as the settlement batteries were offered as either self scheduled with a zero offer, or as a zero priced offer, they must be cleared despite the fact that these units would not necessarily have cleared based on economics.[112] In order to comply with this condition, PJM cleared additional MW beyond what was needed for the regulation requirement in cases where the settlement battery units did not clear but met the offer rules of the settlement. This resulted in excess charges to customers for regulation service.

The total additional regulation credits received as a result of the settlement, as well as the additional regulation MW cleared as a result of the settlement, from July 2020 through December 2023, are shown in Table 10-39. From July 2020 through December 2023, the battery settlement provided $5.6 million in excess regulation credits, and resulted in 32,536.1 MW of additional cleared regulation. The term of the settlement was for 42 months, and ended December 31, 2023.

Total		$5,614,484	32,536.1

Regulation Signal

As with any signal design for substitutable resources, the MBF function should be determined by the ability of RegA and RegD resources to follow their signals, including conditions under which neutrality cannot be maintained by RegD resources. The ability of energy limited RegD to provide ACE control depends on the availability of excess RegA capability to support RegD under the conditional neutrality design. When RegD resources are largely energy limited resources, a correctly calculated MBF would exhibit a rapid decrease in the MBF value for every MW of RegD added. The result is that only a small amount of energy limited RegD is economic. The current and proposed signals and corresponding MBF functions do not reflect these principles or the actual substitutability of resource types.

Through the ongoing stakeholder regulation task force, the MMU has proposed several changes to address the current issues with the regulation signal market design. The MMU proposes that the two signals be combined into one, simplified regulation signal. All units would be cleared based on their total performance adjusted offers, with performance scores used as a tie breaker for equal offers (the status quo). Performance scores would be modified to only include a precision score. The move to a single signal would also eliminate the 30-minute signal neutrality but the regulation market clearing period would be shortened from one hour to 30 minutes. This would allow units with issues providing for a full hour to leave the market if needed without the regulation signal being tailored to uneconomically accommodate specific unit types.

Marginal Benefit Factor Issues

The MBF function, as implemented in the PJM Regulation Market, is not equal to the MRTS between RegA and RegD. The MBF is not consistently applied throughout the market design, from optimization to settlement, and market clearing does not confirm that the resulting combinations of RegA and RegD are realistic and can meet the defined regulation demand. The calculation of total regulation cleared using the MBF is incorrect.[113]

The result has been that the PJM Regulation Market has over procured RegD relative to RegA in most hours, has provided a consistently inefficient market signal to participants regarding the value of RegD in every hour, and has overpaid for RegD. This over procurement has degraded the ability of PJM to control ACE in some hours while at the same time increasing the cost of regulation. When the price paid for RegD is above the level defined by an accurate MBF function, there is an artificial incentive for inefficient entry of RegD resources.

PJM and the MMU filed a joint proposal with FERC on October 17, 2017, to address issues with the inconsistent application of the marginal benefit factor throughout the optimization and settlement process in the PJM Regulation Market, but the proposal was rejected by FERC.[114]

Marginal Benefit Factor Not Correctly Defined

The MBF used in the PJM Regulation Market prior to the December 14, 2015, changes did not accurately reflect the MRTS between RegA and RegD resources under the old market design, and it does not accurately reflect the MRTS between RegA and RegD resources under the current design. The MBF function is incorrectly defined and improperly implemented in the current PJM Regulation Market.

The MBF should be the marginal rate of technical substitution between RegA and RegD MW at different, feasible combinations of RegA and RegD that can be used to provide a defined level of regulation service. The objective of the market design is to find, given the relative costs of RegA and RegD MW, the least cost feasible combination of RegA and RegD MW. If the MBF function is incorrectly defined, or improperly implemented in the market clearing and settlement, the resulting combinations of RegA and RegD will not represent the least cost solution and may not be a feasible way to reach the target level of regulation.

The MBF is not included in PJM's settlement process. This is a design flaw that results in incorrect payments for regulation. The issue results from two FERC orders. From October 1, 2012, through October 31, 2013, PJM implemented a

113 The MBF, as used in this report, refers to PJM's incorrectly calculated MBF and not the MBF equivalent to the MRTS.

114 See 162 FERC ¶ 61,295 (2018), *reh'g denied*, 170 FERC ¶ 61,259 (2020).

FERC order that required the MBF to be fixed at 1.0 for settlement calculations only. On October 2, 2013, FERC directed PJM to eliminate the use of the MBF entirely from settlement calculations of the capability and performance credits and replace it with the RegD to RegA mileage ratio in the performance credit paid to RegD resources, effective retroactively to October 1, 2012.[115] That rule continues in effect. The result of the current FERC order is that the MBF is used in market clearing to determine the relative value of an additional MW of RegD, but the MBF is not used in the settlement for RegD.

If the MBF were consistently applied, every resource would receive the same clearing price per marginal effective MW. But the MBF is not consistently applied and resources do not receive the same clearing price per marginal effective MW.

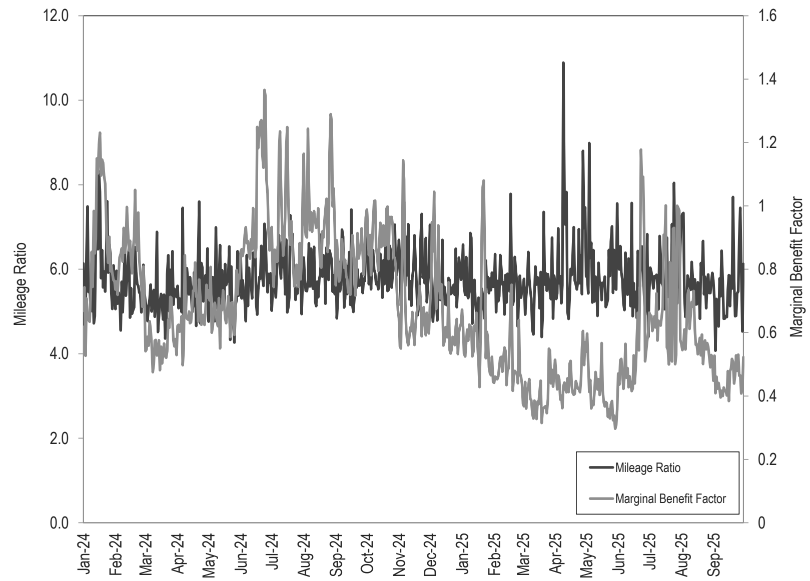
The change in design decreased RegA mileage (the change in MW output in response to regulation signal per MW of capability), increased the proportion of cleared RegD resources' capability that was called by the RegD signal (increased REG for a given MW) to better match offered capability, increased the mileage required of RegD resources and changed the energy neutrality component of the signal from a strict 15 minute neutrality to a conditional 30 minute neutrality. The changes in signal design increased the mileage ratio (the ratio of RegD mileage to RegA mileage). In addition, to adapt to the 30 minute neutrality requirement, some RegD resources decreased their offered capability to maintain their performance.

Figure 10-34 shows the daily average MBF and the mileage ratio. The weighted average mileage ratio increased from 5.71 in the first nine months of 2024, to 5.78 in the first nine months of 2025 (an increase of 1.2 percent). The average MBF decreased from 0.82 in the first nine months of 2024, to 0.52 in the first nine months of 2025 (a decrease of 36.1 percent). The high mileage ratios are the result of the mechanics of the mileage ratio calculation. Extreme mileage ratios result when the RegA signal is fixed at a single value (pegged) to control ACE and the RegD signal is not. If RegA is held at a constant MW output, mileage is zero for RegA. The result of a fixed RegA signal is that RegA mileage is very small and therefore the mileage ratio is very large.

115 See 145 FERC ¶ 61,011 (2013).

These results are an example of why it is not appropriate to use the mileage ratio, rather than the MBF, to measure the relative value of RegA and RegD resources. In these events, RegA resources are providing ACE control by providing a fixed level of MW output which means zero mileage, while RegD resources alternate between helping and hurting ACE control, both of which result in positive mileage.

Figure 10-34 Daily average MBF and mileage ratio: January 2024 through September 2025



The increase in the average mileage ratio caused by the signal design changes introduced on January 9, 2017, caused a large increase in payments to RegD resources on a performance adjusted MW basis.

Table 10-40 shows RegD resource payments on a performance adjusted actual MW basis and RegA resource payments on a performance adjusted MW basis by month, from January 1, 2024, through September 30, 2025. Due to significantly higher LOC as a result of higher LMPs, the average regulation market clearing price in the first nine months of 2025 was $11.12 higher than in the first nine months of 2024 (See Table 10-54.) In the first nine months of 2025, RegD resources earned 17.6 percent more per performance adjusted actual MW than RegA resources (compared to 15.8 percent more in the first nine months of 2024) due to the inclusion of the mileage ratio in RegD MW settlement.

Table 10-40 Average monthly price paid per performance adjusted actual MW of RegD and RegA: January 2024 through September 2025

		Settlement Payments		
Year	Month	RegD ($/Performance Adjusted MW)	RegA ($ Performance Adjusted MW)	Percent RegD Overpayment ($/Performance Adjusted MW)

The current settlement process does not result in paying RegA and RegD resources the same price per effective MW. RegA resources are paid on the basis of dollars per effective MW of RegA. RegD resources are not paid in terms of dollars per effective MW of RegA because the MBF is not used in settlements. Instead of being paid based on the MBF, (RMCCP + RMPCP)*MBF, RegD resources are paid based on the mileage ratio (RMCCP + (RMPCP*mileage ratio)). Because the RMCCP component makes up the majority of the overall clearing price, when the MBF is above one, RegD resources can be underpaid on a per effective MW basis by the current payment method, unless offset by a high mileage ratio. When the MBF is less than one, RegD resources are overpaid on a per effective MW basis, unless offset by a low mileage ratio. The average MBF was less than 1.0 in the first nine months of 2025 (0.52).

The effect of using the mileage ratio instead of the MBF for purposes of settlement is illustrated in Table 10-41. Table 10-41 shows how much RegD resources are currently being paid, adjusted to a per effective MW basis, on average, in 2024 and the first nine months of 2025 under the current rules, compared to how much RegD resources should have been paid if they were actually paid for effective MW. Using the MBF consistently throughout the PJM regulation market would result in RegA and RegD resources being paid exactly the same on a per effective MW basis. However, the PJM regulation market only uses the MBF in the market clearing and setting of price on a dollar per effective MW basis, it does not use the MBF to convert RegD MW into effective MW for purposes of settlement. Because the MBF is not used to convert RegD MW into effective MW for purposes of settlement, RegD resources are paid the dollar per effective MW price, but this is paid for performance adjusted MW, not for effective MW. This causes the MW value of RegD resources to be inflated in settlement when the MBF is less than one and to be undervalued in settlement when the MBF is greater than one. In the first nine months of 2025, the MBF averaged 0.52, while the average daily mileage ratio was 5.78, resulting in RegD resources being paid $28.9 million more than they would have been paid on an effective MW basis if the MBF were correctly implemented. In the first nine months of 2024, the MBF averaged 0.82, and the average mileage ratio was 5.71, resulting in RegD resources being paid $8.7 million more than they would have been paid if the MBF were correctly implemented.

Table 10-41 Average monthly price paid per effective MW of RegD and RegA under mileage and MBF based settlement: January 2024 through September 2025

		RegD Settlement Payments				
Year	Month	Mileage Based RegD ($/Effective MW)	Marginal Rate of Technical Substitution Based RegD ($/Effective MW)	RegA ($/Effective MW)	Percent RegD Overpayment ($/Effective MW)	Total RegD Overpayment ($)

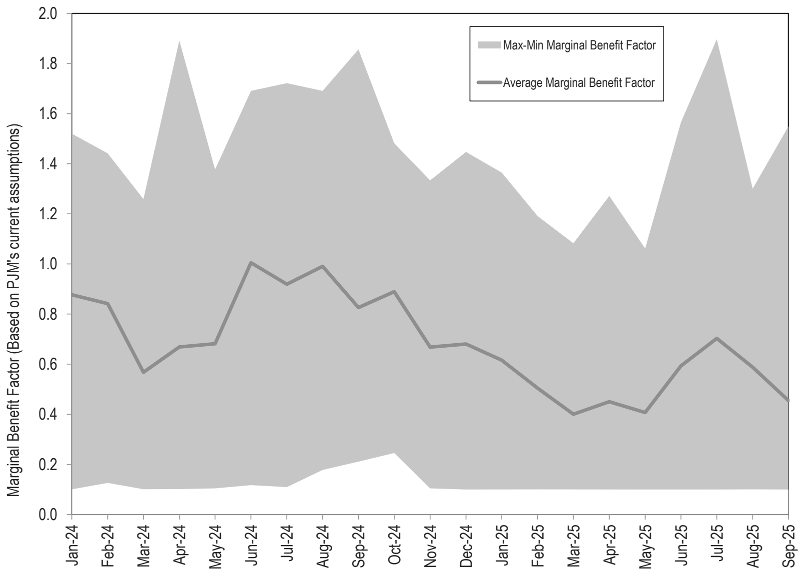
Figure 10-35 shows, the monthly maximum, minimum and average MBF, for January 2024 through September 2025. The average daily MBF in the first nine months of 2025 was 0.52. The average daily MBF in the first nine months of 2024 was 0.82. The bottom of the MBF range results from PJM's administratively defined MBF minimum threshold of 0.1.

Figure 10-35 Maximum, minimum, and average PJM calculated MBF by month: January 2024 through September 2025



The MMU recommends that the regulation market be modified to incorporate a consistent and correct application of the MBF throughout the optimization, assignment and settlement process.[116]

The overpayment of RegD has resulted in offers from RegD resources that are almost all at an effective cost of $0.00 ($0.00 offers plus self scheduled offers). RegD MW providers are ensured that such offers will clear and will be paid a price determined by the offers of RegA resources. This is evidence of the impact of the flaws in the clearing engine and the overpayment of RegD resources on the offer behavior of RegD resources.

Table 10-42 shows, by month, cleared RegD MW with an effective price of $0.00 (units with zero offers plus self scheduled units) for January 2024 through September 2025. In the first nine months of 2025, an average of 74.6 percent of all RegD MW clearing the market had an effective offer of $0.00. In the first nine months of 2024, an average of 92.7 percent of all cleared RegD MW had an effective cost of $0.00. In the first nine months of 2025, an average of 79.7 percent of all RegD offers were self scheduled, compared to an average of 67.2 percent of all RegD offers in the first nine months of 2024.

The high percentage of self scheduled offers is a result of the incentives created by the flaws in the regulation market. Because self scheduled offers are price takers, they are cleared along with the zero cost offers in the market clearing engine. However, unlike zero cost offers, self scheduled offers do not risk having an LOC added to their offer during the market clearing process, ensuring that self scheduled offers have a zero cost during market clearing. Given the increasing saturation of the regulation market with RegD MW, specifically demand response and battery units which do not receive LOC, market participants eligible for LOC that offer at zero instead of self scheduling, run the risk of an LOC added to their offer, and thus not clearing the market.

The average monthly RegD cleared in the market increased 94.6 MW (49.6 percent), from 190.8 MW in the first nine months of 2024 to 285.4 MW in the first nine months of 2025. The average monthly RegD cleared with an effective cost of zero increased 35.7 MW (20.2 percent), from 176.8 MW in the first nine months of 2024 to 212.6 MW in the first nine months of 2025. Self scheduled RegD cleared MW increased 99.7 MW (77.7 percent), from 128.2 MW in the first nine months of 2024 to 227.8 MW in the first nine months of 2025. Average cleared RegD MW with a zero cost offer increased 3.9 MW (8.0 percent), from 48.6 MW in the first nine months of 2024 to 52.6 MW in the first nine months of 2025. Dual offers are not solved correctly in the regulation market clearing engine, and reduce the amount of RegD that

116 See "Regulation Market Review," Operating Committee (May 5, 2015) <http://www.pjm.com/~/media/committees-groups/committees/oc/20150505/20150505-item-17-regulation-market-review.ashx>.

clears. The decrease of dual offers in the first nine months of 2025 resulted in an increase in average monthly cleared RegD regulation and a decrease in the average monthly MBF seen in Figure 10-35.

Table 10-42 Average cleared RegD MW and average cleared RegD with an effective price of $0.00 by month: January 2024 through September 2025

		Average Performance Adjusted Cleared RegD MW

Incorrect MBF and total effective MW when clearing units with dual product offers

Under PJM market rules, regulation units that have the capability to provide both RegA and RegD MW are permitted to submit an offer for both signal types in the same market hour. While the objective of the PJM market design is to find the least cost combination of RegA and RegD resources to provide the required level of regulation service, the method of clearing the regulation market for an hour in which one or more units has a dual offer is incorrect and leads to solutions that are not the most economic. The result of the flaw is that the MBF in the regulation market clearing phase is incorrectly low compared to the MBF in the market solution phase, too little RegD is cleared relative to the efficient amount, the RegD resources that do clear are underpaid when the resulting MBF is greater than 1.0 and the actual amount of effective MW procured is higher than the regulation requirement.

In order for the clearing engine to provide the correct economic solution when the pool of available resources contains one or more units with dual offers, the calculation would have to be performed iteratively to determine which of the dual offers would provide the least cost solution. But this is not how PJM clears the regulation market when there are dual offer units. PJM rank orders the regulation supply curve by potential effective cost assuming the dual offer resources are available as both RegA and RegD resources simultaneously, and assigns every RegD resource, including dual offer resources, a unit specific benefit factor.

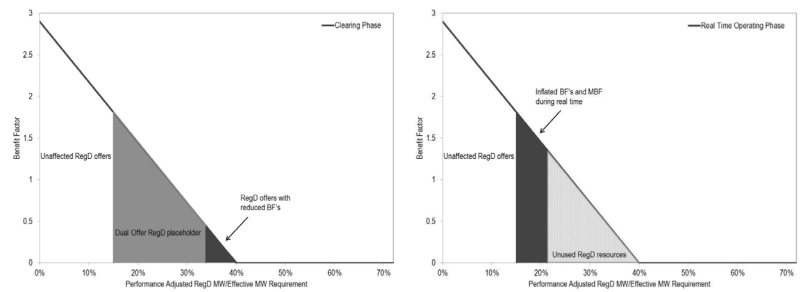
Each dual offer resource is assigned to run as either a RegD or RegA resource based on which of the two offers has a lower effective cost. But PJM does not redefine the supply curve using appropriately recalculated unit specific benefit factors for the remaining RegD resources prior to clearing the market.

During the clearing phase, the MBF of RegD resources is a function of the RegD MW that clear. The MBF for all RegD resources declines as more RegD resources are cleared. Based on this relationship, in the case where a dual offer unit is assigned to be a RegA resource rather than a RegD resource, the MBF of remaining RegD resources in the supply curve should increase. The placeholder RegD MW from the dual offer should be removed, the cleared MW from below the placeholder should be shifted up the supply/MBF curve, and additional RegD MW offers that were pushed below an MBF of zero and initially not included, should be considered. But PJM does not recalculate the MBF values for the remaining RegD resources when determining the cleared effective MW needed to satisfy the regulation requirement during the clearing phase. The result is that the MBF in the clearing phase is incorrectly low, and the actual amount of effective MW procured is higher.

After meeting the target effective MW to satisfy the regulation requirement for that hour through the clearing process, the unit specific benefit factors of those displaced units are recalculated in the real-time operating phase and increased based on their actual contribution. The effective MW contributions of those originally displaced units are correctly calculated in the operating phase, but because the supply for that hour has already been set based on their incorrect effective MW, the solution includes more effective MW than calculated in the clearing phase. As a result, the market solution includes more than the target level of effective MW in the actual operating hour.

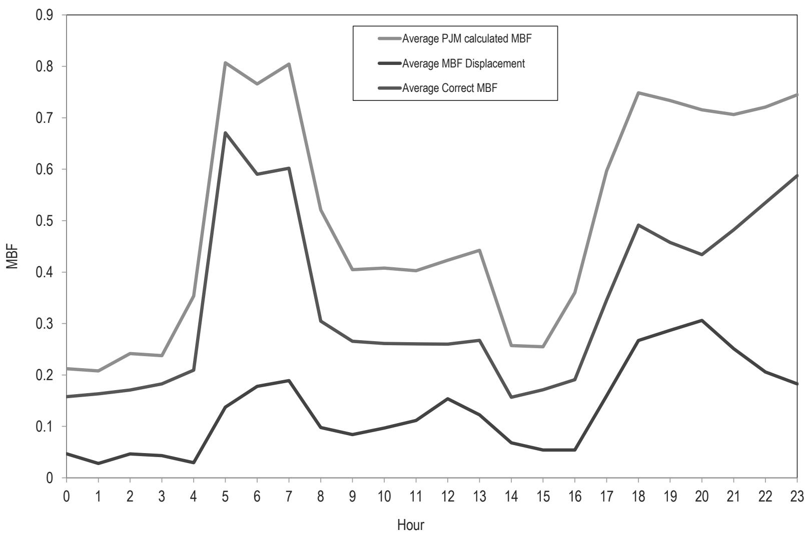
The issue is illustrated in Figure 10-36. The example shows a clearing phase and a real time operating phase. In this example, a 150 MW unit offers both RegA and RegD. The 150 MW unit's position in the RegD effective cost curve and the potential effective MW are represented as the orange area under the curve in the clearing phase. The effective MW of the cleared RegD resources with higher effective costs are represented by the blue triangle in the clearing phase. Not shown are additional RegD MW with higher effective costs that were assigned an MBF of 0 and not cleared. The 150 MW dual offer unit is chosen to operate as a RegA resource in the operational hour. As a result, the cleared supply for RegA in the clearing phase is the same RegA supply realized in the real time operating phase. But that is not the case for the RegD supply. Since the supply curve and unit specific benefit factors of RegD MW are not recalculated in the clearing phase after the 150 MW RegD offer is removed, the amount of effective MW realized in the real-time operating phase is inconsistent with the clearing phase. Because the RegD portion of the 150 MW dual offer unit was not chosen to be RegD MW, the RegD resources represented by the blue triangle in the clearing phase will contribute more effective MW (the blue area in the real-time solution phase) in the real-time solution phase than was assumed in the clearing phase because the MBF in the clearing phase was too low. Since the blue area under the curve in the real-time solution phase is greater than the blue area in the clearing phase and the amount of RegA remains the same between the clearing phase and real-time operating phase, the market will have cleared too many effective MW relative to the effective MW requirement. The MBF in the operating phase is higher than if the clearing had been solved correctly.

Figure 10-36 Clearing phase BF/effective MW reduction, real-time BF/ effective MW inflation, and exclusion of available RegD resources



In the first nine months of 2025, 92.2 percent of all hours had at least one unit with a dual offer. In the first nine months of 2025, 64.7 percent of all hours had at least one dual offer unit that was chosen to run as RegA, resulting in an average MBF increase of 0.12 in the operating phase. The average MBF increase due to dual offers clearing as RegA in the first nine months of 2024 was 0.27. If the market had been cleared correctly, the correct average MBF would have been significantly lower in real time (operating phase), because additional RegD offers with lower benefit factors that were initially excluded, would have been included after the removal of the dual offer placeholder, reducing the MBF. Figure 10-37 illustrates the PJM calculated average MBF in real time (operating phase), the average amount the MBF is artificially increased (MBF displacement) due to dual offers clearing as RegA, and what the correct average MBF would have been in each hour of the day for the first nine months of 2025 if the clearing solution were solved correctly.

Figure 10-37 Effect of PJM's current dual offer clearing method on the average MBF in each hour of the day: January through September, 2025



Absent the ability to correctly clear dual offers, the MMU recommends that the ability of resources to submit dual offers be removed. Under this revision to the rules, resources could offer as either RegA or RegD in a given hour, but not both within the same market hour.

Price Spikes

Beginning in 2018, extreme price spikes were identified in the regulation market. The price spikes were caused by a combination of the inconsistent application of the MBF in the market design and the discrepancy between the hour ahead estimated LOC and the actual realized within hour LOC.

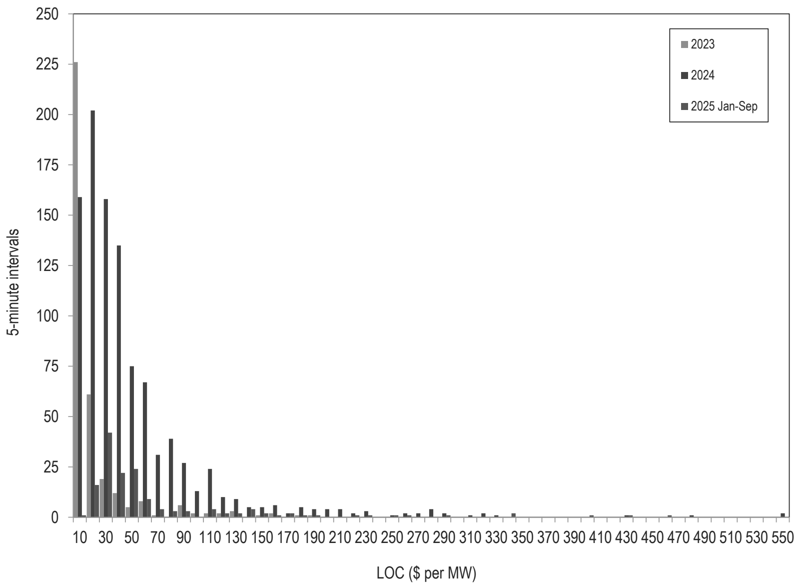
The regulation market is cleared on an hour ahead basis, using offers that are adjusted by dividing each component of an offer (capability, performance, and lost opportunity cost) by the product of the unit specific benefit factor and unit specific performance score. To calculate the hour ahead estimate of the adjusted LOC offer component, hour ahead projections of LMPs are used. Units are then cleared based on the sum of each of their hour ahead adjusted offer components. The actual LOC is used to determine the final, actual interval specific all in offer of RegD resources.

In some cases the estimated LOC is very low or zero but the actual within hour LOC is a positive number. In instances where the MBF of the within hour marginal unit is less than one (e.g. the marginal unit is a RegD unit), this discrepancy in the estimated and realized LOC will cause a large discrepancy between the expected offer price (as low as $0/MW) and the realized offer price of the resource in the actual market result. This will cause a significant price spike in the regulation market. In cases where the MBF of the marginal resource is very low, such as 0.001, the price spikes can be very significant for a small change between expected and actual LOC. In January 2019, FERC approved PJM's proposal to create a 0.1 floor for the MBF to reduce the occurrence of these price spikes.[117] This change reduced the amount and frequency of the price spikes, but it was not designed to eliminate them and it did not eliminate them.

Figure 10-38 shows the LOC in each five minute interval in which the marginal unit had a unit specific benefit factor less than one (e.g. a RegD unit) and the LOC was greater than zero from 2023 through the first nine months of 2025.

117 See 166 FERC ¶ 61,040 (2019).

Figure 10-38 LOC distribution in each five minute interval with a RegD marginal unit and an LOC greater than zero: 2023, 2024, and January through September, 2025



For a RegD resource to clear the regulation market with an MBF of 0.001, the resource's offer, in dollars per marginal effective MW, must be less than or equal to competing offers from RegA MW. A RegD offer of 1 MW with an MBF of 0.001 and a price of $1 per MW, would provide 0.001 effective MW at a price of $1,000 per effective MW. So long as RegA MW are available for less than $1,000 per effective MW, this resource will not clear. The only way for RegD MW to clear to the point where the MBF of the last MW is 0.001, is if the offer price of the relevant resources that clear, including estimated LOC, is $0.00. But, if the same resource(s) has a positive LOC within the hour, based on real-time changes in LMP, the zero priced offer is adjusted to reflect the positive LOC, resulting in an extremely high offer and clearing price for regulation.

While an incorrect estimate of a potential LOC can result in an extremely high price, the resulting regulation market prices are mathematically correct for the price of each effective MW. The prices in every interval reflect the marginal costs of regulation given the resources dispatched and accurately reflect the marginal offer of minimally effective resources which had unexpectedly high LOC components of their within hour offers. But, due to the current market design's failure to use the MBF in settlement, RegD is not paid on a dollar per effective MW basis. This disconnect between the process of setting price and the process of paying resources is the primary source of the market failure in PJM's Regulation Market and the cause of the observed price spikes in the regulation market. In the example, the 0.001 MW from the RegD resource should be paid $1,000 times 0.001 MW or $1.00. But the current rules would pay the RegD resource $1,000 times 1.0 MW or $1,000. If the market clearing and the settlements rules were consistent, the incentive for this behavior would be eliminated. The current rules provide a strong incentive for this behavior.

The prices spikes observed in PJM's Regulation Market are a symptom of a market failure in PJM's Regulation Market caused by an inconsistent application of the MBF between market clearing and market settlement. Due to the inconsistent application of the MBF, the current market results are not consistent with a competitive market outcome. In any market, resources should be paid the marginal clearing price for their marginal contribution. In the regulation market, all resources should be paid the marginal clearing price per effective MW and all resources in the regulation market should be paid for each of their effective MW. PJM's Regulation Market does not do this. PJM's market applies the MBF in determining the relative and total value of RegD MW in the market solution for purposes of market clearing and price, but does not apply the same logic in determining the payment of RegD for purposes of settlement. As a result, market prices do not align with payment for contributions to regulation service in market settlements.

The inconsistent application of the MBF in PJM's regulation market design is generating perverse incentives and perverse market results. The price spikes are a symptom of the problem, not the problem itself.

Uplift Calculation Issues

Regulation uplift is calculated by comparing a resource's regulation offer price plus its regulation lost opportunity cost (including shoulder LOC if applicable) adjusted by the performance score, to the clearing price credits the unit received.[118] If the sum of the resource's offer plus LOC is greater than the amount of clearing price credits received, additional uplift credits are given equal to the difference.

The calculation of regulation uplift during settlements for coal and natural gas units is incorrect, and results in the overpayment of uplift.[119] In order to determine the amount of regulation uplift, the difference between the MW output of the unit while it was providing regulation is compared to the desired MW output of the unit if it had not provided regulation. The desired MW output at LMP used in the calculation of regulation uplift during settlements is determined based on a unit's energy offer and the LMP during the interval being evaluated. But this desired MW does not account for the ability of a unit to actually produce the desired output because it ignores the fact that units have a limited physical ability ramp. It does not take into account the ramp rate. This results in the overpayment of uplift by paying for MW that the unit could not have produced given their energy market output at the beginning of the interval and their ramp rate.

Table 10-43 shows the amount of uplift overpayment by fuel type for the first nine months of 2025, as a result of the ramp rate not being used in the current calculation. The overpayments are calculated using a desired MW level that can be achieved in a five minute market interval based on the units' ramp rates. In the first nine months of 2025, overpayments totaled $18.7 million. Coal units received 47.0 percent of the overpayment while providing 5.2 percent of settled regulation MW.

The MMU recommends that the ramp rate limited desired MW output be used in the regulation uplift calculation, to reflect the physical limits of the unit's ability to ramp and to eliminate overpayment for opportunity costs when the payment uses an unachievable MW.

118 The clearing price for each interval is set by the marginal unit's total offer (capability and performance offers plus LOC), adjusted by the marginal unit's performance score, and does not include any shoulder LOC.

119 Hydro units operate on a schedule rather than an energy bid, therefore a different equation is used to calculate their regulation LOC and uplift. The issue discussed does not effect that calculation. Also, demand response and battery units do not receive uplift.

Table 10-43 Amount of LOC overpayment: January 2024 through September 2025

		Uplift overpayment		
Year	Month	Coal	Natural Gas	Total
2024	Jan	$1,232,475	$668,296	$1,900,771
	Feb	$776,377	$351,419	$1,127,796

	Total	$8,794,183	$9,912,700	$18,706,883

Market Redesign

PJM proposes to separate the regulation market into two products: one that only needs to respond when the regulation signal is above zero (RegUp), and one that only needs to respond when the regulation signal is below zero (RegDown). This change would also allow units to clear both signals and operate the way they do currently. PJM has not done any systematic testing of the proposal. PJM has not explained what problem this design change is intended to fix, or analyzed what impact this design would have on reliability, or how this will affect the cost of regulation. The MMU recommends a single product market with a single signal.

On June 14, 2024, the FERC approved PJM's proposed market redesign, to be implemented in two phases. Phase one, using one signal and one market price, will go into effect on October 1, 2025, and will implement the proposed changes to the LOC and performance score. Phase two will go into effect on October 1, 2026, and will implement the RegUp and RegDown signal with a separate price for RegUp and for RegDown.[120]

Market Structure

Supply

Table 10-44 shows average hourly offered MW (actual and effective), and average hourly cleared MW (actual and effective) for all hours in the first nine months of 2025.[121] Actual MW are adjusted by the historic 100-hour moving average performance score to get performance adjusted MW, and by the resource specific benefit factor to get effective MW. A resource can choose to follow either signal. For that reason, the sum of each signal type's capability can exceed the full regulation capability. Offered MW are calculated based on the offers from units that are designated as available for the day. These are daily offers that can be modified on an hourly basis up to 65 minutes before the hour.[122] Eligible MW are calculated from the hourly offers from units with daily offers and units that are offered as unavailable for the day, but still offer MW into some hours. Units with daily offers are permitted to offer above or below their daily offer from hour to hour. As a result of these hourly MW adjustments, the average hourly Eligible MW can be higher than the Offered MW.

In the first nine months of 2025, the average hourly offered supply of regulation for nonramp hours was 788.7 actual MW (787.2 effective MW). This was an increase of 93.2 actual MW (an increase of 78.9 effective MW) from the first nine months of 2024, when the average hourly offered supply of regulation was 695.5 actual MW (708.3 effective MW). In the first nine months of 2025, the average hourly offered supply of regulation for ramp hours was 1,063.0 actual MW (1,119.1 effective MW). This was an increase of 68.6 actual MW (an increase of 72.1 effective MW) from the first nine months of 2024, when the average hourly offered supply of regulation was 994.4 actual MW (1,047.0 effective MW).[123]

The ratio of the average hourly offered supply of regulation to average hourly regulation demand (actual cleared MW) for nonramp hours was 1.62 in the first nine months of 2025 (1.45 in the first nine months of 2024). The ratio of the average hourly offered supply of regulation to average hourly regulation demand (actual cleared MW) for ramp hours was 1.54 in the first nine months of 2025 (1.42 in the first nine months of 2024).

Table 10-44 Hourly average actual and effective MW offered and cleared: January through September, 2025[124]

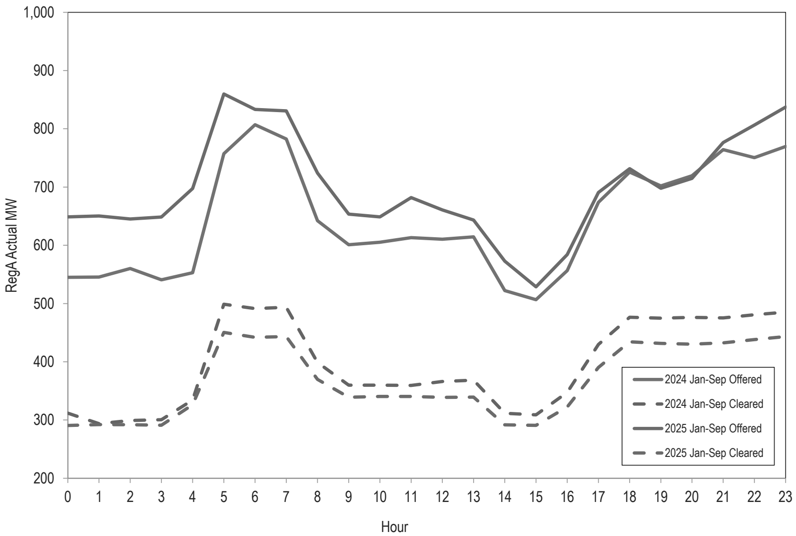
			By Resource Type		By Signal Type	
		All Regulation	Generating Resources	Demand Resources	RegA Following Resources	RegD Following Resources
Actual Offered MW	Ramp	1,063.0	1,000.5	62.6	800.3	262.8
	Nonramp	788.7	744.7	44.1	580.3	208.4
Effective Offered MW	Ramp	1,119.1	1,032.5	86.6	697.4	421.7
	Nonramp	787.2	728.4	58.8	503.5	283.7
Actual Cleared MW	Ramp	690.7	635.8	54.9	440.8	249.9
	Nonramp	486.7	450.7	36.0	280.4	206.3
Effective Cleared MW	Ramp	800.0	720.6	79.4	385.0	415.0
	Nonramp	526.5	474.3	52.2	243.6	282.9

The average hourly offered and cleared actual MW from RegA resources are shown in Figure 10-39. The average hourly offered MW from RegA resources during ramp hours for the first nine months of 2025 was 800.3 actual MW, an increase of 4.3 percent from the first nine months of 2024 (767.2 actual MW.) The average hourly offered MW from RegA resources during nonramp hours for the first nine months of 2025 was 580.3 actual MW, an increase of 16.7 percent from the first nine months of 2024 (497.4 actual MW). The average hourly cleared MW from RegA resources during ramp hours for the first nine months of 2025 was 440.8 actual MW, a decrease of 9.7 percent from the first

120 See Docket No. ER24-1772-000.
121 Unless otherwise noted, analysis provided in this section uses PJM market data based on PJM's internal calculations of effective MW values, based on PJM's currently incorrect MBF curve. The MMU is working with PJM to correct the MBF curve.
122 See "PJM Manual 11: Energy & Ancillary Services Market Operations," § 3.2.2 Regulation Market Eligibility, Rev. 133 (Dec. 17, 2024).
123 Effective MW equal actual MW multiplied by the performance score and benefit factor for each unit. In the case of RegA, the benefit factor is always equal to one, and performance scores are always less than one, so effective MW of RegA are less than actual MW. For RegD resources effective MW can be larger than actual MW, if the benefit factor is greater than one. When adding RegA and RegD total MW together, actual MW can be larger or smaller than effective MW, depending on the influence of RegA MW and RegD MW.
124 PJM operations treats some nonramp hours as ramp hours, with a regulation requirement of 800 MW rather than 525 MW. All ramp/nonramp analysis performed is based on the requirement used in each hour rather than the definitions given in Table 10-37. A ramp hour occurring during what is normally a nonramp period is treated as a ramp hour.

nine months of 2024 (488.1 actual MW). The average hourly cleared MW from RegA resources during nonramp hours for the first nine months of 2025 was 280.4 actual MW, a decrease of 1.8 percent from the first nine months of 2024 (285.5 actual MW).

Figure 10-39 Average hourly RegA actual MW offered and cleared: January through September, 2024 and 2025[125]



The average hourly offered MW from RegD resources during ramp hours for the first nine months of 2025 was 262.8 actual MW, an increase of 15.6 percent from the first nine months of 2024 (227.2 actual MW). (Figure 10-40) The average hourly offered MW from RegD resources during nonramp hours for the first nine months of 2025 was 208.4 actual MW, an increase of 5.2 percent from the first nine months of 2024 (198.1 actual MW) (Figure 10-40). The average hourly cleared MW from RegD resources during ramp hours for the first nine months of 2025 was 249.9 actual MW, an increase of 18.7 percent from the first nine months of 2024 (210.5 actual MW). The average hourly cleared MW from RegD resources during nonramp hours for the first nine months of 2025 was 206.3 actual MW, an increase of 6.4 percent from the first nine months of 2024 (193.9 actual MW).

Figure 10-40 Average hourly RegD actual MW offered and cleared: January through September, 2024 and 2025[126]

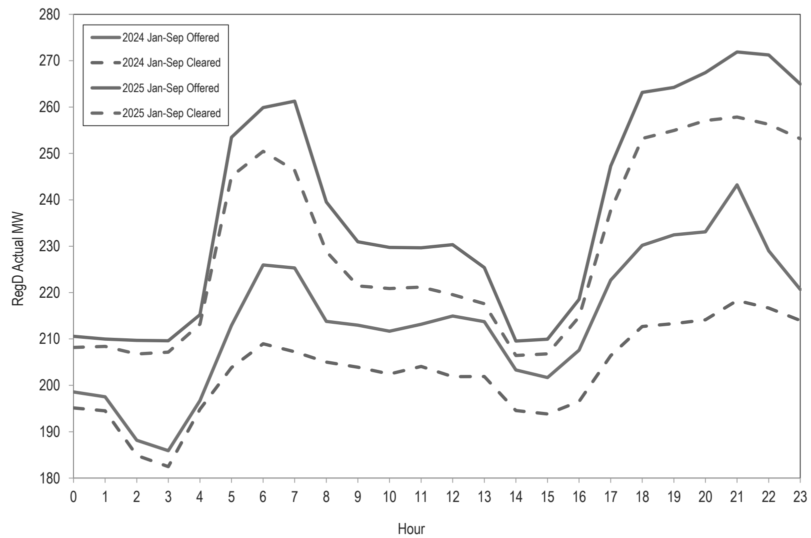


Table 10-46 provides the settled regulation MW by source unit type, the total settled regulation MW provided by all resources, the percent of settled regulation provided by unit type, and the clearing price, uplift, and total regulation credits. In Table 10-46, the MW have been adjusted by the performance score since this adjustment forms the basis of payment for units providing regulation. Total regulation performance adjusted settled MW increased 1.8 percentage points from 3,331,636.4 MW in the first nine months of 2024 to 3,390,895.0 MW in the first nine months of 2025. The average proportion of regulation provided by battery units increased the most, by 6.1 percentage points from 27.3 percent in the first nine months of 2024 to 33.5 percent in the first nine months of 2025. Natural Gas units had the largest decrease in average proportion of regulation provided, decreasing 8.0

125 Offered MW includes MW from units that are dual offering as both RegA and RegD.

126 Offered MW includes MW from units that are dual offering as both RegA and RegD.

percentage points, from 43.2 percent in the first nine months of 2024 to 35.2 percent in the first nine months of 2025. The total regulation credits in the first nine months of 2025 were $178,968,227, an increase of 36.1 percent from $131,490,372 in the first nine months of 2024. The increase in regulation credits is due to higher energy prices in the first nine months of 2025 compared to the first nine months of 2024, resulting in a higher LOC component of the clearing price (LOC accounted for 83.2 percent of the daily weighted average clearing price), as well as higher uplift due to LOC.

When a resource offers into the regulation market, an estimated regulation LOC is added by PJM to form a total offer (units self scheduled or not providing in the energy market have a regulation LOC of zero). After a unit clears, the actual five minute interval LMP is used to calculate each unit's regulation LOC, update their total offers, and determine a marginal unit/clearing price in each five minute interval. This within hour calculation of total offers, including LOC, uses each cleared resource's rolling 100 hour average performance score. During settlements, each unit's regulation LOC and total offers are recalculated using each unit's within hour actual performance score. This recalculated LOC and offer using the actual within hour performance score is not used to recalculate the within hour clearing price. This means that the clearing price for the hour will not equal the correct clearing price. Where the resulting market price is lower than an individual resource offer adjusted for the within hour performance score, the resource is paid uplift to make up the difference.

The top 10 units that received the most regulation uplift in the first nine months of 2025 are shown in Table 10-45.

Table 10-45 Top 10 recipients of regulation uplift credits: January through September, 2025

Rank	Parent Company	Unit Name	Fuel Type	Total Regulation Uplift Credit	Share of Total Regulation Uplift Credits
1	American Electric Power Company Inc	AEP MOUNTAINEER 1 F	COAL	$3,109,318	12.6%
2	American Electric Power Company Inc	AEP MITCHELL - KAMMER 2 F	COAL	$2,249,237	9.1%
3	American Electric Power Company Inc	AEP MITCHELL - KAMMER 1 F	COAL	$2,139,957	8.6%
4	American Electric Power Company Inc	AEP AMOS 1 F	COAL	$1,869,162	7.5%
5	Dominion Energy Inc	VP BATH COUNTY 1-6 H	HYDRO	$1,675,744	6.8%
6	American Electric Power Company Inc	AEP MITCHELL - KAMMER 2 F	COAL	$1,600,309	6.5%
7	American Electric Power Company Inc	AEP BIG SANDY 1 F	NATURAL GAS	$1,560,572	6.3%
8	Constellation Energy Generation LLC	PE MUDDY RUN 1-8 H	HYDRO	$1,326,908	5.4%
9	American Electric Power Company Inc	AEP AMOS 3 F	COAL	$1,146,151	4.6%
10	Dominion Energy Inc	VP BATH COUNTY 1-6 H	HYDRO	$1,116,107	4.5%
Total of Top 10				$17,793,466	71.9%
Total Regulation Uplift Credits				$24,760,125	100.0%

The uplift credits received for each unit type are shown in Table 10-46. The total uplift credits received increased 14.0 percent from $21,719,251 in the first nine months of 2024 to $24,760,125 in the first nine months of 2025. This increase, like the increase in total credits, is due in part to higher LOC components of regulation prices and offers as a result of higher energy prices in the first nine months of 2025 compared to the first nine months of 2024. Natural Gas units had the largest increase in uplift payments, increasing from $6,549,837 (30.2 percent of total uplift) in the first nine months of 2024, to $10,907,339 (44.1 percent of total uplift) in the first nine months of 2025.

Table 10-46 PJM regulation by source: January through September, 2024 and 2025[127]

Year (Jan-Sep)	Source	Number of Units	Performance Adjusted Settled Regulation (MW)	Percent of Settled Regulation	Clearing Price Credits	Uplift Credits	Total Regulation Credits
2024	Battery	22	911,076	27.3%	$31,382,451	$304	$31,382,755
	Coal	19	174,473	5.2%	$6,844,392	$13,080,694	$19,925,085
	Hydro	25	614,237	18.4%	$22,551,361	$2,088,417	$24,639,778
	Natural Gas	141	1,439,637	43.2%	$42,695,360	$6,549,837	$49,245,197
	DR	19	192,213	5.8%	$6,297,557	$0	$6,297,557
Total		226	3,331,636.4	100.0%	$109,771,121	$21,719,251	$131,490,372
2025	Battery	24	1,135,815	33.5%	$53,885,712	$151	$53,885,863
	Coal	19	174,651	5.2%	$7,252,501	$10,099,825	$17,352,326
	Hydro	27	694,011	20.5%	$32,678,952	$3,752,810	$36,431,762
	Natural Gas	142	1,193,143	35.2%	$51,245,236	$10,907,339	$62,152,575
	DR	17	193,274	5.7%	$9,145,699	$0	$9,145,699
Total		229	3,390,895.0	100.0%	$154,208,101	$24,760,125	$178,968,227

Battery Projects in the Queue

Significant flaws in the regulation market design have led to an over procurement of RegD MW primarily in the form of storage capacity. The incorrect market signals have contributed to the significant rise in storage projects entering PJM's interconnection queue from 2019 to 2023, despite clear evidence that the market design is flawed and despite operational evidence that the RegD market is saturated (Table 10-47).

Table 10-47 Active battery storage projects by submitted year: January 2014 through September 2025

Year	Number of Storage Projects	Total Capacity (MW)
2014	1	10.0
2015	1	20.0
2016	0	0.0
2017	0	0.0
2018	6	432.0
2019	31	2,057.3
2020	39	3,476.0
2021	103	7,444.9
2022	0	0.0
2023	0	0.0
2024	0	0.0
2025 (Jan-Sep)	4	1,675.0
Total	185	15,115.2

127 Biomass data have been added to the natural gas category based on confidentiality rules.

The supply of regulation can be affected by regulating units retiring from service. If all units that are requesting retirement through the first nine months of 2025 retire, the supply of regulation in PJM will be reduced by less than one percent.

Demand

The demand for regulation does not change with price. The regulation requirement is set by PJM to meet NERC control standards, based on reliability objectives, which means that a significant amount of judgment is exercised by PJM in determining the actual demand. Prior to October 1, 2012, the regulation requirement was 1.0 percent of the forecast peak load for on peak hours and 1.0 percent of the forecast valley load for off peak hours. Between October 1, 2012, and December 31, 2012, PJM changed the regulation requirement several times. It had been scheduled to be reduced from 1.0 percent of peak load forecast to 0.9 percent on October 1, 2012, but instead it was changed from 1.0 percent of peak load forecast to 0.78 percent of peak load forecast. It was further reduced to 0.74 percent of peak load forecast on November 22, 2012 and reduced again to 0.70 percent of peak load forecast on December 18, 2012. On December 14, 2013, it was reduced to 700 effective MW during peak hours and 525 effective MW during off peak hours. The regulation requirement remained 700 effective MW during peak hours and 525 effective MW during off peak hours until January 9, 2017. A change to the regulation requirement was approved by the RMISTF in 2016, with an implementation date of January 9, 2017. The regulation requirement was increased from 700 effective MW to 800 effective MW during ramp hours (Table 10-37).

Table 10-48 shows the average hourly required regulation by month and the ratio of supply to demand for both actual and effective MW, for ramp and nonramp hours. The average hourly required regulation by month is an average of the ramp and nonramp hours in the month. Changes in the actual MW required to satisfy the regulation requirement are the result of the amount of RegD actual MW cleared. When more RegD MW are cleared, the MBF is lower, resulting in those actual MW being worth less effective MW, requiring more actual MW to satisfy the requirement. When MBFs are higher, the actual MW of RegD are worth more effective MW, reducing the amount of actual MW needed to satisfy the requirement.

The nonramp regulation requirement of 525.0 effective MW was provided by a combination of cleared RegA and RegD resources equal to 486.9 hourly average performance adjusted actual MW in the first nine months of 2025. This is an increase of 8.3 performance adjusted actual MW from the first nine months of 2024, when the average hourly total regulation cleared performance adjusted actual MW for nonramp hours were 478.5 performance adjusted actual MW. The ramp regulation requirement of 800.0 effective MW was provided by a combination of cleared RegA and RegD resources equal to 690.8 hourly average performance adjusted actual MW in the first nine months of 2025. This is a decrease of 6.6 performance adjusted actual MW from the first nine months of 2024, where the average hourly regulation cleared MW for ramp hours were 697.5 performance adjusted actual MW.[128]

Table 10-48 Required regulation and ratio of supply to requirement January 2024 through September 2025

		Average Required Regulation (MW)		Average Required Regulation (Effective MW)		Ratio of Supply MW to MW Requirement		Ratio of Supply Effective MW to Effective MW Requirement	
Hours	Month	2024	2025	2024	2025	2024	2025	2024	2025
Ramp	Jan	705.7	695.2	800.1	800.0	1.39	1.49	1.29	1.36
	Feb	691.8	689.8	800.0	800.0	1.36	1.44	1.27	1.33

	Aug	473.9	481.6	525.1	525.1	1.40	1.65	1.30	1.52
	Sep	473.7	486.5	525.5	525.1	1.47	1.74	1.35	1.59
	Oct	461.7	-	525.2	-	1.69	-	1.51	-
	Nov	479.6	-	525.0	-	1.71	-	1.55	-
	Dec	482.4	-	525.0	-	1.62	-	1.48	-

128 The supply of performance adjusted MW is less than the demand because the regulation requirement is based on effective MW. Effective MW are performance adjusted MW multiplied by the MBF.

Market Concentration

In the first nine months of 2025, the effective MW weighted average HHI of RegA resources was 2632 which is highly concentrated and the effective MW weighted average HHI of RegD resources was 2015 which is also highly concentrated.

Table 10-49 includes a monthly summary of three pivotal supplier (TPS) results. In the first nine months of 2025, the three pivotal supplier test was failed in 94.2 percent of hours. The MMU concludes that the PJM Regulation Market in the first nine months of 2025 was characterized by structural market power. The results presented here are calculated by PJM. The MMU has been unable to verify these results, as some of the underlying data necessary to replicate these calculations are not saved. PJM submitted a request to the vendor more than five years ago to save all data necessary for verification.

Table 10-49 Regulation market monthly three pivotal supplier results: January 2024 through September 2025

	Percent of Hours Pivotal	
Month	2024	2025
Jan	96.2%	95.0%
Feb	98.1%	96.6%
Mar	94.4%	91.9%

Oct	91.9%	
Nov	92.5%	
Dec	93.5%	
Average	94.7%	94.2%

Market Conduct

Offers

Resources seeking to regulate must qualify to follow a regulation signal by passing a test for that signal with at least a 75 percent performance score. The regulating resource must be able to supply at least 0.1 MW of regulation and not allow the sum of its regulating ramp rate and energy ramp rate to exceed its overall ramp rate.[129] When offering into the regulation market, regulating resources must submit a cost-based offer and may submit a price-based offer (capped at $100 per MW) by 1415 the day before the operating day. Regulation resources are also permitted to change and/or submit intraday offers.[130]

Offers in the PJM Regulation Market consist of a capability component for the MW of regulation capability provided and a performance component for the miles (ΔMW of regulation movement) provided. The capability component for cost-based offers is not to exceed the increased fuel costs resulting from operating the regulating unit at a lower output level than its economically optimal output level, plus a $12.00 per MW margin. The $12.00 margin embeds market power in the regulation offers, is not part of the cost of regulation, and should be eliminated. The performance component for cost-based offers is not to exceed the increased costs (increased short run marginal costs including increased fuel costs) resulting from moving the unit up and down to provide regulation. Batteries and flywheels have zero cost for lower efficiency from providing regulation instead of energy, as they are not net energy producers. There is an energy storage loss component for batteries and flywheels as a cost component of regulation performance offers to reflect the net energy consumed to provide regulation service.[131]

Up until 65 minutes before the operating hour, the regulating resource must provide: status (available, unavailable, or self scheduled); capability (movement up and down in MW); regulation maximum and regulation minimum (the highest and lowest levels of energy output while regulating in MW); and the regulation signal type (RegA or RegD). Resources may offer regulation for both the RegA and RegD signals, but will be assigned to follow

129 See "PJM Manual 11: Energy & Ancillary Services Market Operations," § 3.2.1 Regulation Market Eligibility, Rev. 132 (Sept. 1, 2024).
130 Id. at 3.2.2, at p 62.
131 See "PJM Manual 15: Cost Development Guidelines," § 7.8 Regulation Cost, Rev. 45 (Sept. 1, 2024).

only one signal for a given operating hour. Resources have the option to submit a minimum level of regulation they are willing to provide.[132]

All LSEs are required to provide regulation in proportion to their load share. LSEs can purchase regulation in the regulation market, purchase regulation from other providers bilaterally, or self schedule regulation to satisfy their obligation (Table 10-52).[133] Figure 10-41 compares average hourly regulation and self scheduled regulation during ramp and nonramp hours on an effective MW basis. Self scheduled regulation averaged 52.2 percent of all effective MW during ramp hours (53.3 percent in the first nine months of 2024) and 59.2 percent of all effective MW during nonramp hours (69.3 percent in the first nine months of 2024) in the first nine months of 2025. Over all hours in the first nine months of 2025, self scheduled regulation averaged 55.0 percent of all effective MW (59.6 percent in the first nine months of 2024) (See Table 10-50). The average hourly regulation is the amount of regulation that actually cleared and is not the same as the regulation requirement because PJM clears the market within a two percent band around the requirement.[134]

132 See "PJM Manual 11: Energy & Ancillary Services Market Operations," § 3.2.1 Regulation Market Eligibility, Rev. 133 (Dec. 17, 2024).

134 See "PJM Manual 11: Energy & Ancillary Services Market Operations," § 3.2.1 Regulation Market Eligibility, Rev. 133 (Dec. 17, 2024).

Figure 10-41 Nonramp and ramp regulation levels: January 2024 through September 2025

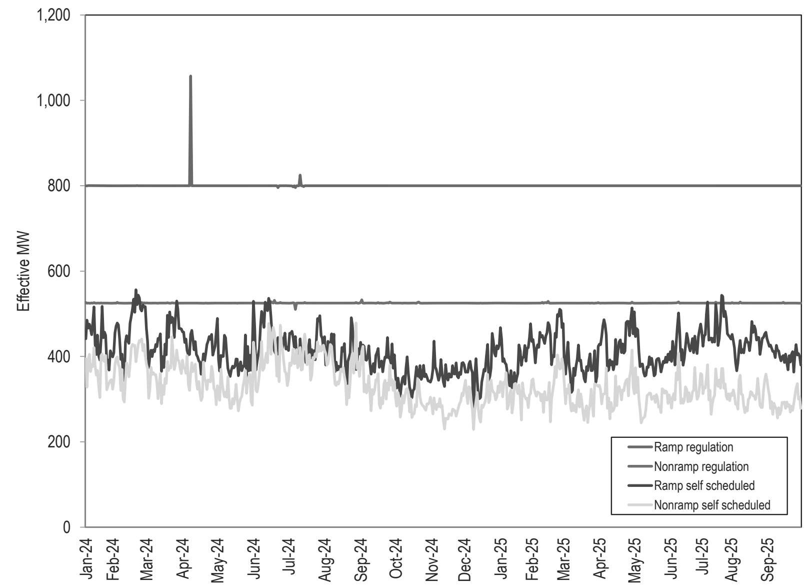

Table 10-50 Total Effective MW and Self Scheduled Effective MW during ramp and non ramp hours: January 2024 through September 2025

Year (Jan-Sep)		Effective MW	Self Scheduled Effective MW	Percent Effective MW
2024	Ramp	213,067.1	113,588.9	53.3%
	Non Ramp	139,681.2	96,799.8	69.3%
Total		352,748.4	210,388.7	59.6%
2025	Ramp	207,203.3	108,229.0	52.2%
	Non Ramp	136,001.9	80,496.8	59.2%
Total		343,205.1	188,725.8	55.0%

Table 10-51 shows the role of RegD resources in the regulation market. RegD resources are both a growing proportion of the market (10.9 percent of the total effective MW at the start of the performance based regulation market design in October 2012 and 52.6 percent of the total effective MW in September 2025), and a growing proportion of resources that self schedule (25.0 percent of all self scheduled effective MW in October 2012 and 71.2 percent of all self scheduled effective MW in September 2025). In the first nine months of 2025, the average RegD percentage of total self scheduled effective MW was 68.7 percent, an increase of 5.7 percentage points from the first nine months of 2024, when the average was 63.0 percent.

Table 10-51 RegD self scheduled regulation by month: January 2024 through September 2025

Year	Month	RegD Self Scheduled Effective MW	RegD Effective MW	Total Self Scheduled Effective MW	Total Effective MW	RegD Percent of Total Self Scheduled Effective MW	RegD Percent of Total Effective MW
2024	Jan	247.3	348.5	404.2	708.4	61.2%	49.2%
2024	Feb	247.2	333.6	431.4	674.0	57.3%	49.5%
2024	Mar	251.6	332.6	395.0	639.8	63.7%	52.0%
2024	Apr	246.3	328.7	378.4	646.1	65.1%	50.9%
2024	May	244.2	326.1	347.9	639.6	70.2%	51.0%
2024	Jun	269.3	343.2	432.9	716.4	62.2%	47.9%
2024	Jul	257.8	350.8	415.0	711.5	62.1%	49.3%

2024	Sep	227.2	318.7	359.3	639.7	63.2%	49.8%
2024	Oct	239.5	313.9	315.8	639.7	75.8%	49.1%
2024	Nov	247.9	332.3	315.4	651.0	78.6%	51.0%
2024	Dec	230.7	344.9	339.5	673.9	68.0%	51.2%
Average		246.1	334.6	377.2	619.0	65.8%	49.9%
2025	Jan	241.2	359.0	356.5	692.8	67.6%	51.8%
2025	Feb	248.1	360.8	394.8	681.5	62.8%	52.9%
2025	Mar	228.9	341.4	331.6	639.8	69.0%	53.4%
2025	Apr	233.6	339.0	365.6	639.7	63.9%	53.0%
2025	May	245.5	340.8	338.9	639.5	72.5%	53.3%
2025	Jun	281.3	373.3	390.7	712.8	72.0%	52.4%
2025	Jul	287.2	370.8	419.2	719.9	68.5%	51.5%
2025	Aug	272.1	364.3	385.2	696.8	70.6%	52.3%
2025	Sep	241.0	336.5	338.3	639.6	71.2%	52.6%
Average		253.2	354.0	369.0	673.6	68.7%	52.6%

LSE's can satisfy their obligation to provide regulation by purchasing in the spot market, self scheduling, or through bilateral agreements. Increased self scheduled regulation lowers the requirement for cleared regulation, resulting in fewer MW cleared in the market and lower clearing prices. For total spot market regulation and self scheduled regulation, Table 10-52 shows monthly data for January 2024 through September 2025, and Table 10-53 shows annual data for January through September, 2012 through 2025. Table 10-52 and Table 10-53 are based on settled (purchased) MW.

Table 10-52 Regulation sources: spot market and self scheduled purchases: January 2024 through September 2025

Table 10-53 Regulation sources: spot market and self scheduled: January through September, 2012 through 2025

Year (Jan-Sep)	Spot Market Regulation (Unadjusted MW)	Self Scheduled Regulation (Unadjusted MW)
2012	5,110,747.9	1,122,671.9
2013	2,528,830.3	1,478,608.5
2014	1,836,488.7	1,543,266.0
2015	1,897,225.7	1,380,004.7
2016	1,672,795.5	1,598,231.6
2017	1,849,333.5	1,372,996.2
2018	2,124,551.1	1,135,540.8
2019	1,755,035.6	1,405,707.9
2020	1,608,960.6	1,667,128.2
2021	1,766,633.1	1,555,694.7
2022	1,870,452.6	1,201,997.0
2023	1,421,896.6	1,625,251.4
2024	1,232,309.5	1,760,055.5
2025	1,249,116.4	1,771,111.6

In the first nine months of 2025, DR provided an average of 54.9 MW of regulation per hour during ramp hours (53.4 MW of regulation per hour during ramp hours in the first nine months of 2024), and an average of 36.0 MW of regulation per hour during nonramp hours (42.4 MW of regulation per hour during nonramp hours in the first nine months of 2024). Generating units supplied an average of 635.8 MW of regulation per hour during ramp hours in the first nine months of 2025 (645.3 MW of regulation per hour during ramp hours in the first nine months of 2024), and an average of 450.7 MW per hour during nonramp hours in the first nine months of 2025 (437.0 MW of regulation per hour during nonramp hours in the first nine months of 2024).

Market Performance

Price

Table 10-54 shows the regulation price and regulation cost per MW for January through September, 2009 through 2025. The weighted average RMCP for the first nine months of 2025 was $42.42 per MW. This is an increase of $11.12 per MW, or 35.5 percent, from the weighted average RMCP of $31.30 per MW in the first nine months of 2024. This increase in the regulation clearing price was the result of an increase in energy prices in the first nine months of 2025 and the related increase in the opportunity cost component of RMCP.

Table 10-54 Comparison of average price and cost for regulation: January through September, 2009 through 2025

Year (Jan-Sep)	Weighted Regulation Market Price	Weighted Regulation Market Cost	Regulation Price as Percent of Cost
2009	$24.94	$32.28	77.3%
2010	$19.47	$34.54	56.4%
2011	$17.04	$32.70	52.1%
2012	$15.16	$21.07	71.9%
2013	$33.29	$38.49	86.5%
2014	$50.19	$60.94	82.4%
2015	$35.56	$43.00	82.7%
2016	$16.52	$18.99	87.0%
2017	$15.70	$21.70	72.4%
2018	$28.21	$35.06	80.5%
2019	$14.97	$19.15	78.1%
2020	$12.59	$15.59	80.8%
2021	$20.91	$25.37	82.4%
2022	$51.04	$63.46	80.4%
2023	$22.04	$29.03	75.9%
2024	$31.30	$39.72	78.8%
2025	$42.42	$52.35	81.0%

The introduction of fast start pricing in the PJM energy market on September 1, 2021, had an effect on the regulation market LOC included in regulation offers and in the resulting clearing price for regulation. Table 10-55 shows the effect of fast start pricing on the regulation market monthly capability component of price and the total regulation market clearing price from September 2021 through September 2025. In the first nine months of 2025, fast start pricing increased the average regulation market clearing price by $3.48 (an increase of 9.0 percent), from $38.92 to $42.41, compared to dispatch pricing. This resulted in an additional $11.8 million in regulation credits.

Table 10-55 Comparison of fast start and dispatch pricing: September 2021 through September 2025[135]

Year	Month	Capability Clearing Price Dispatch	Capability Clearing Price Fast Start	Regulation Market Clearing Price Dispatch	Regulation Market Clearing Price Fast Start	Percent Fast Start Increase
2021	Sep	$27.22	$29.08	$28.55	$30.41	6.5%
	Oct	$35.64	$39.92	$37.12	$41.40	11.5%
	Nov	$50.56	$54.40	$52.43	$56.28	7.3%
	Dec	$25.62	$27.37	$27.05	$28.79	6.4%
2022	Jan	$68.25	$71.14	$69.68	$72.56	4.1%
	Feb	$31.14	$31.93	$32.76	$33.55	2.4%
	Mar	$23.91	$25.94	$25.70	$27.73	7.9%

Weighted Average Price ($/Perf. Adj. Actual MW)

135 The performance component of the regulation market clearing price is unaffected by fast start pricing.

Figure 10-42 shows the capability price, performance price, and the opportunity cost component for the PJM Regulation Market on a performance adjusted MW basis. The regulation clearing price is determined based on the marginal unit's total offer (RCP + RPP + PJM calculated LOC). Then the maximum performance offer price (RPP) of any of the cleared units is used to set the marginal performance clearing price for the purposes of settlements. The difference between the marginal total clearing price and the highest performance clearing price (RMPCP) is the marginal capability clearing price (RMCCP). The capability price presented here is equal to the clearing price, minus the maximum cleared performance offer price. This data is based on actual five minute interval operational data.

Figure 10-42 illustrates the components of the regulation market clearing price. Each section represents the contribution of the lost opportunity cost (green area), capability price (blue area), and performance price (orange area), to the total price. From this figure, it is clear that the lost opportunity cost is the largest component of the total clearing price. In the first nine months of 2025, LOC accounted for 86.6 percent of the daily weighted average capability price, and 83.2 percent of the daily weighted average total clearing price.

Figure 10-42 Regulation market clearing price components (Dollars per MW): January through September, 2025

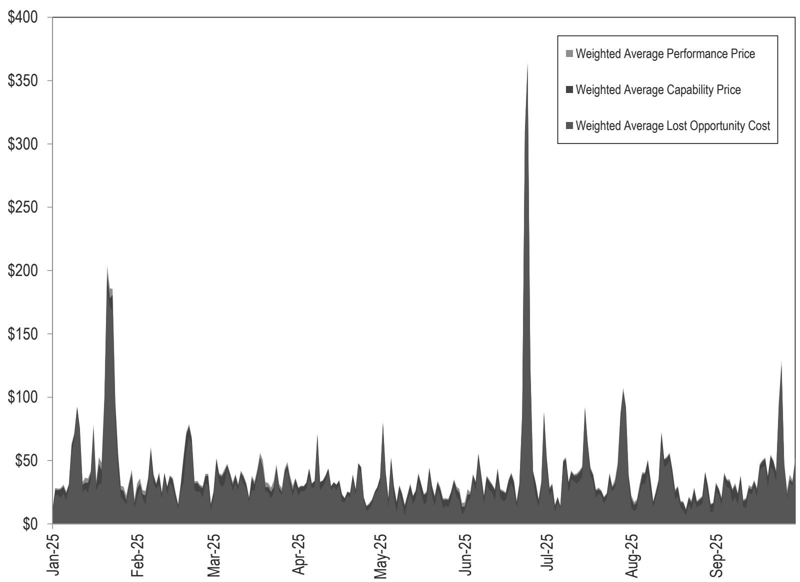

Table 10-56 shows the capability and performance components of the monthly average regulation prices. These components differ from the components of the marginal unit's offers in Figure 10-42 because the performance component of the settlement price for each hour is determined from the average of the highest performance offers in each five minute interval, calculated independent of the marginal unit's offers in those intervals.

Table 10-56 Regulation market monthly component of price (Dollars per MW): January through September, 2025

Year	Month	Weighted Average Regulation Market Capability Clearing Price ($/Perf. Adj. Actual MW)	Weighted Average Regulation Market Performance Clearing Price ($/Perf. Adj. Actual MW)	Weighted Average Regulation Market Clearing Price ($/Perf. Adj. Actual MW)
2025	Jan	$59.04	$2.95	$61.99
	Feb	$36.62	$1.79	$38.41
	Mar	$35.60	$2.33	$37.93
	Apr	$31.51	$0.51	$32.02
	May	$28.74	$1.17	$29.91
	Jun	$61.08	$1.35	$62.43
	Jul	$43.07	$1.49	$44.56
	Aug	$29.39	$1.38	$30.77
	Sep	$39.27	$1.80	$41.06
Average		$40.76	$1.65	$42.41

Monthly and total annual scheduled regulation MW and regulation charges, as well as monthly average regulation price and regulation cost are shown Table 10-57. Total scheduled regulation is based on settled performance adjusted MW. The total of all regulation charges in the first nine months of 2025 was $182,648,615, compared to $136,117,391 in the first nine months of 2024.

Table 10-57 Total regulation charges: January 2024 through September 2025

Year	Month	Scheduled Regulation (MW)	Total Regulation Charges ($)	Weighted Average Regulation Market Price ($/MW)	Cost of Regulation ($/MW)	Price as Percent of Cost
2024	Jan	408,753.4	$20,438,488	$38.28	$50.00	76.6%
	Feb	359,472.4	$9,511,886	$20.42	$26.46	77.2%
	Mar	373,821.3	$11,459,995	$24.04	$30.66	78.4%
	Apr	365,623.4	$11,540,004	$24.90	$31.56	78.9%

The capability, performance, and opportunity cost components of the cost of regulation are shown in Table 10-58. Total scheduled regulation is based on settled performance adjusted MW. In the first nine months of 2025, the average total cost of regulation was $52.35 per MW, 33.2 percent higher than $39.31 in the first nine months of 2024. In the first nine months of 2025, the monthly average capability component cost of regulation was $40.75, 34.8 percent higher than $30.24 in the first nine months of 2024. In the first nine months of 2025, the monthly average performance component cost of regulation was $4.49, 62.7 percent higher than $2.76 in the first nine months of 2024. The increase of the average total cost in the first nine months of 2025 versus the first nine months of 2024, was primarily a result of higher LOC values due to higher prices in the energy market.

Table 10-58 Components of regulation cost: January 2024 through September 2025

Year	Month	Scheduled Regulation (MW)	Cost of Regulation Capability ($/MW)	Cost of Regulation Performance ($/MW)	Opportunity Cost ($/MW)	Total Cost ($/MW)
2024	Jan	408,753.4	$36.74	$3.97	$7.81	$48.52

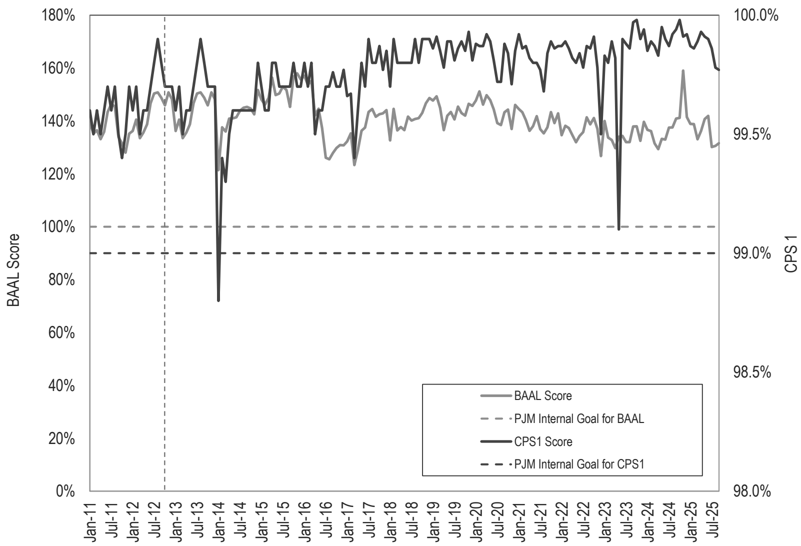
Performance Standards

PJM's performance as measured by CPS1 and BAAL standards is shown in Figure 10-43 for every month from January 2011 through September 2025 with the dashed vertical line marking the date (October 1, 2012) of the implementation of the Performance Based Regulation Market design.[136] The horizontal dashed lines represent PJM internal goals for CPS1 and BAAL performance.

Figure 10-43 Monthly CPS1 and BAAL performance: January 2011 through September 2025



136 See *2019 Annual State of the Market Report for PJM*, Appendix F: Ancillary Services.

Black Start Service

Black start service is required for the reliable restoration of the grid following a blackout. Black start service is the ability of a generating unit to start without an outside electrical supply, or the demonstrated ability of a generating unit to automatically remain operating at reduced levels when disconnected from the grid (automatic load rejection or ALR).[137]

PJM does not have a market to provide black start service, but compensates black start resource owners on the basis of cost of service rates defined in the tariff.[138] Currently, there are a small number of units in unique circumstances with bilateral agreements with their transmission operator (TO) to provide black start service that were entered into prior to joining PJM. These units are compensated directly by the TO.

PJM defines required black start capability zonally, while recognizing that the most effective way to provide black start service is a regional approach that recognizes cost effective ways to provide black start across transmission zonal boundaries.[139] PJM does not adequately use a regional or cross zonal approach to providing black start. Under the current rules PJM has substantial flexibility in procuring black start resources and is responsible for black start resource selection.[140] But PJM's stated principles for system restoration are not fully incorporated into the rules in Schedule 6A. Costs should also be allocated on a regional basis to reflect the regional benefits of black start service.

The MMU recommends that black start planning and coordination be on a regional basis recognizing cross zonal cranking paths and not on a narrowly or purely zonal basis. Similarly, the region as a whole benefits from black start service, regardless of the transmission zone in which it is located, and the costs of black start service should be shared equally across the region.

137 OATT Schedule 1 § 1.3BB.
138 See OATT Schedule 6A para. 18.
139 See Motion for Leave to Answer and Answer of PJM Interconnection, L.L.C to Comments, FERC Docket No. ER13-1911-000 (August 19, 2013) at 5 ("To be sure, restoration plans utilizing interconnecting Transmission Owners is not new and is currently included in all restoration plans today. Geographic or political boundaries play no role in the evaluation of the most reliable and efficient restoration strategies.").
140 See Docket No. ER13-1911-000.

Fuel Assurance

By order issued October 6, 2023, the FERC approved revisions to Schedule 6A concerning fuel assurance for black start units, effective July 12, 2023.[141] The revisions were approved over the protest of the MMU, which identified significant flaws.[142] The planning criteria for fuel assured units and charges are applied on a zonal basis and not a regional basis, even though PJM is a regional transmission operator. The revisions to the tariff ignore the attributes of existing fuel assured units if they do not offer into the fuel assurance RFP. Intermittent resources are treated as if they are fuel assured. The X factor for fuel assured hydro units is arbitrarily doubled from 0.01 to 0.02. The incentive factor for fuel assured units is arbitrarily doubled from 10 percent to 20 percent. For black start units in service prior to June 6, 2021, the rules apply CRF rates that ignore significant reductions in federal tax rates, including depreciation provisions, resulting in significant overpayments by PJM customers. The rules do not address environmental permits, which may limit the ability of units to provide black start service. The rules do not define DER's provision of black start service. The rules do not require testing units without notice to operators. The rules do not address the availability of natural gas and stored water levels. Reporting requirements for onsite fuel are not adequate. The reliability backstop improperly depends on TOs to secure black start service if PJM has two failed auctions.

The MMU recommends that the fuel assurance rules be modified to recognize actual fuel assured resources within and across zones.

Definition of Black Start Costs

In the November 8, 2024, MIC meeting PJM proposed to change the definition of Net CONE used in the Black Start Base Formula Rate (BFR) calculation.[143] The Base Formula Rate is a formula based cost of service rate and not a market based rate. The rationale was that Net CONE values based on a combined cycle reference resource defined for the capacity market could be negative at times. PJM did not retract its proposal even after PJM decided to use a combustion turbine as the reference resource rather than a combined cycle as the reference resource. That change eliminated PJM's identified issue with negative Net CONE values. The MMU presented historical information on payments under the BFR rate and argued that no change is needed to the Net CONE calculation.[144] PJM filed its proposal with the Commission on April 30, 2025.[145] The MMU filed a protest, and, after a deficiency letter issued and PJM responded, filed additional comments.[146]

Ultimately PJM's argument is simply that the current tariff calculation would result in a short term decrease in black start payments under the Base Formula Rate which includes Net CONE, and PJM did not want the rate to decrease. PJM proposed to use average Net CONE for the entire RTO over the last five years as a fixed value subject to escalation. PJM's approach means that both Gross CONE and the net revenue offset will be escalated using an inflation index. It is illogical to escalate net revenue because net revenue is a function of the dynamics of the energy market and the fuel markets. Given the current and expected high levels of Gross CONE compared to the five year average, PJM's proposal could actually reduce payments to these black start resources compared to the status quo. PJM did not address that possibility. PJM failed to explain why their proposal is a reasonable approach to compensating these resources for providing black start service. PJM provided no information about the actual costs of providing black start service. PJM provided no information about the actual mark up over costs currently paid to these black start resources. PJM's proposal does not approximate black start service costs and fails to even attempt to demonstrate any relationship to black start service costs. Under an approach that uses Net CONE, PJM does not justify using system wide Net CONE rather than locational Net CONE.

The MMU's position is that if the black start rate under the Base Formula Rate is to be reevaluated, it should be based on the actual cost of providing the black start service, plus an incentive, rather than the unsupported use of Net CONE, escalated each year.

Black Start Backstop Process

PJM Manual 14D defines a Black Start Reliability Backstop Process that is implemented in the event that PJM does not acquire enough black start resources through the RFP process. One option under this process is that one or more Transmission Owners can take responsibility for procuring the needed black start resources in their zones.

The triggers that initiate the backstop process are: a black start generation shortage or a failure to meet the fuel assurance criteria in a zone; and two failed RFPs; and no cross-zonal solutions available; and no RTEP transmission solutions available.[147] The steps in the reliability backstop process are defined in Manual 14D.[148]

The backstop process for black start service is flawed. PJM has units in each zone which are fuel assured capable but are ignored if they do not bid into a fuel assured RFP. There is no reason to believe that TOs can procure black start more effectively than PJM. TOs should not own generation under cost of service regulation because it is inconsistent with competitive markets. PJM should continue its efforts until their goals are met. It is PJM's responsibility to manage black start capability.[149]

The MMU recommends that the reliability backstop for black start service be eliminated. There is no reason that PJM cannot acquire black start resources if the TOs can acquire black start resources.

RFPs for Black Start Service

PJM requires a minimum of one fuel assured black start site in each zone or two non fuel assured black start sites connected to different pipelines per zone.[150] New or existing black start units that wish to be designated as fuel assured black start units must offer into the PJM fuel assured RFP.[151]

In order for a unit to be considered fuel assured, it must have one of five characteristics: onsite fuel; be capable of operating independently on two or more pipelines; be directly connected to a natural gas gathering system; hydro, non-hydro and intermittent resources must be capable of 16 hours full load with 90 percent confidence. A zone meets the fuel assurance requirement if the zone includes a minimum of two gas units connected to two separate natural gas pipelines.[152]

On April 7, 2021, PJM issued an incremental RFP for black start service in the BGE and PEPCO Zones. On November 1, 2021, PJM made awards for the April 7, 2021, incremental RFP. The in service date was May 2024. On August 1, 2022, PJM issued an incremental RFP for black start service in the PECO Zone. No awards were made.

On June 20, 2023, PJM issued an RTO wide request for proposals (RFP) in accordance with the five year black start selection process. The RFP was for black start service and fuel assured black start service. PJM awarded ten existing black start units fuel assured black start service status.

On April 29, 2024, PJM issued an incremental RFP for fuel assured black start service, because the 2023 RFP did not attract offers for fuel assured black start units in all zones. There were not enough offers in the incremental fuel assured black start RFP issued April 29, 2024.

Despite the fact that April 29, 2024 auction process is not expected to be completed until January 2026, PJM has started the reliability backstop process.

The premature implementation of the reliability backstop process illustrates the inefficiency and excess cost to customers of ignoring the attributes of existing fuel assured units if they do not offer into the fuel assurance RFP. PJM has failed to consider whether existing black start resources meet the fuel assurance goals regardless of whether they applied for fuel assurance status.

152 See "PJM Manual 12: Balancing Operations," §4.5.7 Minimum Critical Black Start Unit and Fuel Assurance Black Start Unit Requirements, Rev. 55 (June. 18, 2025).

Black Start Charges

Total black start charges are the sum of black start revenue requirement charges and black start uplift (operating reserve) charges.

Black start revenue requirements for black start units consist of fixed black start service costs, variable black start service costs, training costs, fuel storage costs, and an incentive factor applicable when CRF rates are not used. The tariff specifies how to calculate each component of the revenue requirement formula.[153]

Fixed black start service costs are calculated using one of three methods chosen by the black start provider from the options defined in the OATT Schedule 6A: base formula rate; capital cost recovery rate; or incremental black start NERC-CIP cost recovery. The base formula rate is Net CONE multiplied by the black start unit's capacity multiplied by the X factor. The X factor is 0.01 for hydro units and 0.02 for CT units. The capital recovery rate is the capital investment multiplied by the CRF rate. The incremental NERC-CIP cost, for existing black start resources that need to add additional capital to meet NERC-CIP requirements, is calculated using the capital cost recovery rate. Black start uplift charges are paid to units committed in real time to provide black start service or for black start testing.[154] Total black start charges are allocated monthly to PJM customers based on their zone and nonzone peak transmission use and point to point transmission reservations.[155]

No black start units have requested new or additional black start NERC – CIP Capital Costs.[156]

In the first nine months of 2025, total black start charges were $39.6 million, a decrease of $15.6 million (28.3 percent) from the first nine months 2024. In the first nine months of 2025, total revenue requirement charges were $39.2 million, a decrease of $15.7 million (28.6 percent) from the first nine months 2024. In the first nine months of 2025, total uplift charges were $0.4 million, a increase of $0.10 million (30.4 percent) from the first nine months 2024. Table 10-59 shows total charges for January through September of each year from 2010 through 2025.[157]

Table 10-59 Black start revenue requirement charges: January through September, 2010 through 2025

Jan-Sep	Revenue Requirement Charges	Uplift Charges	Total
2010	$8,527,000	$0	$8,527,000
2011	$9,996,898	$0	$9,996,898
2012	$13,288,491	$0	$13,288,491
2013	$15,728,447	$68,903,357	$84,631,804
2014	$18,395,320	$26,661,658	$45,056,978
2015	$39,718,855	$5,070,944	$44,789,799
2016	$51,565,656	$180,265	$51,745,921
2017	$52,422,434	$186,752	$52,609,186
2018	$48,938,203	$152,720	$49,090,923
2019	$48,231,346	$175,400	$48,406,746
2020	$49,052,199	$163,301	$49,215,499
2021	$50,278,321	$203,620	$50,481,941
2022	$51,357,993	$352,984	$51,710,976
2023	$49,897,290	$261,396	$50,158,686
2024	$54,904,846	$313,896	$55,218,742
2025	$39,208,630	$409,395	$39,618,025

153 *See* OATT Schedule 6A para. 18.
154 There are no black start units currently using the ALR option.
155 OATT Schedule 6A (paras. 25, 26 and 27 outline how charges are to be applied).
156 OATT Schedule 6A para. 21. "The Market Monitoring Unit shall include a Black Start Service summary in its annual State of the Market report which will set forth a descriptive summary of the new or additional Black Start NERC-CIP Capital costs requested by Black Start Units, and include a list of the types of capital costs requested and the overall cost of such capital improvements on an aggregate basis such that no data is attributable to an individual Black Start Unit."
157 Starting December 1, 2012, PJM defined a separate black start uplift category. ALR units accounted for the high uplift charges in 2013 – 2015. All ALR units had been replaced by April 2015.

Black start zonal charges in 2025 ranged from $0 in the OVEC and REC Zones to $6,582,256 in the AEP Zone. For each zone, Table 10-60 shows black start charges, zonal peak loads, and black start rates (calculated as charges per MW-day).[158] [159]

Table 10-60 Black start zonal charges: January through September, 2024 and 2025[160]

	Jan-Sep 2024					Jan-Sep 2025				
Zone	Revenue Requirement Charges	Uplift Charges	Total Charges	Peak Load (MW)	Black Start Rate ($/MW-day)	Revenue Requirement Charges	Uplift Charges	Total Charges	Peak Load (MW)	Black Start Rate ($/MW-day)

158 See "PJM Manual 27: Open Access Transmission Tariff Accounting,"§ 7.3 Black Start Service Charges, Rev. 102 (Jan. 23, 2025).
159 For each zone and import export/wheels the black start rates ($/MW day) are calculated by taking total charges by zone and divided by peak load then divided by days in the period.
160 Peak load for each zone is used to calculate the black start rate per MW day.

Table 10-61 provides a revenue requirement estimate by zone for the 2025/2026, 2026/2027, and 2027/2028 Delivery Years.[161] Revenue requirement values are rounded up to the nearest $50,000, reflecting the uncertainty about future black start revenue requirement costs. These values are illustrative only. The estimates are based on the best available data including current black start unit revenue requirements, expected black start unit termination and in service dates, changes in recovery rates, and owner provided cost estimates of incoming black start units at the time of publication and may change significantly. The estimates do not reflect the impact of FERC decisions that could affect compensation for black start.

Table 10-61 Black start zonal revenue requirement estimate: 2025/2026 through 2027/2028 Delivery Years

Zone	2025 / 2026 Revenue Requirement	2026 / 2027 Revenue Requirement	2027 / 2028 Revenue Requirement
ACEC	$2,450,000	$2,450,000	$2,300,000

161 The System Restoration Strategy Task Force requested that the MMU provide estimated black start revenue requirements.

CRF Issues

The capital recovery factor (CRF) defines the revenue requirement of black start units when new equipment is added to provide black start capability.[162] The CRF is a rate, which when multiplied by the investment, provides for a return on and of capital over a defined time period. CRFs are calculated using a formula (or a correctly defined standard financial model) that accounts for the weighted average cost of capital and its components, plus depreciation and taxes. The PJM CRF table was created in 2007 as part of the new RPM capacity market design.[163] That CRF table provided for the accelerated return of incremental investment in capacity resources based on concerns about the fact that some old coal units would be making substantial investments related to pollution control. The CRF values were later added to the black start rules.[164] The CRF table in the tariff included assumptions about tax rates that were significantly too high after the changes to the tax code in 2017. The PJM tariff tables including CRF values should have been changed for both black start and the capacity market when the tax laws changed in 2017.

The CRF table for existing black start units includes the column header, term of black start commitment, which is misleading and incorrect. The column is simply the cost recovery period. Accelerated recovery reduces risk to black start units and should not be the basis for a shorter commitment. Full payment of all costs of black start investment on an accelerated basis should not be a reason for a shortened commitment period. Regardless of the recovery period, payment of the full costs of the black start investment should require commitment for the life of the unit.[165] In addition, there is no need for such short recovery periods for black start investment costs. Two periods, based on unit age, are more than adequate.

162 *See* OATT Schedule 6A para. 18.
163 See OATT Attachment DD § 6.8(a).
164 See OATT Schedule 6A.
165 PJM's recent filing to revise Schedule 6A includes a required commitment to provide black start service for the life of the unit. See FERC Docket No. ER21-1635.

The U.S. Internal Revenue Code changed significantly in December 2017.[166] [167] The PJM CRF table did not change to reflect these changes.[168] [169] As a result, CRF values have overcompensated black start units since the changes to the tax code. The new tax law allows for a more accelerated depreciation and reduced the corporate tax rate to 21 percent.

Updated CRF rates, incorporating the tax code changes and applicable to all black start units, should have been implemented immediately. The updated CRF rates should apply to all black start units because the actual tax payments for all black start units were reduced by the tax law changes. Without this change, black start units are receiving and will continue to receive an unexpected and inappropriate windfall.

On April 7, 2021, PJM filed with FERC to update the CRF values for new black start service units.[170] PJM proposed to bifurcate the CRF calculation, applying an updated CRF calculation that incorporates the new federal tax law to new black start units while leaving the outdated and incorrect CRF in place for existing black start units. Rather than fix the inaccurate CRF values used for existing black start units, PJM's filing would have made the use of inaccurate values permanent. The MMU filed comments on April 28, 2021.[171] The MMU objected to the continued use of the outdated CRF for existing units. The MMU also introduced a CRF formula for calculating the CRF for new black start units and requested that the CRF formula be included in the tariff.[172] [173] On August 10, 2021, FERC issued an order ("August 10th Order") that accepted PJM's tariff revisions that apply to new black start units (selected for service after June 6, 2021) and directed PJM to include the CRF formula proposed by the MMU.[174] The August 10th Order also established a show cause proceeding in a new docket to "determine whether the existing rates for generating units providing Black Start Service (Black Start Units), which are based on a federal corporate income tax that pre-dates the Tax Cuts and Jobs Act of 2017 (TCJA), remains just and reasonable."[175] The MMU requested rehearing over the Commission's conclusion that the MMU had requested "retroactive changes to the rates previously paid to generators."[176] [177] The request for rehearing was denied.[178] PJM's compliance filing to address the August 10 Order was accepted by letter order, subject to edits proposed by the MMU, on December 16, 2021.[179]

PJM's response to the show cause directive in the August 10th Order continued to support the use of the outdated CRF despite the Commission's statement that the CRF values "appear to be unjust, unreasonable, unduly discriminatory or preferential, or otherwise unlawful."[180] [181] The MMU responded with analysis showing that PJM's proposal for maintaining the outdated CRF values would result in significant over recovery of black start capital investments.[182] In March 2023, FERC issued an order establishing hearing and settlement judge procedures.[183] Settlement talks continued and in January 2024 Commission Trial Staff moved to suspend the proceeding because a settlement had been reached in principle.[184] The MMU filed comments in opposition to the settlement, and the settlement was not certified to the Commission.[185] [186] The hearing process then resumed, but rather than hold a hearing, PJM, with the support of FERC Staff, submitted a second offer of settlement on behalf of itself and certain black start unit owners, AMP, ODEC and the PJM ICC. The settlement included exactly the same values as the first settlement, but also included affidavits. By order issued September 23, 2025, the Commission approved the second offer of settlement over the MMU's objection.[187]

166 Tax Cuts and Jobs Act, Pub. L. No. 115-97, 131 Stat. 2096, Stat. 2105 (2017).
167 26 U.S. Code §11(b).
168 The corporate tax rate was lowered to 21 percent and bonus depreciation, which allows generator owners to depreciate 100 percent of the capital investment in the first year of operation, was introduced.
169 Bonus depreciation is 100 percent for capital investments placed in service after September 27, 2017 and before January 1, 2023. Bonus depreciation is 80 percent for capital investments placed in service after December 31, 2022 and before January 1, 2024, and the bonus depreciation level is reduced by 20 percent for each subsequent year through 2026. Capital investments placed in service after December 31, 2026 are not eligible for bonus depreciation. See 26 U.S. Code §168(k)(6)(A).

There are 49 black start generators that have received payments based on the outdated CRF. Thirteen of the units have completed their black start capital cost recovery terms. Sixteen units started their black start service prior to January 1, 2018, and are currently receiving capital recovery payments. These units would not have been eligible for the TCJA bonus depreciation. The remaining 20 black start generators began their service terms after January 1, 2018, and are currently receiving capital recovery payments. Units with capital investments that began black start service after January 1, 2018, would have been eligible for bonus depreciation.

The November 15, 2024 settlement reduced the capital recovery payments for 38 black start generators. Table 10-62 shows the new CRF values from the settlement. The settlement CRF values became effective on January 1, 2024.

Table 10-62 Settlement CRF Values

Capital Recovery Period (years)	Original CRF Value	November 2024 Settlement CRF Value
5	0.363	0.310
10	0.198	0.177
15	0.146	0.135
20	0.125	0.118

There is no financial basis for the settlement CRF values and the settlement will result in significant over recovery for the owners of the black start generators. The settlement reduced the excess recovery payments from $89.7 million to $74.1 million.

Of the 36 units that are still receiving black start recovery payments, all but ten have fully recovered the capital investment. In other words, the owners of the units have received sufficient revenue to cover the return on and the return of the capital investments and the income tax liabilities associated with the capital recovery revenue. If recovery payments for these 26 units were stopped immediately and if the recovery payments for the ten other units were stopped in the future when the units reached full recovery, an additional $58.9 million in excess payments could be avoided.

On July 4, 2025, with the enactment of the One Big Beautiful Bill Act ("OBBBA"), the bonus depreciation rules changed again. Section 70301 of OBBBA (I.R.C. § 168(k)) allows 100 percent bonus depreciation for "qualified production property ("QPP") acquired and placed in service on or after January 20, 2025.[188] QPP means nonresidential real property used in manufacturing, production, or refining of tangible personal property in the United States.[189] To be eligible, construction must begin after January 19, 2025, and before January 1, 2029, and the property must be placed in service before January 1, 2031.[190] The formula rate calculation of the CRF values in Paragraph 18 of OATT Schedule 6A for units entering service after June 6, 2021, must be implemented to reflect the correct bonus depreciation. It is essential that PJM not repeat its earlier mistake when it ignored the tax law changes in 2017.

Reactive Service and Capability

Under Schedule 2 to the OATT, suppliers of reactive power have been compensated separately for both reactive service and reactive capability.[191] [192] [193] [194]

On October 17, 2024, the Commission issued a final rule, Order No. 904, eliminating separate payments for reactive in all jurisdictional markets, including PJM.[195] On January 28, 2025, PJM submitted a compliance filing to implement Order No. 904 ("Compliance Filing").[196] The Compliance Filing proposed a transition mechanism lasting through May 31, 2026. On August 4, 2025, the Commission accepted PJM's termination of separate Schedule 2 payments after May 31, 2026, but rejected PJM's proposed transition mechanism and the MMU's proposed enhancements to that mechanism.[197] The current rules apply until payments under Schedule 2 terminate.

Reactive Costs

Customers in PJM paid total reactive capability charges of $273.1 million in the first nine months of 2025. Under the current rules, effective through May 31, 2026, compensation for reactive capability is approved separately for each resource or resource group by FERC per Schedule 2 of the OATT.[198] Reactive capability credits are based on FERC approved filings for individual unit revenue requirements that are typically black box settlements.[199] Reactive service credits are paid to units that operate in real time outside of their normal range at the direction of PJM for the purpose of providing reactive service. Compensation for reactive power service is based on real-time lost opportunity costs.[200]

Total reactive capability charges are the sum of FERC approved reactive supply revenue requirements. Zonal reactive supply revenue requirement charges are allocated monthly to PJM customers based on their zonal and to any nonzonal (outside of PJM) peak transmission use and daily average point to point transmission reservations.[201] [202]

In the first nine months of 2025, total reactive charges were $273.7 million, a decrease of $12.1 million (4.24 percent) from the first nine months of 2024. In the first nine months of 2025, total reactive capability charges were $273.1 million, a decrease of $11.7 million (4.1 percent) from the first nine months 2024. In the first nine months of 2025, total reactive service charges were $0.59 million, a decrease of $0.416 million (41.39 percent) from the first nine months 2024. Total zonal reactive service charges ranged from $0 in the REC and OVEC Zones, to $42.7 million in the AEP Zone in the first nine months of 2025.

Table 10-63 shows reactive service charges for January through September of each year from 2010 through 2025.

198 See "PJM Manual 27: Open Access Transmission Tariff Accounting,"§ 3.2 Reactive Supply and Voltage Control Credits, Rev. 102 (Jan. 23, 2025); 192 FERC ¶ 61,113 (2025).

Table 10-66 shows the settled reactive capability revenue requirements by technology effective on September 1, 2025, for active units.[203] These revenue requirements do not include revenue requirements that were filed but not yet final. The table demonstrates the wide disparity in payments for reactive capability that result from the current cost of service rate case model settlement process.

203 The total amount in the final row of Table 10-66 is the amount that would be paid if the total rate effective on September 1, 2025 were effective for an entire year. The total rates effective on any given day depend on requests made by resource owners in filings to FERC and FERC approval of those rates.

Table 10-66 Total settled reactive revenue requirements by unit type and fuel type for active units[204]: September 1, 2025

Unit Type	Fuel Type	Total Revenue Requirement per Year	MW	Number of Resources	Revenue Requirement per MW-year	Minimum Revenue Requirement per MW-year	Maximum Revenue Requirement per MW-year
CC	Gas	$122,213,638.36	48,906.6	152	$371,800.95	$302.10	$22,500.00
CT	Gas	$44,998,557.53	27,734.0	245	$531,994.39	$103.64	$19,610.84
CT	Oil	$4,034,823.25	2,714.9	98	$143,701.18	$289.74	$4,052.58
Diesel	Oil	$839,703.17	145.3	31	$183,630.75	$395.37	$8,812.75
Diesel	Other - Gas	$1,117,240.13	102.6	12	$118,519.87	$3,984.09	$13,468.38

Frequency Control

There are four distinct types of frequency control, distinguished by response timeframe and operational nature: Inertial Response, Primary Frequency Response, Secondary Frequency Control (Regulation), and Tertiary Frequency Control (Primary Reserve).

- **Inertial Response.** Inertial response to frequency excursion is the natural resistance of rotating mass turbine generators to changes in their stored kinetic energy. This response is immediate and resists short term changes to ACE from the instant of the disturbance up to twenty seconds after the disturbance.
- **Primary Frequency Response.** Primary frequency response is a response to a disturbance based on a local detection of frequency and local operational control settings. Primary frequency response begins within a few seconds and extends up to a minute. The purpose of primary frequency response is to arrest and stabilize the system until other measures (secondary and tertiary frequency response) become active.
- **Secondary Frequency Control.** Secondary frequency control is called regulation. In PJM it begins to respond within 10 to 15 seconds and can continue up to an hour. Regulation is controlled by PJM which detects the grid frequency, calculates a counterbalancing signal, and transmits that signal to all regulating resources.
- **Tertiary Frequency Control.** Tertiary frequency control and imbalance control lasting 10 minutes to an hour is called primary reserve.

204 For aggregate requirements, in which a single payment is made for the combined output of multiple units, the aggregate requirement was distributed in proportion to unit size for calculating a resource's individual revenue requirement. For wind, solar, and hydro resources, that size is the ELCC. For all other resources, that size is the ICAP.

Primary Frequency Response

Primary Frequency Response ("PFR") is achieved through the use of automatic governors installed on generators. A governor can be either an electronic or mechanical device that increases or decreases a generator's output based on frequency changes in the system. Governors are set to respond to any frequency changes larger than a defined minimum, called a deadband, which is expressed in Hertz (Hz). Governors have a frequency change limit, called droop, which is expressed as a percentage of the frequency change from the optimal 60 Hz (e.g. 2 percent droop equals 0.02 * 60 Hz, or 1.2 Hz). Governor droop changes resource output in proportion to the deviation of frequency once frequency has exceeded the deadband limit. Primary frequency response alone does not restore frequency to the original scheduled value primarily because governor directed changes only occur when frequency is beyond the governor deadband.

On February 15, 2018, the Commission issued Order No. 842, which modified the pro forma large and small generator interconnection agreements and procedures to require all newly interconnecting non nuclear generating facilities, both synchronous and nonsynchronous, to include equipment for primary frequency response capability as a condition to receive interconnection service. Such equipment must include a governor or equivalent controls with the capability of operating at a maximum five percent droop and ±0.036 Hz deadband (or the equivalent or better).[205] PJM filed revisions in compliance with Order No. 842 that substantively incorporated the pro forma agreements into its market rules.[206]

PJM evaluates generators' primary frequency capabilities using two to three frequency events per month, with events being chosen based on the criteria that the frequency stays outside ±0.040 Hz deadband for at least one minute, and the minimum/maximum frequency reaches ±0.053 Hz. Nuclear units, offline units, units with no available headroom/footroom, units assigned regulation, and units with an active eDART ticket for governor outage are not evaluated. The performance of each unit is evaluated, with each event evaluated separately with a responsive/non-responsive pass/fail determination, and then averaged quarterly. A quarterly unit performance of 50 percent or greater is considered responsive.[207]

There are several current issues with PJM's enforcement and evaluation of generations PFR requirements. Despite the 2018 FERC order, PJM has not maintained an accurate, up to date list of all units subject to evaluation. This means that as new units have come online (since approximately 2020), they are not being tested at all during the monthly frequency events. In addition, PJM does not currently have an objective metric to determine what response constitutes a unit passing a test during these frequency events. Instead, the telemetric response of each unit is compared to the frequency conditions during an event, and a judgement is made as to whether or not the unit has adequately responded. Further, this underlying unit data and results of these primary frequency response events are not saved in PJM's databases, so the MMU is not currently able to verify the results of these tests. In the event of a unit's noncompliance, PJM does not have a defined penalty and remediation process.

The MMU recommends that PJM update and maintain a full list of generation resources required to provide PFR, save all of the results and underlying data associated with testing PFR capabilities, develop the metric(s) necessary to objectively evaluate each unit's PFR during events, and create the necessary tariff/manual language to properly enforce the NERC mandated requirements.

The MMU is working with PJM to update PJM's list of units that are subject to evaluation and to develop a set of metrics for monitoring compliance and measuring performance by units subject to Order No. 842.

The MMU recommends that the same capability be required of both new and existing resources. The MMU agrees with Order No. 842 that RTOs not be required to provide additional compensation specifically for frequency response. The current PJM market design provides the ability to cover all costs, including these. The current market design provides compensation, through heat rate adjusted energy offers, for any costs associated with providing

207 See PJM Manual 12: Balancing Operations, § 3.6.2. Rev. 53 (July 24, 2024).

frequency response. PJM rules appropriately require frequency response as a condition to receive interconnection service.[208]

On August 15, 2024, NERC proposed Project 2020-02, a modification to the PRC-029-1 reliability standard, called, "The frequency and voltage ride through requirement for inverter based generating resources ("IBRs")." This proposed standard is intended to address the risk to reliability associated with the rapid adoption of IBRs, by requiring that Category 2 Generator Owner and Generator Operator ("Category 2 GO/GOP") IBRs remain operational during and after defined frequency and voltage excursions.[209] [210] To achieve this, IBRs must continue to deliver predisturbance levels of active and reactive power, and would only be permitted to trip to avoid equipment damage. This proposal was adopted by the NERC board on October 8, 2024.[211] NERC is currently working with the regional entities to register IBRs, with an effective registration date of May 15, 2026.[212] PJM has identified and submitted to NERC a list of 50 units that meet the criteria for Category 2 GO/GOP IBRs.

208 See 164 FERC ¶ 61,224 at P 2 (2018).
209 "Category 2 GO/GOP," is defined as Generator Owners and Generator Operators that, "...own or operate IBRs that: (i) either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, and (ii) are connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV." Congestion and Marginal Losses

When there are binding transmission constraints and locational price differences, load pays more for energy than generation is paid to produce that energy.[1] The difference is congestion.[2] As a result, congestion belongs to load and should be returned to load. Congestion is not the difference in CLMP between nodes. Congestion is not the billing line item labeled congestion.[3]

Congestion is not a useful metric for determining whether there is a benefit to building more transmission. Analyses that use congestion to support the need for transmission expansion incorrectly count congestion as a cost to load without accounting for how the congestion dollars are or are not returned to the load through ARRs and FTRs.

If FTRs worked perfectly and were assigned directly to load, FTRs would return all congestion to the load that paid the congestion. Congestion is not a cost, it is an accounting result of a market based on locational energy prices in which all load in a constrained area pays the higher single market clearing locational price, resulting in excess payments by load that are not paid to generation, which should be returned to load.

Counterintuitively, congestion can actually increase when the transmission capacity between areas with lower cost generation and areas with higher cost generation is expanded but does not fully eliminate the need for some higher cost local generation. The smaller the amount of higher cost local generation needed to meet load, the more of the local load is met via low cost generation delivered over the transmission system and therefore the higher can be the difference between what load pays and generation receives, congestion.

For all these reasons, if done correctly and if FTRs/ARRs returned 100 percent of congestion to load, the cost/benefit analysis for transmission projects would include the total net change in production costs and would not include congestion. The change in production costs correctly measures the changes in cost to load that result from a project. There clearly can be benefits to transmission expansion but congestion is not the correct metric for measuring those benefits. The correct metric is the change in production costs which measures the reduction in the reliance on higher cost generation to meet load in the presence of a transmission constraint.

This issue also illustrates the unintended and negative consequences of misunderstanding congestion and FTRs. The unintended result is to overstate the benefits of transmission expansion by not correctly recognizing how congestion dollars should be returned to load. Even in the case where there is only a partial return of congestion to load, the actual return of congestion to load must be accounted for in order to correctly identify the benefits. Ignoring the return of congestion to load from ARRs/FTRs overstates the potential benefits of transmission expansion, and ignores the value of smaller upgrades that may not eliminate a constraint, but may reduce production costs and therefore the average cost of energy for load.

The locational marginal price (LMP) is the incremental price of energy at a bus. The LMP at a bus can be divided into three components: the system marginal price (SMP) or energy component, the congestion component (CLMP), and the marginal loss component (MLMP). SMP, MLMP and CLMP are the simultaneous products of the least cost, security constrained dispatch of system resources to meet system load and the use of a load-weighted reference bus. The relative values of SMP and CLMP are arbitrary and depend on the reference bus.

SMP is defined as the incremental price of energy for the system, given the current dispatch, at the load-weighted reference bus, or LMP net of losses and congestion. SMP is the LMP at the load-weighted reference bus. The load-weighted reference bus is not a fixed location but varies with the distribution of load at system load buses. For SMP, energy means the component of LMP not associated with a binding transmission constraint. All other locational prices that result from the least cost, security constrained market solution are higher or lower than this reference point price (SMP) as a result of binding constraints. The reference bus is a point of reference. For a given market solution, changing the reference bus does not change the LMP for any node on the system, but changes only the elements of the nodal prices that are positive or negative due to the binding constraints in that solution, further illustrating that the relative levels of SMP and LMP are arbitrary.

1 Load is generically referred to as withdrawals and generation is generically referred to as injections, unless specified otherwise.
2 The difference in losses is not part of congestion.
3 PJM billing examples can be found in *2022 Annual State of the Market Report for PJM*, Appendix F: Congestion and Marginal Losses.

CLMP is defined as the incremental price of meeting load at each bus when a transmission constraint is binding, based on the shadow price associated with the relief of a binding transmission constraint in the security constrained optimization. (The shadow price is the difference between the CLMPs across the transmission constraint.) There can be multiple binding transmission constraints. CLMPs are positive or negative depending on location relative to binding constraints and relative to the load-weighted reference bus. In an unconstrained system CLMPs will be zero. This means that CLMP at a bus is not congestion. The difference between CLMPs at buses is not congestion, it is just the absolute LMP difference between the two buses caused by transmission constraints, or the shadow price. CLMP is the portion of the LMP at a bus that indicates whether the LMP at that bus is higher or lower than the marginal price of energy SMP at the selected reference bus due to binding transmission constraints. The relative values of SMP and CLMP are arbitrary and depend on the reference bus.

MLMP is defined as the incremental price of losses at a bus, based on marginal loss factors in the security constrained optimization. Losses refer to energy lost to physical resistance in the transmission network as power is moved from generation to load.

Total losses refer to total system wide transmission losses as a result of moving power from injections to withdrawals on the system. Marginal losses are the incremental change in system losses caused by changes in load and generation.

Congestion is neither good nor bad, but is a direct measure of the extent to which there are multiple marginal generating units with different offers dispatched to serve load as a result of transmission constraints. Congestion occurs when available, least-cost energy cannot be delivered to all load because transmission facilities are not adequate to deliver that energy to one or more areas, and higher cost units in the constrained area(s) must be dispatched to meet the load.[4] When the least-cost available energy cannot be delivered to load in a transmission constrained area, higher cost units in the constrained area must be dispatched to meet that load. The result is that the price of energy in the constrained area is higher than in the unconstrained area because of the combination of transmission limitations and the cost of local generation. Congestion is the difference between the total cost of energy paid by load in the transmission constrained area based on the single higher price at load buses and the total revenue received by generation based on the prices at the generator buses to provide that energy, after virtual bids have been settled. Congestion equals the sum of day-ahead and balancing congestion. The actual incremental cost paid by load in the constrained area is the difference in price (shadow price) times the MW of load served by higher cost local generation. This is also the higher production costs that result from the constraint.

The energy, marginal losses and congestion metrics must be interpreted carefully.

In PJM accounting, the term total congestion refers to net implicit CLMP charges plus net explicit CLMP charges plus net inadvertent CLMP charges. The net implicit CLMP charges are the implicit withdrawal CLMP charges less implicit injection CLMP credits.

As with congestion, total system energy costs are more precisely termed net system energy costs and total marginal loss costs are more precisely termed net marginal loss costs. Ignoring interchange, total generation MWh must be greater than total load MWh in any hour in order to provide for losses. Since the hourly integrated energy component of LMP is the same for every bus within every hour, the net energy bill is negative (ignoring net interchange), with more generation credits than load payments in every hour.[5]

While PJM accounting focuses on CLMPs, the individual CLMP values at any bus are irrelevant to the calculation of congestion, as CLMPs are just an artificial deconstruction of LMP based on a selected reference bus. Holding aside the marginal loss component of LMP, differences in the LMPs are caused by binding constraints in the least cost security constrained dispatch

4 This is referred to as dispatching units out of economic merit order. Economic merit order is the order of all generator offers from lowest to highest cost. Congestion occurs when loadings on transmission facilities mean the next unit in merit order cannot be used and a higher cost unit must be used in its place. Dispatch within the constrained area follows merit order for the units available to relieve the constraint.

5 The total congestion and marginal losses for the first 9 months of 2025 were calculated as of October 31, 2025, and are subject to change, based on continued PJM billing updates.

market solution and total congestion is the net surplus revenue that remains after all sources and sinks are credited or charged their LMPs. Changing the components of LMP by electing a different reference bus does not change the LMPs or the difference between LMPs for a given market solution, it merely changes the components of the LMP. This means that no particular importance should be assigned to the levels of SMP and CLMP at a bus.

Local congestion is the congestion paid by load at a specific bus or set of buses and is calculated on a constraint specific basis. For a given market solution, a change in the reference bus does not change the LMP at any bus and does not change total congestion paid by load and does not change the local congestion paid by load at a specific location. Holding aside the marginal loss component of LMP, local congestion is the sum of the total LMP charges to load at the defined set of buses minus the sum of the total LMP credits received by all generation that supplied that load, given the set of all binding transmission constraints, regardless of location. Local congestion reflects the underlying characteristics of the complete power system as it affects the defined area, including the nature and capability of transmission facilities, the offers and geographic distribution of generation facilities, the level and geographic distribution of incremental bids and offers and the geographic and temporal distribution of load. Local congestion fully reflects the least cost security constrained system solution and the LMPs that result from that solution.

PJM implemented fast start pricing in both day-ahead and real-time markets starting September 1, 2021. PJM's fast start pricing logic results in pricing run locational marginal prices (PLMP). PLMP is the price that load pays and generators receive in the PJM energy market.

While PLMP is the official settlement price, PJM continues to calculate LMP based on the logic that PJM uses to actually dispatch system resources and used prior to the introduction of fast start to consistently define dispatch and prices. The LMPs from the dispatch run are dispatch run locational marginal prices (DLMP). While the settlement prices are PLMP, settlement MW are based on the dispatch run in the day-ahead market and are metered output in the real-time market.

PJM inappropriately uses artificial constraints in the day-ahead and real-time markets to force specific resources (generation or demand response) to be marginal in order to have those resources set price. The resultant, artificially uniform source dfax and sink dfax of the artificial constraint can be modified, along with the line limits, by PJM to meet market outcome goals and are a source of often significant modeling differences between the day-ahead and real-time market. These modeling differences result in inefficient market outcomes and false arbitrage opportunities for virtual transactions. These artificial constraints have been used to hide uplift costs by making uplift costs negative congestion charges. The use of artificial constraints is an inappropriate use of PJM discretion as the market operator, putting PJM in the position of a market actor, arbitrarily changing market results, market prices, generation revenues, congestion costs and load charges.

Overview

Congestion Cost

- **Total Congestion.** Total congestion costs increased by $848.0 million or 61.2 percent, from $1,385.8 million in the first nine months of 2024 to $2,233.8 million in the first nine months of 2025.
- **Day-Ahead Congestion.** Day-ahead congestion costs increased by $985.1 million or 60.9 percent, from $1,618.5 million in the first nine months of 2024 to $2,603.6 million in the first nine months of 2025.
- **Balancing Congestion.** Negative balancing congestion costs increased by $137.1 million, from -$232.7 million in the first nine months of 2024 to -$369.8 million in the first nine months of 2025. Negative balancing explicit charges increased by $45.6 million, from -$148.0 million in the first nine months of 2024 to -$193.6 million in the first nine months of 2025.
- **Real-Time Congestion.** Real-time congestion costs increased by $1,143.6 million, from $1,659.3 million in the first nine months of 2024 to $2,802.9 million in the first nine months of 2025.

- **Monthly Congestion.** Monthly total congestion costs in the first nine months of 2025 ranged from $124.5 million in February to $608.9 million in July.
- **Geographic Differences in CLMP.** Differences in CLMP between southern and eastern control zones in PJM were primarily a result of binding constraints on the Pleasant View Line, Lenox – North Meshoppen Line, Pleasant View – Ashburn Line, the Goose Creek Transformer, and Ashburn – Goose Creek Line.
- **Congestion Frequency.** Congestion frequency continued to be significantly higher in the day-ahead energy market than in the real-time energy market in the first nine months of 2025. The number of congestion event hours in the day-ahead energy market was about five times the number of congestion event hours in the real-time energy market.

  Day-ahead congestion frequency decreased by 1.9 percent from 57,459 congestion event hours in the first nine months of 2024 to 56,377 congestion event hours in the first nine months of 2025.

  Real-time congestion frequency increased by 4.4 percent from 20,748 congestion event hours in the first nine months of 2024 to 21,659 congestion event hours in the first nine months of 2025.
- **Congested Facilities.** Day-ahead, congestion event hours decreased on transformers and lines and increased on interfaces and flowgates.

  The Pleasant View Transformer was the largest contributor to congestion costs in the first nine months of 2025. With $286.5 million in total congestion costs, it accounted for 12.8 percent of the total PJM congestion costs in the first nine months of 2025.
- **CT Price Setting Logic and Closed Loop Interface Related Congestion.** PJM's use of CT pricing logic officially ended with the implementation of fast start pricing on September 1, 2021. While CT pricing logic was officially discontinued, PJM continues to use a related logic to force inflexible units and demand response to be on the margin in both real time and day ahead. None of the PJM defined closed loop interfaces were binding in the first nine months of 2024 or 2025.
- **Zonal Congestion.** DOM had the highest zonal congestion costs among all control zones in the first nine months of 2025. DOM had $414.9 million in zonal congestion costs, comprised of $482.06 million in day-ahead congestion costs and -$67.1 million in balancing congestion costs.

Marginal Loss Cost

- **Total Marginal Loss Costs.** Total marginal loss costs increased by $400.4 million or 57.6 percent, from $695.2 million in the first nine months of 2024 to $1,095.5 million in the first nine months of 2025. The loss MWh in PJM increased by 745.4 GWh or 6.2 percent, from 12,066.6 GWh in the first nine months of 2024 to 12,812.0 GWh in the first nine months of 2025. The loss component of real-time LMP in the first nine months of 2025 was $0.04, compared to $0.03 in the first nine months of 2024.
- **Day-Ahead Marginal Loss Costs.** Day-ahead marginal loss costs increased by $404.2 million or 54.2 percent, from $745.3 million in the first nine months of 2024 to $1,149.5 million in the first nine months of 2025.
- **Balancing Marginal Loss Costs.** Negative balancing marginal loss costs increased by $3.8 million or 7.6 percent, from -$50.1 million in the first nine months of 2024 to -$53.9 million in the first nine months of 2025.
- **Total Marginal Loss Surplus.** The total marginal loss surplus increased by $146.7 million or 56.8 percent, from $258.5 million in the first nine months of 2024, to $405.2 million in the first nine months of 2025.
- **Monthly Total Marginal Loss Costs.** Monthly total marginal loss costs in the first nine months of 2025 ranged from $74.9 million in May to $222.8 million in January.

System Energy Cost

- **Total System Energy Costs.** Total system energy costs decreased by $253.4 million or 58.3 percent, from -$434.8 million in the first nine months of 2024 to -$688.2 million in the first nine months of 2025.
- **Day-Ahead System Energy Costs.** Day-ahead system energy costs decreased by $255.5 million or 48.9 percent, from -$522.9 million in the first nine months of 2024 to -$778.5 million in the first nine months of 2025.

- **Balancing System Energy Costs.** Balancing system energy costs increased by $17.9 million or 22.7 percent, from $78.7 million in the first nine months of 2024 to $96.5 million in the first nine months of 2025.
- **Monthly Total System Energy Costs.** Monthly total system energy costs in the first nine months of 2025 ranged from -$137.8 million in January to -$46.4 million in May.

Conclusion

Congestion is defined as the total payments by load in excess of the total payments to generation, excluding marginal losses. The level and distribution of congestion reflects the underlying characteristics of the power system, including the nature and defined capability of transmission facilities, the offers and geographic distribution of generation facilities, the level and geographic distribution of incremental bids and offers and the geographic and temporal distribution of load.

Total congestion costs increased by $848.0 million or 61.2 percent, from $1,385.8 million in the first nine months of 2024 to $2,233.8 million in the first nine months of 2025.

Monthly total congestion costs ranged from $124.5 million in February to $608.9 million in July in the first nine months of 2025.

The current ARR/FTR design does not ensure that load receives the rights to all congestion revenues. The congestion offset provided by ARRs and self-scheduled FTRs in the first four months of the 2025/2026 planning period was 66.6 percent. The cumulative offset of congestion by ARRs for the 2011/2012 planning period through the first four months of the 2025/2026 planning period, using the rules effective for each planning period, was 68.7 percent. Load has received $5.4 billion less than load should have received from the 2011/2012 planning period through the first four months of the 2025/2026 planning period.

Issues

Artificial Constraints, Closed Loop Interfaces and CT Pricing Logic

PJM has used, and in some cases, continues to use, artificial constraints in the day-ahead and real-time markets to force specific resources (generation or demand response) to be marginal in order to have those resources set price. Some of these artificial constraints, such as CT pricing logic and closed loop interfaces, result in negative congestion charges that are an artifact of the artificial nature of the constraints that cause generation to be paid more than load pays for energy affected by the constraint. PJM also makes use of artificial constraints that function like closed loop interfaces but which result in positive or negative balancing congestion. These constraints are called Real-Time Short-Term Marginal Value Overrides. These constraints are similar to a closed loop interface in that they enforce artificially uniform price effects, but unlike closed loop interfaces that only affect prices on the constrained side, these artificial constraints enforce artificially uniform price spreads between the two sides of the constraint through large uniform dfax on the constrained side and small uniform dfax on the unconstrained side. These artificial constraints take the form of interfaces or enforced contingencies (modifications) on existing constraints. The uniform source dfax and uniform sink dfax of the artificial constraint can be modified, along with the transmission line limits, by PJM to meet market outcome goals and are a source of often significant modeling differences between the day-ahead and real-time market. These modeling differences result in inefficient market outcomes and false arbitrage opportunities for virtual transactions. This is an inappropriate use of these tools as it puts PJM in the position of a market actor, arbitrarily changing market results, market prices, generation revenues, congestion costs and load charges. One of the side effects of these changes in parameters, besides causing modeling differences between the day-ahead and real-time market, is that the apparent location of the interface or parent constraint can move intraday relative to source and sink points.

While CT pricing logic was officially discontinued by PJM with the implementation of fast start pricing on September 1, 2021, PJM continues to use the same basic logic (Real-Time Short-Term Marginal Value Overrides) to force inflexible units to be on the margin in both real time and day ahead. PJM used CT pricing logic to force otherwise uneconomic resources to be marginal and set price in the day-ahead or real-time market solution. PJM used CT pricing logic to create an artificial constraint with a variable flow limit, paired with an artificial override of the inflexible resource's economic minimum, to make the resource marginal in PJM's LMP security constrained pricing logic. The purpose of forcing inflexible units to be marginal is to artificially reduce the uplift associated with the dispatch of inflexible resources.

Through the assumption of artificial flexibility of the affected unit and artificially creating a constraint for which the otherwise inflexible resource can be marginal, PJM's use of CT pricing logic forced the affected resource bus LMP to match the marginal offer of the resource. PJM adjusts the constraint limit based on the output of the resource. Sometimes the constraint limit does not match the flows on the constraint, and the constraint violates instead of binding, resulting in prices set by the transmission constraint penalty factor.

In the case of a closed loop interface, all buses within the interface were modeled with a distribution factor (dfax) of 1.0 to the constraint and therefore with the same constraint related congestion component of price at the marginal resource's bus. In the CT pricing logic case, the constraint affected the CLMP of constrained side buses in proportion to their dfax to that constraint.[6] One objective of making inflexible resources marginal was to artificially minimize the uplift costs associated with the inflexible resources that PJM commits for system security reasons.

The use of artificial constraints was and is a source of modeling differences between the day-ahead and real-time markets. When artificial constraints are not included in the day-ahead market in exactly the same way as in the real-time market, including specific constraints and limits, the differences between the day-ahead and real-time market model result in positive or negative balancing congestion.

Failure to model the same constraints in the day-ahead and real-time markets results in pricing and congestion settlement differences between the day-ahead and real-time market. Any modeling differences create false arbitrage opportunities for virtual bids and contribute to negative balancing congestion.

Use of artificial constraints, closed loop interfaces and CT price setting logic requires manipulation of the economic dispatch model. Closed loop interfaces and CT price setting logic, like fast start pricing logic that replaced it, force higher cost inflexible units to be marginal.

Like closed loop interfaces and CT pricing logic, some of the artificially enforced constraint results in negative congestion. As a result, more power is produced in the artificial closed loop or constrained area than would result without the artificial constraint. This means that there are more generation credits than load charges in the constrained area. The constrained area exports power, the lower cost generators outside the constrained area are backed down and prices are lower outside the constrained area as a result. All of the generation within the artificially constrained area is paid the higher CLMP, but only a smaller amount of load (in some cases no load) in the constrained area pays this higher CLMP. As a result, load pays less than generation receives in the artificially constrained area. This difference is negative congestion. In the day-ahead market this reduces the total congestion dollars that are available to FTR holders. In the balancing market these costs are allocated directly to load as negative balancing charges.

6 The constrained side means the higher priced side with a positive CLMP created by the constraint.

Locational Marginal Price (LMP)

Components

PJM uses a distributed load reference bus. With a distributed load reference bus, the energy component of LMP is a load-weighted system price. Some price effects of binding constraints may be included in the load-weighted reference bus price.

LMP at a bus reflects the incremental price of energy at that bus. LMP at any bus can be disaggregated into three components: the system marginal price (SMP), marginal loss component (MLMP), and congestion component (CLMP).

SMP, MLMP and CLMP are a product of the least cost, security constrained dispatch of system resources to meet system load. SMP is the incremental cost of system energy, given the current dispatch and given the choice of reference bus. SMP is LMP net of losses and congestion. Losses refer to energy lost to physical resistance in the transmission and distribution network as power is moved from generation to load. Marginal losses are the incremental change in system power losses caused by changes in the system load and generation patterns.[7] The first derivative of total losses with respect to the power flow is marginal losses. Congestion cost reflects the incremental cost of relieving transmission constraints while maintaining system power balance. Congestion occurs when available, least-cost energy cannot be delivered to all loads because transmission facilities are not adequate to deliver that energy. When the least-cost available energy cannot be delivered to load in a transmission constrained area, higher cost units in the constrained area must be dispatched to meet that load.[8] The result is that the price of energy in the constrained area is higher than in the unconstrained area because of the combination of transmission limitations and the cost of local generation. Load in the constrained area pays the higher price for all energy including energy from low cost generation and energy from high cost generation. Congestion is the difference between the total cost of energy paid by load in the transmission constrained area and the total revenue received by generation to meet the load in the transmission constrained area, net of losses. Congestion equals the sum of day-ahead and balancing congestion.

Table 11-1 shows the PJM real-time load-weighted average LMP components for the first nine months of 2008 through 2025.[9]

The real-time load-weighted average LMP increased by $16.21 or 47.2 percent from $34.31 in the first nine months of 2024 to $50.51 in the first nine months of 2025. The real-time load-weighted average congestion component was $0.12 in the first nine months of 2025, compared to $0.07 in the first nine months of 2024. The real-time load-weighted average loss component in the first nine months of 2025 was $0.04, compared to $0.03 in the first nine months of 2024. The real-time load-weighted average system energy component increased by $16.14 or 47.2 percent from $34.21 in the first nine months of 2024 to $50.34 in the first nine months of 2025. Using a load-weighted reference bus, the real-time load-weighted average congestion component of LMP should be zero. PJM's load-weighted reference bus congestion component is zero at the time that LMPs are set based on state estimator data. Metering updates during the settlement process change the load weights after the fact, but the reference bus price (SMP) is not updated with these changes over time. As a result, the average congestion and loss components used in real-time settlement are not zero.

7 For additional information, see the *MMU Technical Reference for PJM Markets*, at "Marginal Losses," <http://www.monitoringanalytics.com/reports/Technical_References/references.shtml>.

8 This is referred to as dispatching units out of economic merit order. Economic merit order is the order of all generator offers from lowest to highest cost. Congestion occurs when loadings on transmission facilities mean the next unit in merit order cannot be used and a higher cost unit must be used in its place.

9 The PJM real-time, load-weighted price is weighted by accounting load, which differs from the state-estimated load used in determination of the energy component (SMP). In the real-time energy market, the distributed load reference bus is weighted by state-estimated load in real time. When the LMP is calculated in real time, the energy component equals the system load-weighted price. But real-time bus-specific loads are adjusted, after the fact, based on updated load information from meters. This meter adjusted load is accounting load that is used in settlements and is used to calculate reported PJM load-weighted prices. This after the fact adjustment means that the real-time energy market energy component of LMP (SMP) and the PJM real-time load-weighted LMP are not equal. The difference between the real-time energy component of LMP and the PJM wide real-time load-weighted average LMP is a result of the difference between state-estimated and metered loads used to weight the load-weighted reference bus and the load-weighted LMP. Without these adjustments, the congestion component of system average LMP would be zero.

Table 11-1 Real-time load-weighted average LMP components (Dollars per MWh): January through September, 2008 through 2025[10]

(Jan - Sep)	Real-Time LMP	Energy Component	Congestion Component	Loss Component
2008	$77.27	$77.15	$0.07	$0.05
2009	$39.57	$39.49	$0.04	$0.03
2010	$49.91	$49.81	$0.06	$0.04
2011	$49.48	$49.40	$0.05	$0.03
2012	$35.02	$34.97	$0.04	$0.01
2013	$39.75	$39.72	$0.01	$0.02
2014	$58.60	$58.61	($0.03)	$0.02
2015	$38.94	$38.89	$0.03	$0.02
2016	$29.32	$29.27	$0.04	$0.02
2017	$30.36	$30.32	$0.02	$0.01
2018	$39.43	$39.37	$0.04	$0.02
2019	$27.60	$27.56	$0.02	$0.02
2020	$21.22	$21.19	$0.02	$0.01
2021	$35.68	$35.63	$0.03	$0.02
2022	$77.84	$77.68	$0.10	$0.06
2023	$30.87	$30.80	$0.05	$0.02
2024	$34.31	$34.21	$0.07	$0.03
2025	$50.51	$50.34	$0.12	$0.04

Table 11-2 shows the PJM day-ahead load-weighted average LMP components for the first nine months of 2008 through 2025. The day-ahead load-weighted average LMP increased by $16.03, or 47.4 percent, from $33.85 in the first nine months of 2024 to $49.88 in the first nine months of 2025. The day-ahead load-weighted average congestion component increased by $0.01 from $0.13 in the first nine months of 2024 to $0.14 in the first nine months of 2025. The day-ahead load-weighted average loss component was $0.07 in the first nine months of 2025, compared to $0.07 in the first nine months of 2024. The day-ahead load-weighted average energy component increased by $16.02, or 47.6 percent, from $33.65 in the first nine months of 2024 to $49.67 in the first nine months of 2025. Using a load-weighted reference bus, the day-ahead load-weighted average congestion component of LMP should be zero. PJM's load-weighted reference bus congestion component is zero based on day-ahead firm load weights. Total billing however, includes price sensitive demand and virtual load congestion related charges, which makes the total load weights in accounting different than the load weights used to determine the SMP at the load-weighted reference bus. The resulting load-weighted average price from settlement for congestion and marginal losses components of price in day ahead is therefore not zero, although this component is not fully accurate.

Table 11-2 Day-ahead load-weighted average LMP components (Dollars per MWh): January through September, 2008 through 2025

(Jan - Sep)	Day-Ahead LMP	Energy Component	Congestion Component	Loss Component
2008	$75.96	$76.30	($0.09)	($0.24)
2009	$39.35	$39.50	($0.05)	($0.10)
2010	$49.12	$49.05	$0.11	($0.03)
2011	$48.34	$48.55	($0.05)	($0.16)
2012	$34.29	$34.19	$0.12	($0.02)
2013	$39.49	$39.35	$0.14	($0.00)
2014	$59.08	$58.84	$0.26	($0.01)
2015	$39.51	$39.25	$0.28	($0.02)
2016	$29.69	$29.54	$0.17	($0.01)
2017	$30.26	$30.24	$0.04	($0.02)
2018	$38.71	$38.60	$0.12	($0.01)
2019	$27.70	$27.63	$0.08	($0.01)
2020	$20.95	$20.88	$0.07	($0.01)
2021	$35.51	$35.31	$0.17	$0.03
2022	$76.97	$76.47	$0.32	$0.18
2023	$31.90	$31.80	$0.09	$0.01
2024	$33.85	$33.65	$0.13	$0.07
2025	$49.88	$49.67	$0.14	$0.07

10 Calculated values shown in Section 11, "Congestion and Marginal Losses," are based on unrounded, underlying data and may differ from calculations based on the rounded values in the tables.

Table 11-3 shows the PJM real-time load-weighted average LMP by constrained and unconstrained hours. A constrained hour is any hour during which one or more facilities are congested.

Table 11-3 Real-time load-weighted average LMP by constrained and unconstrained hours (Dollars per MWh): January 2024 through September 2025

	2024		2025	
	Constrained Hours	Unconstrained Hours	Constrained Hours	Unconstrained Hours
Jan	$43.09	$32.13	$63.62	$39.41
Feb	$24.92	$20.34	$48.92	$41.67
Mar	$23.10	$24.20	$42.11	$0.00
Apr	$27.27	$25.54	$46.14	$21.60
May	$36.74	$18.92	$37.27	$25.96
Jun	$33.68	$15.68	$68.44	$22.42
Jul	$47.67	$18.96	$60.05	$39.23
Aug	$37.24	$17.81	$40.75	$23.95
Sep	$33.09	$15.18	$43.82	$21.96
Oct	$32.52	$19.01		
Nov	$28.52	$26.30		
Dec	$35.03	$18.89

Zonal Components

The load weighted congestion component of LMPs (CLMPs) provided in the following tables (Table 11-5 and Table 11-6) are not a metric of the amount of congestion paid by load in a zone. The listed CLMPs show whether prices (LMPs) in a zone are higher or lower than the load weighted average price in the PJM system due to transmission constraints.

The real-time components of LMP for each control zone are presented in Table 11-5 for the first nine months of 2024 and 2025. In the first nine months of 2025, DOM had the highest real-time congestion component of LMP, $13.09, and COMED had the lowest real-time congestion component of LMP, -$7.12.

Table 11-5 Zonal real-time load-weighted average LMP components (Dollars per MWh): January through September, 2024 and 2025

	2024 (Jan - Sep)				2025 (Jan - Sep)			
	Real-Time LMP	Energy Component	Congestion Component	Loss Component	Real-Time LMP	Energy Component	Congestion Component	Loss Component

11 The real-time components of LMP are the simple average of the hourly components for each hub. Some hubs include only generation buses and do not include load buses. The real-time components of LMP were previously reported as the real-time, load-weighted, average of the hourly components of LMP.

Congestion

Congestion Accounting

In PJM accounting, total congestion costs equal net implicit CLMP charges, plus net explicit CLMP charges, plus net inadvertent CLMP charges. Implicit CLMP charges equal implicit withdrawal charges less implicit injection credits. Explicit CLMP charges are the net CLMP charges associated with the injection credits and withdrawal charges for point to point energy transactions. Inadvertent CLMP charges are not directly attributable to specific participants that are distributed on a load ratio basis. Each of these categories of congestion costs is comprised of day-ahead and balancing congestion costs.

While PJM accounting focuses on CLMPs, the individual CLMP values at any bus are irrelevant to the calculation of congestion, as CLMPs are just an artificial deconstruction of LMP based on a selected reference bus. Holding aside the marginal loss component of LMP, differences in the LMPs are caused by binding constraints in the least cost security constrained dispatch market solution, and total congestion is the net surplus revenue that remains after all sources and sinks are credited or charged their LMPs. Changing the components of LMP by electing a different reference bus does not change the LMPs or the difference between LMPs for a given market solution or actual congestion, it merely changes the components of the LMP.

Congestion occurs in the day-ahead and real-time energy markets.[12] Day-ahead congestion costs are based on day-ahead MWh while balancing congestion costs are based on deviations between day-ahead and real-time MWh priced at the congestion price in the real-time energy market.

Implicit CLMP charges are the CLMP charges calculated for energy injected or withdrawn at a location. The explicit CLMP charges are the CLMP charges calculated for transactions with a defined source and a sink. For example, implicit CLMP charges are calculated for network load and explicit CLMP charges are calculated for up to congestion transactions (UTCs). Inadvertent CLMP charges are CLMP charges resulting from the differences between the net actual energy flow and the net scheduled energy flow into or out of the PJM control area each hour.

12 When the term *congestion charge* is used in documents by PJM's Market Settlement Operations, it has the same meaning as the term *congestion costs* as used here.

CLMP charges and CLMP credits are calculated for both the day-ahead and balancing energy markets.

- **Day-Ahead Implicit Load CLMP Charges.** Day-ahead implicit withdrawal charges are calculated for all cleared demand, decrement bids and day-ahead energy market sale transactions. Day-ahead implicit withdrawal charges are calculated using MW and the load bus CLMP, the decrement bid bus CLMP or the CLMP at the source of the sale transaction.
- **Day-Ahead Implicit Generation CLMP Credits.** Day-ahead implicit injection credits are calculated for all cleared generation, increment offers and day-ahead energy market purchase transactions.[13] Day-ahead implicit injection credits are calculated using MW and the generator bus CLMP, the increment offer's bus CLMP or the CLMP at the sink of the purchase transaction.
- **Balancing Implicit Load CLMP Charges.** Balancing implicit withdrawal charges are calculated for all deviations between a PJM member's real-time load and energy sale transactions and their day-ahead cleared demand, decrement bids and energy sale transactions. Balancing implicit withdrawal charges are calculated using MW deviations and the real-time CLMP for each aggregate where a deviation exists.
- **Balancing Implicit Generation CLMP Credits.** Balancing implicit injection credits are calculated for all deviations between a PJM member's real-time generation and energy purchase transactions and the day-ahead cleared generation, increment offers and energy purchase transactions. Balancing implicit injection credits are calculated using MW deviations and the real-time CLMP for each aggregate where a deviation exists.

13 Internal bilateral transactions are included in the tariff definitions of Market Participant Energy Injections and Market Participant Energy Withdrawals. The purchase part of an internal bilateral transaction is an injection to the buyer and the sale part of an internal bilateral transaction is a withdrawal to the seller. The tariff (Attachment K) also says market participants will be charged implicit CLMP charges for all Market Participant Energy Withdrawals and will be credited implicit CLMP credits for all Market Participant Energy Injections. The seller of an internal bilateral transaction will be charged implicit CLMP charges at the source and the buyer of an internal bilateral transaction will be credited implicit CLMP credits at the sink. Internal bilateral transaction CLMP credits and charges sum to zero, as the IBT is merely a transfer of ownership injection and withdrawal MW and associated charges and credits between participants, meaning that the sum of all MW and all credits and all charges with and without IBTs are the same.

- **Explicit CLMP Charges.** Explicit CLMP charges are the net CLMP costs associated with point to point energy transactions. Day-ahead explicit CLMP charges equal the product of the transacted MW and CLMP differences between sources (origins) and sinks (destinations) in the day-ahead energy market. Balancing explicit CLMP charges equal the product of the deviations between the real-time and day-ahead transacted MW and the differences between the real-time CLMP at the transactions' sources and sinks. Explicit CLMP charges are calculated for internal purchase, import and export transaction, and up to congestion transactions (UTCs.)
- **Inadvertent CLMP Charges.** Inadvertent CLMP charges are charges resulting from the differences between the net actual energy flow and the net scheduled energy flow into or out of the PJM control area each hour. This inadvertent interchange of energy may be positive or negative, where positive interchange typically results in a charge while negative interchange typically results in a credit. Inadvertent CLMP charges are common costs, not directly attributable to specific participants that are distributed on a load ratio basis.[14]

The congestion accounting calculation equations are in Table 11-9.

Table 11-9 Congestion accounting calculations

Congestion Category	Calculation
Day-Ahead Implicit Withdrawal CLMP Charges	Day-Ahead Demand MWh * Day-Ahead CLMP
Day-Ahead Implicit Injection CLMP Credits	Day-Ahead Supply MWh * Day-Ahead CLMP
Day-Ahead Explicit CLMP Charges	Day-Ahead Transaction MW * (Day-Ahead Sink CLMP - Day-Ahead Source CLMP)
Day-Ahead Total Congestion Costs	Day-Ahead Implicit Withdrawal CLMP Charges - Day-Ahead Implicit Injection CLMP Credits + Day-Ahead Explicit CLMP Charges
Balancing Implicit Withdrawal CLMP Charges	Balancing Demand MWh * Real-Time CLMP
Balancing Implicit Injection CLMP Credits	Balancing Supply MWh * Real-Time CLMP
Balancing Explicit CLMP Costs	Balancing Transaction MW * (Real-Time Sink CLMP - Real-Time Source CLMP)
Balancing Total Congestion Costs	Balancing Implicit Withdrawal CLMP Charges - Balancing Implicit Injection CLMP Credits + Balancing Explicit CLMP Costs
Total Congestion Costs	Day-Ahead Total Congestion Costs + Balancing Total Congestion Costs

MWh Category	Definition
Day-Ahead Demand MWh	Cleared Demand, Decrement Bids, Energy Sale Transactions
Day-Ahead Supply MWh	Cleared Generation, Increment Bids, Energy Purchase Transactions
Real-Time Demand MWh	Load and Energy Sale Transactions
Real-Time Supply MWh	Generation and Energy Purchase Transactions
Balancing Demand MWh	Real-Time Demand MWh - Day-Ahead Demand MWh
Balancing Supply MWh	Real-Time Supply MWh - Day-Ahead Supply MWh

PJM billing items include Day-Ahead Transmission Congestion Charges, Day-Ahead Transmission Congestion Credits, Balancing Transmission Congestion Charges, and Balancing Transmission Congestion Credits. Those line items are calculated for each PJM member. The congestion bill shows the CLMP charges or credits collected from the PJM market participants. However, the sum of an individual customer's CLMP credits or charges on the customer's bill is not a measure of the congestion paid by that customer.

The congestion paid by a customer is the difference between what the customer paid for energy and what all network sources of that energy were paid to serve that customer. A load customer's congestion bill, in contrast, merely indicates whether the LMP they paid for their withdrawals is higher or lower than the system energy price due to transmission constraints. The customer's bill does not measure congestion paid by the customer, only how much the customer was charged and credited for their MW positions. The congestion costs associated with specific constraints are the sum of the total day-ahead and balancing congestion costs associated with those constraints. Zonal congestion is calculated on a constraint by constraint basis. The congestion calculations are the total difference between what the zonal load pays in CLMP charges and what the generation that serves that load is paid, regardless of whether the zone is a net importer or a net exporter of generation. CLMPs can be both positive and negative and CLMP charges and CLMP credits can be both positive and negative. CLMP charges, positive or negative, are paid by withdrawals and CLMP credits, positive or negative, are paid to injections. Total congestion costs (the sum of charges and credits), when positive, measure the net congestion payment by a participant group and when

14 PJM Operating Agreement Schedule 1 §3.7.

negative, measure the net congestion credit paid to a participant group. Explicit CLMP charges, when positive, measure the CLMP payment from a PJM member and when negative, measure the CLMP credit paid to a PJM member. Explicit CLMP charges are calculated for up to congestion transactions (UTCs). In all cases, whether positive or negative, CLMP charges and credits merely indicate whether the LMP being paid by withdrawals or credited to injections is higher or lower than the system weighted average price due to binding transmission constraints.

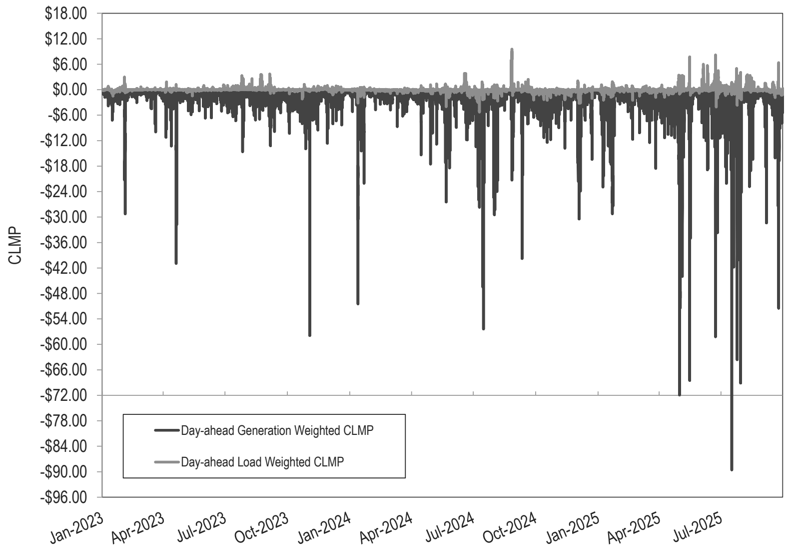
The congestion accounting definitions are misleading. Load pays congestion. Congestion is the difference between what load pays for energy and what generation is paid for energy due to binding transmission constraints. Generation does not pay congestion. Some generation receives a price lower than SMP and some generation receives a price greater than SMP but that does not mean that generation is paying congestion. It means only that generation is being paid an LMP that is higher or lower than the system load-weighted average LMP.

The CLMP is calculated with respect to the LMP at the system reference bus, also called the system marginal price (SMP). When a transmission constraint occurs, the resulting CLMP is positive on one side of the constraint and negative on the other side of the constraint and the corresponding CLMP costs are positive or negative. For each transmission constraint, the CLMP reflects the cost of a constraint at a pricing node and is equal to the product of the constraint shadow price and the distribution factor from the constraint to the pricing node. The total CLMP at a pricing node is the sum of all constraint contributions to LMP and is equal to the difference between the actual LMP that results from transmission constraints, excluding losses, and the SMP. If an area experiences lower prices because of a constraint, the CLMP in that area is negative.[15]

Load-weighted LMP components are calculated relative to a load-weighted, average LMP. At the load-weighted reference bus, which represents the load center of the system, the LMP calculation is designed to include no congestion or loss components, but it may include congestion. The load-weighted average CLMP across all load buses, calculated relative to that reference bus, is equal to, or very close to, zero, with non-zero results caused by state estimator error and after the fact meter updates. The sum of load related CLMP charges is logically zero and the small reported differences are the result of accounting issues. A positive CLMP at a load bus indicates that the load at that bus has a total energy price higher than the average LMP, due to transmission constraints. A negative CLMP at a load bus indicates that the load at that bus has a total energy price lower than the average LMP, due to transmission constraints. The LMPs at the load buses are a function of marginal generation bus LMPs determined through the least cost security constrained economic dispatch which accounts for transmission constraints and marginal losses. Due to transmission constraints, the average generation weighted CLMP for generation resources is lower than the LMP at the load-weighted reference bus price. Calculated relative to the load reference bus which has a CLMP of zero, this means that the average of the generation bus CLMPs is negative. This means that total generation CLMP credits are negative. Figure 11-1 shows the weighted average CLMPs of generation and load in the day-ahead market. Figure 11-1 shows that from January 2023 to September 2025, day-ahead generation weighted CLMPs were generally negative and day-ahead, load weighted CLMPs were generally positive, indicating that load was charged a higher weighted average LMP for energy as a result of transmission constraints than the weighted average LMP generation was paid to provide that energy. This means that total CLMP load payments are higher than total CLMP generation credits. The difference in load payments and generation credits (load charges minus generation credits) is congestion (Table 11-12 and Table 11-13). This result is a product of the least cost, security constrained dispatch and the use of a load-weighted reference bus that is used for the determination of the components of LMP. More generally, in a least cost, security constrained market solution the weighted average LMP at load buses is higher than the weighted average price at generation buses.

15 For an example of the congestion accounting methods used in this section, see *MMU Technical Reference for PJM Markets*, at "FTRs and ARRs," <http://www.monitoringanalytics.com/reports/Technical_References/docs/2010-som-pjm-technical-reference.pdf>.

Figure 11-1 Day-ahead generation weighted CLMPs and day-ahead load-weighted CLMPs: January 2023 through September 2025



Total Congestion

Total congestion costs in PJM in the first nine months of 2025 were $2,233.8 million, comprised of implicit withdrawal charges of $852.8 million, minus implicit injection credits of -$1,472.3 million, plus explicit charges of -$91.2 million. Total congestion is the difference between what load pays for energy and what generation is paid for energy, due to binding transmission constraints.

Table 11-10 shows total congestion for January through September, 2008 through 2025. Total congestion costs in Table 11-10 include congestion associated with PJM facilities and those associated with reciprocal, coordinated flowgates in MISO and in NYISO.[16] [17]

Table 11-10 Total congestion costs (Dollars (Millions)): January through September, 2008 through 2025[18]

(Jan - Sep)	Congestion Cost	Percent Change	Total PJM Billing	Percent of PJM Billing
2008	$1,778	NA	$26,979	6.6%
2009	$544	(69.4%)	$19,927	2.7%
2010	$1,134	108.7%	$26,249	4.3%
2011	$875	(22.9%)	$28,836	3.0%
2012	$425	(51.4%)	$22,119	1.9%
2013	$510	19.9%	$25,153	2.0%
2014	$1,705	234.6%	$40,770	4.2%
2015	$1,143	(33.0%)	$33,710	3.4%
2016	$822	(28.1%)	$29,490	2.8%
2017	$455	(44.6%)	$29,510	1.5%
2018	$1,116	145.1%	$37,950	2.9%
2019	$419	(62.5%)	$31,850	1.3%
2020	$396	(5.5%)	$27,070	1.5%
2021	$615	55.1%	$37,520	1.6%
2022	$1,863	203.2%	$66,110	2.8%
2023	$760	(59.2%)	$36,380	2.1%
2024	$1,386	82.2%	$39,070	3.5%
2025	$2,234	61.2%	$57,770	3.9%

CLMP charges and credits are not congestion. CLMP charges and credits reflect marginal energy price differences caused by binding system constraints. Congestion is the sum of all congestion related charges and credits. In a two settlement system all virtual bids have net zero MW after their day-ahead and balancing positions are cleared, which means that virtual bids are fully settled in terms of CLMP credits and charges at the close of the market for any particular day, with either a net loss or profit due to differences between day-ahead and real-time prices. Net payouts (negative credits) to virtual bids appear as negative adjustments to either day-ahead or balancing congestion and net charges to virtual bids appear as positive adjustments to either day-ahead or balancing congestion.

Table 11-11 shows total congestion by day-ahead and balancing component for January through September, 2008 through 2025.

16 See "Joint Operating Agreement Between the Midwest Independent Transmission System Operator, Inc. and PJM Interconnection, L.L.C.," (December 11, 2008) Section 6.1, Effective Date: May 30, 2016. <http://www.pjm.com/documents/agreements.aspx>.
17 See "NYISO Tariffs New York Independent System Operator, Inc.," (June 21, 2017) 35.12.1, Effective Date: May 1, 2017. <http://www.pjm.com/documents/agreements.aspx>.

18 In Table 11-10, the MMU uses Total PJM Billing values provided by PJM. For 2019 and after, the MMU has modified the Total PJM Billing calculation to better reflect historical PJM total billing through the PJM settlement process.

Table 11-11 Total CLMP credits and charges by accounting category (Dollars (Millions)): January through September, 2008 through 2025

	Day-Ahead				Balancing					
(Jan - Sep)	Implicit Withdrawal Charges	Implicit Injection Credits	Explicit Charges	Total	Implicit Withdrawal Charges	Implicit Injection Credits	Explicit Charges	Total	Inadvertent Charges	Congestion Costs
2008	$1,126.9	($971.2)	$152.8	$2,250.9	($204.9)	$90.5	($177.3)	($472.7)	$0.0	$1,778.2

Charges and Credits versus Congestion: Virtual Transactions, Load and Generation

In PJM's two settlement system, there is a day-ahead market and a real-time, balancing market that make up a market day.

In a two settlement system all virtual bids have net zero MW after their day-ahead and balancing positions are cleared, which means that virtual bids are fully settled in terms of CLMP credits and charges at the close of each market day, with either a net loss or profit due to differences between day-ahead and real-time prices. Net payouts (negative credits) to virtual bids appear as negative adjustments to either day-ahead or balancing congestion and net charges to virtual bids appear as positive adjustments to either day-ahead or balancing congestion.

Unlike virtual bids, physical load and generation have net MW at the close of a market day's day-ahead and balancing settlement.

Generation does not pay congestion. Some generation receives a price lower than SMP and some generation receives a price greater than SMP but that does not mean that generation is paying congestion. It means that generation is being paid an LMP that is higher or lower than the system load-weighted average LMP.

The residual difference between total load charges (day-ahead and balancing) and generation credits (day-ahead and balancing) after virtual bids have settled their day-ahead and balancing positions is congestion. That is, congestion is the difference between what withdrawals (load) pay for energy and what injections (generation) are paid for energy due to binding transmission constraints, after virtual bids are settled at the end of the market day. Load is the source of the net surplus after generation is paid and virtuals are settled at the end of the market day. Load pays congestion.

Table 11-12 and Table 11-13 show the total CLMP charges and credits for each transaction type in the first nine months of 2025 and 2024. Table 11-12 shows that in the first nine months of 2025 DECs were paid $25.1 million in CLMP charges in the day-ahead market, were paid $42.1 million in CLMP credits in the balancing energy market, resulting in a net payment of $67.2 million. In the first nine months of 2025, INCs paid $128.5 million in CLMP charges in the day-ahead market, were paid $177.2 million in CLMP credits in the balancing energy market resulting in a net payment of $48.7 million. In the first nine months of 2025, up to congestion (UTCs) paid $99.8 million in CLMP charges in the day-ahead market, were paid $190.2 million in CLMP credits in the balancing market resulting in a total payment of $90.4 million in total CLMP credits.

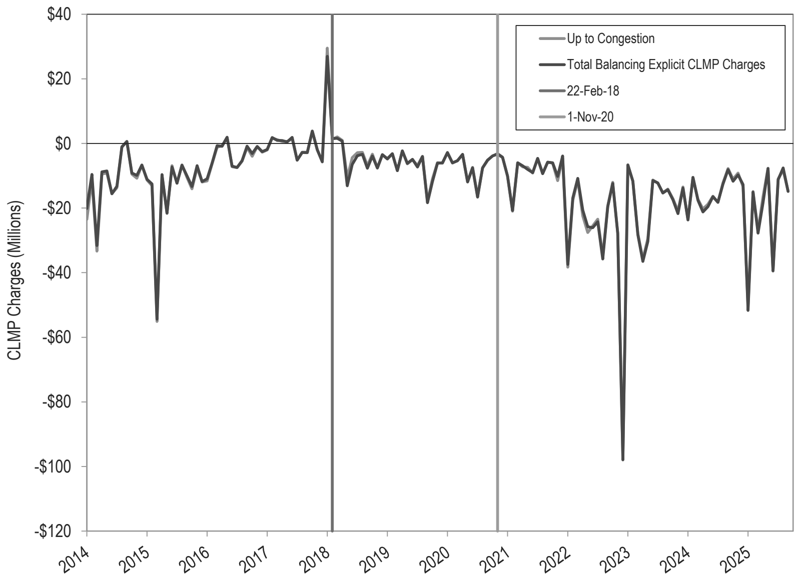
UTCs and Negative Balancing Explicit CLMP Charges

Figure 11-2 shows the change in up to congestion balancing explicit CLMP charges from January 2014 through September 2025. Figure 11-2 shows that UTCs account for almost all balancing explicit CLMP charges in PJM. As shown in Figure 11-2, UTCs are generally paid balancing CLMP credits, which take the form of negative balancing CLMP charges being allocated to UTC positions. In the first nine months of 2025, 98.3 percent (-$190.2 million out of -$193.6 million) of negative balancing explicit CLMP charges was incurred by UTCs and 5.9 percent (-$21.9 out of -$369.8 million) was incurred by Explicit Congestion Only, Export, Import and Wheel In transactions (Table 11-12). The vertical line at February 22, 2018, marks the date on which the FERC order that limited UTC trading to hubs, residual metered load, and interfaces was effective.[19] The vertical line at November 1, 2020, marks the date on which the FERC order that required PJM to allocate uplift to up to congestion transactions was effective.[20]

Negative balancing explicit CLMP charges were substantially higher in December 2022 than in other months as a result of transmission constraint penalty factors in the real-time market in 2022. The total negative balancing explicit CLMP charges on December 7 and 8, 2022, and the Winter Storm Elliott days of December 23 through 26, 2022, were 64.1 percent (-$62.3 million out of -$97.2 million) of total negative balancing explicit CLMP charges in December 2022.

19 For additional information about the FERC order, see the *2022 Annual State of the Market Report for PJM*, Appendix F: Congestion and Marginal Losses.
20 172 FERC ¶ 61,046 (2020).

Figure 11-2 Monthly balancing explicit CLMP charges incurred by UTCs: January 2014 through September 2025



Balancing congestion is caused by settling real-time deviations from day-ahead positions at real-time prices. Whether balancing congestion is positive or negative depends on the differences between market solutions (changes in load and/or generation) and differences between the day-ahead and real-time market models including modeled constraints, the transfer capability (line limits) of the modeled constraints and the differences in deviations between day-ahead and real-time flows that result. The deviations are priced at the real-time LMPs.

For example, one source of negative balancing congestion is that the PJM system has less transmission transfer capability in the real-time market than is modeled in the day-ahead market. In order to reduce processing time in the presence of large number of virtual bids and offers, PJM only enforces or models a subset of its physical transmission limits in the day-ahead market. Transmission constraints not modeled in the day-ahead market have unlimited transfer capability in the day-ahead market model. The inclusion of the actual, lower transmission capability in the real-time market requires the use of more high cost generation and the use of less low cost generation to serve load, which means a decrease in congestion.[21] The reduction in real-time congestion compared to day-ahead congestion creates negative balancing congestion.

As a day-ahead spread bid, UTCs can take advantage of and profit from LMP differences caused by modeling differences between the day-ahead and real-time market. UTCs clear between source and sink points with little or no price difference in the day-ahead market, and settle the resulting deviations at higher real-time price differences in the real-time market. The result is negative balancing congestion caused by and paid to UTCs in the form of CLMP credits. This is an example of false arbitrage because the UTCs cannot cause prices to converge and the profits to decrease. As a result of the FERC order requiring load to pay balancing congestion, load is responsible for paying the balancing congestion caused by UTCs.[22]

Table 11-16 provides an example of how UTCs can profit from differences in day-ahead and real-time models and generate negative balancing congestion. In the example, Bus A and Bus B are linked by a transmission line. In the day-ahead market the transmission limit is modeled as 9,999 MW (no limit is enforced in the day-ahead market solution). In the real-time market the physical limit between bus A and bus B is 50 MW. Generation at A has a price of $1.00 and Generation at B has a price of $6. There is 100 MW of load at bus A and 100 MW of load at bus B. There is a UTC of 200 MW that will source at bus A and sink at bus B if the spread in the prices between A and B is less than $1.

As a result of the fact that the transmission capability between A and B is unlimited in the day-ahead market, all of load at A and B can be met with

21 Although it seems counter intuitive, as the amount of low cost generation decreases and the amount of high cost generation increases, the difference between load payments to generation and the payments received by generators goes down. High cost generation receives what load pays.

22 On September 15, 2016, FERC ordered PJM to allocate balancing congestion to load, rather than to FTRs, to modify PJM's Stage 1A ARR allocation process and to continue to use portfolio netting. 153 FERC ¶ 61,180 (2016).

the $1 generation at bus A. The constraint between A and B does not bind in day-ahead so the price at A and B is $1. The price spread between bus A and bus B is zero, which is less than the UTC spread requirement of $1, so the UTC clears. The UTC causes a 200 MW injection at A and 200 MW withdrawal at B, creating 200 MW of flow between bus A and bus B. The 300 MW of combined flow from generation at A and UTC injections at A to the load and UTC sink at B does not exceed the DA modeled limit between A and B. This means that all 200 MW of the UTC injection at A and 200 MW of withdrawal at B can clear without forcing a price spread between A and B. Total day-ahead congestion, which is the difference between CLMP charges and credits, is zero. There is no price difference between the two nodes and every MW of injection and every MW of withdrawal at bus A and bus B settles at the same price.

In the real-time market, the transmission line between bus A and bus B has a 50 MW limit. The UTC does not physically exist in the real-time market and therefore has deviations at Bus A (-200 MW) and at Bus B (+200 MW). The UTC must buy at bus A at the real-time price and sell at bus B at the real-time price to settle its deviations. The load at A (100 MW) and B (100 MW) does not change, so there are no load deviations. With only 50 MW of transmission capability between A and B, the generation at A cannot be used to meet total load on the system. Generation from A meets the load at A (100 MW) and can supply only 50 MW of the 100 MW of load at B. Due to the binding constraint between A and B, the remaining 50 MW of load at B must be met with local generation at B at a cost of $6 and the price at A remains $1.

The UTC must buy 200 MW at A at the real-time price of $1 and sell 200 MW at B at the real-time price of $6. The UTC pays $200 at A and is paid $1,200 at B. The result is a net payment to the UTC of $1,000 in balancing credits.

Table 11-16 shows the balancing credits and charges associated with the real-time deviations in the example. Total congestion (day-ahead plus balancing congestion) in this example is negative $1,250. Total CLMP credits (payments) to generation and the UTC exceed the total charges collected from load. The negative balancing congestion that results is paid by the load under the FERC order.[23]

23 See 153 FERC ¶ 61,180 (2016).

The UTC did not and could not contribute to price convergence between the day-ahead and real-time market and did not and could not improve efficiency in system dispatch or commitment. The UTC took advantage of the modeling differences between the day-ahead and real-time markets. The UTC did significantly increase payments by load. Load was required to pay the UTC $1,000 in negative balancing, over and above the costs of generation that was needed to meet real-time load. The differences in modeling would have resulted in only $250 in negative balancing congestion if there had been no UTCs.

Table 11-16 Example of UTC causing and profiting from negative balancing congestion

Prices	Bus A	Transfer Capability (Line Limit MW)	Bus B	
LMP DA	$1.00	9,999	$1.00

Zonal and Load Aggregate Congestion

Zonal, and load aggregate, congestion is calculated on a constraint specific basis for a specific location or set of load pricing nodes (a zone or an aggregate). Local congestion is the difference between what load pays for energy and what generation is paid for energy due to individual binding transmission constraints. Local congestion includes all energy charges or credits incurred to serve a specific load, zone or load aggregate. Local congestion calculations account for the total difference between what the specified load pays and what the generation that serves that load is paid, regardless of whether the zone is a net importer or a net exporter of generation.

Local congestion is calculated on a constraint specific basis. Congestion is the total congestion payments by load at the buses within a defined area minus total CLMP credits received by generation that supplied that load, given the transmission constraints. Congestion reflects the underlying characteristics of the entire power system as it affects the defined area, including the nature and capability of transmission facilities, the offers and geographic distribution of generation facilities, the level and geographic distribution of decremental bids and incremental offers and the geographic and temporal distribution of load.

On a system wide basis, congestion results from transmission constraints that prevent the lowest cost generation from serving some load that must be served by higher cost generation.

The total congestion caused by a constraint is equal to the product of the constraint shadow price times the net flow on the binding constraint. (The shadow price is the difference between the CLMPs across the constraint.) Total congestion caused by the constraint can also be calculated using the CLMPs caused by the constraint at every bus and the net MW injections or MW withdrawals at every affected bus. Congestion associated with a specific constraint is equal to load CLMP charges (CLMP of that specific constraint at each bus times load MW at each bus) caused by that constraint in excess of generation CLMP credits (CLMP of that specific constraint at each bus times generation MW at each bus) caused by that constraint. Equivalently, total congestion caused by the constraint can also be calculated by the shadow price of the constraint times the market flow on that constraint.

Congestion paid by zonal load is a function of the load share of the total load market flow on all binding constraints. Congestion is the difference between what load pays for energy due to binding transmission constraints and what generation, whether inside or outside the load's zone, is paid to serve that load. This calculation is done for both day-ahead congestion and balancing congestion.

Table 11-17 shows day-ahead and balancing congestion by zone and the proportion of congestion resulting from constraints that are external to or internal to each zone, in the first nine months of 2025. Constraints are internal to a zone if both the source and sink points of the constraint are in the zone. DOM had the largest zonal congestion costs among all control zones in the first nine months of 2025. DOM had $414.9 million in zonal congestion costs, comprised of $482.0 million in zonal day-ahead congestion costs and -$67.1 million in zonal balancing congestion costs. The Pleasant View Transformer, the Lenox – North Meshoppen Line, the Pleasant View – Ashburn Line, the Goose Creek Transformer, and the Ashburn – Goose Creek Line contributed $189.8 million, or 25.7 percent of the DOM zonal congestion costs.[24]

Table 11-18 shows congestion costs by zone in the first nine months of 2024.

24 For additional information about the top 20 constraints that affected each zone, see the *2022 Annual State of the Market Report for PJM*, Appendix F: Congestion and Marginal Losses.

In cases where PJM has used an artificial constraint that causes net negative congestion and/or there is no load bus on the constrained side of a binding constraint, the congestion of the artificial constraint is handled as a special case. In the first nine months of 2025, the total congestion costs associated with these special cases were -$1.7 million or -0.0 percent of the total congestion costs. Table 11-17 and Table 11-18 include congestion allocations from these special case artificial constraints.

There are five categories of artificial constraint based specific allocation special cases that can cause negative congestion: congestion associated with artificial constraints with no downstream load bus (no load bus); congestion associated with artificial constraints with downstream load buses with zero value CLMPs (zero CLMP); congestion associated with closed loop interfaces (closed loop interfaces); congestion associated with CT price setting logic (CT price setting logic); and congestion associated with nontransmission artificial facility constraints in the day-ahead energy market and/or any unaccounted for difference between PJM billed CLMP charges and calculated congestion costs including rounding errors (unclassified).[25]

25 While CT pricing logic was officially discontinued by PJM on September 1, 2021, PJM continued to use a related logic to force inflexible units to be on the margin in both real time and day ahead. These results have been included in the CT Pricing Logic totals.

Table 11-19 and Table 11-20 show total congestion by type of special case, congestion, and total congestion by zone. Closed loop interfaces and CT pricing logic, and similar artificial constraints employed by PJM to force resources to be marginal, generally result in negative congestion on a constraint specific basis. PJM's use of both the closed loop interfaces and CT Pricing Logic forces the affected resource bus LMP to match the marginal offer of the resource. This causes higher CLMP payments to the affected generation than the CLMP load charges to any affected load, resulting in negative congestion associated with the constraint. None of the closed loop interfaces were binding in the first nine months of 2024 or 2025. The congestion associated with Real-Time Short-Term Marginal Value Overrides is included in the Normal Constraint Congestion totals.

Table 11-21 show total balancing congestion caused by each of the Real-Time Short-Term Marginal Value Overrides constraints PJM used in the first nine months of 2025 (Table 11-21). The congestion associated with Real-Time Short-Term Marginal Value Overrides is included in the Normal Constraint Congestion totals. Real-Time Short-Term Marginal Value Overrides are artificial transmission contingencies on physical transmission elements. Real-Time Short-Term Marginal Value Overrides temporarily force a generator to be marginal. Real-Time Short-Term Marginal Value Overrides are typically in place for a period of from several hours to a few days. Real-Time Short-Term Marginal Value Overrides are similar to a closed loop interface in that they enforce artificially uniform price effects, but unlike closed loop interfaces that only affect prices on the constrained side, these artificial constraints enforce artificially uniform price spreads between the two sides of the constraint through large uniform dfax on the constrained side and small uniform dfax on the unconstrained side. The uniform source dfax and uniform sink dfax of the artificial constraint can be modified, along with the transmission line limits, by PJM to meet market outcome goals and are a source of significant modeling differences between the day-ahead and real-time market.

Table 11-21 CLMP charges and credits and congestion collected by Real-Time Short-Term Marginal Value Overrides by affected Constraint: January through September, 2025

				CLMP Credits and Charges (Millions)				Percent of Total Congestion Caused by Real-Time Short-Term Marginal Value Overrides

Fast Start Pricing Effect on Zonal Congestion

PJM implemented fast start pricing in both day-ahead and real-time markets starting September 1, 2021. Table 11-22 compares the congestion costs between the dispatch run and the pricing run in the first nine months of 2025. The table shows that the implementation of fast starting pricing logic caused day-ahead total congestion costs to increase $0.8 million (or 0.0 percent), caused negative balancing congestion costs to decrease $18.4 million (or 5.2 percent), and caused total congestion costs to decrease $17.5 million (or 0.8 percent) from the dispatch run to the pricing run in the first nine months of 2025. In comparing the two pricing results, the same MW, from the dispatch run in the day-ahead market and metered output in the real-time market, are used in the accounting cost calculations.

Monthly Congestion

Table 11-23 shows day-ahead, balancing and inadvertent congestion costs by month for January 2024 through September 2025.

Total negative balancing congestion costs in the first nine months of 2025 were highest in July. The top constraint that contributed to the total balancing congestion costs in the first nine months of 2025 was the AEP – DOM Interface. The constraint accounted for 28.5 percent of the total balancing congestion costs in the first nine months of 2025. The majority (30.2 percent) of negative balancing congestion costs for the AEP – DOM Interface were the result of Generation.

In the first nine months of 2025, total congestion costs were highest in July and lowest in February.

Table 11-23 Monthly congestion costs by market (Dollars (Millions)): January 2024 through September 2025

	Congestion Costs (Millions)							
	2024				2025

Total	$2,058.6	($304.2)	$0.0	$1,754.4	$2,603.6	($369.8)	($0.0)	$2,233.8

Figure 11-3 shows PJM monthly total congestion cost for January 2008 through September 2025.

Figure 11-3 Monthly total congestion cost (Dollars (Millions)): January 2008 through September 2025

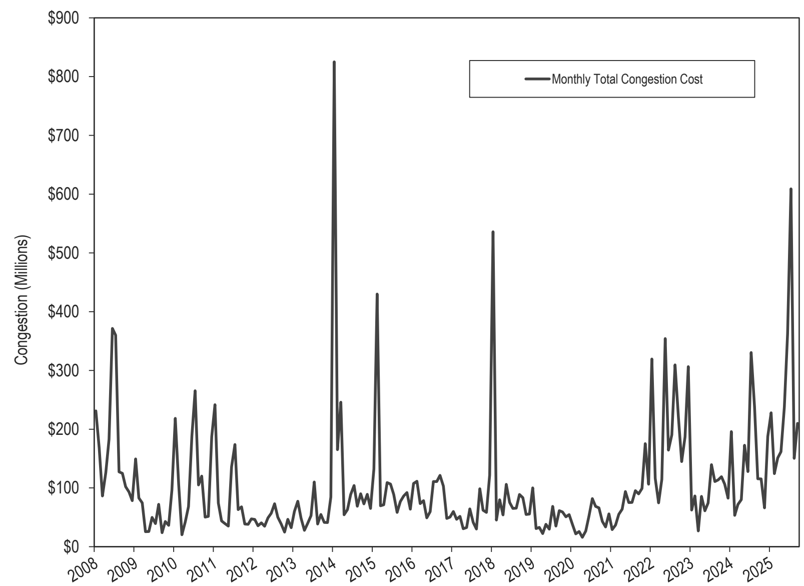

Table 11-24 shows monthly total CLMP credits and charges for each virtual transaction type for January 2024 through September 2025. Virtual transaction CLMP charges, when positive, are the total CLMP charges to the virtual transactions and when negative, are the total CLMP credits to the virtual transactions. The negative totals in Table 11-24 show that virtuals were paid, in net, CLMP credits in the first nine months of 2025 and 2024. In the first nine months of 2025, 43.8 percent of the total credits to virtuals went to UTCs, compared to 34.7 percent in the first nine months of 2024. In the first nine months of 2025, the average hourly cleared UTC MW decreased by 10.1 percent, compared to the first nine months of 2024.

Table 11-24 Monthly CLMP charges by virtual transaction type (Dollars (Millions)): January 2024 through September 2025

Congested Facilities

A congestion event exists when a unit or units must be dispatched out of merit order to control for the potential impact of a contingency on a monitored facility or to control an actual overload. A congestion event hour exists when a specific facility is constrained for one or more five-minute intervals within an hour. A congestion event hour differs from a constrained hour, which is any hour during which one or more facilities are congested. If two facilities are constrained during an hour, the result is one constrained hour and two congestion event hours. Constraints are often simultaneous, so the number of congestion event hours usually exceeds the number of constrained hours and the number of congestion event hours usually exceeds the number of hours in a year.

In order to have a consistent metric for real-time and day-ahead congestion frequency, real-time congestion frequency is measured using the convention that an hour is constrained if any of its component five-minute intervals is constrained. This is consistent with the way in which PJM reports real-time congestion.

In the first nine months of 2025, there were 56,377 day-ahead congestion event hours compared to 57,459 day-ahead congestion event hours in the first nine months of 2024. Of the day-ahead congestion event hours in the first nine months of 2025, only 11,626 (20.6 percent) were also constrained in the real-time energy market (Table 11-26). In the first nine months of 2025, there were 21,659 real-time, congestion event hours compared to 20,748 real-time, congestion event hours in the first nine months of 2024. Of the real-time congestion event hours in the first nine months of 2025, 11,629 (53.7 percent) were also constrained in the day-ahead energy market (Table 11-27).

Congestion Event Hours

Table 11-25 compares the monthly day-ahead and real-time congestion event hours in 2024 and the first nine months of 2025. Day-ahead congestion event hours are significantly greater than real-time congestion event hours.

Table 11-25 Monthly day-ahead and real-time congestion event hours: January 2024 through September 2025

	Day-Ahead Congestion Event Hours		Real-Time Congestion Event Hours	
	2024	2025	2024	2025
Jan	6,003	6,599	2,037	2,493
Feb	5,516	6,213	1,709	2,136
Mar	7,877	8,016	2,527	3,662
Apr	6,464	5,238	2,648	2,446
May	6,833	4,653	2,930	1,692
Jun	6,601	6,727	2,731	2,661
Jul	6,379	6,835	2,397	2,200
Aug	5,822	6,985	1,885	1,618
Sep	5,974	6,985	1,884	2,453
Oct	7,039		2,472	
Nov	5,782		1,808	
Dec	8,015		2,652	
Total	78,305	58,251	27,680	21,361

Table 11-26 and Table 11-27 compare day-ahead and real-time congestion event hours. Among the hours for which a facility is constrained in the day-ahead energy market, the number of hours during which the facility is also constrained in the real-time energy market are presented in Table 11-26.[26]

Among the hours for which a facility was constrained in the real-time energy market, the number of hours during which the facility was also constrained in the day-ahead energy market are presented in Table 11-27.

Congestion frequency continued to be significantly higher in the day-ahead energy market than in the real-time energy market in the first nine months of 2025. The number of congestion event hours in the day-ahead energy market was about five times the number of congestion event hours in the real-time energy market.

In the real-time market, PJM has the ability to model and monitor almost all PJM transmission facilities. In the day-ahead market, PJM can model and monitor only a portion of PJM transmission facilities. This difference in modeling is the basis of false arbitrage and the source of significant virtual profits. While more constraints are modeled and monitored in the PJM real-time market than the day-ahead market, there is significantly more network flow in the day-ahead market than in the real-time market as a result of virtual bids and offers. Virtual bids and offers also contribute to day-ahead market flows that do not align with realized real-time physical flows. The number of congestion event hours in the day-ahead energy market was about three times the number of congestion event hours in the real-time energy market, despite the fact that only a portion of PJM transmission facilities are modeled in the day-ahead market.

Table 11-26 Congestion event hours (day-ahead against real-time): January through September, 2024 and 2025

	Congestion Event Hours					
	2024 (Jan - Sep)			2025 (Jan - Sep)

26 Constraints are mapped to transmission facilities. In the day-ahead energy market, within a given hour, a single transmission facility may be associated with multiple constraints. In such situations, the same facility accounts for more than one congestion event hour for a given hour in the day-ahead energy market. Similarly in the real-time market a facility may account for more than one congestion event hour within a given hour.

Table 11-28 shows congestion costs by facility voltage class in the first nine months of 2025. Congestion costs in the first nine months of 2025 increased for all facility voltage classes except for 765 kV and 69 kV compared to the first nine months of 2024.

Congestion by Facility Type and Voltage

Day-ahead, congestion event hours decreased on transformers and lines and increased on flowgates and interfaces in the first nine months of 2025. Congestion event hours on lines decreased by 1,129 congestion event hours from 39,297 day-ahead, congestion event hours in the first nine months of 2024 to 38,168 day-ahead congestion event hours in the first nine months of 2025 (Table 11-30).

Real-time, congestion event hours increased on interfaces, lines and transformers in the first nine months of 2025 (Table 11-31). Lines increased by 1,499 congestion event hours from 12,117 real-time, congestion event hours in the first nine months of 2024 to 13,616 real-time congestion event hours in the first nine months of 2025.

Table 11-30 provides congestion event hour subtotals and congestion cost subtotals comparing the first nine months of 2025 results by facility type: line, transformer, interface, flowgate and unclassified facilities.[27] [28]

27 Unclassified are congestion costs related to nontransmission facility constraints in the day-ahead energy market and any unaccounted for difference between PJM billed CLMP charges and calculated congestion costs including rounding errors. Nontransmission facility constraints include day-ahead market only constraints such as constraints on virtual transactions and constraints associated with phase-angle regulators.

28 The term flowgate refers to MISO reciprocal coordinated flowgates and NYISO M2M flowgates.

Constraint Frequency

Table 11-32 lists the constraints for the first nine months of 2024 and 2025 that were most frequently binding and Table 11-33 shows the constraints which experienced the largest change in congestion event hours from the first nine months of 2024 to the first nine months of 2025. In Table 11-32, constraints are presented in descending order of total day-ahead event hours and real-time event hours in the first nine months of 2025. In Table 11-33, the constraints are presented in descending order of absolute value of day-ahead event hour changes plus real-time event hour changes from the first nine months of 2024 to the first nine months of 2025.

Top Constraints

The top five constraints by congestion costs contributed $961.4 million, or 43.0 percent, of the total PJM congestion costs in the first nine months of 2025. The top five constraints were the Pleasant View Transformer, the Lenox – North Meshoppen Line, the Pleasant View – Ashburn Line, the Goose Creek Transformer, and the Ashburn – Goose Creek Line. Table 11-34 and Table 11-35 show the top constraints contributing to congestion costs by facility for the first nine months of 2025 and 2024.

The Pleasant View Transformer was the largest contributor to congestion costs in the first nine months of 2025 with $286.5 million and 12.8 percent of total PJM congestion costs.

The Lenox – North Meshoppen Line was the second largest contributor to congestion costs in the first nine months of 2025 with $201.2 million and 9.0 percent of total PJM congestion costs. The day-ahead congestion event hours of the Lenox – North Meshoppen Line increased from 1,180 in the first nine months of 2024 to 4,601 in the first nine months of 2025 and the real-time congestion event hours of the Lenox – North Meshoppen Line increased from 988 in the first nine months of 2024 to 3,890 in the first nine months of 2025 (Table 11-32).

The Pleasant View – Ashburn Line was the third largest contributor to congestion costs in the first nine months of 2025 with $185.9 million and 8.3 percent of the total PJM congestion costs. The day-ahead congestion event hours of the Pleasant View – Ashburn Line increased from 515 in the first nine months of 2024 to 882 in the first nine months of 2025 and the real-time congestion event hours of the Pleasant View – Ashburn Line increased from 150 in the first nine months of 2024 to 169 in the first nine months of 2025 (Table 11-32).

The Goose Creek Transformer was the fourth largest contributor to congestion costs in the first nine months of 2025 with $168.9 million and 7.6 percent of the total PJM congestion costs.

The Ashburn – Goose Creek Line was the fifth largest contributor to congestion costs in the first nine months of 2025 with $118.9 million and 5.3 percent of the total PJM congestion costs.

The AEP – DOM Interface was the largest contributor to negative congestion costs in the first nine months of 2025. The constraint accounted for 28.5 percent of the total balancing congestion costs in the first nine months of 2025.

Table 11-34 Top 25 constraints affecting congestion costs: January through September, 2025[29]

Comparing Figure 11-8 (Location of the top 10 constraints by balancing congestion costs) and Figure 11-9 (Location of the top 10 constraints by day-ahead congestion costs) shows the significant differences between the day-ahead and real-time markets.

Congestion Event Summary: Impact of Changes in UTC Volumes

UTCs have a significant impact on congestion events in the day-ahead market and, as a result, contribute to differences between day-ahead and real-time congestion events. The greater the volume of UTCs, the greater the number of congestion events in the day-ahead market and the greater the differences between the day-ahead and real-time congestion events.[31]

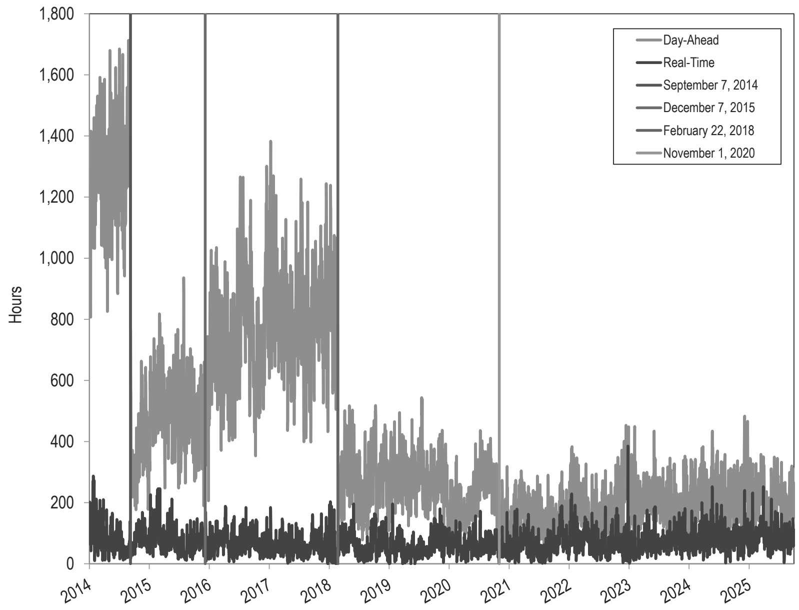
In the first nine months of 2025, the average hourly cleared UTC MW decreased by 10.1 percent, compared to in the first nine months of 2024. Day-ahead congestion event hours decreased by 1.9 percent from 57,459 congestion

31 A series of FERC orders has affected UTC activity which has in turn affected congestion events in the day-ahead market. See Appendix F: Congestion and Marginal Losses.

event hours in the first nine months of 2024 to 56,377 congestion event hours in the first nine months of 2025 (Table 11-26).

Figure 11-10 shows the daily day-ahead and real-time congestion event hours for January 2014 through September 2025.

Figure 11-10 Daily congestion event hours: January 2014 through September 2025



Marginal Losses

Marginal Loss Accounting

Marginal losses occur in the day-ahead and real-time energy markets. PJM calculates marginal loss costs for each PJM member. The loss cost is based on the applicable day-ahead and real-time marginal loss component of LMP (MLMP). Losses are the difference between what load (withdrawals) pay for energy and what generation (injections) are paid for energy, due to transmission line losses.

Losses increase with distance between sources and sinks and the amount of power moved. Total loss collected (loss surplus) increases with load, holding distance and resistance constant. Every incremental increase in load has to be met with a slightly larger increment of generation. The result is that the total energy losses increase as load increases.

Ignoring interchange, total generation MWh must be greater than total load MWh in any hour in order to provide for losses. Total marginal loss costs, analogous to total congestion costs, are equal to the net of the withdrawal loss charges minus injection loss credits, plus explicit loss charges, incurred in both the day-ahead energy market and the balancing energy market.

Total marginal loss costs can be more accurately thought of as net marginal loss costs. Total marginal loss costs equal implicit marginal loss charges plus explicit marginal loss charges plus net inadvertent loss charges. Implicit marginal loss charges equal withdrawal loss charges minus injection loss credits. Net explicit marginal loss costs are the net marginal loss costs associated with point to point energy transactions. Net inadvertent loss charges are the losses associated with the hourly difference between the net actual energy flow and the net scheduled energy flow into or out of the PJM control area.[32] Unlike the other categories of marginal loss accounting, inadvertent loss charges are costs not directly attributable to specific participants. Inadvertent loss charges are assigned to participants based on real-time load (excluding losses) ratio share.[33] Each of these categories of marginal loss costs is comprised of day-ahead and balancing marginal loss costs.

32 PJM Operating Agreement Schedule 1 §3.7.
33 *Id.*

The accounting definitions can be misleading. Load pays losses. Losses are the difference between what load pays for energy and what generation is paid for energy due to losses. Generation does not pay losses. Some generation receives a price lower than SMP and some generation receives a price greater than SMP due to the MLMP but that does not mean that generation is paying or being paid losses. It means that generation is being paid an LMP that is higher or lower than the system load-weighted, average LMP due to losses on the system.

While PJM accounting focuses on MLMPs, the individual MLMP values at any bus are irrelevant to the calculation of total losses. Total losses are the net surplus revenue that remains after all sources and sinks are credited or charged their LMPs. Changing the components of LMP by electing a different reference bus does not change the LMPs or the difference between LMPs for a given market solution or losses, it merely changes the components of the LMP.

The MLMP component of LMP is the marginal cost of energy, due to losses associated with serving load at the bus. The MLMP at the load-weighted reference bus is the marginal cost of energy at the load-weighted reference bus (holding the proportion of load at every bus constant). Due to losses, MLMP is non zero at the load reference bus. The LMP at the load reference bus is the system marginal price of energy (SMP) plus the marginal cost of energy due to losses at the reference bus.

Load-weighted LMP components are calculated relative to a load-weighted, average LMP. LMPs at specific load buses will reflect the fact that marginal generators must produce more (or less) energy due to losses to serve that bus than is needed to serve the load weighted reference bus. The LMP at any bus is a function of the SMP, losses and congestion. Relative to the system marginal price (SMP) at the load weighted reference bus, the loss factor can be either positive or negative.

At the load-weighted reference bus, the LMP includes no congestion component, but does include a loss component. The load weighted average MLMP across all load buses, calculated relative to that reference bus is positive. The LMPs at the load buses are a function of marginal generation bus LMPs determined through the least cost security constrained economic dispatch which accounts for transmission constraints and marginal losses.

Other than the effect on the optimal dispatch point, LMP at the marginal generator bus, and therefore the payment to the generator, is not affected by marginal losses. By paying for losses based on marginal instead of average losses at the load bus, a revenue over collection occurs.

The residual difference between total marginal loss related load charges (day-ahead and balancing) and marginal loss related generation credits (day-ahead and balancing) after virtual bids have settled their marginal loss related credits and charges for their day-ahead and balancing positions is total loss. That is, losses are the difference between what withdrawals (load) are paying for energy and what injections (generation) are being paid for energy due to losses, after virtual bids marginal loss related charges and credits are settled at the end of the market day. Load is the source of the net loss surplus after generation is paid and virtuals are settled at the end of the market day. Load pays losses. Generation does not pay losses.

Day-ahead marginal loss costs are based on day-ahead MWh priced at the marginal loss price component of LMP. Balancing marginal loss costs are based on the load or generation deviations between the day-ahead and real-time energy markets priced at the marginal loss price component of LMP in the real-time energy market. If a participant has real-time generation or load that is greater than its day-ahead generation or load then the deviation will be positive. If there is a positive load deviation at a bus where the real-time LMP has a positive marginal loss component, positive balancing marginal loss costs will result. Similarly, if there is a positive load deviation at a bus where real-time LMP has a negative marginal loss component, negative balancing marginal loss costs will result. If a participant has real-time generation or load that is less than its day-ahead generation or load then the deviation will be negative. If there is a negative load deviation at a bus where real-time LMP has a positive marginal loss component, negative balancing marginal loss costs will result. Similarly, if there is a negative load deviation at a bus where real-time LMP has a negative marginal loss component, positive balancing marginal loss costs will result.

The total marginal loss surplus is the remaining loss amount from collection of marginal losses, after accounting for total system energy costs and net residual market adjustments. The marginal loss surplus is allocated to PJM market participants based on real-time load plus export ratio share as marginal loss credits.[34]

Day-Ahead Implicit Load MLMP Charges

- **Day-Ahead Implicit Load MLMP Charges.** Day-ahead implicit load MLMP charges are calculated for all cleared demand, decrement bids and day-ahead energy market sale transactions. Day-ahead implicit load MLMP charges are calculated using MW and the load bus MLMP, the decrement bid MLMP or the MLMP at the source of the sale transaction.
- **Day-Ahead Implicit Generation MLMP Credits.** Day-ahead implicit generation MLMP credits are calculated for all cleared generation and increment offers and day-ahead energy market purchase transactions. Day-ahead implicit generation MLMP credits are calculated using MW and the generator bus MLMP, the increment offer MLMP or the MLMP at the sink of the purchase transaction.
- **Balancing Implicit Load MLMP Charges.** Balancing implicit load MLMP charges are calculated for all deviations between a PJM member's real-time load and energy sale transactions and their day-ahead cleared demand, decrement bids and energy sale transactions. Balancing implicit load MLMP charges are calculated using MW deviations and the real-time MLMP for each bus where a deviation exists.
- **Balancing Implicit Generation MLMP Credits.** Balancing implicit Generation MLMP credits are calculated for all deviations between a PJM member's real-time generation and energy purchase transactions and the day-ahead cleared generation, increment offers and energy purchase transactions. Balancing implicit Generation MLMP credits are calculated using MW deviations and the real-time MLMP for each bus where a deviation exists.
- **Explicit Loss Charges.** Explicit loss charges are the net loss costs associated with point to point energy transactions, including UTCs. These costs equal the product of the transacted MW and MLMP differences between sources (origins) and sinks (destinations) in the day-ahead energy market. Balancing energy market explicit loss costs equal the product of the differences between the real-time and day-ahead transacted MW and the differences between the real-time MLMP at the transactions' sources and sinks.
- **Inadvertent Loss Charges.** Inadvertent loss charges are the net loss charges resulting from the differences between the net actual energy flow and the net scheduled energy flow into or out of the PJM control area each hour. This inadvertent interchange of energy may be positive or negative, where positive interchange typically results in a charge while negative interchange typically results in a credit. Inadvertent loss charges are common costs, not directly attributable to specific participants, which are distributed on a load plus export ratio basis.[35]

Total Marginal Loss Cost

Total marginal loss is the difference between what withdrawals (load) pay for energy and what injections (generation) are paid for energy due to losses, after generation is paid and virtuals' marginal loss related charges and credits are settled. Load pays losses.

The total marginal loss cost in PJM for the first nine months of 2025 was $1,095.5 million, which was comprised of implicit withdrawal MLMP charges of $67.5 million minus implicit injection MLMP credits of -$1,037.4 million plus explicit loss charges of -$9.4 million plus inadvertent loss charges of $0.0 million (Table 11-37).

Monthly marginal loss costs in the first nine months of 2025 ranged from $74.9 million in May to $222.8 million in January. Total marginal loss surplus increased in the first nine months of 2025 by $146.7 million or 56.8 percent from $258.5 million in the first nine months of 2024 to $405.2 million in the first nine months of 2025.

Table 11-36 shows the total marginal loss component costs and the total PJM billing for January through September, 2008 through 2025.

34 See PJM. "Manual 28: Operating Agreement Accounting," Rev. 98 (December 17, 2024).

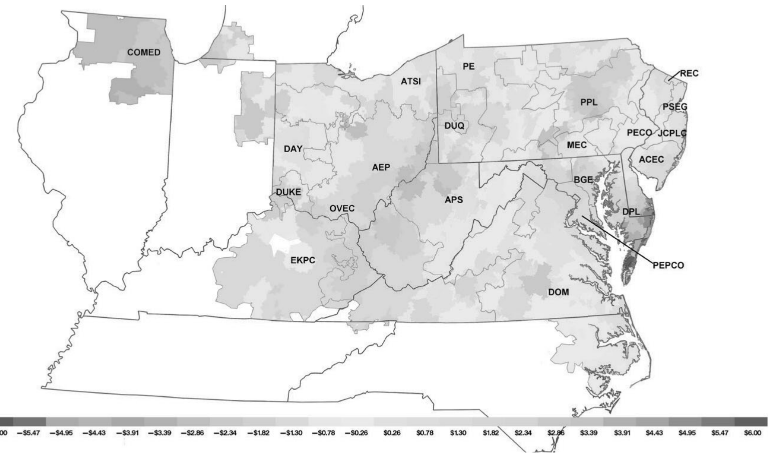
Total marginal loss is the difference between what withdrawals (load) pay for energy and what injections (generation) are paid for energy due to losses, after generation is paid and virtuals' marginal loss related charges and credits are settled. Load pays losses. This figure shows the contour map of the day-ahead, load-weighted average MLMP in the first nine months of 2025.

Figure 11-11 Contour map of the day-ahead, load-weighted average MLMP: January through September 2025



Total marginal loss is the difference between what withdrawals (load) pay for energy and what injections (generation) are paid for energy due to losses, after generation is paid and virtuals' marginal loss related charges and credits are settled. Load pays losses. This figure shows the contour map of the real-time, load-weighted average MLMP in the first nine months of 2025.

36 The loss costs include net inadvertent charges.
37 In Table 11-36, the MMU uses Total PJM Billing values provided by PJM. For 2019 and after, the MMU has modified the Total PJM Billing calculation to better reflect historical PJM total billing through the PJM settlement process.

Figure 11-12 Contour map of the real-time, load-weighted average MLMP: January through September 2025

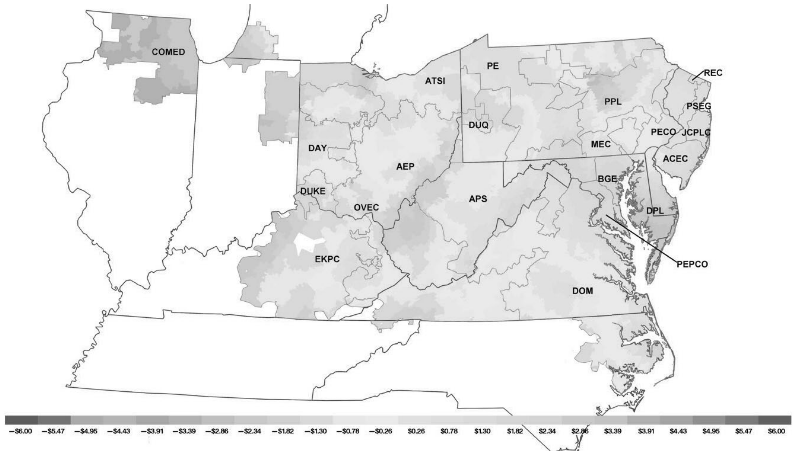


Table 11-37 shows PJM total marginal loss costs by accounting category for January through September, 2008 through 2025. Table 11-38 shows PJM total marginal loss costs by accounting category by market for January through September, 2008 through 2025.

Table 11-37 Total marginal loss costs by accounting category (Dollars (Millions)): January through September, 2008 through 2025

Table 11-39 and Table 11-40 show PJM accounting based total loss costs for each transaction type in the first nine months of 2025 and 2024.

Virtual transaction loss costs, when positive, measure the total loss costs to virtual transactions and when negative, measure the total loss credits to virtual transactions. In the first nine months of 2025, DECs were paid $6.6 million in MLMP credits in the day-ahead market, paid $10.0 million in MLMP in the balancing energy market and paid $3.3 million in total MLMP charges. In the first nine months of 2025, INCs paid $33.9 million in MLMP charges in the day-ahead market, were paid $38.0 million in MLMP credits in the balancing energy market and were paid $4.0 million in total MLMP credits. In the first nine months of 2025, up to congestion paid $48.4 million in MLMP charges in the day-ahead market, were paid $55.0 million in MLMP credits in the balancing energy market and received $6.6 million in total MLMP credits.

Marginal Loss Costs and Loss Credits

Total marginal loss surplus is calculated by adding the total system energy costs (which are negative), the total marginal loss costs (which are positive) and net residual market adjustments (which can be net positive or negative). The total system energy costs are equal to the net implicit energy charges (implicit withdrawal charges minus implicit injection credits) plus net inadvertent energy charges. Total marginal loss costs are equal to the net implicit marginal loss charges (implicit load MLMP charges less implicit generation MLMP credits) plus net explicit loss charges plus net inadvertent loss charges.

Ignoring interchange, total generation MWh must be greater than total load MWh in any hour in order to provide for losses. Since the hourly integrated energy component of LMP is the same for every bus within every hour, the net energy bill is negative (ignoring net interchange), with more injection credits than withdrawal charges in every hour. The greater the level of load the greater the difference between energy charges collected from load (SMP x load MW) and credited to generation (SMP x generation MW). Total system energy costs plus total marginal loss costs plus net residual market adjustments equal marginal loss credits which are distributed to the PJM market participants according to the ratio of their real-time load plus their real-time exports to total PJM real-time load plus real-time exports as marginal loss credits. The net residual market adjustment is calculated as known day-ahead error value minus day-ahead loss MW congestion value and minus balancing loss MW congestion value.

Table 11-44 shows the total system energy costs, the total marginal loss costs collected, the net residual market adjustments and total marginal loss surplus redistributed for January through September, 2008 through 2025. The total marginal loss surplus increased by $146.7 million or 56.8 percent in the first nine months of 2025 from the first nine months of 2024.

Table 11-44 Marginal loss surplus (Dollars (Millions)): January through September, 2008 through 2025[38]

Marginal Loss Surplus (Millions)						
			Net Residual Market Adjustments			
(Jan - Sep)	System Energy Cost	Marginal Loss Costs	Known Day-Ahead Error	Day-Ahead Loss MW Congestion	Balancing Loss MW Congestion	Total Marginal Loss Surplus
2008	($976.0)	$2,048.9	$0.0	$0.0	$0.0	$1,073.0
2009	($484.6)	$992.4	($0.0)	($0.4)	($0.1)	$508.3
2010	($618.6)	$1,259.3	$0.0	($0.6)	($0.1)	$641.5
2011	($651.3)	$1,152.6	$0.1	$1.3	($0.0)	$500.1
2012	($442.6)	$757.6	$0.1	($0.7)	$0.0	$315.7
2013	($527.2)	$797.0	$0.0	$1.7	$0.0	$268.0
2014	($833.9)	$1,243.1	($0.0)	$5.1	$0.1	$404.1
2015	($536.5)	$829.8	($0.3)	$4.7	($0.1)	$288.3
2016	($358.3)	$541.9	$0.0	$2.8	($0.2)	$181.0
2017	($344.0)	$501.0	$0.0	$0.7	($0.1)	$156.5
2018	($498.7)	$757.0	($0.0)	$1.9	($0.1)	$256.4
2019	($339.3)	$502.7	($0.0)	$1.3	($0.1)	$162.1
2020	($234.0)	$349.2	($0.0)	$1.1	($0.1)	$114.2
2021	($430.7)	$670.2	($0.0)	$2.5	($0.1)	$237.0
2022	($979.1)	$1,472.0	($0.0)	$5.6	($0.2)	$487.6
2023	($384.6)	$588.5	($0.0)	$1.3	($0.2)	$202.7
2024	($434.8)	$695.2	($0.0)	$2.1	($0.2)	$258.5
2025	($688.2)	$1,095.5	$0.0	$2.2	$0.0	$405.2

38 The net residual market adjustments included in the table are comprised of the known day-ahead error value minus the sum of the day-ahead loss MW congestion value, balancing loss MW congestion value and measurement error caused by missing data.

System Energy Costs

Energy Accounting

The system energy component of LMP is the system reference bus LMP, also called the system marginal price (SMP). The system energy cost is based on the day-ahead and real-time energy components of LMP. Total system energy costs, analogous to total congestion costs or total loss costs, are equal to the withdrawal energy charges minus injection energy credits, in both the day-ahead energy market and the balancing energy market, plus net inadvertent energy charges. Total system energy costs can be more accurately thought of as net system energy costs. Due to line losses associated with moving energy from generation to load, more energy is injected by generation than is withdrawn by load. Total system energy charges are negative because there are, due to losses, more generation MW being paid SMP (energy component of price) than load MW paying SMP (the energy component of price).

Total System Energy Costs

The total system energy cost for the first nine months of 2025 was -$688.2 million, which was comprised of implicit withdrawal energy charges of $45,181.2 million, implicit injection energy credits of $45,863.1 million, explicit energy charges of $0.0 million and inadvertent energy charges of -$6.2 million. The monthly system energy costs for the first nine months of 2025 ranged from -$137.8 million in January to -$46.4 million in May. Table 11-45 shows total system energy costs and total PJM billing, for January through September, 2008 through 2025.

Table 11-45 Total system energy costs (Dollars (Millions)): January through September, 2008 through 2025[39 40]

(Jan - Sep)	System Energy Costs	Percent Change	Total PJM Billing	Percent of PJM Billing
2008	($976)	NA	$26,979	(3.6%)
2009	($485)	(50.3%)	$19,927	(2.4%)
2010	($619)	27.6%	$26,249	(2.4%)
2011	($651)	5.3%	$28,836	(2.3%)
2012	($443)	(32.0%)	$22,119	(2.0%)
2013	($527)	19.1%	$25,153	(2.1%)
2014	($834)	58.2%	$40,770	(2.0%)
2015	($537)	(35.7%)	$33,710	(1.6%)
2016	($358)	(33.2%)	$29,490	(1.2%)
2017	($344)	(4.0%)	$29,510	(1.2%)
2018	($499)	45.0%	$37,950	(1.3%)
2019	($339)	(32.0%)	$31,850	(1.1%)
2020	($234)	(31.0%)	$27,070	(0.9%)
2021	($431)	84.0%	$37,520	(1.1%)
2022	($979)	127.3%	$66,110	(1.5%)
2023	($385)	(60.7%)	$36,380	(1.1%)
2024	($435)	13.1%	$39,070	(1.1%)
2025	($688)	58.3%	$57,770	(1.2%)

System energy costs for January through September, 2008 through 2025 are shown in Table 11-46 and Table 11-47. Table 11-46 shows PJM system energy costs by accounting category and Table 11-47 shows PJM system energy costs by market category.

39 The system energy costs include net inadvertent charges.
40 In Table 11-45, the MMU uses Total PJM Billing values provided by PJM. For 2019 and after, the MMU has modified the Total PJM Billing calculation to better reflect historical PJM total billing through the PJM settlement process.

Table 11-46 Total system energy costs by accounting category (Dollars (Millions)): January through September, 2008 through 2025

	System Energy Costs (Millions)				
(Jan - Sep)	Implicit Withdrawal Charges	Implicit Injection Credits	Explicit Charges	Inadvertent Charges	Total

Figure 11-14 shows PJM monthly system energy costs for January 2008 through September 2025. Ignoring interchange, total generation MWh must be greater than total load MWh in any hour in order to provide for losses. Since the hourly integrated energy component of LMP (SMP) is the same for every bus in the market in every hour, the net energy bill is always negative (ignoring net interchange): (SMP x withdrawals + SMP x injections) < 0. Assuming power balance is maintained in the presence of losses, the greater the level of load the greater the difference between energy charges collected from load (SMP x load MW) and credited to generation (SMP x generation MW). With higher load levels, there are generally higher SMPs and more negative total energy charges.

Figure 11-14 Monthly system energy costs (Millions): January 2008 through September 2025

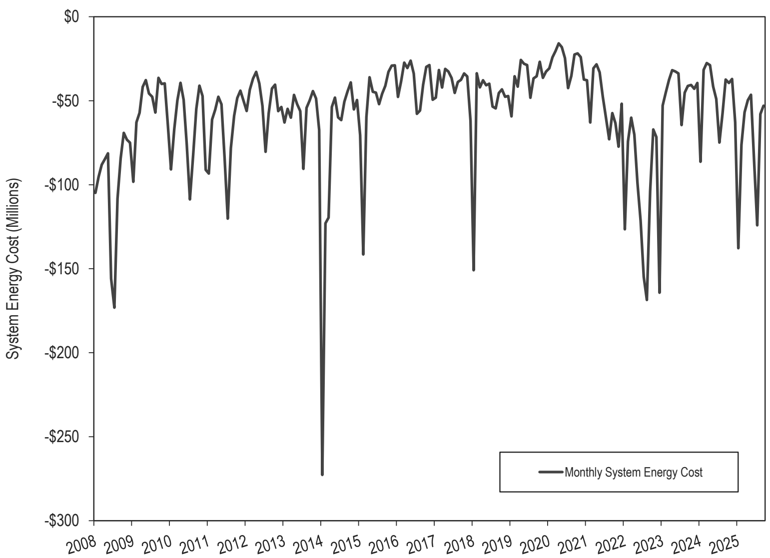

Table 11-52 shows the monthly total system energy costs for each virtual transaction type in the first nine months of 2025 and 2024. In the first nine months of 2025, DECs paid $1,779.9 million in energy charges compared to $1,222.0 million in the first nine months of 2024 in the day-ahead market, were paid $1,805.7 million in energy credits compared to $1,248.2 million in the first nine months of 2024 in the balancing energy market and paid $25.9 million in total energy charges compared to $26.3 million in total energy credits in the first nine months of 2024. In the first nine months of 2025, INCs were paid $1,628.2 million in energy credits compared to $1,005.0 million in the first nine months of 2024 in the day-ahead market, paid $1,643.3 million in energy charges compared to $1,029.2 million in the first nine months of 2024 in the balancing market and were paid $10.7 million in total energy credits compared to $2.1 million in total energy charges in the first nine months of 2024. The system energy costs are zero for UTCs because the system energy costs for UTCs equal the difference in the energy component between source and sink and the energy component is the same at all buses.

Table 11-52 Monthly energy charges by virtual transaction type (Dollars (Millions)): January 2024 through September 2025

		Energy Charges (Millions)						
		DEC			INC			
Year		Day-Ahead	Balancing	Total	Day-Ahead	Balancing	Total	Grand Total
2024	Jan	$185.4	($164.2)	$21.2	($151.0)	$135.1	($15.9)	$5.3

Generation and Transmission Planning[1]

Overview

Generation Interconnection Planning

Existing Generation Mix

- As of September 30, 2025, PJM had a total installed capacity of 200,952.5 MW, of which 38,366.4 MW (19.1 percent) are coal fired steam units, 57,064.2 MW (28.4 percent) are combined cycle units and 33,452.6 MW (16.6 percent) are nuclear units. This measure of installed capacity differs from capacity market installed capacity because it includes energy only units, excludes all external units, and uses nameplate values for solar and wind resources.
- Of the 200,952.5 MW of installed capacity, 72,221.3 MW (35.9 percent) are from units older than 40 years, of which 30,814.3 MW (42.7 percent) are coal fired steam units, 255.0 MW (0.4 percent) are combined cycle units and 25,550.6 MW (35.4 percent) are nuclear units.

Generation Retirements[2]

- As of September 30, 2025, there were 64,079.0 MW of generation that have been, or are planned to be, retired between 2011 and 2030, of which 46,526.8 MW (72.6 percent) are coal fired steam units.
- In the first nine months of 2025, 981.8 MW of generation retired. The largest generator that retired in the first nine months of 2025 was the 410.0 MW Indian River 4 coal fired steam unit located in the DPL Zone. Of the 981.8 MW of generation that retired in the first nine months of 2025, 410.0 MW (41.8 percent) were located in the DPL Zone.
- As of September 30, 2025, there were 8,351.9 MW of generation that have requested retirement after September 30, 2025, of which 2,620.0 MW (31.4 percent) are located in the AEP Zone. Of the generation requesting retirement in the AEP Zone, 2,620.0 MW (100.0 percent) are coal fired steam units.

1 Totals presented in this section include corrections to historical data and may not match totals presented in previous reports.
2 See PJM. Planning. "Generator Deactivations," (Accessed on September 30, 2025) <https://www.pjm.com/planning/service-requests/gen-deactivations>.

Generation Queue

New Service Requests Serial Process[3]

- On November 29, 2022, the Commission issued an order accepting PJM's tariff revisions to improve the queue process.[4] The new queue process includes modifications to implement a cluster/cycle based processing method to replace the first in/first out serial processing method.[5] This change will allow projects to move forward based on a first ready/first out analysis, where readiness is demonstrated through site control and financial milestones and there is an option to exit the study process early based on system impacts. The transition to the new queue process began on July 10, 2023.
- There were 8,190 generation request projects submitted in the new service request serial process queue from 1997 until the implementation of the new cycle process on July 10, 2023. As a result of the transition to the new services cycle process, 312 projects were moved to transition cycle 1 (TC1). There were 1,347 projects eligible to resubmit for evaluation in transition cycle 2 (TC2). Of those 1,347 eligible projects, 550 projects resubmitted and are now being evaluated in TC2. Of the 1,347 eligible projects, 797 projects did not resubmit, and were withdrawn from the queue. There were 1,070 projects initially entered into the AH2 queue and beyond. Those 1,070 projects are now considered invalid and have been removed from the queue. As a result of the transition to the cycle process, the 8,190 projects in the serial process queue have been reduced to 5,461 projects. Projects that will be evaluated in TC1 and TC2, and those projects no longer eligible to be evaluated in the serial process have been removed from the new service requests serial process metrics. New service requests cycle process metrics are reported separately from the serial process metrics.
- As of September 30, 2025, a total of 43,634.4 MW, on an energy basis, were in generation request serial service queues in the status of active,

3 See PJM. Planning. "Serial Service Request Status," (Accessed on September 30, 2025) <https://www.pjm.com/planning/service-requests/serial-service-request-status>.
4 See 181 FERC ¶ 61,162 (2022).
5 See "Interconnection Process Reform," presented at April 27, 2022 meeting of the Members Committee. <https://www.pjm.com/-/media/committees-groups/committees/mc/2022/20220427/20220427-item-01a-1-interconnection-process-reform-presentation.ashx>.

under construction or suspended.[6] Based on historical completion rates, 23,288.8 MW (53.4 percent), on an energy basis, of new generation in the queue are expected to go into service. As projects move through the queue process, projects can be removed from the queue due to incomplete or invalid data, withdrawn by the market participant or placed in service.

- Of the 4,158.8 MW, on an energy basis, of combined cycle projects in the serial queue, 2,958.5 MW (71.1 percent) are expected to go in service based on historical completion rates as of September 30, 2025.
- Of the 3,426.1 MW, on an energy basis, of battery projects in the serial queue, only 931.2 MW (27.2 percent) are expected to go in service based on historical completion rates as of September 30, 2025.
- Of the 34,851.8 MW, on an energy basis, of renewable projects in the serial queue, 18,564.5 MW (53.3 percent) are expected to go in service based on historical completion rates as of September 30, 2025.
- Of the 3,949.1 MW, on a capacity basis that requested CIRs, of combined cycle projects requested in the generation serial queues in the status of active, under construction or suspended, 2,777.1 MW (70.3 percent) are expected to go into service based on historical completion rates. Based on historical completion rates and the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction,[7] the 3,949.1 MW of capacity requests currently under construction, suspended or active in the serial queue would be reduced to 2,055.1 MW of capacity (52.0 percent of the total requested capacity).[8]
- Of the 2,232.3 MW, on a capacity basis that requested CIRs, of battery projects requested in the generation serial queues in the status of active, under construction or suspended, 161.5 MW (7.2 percent) are expected to go into service based on historical completion rates. Based on historical completion rates and the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction, the 2,232.3 MW of capacity requests currently under construction, suspended or active in the serial queue would be reduced to 93.7 MW of capacity (4.2 percent of the total requested capacity).
- Of the 18,186.8 MW, on a capacity basis that requested CIRs, of renewable projects requested in the serial generation queues in the status of active, under construction or suspended, 9,797.0 MW (53.9 percent) are expected to go into service based on historical completion rates. Based on historical completion rates and the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction, the 18,186.8 MW of capacity requests currently under construction, suspended or active in the serial queue would be reduced to 965.8 MW of capacity (5.3 percent of the total requested capacity).
- As of September 30, 2025, 25,603.7 MW of capacity requests (requested CIRs) were in the generation serial queues in the status of active, under construction or suspended. Based on historical completion rates, 13,565.8 MW (53.0 percent) are expected to go into service. Based on historical completion rates and the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction, the 25,603.7 MW of capacity requests currently under construction, suspended or active in the serial queue would be reduced to 3,631.5 MW of capacity (14.2 percent of the total requested capacity).
- As of September 30, 2025, 5,461 projects, representing 609,132.6 MW, have entered the serial queue process since its inception. Of those, 1,267 projects, representing 93,774.7 MW (15.4 percent of the MW), went into service. Of the projects that entered the serial queue process, 3,734 projects, representing 471,723.5 MW (77.4 percent of the MW) withdrew prior to completion. Such projects may create barriers to entry for projects that would otherwise be completed, by taking up queue positions, increasing interconnection costs and creating uncertainty.
- In the first nine months of 2025, 2,117.1 MW from the serial queue went into service. Of the 2,117.1 MW that went in service, 1,883.2 MW (89.0 percent) were solar units, 150.0 MW (7.1 percent) were solar + storage

6 Unless otherwise noted, the queue totals in this report are the winter net MW energy for the interconnection requests ("MW Energy") as shown in the queue.
7 Unless otherwise noted, the ELCC derate factors in this section are based on the *ELCC Class Ratings for 2027/2028 Base Residual Auction*, PJM Interconnection L.L.C. (August 1, 2025) <https://www.pjm.com/-/media/DotCom/planning/res-adeq/elcc/2027-28-bra-elcc-class-ratings.pdf>.
8 Unless otherwise noted, the ELCC derate adjusted MW are calculated using the 2027/2028 Base Residual Auction ELCC factors. The adjusted MW are calculated using the four hour storage ELCC derate for battery resources, tracking solar for solar resources and onshore wind for wind resources.

units, 54.9 MW (2.6 percent) were wind units and 29.0 MW (1.3 percent) were coal fired steam units.

- The number of serial queue entries increased during the past several years, primarily renewable projects. Of the 2,809 projects that entered the serial queue from January 1, 2015, through July 10, 2023, 2,062 projects (73.4 percent) were renewable. Of the 690 projects that entered the serial queue in 2020, 545 projects (79.0 percent) were renewable. Renewable projects make up 85.9 percent of all projects in the serial queue and account for 79.9 percent of the nameplate MW currently active, suspended or under construction in the serial queue as of September 30, 2025.
- On September 30, 2025, 31,841.9 MW, on an energy basis, were in generation request serial queues that had reached the construction service agreement milestone or equivalent, in the status of active, suspended or under construction. Of the 31,841.9 MW, 12,683.3 MW (39.8 percent) had not begun construction, 9,873.5 MW (31.0 percent) had begun construction, but are now suspended, and 9,285.2 MW (29.2 percent) are currently under construction. Reaching the final milestone required prior to construction does not mean a project will immediately begin construction or even that it necessarily will ever begin construction.

New Service Requests Cycle Process[9]

Transition Cycle 1 (TC1)

- Transition cycle 1 (TC1) is comprised of 312 proposed generation projects. Those projects make up 40,650.2 MW. On September 30, 2025, all projects in TC1 were either in the status of active or were withdrawn from the cycle. Of the 40,650.2 MW in TC1, 17,873.8 MW (44.0 percent) were active and 22,776.3 MW (56.0 percent) were withdrawn.
- On September 30, 2025, there were 17,873.8 MW, on an energy basis, of which 8,854.3 MW are on a capacity basis that requested CIRs, in TC1 in the status of active.
- Of the 8,854.3 MW, on a capacity basis that requested CIRs in TC1 in the status of active, 2,152.8 MW (24.3 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.
- Of the 5,082.0 MW, on a capacity basis that requested CIRs, of solar projects requested in TC1 in the status of active, 406.6 MW (8.0 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.
- Of the 1,565.3 MW, on a capacity basis that requested CIRs, of battery projects requested in TC1 in the status of active, 907.9 MW (58.0 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.
- Of the 6,720.0 MW, on a capacity basis that requested CIRs, of renewable projects requested in TC1 in the status of active, 897.9 MW (13.4 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.

Transition Cycle 2 (TC2) and Reliability Resource Initiative (RRI)

- On December 13, 2024, PJM submitted modifications to its Open Access Transmission Tariff to add provisions, through a one-time reliability based expansion of the projects in TC2.[10] On February 11, 2025, the Commission approved the RRI tariff modifications.[11] The proposed RRI Tariff revisions created a second TC2 application window that enabled RRI projects to join TC2 and be studied for interconnection during the transition period.
- PJM received 97 applications (28.6 GW) of RRI projects during the RRI application window. Of these projects, 48 involve uprates, in which existing resources are modified to increase the economic maximum generation capability, and 49 propose building new generation. PJM reviewed the submitted RRI projects using the Commission approved scoring criteria, and approved 51 projects (11,577.4 MW).[12] On September 30, 2025, all RRI projects were either in the status of active or withdrawn from the cycle.

9 See PJM. Planning. "Cycle Service Request Status," (Accessed on September 30, 2025) <https://www.pjm.com/planning/m/cycle-service-request-status>.

10 See *PJM Interconnection L.L.C.* Docket No. ER25-712 (December 13, 2024).

11 190 FERC ¶ 61,084 (February 11, 2025).

12 The RRI proposal was to select the top 50 projects using the approved scoring criteria. The implemented scoring criteria resulted in a tie for the 50th project. This resulted in PJM selecting 51 projects as part of the RRI process.

Of the 11,577.4 MW of approved RRI projects, 10,938.4 MW (94.5 percent) were active and 639.0 MW (5.5 percent) were withdrawn.

- Transition cycle 2 (TC2) is comprised of 647 proposed generation projects. TC2 includes 550 projects submitted during the TC2 window, and 97 projects submitted through the RRI window. Those projects make up 78,329.4 MW. On September 30, 2025, all projects in TC2 were either in the status of active or were withdrawn from the cycle. Of the 78,329.4 MW in TC2, 45,977.6 MW (58.7 percent) were active and 32,351.8 MW (41.3 percent) were withdrawn.
- On September 30, 2025, there were 45,977.6 MW, on an energy basis, of which 32,120.8 MW are on a capacity basis that requested CIRs, in TC2 in the status of active.
- Of the 32,120.8 MW, on a capacity basis that requested CIRs in TC2 in the status of active, 14,167.2 MW (44.1 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.
- Of the 10,051.8 MW, on a capacity basis that requested CIRs, of solar projects requested in TC2 in the status of active, 804.1 MW (8.0 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.
- Of the 7,400.0 MW, on a capacity basis that requested CIRs, of battery projects requested in TC2 in the status of active, 4,292.0 MW (58.0 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.
- Of the 13,167.0 MW, on a capacity basis that requested CIRs, of renewable projects requested in TC2 in the status of active, 1,146.4 MW (8.7 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.

Cycle Process Totals[13]

- On September 30, 2025, there were 959 proposed generation projects in the new services cycle process queues. Those projects make up 118,979.6 MW. On September 30, 2025, all projects in the cycle process queues were either in the status of active or were withdrawn. Of the 118,979.6 MW in the cycle process queues, 63,851.5 MW (53.7 percent) were active and 55,128.1 MW (46.3 percent) were withdrawn.
- On September 30, 2025, there were 63,851.5 MW, on an energy basis, of which 40,975.1 MW are on a capacity basis that requested CIRs, in cycle process queues in the status of active.
- Of the 40,975.1 MW, on a capacity basis that requested CIRs in the cycle process queues in the status of active, 16,320.0 MW (39.8 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.
- Of the 15,133.8 MW, on a capacity basis that requested CIRs, of solar projects requested in cycle process queues in the status of active, 1,210.7 MW (8.0 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.
- Of the 8,965.3 MW, on a capacity basis that requested CIRs, of battery projects requested in cycle process queues in the status of active or under construction, 5,199.9 MW (58.0 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.
- Of the 19,887.0 MW, on a capacity basis that requested CIRs, of renewable projects requested in cycle process queues in the status of active or under construction, 2,044.2 MW (10.3 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.

13 As of September 30, 2025, the cycle process totals include those projects included in TC1 and TC2.

Regional Transmission Expansion Plan (RTEP)

Market Efficiency Process

- There are significant issues with PJM's benefit/cost analysis that should be addressed prior to approval of additional projects. If done correctly and if FTRs/ARRs returned 100 percent of congestion to load, the benefit/cost analysis would include the total net change in production costs and would not include congestion. In addition, PJM's benefit/cost analysis includes only the decreases in costs to load and ignores the increases in costs to load associated with market efficiency projects.
- Through September 30, 2025, PJM has completed five market efficiency cycles under Order No. 1000.[14] PJM delayed the opening of the 2022/2023 Long-Term Window until the reliability violations for the 2022 Window 3 were addressed. In January 2024, PJM completed updating the 2022/2023 market efficiency base case to include the solution selected from the 2022 Window 3. No flowgates experienced historical congestion that required an open window. PJM will continue to analyze the congestion patterns as part of the 2024/2025 Market Efficiency cycle. In February 2024, PJM completed the 2024/2025 market efficiency base case. In May 2024, PJM posted the 2024/2025 Market Efficiency planning assumptions. PJM posted an updated 2024/2025 base case in July 2024, and requested stakeholder feedback by August 31, 2024. As of June 5, 2025, PJM completed its production cost simulations for the 2025 study year using existing topology and production cost simulations using the RTEP topology. As of June 5, 2025, PJM completed its production cost simulation of the 2029 study year with RTEP topology. The long term market efficiency window opened on April 11, 2025, and closed on June 10, 2025. The next step in the annual RTEP project acceleration process (RTEP market efficiency process) is to identify the specific RTEP reliability projects that reduce congestion costs in the simulation results.[15] The chosen projects will be presented in the fourth quarter of 2025.

14 See *Transmission Planning and Cost Allocation by Transmission Owning and Operating Public Utilities*, Order No. 1000, FERC Stats. & Regs. ¶ 31,323 (2011) (Order No. 1000), *order on reh'g*, Order No. 1000-A, 139 FERC ¶ 61,132 (2012).
15 See PJM Operating Agreement, Section 1.5.7 (b) and (c).

PJM MISO Interregional Market Efficiency Process (IMEP)

- PJM and MISO developed a process to facilitate the construction of interregional projects in response to the Commission's concerns about interregional coordination along the PJM-MISO seam. This process, called the Interregional Market Efficiency Process (IMEP), operates on a two year study schedule and is designed to address forward looking congestion.
- The simultaneous use for joint projects of an incorrectly defined benefit/cost method by PJM and the correct method by MISO results in an over allocation of the costs associated with joint PJM/MISO projects to PJM participants and in some cases approval of projects that do not pass a correctly defined benefit/cost test.

PJM MISO Targeted Market Efficiency Process (TMEP)

- PJM and MISO developed the Targeted Market Efficiency Process (TMEP) to facilitate the resolution of historic congestion issues that could be addressed through small, quick implementation projects.

PJM MISO Interregional Transfer Capability Study (ITCS)

- PJM and MISO developed the Interregional Transfer Capability Study (ITCS) to help identify potential transmission projects that could incrementally improve the systems' ability to mitigate constraints, improve market efficiency, respond to extreme weather and increase interregional transfer capability.

Supplemental Transmission Projects

- Supplemental projects are defined to be "transmission expansions or enhancements that are not required for compliance with PJM criteria and are not state public policy projects according to the PJM Operating Agreement. These projects are used as inputs to RTEP models, but are not required for reliability, economic efficiency or operational performance criteria, as determined by PJM."[16] Supplemental projects are exempt from competition.

- The average number of supplemental projects in each expected in service year increased by 1,110.0 percent, from 20 for years 1998 through 2007 (pre Order No. 890) to 242 for years 2008 through 2025 (post Order 890).[17]

End of Life Transmission Projects

- An end of life transmission project is a project submitted for the purpose of replacing existing infrastructure that is at, or is approaching, the end of its useful life. End of life transmission projects should be included in the RTEP process and should be subject to a transparent, robust and clearly defined mechanism to require competition to build the project. Under the current approach, end of life projects are excluded from the RTEP process and exempt from competition.

Board Authorized Transmission Upgrades

- The Transmission Expansion Advisory Committee (TEAC) reviews proposals to improve transmission reliability in PJM and between PJM and neighboring regions. These proposals, which include reliability baseline, network, market efficiency and targeted market efficiency projects, as well as scope changes and project cancellations, but exclude supplemental and end of life projects, are periodically presented to the PJM Board of Managers for authorization.[18] In the first nine months of 2025, the PJM Board approved $7.9 billion in upgrades. As of September 30, 2025, the PJM Board has approved $58.0 billion in system enhancements since 1999.

Transmission Competition

- The MMU makes several recommendations related to the competitive transmission planning process. The recommendations include improved process transparency, incorporation of competition between transmission and generation alternatives, and the removal of barriers to competition from nonincumbent transmission. These recommendations would help ensure that the process is an open and transparent process that results in the most competitive solutions.

- On May 24, 2018, the PJM Markets and Reliability Committee (MRC) approved a motion that required PJM, with input from the MMU, to develop a comparative framework to evaluate the quality and effectiveness of competitive transmission proposals with binding cost containment proposals compared to proposals from incumbent and nonincumbent transmission companies without cost containment provisions.

Qualifying Transmission Upgrades (QTU)

- A Qualifying Transmission Upgrade (QTU) is an upgrade to the transmission system, financed and built by market participants, that increases the Capacity Emergency Transfer Limit (CETL) into an LDA and can be offered into capacity auctions as capacity. Once a QTU is in service, the upgrade is eligible to continue to offer the approved incremental import capability into future RPM Auctions. As of September 30, 2025, no QTUs have cleared a Base Residual Auction or an Incremental Auction.

Transmission Facility Outages

- PJM maintains a list of reportable transmission facilities. When a reportable transmission facility needs to be taken out of service, PJM transmission owners are required to report planned transmission facility outages as early as possible. PJM processes the transmission facility outage requests according to rules in PJM's Manual 3 to decide if the outage is on time or late and whether or not they will allow the outage.[19]

- There were 11,918 transmission outage requests submitted in the first four months of the 2025/2026 planning period. Of the requested outages, 66.6 percent were planned for less than or equal to five days and 13.6 percent were planned for greater than 30 days. Of the requested outages, 31.0 percent were late according to the rules in PJM's Manual 3.

16 See PJM. "Transmission Construction Status," (Accessed on September 30, 2025) <https://www.pjm.com/planning/m/project-construction>.
17 See *Preventing Undue Discrimination and Preference in Transmission Service*, Order No. 890, 118 FERC ¶ 61,119, *order on reh'g*, Order No. 890-A, 121 FERC ¶ 61,297 (2007), *order on reh'g*, Order No. 890-B, 123 FERC ¶ 61,299 (2008), *order on reh'g*, Order No. 890-C, 126 FERC ¶ 61,228, *order on clarification*, Order No. 890-D, 129 FERC ¶ 61,126 (2009).
18 Supplemental Projects, including the end of life subset of supplemental projects, do not require PJM Board of Managers authorization.
19 See "PJM Manual 03: Transmission Operations," Rev. 68 (May 21, 2025).

Recommendations

Generation Retirements

- The MMU recommends that CIRs should end on the date of retirement in order to help ensure competitive markets and competitive access to the grid. The rules need to ensure that incumbents cannot exploit control of CIRs to block or postpone entry of competitors or to exercise market power by requiring high payments for CIRs.[20] (Priority: Medium. First reported 2013. Status: Partially adopted, 2012.)

Generation Queue

- Given the significance of data to market participants and regulators, the MMU recommends that all queue data and supplemental, network and baseline project data, including projected in service dates and estimated and final costs, be regularly updated with accurate and verifiable data. PJM does not update this data. (Priority: High. First reported 2023. Not adopted.)
- The MMU recommends that barriers to entry be addressed in a timely manner in order to help ensure that the capacity market will result in the entry of new capacity to meet the needs of PJM market participants. (Priority: Low. First reported 2012. Status: Not adopted.)
- The MMU recommends that PJM establish an expedited PJM managed queue process to identify commercially viable projects that could help eliminate or reduce the need for specific RMRs or that could address specific reliability needs and allow the identified projects to advance in the queue ahead of projects which have failed to make progress, subject to rules to prevent gaming. (Priority: High. First reported 2024. Status: Not adopted.)
- The MMU recommends improvements in queue management including that PJM establish a review process to ensure that projects are removed from the queue if they are not viable, as well as an expedited process to allow commercially viable projects to advance in the queue ahead of projects which have failed to make progress, subject to rules to prevent gaming.[21] (Priority: Medium. First reported 2013. Status: Partially adopted.)
- The MMU recommends continuing analysis of the study phase of PJM's transmission planning to reduce the need for postponements of study results, to decrease study completion times, and to improve the likelihood that a project at a given phase in the study process will successfully go into service.[22] (Priority: Medium. First reported 2014. Status: Partially adopted.)
- The MMU recommends outsourcing interconnection studies to an independent party to avoid potential conflicts of interest. Currently, these studies are performed by incumbent transmission owners under PJM's direction. This creates potential conflicts of interest, particularly when transmission owners are vertically integrated and the owner of transmission also owns generation. (Priority: Low. First reported 2013. Status: Not adopted.)

Market Efficiency Process

- The MMU recommends that the market efficiency process be eliminated because it is not consistent with a competitive market design. (Priority: Medium. First reported 2019. Status: Not adopted.)
- The MMU recommends that, if the market efficiency process is retained, PJM modify the rules governing benefit/cost analysis, the evaluation process for selecting among competing market efficiency projects and cost allocation for economic projects in order to ensure that all changes in production costs but not congestion costs, including increased costs to load and the risk of project cost increases, in all zones are included in order to ensure that the correct metrics are used for defining benefits. The MMU also recommends that, if the market efficiency process is retained, market efficiency projects that fail to meet PJM benefit/cost criteria in a Schedule 6 annual reevaluation, prior to construction commencing or prior to state

22 Ibid.

approval, be canceled and removed from further consideration. (Priority: Medium. First reported 2018. Status: Not adopted.)

Comparative Cost Framework

- The MMU recommends that PJM modify the project proposal templates to include data necessary to perform a detailed project lifetime financial analysis. The required data includes, but is not limited to: capital expenditure; capital structure; return on equity; cost of debt; tax assumptions; ongoing capital expenditures; ongoing maintenance; and expected life. (Priority: Medium. First reported 2020. Status: Not adopted.)

Transmission Competition

- The MMU recommends, to increase the role of competition, that the exemption of supplemental projects from the Order No. 1000 competitive process be terminated and that the basis for all such exemptions be reviewed and modified to ensure that the supplemental project designation is not used to exempt transmission projects from a transparent, robust and clearly defined mechanism to require competition to build such projects or to effectively replace the RTEP process. (Priority: Medium. First reported 2017. Status: Not adopted. Rejected by FERC.)[23]
- The MMU recommends, to increase the role of competition, that the exemption of end of life projects from the Order No. 1000 competitive process be terminated and that end of life transmission projects be included in the RTEP process and should be subject to a transparent, robust and clearly defined mechanism to require competition to build such projects. (Priority: Medium. First reported 2019. Status: Not adopted. Rejected by FERC.)[24]
- The MMU recommends that PJM enhance the transparency and queue management process for nonincumbent transmission investment. Issues related to data access and complete explanations of cost impacts should be addressed. The goal should be to remove barriers to competition from nonincumbent transmission providers. (Priority: Medium. First reported 2015. Status: Not adopted.)
- The MMU recommends that PJM incorporate the principle that the goal of transmission planning should be the incorporation of transmission investment decisions into market driven processes as much as possible. (Priority: Low. First reported 2001. Status: Not adopted.)
- The MMU recommends the creation of a mechanism to permit a direct comparison, or competition, between transmission and generation alternatives, including which alternative is less costly and who bears the risks associated with each alternative. (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM establish fair terms of access to rights of way and property, such as at substations, in order to remove any barriers to entry and require competition between incumbent transmission providers and nonincumbent transmission providers in the RTEP. (Priority: Medium. First reported 2014. Status: Not adopted.)
- The MMU recommends that rules be implemented to require competition to provide financing for transmission projects. This competition could reduce the cost of capital for transmission projects and significantly reduce total costs to customers. (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends that storage resources not be includable as transmission assets for any reason. (Priority: High. First reported 2020. Status: Not adopted.)

Cost Allocation

- The MMU recommends a comprehensive review of the ways in which the solution based dfax allocation method is implemented. The goal for such a process would be to ensure that the most rational and efficient approach to implementing the solution based dfax method is used in PJM. Such an approach should allocate costs consistent with benefits and appropriately calibrate the incentives for investment in new transmission capability. No

23 The FERC accepted tariff provisions that exclude supplemental projects from competition in the RTEP. 162 FERC ¶ 61,129 (2018), *reh'g denied*, 164 FERC ¶ 61,217 (2018).

24 In recent decisions addressing competing proposals on end of life projects, the Commission accepted a transmission owner proposal excluding end of life projects from competition in the RTEP process, 172 FERC ¶ 61,136 (2020), *reh'g denied*, 173 FERC ¶ 61,225 (2020), *affirmed*, American Municipal Power, Inc., et al. v. FERC, Case No. 20-1449 (D.C. Cir. November 17, 2023), and rejected a proposal from PJM stakeholders that would have included end of life projects in competition in the RTEP process, 173 FERC ¶ 61,242 (2020).

replacement approach should be approved until all potential alternatives, including the status quo, are thoroughly reviewed. (Priority: Medium. First reported 2020. Status: Not adopted.)

- The MMU recommends changing the minimum distribution factor in the allocation from 0.01 to 0.00 and adding a threshold minimum usage impact on the transmission facilities.[25] (Priority: Medium. First reported 2015. Status: Not adopted.)

Transmission Line Ratings

- The MMU recommends that all PJM transmission owners use the same methods to define line ratings and that all PJM transmission owners implement dynamic line ratings (DLR), subject to NERC standards and guidelines, subject to review by NERC, PJM and the MMU, and approval by FERC. (Priority: Medium. First reported 2019. Status: Partially adopted.)
- The MMU recommends that all PJM transmission owners investigate the applicability and potential cost savings of Grid Enhancing Technology (GET) and that all PJM transmission owners implement cost effective GET, subject to NERC standards and guidelines, subject to review by NERC, PJM and the MMU, and approval by FERC. (Priority: Medium. First reported 2024. Status: Not adopted.)
- The MMU recommends that the implementation of Grid Enhancing Technology (GET) be opened to competition from third parties, subject to NERC standards and guidelines, subject to review by NERC, PJM and the MMU, and approval by FERC. (Priority: Medium. First reported 2024. Status: Not adopted.)

Transmission Facility Outages

- The MMU recommends that PJM reevaluate all transmission outage tickets as on time or late as if they were new requests when an outage is rescheduled, create options for late requests based on the reasons, and apply the modified rules for late submissions to any such outages. The MMU recommends that PJM create options for treatment of late outages. The current rules apply more stringent rules, based on controlling actions, to late outages without distinguishing among reasons for late outages. (Priority: Low. First reported 2014. Status: Not adopted.)
- The MMU recommends that PJM draft a definition of the economic and physical congestion analysis required for transmission outage requests and associated triggers, including both the extent of overloaded facilities and the level of economic congestion, to include in PJM manuals after appropriate review with appropriate rules for on time and late outage requests. (Priority: Medium. First reported 2015. Status: Not adopted.)
- The MMU recommends that PJM create options for late requests based on the reasons, and modify the rules to reduce or eliminate the approval of late outage requests submitted or rescheduled after the FTR auction bidding opening date, based on those options. (Priority: Low. First reported 2015. Status: Not adopted.)
- The MMU recommends that PJM not permit transmission owners to divide long duration outages into smaller segments to avoid complying with the requirements for long duration outages. (Priority: Low. First reported 2015. Status: Not adopted.)

Conclusion

The goal of the PJM market design should be to enhance competition and to ensure that competition is the core element of all PJM markets. Transmission investments have not been fully incorporated into competitive markets. The construction of new transmission facilities has significant impacts on the energy and capacity markets. When generating units retire or load increases, there is no market mechanism in place that would require or even permit direct competition between transmission and generation to meet loads in the affected area. In addition, despite FERC Order No. 1000, there is not yet a transparent, robust and clearly defined mechanism to require competition to build transmission projects, to ensure that competitors provide a total project cost cap, or to obtain least cost financing through the capital markets.

The MMU recognizes that the Commission has issued orders that are inconsistent with the recommendations of the MMU and that PJM cannot unilaterally

25 See *2015 State of the Market Report for PJM*, Volume 2, Section 12: Generation and Transmission Planning, at 463, Cost Allocation Issues.

modify those directives. It remains the recommendation of the MMU that the PJM rules for competitive transmission development through the RTEP should build upon FERC Order No. 1000 to create real competition between incumbent transmission providers and nonincumbent transmission providers. The ability of transmission owners to block competition for supplemental projects and end of life projects and the reasons for that policy should be reevaluated. PJM should enhance the transparency and queue management process for nonincumbent transmission investment. Issues related to data access and complete explanations of cost impacts should be addressed. The goal should be to remove barriers to competition from nonincumbent transmission.

Order No. 1000 removed the right of first refusal (ROFR) for transmission projects for incumbent transmission owners except for the case of supplemental projects. This created an incentive for incumbent transmission owners to designate projects as supplemental projects to avoid the Order No. 1000 competitive provisions. Two PJM states, Indiana and Michigan, have passed laws that provide ROFR to incumbent utilities/transmission owners.[26] [27]

Given the significant impact of transmission line ratings on all aspects of wholesale power markets, ensuring and improving the accuracy and transparency of line ratings is essential. Line ratings should incorporate ambient temperature conditions, wind speed and other relevant operating conditions. PJM real-time prices are calculated every five minutes for thousands of nodes. PJM prices are extremely sensitive to transmission line ratings. For consistency with the dynamic nature of wholesale power markets, line ratings should be updated in real time to reflect real time conditions and to help ensure that real-time prices are based on actual current line ratings. New technologies that permit dynamic line ratings (DLR) should be implemented. All PJM Transmission Owners should be required to immediately adopt current dynamic line rating (DLR) methods for all transmission facilities, subject to NERC standards and guidelines, subject to review by NERC, PJM and the MMU, and approval by FERC.

26 See IN Code § 8-1-38-9, effective 7/1/2023. Applies to transmission facilities approved for construction through an RTO planning process. Incumbent Transmission Owner must exercise within 90 days.

27 See MCL §460.593, effective 12/17/2021. Applies to regionally cost shared transmission lines included in a plan adopted by a recognized planning authority. Must be exercised by the incumbent (s) within 90 days after plan is adopted/approved.

Given the slow pace of adoption by Transmission Owners of Grid Enhancing Technologies (GETs), PJM and the Commission should introduce rules that would allow third parties to propose adding GETs to the transmission system, subject to NERC standards and guidelines, subject to review by NERC, PJM and the MMU, and approval by FERC. The third parties would be compensated in the same way that TOs would be compensated for comparable investments.

Another element of opening competition would be to consider transmission owners' ownership of property and rights of way at or around transmission substations. In many cases, the land acquired included property intended to support future expansion of the grid. Incumbents have included the costs of the property in their rate base, paid for by customers. PJM now has the responsibility for planning the development of the grid under its RTEP process. Property bought to facilitate future expansion should be a part of the RTEP process and be made available to all providers on equal terms.

It would be antithetical to competition to permit transmission owners to own black start units under the backstop rules, to own batteries (storage as a transmission asset) or to permit transmission owners to build new generation, all under the antiquated cost of service regulation rules that were displaced by more efficient competitive markets. Such an approach would undermine competitive markets and require market projects built with investors' capital at risk to compete with subsidized resources.

The process for determining the reasonableness or purpose of supplemental transmission projects that are asserted to be not needed for reliability, economic efficiency or operational performance as defined under the RTEP process needs additional oversight and transparency. If there is a need for a supplemental project, that need should be clearly defined and there should be a transparent, robust and clearly defined mechanism to require competition to build the project. If there is no defined need for a supplemental project for reliability, economic efficiency or operational performance then the project should not be included in rates.

Managing the generation queues is a complex process. The PJM queue evaluation process will be significantly improved, based on the proposal submitted by PJM on June 14, 2022, and approved by FERC on November 29, 2022.[28] [29] The new rules include significant modifications to the interconnection process designed to address some of the key underlying issues and significantly improve the efficiency of the process. These modifications include process efficiency enhancements, recognition of project clusters affecting the same transmission facilities, incentives to reduce the entry of speculative projects in the queue, and incentives to remove projects that are not expected to reach commercial operation. The new process should help to reduce backlog and to remove projects that are not viable earlier to help improve the overall efficiency of the queue process.

While the changes in the queue process will clearly improve the process, the MMU's recommendations related to the queue process will remain until the new process is fully in place and it can be evaluated. The impact of the modifications to the queue process will need to be evaluated to determine if they successfully remove projects from the queue if they are not viable, and allow commercially viable projects to advance in the queue ahead of projects which have failed to make progress. The behavior of project developers also creates issues with queue management. When developers put multiple projects in the queue to maintain their own optionality while planning to build only one they also affect all the projects that follow them in the queue. Project developers may also enter speculative projects in the queue and then put the project in suspended status while they address financing. The impacts of such behavior and the incentives for such behavior are addressed in the new process which includes nonrefundable fees, credit requirements, enhanced site control, elimination of the ability to suspend a project and milestone requirements. The impact of these aspects of the revised interconnection process should continue to be evaluated to ensure that they are having the desired effect on project developer behavior. Initial results from the transition cycles have shown that developers are withdrawing their projects at the specified decision points, which is helping to remove speculative projects from the queue process sooner. Whether the new cycle process will result in enough new dispatchable and renewable generation to meet system needs cannot be determined until after a full cycle has been completed, projects go in service and completion rates can be evaluated. The PJM queue evaluation process should continue to be improved to help ensure that barriers to competition for new generation investments are not created. Issues that need to be addressed include the ownership rights to CIRs and whether transmission owners should perform interconnection studies.

The roles and efficiency of PJM, TOs and developers in the queue process all need to be examined and enhanced in order to help ensure that the queue process can function effectively and efficiently as the gateway to competition in the energy and capacity markets and not as a barrier to competition.

The Commission should require PJM, for example, to enhance the transparency and queue management process for nonincumbent transmission investment. Issues related to data access and complete explanations of cost impacts should be addressed. The goal should be to remove barriers to competition from nonincumbent transmission.

On January 31, 2025, PJM submitted revisions to the PJM Tariff to expedite the transfer of CIRs from deactivating generating resources to new replacement resources.[30] The Market Monitor filed opposing comments.[31] The Commission rejected the filing, finding (i) "that the lack of a maximum time limit for Commercial Operation Date extensions, which introduces the opportunity to delay commercial operation for an indefinite period of time, would result in a generator replacement process that does not promote the efficient interconnection of new resources;" and (ii) "because the unrestricted opportunity for a Replacement Generation Resource Project Developer to significantly delay commercial operation may result in CIRs and associated transmission capacity dedicated to accommodate the Replacement Generation Resource's operation going unused."[32] PJM has filed a new proposal for rule transferring CIRs to replacement resources which attempts to correct the deficiencies identified by FERC but continues to be flawed.[33]

The suggestion that generation owners should be permitted to avoid the queue process and directly transfer the generation CIRs to an affiliate or directly

28 See *PJM*, Docket No. ER22-2110 (June 14, 2022).
29 See 181 FERC ¶ 61,162 (2022).
30 See PJM Interconnection, L.L.C., Docket No. ER25-1128 (January 31, 2025).
31 See Comments of the Independent Market Monitor for PJM, Docket No. ER25-1128-000 (February 21, 2025).
32 192 FERC ¶ 61,137 at PP 38–39 (2025).

sell the CIRs to an unaffiliated entity should be rejected.[34] [35] This proposed approach is about creating a process to maximize the value of existing CIRs to incumbent generators and not about facilitating the efficient replacement of retiring resources. In effect, this approach, if adopted by the large number of retiring units, would create a chaotic, bilateral private queue process that would create market power and facilitate the exercise of market power in the sale of CIRs by incumbent generators. In effect the proposed approach would replace a significant part of the recently redesigned PJM queue process. The proposed continuation of retention of CIRs by incumbent generators creates the potential for delays of up to a year and the proponents have proposed the option to request further delays. This approach would inappropriately delegate the authority from PJM to the incumbent generator to choose the new resource based on highest offer for CIRs rather than based on PJM defined system reliability needs. There would be no requirement to even be a capacity resource and there would be no requirement to offer the capacity into the capacity market. After the entire process, the contribution to PJM reliability could be zero. PJM's recently proposed expedited process for addressing reliability needs (RRI) is preferable and should be considered as the preferred alternative to the proposed approach from the Planning Committee stakeholder process.

The MMU recommends that PJM establish an expedited PJM managed queue process to identify commercially viable projects that could help eliminate or reduce the need for specific RMRs or that could address specific reliability needs and allow the identified projects to advance in the queue ahead of projects which have failed to make progress, subject to rules to prevent gaming. Rules should be developed to permit PJM to advance projects in the queue if they would resolve immediate reliability issues that result, for example, from unit retirements. The rules should be consistent with the flexibility included in the new queue process but add the option for PJM to expedite the interconnection and commercial operation of projects in the queue that would address identified reliability issues, consistent with the standing of the projects in the queue.

The PJM queue process should continue to define available and needed CIRs for all capacity queue projects. CIRs from retiring units should be made available to the next resource in the queue that can use them, on the retirement date of the retiring resource. Generation owners do not have property rights in CIRs. The value of CIRs is a result of the entire transmission system which has been paid for by customers and other generators. The value of CIRs is a result of the existence of a network and is not a result solely or even primarily of the investment that may or may not have been required in order to get CIRs. The cost of CIRs is part of project costs included in generation owners' investment decisions like any other project cost and subject to the same risk and reward structure. Open access to the transmission system by new resources should not be limited by claims to own the access rights by retiring units. In addition, the proposal to bypass the PJM interconnection process with a private, bilateral process ignores the fact that if the new resource is a renewable resource or a storage resource, the new resource does not have a capacity market must offer requirement. The PJM interconnection process could be bypassed, CIRs transferred and then the resource does not offer into the capacity market. In that case, scarce CIRs will be withheld by a generator who does not provide capacity and customers have to pay for an additional capacity resource instead.

The fundamental purpose of the queue process is to provide open access to the grid for supply resources. More specifically, the fundamental purpose of the queue process for capacity resources is to provide open access to the grid and to ensure that the energy from capacity resources is deliverable so that capacity resources can meet their must offer obligations in the energy market and provide reliable energy supply during all conditions. In order to ensure that open access, all capacity resources should be required to have a must offer obligation in the capacity market. If they do not, such resources are effectively withholding access to the grid from capacity resources that would take on a must offer obligation in the capacity market. The result creates market power for the resources with no must offer obligation, noncompetitively limits access

34 See PJM. "*Enhancing Capacity Interconnection Rights (CIR) Transfer Efficiency: Problem / Opportunity Statement*," <https://www.pjm.com/-/media/committees-groups/subcommittees/ips/2023/20230731/20230731-item-08b---enhancing-capacity-interconnection-rights---cir---transfer-efficiency-problem-statement.ashx>.

35 On April 30, 2024, the CIR Transfer Efficiency issue was transferred from the Interconnection Process Subcommittee (IPS) to the Planning Committee (PC).

to the grid, increases capacity market prices above the competitive level, and creates uncertainty and unpredictable volatility in the capacity market.

The addition of a planned transmission project changes the parameters of the capacity auction for the area, changes the amount of capacity needed in the area, changes the capacity market supply and demand fundamentals in the area and may effectively forestall the ability of generation to compete. But there is no mechanism to permit a direct comparison, let alone competition, between transmission and generation alternatives. There is no mechanism to evaluate whether the generation or transmission alternative is less costly, whether there is more risk associated with the generation or transmission alternatives, or who bears the risks associated with each alternative. Creating such a mechanism should be an explicit goal of PJM market design.

The current market efficiency process does exactly the opposite by permitting transmission projects to be approved without competition from generation. The broader issue is that the market efficiency project approach explicitly allows transmission projects to compete against future generation projects, but without allowing the generation projects to compete. Projecting speculative transmission related benefits for 15 years based on the existing generation fleet and existing patterns of congestion eliminates the potential for new generation to respond to market signals. The market efficiency process allows assets built under the cost of service regulatory paradigm to displace generation assets built under the competitive market paradigm. In addition, there are significant issues with PJM's current benefit/cost analysis which cause it to consistently overstate the potential benefits of market efficiency projects. The market efficiency process is misnamed. The MMU recommends that the market efficiency process be eliminated.

In addition, the use of an incorrectly defined cost-benefit method by PJM and the correct method by MISO results in an over allocation of the costs associated with joint PJM/MISO transmission projects to PJM participants and in some cases approval of projects that do not pass a correctly defined benefit/cost test.

If it is retained, there are significant issues with PJM's benefit/cost analysis that should be addressed prior to approval of additional projects. The current benefit/cost analysis explicitly and incorrectly ignores the increased costs to load in zones that results from an RTEP project when calculating the energy market benefits. All increases and decreases in costs should be included in all zones and LDAs. The definition of benefits should also be reevaluated.

The benefit/cost analysis should also account for the fact that the transmission project costs are not subject to cost caps and may exceed the estimated costs by a wide margin. When actual costs exceed estimated costs, the benefit/cost analysis is effectively meaningless and low estimated costs may result in inappropriately favoring transmission projects over market generation projects. The risk of cost increases for transmission projects should be incorporated in the benefit/cost analysis.

Recent proposals to use storage as a transmission asset (SATA) raises a number of additional concerns about PJM's benefit/cost analysis. Storage is a market asset and should not be owned by transmission owners. PJM should not be evaluating SATA at all without a decision from FERC that SATA is allowable in PJM. At present it is not allowed.

A significant flaw in PJM's benefit/cost analysis is that projected benefits are based on load forecasts which are currently dominated by projected large data center loads that are not verified by PJM and cannot be verified by PJM. That creates a bias towards finding transmission projects beneficial despite the fact that data center loads are imposing transmission costs on other customers as a result.

There are currently no market incentives for transmission owners to plan, submit and complete transmission outages in a timely and efficient manner. Requiring transmission owners to pay does not create an effective incentive when those payments are passed through to transmission customers. The process for the submission of planned transmission outages needs to be carefully reviewed and redesigned to limit the ability of transmission owners to submit transmission outages that are late for FTR auction bid submission dates and are late for the day-ahead energy market and that have large and unnecessary impacts on the PJM energy market. The submission of late transmission outages can inappropriately affect market outcomes when market participants do not have the ability to modify market bids and offers. The PJM process for evaluating the congestion impact of transmission outages needs to be clearly defined and upgraded to provide for management of transmission outages to minimize market impacts. The MMU continues to recommend that PJM draft a clear and expanded definition of the congestion analysis required for transmission outage requests that is incorporated in the PJM Market Rules. PJM Manual 38 currently defines congestion resulting from a transmission outage as an overload on transmission facilities rather than using the general economic definition of congestion resulting from out of merit generation to control constraints. PJM does not currently evaluate the economic impact of congestion when reviewing proposed transmission outages.[36]

The treatment by PJM and Dominion Virginia Power of the outage for the Lanexa – Dunnsville Line illustrates some of the issues with the current process. The outage was submitted and delayed more than once. PJM's analysis of expected congestion did not highlight the magnitude of the issue. Dominion Virginia Power did not stage the outage so as to minimize market disruption and congestion until after there were significant disruptions and congestion.

As an example of the complexities of defining the benefits of transmission investments, the reduction in congestion is frequently and incorrectly cited as a metric of benefits. Congestion is frequently misunderstood. Congestion is not static. Congestion exhibits dynamic intertemporal variability and dynamic locational variability. More importantly, congestion is not the correct metric for evaluating the potential benefits of enhancing the transmission grid. The correct metric is the total net change in production costs.

There is not a secular trend towards increasing congestion in PJM. Congestion is volatile on a monthly basis. Congestion is also volatile on an hourly and daily basis. For example, higher congestion can result from changes in seasonal and daily/hourly fuel costs.

The level and distribution of congestion at a point in time is a function of the location and size of generating units, the relative costs of the fuels burned and the associated marginal costs of generating units, the location and size of load and the locational capability of the transmission grid. Each of these factors changes over time.

The geographic distribution of congestion is dynamic. The nature and location of congestion in the PJM system has changed significantly over the last 10 years and continues to change. The nature and location of congestion in PJM can also change from one day to the next as a result of changes in relative fuel costs. As a result, building transmission to address a specific pattern of congestion does not make sense, unless the technology can be easily moved to new locations as conditions change. The transmission system is only one of many reasons that congestion exists. The dynamic nature of congestion and the multiple, interactive causes of congestion make it virtually impossible to identify the standalone impacts of an individual transmission investment on future congestion. It is possible, for example, that congestion occurring during a period of a few days in the winter as a result of very high fuel prices, significantly increases the reported level of congestion for the entire year. This has occurred in PJM. It would be a mistake to consider that level of congestion to be a signal to build transmission.

At a more fundamental level, congestion is not the correct metric for evaluating the potential benefits of enhancing the transmission grid. When there are binding transmission constraints and locational price differences, load pays more for energy than generation is paid to produce that energy. The difference is congestion. Congestion is neither good nor bad, but is a direct measure of the extent to which there are multiple marginal generating units with different offers dispatched to serve load as a result of transmission constraints. Congestion occurs when available, least-cost energy cannot be delivered to all load because transmission facilities are not adequate to deliver that energy to one or more areas, and higher cost units in the constrained area(s) must be dispatched to meet the load. The result is that the price of energy in the constrained area(s) is higher than in the unconstrained area. Load in the constrained area pays the higher price for all energy including

36 PJM, "Manual 38: Operations Planning," Rev. 19 (January 23, 2025) at 19-20.

energy from low cost generation and energy from high cost generation, while only high cost generators are paid the high price at their bus and low cost generators are paid only the low price at their bus.

If FTRs worked perfectly and were assigned directly to load, FTRs would return all congestion to the load that paid the congestion. Congestion is not a cost, it is an accounting result of a market based on locational energy prices in which all load in a constrained area pays the higher single market clearing locational price, resulting in excess payments by load that are not paid to generation, which should be returned to load.

Counterintuitively, congestion actually increases when the transmission capacity between areas with lower cost generation and areas with higher cost generation increases but does not fully eliminate the need for some higher cost local generation. The smaller the amount of higher cost local generation needed to meet load, the more of the local load is met via low cost generation delivered over the transmission system and therefore the higher is the difference between what load pays and generation receives, congestion.

For all these reasons, if done correctly and if FTRs/ARRs returned 100 percent of congestion to load, the benefit/cost analysis for transmission projects would include the total net change in production costs and would not include congestion. The change in production costs correctly measures the changes in cost to load that result from a project.

The PJM Regional Transmission Expansion Plan (RTEP) successfully addresses the need for transmission investment to reliably meet load. Together with the requirement that new generation pay interconnection costs, the RTEP process has resulted in the appropriate level of new transmission investment in PJM. There is no evidence that the PJM planning process is not adequate to meet the requirements of the PJM markets. Additional transmission investment is not a panacea. Transmission investment is expensive and long lived and it is essential that transmission investments be carefully planned for clearly identified needs in order to ensure that power markets can continue to provide reliable service at a competitive price.

PJM must make out of market payments to units that want to retire (deactivate) but that PJM requires to remain in service, for limited operation, for a defined period because the unit is needed for reliability.[37] This provision has been known as Reliability Must Run (RMR) service but RMR is not defined in the PJM tariff. The correct term is Part V reliability service. The need to retain uneconomic units in service reflects a flawed market design and/or planning process problems. If a unit is needed for reliability, the market should reflect a locational value consistent with that need which would result in the unit remaining in service or being replaced by a competitor unit. The planning process should evaluate the impact of the loss of units at risk and determine in advance whether transmission upgrades are required in order to limit the duration of Part V service for individual units. It is essential that the deactivation provisions of the tariff be evaluated and modified. It is also essential that PJM look forward and attempt to plan for foreseeable unit retirements, whether for economic or regulatory reasons. PJM should consider an expedited queue process for projects that could replace the retiring capacity including the immediate transfer of the retiring unit's CIRs to units in the queue in order to permit generation to compete as an alternative to the current transmission only approach.

An area in northern Virginia in the Dominion Transmission Zone, known as Data Center Alley, has experienced significant load growth from data centers. Dominion has presented 44 supplemental project requests to serve the increase in load through the summer of 2025. As part of the supplemental planning process, PJM performs a do no harm analysis. PJM identified the need for additional baseline reinforcements to support the load growth. These baseline reinforcements were addressed in the 2022 RTEP Window 3, when the PJM board approved $1.4 billion of necessary baseline upgrades specific to the Data Center Alley reinforcements.[38] These regional transmission costs were allocated according to Schedule 12 of PJM's Open Access Transmission Tariff (OATT), where costs are shared across all zones by a combination of load ratio share and distribution factor impacts. The transmission owners include these project costs in their base case, and all retail customers in the PJM footprint

37 OATT Part V §114.
38 See "*Transmission Expansion Advisory Committee (TEAC) Recommendations to the PJM Board,*" December 2023. <https://www.pjm.com/-/media/committees-groups/committees/teac/2023/20231205/20231205-pjm-teac-board-whitepaper-december-2023.ashx>.

pay for those upgrade costs through increased energy bills. The cost allocation of the $1.4 billion in baseline upgrades are assigned to all retail customers and not solely to the customers requesting interconnection.

The high level of customer requests in Data Center Alley resulted in the need for significant baseline reliability upgrades. These costs were allocated per Schedule 12 of the PJM OATT. Not all customer requests result in reliability upgrades. Transmission upgrades for customer requests that are submitted through the supplemental planning process are allocated 100 percent to the zone where they are interconnecting. The transmission owner of that zone then includes those project costs in their rate base, and all retail customers in that zone pay those costs.

The Virginia case illustrates the imposition of transmission costs by data centers on other PJM customers. These additional transmission costs are in addition to the significant capacity market costs imposed on other customers by the actual and forecast addition of large data centers.

The main focus of PJM's planning requirements has been to ensure adequate transmission to allow for generation to reliably serve load. Historically, PJM has had enough excess generation to serve the forecasted load in the RTEP process. In recent years, due in part to the significant increase in load resulting from large load data center interconnection requests and an increase in thermal unit deactivations, meeting forecasted loads and reserves with existing generation has become an issue. In order to solve the RTEP study cases, PJM must make assumptions about the existing and future generation to include in the RTEP model based on the need to serve load. The RTEP analysis first includes all existing generation that is expected to remain in service for the year being studied. When the forecasted load exceeds the expected in service generation, the RTEP analysis includes future generation. Planned generators with a signed interconnection service agreement (ISA) or generation interconnection agreement (GIA), or that cleared a BRA, are included. When the PJM load in the RTEP analysis exceeds the sum of existing generation and generation with an executed final agreement, the RTEP analysis simply adds speculative new generation that is in its Phase 3 system impact study status to meet the load. If needed, additional generation (pre-GIA stage or with a suspended status) may be modeled (assumed) consistent with the procedures noted in Manual 14B.[39] [40] The RTEP analysis is not adequately coordinated with PJM markets analysis including the energy and capacity markets.

Generation Interconnection Planning

Existing Generation Mix

Table 12-1 shows the existing PJM capacity by control zone and unit type.[41] [42] As of September 30, 2025, PJM had an installed capacity of 200,952.5 MW, of which 38,366.4 MW (19.1 percent) are coal fired steam units, 57,064.2 MW (28.4 percent) are combined cycle units and 33,452.6 MW (16.6 percent) are nuclear units. This measure of installed capacity differs from capacity market installed capacity because it includes energy only units, external units and uses nameplate values for solar and wind resources.

The AEP Zone has the most installed capacity of any PJM zone. Of the 200,952.5 MW of PJM installed capacity, 37,391.3 MW (18.6 percent) are in the AEP Zone, of which 13,463.0 MW (36.0 percent) are coal fired steam units, 9,294.0 MW (24.9 percent) are combined cycle units and 2,071.0 MW (5.5 percent) are nuclear units.

39 See "Review of 2025 RTEP Assumptions," presented at the January 7, 2025 meeting of the Transmission Expansion Advisory Committee. <https://www.pjm.com/-/media/DotCom/committees-groups/committees/teac/2025/20250107/20250107-item-11---2025-rtep-assumption.pdf>.
40 See "PJM Manual 14B: PJM Region Transmission Planning Process," Rev. 57 (September 25, 2024).
41 The unit type RICE refers to Reciprocating Internal Combustion Engines.
42 XIC refers to external installed capacity.

43 The capacity described in this section refers to all capacity in PJM at the summer installed capacity rating, regardless of whether the capacity entered the RPM Auction.

Table 12-2 shows the installed capacity by state for each fuel type. Pennsylvania has the most installed capacity of any PJM state. Of the 200,952.5 MW of installed capacity, 47,504.4 MW (23.6 percent) are in Pennsylvania, of which 6,109.4 MW (12.9 percent) are coal fired steam units, 18,292.2 MW (38.5 percent) are combined cycle units and 8,843.8 MW (18.6 percent) are nuclear units.

Table 12-3 and Figure 12-1 show the age of existing PJM generators, by unit type, as of September 30, 2025. Of the 200,952.5 MW of installed capacity, 72,221.3 MW (35.9 percent) are from units older than 40 years, of which 30,814.3 MW (42.7 percent) are coal fired steam units, 255.0 MW (0.4 percent) are combined cycle units and 25,550.6 MW (35.4 percent) are nuclear units.

Table 12-3 Capacity (MW) by unit type and age (years): September 30, 2025

Generation Retirements[44] [45] [46]

Generating units generally plan to retire when they are not economic and do not expect to be economic. Generating units may also plan to retire if environmental restrictions make it too costly to comply or impossible to comply. The MMU performs an analysis of the economics of all units that plan to retire in order to verify that the units are not economic and there is no potential exercise of market power through physical withholding that could advantage the owner's portfolio.[47] The definition of economic is that unit net revenues are greater than or equal to the unit's avoidable or going forward costs.

PJM does not have the authority to order generating plants to continue operating. PJM's responsibility is to ensure system reliability. When a unit retirement creates reliability issues based on existing and planned generation facilities and on existing and planned transmission facilities, PJM identifies transmission solutions. The U. S. Department of Energy does have the authority to temporarily order generating plants to continue operating under section 202(c) of the Federal Power Act in the event of emergency or reliability issues.[48]

Rules that preserve ownership of the Capacity Interconnection Rights (CIRs) associated with retired units, and with the conversion from Capacity Performance (CP) to energy only status, impose significant costs on new entrants. Currently, CIRs persist for one year if unused, and that period can be further extended, at no cost, if the CIRs are assigned to a new project in the interconnection queue at the same point of interconnection.[49] There are currently no rules governing the retention of CIRs when units want to convert to energy only status or require time to upgrade to retain CP status. The rules governing conversion or upgrades should be the same as the rules governing retired units. Reforms that require the holders of CIRs to use or lose them, and that terminate CIRs on the date of retirement, would make new entry appropriately more attractive. There is no good economic and policy rationale for extending ownership rights to CIRs for inactive units. Incumbent providers receive a significant advantage simply by imposing on new entrants the entire cost of system upgrades needed to accommodate new entrants. In May 2012, PJM stakeholders (through the Interconnection Process Senior Task Force (IPSTF)) modified the rules to reduce the length of time for which CIRs are retained by the current owner after unit retirements from three years to one.[50] The MMU recognized the progress made in this rule change, but it did not fully address the issues. Even if the policy treatment of such CIRs remains unchanged, the rules need to ensure that incumbents cannot exploit control of CIRs to block or postpone entry of competitors or to exercise market power by requiring high payments for CIRs. The MMU recommends that CIRs should end on the date of retirement in order to help ensure competitive markets and competitive access to the grid.

Generation Retirements 2011 through 2030

Table 12-6 shows that as of September 30, 2025, there were 64,079.0 MW of generation that have been, or are planned to be, retired from 2011 through 2030, of which 46,526.8 MW (72.6 percent) are coal fired steam units. Retirements are primarily a result of the inability of coal and other units to compete with efficient combined cycle units burning low cost gas.

44 See PJM. Planning. "Generator Deactivations," (Accessed on September 30, 2025) <https://www.pjm.com/planning/service-requests/gen-deactivations>.
45 Generation retirements reported in this section do not include external units. Therefore, retirement totals reported in this section may not match totals reported elsewhere in this report where external units are included.
46 For additional information on canceled unit retirement requests, see *2025 Quarterly State of the Market Report for PJM: January through September*, Section 5: Capacity, "Timing of Unit Retirements".
47 See OATT Part V and Attachment M–Appendix § IV.
48 See 16 U.S.C. § 824a(c).
49 See OATT § 230.3.3.
50 See PJM Interconnection, L.L.C., Docket No. ER12-1177 (Feb. 29, 2012).

Table 12-7 shows the capacity, average size, and average age of units retiring in PJM, from 2011 through 2030, while Table 12-8 shows these retirements by state. Of the 64,079.0 MW of units that has been, or are planned to be, retired from 2011 through 2030, 46,526.8 MW (72.6 percent) are coal fired steam units. These coal fired steam units have an average age of 52.2 years and an average size of 238.6 MW. Over half of the retiring coal fired steam units, 51.1 percent, are located in Ohio or Pennsylvania.

Current Year Generation Retirements

Table 12-10 shows that in the first nine months of 2025, 981.8 MW of generation retired. The largest generator that retired in the first nine months of 2025 was the 410.0 MW Indian River 4 coal fired steam unit located in the DPL Zone. Of the 981.8 MW of generation that retired in the first nine months of 2025, 410.0 MW (41.8 percent) were located in the DPL Zone.

Planned Generation Retirements

Table 12-11 shows that, as of September 30, 2025, there were 8,351.9 MW of generation that have requested retirement after September 30, 2025. Of the 8,351.9 MW requesting retirement, 5,117.0 MW (61.3 percent) are coal fired steam units. Of the 8,351.9 MW of planned retirements, 2,620.0 MW (31.4 percent) are located in the AEP Zone. Of the generation requesting retirement in the AEP Zone, 2,620.0 MW (100.0 percent) are coal fired steam units.

In addition to the 8,351.9 MW of announced unit retirements as of September 30, 2025, there are significantly more unit retirements expected as a result of environmental regulations and for economic reasons.[51]

51 For more information, see *2025 Quarterly State of the Market Report for PJM: January through September*, Section 7: Net Revenue.

Generation Queue[52]

Any entity that requests interconnection of a new generating facility, including increases to the capacity of an existing generating unit, or that requests interconnection of a merchant transmission facility, must follow the process defined in the PJM tariff to obtain interconnection service.[53] PJM's process is designed to ensure that new generation is added in a reliable and systematic manner. The process is complex and time consuming at least in part as a result of the required analyses. The cost, time and uncertainty associated with interconnecting to the grid may create barriers to entry for potential entrants. But the behavior of project developers also creates issues with queue management and exacerbates the barriers.

Generation request queues are groups of proposed projects, including new units, reratings of existing units, capacity resources and energy only resources. Each queue is open for a fixed amount of time. Studies commence on all projects in a given queue when that queue closes. Projects submitted to the queue undergo a deficiency review to ensure that all required information is provided. A queue position is assigned once the project has met the submission requirements. Projects that do not meet submission requirements are removed from the queue.

In 2022, after a lengthy stakeholder process (Interconnection Process Reform Task Force (IPRTF)) PJM filed significant changes to improve overall queue management. On November 29, 2022, the Commission issued an order accepting PJM's tariff revisions modifying how PJM manages the new services queue.[54] The new queue process includes modifications to implement a cluster/cycle based processing method to replace the first in/first out processing method.[55] This change will allow projects to move forward based on a first ready/first out analysis, where readiness is demonstrated through site control and financial milestones and there is an option to exit the study process early based on system impacts.

52 Unless otherwise noted, the queue totals in this report are the winter net MW energy for the interconnection requests ("MW Energy") as shown in the queue.
53 See OATT Parts IV & VI.
54 181 FERC ¶ 61,162 (2022).
55 See "Interconnection Process Reform," presented at April 27, 2022 meeting of the Members Committee. <https://www.pjm.com/-/media/committees-groups/committees/mc/2022/20220427/20220427-item-01a-1-interconnection-process-reform-presentation.ashx>.

The new cycle process also includes defining progress to completion through three phases, with a customer decision at the end of each. The new cycle process requires a stronger definition of site control, and includes readiness deposits (some of which are nonrefundable) based on the phase of development. Additional process modifications include limits to technology changes, improvements to the application review phase, removal of optional interconnection study processes, modifications to the study schedules to reduce the number of restudies required in the event of project modifications, adjusting the queue window schedule to coincide with the previous clusters' milestones, and modifications to cost responsibility by assigning responsibility to all projects within a queue cycle. The new cycle process should help to reduce backlog and to remove projects that are not viable earlier to help improve the overall efficiency of the queue process.

The transition to the new cycle process began on July 10, 2023. The last open series queue prior to July 10, 2023, was AJ1. The new cycle process includes a transition which treats projects based on their series queue status. All projects through series queue window AD2 will continue as part of the series queue process. The transition process assigned series queue projects in queue windows AE1 through AH1 to transition cycle 1 (TC1) and transition cycle 2 (TC2) and also provides for the expedited treatment (fast track) of projects submitted in the AE1 through AG1 queue windows with upgrade costs less than $5 million. The start of the transition to the new cycle process on July 10, 2023, also started the 60 day readiness review period for active projects in the AE1 through AG1 queues. During this time, project developers provided evidence of site control and provided the necessary readiness deposit.[56] Those projects in the AE1 through AG1 series queues that had not yet received an interconnection service agreement or a wholesale market power agreement and also met readiness requirements were reviewed to determine if they were eligible for the fast track process, or if they will be studied as part of transition cycle 1. Of the 734 projects in queues AE1 through AG1 reviewed, 306 projects (41.7 percent) qualified for the expedited process, 312 projects (42.5 percent) were assigned to transition cycle 1 and 116 projects (15.8 percent) were withdrawn from the queue.

56 See "PJM Manual 14H: New Service Requests Cycle Process," Rev. 02 (July 23, 2025) for a complete list of all readiness requirements.

The transition process must also account for the fact that PJM significantly underestimated the level of CIRs required for intermittent resources. PJM had required only CIRs equal to the ELCC rating of intermittent resources when in fact those resources required CIRs equal to the maximum output that contributed to the ELCC rating. In general, CIRs were understated by the difference between the ELCC derating factor and the maximum facility output of the intermittent resource. PJM filed revised rules and FERC approved them.[57] PJM has created a process to permit such resources to increase their CIRs to the required level through appropriate investments in interconnection facilities. This process will occur coincident with the start of the new service request Cycle 1.

The MMU recommends improvements in queue management including that PJM establish a review process to ensure that projects are removed from the queue if they are not viable, as well as a process to allow commercially viable projects to advance in the queue ahead of projects which have failed to make progress, subject to rules to prevent gaming.[58]

New Service Requests Serial Process

Interconnection Process Studies and Agreements[59]

Prior to implementation of the new cycle process, PJM used a serial service process. In the study stage of the interconnection planning serial process, a series of studies were performed to determine the feasibility, impact, and cost of projects in the queue. Table 12-12 is an overview of the studies PJM performed in the study stage of the interconnection serial process. System impact and facilities studies were often redone when a project was withdrawn in order to determine the impact on the projects remaining in the queue.

57 183 FERC ¶61,009.
58 Once implemented, the approved solutions from PJM's Interconnection Process Reform Task Force (IPRTF) should result in improvements in these areas.
59 See "PJM Manual 14A: New Services Request Process," Rev. 30 (July 26, 2023) for a complete explanation of the interconnection process studies and agreements.

Table 12-12 Interconnection planning serial process: study stage

Study	Purpose
Feasibility Study	The feasibility study determines preliminary estimates of the type, scope, cost and lead time for construction of facilities required to interconnect the project.
System Impact Study	The system impact study is a comprehensive regional analysis of the impact of adding the new generation and/or transmission facility to the system. The study identifies the system constraints related to the project and the necessary attachment facilities, local upgrades, and network upgrades. The study refines and more comprehensively estimates cost responsibility and construction lead times for facilities and upgrades.
Facilities Study	In the facilities study, stability analysis is performed and the system impact study results are modified as necessary to reflect changes in the characteristics of other projects in the queue.

In addition to the feasibility, system impact and facilities studies, PJM would also perform additional studies under certain circumstances. These studies included the affected systems study, interim deliverability study and the long term firm transmission studies. Table 12-13 is an overview of the additional studies PJM could have performed.

Table 12-13 Interconnection planning serial process: study stage – additional studies

Study	Purpose
Affected System Study	PJM and its neighboring balancing authorities conduct interconnection studies to determine the impacts of interconnection requests on the neighboring transmission system.
Interim Deliverability Studies	Interim deliverability studies are conducted on a periodic basis in support of RPM auctions and other interconnection studies to determine if a new facility may come on line prior to its scheduled date. These studies evaluate the available system capability and provide the customer(s) with the availability of service by planning year. Interim deliverability studies use the same criteria used for the evaluation of the need for reinforcements associated with a project under study.
Long Term Firm Transmission Studies	Transmission service requests that extend beyond the available transfer capability horizon of 18 months are evaluated along with the other requests for service in the PJM new services queue to ensure deliverability. Long term firm transmission studies follow the same feasibility, system impact and facilities study process as new generation.

After the completion of a facility study, the project would enter the construction stage of the interconnection process. The final agreements required depended on the type of project. These agreements included a Construction Service Agreement (CSA), Interconnection Service Agreement (ISA), Upgrade Construction Service Agreement (UCSA), Wholesale Market

Participant Agreement (WMPA) or Transmission Service Agreement (TSA). Table 12-14 is an overview of the agreements in the construction stage of the interconnection serial process.

Table 12-14 Interconnection planning serial process: construction stage agreements

Agreement	Purpose
Interconnection Service Agreement (ISA)	An ISA defines the generation or transmission developer's cost responsibility for required system upgrades. For generation interconnection customers, the ISA defines the capacity interconnection rights for a capacity resource and any operational restrictions or other limitations. For transmission interconnection customers, the ISA defines transmission injection and withdrawal rights and applicable incremental delivery, available transfer capability revenue and auction revenue rights.
Interim Interconnection Service Agreements (I-ISA)	If a developer wishes to start project construction activities prior to completion of the generation or transmission interconnection facilities study, the interim ISA would commit the developer to pay all costs incurred for the construction activities being advanced.
Interconnection Construction Service Agreement (CSA)	The CSA defines the standard terms and conditions of the interconnection, including construction responsibility, includes a construction schedule and contains notification and insurance obligations.
Upgrade Construction Service Agreement (USCA)	A new service customer who proposes to make an upgrade to an existing transmission facility or who seeks incremental auction revenue rights (IARRs) will receive an upgrade construction service agreement after their study process is completed.
Wholesale Market Participation Agreement (WMPA)	Developers interconnecting to non-FERC jurisdictional facilities who intend to participate in the PJM wholesale market will receive a three party agreement (WMPA). The WMPA is a non-Tariff agreement which must be filed with the FERC. The WMPA is essentially an ISA without interconnection provisions.

Planned Generation Additions

There were 8,190 generation request projects submitted in the new service request serial process queue from 1997 until the implementation of the new cycle process on July 10, 2023. As a result of the transition to the new services cycle process, 312 projects were moved to transition cycle 1 (TC1). There were 1,347 projects eligible to resubmit for evaluation in transition cycle 2 (TC2). Of those 1,347 eligible projects, 550 projects resubmitted and are now being evaluated in TC2. Of the 1,347 eligible projects, 797 projects did not resubmit, and were withdrawn from the queue. There were 1,070 projects initially entered into the AH2 queue and beyond. Those 1,070 projects are now considered invalid and have been removed from the queue. As a result of the transition to the cycle process, the 8,190 projects in the serial process queue has been reduced to 5,461 projects. Projects that will be evaluated in TC1 and TC2, and those projects no longer eligible to be evaluated in the serial process have been removed from the new service requests serial process metrics. New service requests cycle process metrics are reported separately from the serial process metrics.

Expected net revenues provide incentives to build new generation to serve PJM markets. The amount of planned new generation in PJM reflects investors' perception of the incentives provided by the combination of revenues from the PJM energy, capacity and ancillary service markets and from federal and state subsidies and incentives. On September 30, 2025, 43,634.4 MW were in generation request serial queues in the status of active, under construction or suspended, for construction through 2031. Although it is clear that not all generation in the queues will be built, PJM has added capacity steadily since markets were implemented on April 1, 1999.[60]

As projects move through the queue process, projects can be removed from the queue due to incomplete or invalid data, withdrawn by the market participant or placed in service. Table 12-15 shows the total MW in the serial queues by expected completion year and MW changes in the serial queue between December 31, 2024, and September 30, 2025, for ongoing projects, i.e. projects with the status active, under construction or suspended.[61]

60 See "*PJM Generation Capacity and Funding Sources 2007/2008 through 2021/2022 Delivery Years,*" <http://www.monitoringanalytics.com/reports/Reports/2020/IMM_2020_PJM_Generation_Capacity_and_Funding_Sources_20072008_through_20212022_DY_20200915.pdf>.

61 Expected completion dates are entered when the project enters the queue. Actual completion dates are generally different than expected completion dates.

Table 12-15 Serial queue comparison by expected completion year (MW): December 31, 2024 and September 30, 2025[62]

			Year Change	
Year	As of 12/31/2024	As of 9/30/2025	MW	Percent

Table 12-16 shows the project status changes in more detail and how scheduled serial queue MW have changed between December 31, 2024, and September 30, 2025. For example, of the total 35,266.7 MW marked as active on December 31, 2024, 6,999.0 MW were withdrawn, 1,844.9 MW were suspended, 5,916.8 MW started construction, and 34.9 MW went into service by September 30, 2025. Analysis of projects that were suspended on December 31, 2024 show that 1,895.7 MW came out of suspension and are now active as of September 30, 2025.

62 Unless otherwise noted, wind and solar capacity totals in this section have not been adjusted to reflect derating.

Table 12-16 Change in project status (MW): December 31, 2024, to September 30, 2025

		Status at 9/30/2025				
Status at 12/31/2024	Total at 12/31/2024	Active	In Service	Under Construction	Suspended	Withdrawn
(Entered during 2025)	0.0	0.0	0.0	0.0	0.0	0.0
Active	35,266.7	20,471.1	34.9	5,916.8	1,844.9	6,999.0
In Service	91,834.5	0.0	91,257.5	577.0	0.0	0.0
Under Construction	6,770.8	0.0	2,409.3	4,046.5	300.0	15.0
Suspended	12,137.9	1,895.7	65.0	853.9	7,728.6	1,594.8
Withdrawn	463,122.8	0.0	8.0	0.0	0.0	463,114.8
Total	609,132.6	22,366.7	93,774.7	11,394.2	9,873.5	471,723.5

On September 30, 2025, 43,634.4 were in generation request serial queues in the status of active, suspended or under construction. Table 12-17 shows each status by unit type. Of the 22,366.7 MW in the status of active on September 30, 2025, 1,220.0 MW (5.5 percent) were combined cycle projects. Of the 11,394.2 MW in the status of under construction, 1,668.8 MW (14.6 percent) were combined cycle projects and 7,148.9 MW (62.7 percent) were solar projects. A significant amount of renewable hybrid projects (defined as solar + storage, solar + wind and wind + storage projects) have entered the queue in recent years. Of the 43,634.4 MW in the serial queues in the status of active on September 30, 2025, 2,268.3 MW (10.1 percent) were renewable hybrid projects. Of the 11,394.2 MW in the status of under construction, 103.9 MW (0.9 percent) were renewable hybrid projects.

Total	3,426.1	4,158.8	1,117.7	0.0	0.0	0.0	0.0	51.0	44.0	0.0	0.0	0.0	26,729.0	2,522.2	0.0	36.0	0.0	0.0	0.0	5,549.7	0.0	43,634.4

A significant shift in the distribution of unit types within the PJM footprint continues to develop as renewable, hybrid and other intermittent resources enter the queue, fewer natural gas fired units enter the queue, and coal fired steam units retire. As of September 30, 2025, of the 43,634.4 MW in the generation request serial queues in the status of active, suspended or under construction, 26,729.0 MW (61.3 percent) were solar projects, 5,549.7 MW (12.7 percent) were wind projects, 5,276.5 MW (12.1 percent) were natural gas fired projects (including combined cycle units, CTs, RICE units, and natural gas fired steam units), 2,522.2 MW (5.8 percent) were renewable hybrid projects (solar + storage, solar + wind and wind + storage units), and 36.0 MW (0.08 percent) were coal fired steam projects.

As of September 30, 2025, there were 5,117.0 MW of coal fired steam units and 2,500.0 MW of natural gas units slated for deactivation between October 1, 2025, and December 31, 2030 (See Table 12-11). The ongoing replacement of coal fired steam units by natural gas units will continue to significantly affect future congestion, the role of firm and interruptible gas supply, and natural gas supply infrastructure. The growing level of renewables, hybrids and other intermittents will have increasingly significant impacts on the energy and capacity markets.

On September 30, 2025, 31,841.9 MW, on an energy basis, were in generation request serial queues that had reached the construction service agreement milestone or equivalent, in the status of active, suspended or under construction. Table 12-18 shows the status by unit type. Of the 31,841.9 MW, 12,683.3 MW (39.8 percent) had not begun construction, 9,873.5 MW (31.0 percent) began construction, but are now suspended and 9,285.2 MW (29.2 percent) are currently under construction. Reaching the final milestone required prior to construction does not mean a project will immediately begin construction or even that it necessarily will ever begin construction.

Table 12-19 shows the total MW in the status of active, in service, under construction, suspended, or withdrawn for each serial queue since the beginning of the RTEP process and the total MW that had been included in each queue. All projects in queues A-Z2 are either in service or have been withdrawn. As of September

30, 2025, there were 43,634.4 MW in serial queues that are not yet in service or withdrawn, of which 9,873.5 MW (22.6 percent) are suspended, 11,394.2 MW (26.1 percent) are under construction and 22,366.7 MW (51.3 percent) have not begun construction.

63 Projects listed as partially in service are counted as in service for the purposes of this analysis.

Table 12-20 shows the projects with a status of active, suspended or under construction, by unit type, and control zone. As of September 30, 2025, 43,634.4 MW were in generation request serial queues for construction through 2031. Table 12-20 also shows the planned retirements for each zone.

Table 12-20 Serial queue totals for projects (active, suspended and under construction) by LDA, control zone and unit type (MW): September 30, 2025[64]

Withdrawn Projects

The serial queue contains a substantial number of projects that are not likely to be built. The serial queue process results in a substantial number of projects that are withdrawn. Manual 14B requires PJM to apply a commercial probability factor at the feasibility study stage to improve the accuracy of capacity and cost estimates. The commercial probability factor is based on the historical incidence of projects dropping out of the queue at the impact study stage, but the actual calculation of commercial probability factors is less than transparent.[65] The impact and facilities studies are performed using the full amount of planned generation in the queues.

Table 12-21 shows the milestone status when projects were withdrawn, for all withdrawn projects in the serial queue. Of the 3,734 projects withdrawn as of September 30, 2025, 1,577 (42.2 percent) were withdrawn before the system impact study was completed. Once a Construction Service Agreement (CSA) is executed, the financial obligation for any necessary transmission upgrades cannot be retracted. Of the 3,734 projects withdrawn, 826 projects (22.1 percent) were withdrawn after the completion of a Construction Service Agreement as of September 30, 2025.

64 This data includes only projects with a status of active, under construction, or suspended.
65 See "PJM Manual 14B: PJM Region Transmission Planning Process," Rev. 57 (September 25, 2024).

Table 12-21 Last milestone at time of withdrawal: January 1, 1997 through September 30, 2025

Milestone Completed	Projects Withdrawn	Percent	Average Days	Maximum Days	MW Withdrawn
Never Started	513	13.7%	81	868	53,163.6
Feasibility Study	1,064	28.5%	291	1,633	196,263.0
System Impact Study	907	24.3%	829	3,248	115,206.2
Facilities Study	424	11.4%	1,291	4,107	58,275.1
Construction Service Agreement (CSA) or beyond	826	22.1%	1,502	7,864	48,815.7
Total	3,734	100.0%			471,723.5

Average Time in Serial Queue

Table 12-22 shows the time spent at various stages in the serial queue process and the completion time for the studies performed. For completed projects, there is an average time of 1,254 days, or 3.4 years, between entering a serial queue and going into service. For withdrawn projects, there is an average time of 792 days, or 2.2 years, between entering a serial queue and withdrawing.

Table 12-22 Project serial queue times by status (days): September 30, 2025[66]

Status	Average (Days)	Standard Deviation	Maximum
Active	2,272	422	3,806
In-Service	1,254	867	6,628
Suspended	2,503	404	3,683
Under Construction	2,696	532	4,060
Withdrawn	792	796	7,864

Table 12-23 presents information on the time in the stages of the serial queue for those projects not yet in service or already withdrawn. Of the 460 projects in the serial queue, in the status of active, under construction or suspended, as of September 30, 2025, three (0.7 percent) had a completed system impact study, 118 (27.7 percent) had a completed facilities study and 339 (73.7 percent) had a completed construction service agreement.

Table 12-23 Project serial queue times by milestone (days): September 30, 2025

Milestone Reached	Number of Projects	Percent of Total Projects	Average Days	Maximum Days
Under Review	0	0.0%	0	0
Feasibility Study	0	0.0%	0	0
System Impact Study	3	0.7%	2,035	2,244
Facilities Study	118	25.7%	2,074	2,563
Construction Service Agreement (CSA) or beyond	339	73.7%	2,542	4,060
Total	460	100.0%		

Table 12-24 shows the time spent in the serial queue by fuel type, and year the project entered the queue, for projects that are in service. The time from when a project enters the serial queue to the time the project goes in service has generally been decreasing compared to the period prior to 2017 although there are significant exceptions. For example, for a battery project entering the serial queue in 2015, there was an average of 2,062 days from the time it entered the queue until it went in service, compared to 1,409 days when entering the queue in 2018.

66 The queue data shows that some projects were withdrawn and a withdrawal date was not identified. These projects were removed for the purposes of this analysis.

Table 12-24 Average time in serial queue (days) by fuel type and year submitted (In Service Projects): September 30, 2025[67]

Wind + Storage							2,680									

67 A blank cell in this table means that no project of that fuel type, which was submitted to the queue in that year, subsequently went in service.

Table 12-25 shows 609,132.6 MW have entered PJM generation serial queues from January 1, 1997, through June 10, 2023. Table 12-25 presents totals by fuel type and projected in service date as of September 30, 2025. Of the 609,132.6 MW to enter the serial queue, 348,159.4 MW (57.2 percent) were thermal units.

Table 12-26 shows there were 43,634.4 MW in the serial queue in the status of active, under construction and suspended as of September 30, 2025. Table 12-26 presents totals by fuel type and projected in service date. Of the 43,634.4 MW, 5,312.5 MW (12.2 percent) are thermal units. Of the 43,634.4 MW with projected in service dates between 2025 and 2031, 5,276.5 MW (12.1 percent) are thermal units.

Table 12-26 Total (MW Energy) by unit type and projected in service year (active, under construction and suspended): September 30, 2025

Table 12-27 shows there were 471,723.5 MW withdrawn from the serial queue from January 1, 1997, through September 30, 2025. Table 12-27 presents totals by fuel type and projected in service date. Of the 471,723.5 MW withdrawn from the serial queue, 280,279.1 MW (59.4 percent) were thermal units. Of the 14,457.3 MW withdrawn with projected in service dates between 2025 and 2031, 2,423.0 MW (16.8 percent) were thermal units.

Completion Rates

The probability of a project going into service increases as each step of the serial planning process is completed. Table 12-28 shows the historic completion rates (MW energy) by unit type for projects that have completed the system impact study (SIS), facilities study agreement (FSA) and any milestone completed beyond the FSA including a Construction Service Agreement (CSA), Interconnection Service Agreement (ISA), Upgrade Construction Service Agreement (UCSA) and Wholesale Market Participant Agreement (WMPA) as well as the historic completion rates for all projects including those withdrawn before reaching the SIS milestone.[68] For each unit type, the total MW in service was divided by the total energy MW entered in the serial queue. To calculate the completion rates for projects that reached the individual milestones, only those projects that reached a final status of withdrawn or in service were evaluated. For example, if a project was withdrawn after the completion of its SIS, but before the completion of the FSA, the totals would be included in the calculation of the SIS completion rate, but not in the calculation of the FSA or CSA completion rates. Similarly, if a project was withdrawn after the completion of its FSA, but before the completion of the CSA, the totals would be included in the calculation of the SIS and FSA completion rates, but not in the calculation of the CSA completion rate. The completion rates show that of all battery projects to ever enter the serial queue and complete the system impact study stage, 6.7 percent of the queued MW have gone into service. The completion rate for battery projects increases to 17.9 percent when battery projects complete the facility study agreement and further increases to 37.3 percent when battery projects complete the construction service agreement. Of all battery projects to enter the serial queue, only 3.0 percent of the queued MW have gone into service.

Table 12-28 Historic completion rates (MW energy) by unit type for projects with a completed SIS, FSA and CSA: September 30, 2025

Unit Type	Completion Rate (SIS)	Completion Rate (FSA)	Completion Rate (CSA)	Completion Rate (ALL)
Battery	6.7%	17.9%	37.3%	3.0%
CC	33.9%	49.6%	71.4%	16.6%

On September 30, 2025, 43,634.4 MW were in generation request serial queues in the status of active, under construction or suspended. Of the total 43,634.4 MW in the queue, 31,841.9 MW (72.9 percent) have reached the CSA milestone and 11,792.5 MW (27.1 percent) have not received a completed CSA. Based on historical completion rates, (applying the unit type specific completion rates for those projects that have reached the SIS, FSA or any milestone beyond the FSA, and using the overall completion rates for those projects that have not yet reached the SIS milestone), 23,288.8 MW (53.3 percent) of new generation in the serial queue are expected to go into service.

Table 12-29 shows the percent of all project MW, by unit type, to go in service by year submitted to the serial queue. Of all battery projects that entered the

68 All milestones after the FSA are included in the totals under the CSA headings of the tables within Section 12, "Generation and Transmission Planning."

serial queue in 2010, 65.5 percent reached the status of in service by September 30, 2025. Of all battery projects that entered the serial queue in 2016, only 1.3 percent have reached the status of in service as of September 30, 2025.

Table 12-30 shows the total MW that went in service each year, by unit type, since 1999. In the first nine months of 2025, 2,117.1 MW from the serial queue went in service. Of the 2,117.1 MW that went in service, 1,883.2 MW (89.0 percent) were solar units, 150 MW (7.1 percent) were solar + storage units, 54.9 MW (2.6 percent) were wind units and 29.0 MW (1.4 percent) were coal fired steam units.

Table 12-30 Total (MW Energy) by unit type and year project went in service: September 30, 2025

Analysis by Fuel Group

The time it takes to complete a study depends on the backlog and the number of projects in the serial queue, but not on the size of the project. Table 12-31 shows the number of projects that entered the serial queue by year and by fuel group. The fuel groups are nuclear units, renewable units (including hydro run of river, solar and wind units (including renewable solar and wind hybrids), storage units (including battery and pumped storage hydro units), thermal units (including combined cycle, CT natural gas and oil, RICE natural gas and oil and steam coal, natural gas and oil) and other units (all other fuels). The number of serial queue entries had increased during the past several years, primarily by renewable projects. Of the 2,809 projects entered from January 2015 through June 2023, 2,062 projects (73.4 percent) were renewable.

Table 12-31 Number of projects entered in the serial queue by fuel group: September 30, 2025

	Fuel Group										
Year Entered	Nuclear	Percent Nuclear	Renewable	Percent Renewable	Storage	Percent Storage	Thermal	Percent Thermal	Other	Percent Other	Total

As of September 30, 2025, renewable projects make up 85.9 percent of all projects in the serial queue and those projects account for 79.9 percent of the nameplate MW currently active, suspended or under construction.

Table 12-32 Serial queue details by fuel group: September 30, 2025

Fuel Group	Number of Projects	Percent of Projects	MW	Percent MW
Nuclear	1	0.2%	44.0	0.1%
Renewable	395	85.9%	34,851.8	79.9%
Storage	47	10.2%	3,426.1	7.9%
Thermal	17	3.7%	5,312.5	12.2%
Other	0	0.0%	0.0	0.0%
Total	460	100.0%	43,634.4	100.0%

Historical completion rates for renewable projects may not be an accurate predictor of completion rates for current renewable projects. The outcomes for current projects will provide additional information and improve the ability to assess the likely future generation mix based on the type of projects in the queue.

Since wind resources cannot be dispatched on demand, PJM rules previously required that the unforced capacity of wind resources be derated to 20 percent of nameplate capacity until actual generation data are available. Beginning with Queue U, PJM derated wind resources to 13 percent of nameplate capacity until there was operational data to support a different conclusion.[69] PJM derated solar resources to 38 percent of nameplate capacity. Effective June 1, 2017, PJM adjusted the derates of wind and solar resources. The capacity factor derates for wind resources are dependent on the wind farm locations and have an average derate of 16.2 percent. The capacity factor derates for solar resources are dependent on the solar installation type and have an average derate of 46.7 percent.

Beginning with the 2023/2024 Delivery Year, unforced capacity for intermittent resources and limited duration resources are determined by PJM's effective load carrying capability (ELCC) analysis. The PJM ELCC analysis will determine capacity derates by resource class for each Delivery Year. The unforced capacity derate for a specific resource will equal the product of the ELCC class rating and a resource specific performance factor. For example, the 2027/2028 Base Residual Auction ELCC class rating for onshore wind resources is 41.0 percent, for solar resources with tracking panels is 8.0 percent and for solar resources with fixed panels is 7.0 percent.[70] The ELCC class rating for battery or energy storage resources replaces the 10 hour rule that was previously used to determine the unforced capacity value for an energy storage resource. PJM defined four different energy storage classes differentiated by duration. The ELCC class rating is 58.0 percent for storage resources that can continuously generate energy at the nameplate capacity for four hours (four hour storage). The ELCC class rating is 67.0 percent for six hour storage and 70.0 percent for eight hour storage and 78.0 percent for 10 hour storage.[71]

While renewables currently make up the majority of both projects and nameplate MW in the serial queue, historical completion rates and derating factors must be accounted for when evaluating the share of capacity resources that are likely to be contributed by renewables. Table 12-33 shows the total MW of all projects in the serial queue as of September 30, 2025, in the status of active, suspended and under construction, by unit type. Table 12-33 also shows the total MW Energy and MW Capacity for each fuel type adjusted based on current historical completion rates and, for Capacity MW in the queue, adjusted for ELCC derates.[72]

Table 12-33 shows that of the 4,158.8 MW, on an energy basis, of combined cycle projects in the serial queue, 2,958.5 MW (71.1 percent) are expected to go in service based on historical completion rates as of September 30, 2025.

Of the 3,426.1 MW, on an energy basis, of battery projects in the serial queue, 931.2 MW (27.2 percent) are expected to go in service based on historical completion rates as of September 30, 2025.

Of the 34,851.8 MW, on an energy basis, of renewable projects in the serial queue, 18,564.5 MW (53.3 percent) are expected to go in service based on historical completion rates as of September 30, 2025.

Of the 3,949.1 MW, on a capacity basis that requested CIRs, of combined cycle projects requested in the generation serial queues in the status of active, under construction or suspended, 2,777.1 MW (70.3 percent) are expected to go into service based on historical completion rates. Based on historical completion rates and the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction, the 3,949.1 MW of capacity requests currently under construction, suspended or active in the serial queue would be reduced to 2,055.1 MW of capacity (52.0 percent of the total requested capacity).

69 See "PJM Manual 14B: PJM Region Transmission Planning Process," Rev. 57 (September 25, 2024).
70 Unless otherwise noted, the ELCC derate factors in this section are based on the *ELCC Class Ratings for 2027/2028 Base Residual Auction*, PJM Interconnection L.L.C. (August 1, 2025) <https://www.pjm.com/-/media/DotCom/planning/res-adeq/elcc/2027-28-bra-elcc-class-ratings.pdf>
71 Additional information available in *PJM Manual 21A: Determination of Accredited UCAP Using Effective Load Carrying Capability Analysis*, PJM Interconnection L.L.C., Rev. 5 (June 27, 2024).
72 Unless otherwise noted, the ELCC derate adjusted MW are calculated using the 2027/2028 Base Residual Auction ELCC factors. The adjusted MW are calculated using the four hour storage ELCC derate of 58.0 percent for battery resources, 41.0 percent ELCC derate for wind resources and 8.0 percent ELCC derate for solar resources.

Of the 2,232.3 MW, on a capacity basis that requested CIRs, of battery projects requested in the generation serial queues in the status of active, under construction or suspended, 161.5 MW (7.2 percent) are expected to go into service based on historical completion rates. Based on historical completion rates and the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction, the 2,232.3 MW of capacity requests currently under construction, suspended or active in the serial queue would be reduced to 93.7 MW of capacity (4.2 percent of the total requested capacity).

Of the 18,186.8 MW, on a capacity basis that requested CIRs, of renewable projects requested in the generation serial queues in the status of active, under construction or suspended, 9,797.0 MW (53.9 percent) are expected to go into service based on historical completion rates. Based on historical completion rates and the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction, the 18,186.8 MW of capacity requests currently under construction, suspended or active in the serial queue would be reduced to 965.8 MW of capacity (5.3 percent of the total requested capacity).

As of September 30, 2025, 25,603.7 MW of capacity requests (requested CIRs) were in the generation serial queues in the status of active, under construction or suspended. Based on historical completion rates, 13,565.8 MW (53.0 percent) are expected to go into service. Based on historical completion rates and the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction, the 25,603.7 MW of capacity requests currently under construction, suspended or active in the serial queue would be reduced to 3,631.5 MW of capacity (14.2 percent of the total requested capacity).

Table 12-33 Serial queue totals for projects (active, suspended and under construction) by unit type adjusted for current historical completion rates and ELCC derates (MW): September 30, 2025

	Energy (MW)		Capacity (MW)

Analysis by Unit Type and Project Classification

Table 12-34 shows the status of all generation serial queue projects by unit type and project classification as of September 30, 2025. As of September 30, 2025, 5,461 projects, representing 609,132.6 MW, have entered the serial queue process from 1997 until the implementation of the new cycle process on July 10, 2023. Of those, 1,267 projects, representing 93,774.7 MW (15.4 percent of the MW), went into service. Of the projects that entered the serial queue process, 3,734 projects, representing 471,232.5 MW (77.4 percent of the MW) withdrew prior to completion. Such projects may create barriers to entry for projects that would otherwise be completed by taking up queue positions, increasing interconnection costs and creating uncertainty.

A total of 4,354 projects have been classified as new generation and 1,107 projects have been classified as upgrades. Natural gas, wind, solar and renewable hybrid projects (including solar + storage, solar + wind and wind + storage) have accounted for 4,361 projects (79.9 percent) of all 5,461 generation serial queue projects to enter the queue since January 1, 1997.

Table 12-35 shows the totals in Table 12-34 by share of classification as new generation or upgrade. Within a unit type the shares of upgrades add to 100 percent and the shares of new generation add to 100 percent. For example, 79.2 percent of all hydro run of river projects classified as upgrades are currently in service in PJM, 16.7 percent of hydro run of river upgrades were withdrawn and 4.2 percent of hydro run of river upgrades are active in the serial queue.

Table 12-35 Status of all generation serial queue projects as a percent of total projects by classification: September 30, 2025

Table 12-36 shows the total MW of projects in the PJM generation status queue by unit type and project classification. For example, the 487 new generation wind projects that have been withdrawn from the serial queue as of September 30, 2025, (as shown in Table 12-34) constitute 90,541.2 MW. The 440 new generation combined cycle projects that have been withdrawn in the same time period constitute 221,887.8 MW.

Table 12-36 Status of all generation (MW) in the generation serial queue: September 30, 2025

Table 12-37 shows the MW totals in Table 12-36 by share by classification as new generation or upgrade. Within a unit type the shares of upgrades add to 100 percent and the shares of new generation add to 100 percent. For example, 85.1 percent of wind project MW classified as new generation have been withdrawn from the serial queue between January 1, 1997, and September 30, 2025.

Table 12-37 Status of all generation serial queue projects as percent of total MW in project classification: September 30, 2025

Table 12-38 shows the project MW that entered the PJM generation serial queue by unit type and year of entry. Since 2016, 82.5 percent of all new projects entering the generation serial queue have been combined cycle (19.6 percent), wind (17.2 percent) or solar projects (45.7 percent). Prior to 2015, no renewable hybrid units (solar + storage, solar + wind and wind + storage) entered the queue. In the time period from January 1, 2015 through June 10, 2023, 14,641.9 MW of renewable hybrid units have entered the serial queue.

Combined Cycle Project Analysis

Table 12-39 shows the status of all combined cycle projects by number of projects that entered PJM generation serial queues from January 1, 1997, through July 10, 2023, by zone. Of the nine combined cycle projects classified as new generation or upgrade currently active, suspended or under construction in the PJM generation serial queue, four projects (44.4 percent) are located in the APS Zone.

Table 12-39 Status of all combined cycle serial queue projects by zone (number of projects): September 30, 2025

Of the nine combined cycle units in the serial queue as of September 30, 2025, in the status of active, under construction or suspended, no units had a projected in service date prior to January 1, 2025 and nine units, representing 4,158.8 MW had a projected in service date between January 1, 2025, and December 31, 2029.

Combustion Turbine – Natural Gas Project Analysis

Table 12-41 shows the status of all combustion turbine natural gas projects by number of projects that entered PJM generation queues from January 1, 1997, through July 10, 2023, by zone. Of the seven combustion turbine natural gas projects classified as new generation or upgrade currently active, suspended or under construction in the PJM generation serial queue, four projects (57.1 percent) are located in the ATSI Zone.

Table 12-42 shows the status of all combustion turbine natural gas projects by MW that entered PJM generation serial queues from January 1, 1997, through July 10, 2023, by zone. Of the 1,117.7 MW of combustion turbine natural gas projects classified as new generation or upgrade currently active, suspended or under construction in the PJM generation serial queue, 569.0 MW (50.9 percent) are located in the DOM Zone.

Of the seven combustion turbine natural gas units in the serial queue as of September 30, 2025, in the status of active, under construction or suspended, no units had a projected in service date prior to January 1, 2025 and seven units, representing 1,117.7 MW had a projected in service date between January 1, 2025, and December 31, 2031.

Wind Project Analysis

Table 12-43 shows the status of all wind generation projects, by number of projects that entered PJM generation serial queues from January 1, 1997, through July 10, 2023, by zone. Of the 27 wind projects classified as new generation or upgrade currently active, suspended or under construction in the PJM serial generation queue, 11 projects (40.7 percent) are located in the COMED Zone.

Of the 27 wind units in the serial queue as of September 30, 2025, in the status of active, under construction or suspended, two units, representing 160.0 MW had a projected in service date prior to January 1, 2025 and 25 units, representing 5,389.7 MW had a projected in service date between January 1, 2025, and December 31, 2029.

A total of 48 offshore wind projects entered PJM generation serial queues from January 1, 1997, through July 10, 2023. Offshore wind projects are included in the wind generation statistics. Of the 27 wind projects classified as new generation or upgrade currently active, suspended or under construction in the PJM generation serial queue (Table 12-43), four projects (14.8 percent) are offshore wind. Of the 5,549.7 MW of wind projects classified as new generation or upgrade currently active, suspended or under construction in the PJM generation serial queue (Table 12-44), 1,503.1 MW (27.1 percent) are offshore wind projects. Table 12-43 shows that 519 wind projects have been withdrawn from the serial queue. Of those 519 wind projects, 43 projects (8.3 percent) were offshore wind. Table 12-44 shows that those 519 wind projects that have been withdrawn from the serial queue totaled 92,692.2 MW. Of the 92,692.2 MW of withdrawn wind projects, 16,787.2 MW (18.1 percent) were offshore wind projects.

Solar Project Analysis

Table 12-45 shows the status of all solar generation projects by number of projects that entered PJM generation serial queues from January 1, 1997, through July 10, 2023, by zone. Of the 338 solar projects classified as new generation or upgrade currently active, suspended or under construction in the PJM generation serial queue, 100 projects (29.6 percent) are located in the AEP Zone.

Of the 338 solar units in the serial queue as of September 30, 2025, in the status of active, under construction or suspended, 21 units, representing 1,641.3 MW had a projected in service date prior to January 1, 2025 and 317 units, representing 25,087.7 MW had a projected in service date between January 1, 2025, and December 31, 2031.

Battery Project Analysis

Table 12-47 shows the status of all battery generation projects by number of projects that entered PJM generation serial queues from January 1, 1997, through July 10, 2023, by zone. Of the 47 battery projects currently active, suspended or under construction in the PJM generation serial queue, 12 projects (25.5 percent) are located in the AEP Zone.

73 PJM does not currently have a definition of a hybrid resource.

Of the 29 renewable hybrid units in the serial queue as of September 30, 2025, in the status of active, under construction or suspended, two units, representing 6.6 MW had a projected in service date prior to January 1, 2025 and 27 units, representing 2,515.6 MW had a projected in service date between January 1, 2025, and December 31, 2031.

New Service Requests Cycle Process[74]

Interconnection Process Studies and Agreements

The transition to the new queue process began on July 10, 2023. The new queue process includes modifications to implement a cluster/cycle based processing method to replace the first in/first out processing method.[75] Each cycle consists of the: application phase, phase I, decision point I, phase II, decision point II, phase III, decision point III, and the final agreement negotiation phase.

Application Phase

The application phase includes the submission and review of a new service request. A new service request could be a request to interconnect a new generating facility, a request to increase the capability of an existing generating facility, a request to interconnect a merchant transmission facility, a request to increase the capability of an existing merchant transmission facility, a request to interconnect a generating facility to distribution facilities located in PJM that are to be used for transmission of power in interstate commerce, and to make wholesale sales or a long term firm transmission service request outside of the 18 month available transfer capability (ATC) horizon. The deadline for submitting applications for a new cycle corresponds with the completion of phase II of the previous cycle. For an application to be considered complete, and included in a cycle, PJM must receive a completed and executed application and studies agreement (ASA), required technical information, a wire transfer for the entirety of study deposit, a wire transfer or letter of credit for the entirety of Readiness Deposit No. 1 and, for generation requests, evidence of site control.

74 Material in this section is based on information found in PJM Manual 14H. See "PJM Manual 14H: New Service Requests Cycle Process," Rev. 02 (July 23, 2025).

75 See "Interconnection Process Reform," presented at April 27, 2022 meeting of the Members Committee. <https://www.pjm.com/-/media/committees-groups/committees/mc/2022/20220427/20220427-item-01a-1-interconnection-process-reform-presentation.ashx>.

Phase I

Phase I of a cycle begins after the application phase of a cycle is completed and a group of valid new service requests is established. During phase I of a cycle, PJM performs a phase I system impact study (SIS). The phase I SIS is conducted on an aggregate basis within a cycle, and results are provided in a single cycle format. The phase I SIS results are posted on PJM's website. The phase I SIS evaluates each new service request on a summer peak, winter peak and light load RTEP base case. PJM only performs a load flow analysis during the phase I system impact study. In phase I of the cycle, PJM also conducts an affected system screen and provides each affected system operator with a list of new service requests within the cycle including potential impacts to their system. During phase I, PJM creates both the short circuit and stability base cases that will be used in the phase II SIS.

Decision Point I

New service requests that are studied in phase I will enter decision point I. After reviewing the results of the phase I SIS, the project developer must decide whether or not to move forward to phase II of the process. Decision point I starts on the first business day following the end of phase I and closes 30 calendar days later. Before the close of decision point I, the project developer can choose to either remain in the cycle by meeting the decision point I requirements or to withdraw its new service request. If a project developer fails to submit all required deposits, evidence, and data before the close of decision point I, the new service request will be terminated and withdrawn.

Phase II

After the decision point I phase of a cycle is completed and a group of valid new service requests is established, phase II of a cycle will begin. During phase II of a cycle, PJM performs the phase II SIS. PJM retools the load flow results from the phase I SIS (summer peak, winter peak and light load) based on decisions made during decision point I. PJM also conducts any required voltage analyses, performs short circuit and stability analyses and coordinates with affected systems to confirm which projects in the cycle will require affected system studies. If the affected system operator indicates that an affected system study is required, PJM notifies the project developer of the need for an affected system study and the requirement to execute an affected system study agreement with the impacted affected system operator. If applicable and available, PJM includes the results of the affected system operator's affected system study in the phase II SIS results.

The phase II SIS includes a facilities study by the affected transmission owner that identifies any required network upgrades. The facilities studies will include good faith estimates of the costs to be charged to each affected new service customer for the network upgrades that are necessary to accommodate each new service request evaluated in the study, the time required to complete detailed design and construction of the facilities and upgrades and a description of any site-specific environmental issues or requirements that could reasonably be anticipated to affect the cost or time required to complete construction of such facilities and upgrades.

Decision Point II

New service requests that are studied in phase II will enter decision point II. After reviewing the results of the phase II SIS, the project developer must decide whether or not to move forward to phase III of the process. Decision point II starts on the first business day following the end of phase II and closes 30 calendar days later. Before the close of decision point II, the project developer can choose to either remain in the cycle by meeting the decision point II requirements or to withdraw its new service request. If a project developer fails to submit all required deposits, evidence, and data before the close of decision point II, the new service request will be terminated and withdrawn.

Phase III

After the decision point II phase of a cycle is completed and a group of valid new service requests is established, phase III of a cycle will begin. During phase III of a cycle, PJM performs the phase III SIS. PJM retools the load flow, short circuit and stability results from the phase II SIS based on decisions made during decision point II. PJM also coordinates with affected systems to conduct any studies required to determine the final impact of a new service request on any affected system. If applicable and available, PJM includes the results of the affected system operator's final affected system study in the phase III SIS results.

Decision Point III

New service requests that are studied in phase III will enter decision point III. After reviewing the results of the phase III SIS, the project developer must decide whether or not to move forward to the final agreement negotiation phase. Decision point III starts on the first business day following the end of phase III and runs concurrently with the final agreement negotiation phase. The project developer can choose to either remain in the cycle by meeting the decision point III requirements or to withdraw its new service request. If a project developer fails to submit all required deposits, evidence, and data before the close of decision point III, the new service request will be terminated and withdrawn.

Final Agreement Negotiation Phase

The final agreement negotiation phase starts on the first business day immediately following the end of phase III, and runs concurrently with decision point III. The purpose of the final agreement negotiation phase is to negotiate, execute and enter into the applicable final interconnection related service agreement, conduct any remaining analyses or updated analyses based on new service requests withdrawn during decision point III and adjust the security obligation based on new service requests withdrawn during decision point III and/or during the final agreement negotiation phase. PJM uses reasonable efforts to complete the final agreement negotiation phase within 60 days. Table 12-51 is an overview of the agreements used in the new service requests cycle process.

Table 12-51 Final agreements: new service requests cycle process

Agreement	Purpose
Generation Interconnection Agreement (GIA)	The GIA defines the obligations of the project developer regarding cost responsibility for any required system upgrades. The GIA also confers the rights associated with the interconnection of a generating facility as a capacity resource and any operational restrictions or other limitations on which those rights depend. For transmission project developers, the GIA confers transmission injection and withdrawal rights and applicable incremental delivery rights and incremental auction revenue rights.The GIA further identifies any changes in construction responsibility from the standard option for transmission owner interconnection facilities due to the project developer exercising the negotiated contract option or option to build.
Construction Service Agreement (CSA)	The CSA defines the standard terms and conditions of the interconnection, including construction responsibility, includes a construction schedule and contains notification and insurance obligations.The CSA is included as a schedule within a GIA; however, a stand-alone CSA may be implemented in circumstances in which network upgrades to the system of a transmission owner are required to accommodate the interconnection request of a project developer, whose facilities do not directly interconnect to the transmission owner's system. Examples include project developers who are affected system customers (external to the PJM region), that require network upgrades to be constructed by PJM transmission owners, or project developers requiring upgrades to be constructed by PJM transmission owners, other than their interconnecting transmission owner
Upgrade Construction Service Agreement (USCA)	A new service customer who proposes to make an upgrade to an existing transmission facility or who seeks incremental auction revenue rights (IARRs) will receive an upgrade construction service agreement after their study process is completed.
Network Upgrade Cost Responsibility Agreement (NUCRA)	The NUCRA refers to the agreement entered into by two or more project developers and PJM, relating to construction of common use upgrades (network upgrades needed for the interconnection of generating or merchant transmission facilities for more than one project developer that share cost responsibility) and coordination of the construction and interconnection of associated generating facilities. A separate NUCRA will be executed for each set of common use upgrades on the system of a specific transmission owner that is associated with the interconnection of a generating facility or merchant transmission facility. The NUCRA includes the identified common use upgrades scope and schedule of work, the cost responsibility for the project developers that share cost responsibility, as well as the terms and conditions for the agreement.
Wholesale Market Participation Agreement (WMPA)	Developers interconnecting to non-FERC jurisdictional facilities who intend to participate in the PJM wholesale market will receive a three party agreement (WMPA). The WMPA is a non-Tariff agreement which must be filed with the FERC. The WMPA is essentially an ISA without interconnection provisions.

Transition Cycle 1 (TC1)

On November 29, 2022, the Commission issued an order accepting PJM's tariff revisions to improve the queue process.[76] The new queue process includes modifications to implement a cluster/cycle based processing method to replace the first in/first out processing method.[77] This change will allow projects to move forward based on a first ready/first out analysis, where readiness is demonstrated through site control and financial milestones and there is an option to exit the study process early based on system impacts. The transition to the new queue process began on July 10, 2023.

On May 20, 2024, PJM completed the phase I system impact study for transition cycle 1 (TC1). Developers had 30 days (until June 20, 2024) to decide whether to proceed with their new service requests into the next study phase of TC1 or to withdraw their projects. Continuing with phase II required developers to meet the decision point I requirements (including additional readiness deposits and proof of site control).[78]

On December 20, 2024, PJM completed the phase II system impact study for TC1. Developers had 30 days (until January 19, 2025) to decide whether to proceed with their new service requests into the next study phase of TC1 or to withdraw their projects. Continuing with phase III requires developers to meet the decision point II requirements, (including additional readiness deposits and proof of site control).[79]

On April 21, 2025, phase III of TC1 began. During phase III, PJM performed the phase III SIS. PJM retooled the load flow, short circuit and stability results from the phase II SIS based on decisions made during decision point II. PJM also coordinated with affected systems to conduct any studies required to determine the final impact of a new service request on any affected system. Phase III of TC1 completed on September 19, 2025. The TC1 decision point III runs for 30 days, and is scheduled to be completed on October 21, 2025. Additionally, the TC1 final agreement phase also began at the completion of phase III, and is scheduled to be completed on November 20, 2025.

78 See "PJM Manual 14H: New Service Requests Cycle Process," Rev. 02 (July 23, 2025) for a complete list of all readiness requirements.
79 See "PJM Manual 14H: New Service Requests Cycle Process," Rev. 02 (July 23, 2025) for a complete list of all readiness requirements.

Planned Generation Additions

TC1 is comprised of 312 proposed generation projects. Those projects make up 40,650.2 MW. On September 30, 2025, all projects in TC1 were either in the status of active or were withdrawn from the cycle. Table 12-52 shows each status by unit type. Of the 40,650.2 MW in TC1, 17,873.8 MW (44.0 percent) were active and 22,776.3 MW (56.0 percent) were withdrawn. Of the 17,873.8 MW in the status of active, 9,762.3 MW (54.6 percent) were solar projects, 4,377.3 MW (24.5 percent) were wind projects, and 2,254.2 MW (12.6 percent) were battery projects.

Table 12-52 Transition cycle 1 project status (MW) by unit type: September 30, 2025

Table 12-54 shows that on September 30, 2025 there were 17,873.8 MW, on an energy basis, of which 8,854.3 MW are on a capacity basis that requested CIRs, in TC1 in the status of active or under construction. Table 12-54 also shows the total capacity MW adjusted for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.

Of the 8,854.3 MW, on a capacity basis that requested CIRs in TC1 in the status of active or under construction, 2,152.8 MW (24.3 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.

Of the 5,082.0 MW, on a capacity basis that requested CIRs, of solar projects requested in TC1 in the status of active or under construction, 406.6 MW (8.0 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.

Of the 1,565.3 MW, on a capacity basis that requested CIRs, of battery projects requested in TC1 in the status of active or under construction, 907.9 MW (58.0 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.

Of the 6,720.0 MW, on a capacity basis that requested CIRs, of renewable projects requested in TC1 in the status of active or under construction, 897.9 MW (13.4 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.

Table 12-54 Transition cycle 1 totals for projects (active and under construction) by unit type adjusted for ELCC derates (MW): September 30, 2025

Withdrawn Projects

Table 12-55 shows the status of all TC1 projects as they have progressed through the cycle process. Of the 312 projects included in TC1, 121 projects (38.8 percent of all projects and 38.9 percent of the total MW) were withdrawn during phase I or decision point I and 61 projects (19.6 percent of all projects and 17.1 percent of the total MW) were withdrawn during phase II or decision point II. On September 30, 2025, 130 projects (41.6 percent of all projects and 44.0 percent of the total MW) remain active in TC1.

Table 12-55 Transition cycle 1 status: September 30, 2025

	Number of Projects	Percent of Projects	MW Energy	Percent of MW Energy
Transition cycle 1 approved projects	312	100.0%	40,650.2	100.0%
Withdrawn prior to start of phase I	0	0.0%	0.0	0.0%
Withdrawn during phase I or decision point I	121	38.8%	15,821.8	38.9%
Withdrawn during phase II or decision point II	61	19.6%	6,954.5	17.1%
Active as of September 30, 2025	128	41.0%	17,353.8	42.7%
In final agreement stage as of September 30, 2025	2	0.6%	520.0	1.3%
Under construction	0	0.0%	0.0	0.0%
In Service	0	0.0%	0.0	0.0%

Table 12-56 shows 40,650.2MW have entered TC1. Table 12-56 presents totals by fuel type and projected in service date as of September 30, 2025. Of the 40,650.2 MW to enter TC1, 569.0 MW (1.4 percent) were thermal units.

Table 12-58 shows there were 22,776.3 MW withdrawn from TC1. Table 12-58 presents totals by fuel type and projected in service date. Of the 22,776.3 MW withdrawn from TC1, none were identified as thermal units.

Analysis by Fuel Group

Table 12-59 shows the number of projects that entered TC1 by year and by fuel group. The fuel groups are nuclear units, renewable units (including hydro run of river, solar and wind units (including renewable solar and wind hybrids), storage units (including battery and pumped storage hydro units), thermal units (including combined cycle, CT natural gas and oil, RICE natural gas and oil and steam coal, natural gas and oil) and other units (all other fuels). The 312 projects submitted to TC1 were made up of 233 renewable projects (74.7 percent), 77 storage projects (24.7 percent) and two thermal projects (0.6 percent).

Table 12-59 Transition cycle 1 number of projects by fuel group: September 30, 2025

	Fuel Group										
Year Entered	Nuclear	Percent Nuclear	Renewable	Percent Renewable	Storage	Percent Storage	Thermal	Percent Thermal	Other	Percent Other	Total
2018	0	0.0%	4	80.0%	0	0.0%	1	20.0%	0	0.00%	5
2019	0	0.0%	57	78.1%	15	20.5%	1	1.4%	0	0.00%	73
2020	0	0.0%	172	73.5%	62	26.5%	0	0.0%	0	0.00%	234
Total	0	0.0%	233	74.7%	77	24.7%	2	0.6%	0	0.00%	312

As of September 30, 2025, there were 130 projects in TC1 in the status of active or under construction. Those 130 projects consisted of 104 renewable projects (80.0 percent of all projects and 84.2 percent of the nameplate MW), 25 storage projects (19.2 percent of all projects and 12.6 percent of the nameplate MW) and one thermal project (0.8 percent of all projects and 3.2 percent of the nameplate MW) (Table 12-60).

Table 12-60 Transition cycle 1 details by fuel group: September 30, 2025

Fuel Group	Number of Projects	Percent of Projects	MW	Percent MW
Nuclear	0	0.0%	0.0	0.0%
Renewable	104	80.0%	15,050.6	84.2%
Storage	25	19.2%	2,254.2	12.6%
Thermal	1	0.8%	569.0	3.2%
Other	0	0.0%	0.0	0.0%
Total	130	100.0%	17,873.8	100.0%

Analysis by Unit Type and Project Classification

Table 12-61 shows the status of all new generation projects in TC1 by unit type and project classification as of September 30, 2025. Project classification is defined as either new generation or an uprate in which existing resources are modified to increase the economic maximum generation capability. There were 312 projects, representing 40,650.2 MW, entered into TC1. Of those, 312 projects, 182 projects, representing 22,776.3 MW (56.0 percent of the MW) withdrew prior to completion.

A total of 218 projects have been classified as new generation and 94 projects have been classified as upgrades. Natural gas, wind, solar and renewable hybrid projects (including solar + storage, solar + wind and wind + storage) have accounted for 235 projects (75.3 percent) of all 312 generation projects to enter TC1.

Table 12-61 Transition Cycle 1 status of all generation projects: September 30, 2025

Table 12-62 shows the totals in Table 12-61 by share of classification as new generation or upgrade. Within a unit type the shares of upgrades add to 100 percent and the shares of new generation add to 100 percent. For example, 31.1 percent of all battery projects in TC1 classified as upgrades were active and 68.9 percent of battery projects classified as upgrades were withdrawn from TC1 as of September 30, 2025.

Table 12-63 shows the total MW of projects in TC1 by unit type and project classification. For example, the 21 new generation battery projects that have been withdrawn from TC1 as of September 30, 2025, (as shown in Table 12-61) constitute 2,929.7 MW. The 73 new generation solar projects that have been withdrawn in the same time period constitute 9,722.7 MW.

Transition Cycle 2 (TC2) and Reliability Resource Initiative (RRI)

On December 13, 2024, PJM submitted modifications to its Open Access Transmission Tariff to add provisions, through a one-time reliability based expansion of the projects in TC2.[80] The MMU supports the stated goals of the December 13th Filing, and supported approval of the December 13th Filing, but also identified significant flaws that compromise the ability of the proposal to achieve its stated goals.[81] PJM's RRI scoring criteria placed undue emphasis on ELCC values rather than on dispatchability. PJM stated that the goal is to be fuel and technology neutral. That is not the appropriate objective when there are defined differences in reliability and dispatchability across resource types, by fuel and technology. The goal of the December 13th Filing should have been to select the most reliable fuel and technology combinations. PJM also focused on an arbitrary number of projects (50) that could qualify as RRI projects rather than on a target level of MW needed for reliability. PJM should have identified the number of MW, with the required reliability characteristics, that it believes are needed to address PJM's identified reliability shortfall and use the RRI process to obtain those MW. PJM's RRI scoring criteria should have been a series of thresholds that must be met in sequence rather than a single formula that considers all elements simultaneously and assumes that the criteria are comparable through relative weights. The first threshold should have been that the resource is in the right location to address the identified locational reliability issue. The second threshold should have been that the operational characteristics of the resource fully address the identified reliability issue including technology and fuel source(s). The third threshold should have been commercial viability within a defined time period with detailed tracking and strong financial incentives. No RRI resource should have been approved unless it met all three thresholds.

In addition to the one time RRI process, the MMU recommends that PJM establish an ongoing expedited PJM managed queue process to identify commercially viable projects that could help eliminate or reduce the need for specific RMRs or that could address specific reliability needs and allow the identified projects to advance in the queue ahead of projects which have failed to make progress, subject to rules to prevent gaming.[82] While it is important to respect the existing, improved PJM queue process, it is also essential to provide strong and clear incentives for projects to actually resolve reliability issues and to actually guarantee timely in service dates in order to help ensure that the queue is not a mirage as it has been in significant part for its recent history. Recognizing that improved queue rules are being implemented, the history of queue projects becoming actual in service capacity resources suggests strongly that such incentives have not been provided by the queue process.

On February 11, 2025, the Commission approved the RRI tariff modifications.[83] The proposed RRI Tariff revisions created a second TC2 application window that enabled RRI projects to join TC2 and be studied for interconnection during the transition period.

PJM included a range of important enforceable provisions that help ensure that the selected RRI resources will actually go online as promised. These provisions include a must offer obligation which is essential to the efficacy of the entire filing as capacity resources that do not offer do not help solve the identified problem. The MMU supports these provisions.

PJM received 97 applications (28.6 GW) of RRI projects during the RRI application window. Of these projects, 48 involve uprates, in which existing resources are modified to increase the economic maximum generation capability, and 49 propose building new generation. The RRI application window did not limit the number and type of projects (or any restriction on fuel type of projects) that may apply to enter the RRI process. However, PJM restricted the number of RRI projects to be added to TC2 by scoring all the RRI applications using weighted criteria to determine the 50 projects that best

80 See *PJM Interconnection L.L.C.* Docket No. ER25-712 (December 13, 2024).
81 See IMM Comments. *PJM Interconnection L.L.C.* Docket No. ER25-712

82 The MMU has consistently supported a stronger role for PJM in addressing immediate reliability needs. As part of the CIR Transfer Efficiency initiative, the MMU proposed to allow PJM to initiate an expedited fast track process to address PJM identified reliability issues. The proposed expedited process would have allowed PJM to open a limited scope expedited reliability process to select projects that address the reliability issues. See "CIR Transfer Efficiency IMM Package," MMU presentation to the PJM Planning Committee (October 8, 2024), <https://www.monitoringanalytics.com/reports/Presentations/2024/IMM_PC_CIR_Transfer_Efficiency_IMM_Package_20241008_v2.pdf>.
83 190 FERC ¶ 61,084 (February 11, 2025).

satisfy the need for reliable capacity that can be available relatively quickly. The submitted RRI projects were reviewed to determine which projects will be added to TC2.

PJM reviewed the submitted RRI projects using the Commission approved scoring criteria, and approved 51 projects (11,577.4 MW).[84] Table 12-65 shows the status of the 51 approved RRI projects by unit type. On September 30, 2025, all approved RRI projects were either in the status of active or were withdrawn from the cycle. Of the 11,577.4 MW of approved RRI projects, 10,938.4 MW (94.5 percent) were active and 639.0 MW (5.5 percent) were withdrawn. Of the 10,938.4 MW in the status of active, 7,749.6 MW (70.8 percent) were combined cycle projects, and 1,675.0 MW (15.3 percent) were battery projects.

Table 12-65 RRI project status (MW) by unit type: September 30, 2025

	Battery	Combined Cycle	CT - Natural Gas	CT - Oil	CT - Other	Fuel Cell	Hydro - Pumped Storage	Hydro - Run of River	Nuclear	RICE - Natural Gas	RICE - Oil	RICE - Other	Solar	Solar + Storage	Solar + Wind	Steam - Coal	Steam - Natural Gas	Steam - Oil	Steam - Other	Wind	Wind + Storage	Total
Active	1,675.0	7,749.6	11.0	0.0	0.0	0.0	0.0	0.0	1,502.8	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	10,938.4
Withdrawn	600.0	39.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	639.0
Total	2,275.0	7,788.6	11.0	0.0	0.0	0.0	0.0	0.0	1,502.8	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	11,577.4

Table 12-66 shows that on September 30, 2025 there were 10,938.4 MW, on an energy basis, of which 10,439.8 MW are on a capacity basis that requested CIRs, of RRI projects in the status of active or under construction. Table 12-66 also shows the total capacity MW adjusted for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.

Of the 10,439.8 MW, on a capacity basis that requested CIRs, of RRI projects in the status of active or under construction, 7,726.7 MW (74.0 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.

Of the 7,420.9 MW, on a capacity basis that requested CIRs, of RRI combined cycle projects in the status of active or under construction, 5,491.5 MW (74.0 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.

Of the 1,675.0 MW, on a capacity basis that requested CIRs, of RRI battery projects in the status of active or under construction, 971.5 MW (58.0 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.

84 The RRI proposal was to select the top 50 projects using the approved scoring criteria. The implemented scoring criteria resulted in a tie for the 50th project. This resulted in PJM selecting 51 projects as part of the RRI process.

Table 12-66 RRI totals for projects (active and under construction) by unit type adjusted for ELCC derates (MW): September 30, 2025

The application phase for TC2 opened on June 20, 2024, coincident with the close of phase I of transition cycle 1. The application phase required all active projects in queues AG2 and AH1 to reapply under the new rules. The application phase of TC2 was open for 180 days, and closed on December 17, 2024.

There were 1,347 projects (103,151.7 MW) eligible to resubmit for evaluation in TC2. Of those 1,347 eligible projects, 550 projects (50,023.2 MW) resubmitted and are now being evaluated in TC2. Of the 1,347 eligible projects, 797 projects (53,155.5 MW) did not resubmit, and were withdrawn from the queue.

The TC2 application review stage began at the close of the application phase. PJM will review the submissions for required data and deposits and build the models required for the TC2 system impact studies. The TC2 application review stage completed on July 6, 2025. Phase I of TC2 began on July 7, 2025 and is set to be completed on October 31, 2025.

Planned Generation Additions

TC2 is comprised of 647 proposed generation projects. TC2 includes 550 projects submitted during the TC2 window, and 97 projects submitted through the RRI window. Those projects make up 78,329.4 MW. On September 30, 2025, all projects in TC2 were either in the status of active or were withdrawn from the cycle. Table 12-67 shows each status by unit type. Of the 78,329.4 MW in TC2, 45,977.6 MW (58.7 percent) were active and 32,351.8 MW (41.3 percent) were withdrawn. Of the 45,977.6 MW in the status of active, 19,308.1 MW (42.0 percent) are solar projects, 1,235.2 MW (2.7 percent) are wind projects, and 9,404.9 MW (20.5 percent) are battery projects.

Table 12-69 shows that on September 30, 2025 there were 45,977.6 MW, on an energy basis, of which 32,120.8 MW are on a capacity basis that requested CIRs, in TC2 in the status of active or under construction. Table 12-69 also shows the total capacity MW adjusted for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.

Of the 32,120.8 MW, on a capacity basis that requested CIRs in TC2 in the status of active or under construction, 14,167.2 MW (44.1 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.

Of the 10,051.8 MW, on a capacity basis that requested CIRs, of solar projects requested in TC2 in the status of active or under construction, 804.1 MW (8.0 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.

Of the 7,400.0 MW, on a capacity basis that requested CIRs, of battery projects requested in TC2 in the status of active or under construction, 4,292.0 MW (58.0 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.

Of the 13,167.0 MW, on a capacity basis that requested CIRs, of renewable projects requested in TC2 in the status of active or under construction, 1,146.4 MW (8.7 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.

Withdrawn Projects

Table 12-70 shows the status of all TC2 projects as they have progressed through the cycle process. Of the 647 projects included in TC2, 46 projects (7.1 percent of all projects and 21.7 percent of the total MW) were withdrawn as part of the RRI evaluation, 51 projects (7.9 percent of all projects and 6.6 percent of the total MW) were withdrawn prior to the beginning of phase I, and 100 projects (15.5 percent of all projects and 12.9 percent of the total MW) were withdrawn during phase I or decision point I. On September 30, 2025, 450 projects (69.6 percent of all projects and 58.7 percent of the total MW) remain active in TC2.

Table 12-70 Transition cycle 2 and RRI status: September 30, 2025

	Number of Projects	Percent of Projects	MW Energy	Percent of MW Energy
Transition cycle 2 approved projects	647	100.0%	78,329.4	100.0%
RRI projects not selected	46	7.1%	17,014.8	21.7%
Withdrawn prior to start of phase I	51	7.9%	5,201.1	6.6%
Withdrawn during phase I or decision point I	100	15.5%	10,135.8	12.9%
Withdrawn during phase II or decision point II	0	0.0%	0.0	0.0%
Active as of September 30, 2025	450	69.6%	45,977.6	58.7%

Analysis by Fuel Group

Table 12-74 shows the number of projects that entered TC2 by year and by fuel group. The fuel groups are nuclear units, renewable units (including hydro run of river, solar and wind units (including renewable solar and wind hybrids), storage units (including battery and pumped storage hydro units), thermal units (including combined cycle, CT natural gas and oil, RICE natural gas and oil and steam coal, natural gas and oil) and other units (all other fuels). The 647 projects submitted to TC2 were made up of 389 renewable projects (60.1 percent), 190 storage projects (29.4 percent), 58 thermal projects (9.0 percent), five nuclear projects (0.8 percent) and five other fuel projects (0.8 percent).

Table 12-74 Transition cycle 2 and RRI number of projects by fuel group: September 30, 2025

	Fuel Group

2025	5	5.2%	5	5.2%	32	33.0%	54	55.7%	1	1.0%	97
Total	5	0.8%	389	60.1%	190	29.4%	58	9.0%	5	0.8%	647

As of September 30, 2025, there were 450 projects in TC2 in the status of active or under construction. Those 450 projects consisted of 288 renewable projects (64.0 percent of all projects and 53.2 percent of the nameplate MW), 111 storage projects (24.7 percent of all projects and 20.5 percent of the nameplate MW), 43 thermal projects (9.6 percent of all projects and 23.1 percent of the nameplate MW), five nuclear projects (1.1 percent of all projects and 3.3 percent of the nameplate MW) and three other fuel type projects (0.7 percent of all projects and .03 percent of the nameplate MW) (Table 12-75).

Table 12-75 Transition cycle 2 and RRI details by fuel group: September 30, 2025

Fuel Group	Number of Projects	Percent of Projects	MW	Percent MW
Nuclear	5	1.1%	1,502.8	3.3%
Renewable	288	64.0%	24,442.2	53.2%
Storage	111	24.7%	9,404.9	20.5%
Thermal	43	9.6%	10,612.6	23.1%
Other	3	0.7%	15.1	0.0%
Total	450	100.0%	45,977.6	100.0%

Analysis by Unit Type and Project Classification

Table 12-76 shows the status of all new generation projects in TC2 by unit type and project classification as of September 30, 2025. Project classification is defined as either new generation or an uprate in which existing resources are modified to increase the economic maximum generation capability. There were 647 projects, representing 78,329.4 MW, entered into TC2. Of those, 647 projects, 197 projects, representing 32,351.8 MW (41.3 percent of the MW) withdrew prior to completion.

A total of 426 projects have been classified as new generation and 221 projects have been classified as upgrades. Natural gas, wind, solar and renewable hybrid projects (including solar + storage, solar + wind and wind + storage) have accounted for 444 projects (68.6 percent) of all 647 generation projects to enter TC2.

Table 12-76 Transition Cycle 2 and RRI status of all generation projects: September 30, 2025

		Number of Projects

Table 12-77 shows the totals in Table 12-76 by share of classification as new generation or upgrade. Within a unit type the shares of upgrades add to 100 percent and the shares of new generation add to 100 percent. For example, 56.5 percent of all battery projects in TC2 classified as upgrades were active and 43.5 percent of battery projects classified as upgrades were withdrawn from TC2 as of September 30, 2025.

Table 12-78 shows the total MW of projects in TC2 by unit type and project classification. For example, the 42 new generation battery projects that have been withdrawn from TC2 as of September 30, 2025, (as shown in Table 12-76) constitute 7,870.5 MW. The 55 new generation solar projects that have been withdrawn in the same time period constitute 5,265.2 MW.

Cycle Process Totals[85]

On September 30, 2025, there were 959 proposed generation projects in the new services cycle process queues. Those projects make up 118,979.6 MW. On September 30, 2025, all projects in the cycle process queues were either in the status of active or were withdrawn. Table 12-80 shows each status by unit type. Of the 118,979.6 MW in the cycle process queues, 63,851.5 MW (53.7 percent) were active and 55,128.1 MW (46.3 percent) were withdrawn. Of the 63,851.5 MW in the status of active, 29,070.4 MW (45.5 percent) were solar projects, 5,612.5 MW (8.8 percent) were wind projects, and 11,659.1 MW (18.3 percent) were battery projects.

Table 12-80 All cycles (TC1, TC2 and RRI) project status (MW) by unit type: September 30, 2025

Table 12-81 shows that on September 30, 2025 there were 63,851.5 MW, on an energy basis, of which 40,975.1 MW are on a capacity basis that requested CIRs, in cycle process queues in the status of active or under construction. Table 12-81 also shows the total capacity MW adjusted for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.

Of the 40,975.1 MW, on a capacity basis that requested CIRs in the cycle process queues in the status of active or under construction, 16,320.0 MW (39.8 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.

85 As of September 30, 2025, the cycle process totals include those projects included in TC1 and TC2.

Of the 15,133.8 MW, on a capacity basis that requested CIRs, of solar projects requested in cycle process queues in the status of active or under construction, 1,210.7 MW (8.0 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.

Of the 8,965.3 MW, on a capacity basis that requested CIRs, of battery projects requested in cycle process queues in the status of active or under construction, 5,199.9 MW (58.0 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.

Of the 19,887.0 MW, on a capacity basis that requested CIRs, of renewable projects requested in cycle process queues in the status of active or under construction, 2,044.2 MW (10.3 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.

Table 12-81 All cycles (TC1, TC2 and RRI) projects (active and under construction) by unit type adjusted for ELCC derates (MW): September 30, 2025

Surplus Interconnection Service (SIS)

FERC Order 845 required transmission providers to create a process for interconnection customers to use surplus interconnection service at existing points of interconnection.[86] Surplus interconnection service is defined as "any unneeded portion of interconnection service established in a large generator interconnection agreement (LGIA), such that if surplus interconnection service is utilized, the total amount of interconnection service at the point of interconnection would remain the same."[87] For example, a developer may request SIS to add a solar facility at the location of an existing battery storage facility. In this example, the battery storage facility operates at night only, while the solar facility operates during the day. The net output at the point of interconnection would never exceed the maximum facility output as

86 See *Reform of Generator Interconnection Procedures and Agreements, Order No. 845*, 163 FERC ¶ 61,043 (2018).
87 Id. At Pg. 373

studied for the existing battery storage facility's generation interconnection agreement.

Surplus interconnection service requests can be made by a project developer or one of its affiliates whose generating facility is already interconnected to the PJM transmission system or has executed (or requested to file unexecuted) an interconnection service agreement (ISA) or generation interconnection agreement (GIA), or by an unaffiliated project developer. The project developer, or one of its affiliates, has priority to use the service. However, if a project developer or affiliate does not submit a request for SIS, an unaffiliated project developer may request service. Under the SIS process, projects that do not trigger transmission system upgrades qualify for expedited review by PJM outside the interconnection queue. In order for a SIS request to be approved, no new network upgrades must be required to accommodate the request.[88]

If surplus interconnection service is requested on a generating facility that is an energy only resource, the generating facility requesting the SIS will also be an energy only resource. If surplus interconnection service is requested on a generating facility that is a capacity resource, the generating facility requesting surplus interconnection service may be an energy resource or a capacity resource, not to exceed the amount of CIRs established in the ISA or GIA. Requests for SIS are not posted publicly by PJM.

Interconnection Costs for New Projects

Any entity that requests interconnection of a new generating facility, including increases to the capacity of an existing generating unit, or that requests interconnection of a merchant transmission facility, must follow the process defined in the PJM tariff to obtain interconnection service.[89] PJM's process is designed to ensure that new generation is added in a reliable and systematic manner. As part of the interconnection planning process, a series of studies are performed to determine the feasibility, impact, and cost of interconnecting projects in the queue. Interconnection requests are for energy only resources and for capacity resources.

88 See "PJM Manual 14H: New Service Requests Cycle Process," Rev. 02 (July 23, 2025).
89 See OATT Parts IV & VI.

Interconnecting capacity resources must meet a higher standard than energy only resources. For interconnecting capacity resources, PJM performs deliverability studies that ensure that the energy from the proposed generator can be reliably provided to the PJM region. Deliverability studies identify network upgrades needed to ensure that the transmission system is capable of delivering the aggregate system generating capacity at peak load, including the new resource, with all firm transmission service modeled.[90] The interconnection service agreement identifies the transmission modifications needed to maintain the reliability of the transmission system as a result of a new service request. These identified modifications are known as network upgrades. In general, there are fewer network upgrades associated with energy only resources, as energy only resources are not required to be deliverable to the entire PJM footprint.[91] On September 30, 2025, there were 2,073 active network transmission upgrades. If a project is withdrawn from the queue, the network upgrades associated with that project are no longer required, unless it is required to support another queue project.

While not all projects in the queue require network upgrades, the number of planned network transmission upgrades is strongly correlated with the number of active projects in the queue. The number of planned network upgrades is also strongly correlated with the number of new generation projects requesting interconnection as a capacity resource. After the execution of an interconnection service agreement, queue projects become part of the RTEP study and the costs of any upgrade later necessary to preserve their Capacity Interconnection Rights are included as part of the overall transmission system costs paid by all transmission customers.

The system impact study is a detailed system analysis performed for new service requests that tests deliverability under peak load conditions and light load conditions. The system impact study identifies system constraints caused by the request and the local upgrades and network upgrades required to solve those constraints. The system impact study includes power flow analysis and short circuit analysis. The power flow analysis includes expected output level from the new resource under summer peak and light load system

90 See "PJM Manual 14B: PJM Regional Transmission Planning Process," Rev. 57 (September 25, 2024).
91 See "PJM Manual 14G: Generation Interconnection Requests," Rev. 8 (July 26, 2023).

conditions.[92] PJM's recent improvements to the deliverability analyses reflect more accurate information about the expected performance of intermittent resources, by type of resource (solar fixed, solar tracking, onshore wind and offshore wind), by season (summer, winter and light load) and by region (PJM West, Mid-Atlantic and Dominion), under each of these system conditions. Those modifications are necessary to accurately reflect the expected output of intermittent resources under various seasons and system conditions as the penetration and role of intermittents in PJM increases.[93] For example, the expected output of onshore wind varies from its maximum facility output to zero, depending on weather conditions, and the expected output levels are used for each system load condition.[94]

Capacity resources receive Capacity Interconnection Rights (CIRs) based on the deliverable MW which result from a combination of upgrades paid for by each project and existing system capability. Intermittent resources also require CIRs. The level of CIRs required for intermittent resources has been significantly understated because the required CIRs have been based on the derated capacity value of intermittents rather than the maximum energy injections required to achieve the derated value.

After a lengthy stakeholder process, on April 7, 2023, FERC approved updates to PJM's ELCC method that cap the level of an intermittent generator's output used to calculate the generator's reliability contribution (ELCC derated MW) at the generator's CIR level.[95] Rules prior to the FERC order allowed generation at a level greater than the CIR value, and that was therefore not deliverable, to be inappropriately included in the ELCC calculations. For example, if a 100 MW solar resource has CIRs of 60 MW, generation in excess of 60 MW will not be included in the ELCC calculations under the updated rules. Prior to the update, the generation in excess of the CIR level was included, overstating the ELCC ratings and reliability contribution of ELCC resources. The overstatement of intermittent capacity has inefficiently suppressed capacity market clearing prices.[96] [97] In order to retain the prior, incorrectly calculated ELCC values, existing intermittent generating units are required to increase their CIRs by going through an expedited queue process. The ELCC updates established a transitional period during which intermittent generators can be awarded temporary increases in their CIRs based on the availability of transmission system capability.[98] PJM expects a transitional period of four years, beginning with the 2025/2026 Base Residual Auction, to be sufficient time for intermittent resources to reenter the queue and be awarded additional CIRs. New intermittent generators will be required to pay for CIRs consistent with their calculated reliability contribution.

Figure 12-5 shows the latest estimated interconnection costs for new generators (network transmission project cost) by projected and actual in service year for generators that are in service (red line), and for the total of generators in service and still in the queue in active status (blue line). The estimated costs for in service projects (red line) are much lower than the estimated costs that also include all projects in the queue (blue line). The increase in estimated total network upgrade costs for planned projects is a result of the large number of requests in the new services queue and the existing backlog (Figure 12-5). However, as generators withdraw from the queue, the overall network costs decrease. The estimated network upgrade costs for in service projects are much lower. The projected in service dates for network projects are not updated regularly, and therefore, may not be an accurate predictor of when these projects are actually expected to go in service. Figure 12-5 shows a significant level of estimated interconnection costs for resources with projected in service dates as far back as 2008 and a peak for projects with a projected in service date of 2021. Even the costs for projects that are in service are only estimates because PJM does not track final project costs. The final in service costs include only the last estimate provided by PJM before the project went in service. PJM's data collection, management and retention related to transmission spending of all types is inadequate and needs a significant upgrade. The failure to collect data on estimated and final project

92 Winter peak load is included in the generation deliverability powerflow analysis during the RTEP baseline reliability analysis, but is not currently performed for new interconnection requests. The light load analysis ensures generation deliverability during light load conditions, which is defined as 50 percent of the annual peak demand.

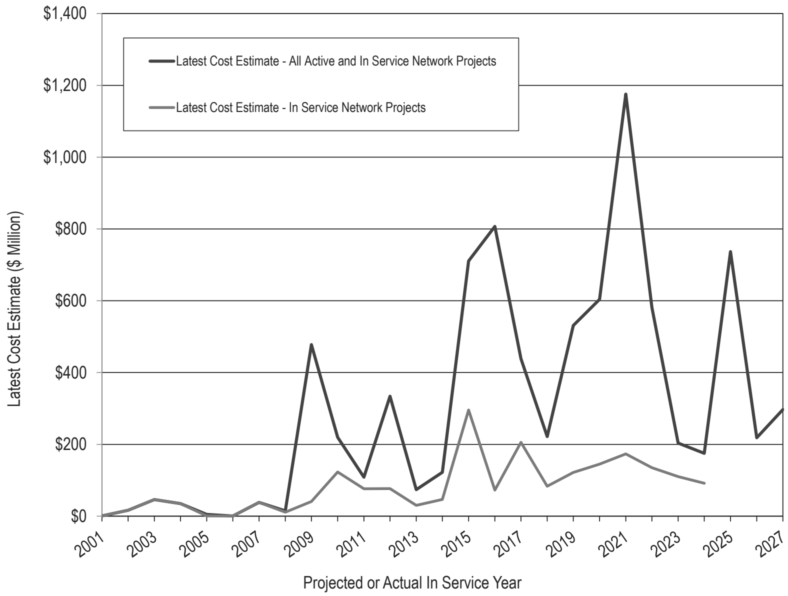
costs makes it impossible to track transmission project costs for all project types. Given the significance of data to market participants and regulators, the MMU recommends that all queue data and supplemental, network and baseline project data, including projected in service dates and estimated and final costs, be regularly updated with accurate and verifiable data.

Figure 12-5 Cost estimates of network projects by projected and actual in service year: January 1, 2001 through December 31, 2027



Regional Transmission Expansion Plan (RTEP)[99]

The PJM RTEP process is designed to identify needed transmission system additions and improvements to continue to provide reliable service throughout the RTO. The objective of the RTEP process is to provide PJM with an optimal set of solutions necessary to solve reliability issues, operational performance issues and transmission constraints.

The RTEP process initially considered only factors such as load growth and the generation interconnection requests in its development of the 15 year plan. Currently, the RTEP process includes a broader range of inputs including the effects of public policy, market efficiency, interregional coordination and the effects of aging infrastructure.

RTEP Process

The PJM RTEP process is a 24 month planning process that identifies reliability issues for the next 15 year period. This 24 month planning process includes a process to build power flow models that represent the expected future system topology, studies to identify issues, stakeholder input and PJM Board of Managers approvals. The 24 month planning process is made up of overlapping 18 month planning cycles to identify and develop shorter lead time transmission upgrades and one 24 month planning cycle to provide sufficient time for the identification and development of longer lead time transmission upgrades that may be required to satisfy planning criteria.

Market Efficiency Process

PJM's Regional Transmission Expansion Plan (RTEP) process includes a market efficiency analysis. The stated purpose of the market efficiency analysis is to: determine which reliability based enhancements have economic benefit if accelerated; identify new transmission enhancements that result in economic benefits; and identify economic benefits associated with modification to existing RTEP reliability based enhancements that when modified would relieve one or more economic constraints. The PJM market efficiency analysis is badly flawed and results in concluding there are net benefits when there

99 The material in this section is based in part on the PJM Manual 14B: PJM Region Transmission Planning Process. See PJM. "PJM Manual 14B: PJM Region Transmission Planning Process," Rev. 57 (September 25, 2024).

are not. PJM presents the RTEP market efficiency enhancements to the PJM Board, along with stakeholder input, for Board approval.

To be recommended to the PJM Board of Managers for approval, the relative benefits and costs of the economic based enhancement or expansion of the proposed project must reduce congestion on one or more constraints by at least one dollar, meet a ratio threshold of at least 1.25:1 and have an independent cost review, performed by PJM, if expected costs are over $50 million. PJM provides the review of a project with a projected cost of over $50 million using its own staff or outside consultants. PJM presents its findings to the TEAC where PJM's findings are reviewed by the stakeholders. While stakeholders can comment on the findings, PJM makes the final decision about what costs will be used for the purpose of calculating the benefit/cost ratio for the project. The benefit/cost ratio is the ratio of the present value of the total annual benefit for 15 years to the present value of the total annual cost for the first 15 years of the life of the enhancement or expansion.

The market efficiency process is comprised of a 12 month cycle and a 24 month cycle, both of which begin and end on the calendar year. The 12 month cycle is used for analysis of modifications and accelerations to approved RTEP projects only. The 24 month cycle is used for analysis of new economic transmission projects for years five through 15. This long-term proposal window takes place concurrently with the long-term proposal window for reliability projects.

PJM's first market efficiency analysis was performed in 2013, prior to Order 1000. The 2013 window was open from August 12, 2013, through September 26, 2013. This window accepted proposals to address historical congestion on 25 identified flowgates. PJM received 17 proposals from six entities. One project, submitted by an incumbent transmission owner, was approved by the PJM Board.

The first market efficiency cycle conducted under Order 1000 was performed during the 2014/2015 RTEP long term window. The 2014/2015 long term window was open from November 1, 2014, through February 28, 2015. This window accepted proposals to address historical congestion on 12 identified flowgates. PJM received 93 proposals from 19 entities. Thirteen projects, all submitted by an incumbent transmission owner, were approved by the PJM Board.

The second market efficiency cycle was performed during the 2016/2017 RTEP long term window. The 2016/2017 long term window was open from November 1, 2016, through February 28, 2017. This window accepted proposals to address historical congestion on four identified flowgates. PJM received 96 proposals from 20 entities. Four projects, all submitted by an incumbent transmission owner, were approved by the PJM Board.

PJM also held an addendum 2016/2017 long term window. This 2016/2017 1A long term window was open from September 14, 2017, through September 28, 2017. This window accepted proposals to address historical congestion on one identified flowgate. PJM received three proposals from two entities. One project, submitted by an incumbent transmission owner, was approved by the PJM Board.

The fourth market efficiency cycle was performed for the 2018/2019 RTEP long term window. The 2018/2019 long term window was open from November 2, 2018, through March 15, 2019. This window accepted proposals to address historical congestion on one internal and three interregional flowgates. PJM received 33 proposals from 10 entities. One project, submitted by an incumbent transmission owner, was approved by the PJM Board to address the historical congestion on the internal flowgate, and one project, submitted by an incumbent transmission owner, was approved by the PJM Board to address the historical congestion on one of the interregional flowgates.[100]

The fifth market efficiency cycle was performed for the 2020/2021 RTEP long term window. The 2020/2021 RTEP long term window was open from November 11, 2020, through May 11, 2021. This window accepted proposals to address historical congestion on four internal flowgates. PJM received 24 proposals from seven entities. Four projects, all submitted by an incumbent transmission owner, were approved by the PJM Board.

100 No proposals effectively resolved the congestion on two of the three identified interregional market efficiency flowgates.

The sixth market efficiency cycle was performed during the 2022/2023 RTEP long term window. The 2022/2023 RTEP long term window was delayed until the reliability violations for the 2022 Window 3 (Dominion data center loads) could be addressed. On November 21, 2023, PJM requested that the Commission grant a waiver to extend the time for PJM to complete its annual review of the benefit/cost analysis associated with the market efficiency cycle.[101] PJM requested the waiver to remain in effect until PJM completes its 2023 annual review no later than the end of the second quarter of 2024. On December 21, 2023, The Commission approved the waiver request.[102] In January 2024, PJM completed updating the 2022/2023 market efficiency base case to include the solution selected from the 2022 Window 3. No flowgates experienced historical congestion that required an open window.

In February 2024, PJM completed the 2024/2025 market efficiency base case. In May 2024, PJM posted the 2024/2025 Market Efficiency planning assumptions. PJM posted an updated 2024/2025 base case in July 2024, and requested stakeholder feedback on three congestion drivers (Museville-Smith Mountain 128 kV in AEP, West Point-Laxena 115 kV in DOM and Garrett-Garrett Tap 115 kV in PN-APS) by August 31, 2024. The long term market efficiency window opened on April 11, 2025 and was closed on June 10, 2025. PJM received 14 proposals from (six proposals for Museville-Smith Mountain 128 kV, seven proposals West Point-Laxena 115 kV and one proposal for Garrett-Garrett Tap 115 kV) five entities. PJM is currently evaluating the proposals.

The Benefit/Cost Evaluation

For an RTEP project to be recommended to the PJM Board of Managers for approval as a market efficiency project, the relative benefits and costs of the economic based enhancement or expansion must meet a benefit/cost ratio threshold of at least 1.25:1.

The total benefit of a project is calculated as the sum of the net present value of calculated energy market benefits and calculated reliability pricing model (RPM) benefits for a 15 year period, starting with the projected in service date of the project. Depending on the type of project being evaluated PJM may measure benefits as reductions in estimated load charges and production costs in the energy market and reductions in estimated load capacity payments and in system capacity costs in the capacity market, but does not weight increases and decreases in benefits equally. There are significant issues with PJM's definition of benefits. If done correctly and if FTRs/ARRs returned 100 percent of congestion to load, the benefit/cost analysis would include the total net change in production costs and would not include congestion. The change in production costs correctly measures the changes in cost to load that result from a project.

The energy market benefit analysis uses an energy market simulation tool that produces an hourly least-cost, security constrained market solution, including total operational costs, hourly LMPs, bus specific injections and bus specific withdrawals for each modeled year with and without the proposed RTEP project. Using the output from the model, PJM calculates changes in energy production costs and load energy payments.

The definition of the energy benefit analysis depends on whether the project is regional or subregional. A regional project is any project rated at or above 230 kV. A subregional project is any project rated at less than 230 kv. For a regional project, the energy benefit for each modeled year is equal to 50 percent of the change in system wide total system energy production costs with and without the project plus 50 percent of the change in zonal load payments with and without the project but, inexplicably, only for those zones where the project reduces the load payments and ignoring zones where the project increases load payments. For subregional projects, the calculation of benefits for each modeled year ignores any impact on system wide energy production costs and is instead based only the change in zonal load energy payments with and without the project, but again only for those zones where the project reduces the load energy payments and ignoring zones where the project increases load payments.

In both the regional and subregional analysis, changes in zonal load energy payments subtract the estimated value of any Auction Revenue Rights (ARR) that sink in that zone. An increase in ARR revenues that result from a project

101 See *PJM Interconnection, L.L.C*, Docket No. ER24-477-000 (November 21, 2023).
102 185 FERC ¶61,212.

would reduce the benefits of that project to load. If done correctly and if ARRs returned 100 percent of congestion to load, the changes in load payments would equal the change in production costs. However, the calculated ARR credits in the benefit/cost analysis ignore any increases in ARR MW and include only the reduction in the estimated CLMP differences. Estimated ARR credits are calculated for each simulated year using the most recent planning year's actual ARR MW combined with the simulation's CLMP differences between ARR source and sink points. ARR MW are not adjusted to reflect any increase in ARR MW created by the RTEP upgrade. This means that the reduction in the ARR offset value is too large, the reduction in load payments is overstated, and the value of the proposed project is artificially increased.

The Reliability Pricing Model (RPM) Benefit analysis uses the RPM solution software, with and without the proposed RTEP project, using a set of estimated capacity offers.

The definition of the benefit in the RPM benefit analysis depends on whether the project is regional or subregional. For a regional project, the RPM benefit for each modeled year is equal to 50 percent of the change in system wide total system capacity payments with and without the project plus 50 percent of the change in zonal capacity payments with and without the project, including only those zones where the project reduced the capacity payments. For subregional projects, the reliability pricing model benefits for each modeled year ignores any impact on system wide total capacity payments and is equal to the change in zonal capacity payments with and without the project, including only those zones where the project reduced the capacity payments.

The difference in the benefits calculation used in the regional and subregional benefit/cost threshold tests is related to how the direct costs of the transmission projects are allocated for approved regional and subregional projects. The costs of an approved regional project are allocated so that 50 percent of the total costs are allocated on a system wide load ratio share basis and the remaining 50 percent of the total costs are allocated to zones with projected energy market benefits and reliability pricing model benefits in proportion to those projected positive benefits. The costs of an approved subregional project are allocated so that the total costs of the project is allocated to zones with projected energy market benefits and reliability pricing model benefits in proportion to those projected positive benefits. The allocation will be incorrect to the extent that the benefits calculations are incorrect.

There are significant issues with PJM's benefit/cost analysis. The current rules governing benefit/cost analysis of competing transmission projects do not correctly measure the relative costs and benefits of transmission projects. PJM measures benefits as reductions in estimated load charges and production costs in the energy market and reductions in estimated load capacity payments in the capacity market, but PJM's analysis ignores any increases in costs. This means that PJM's benefit/cost analysis systematically overstates the benefits of transmission projects. ARR MW allocations are not adjusted to reflect any potential changes in ARR MW that result from the RTEP upgrade. This means that the reduction in the ARR offset value is too large, the ARR offset is too small, and the result is to artificially increase the value of the proposed project. The correct metric is the change in production costs. In addition, the current rules do not account for the fact that the benefits of projects are uncertain and highly sensitive to the modeling assumptions used, or for the fact that the project costs are nonbinding estimates, are not subject to cost caps and may significantly exceed the estimated costs. These flaws have contributed to PJM approving market efficiency projects with forecasted benefits that only appear to, but do not actually exceed the forecasted costs. In addition, there is no after the fact analysis to validate the planning assumptions and there is no data gathered on the actual costs and benefits that would permit such an analysis.

Recent proposals to use storage as a transmission asset (SATA) raises a number of additional concerns about PJM's benefit/cost analysis. Storage is a market asset and should not be owned by transmission owners. PJM should not be evaluating SATA at all without a decision from FERC that SATA is allowable in PJM. At present it is not allowed. PJM's benefit/cost analysis uses a 15 year forecast for purposes of evaluating benefits and costs of traditional transmission assets with an expected useful life of 50 years or more. Using the same 15 year horizon does not make sense for SATA resources with an expected useful life of 10 years or less, depending on use. In addition, there is no basis for assuming anything about the actual use of a transmission storage asset and therefor any imputed benefits. Using a 15 year benefit horizon exaggerates the forecasted benefit stream relative to the stream of benefits that could be produced over the expected useful life relative to traditional transmission assets. Further, the rules for how to account for the actual, and forecasted, revenues and charges for operating the SATA to provide transmission load relief have not been established. Without clear rules on how to allocate operational revenues and costs, and without detailed information about exactly the storage would be used, it is impossible to develop forecasted benefits and/or costs of a SATA project.

The broader issue is that the market efficiency project approach explicitly allows transmission projects to compete against future generation projects, but without allowing the generation projects to compete. Projecting speculative transmission related benefits for 15 years based on the existing generation fleet and existing patterns of congestion eliminates the potential for new generation to respond to market signals. The market efficiency process allows assets built under the cost of service regulatory paradigm to displace generation assets built under the competitive market paradigm. This is particularly noteworthy for the SATA case in which transmission owners would built market capacity assets under cost of service regulation that competes directly with market assets.

A significant flaw in PJM's benefit/cost analysis is that projected benefits are based on load forecasts which are currently dominated by projected large data center loads that are not verified by PJM and cannot be verified by PJM. That creates a bias towards finding transmission projects beneficial despite the fact that data center loads are imposing transmission costs on other customers as a result.

The MMU recommends that the market efficiency process be eliminated.

PJM MISO Interregional Market Efficiency Process (IMEP)

PJM and MISO developed a process to facilitate the construction of interregional projects in response to the Commission's concerns about interregional coordination along the PJM-MISO seam. This process, called the Interregional Market Efficiency Process (IMEP), operates on a two year study schedule and is designed to address forward looking congestion. To qualify as an IMEP project, the project must be evaluated in a joint study process, qualify as an economic transmission enhancement in both PJM and MISO transmission expansion models and meet specific IMEP cost benefit criteria.[103] The allocation of costs to each RTO for IMEPs will be in proportion to the benefits received.

While the IMEP process is a joint effort, PJM and MISO perform their own analysis of benefits to their own system and each uses a different modeling approach and a different metric for determining the benefits of a proposed project. PJM uses the benefit/cost analysis used for its own internal market efficiency projects which will, by definition, overstate project benefits by ignoring areas where energy costs are increased. MISO, on the other hand, measures benefits as changes in projected system wide production cost caused by the project. The use of different approaches to measuring benefits is an issue when studying potential benefits of projects in a joint effort, and when using the defined benefits to allocate the costs of IMEP projects to each RTO. PJM's approach will over allocate the costs of IMEP projects to PJM members and under allocate costs to MISO members.

No interregional constraints were identified in either PJM's or MISO's regional processes. Therefore, an IMEP study was not required during the 2020/2021 IMEP cycle. No interregional constraints were identified in either PJM or MISO's regional processes. Therefore, an IMEP study was not required during the 2022/2023 IMEP cycle.

PJM and MISO began coordinating on interregional congestion issues to identify potential constraints to address in the 2024/2025 IMEP cycle. The

103 See "Joint Operating Agreement Between the Midwest Independent Transmission System Operator, Inc. and PJM Interconnection, L.L.C.," (December 11, 2008) <https://www.pjm.com/directory/merged-tariffs/miso-joa.pdf>.

joint regional planning committee (JRPC) decided to not initiate a coordinated system plan in 2025, and will instead prioritize the interregional transfer capability study (ITCS).

PJM MISO Targeted Market Efficiency Process (TMEP)

PJM and MISO developed the Targeted Market Efficiency Process (TMEP) to facilitate the resolution of historic congestion issues that could be addressed through small, quick implementation projects. The TMEP process operates on a 12 month study schedule. To qualify as a TMEP project, the project must have an estimated in service date by the third summer peak season from the year the project was approved, have an estimated cost of less than $20 million and must have estimated benefits, based on the projected congestion reduction over a four year period that exceed the expected installed capacity cost of the proposed project.[104] [105] The TMEP process calculates congestion and assigns congestion costs to load but fails to account for the offsetting value of ARRs and FTRs. The current rules incorrectly count congestion as a cost to load without accounting for how the congestion dollars are or are not returned to the load through ARRs and FTRs. The correct benefit metric is the change in production costs.

The benefit of a proposed TMEP project is calculated as the value of reducing congestion on the affected constraint over a four year period. PJM and MISO calculate the estimated value of eliminating congestion by calculating the average congestion for the two prior years prior and multiplying by four. Congestion is correctly calculated as the shadow price (difference in CLMP) times the market flow on the line.

The allocation of costs to each RTO for an approved TMEP project will be in proportion to the benefits, as calculated by PJM and MISO, received by that RTO.[106] The proportion of benefits is calculated using the change in the average shadow price of the constraint times the dfax to the affected downstream buses times the MW of load at the buses. This correctly identifies the proportion of the benefits that go to the load that would benefit from the project. Within an RTO, the RTO's share of the cost of the approved project is allocated to each transmission control area in proportion to the benefits received by each transmission control area.

PJM and MISO did not conduct a TMEP study in 2019. As a result of decreases in M2M congestion and the addition of transmission upgrades already in process that affect the top congested historical M2M flowgates, PJM and MISO did not conduct a TMEP study in 2020. PJM and MISO agreed to assess the impact of planned upgrades and congestion using an additional year of market data. As a result, PJM and MISO did not conduct a TMEP study in 2021. The 2022 TMEP study focused on 23 flowgates as potential TMEP projects. Of the 23 initial flowgates, 19 were eliminated due to their relationship with other existing reliability projects already included in PJM's RTEP or MISO's MTEP plans, or the identified congestion was caused by outages.[107] Two projects were eliminated after studies showed that congestion was not persistent in October 2022, and an additional project was eliminated in December 2022 after further studies showed congestion was not persistent, leaving one TMEP project (Powerton - Towerline 138 kV) that was approved for implementation by the PJM Board on February 15, 2023, and by the MISO Board on March 23, 2023.[108] [109] [110] For both 2023 and 2024, the RTOs decided not to initiate a Coordinated System Plan (CSP) study, and to continue to assess the impact of planned upgrades and congestion persistence with additional market data.

PJM and MISO began coordinating on interregional congestion issues to identify potential constraints to address in the 2024/2025 TMEP cycle. The joint regional planning committee (JRPC) decided to not initiate a coordinated system plan in 2025, and will instead prioritize the interregional transfer capability study (ITCS). PJM and MISO are planning for an update in the winter of 2025.

110 See "PJM-MISO IPSAC," presented at the December 11, 2023 meeting of the PJM-MISO Inter-regional Planning Stakeholder Advisory Committee <https://www.pjm.com/-/media/committees-groups/stakeholder-meetings/ipsac/2024/20240325/20240325-miso-seam-identified-issues-and-solutions-.ashx>

The PJM and MISO TMEP process for measuring the projected benefits of a TMEP transmission projects is flawed. The current rules incorrectly count congestion as a cost to load without accounting for how the congestion dollars are or are not returned to the load through ARRs and FTRs. The benefit of a TMEP transmission upgrade should be the expected difference in the total production cost of energy before and after the upgrade to all affected load. This measurement would include the change in expected LMP of all affected load before and after the upgrade, times the MW of load, plus the change in congestion dollars returned to the affected load before and after the upgrade. Congestion revenue returned to load is not a cost to the load, it is a credit against the overpayment of load payments compared to generation credits caused by the transmission constraint. Ignoring the return of congestion from ARRs/FTRs overstates the potential benefits of eliminating congestion through the TMEP upgrades, and ignores the value of smaller upgrades that may not eliminate a constraint, but may reduce the average cost of energy for load.

PJM MISO Interregional Transfer Capability Study (ITCS)

PJM and MISO are performing an Interregional Transfer Capability Study (ITCS).[111] PJM and MISO are coordinating assumptions and models, but will not perform a joint study. The PJM/MISO Interregional Transfer Capability Study is part of PJM's and MISO's strategy to comply with FERC Order No. 1920. The ITCS study appears to mirror PJM's multi driver RTEP process in that it identifies several drivers (efficiency, reliability, transfer needs) for evaluating the value or need for a project, though neither MISO nor PJM provide any specificity as to the exact metrics for the evaluation of the benefits or costs within each identified driver, how the drivers will be weighted or how costs of potential projects should be allocated. The stated purpose of the PJM/MISO Interregional Transfer Capability Study is to allow PJM and MISO to consider needs, assumptions, cost allocations and analysis outside the limits of the existing PJM/MIO JOA/CSP process. The goal of the PJM and MISO ITCS is to identify opportunities to enhance transfer capability on an incremental basis over and above other JOA/CSP based studies.

111 See PJM and MISO Interregional Capability Study (ICTS) FAQ <https://www.pjm.com/-/media/DotCom/planning/interregional-planning/pjm-and-miso-interregional-transfer-capability-study-faq.pdf>.

The ITCS study is intended to look out through 2032. In its ITCS study, PJM plans to use a model that blends MISO planning models for MISO's footprint and a set of PJM's long-term planning assumptions for PJM's footprint. PJM is calling this a blended model. PJM's blended model will use the 2023 Regional Transmission Expansion Plan (RTEP) topology with 2022 RTEP Window 3 solutions, the PJM 2024 official Load Forecast, retirements due to federal regulations and state laws based on the Independent State Agencies Committee (ISAC) workbook and the assumption of sufficient replacement generation or storage for resource adequacy (i.e. to meet 1-in-10 Loss of Load Expectation) selected from interconnection requests and withdrawals. Although it is a feature of many transmission planning studies, simply assuming specific generating assets is not a reasonable way to do transmission planning with significant cost impacts on customers.

Preliminary results from the ITCS study identified various transfer, reliability and economic issues from both PJM and MISO.[112] PJM and MISO presented results and near and long term actions resulting from the ITCS study on June 25, 2025.[113] Interregional constraints were identified in the 2024/2025 PJM and MISO's joint ITCS analysis.[114] MISO opened a proposal window for the identified MISO and MISO intertie constraints that closed in May of 2025. MISO received 34 unique proposals from eight entities. Based on these proposals MISO developed 54 potential solution ideas for further evaluation by PJM and MISO. PJM and MISO have stated that they do not have a defined project type (and related cost allocation) to address all of the issues/benefits for the solutions identified in the ITCS process. PJM is reviewing the MISO potential solutions to see if any of the proposals are captured in the PJM RTEP reliability, RTEP Market Efficiency and/or the M-3 (Supplemental) process. In the case of any overlaps between RTEP and ITCS, PJM will consider the ITCS needs in RTEP solutions. PJM and MISO are planning for an update in the winter of 2025.

112 See "PJM/MISO Interregional Transfer Capability Study," presented at the March 7, 2025 meeting of the PJM/MISO Interregional Planning Stakeholder Advisory Committee <https://www.pjm.com/-/media/DotCom/committees-groups/stakeholder-meetings/ipsac/2025/20250307/20250307-miso-pjm-ipsac-interregional-transfer-capability-study-itcs-to-pjm---working-draft.pdf>.

Multi Driver Process

On September 12, 2014, PJM filed revisions to the tariff to include provisions allowing PJM to include multi driver projects in its regional transmission expansion plan.[115] When a transmission project addresses a combination of reliability, market efficiency and/or public policy objectives, it is termed a multi driver project. PJM may choose a solution using either the proportional multi driver method or the incremental multi driver method. The proportional method combines separate solutions that address reliability, economics and/or public policy into a single transmission enhancement or expansion project. The incremental method expands a proposed single driver solution to include one or more additional component(s) to address a combination of reliability, economic and/or public policy drivers.[116] On February 20, 2015, the Commission approved the tariff revisions with an effective date of November 12, 2014.[117]

On June 7, 2022, PJM opened its first multi driver proposal window. The window seeks to address reliability and market efficiency needs on three identified facilities. PJM accepted proposed solutions until August 8, 2022. PJM received 14 proposals from three entities. After conducting a cost review, a reliability analysis and a market efficiency analysis on the 14 proposals and a combination of the proposals, PJM proposed a combination of two proposals made by two companies (Project 644 + 908) as its preferred solution. The preferred solution has an estimated capital cost of $82.30 million with a PJM determined expected benefit/cost ratio of 1.99.[118] PJM shared its recommendation with MISO for their evaluation. MISO did not indicate any concern with the proposed solution. On February 7, 2023, the PJM Board approved the recommended solution (Project 644 + 908).

The benefit/cost analysis used in the multi driver review is the same flawed benefit/cost analysis that PJM uses for evaluating Market Efficiency projects. PJM's assumed benefit of the combined project was calculated as the sum of the present value of positive (energy cost reductions to some loads) effects of $169.8 million. The sum of the present value of negative effects (energy cost increases to other loads), which was ignored in the PJM calculation of benefits, was $149.1 million. The total benefit of the proposed multi driver project is therefore only $20.7 million, not the $169.8 asserted by PJM, even ignoring the use of changes in congestion rather than changes in production costs. Using the total positive and negative effects to compare to the net present value of costs in the PJM's analysis, the benefit/cost ratio is 0.24, not 1.99. All $149.1 million of the increases in energy costs (negative benefits) would be paid by load in the ComEd Zone. Based on the requirement of benefit/cost ratio of 1.25, the energy efficiency portion of the multi driver project should have been rejected.

State Agreement Approach (SAA)

PJM's State Agreement Approach (SAA) is a provision in PJM's Operating Agreement that allows states to propose transmission projects for inclusion in PJM's Regional Transmission Expansion Plan if the state agrees to assume the full cost of the proposed transmission projects. The purpose of the SAA is to allow states to pursue their public policy goals without imposing costs on other states. The SAA can also be used by a group of states that agree to a transmission project as part of a collaborative goal. Under the SAA, a state can elect to select the entity to complete the project or the states can request that PJM open a competitive window to seek transmission solutions from developers that address the required upgrades. SAA projects are classified as public policy baseline projects or as a supplemental project developed by the selected PJM Transmission Owner. The state decides whether to pursue a project that comes out of the SAA process.

Five states (Delaware, Maryland, North Carolina, Virginia and New Jersey) made a joint request to PJM to conduct a two phase study (The Offshore Wind Transmission Study) to determine reinforcements to the onshore grid to reliably deliver 6,416 to 17,016 of offshore wind plus additional RPS target requirements.[119] The phase one study, published on October 19, 2021, examined, at a high level, enhancements to the existing infrastructure needed to reliably integrate the proposed offshore wind generation, but did not

118 See "2022 RTEP Multi-Driver Proposal Window No. 1," presented at the December 6, 2022 meeting of the Transmission Expansion Advisory Committee <https://www.pjm.com/-/media/committees-groups/committees/teac/2022/20221206/item-07---multi-driver-proposal-window-update.ashx>.
119 See Offshore Wind Transmission Study: Phase 1 Results, October 19, 2021 <https://www.pjm.com/-/media/DotCom/library/reports-notices/special-reports/2021/20211019-offshore-wind-transmission-study-phase-1-results.pdf>.

include any estimates of the costs of the transmission infrastructure needed. The phase 1 study did not consider any greenfield transmission solutions, instead using existing facilities as potential points on injection (POI) and existing transmission paths as locations for upgrades. The study considered six scenarios.

Scenario 1 focused on a short term window that assumed a wind injection total of 6,416 MW and RPS targets through 2027 with a projected cost of $627 million. Scenario 1 included generator deactivations that were announced as of October 1, 2020, and were included in PJM's RTEP base case that formed the basis of the study. The other scenarios (Scenario 2 through Scenario 6) were longer term studies that looked out through 2035. Scenario 2, with a projected cost of $2,461.4 million, assumed 14,416 of offshore wind capacity and the same generator deactivations assumed in Scenario 1. Scenarios 2 through 6 assumed 1,739 MW of additional deactivated generation in addition to what was modeled in Scenario 1 and 2. Scenario 3 was abandoned due to legislation being withdrawn that had required the retirement of specific units. Scenario 4 assumed an increase (relative to Scenario 1) of 2,600 MW additional offshore wind connecting to Virginia POI resulting in projected costs of $3,213.1 million in needed upgrades. Scenario 5 assumed a different POI for Scenario 1 New Jersey offshore wind and cost $2,591.8 million in expected upgrade costs. Scenario 6 removed 2,000 MW of New Jersey offshore wind from Scenario 2 resulting in $2,164.3 million in projected upgrade costs.

The states decided to not pursue a joint Phase 2 study.

New Jersey State Agreement Approach for Offshore Wind

In 2021, the New Jersey Board of Public Utilities (NJ BPU) initiated a proposal window under the SAA to meet New Jersey's goal of interconnecting up to 7,500 MW of offshore wind.[120] PJM received 80 proposals covering solutions that addressed onshore and offshore reliability criteria and transmission connections. The NJ BPU selected a proposal to interconnect 3,742 MW of offshore wind to central New Jersey at a total estimated cost for the project of $1.1 billion, with in service dates from December 2027 through June 2030. The costs for the NJ BPU offshore wind project will be recovered from customers in the state of New Jersey. On December 6, 2022, the PJM Board approved the BPU's proposal.

On September 22, 2023, Public Service Electric and Gas Company filed an application for an abandoned plant incentive.[121] The filing seeks "authorization for the ability to recover 100 percent of prudently incurred costs for certain transmission upgrades that PSE&G will construct in the event that the [offshore wind] transmission upgrades are abandoned or cancelled (in whole or in part) for reasons that are outside of PSE&G's control."

On October 31, 2023, Danish wind power developer Ørsted announced that it was canceling two major offshore wind projects, Ocean Wind 1 (1,100 MW) and Ocean Wind 2 (1,148 MW), that were planned off the coast of New Jersey. Ørsted is taking a $2.9 billion impairment attributed to Ocean Wind 1.[122] On September 30, 2025, only nine offshore wind projects remained in the combined serial and cycle queues.

Maryland State Agreement Approach (SAA) for Offshore Wind

On December 5, 2024, the Maryland Public Service Commission (MD PSC) requested that PJM conduct analysis of Maryland's 8,500 MW off shore wind target, assuming three different POI scenarios, in response to the Maryland POWER Act of 2023. PJM provided the requested study on March 21, 2025.[123] On June 23, 2025, the Maryland Public Service Commission requested that PJM issue a competitive solicitation for proposals under the SAA process for onshore injection of 2,000 MW offshore wind at Indian River by 2028 (DP&L), 1,500 MW of offshore wind at Cool Spring by 2030 (DP&L), 1,500 MW of offshore wind at Piney Grove by 2030 (DP&L), 1,500 MW of offshore wind at Nelson by 2030 (DP&L) and 2,000 MW of offshore wind at Calvert Cliff by 2031 (PEPCO).[124] PJM is currently working with the MD PSC to draft a SAA

study agreement, which must be filed and approved by the Federal Energy Regulatory Commission (FERC). The goal is to have PJM open a competitive window in 2026 for the proposed requirements.

Long Term Regional Transmission Planning

On May 13, 2024, the Commission issued Order No. 1920 which requires public utility transmission providers to engage in long-term regional transmission planning over a 20-year planning horizon, develop long-term scenarios to identify long-term transmission needs and enable the identification and evaluation of transmission facilities to meet those transmission needs. Order No. 1920 also requires transmission providers to determine a cost allocation method for long-term regional transmission facilities, make other reforms to enhance transparency in local transmission planning, to correctly size transmission projects and include interregional transmission coordination to support the development of cost-effective projects.[125]

On November 21, 2024, the Commission issued Order No. 1920-A.[126] Order No. 1920-A significantly expanded the role of States in the long-term regional transmission planning. Order No. 1920-A requires states' input into regional transmission planning and cost allocation processes, both in the transmission providers' development of Order No. 1920 compliance filings and the ongoing implementation of these reforms in the future. Order No. 1920-A also increases the states' role in: (i) developing long term scenarios; (ii) requesting additional scenarios beyond the three Long-Term Scenarios required by Order No. 1920; (iii) developing the evaluation processes and criteria for selecting new transmission facilities in the long-term regional transmission; (iv) developing cost allocation approaches for selected transmission facilities; and (v) voluntary funding opportunities.

PJM requested that the Commission extend PJM's deadline to comply with Order No. 1920's compliance directives by six months, (to December 12, 2025), while leaving the implementation deadline of two years after the initial due date of the compliance filing (June 12, 2027) unchanged. The extension was requested to accommodate the States' broader role required by Order No. 1920-A in developing Order No. 1920-compliant Long-Term Regional Transmission Planning protocols.[127]

Supplemental Transmission Projects

Supplemental projects are asserted to be "transmission expansions or enhancements that are not required for compliance with PJM criteria and are not state public policy projects according to the PJM Operating Agreement. These projects are used as inputs to RTEP models, but are not required for reliability, economic efficiency or operational performance criteria, as determined by PJM."[128] Attachment M-3 of the PJM OATT defines the process that Transmission Owners (TO) must follow in adding Supplemental Projects in their local plan.

The M-3 Process requires TOs to present the criteria, assumptions and models that they will use to plan and identify Supplemental Projects on a yearly basis. The criteria identified for Supplemental Projects are very broad and include: equipment material condition, performance and risk, operational flexibility and efficiency, infrastructure resilience, customer service or other, as well as asset management.

While the identification of the criteria violations and solutions are reviewed, and stakeholders have the opportunity to comment, the solution that is submitted in the Local Plan is the Transmission Owner's decision. PJM conducts a do no harm analysis to ensure the Supplemental Projects do not negatively affect the reliability of the system. Supplemental Projects are ultimately included in PJM's Regional Transmission Expansion Plan and are allocated 100 percent to the zone in which the transmission facilities are located. Supplemental Projects may displace projects that would have otherwise been implemented through the RTEP process.

Supplemental projects are currently exempt from the Order No. 1000 competitive process.[129] Transmission owners have a clear incentive to increase

128 See PJM. Planning. "Transmission Construction Status," (Accessed on September 30, 2025) <https://www.pjm.com/planning/project-construction>.
129 FERC accepted tariff provisions that exclude supplemental projects from competition in the RTEP. 162 FERC ¶ 61,129 (2018), *reh'g denied*, 164 FERC ¶ 61,217 (2018).

investments in rate base given that transmission owners are paid for these projects on a cost of service basis.

Figure 12-6 shows the latest cost estimate of all baseline and supplemental projects by expected in service year. Baseline projects are RTEP projects needed for reliability. FERC Order No. 890 was issued on February 16, 2007, and implemented in PJM starting in 2008. Order No. 890 required Transmission Providers to participate in a coordinated, open and transparent planning process. Prior to the implementation of Order No. 890, there were transmission projects planned by transmission owners and included in the PJM planning models that were not included in the totals shown in Figure 12-6, Table 12-82 and Table 12-83 because PJM did not track or report such projects. There has been a significant increase in supplemental projects coincident with the implementation of Order No. 890 starting in 2008 and the competitive planning process introduced by FERC Order No. 1000 starting in 2011.

PJM's data collection, management and retention related to transmission spending of all types is inadequate and needs a significant upgrade. The failure to collect data on estimated and final project costs makes it impossible to track transmission project costs for all project types. Given the significance of data to market participants and regulators, the MMU recommends that all queue data and supplemental, network and baseline project data, including projected in service dates and estimated and final costs, be regularly updated with accurate and verifiable data.

Figure 12-6 Cost estimate of baseline and supplemental projects by expected in service year: January 1, 1998 through December 31, 2025

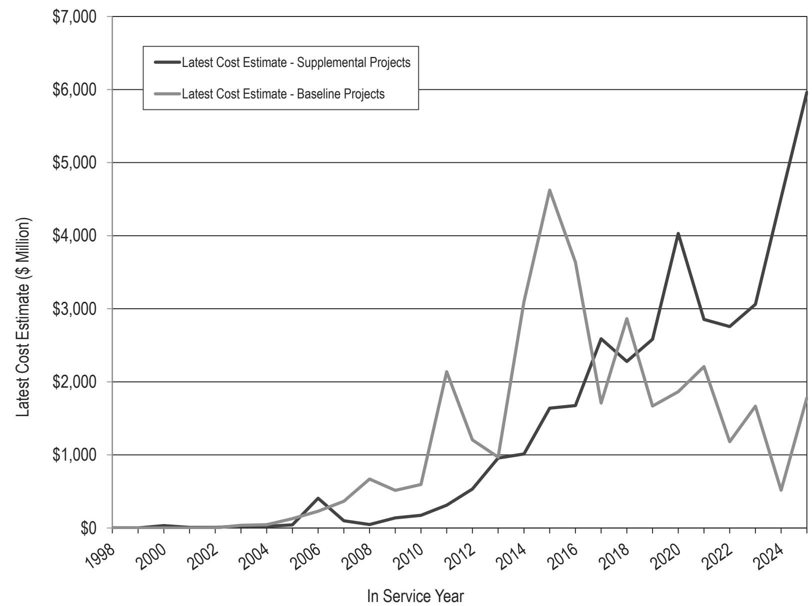

Table 12-82 shows the number of supplemental projects by expected in service year for each transmission zone. The average number of supplemental projects in each expected in service year increased by 1,110.0 percent, from 20 for years 1998 through 2007 (pre Order No. 890) to 242 for years 2008 through 2025 (post Order No. 890). As of September 30, 2025, there were 2,073 supplemental projects with expected in service dates between January 1, 2025 and December 31, 2036.

Table 12-82 Number of supplemental projects by expected in service year and zone: 1998 through 2040

Table 12-83 shows the latest cost estimate of supplemental projects by expected in service year for each transmission zone. The average cost of supplemental projects in each expected in service year increased by 3,156.0 percent, from $64.5 million for years 1998 through 2007 (pre Order No. 890) to $2.1 billion for years 2008 through 2025 (post Order No. 890). As of September 30, 2025, the 1,878 supplemental projects with expected in service dates between January 1, 2025 and December 31, 2029, have a total cost estimate of $25.3 billion.

On September 28, 2023, the Office of Ohio Consumers' Counsel filed a complaint regarding the impact of the volume and costs of supplemental projects on consumers. The complaint requests that the Commission develop a mechanism, to be included in the PJM Tariff and Operating Agreement, whereby "FERC would review the need, prudence and cost-effectiveness of local transmission projects in Ohio." The complaint also requests the Commission to appoint an Independent

Transmission Monitor (ITM) to assist "in reviewing the planning, need, prudence and cost-effectiveness of local transmission projects for consumers in Ohio", and to "consider precluding the Ohio Transmission Utilities from using formula rates for establishing transmission rates."[130] The Office of Ohio Consumers' Counsel's complaint is pending.

On December 19, 2024, a group of consumer interests filed against multiple transmission owners and RTOs/ISOs.[131] The complaint alleges that provisions in the tariffs of the transmission owning utilities and the RTOs/ISOs inappropriately authorize individual transmission owners to plan facilities rated at 100 kilovolts kV and above without regard to efficiency or cost-effectiveness. The complaint does not challenge the rates for any specific locally planned projects, but, rather, alleges that the cumulative effect of tariff provisions allowing local planning of transmission projects rated at 100 kV and above results in unjust and unreasonable transmission rates.[132] The complaint requests issuance of an order that, for transmission facilities rated at 100 kV and above, requires: (i) removal of planning from transmission owner tariffs (and RTO tariffs that confirm such transmission owner planning); (ii) amendment of regional planning tariffs to require that all planning be done at the regional or interregional level (specifying facilities reaching the end of operational life); and (iii) amendment of regional planning tariffs be to require that the regional planning within the existing Order No. 1000 regions be conducted by independent transmission system planners.[133] The complaint recommends that independent transmission planners be structured similar to independent market monitors or be included in an expanded market monitoring function.[134] The consumer interests' planning complaint is pending.

The MMU recommends, to increase the role of competition, that the exemption of supplemental projects from the Order No. 1000 competitive process be terminated.

End of Life Transmission Projects

An end of life transmission project is a project submitted for the purpose of replacing existing infrastructure that is at, or is approaching, the end of its useful life. Under the current process, end of life transmission projects are not subject to the RTEP open window process and have become a form of supplemental project that is exempt from competition under the existing rules.[135]

The MMU recommends, to increase the role of competition, that the exemption of end of life projects from the Order No. 1000 competitive process be terminated and that end of life transmission projects be included in the RTEP process and should be subject to a transparent, robust and clearly defined mechanism to require competition to build such projects.

Competitive Planning Process Exclusions

There are several project types that are currently exempt from the competitive planning process. These project types include:

- **Immediate Need Exclusion.** If the violation needs to be resolved within three years or less, all such projects are excluded from competition. The local Transmission Owner is the Designated Entity.[136]

  On October 17, 2019, the Commission issued an Order Instituting Section 206 Proceedings to determine if RTOs have implemented the exemption in a manner consistent with the Commission's directives under Order 1000.[137] Some supplemental projects are in this category. In a decision issued August 19, 2022, the U.S. Court of Appeals for the D.C Circuit found that FERC reasonably approved MISO's Immediate Need Reliability Exception.[138] The Court rejected arguments challenging the MISO rule because (i) the definition of projects eligible for the exception was insufficiently limited and (ii) the rule allows for designating the incumbent

135 In recent decisions addressing competing proposals on end of life projects, the Commission accepted a transmission owner proposal excluding end of life projects from competition in the RTEP process, 172 FERC ¶ 61,136 (2020), *reh'g denied*, 173 FERC ¶ 61,225 (2020), *affirmed*, American Municipal Power, Inc., et al. v. FERC, Case No. 20-1449 (D.C. Cir. November 17, 2023), and rejected a proposal from PJM stakeholders that would have included end of life projects in competition in the RTEP process, 173 FERC ¶ 61,242 (2020).
136 See OA Schedule 6 § 1.5.8(m).
137 169 FERC ¶ 61,054 (2019).
138 LSP Transmission Holdings II, LLC v. FERC, 45 F.4th 979.

developer before posting of the basis for the exception.[139] The decision was largely based on deference to FERC expertise.[140]

- **Below 200kV.** All projects at voltages less than 200kV are excluded from competition. The local Transmission Owner is the Designated Entity.[141] Some supplemental projects are in this category.
- **Substation Equipment.** If the limiting element(s) is substation equipment, such projects are excluded from competition. The local Transmission Owner is the Designated Entity.[142] Some supplemental projects are in this category.

While the PJM Operating Agreement defines the Designated Entity for projects that are excluded from the competitive planning process, neither the PJM Operating Agreement nor the various commission orders on transmission competition prohibit PJM from permitting competition to provide financing for such projects. The MMU recommends that rules be implemented to require competition to provide financing for transmission projects. This competition could reduce the cost of capital for transmission projects and significantly reduce total costs to customers. In addition, the criteria for and need for all exclusions from the competitive process should be reviewed. There does not appear to be any market reason to exclude transmission projects from competition for any of these exclusion categories.

Dominion Data Center Alley Immediate Need and Long Term Solution

Dominion presented 44 supplemental project requests to serve new data center load through the summer of 2025. PJM identified the need for additional baseline reinforcements to support the load growth. Rather than a competitive process, PJM decided to designate the upgrades as immediate need and allowed Dominion to construct these lines.[143] [144]

The 2022 RTEP Window 3 addressed long term reliability needs as well as the additional baseline reinforcements for Data Center Alley. The proposal window was open from February 24, 2023, to May 31, 2023, and received 72 submissions from 10 entities. The cost estimate for the total scope of work was $5.1 billion, $1.4 billion of which was for the necessary baseline upgrades specific to the Data Center Alley reinforcements.[145] The proposed Data Center Alley solution includes 500kV and 230kV lines extensions, the reconductoring of multiple 230kV lines and substation work.[146]

On December 8, 2023, the Maryland Office of People's Counsel (MDOPC) submitted a letter to the PJM Board.[147] The letter requested that the PJM Board defer the December 11, 2023, vote on the 2022 RTEP Window 3 proposal. The MDOPC letter cited concerns regarding the scale, scope and cost of the proposal. Additionally, the MDOPC expressed concerns that "the current failure to unpack the relative contribution of each of the "drivers" of the need for the W3 projects makes it impossible for the public to understand how cost causation principles apply to the projects." On December 11, 2023, the PJM Board approved the recommended solution. PJM filed the RTEP on January 10, 2024, and the Commission accepted it by order issued April 8, 2024.[148]

Comparative Cost Framework

The MMU recommended that rules be implemented to require that project cost caps on new transmission projects be part of the evaluation of competing projects. On May 24, 2018, the PJM Markets and Reliability Committee (MRC) approved a motion that required PJM, with input from the MMU, to develop a comparative cost framework to evaluate the quality and effectiveness of binding cost containment proposals versus proposals without cost containment provisions. On March 20, 2020, the Commission approved PJM's filing to amend the PJM Operating Agreement to incorporate this requirement.[149]

146 See "*Reliability Analysis Report: 2022 RTEP Window 3*," December 8, 2023. <https://www.pjm.com/-/media/committees-groups/committees/teac/2023/20231205/20231205-2022-rtep-window-3-reliability-analysis-report.ashx>.
147 See "MD Office of People's Counsel Letter regarding 2022 RTEP Window 3 Procurement," <https://www.pjm.com/-/media/about-pjm/who-we-are/public-disclosures/20231208-pjm-board-letter-2023-12-08-md-opc-final.ashx>.
148 See 187 FERC ¶ 61,012. Maryland Office of the People's Counsel filed a protest, which the Commission determined was outside of the scope of the RTEP filing.
149 See 170 FERC ¶ 61,243 (2020).

The 2020 RTEP Window 1 was the first open window that received cost capping proposals to be evaluated under the comparative cost framework. PJM has not provided the requested data to the MMU to allow for an analysis of their financial review process. Without this data and analysis, the MMU cannot verify that the analysis performed under the comparative cost framework was sufficient or adequately followed the process defined in the PJM manual.[150] The existing proposal templates do not provide enough information to adequately perform a financial analysis. The MMU recommends that PJM modify the project proposal templates to include data necessary to perform a detailed project lifetime financial analysis. The required data includes, but is not limited to: capital expenditure; capital structure; return on equity; cost of debt; tax assumptions; ongoing capital expenditures; ongoing maintenance; and expected life.

Storage As A Transmission Asset (SATA)

The PJM Planning Committee considered whether storage devices should be included in the RTEP process as transmission assets.[151] On February 24, 2021, the Markets and Reliability Committee (MRC) voted to defer endorsement of governing document language associated with Storage as a Transmission Asset in reliability planning. The MRC chose to defer the language until a comprehensive proposal addressing all aspects of incorporation of storage resources into markets, operations and planning.

Transmission and generation have, and have always had, a symbiotic relationship in the provision of wholesale power. Transmission needs generation to function and generation needs transmission to function. Transmission can substitute for generation at the margin and generation can substitute for transmission at the margin. This relationship has always been a relatively unexamined area in the design of competitive wholesale power markets. For example, there is little if any explicit consideration of the impact of transmission planning on competitive generation investment in RTO/ISO market rules. Improvement is needed in these areas. Introducing confusion about what assets are classified as generation and what assets are classified as transmission frustrates potential reform and undermines the competitive markets.

On July 22, 2020, through the supplemental planning process, American Electric Power Service Corporation (AEP) filed, on behalf of Kentucky Power Company (Kentucky Power), a Petition for Declaratory Order seeking confirmation that its Middle Creek energy storage project is eligible for cost of service recovery through AEP's formula rates.[152] AEP's Middle Creek energy storage project was a proposed battery storage device that would discharge energy to serve retail load at the Middle Creek substation in the event of a transmission outage. On December 21, 2020, the Commission ruled that the Middle Creek energy storage project did not perform a transmission function, and was ineligible to recover its costs through formula rates.[153]

Storage devices like batteries that are defined to be part of PJM markets should not be treated as transmission assets. These devices should be treated as market assets. The MMU recommends that storage resources not be includable as transmission assets for any reason.

Board Authorized Transmission Upgrades

The Transmission Expansion Advisory Committee (TEAC) regularly reviews internal and external proposals to improve transmission reliability throughout PJM. These proposals, which include reliability baseline, network, market efficiency and targeted market efficiency projects, as well as scope changes and project cancellations, but exclude supplemental and end of life projects, are periodically presented to the PJM Board of Managers for authorization.[154]

An RTEP project can be approved by the PJM Board if the project ensures compliance with NERC, regional and local transmission owner planning criteria or to address market efficiency congestion relief. These projects are considered Baseline Projects. PJM Board approved RTEP projects that are necessary to allow new generation to interconnect reliably are considered Network Projects.

150 See "PJM Manual 14F: Competitive Planning Process," Rev. 10 (October 30, 2024).
151 See PJM. "*Storage As A Transmission Asset: Problem / Opportunity Statement*," <https://pjm.com/-/media/committees-groups/committees/pc/2020/20200605-special/20200605-item-02a-storage-as-a-transmission-asset-problem-statement-clean.ashx>.
152 See *AEP*, Docket No. EL20-58 (July 22, 2020).
153 173 FERC ¶ 61,264 (2020).
154 Supplemental Projects, including the end of life subset of supplemental projects, do not require PJM Board of Managers authorization.

In the first nine months of 2025, the PJM Board approved a net change of $7.9 billion in transmission upgrades. As of September 30, 2025, the PJM Board had approved $58.0 billion in transmission system enhancements since 1999.

Qualifying Transmission Upgrades (QTU)

A Qualifying Transmission Upgrade (QTU) is an upgrade to the transmission system, financed and built by market participants, that increases the Capacity Emergency Transfer Limit (CETL) into an LDA and can be offered into capacity auctions as capacity. Once a QTU is in service, the upgrade is eligible to continue to offer the approved incremental import capability into future RPM Auctions.

If a QTU that was cleared in a Base Residual Auction (BRA) or Incremental Auction (IA) is not completed by the start of the Delivery Year, the submitting party is required to provide replacement capacity. Once a QTU is in service, the upgrade is eligible to continue to offer the approved incremental import capability into future RPM Auctions. As of September 30, 2025, no QTUs have cleared a BRA or IA.

Cost Allocation

Required transmission enhancements are categorized as: supplemental, network or baseline upgrades. The cost allocation of the transmission enhancements depends on the category of upgrades.

Supplemental Upgrade Cost Allocation

Supplemental projects are defined to be "transmission expansions or enhancements that are not required for compliance with PJM criteria and are not state public policy projects according to the PJM Operating Agreement. These projects are used as inputs to RTEP models, but are not required for reliability, economic efficiency or operational performance criteria, as determined by PJM."[155] Supplemental projects are exempt from competition. The costs of supplemental projects are allocated 100 percent to the zone in which the transmission facilities are located.[156]

155 See PJM. "Transmission Construction Status," (Accessed on September 30, 2025) <https://www.pjm.com/planning/m/project-construction>.
156 See OATT Schedule 12(a)(iii).

Network Upgrade Cost Allocation

Any entity that requests interconnection of a new generating facility, including increases to the capacity of an existing generating unit, or that requests interconnection of a merchant transmission facility, must follow the process defined in the PJM tariff to obtain interconnection service.[157] PJM's process is designed to ensure that new generation is added in a reliable and systematic manner. The process assigns the upgrade costs to the project or projects that are causing the costs to be incurred. As part of the interconnection planning process, a series of studies are performed to determine the feasibility, impact, and cost of interconnecting projects in the queue. The interconnection service agreement identifies the transmission modifications needed to maintain the reliability of the transmission system as a result of a new service request. These identified modifications are known as network upgrades. For required network upgrades under the new cluster based service request cycles, the costs of the network upgrades are assigned to individual projects that caused the costs to be incurred.[158]

Baseline Upgrade Cost Allocation

The PJM RTEP process is designed to identify needed transmission system additions and improvements to continue to provide reliable service throughout the RTO. Typically, load growth creates conditions that may create violations of reliability criteria, which in turn require upgrades. The PJM RTEP identifies necessary upgrades to remain compliant with national and regional reliability standards. These modifications are baseline upgrades. Baseline upgrades can also include market efficiency projects.

The costs of regional baseline facilities are allocated 50 percent on a load-ratio share and 50 percent on a directionally weighted solution based DFAX method.[159]

157 See OATT Parts IV & VI.
158 See "PJM Manual 14H: New Service Requests Cycle Process," Rev. 02 (July 23, 2025).
159 See "PJM Manual 14B: PJM Region Transmission Planning Process," Rev. 57 (September 25, 2024) for a complete explanation of the directionally weighted solution based DFAX method.

The costs of the necessary lower voltage facilities required to support the regional baseline facilities with estimated costs greater than or equal to $5 million are assigned on a directionally weighted solution based DFAX method.

The costs of the necessary lower voltage facilities required to support the regional baseline facilities with estimated costs below $5 million are assigned to the zone where the upgrade is located.

In response to complaints against PJM RTEP Baseline Upgrade Filings in 2014 that included cost allocations for $1.5 billion in baseline transmission enhancements and expansions, on November 24, 2015, FERC issued an order directing investigation of "whether there is a definable category of reliability projects within PJM for which the solution-based DFAX cost allocation method may not be just and reasonable, such as projects addressing reliability violations that are not related to flow on the planned transmission facility, and whether an alternative just and reasonable *ex ante* cost allocation method could be established for any such category of projects."[160] FERC convened a technical conference on January 12, 2016, to address the complaints in multiple proceedings and to address these two core issues.[161]

The issues identified in the complaints and at the technical conference included: whether the solutions based allocation method is appropriate for upgrades not related to transmission overload issues; whether the solutions based allocation method correctly identifies all the beneficiaries of the upgrades; whether it is reasonable to allocate a level of costs to a merchant transmission project that could force bankruptcy; and whether the significant shifts in allocation that result from use of the 0.01 distribution factor cutoff are appropriate.

On February 20, 2020, the Commission issued an Order denying rehearing requests.[162] The Commission found that PJM's solution based dfax method for regional cost allocation, including the 0.01 distribution cutoff factor, is just and reasonable.

160 153 FERC ¶ 61,245 at P 35 (2015).
161 See Docket Nos. EL15-18-000 (ConEd), EL15-67-000 (Linden), and EL15-95-000 (Artificial Island).
162 See 170 FERC ¶ 61,122 (2020).

On appeal, the U.S. Court of Appeals for the D.C. Circuit in 2022 found that FERC had failed to explain its distinction between the projects eligible to use the dfax method and those not eligible.[163] The Court objected that without adequate explanation: "The Bergen project 'addresses a non-flow related reliability issue,' just like the non-flow-based stability issue in Artificial Island, but FERC had treated the two projects differently."[164] The Court also rejected the 0.01 distribution cutoff factor as "absurd."[165] The Court remanded issues concerning PJM's solution based dfax method to FERC, where the matter is now pending.[166]

It is clear that the allocation issues are difficult. Nonetheless, allocation methods affect the efficiency of the markets. Allocation methods also affect the degree to which transmission upgrades required to serve data center load are allocated to other customers. The MMU recommends a comprehensive review of the ways in which the solution based dfax is implemented. The goal for such a process would be to ensure that the most rational and efficient approach to implementing the solution based dfax method is used in PJM. Such an approach should allocate costs consistent with benefits and appropriately calibrate the incentives for investment in new transmission capability. No replacement approach should be approved until all potential alternatives are thoroughly reviewed.

As an example, the use of the arbitrary 0.01 distribution factor cutoff can result in large and inappropriate shifts in cost allocation. If the intent of the use of the 0.01 cutoff is to help eliminate small, arbitrary cost allocations to geographically distant areas, this could be achieved by adding a threshold for a minimum usage impact on the line. The MMU recommends changing the minimum distribution factor in the allocation from 0.01 to 0.00 and adding a threshold minimum impact on the load on the line based on a complete analysis of the intent of the allocation and the impacts of the allocation.

166 See FERC Docket Nos. EL21-39-000, et al.

Transmission Line Ratings

Transmission line ratings, and more broadly transmission facility ratings, are the metric for the ability of transmission lines to transmit power from one point to another. Transmission line ratings have significant and frequently underappreciated impacts on competitive wholesale power markets like PJM. Line ratings directly affect energy and capacity prices, the frequency and level of congestion in the day-ahead and real-time energy market, day-ahead nodal price differences and the associated value of FTRs, locational price differences in the capacity market, the need to invest in additional transmission capacity, the need to invest in additional generation capacity, the location of new power plants, and the costs for the interconnection of new power plants. The impact of transmission facility ratings on markets is a function both of the line ratings directly and the use of those ratings by the RTO/ISO.

Congestion payments by load result when lower cost generation is not available to meet all the load in an area as a result of limits on the transmission system. When higher cost local generation is needed to meet part of the local load because of transmission limits, 100 percent of the local load pays the higher price while only the local generation receives the higher price. The difference between what the load pays and generators receive is congestion. Since 2008, congestion costs in PJM have ranged from $0.5 billion to $2.05 billion per year. The fact that PJM rules continue to fail to ensure the return of 100 percent of congestion costs to the load that pays them means that higher congestion increases costs to load.

LMP may, at times, be set by transmission constraint penalty factors. When a transmission constraint is binding and there are no generation alternatives to resolve the constraint, system operators may allow the transmission limit to be violated. When this occurs, the shadow price of the constraint is set by transmission constraint penalty factors. The shadow price directly affects the LMP. Transmission constraint penalty factors were fully implemented in PJM pricing effective February 1, 2019.[167]

167 For more information, see the *2024 Annual State of the Market Report for PJM*, Section 3: Energy Market.

Transmission line ratings can result in short term, significant increases in prices as a result of the application of transmission constraint penalty factors. For example, violation of a transmission constraint, meaning that the flow exceeds the line limit, generally results in at least a $2,000 per MWh price. As the power flows approach their rated limits, PJM dispatchers often reduce the control percent on transmission limits applied in SCED by the setting the limit to an average of 95 percent of its actual limit.[168] Violation of these reduced control percent line ratings results in penalty factors setting prices in SCED.[169]

Holding aside the issues with operators reducing the control percent in SCED, the more important point is that the underlying line ratings have a significant impact on the cost of energy and capacity but have never been reviewed or standardized by ISOs/RTOs or by regulators. The line ratings issues will begin to be addressed beginning on July 12, 2025.[170]

Capacity market prices separate locally when transmission capability into Locational Deliverable Areas (LDA) is not adequate to meet the LDA capacity requirement with the lowest cost capacity. The available transmission capability into LDAs is defined as the Capacity Emergency Transfer Limit (CETL). Higher cost LDAs are the equivalent in the capacity market of congestion in the energy market. Load in the higher cost LDAs pay more for capacity than those in lower cost LDAs. For example, the clearing price for the BGE LDA in the 2021/2022 Base Residual Auction was $200.30 per MW-day. The clearing price for the EMAAC LDA was $165.73 per MW-day.[171]

Transmission line ratings for a given transmission facility vary by the duration of the power flow, by ambient temperatures, by wind speed and by other conditions. Transmission lines can operate with higher loads for shorter periods of time. This is significant when a contingency is expected to last for only a short period. The transmission line rating can mean the difference between substantial congestion costs and no congestion costs.

168 See "Transmission Constraint Control Logic and Penalty Factors," presented at May 10, 2018, meeting of the Markets Implementation Committee Special Session Transmission Constraint Penalty Factors at p14. <https://www.pjm.com/-/media/committees-groups/committees/mic/20180510-special/20180510-item-03-transmission-constraint-penalty-factor-education.ashx>.

170 *Managing Transmission Line Ratings*, Order No. 881, 177 FERC ¶ 61,179 at P 39 (2021) ("Order No. 881"), *order on reh'g*, Order No. 881-A, 179 FERC ¶ 61,125 (2022) ("Order No. 881-A").
171 See the "Analysis of the 2021/2022 RPM Base Residual Auction," <https://www.monitoringanalytics.com/reports/Reports/2018/IMM_Analysis_of_the_20212022_RPM_BRA_Revised_20180824.pdf> (August 24, 2018).

The transmission line rating can mean the difference between a transmission penalty factor and no penalty factor.

In PJM, transmission owners use a range of ratings by duration.[172] PJM requires transmission owners to provide thermal ratings under normal operating conditions, long term emergency operating conditions, short term emergency operating conditions and the extreme load dump conditions. But there is no requirement that the ratings differ for these operating conditions. PJM typically uses normal line ratings for precontingency (base case) constraints and long term emergency line ratings (four hours) for contingency constraints. PJM requires transmission owners to provide temperature based line ratings separately for night and day times. The temperature ranges from 32 degree Fahrenheit or below to 95 degree Fahrenheit or above in nine degree increments. But there is no requirement that the ratings differ for these operating condition temperatures. In PJM, transmission owners are responsible for developing their own methods to compute line ratings subject to a range of NERC guidelines and requirements. PJM does not review or verify the accuracy of transmission owners' methods to compute line ratings. In PJM, transmission owners have substantial discretion in the approach to line ratings.[173]

Given the significant impact of transmission line ratings on all aspects of wholesale power markets, ensuring and improving the accuracy and transparency of line ratings is essential. Line ratings should incorporate ambient temperature conditions, wind speed and other relevant operating conditions. PJM real-time prices are calculated every five minutes for thousands of nodes. PJM prices are extremely sensitive to transmission line ratings. For consistency with the dynamic nature of wholesale power markets, line ratings should be updated in real time to reflect real time conditions and to help ensure that real-time prices are based on actual current line ratings. New technologies that permit dynamic line ratings (DLR) should be implemented.

Line ratings determine the actual value of transmission in market operations. Yet the methods for defining line ratings remain opaque and vary significantly across transmission owners. Under defining line ratings results in over building transmission. Dynamic line ratings are essential to reflect the actual availability of transmission in real time as ambient conditions change. Ensuring that system operators have accurate information about line ratings, including a wide range of line ratings by duration of load, are essential to ensure that all market participants receive the maximum value from the investment in the transmission system.

Given the significant impact of transmission line ratings on all aspects of wholesale power markets, ensuring and improving the accuracy and transparency of line ratings is essential. Line ratings should incorporate ambient temperature conditions, wind speed and other relevant operating conditions. In PJM, real-time prices are calculated every five minutes for thousands of nodes. PJM prices are extremely sensitive to transmission line ratings.

The MMU recommends that all PJM transmission owners use the same methods to define line ratings and implement dynamic line ratings (DLR), subject to NERC standards and guidelines, subject to review by NERC, PJM and the MMU, and approval by FERC. The same facilities should have the same basic ratings under the same operating conditions regardless of the transmission owner. Transmission owner discretion should be minimized or eliminated. The line rating methods should be based on the basic engineering facts of the transmission system components and reflect the impact of actual operating conditions on the ratings of transmission facilities, including ambient temperatures and wind speed when relevant.[174] The line rating methods should be public and fully transparent.

The MMU recommends that PJM routinely review all transmission facility ratings and any changes to those ratings to ensure that the normal, emergency and load dump ratings used in modeling the transmission system are accurate and reflect standard ratings practice.[175] All line rating changes and the detailed reasons for those changes should be public and fully transparent.

172 See "PJM Manual 03: Transmission Operations," Rev. 68 (May 21, 2025) § 2.1.1, at p 30.
173 PJM presentation to the Planning Committee (PC) (May 3, 2018) "Transmission Owner Ratings Development and Reporting in PJM" ("There are no requirements for PJM to approve or verify a TO's ratings or do any kind of consistency check.") at 24.
174 *See* "Transmission Owner Ratings Development and Reporting in PJM," presented at May 3, 2018 meeting of the Planning Committee.
175 *See* the *2024 Annual State of the Market Report for PJM*, Section 3: Energy Market.

The Commission adopted rules that enhance the ability of PJM and the MMU to understand and monitor line ratings on the PJM grid. Order No. 881, issued December 16, 2021, requires that: transmission providers implement ambient adjusted ratings on transmission lines; RTOs/ISOs implement the systems and procedures necessary for hourly ratings updates; transmission providers use uniquely determined emergency ratings; transmission owners share transmission line ratings and transmission line rating methods with RTOs/ISOs and market monitors; transmission providers maintain a database of transmission line ratings and transmission line rating methods on OASIS or other password-protected website.[176] [177]

On rehearing, the Commission provided clarification of market monitors' ability to take action based on information received about transmission line ratings: "We expect that market monitors may use the transmission line rating information available to them in furtherance of their existing responsibilities, which are set forth in the Commission's regulations and the relevant tariffs of each RTO/ISO."[178]

Order No. 881 enhances transparency of information on line ratings and how they are determined. Requiring ambient and hourly adjustments constitutes substantive improvement. Continued reform consistent with the MMU's recommendations is needed in order to ensure consistent and accurate transmission line ratings in PJM.

By letter order issued November 22, 2023, the Commission accepted PJM's filing in compliance with Order Nos. 881 and 881-A, to be implemented no later than July 12, 2025.[179]

Order No. 881 did not require the use of dynamic line ratings ("DLR") based on an insufficient record.[180] On June 27, 2024, the Commission issued an Advanced Notice of Proposed Rulemaking in Docket RM24-6 on the implementation of dynamic line ratings.[181]

179 See Docket No. ER22-2359-000. PJM must notify the Commission of the effective date no later than November 12, 2024.
180 Order No. 881 at PP 25, 254.
181 See 187 FERC ¶ 61,201.

Dynamic Line Ratings (DLR) and Grid Enhancing Technology (GETs)

For consistency with the dynamic nature of wholesale power markets, line ratings should be updated in real time to reflect real time conditions and to help ensure that real time prices are based on actual current line ratings. The relevant real-time conditions include ambient air temperature, wind speeds, solar heating, transmission line tension, and transmission line sag. The widespread adoption of dynamic line ratings should be pursued. The adoption of dynamic line ratings does not require the exorbitant incentives proposed by some. Dynamic line rating technology (DLR) and other Grid Enhancing Technology (GET) should be subject to competition and the costs of implementation should be capped at the costs that would result from the current cost of service method applied to transmission owners. The proposal that providers of GET should receive a share of forecast benefits is not consistent with competition, would pay rates of return many multiples of market rates of return and suffers from the same intractable problem of defining speculative benefits for long periods.

As a first small step towards broader implementation of DLR by all transmission owners in PJM, PPL Electric Utilities, on its own initiative, implemented DLR for three 230 KV transmission lines in northeastern Pennsylvania on October 6, 2022, that have experienced congestion. (The two circuit Susquehanna-Harwood path and the Juniata-Cumberland line.) PPL provides streaming data from the DLR system to PJM operators.

PJM developed technical reference guides to aid in the understanding and consideration of grid enhancing technologies on the PJM system. The technical reference guides provide additional information on dynamic line ratings, advanced power flow controllers, topology control and optimization and advanced conductors.[182]

182 See PJM. About PJM "Grid Optimization Solutions," <https://www.pjm.com/about-pjm/advanced-technologies/grid-optimization-solutions>.

Transmission Facility Outages

Scheduling Transmission Facility Outage Requests

A transmission facility is designated as reportable by PJM if a change in its status can affect a transmission constraint on any Monitored Transmission Facility or could impede free flowing ties within the PJM RTO and/or adjacent areas.[183] When a reportable transmission facility needs to be taken out of service, the transmission owner is required to submit an outage request as early as possible.[184] The specific timeline is shown in Table 12-85.[185]

Transmission outages have significant impacts on PJM markets, including impacts on FTR auctions, on congestion, and on expected market outcomes in the day-ahead and real-time markets. The efficient functioning of the markets depends on clear, enforceable rules governing transmission outages.

The outage data for the FTR market are for outages scheduled to occur in the 2024/2025 planning period and the first four months of the 2025/2026 planning period, regardless of when they were initially submitted.[186] The outage data for the day-ahead market are for outages scheduled to occur from January 2015 through September 2025.

Transmission outages are categorized by duration: greater than 30 calendar days; less than or equal to 30 calendar days; greater than five calendar days; less than or equal to five calendar days.[187] Table 12-84 shows that 66.6 percent of requested outages were planned for less than or equal to five days and 13.6 percent of requested outages were planned for greater than 30 days in the first four months of the 2025/2026 planning period. Table 12-84 also shows that 75.2 percent of the requested outages were planned for less than or equal to five days and 9.1 percent of requested outages were planned for greater than 30 days in the 2024/2025 planning period.

Table 12-84 Transmission facility outage request summary by planned duration: June 2024 through September 2025

	2024/2025 (12 months)		2025/2026 (4 months)	
Planned Duration (Days)	Outage Requests	Percent of Total	Outage Requests	Percent of Total
<=5	15,092	75.2%	7,943	66.6%
>5 & <=30	3,148	15.7%	2,357	19.8%
>30	1,838	9.2%	1,618	13.6%
Total	20,078	100.0%	11,918	100.0%

After receiving a transmission facility outage request from a TO, PJM assigns a received status to the request based on its submission date and outage planned duration. The received status can be On Time or Late, as defined in Table 12-85.[188]

The purpose of the rules defined in Table 12-85 is to require the TOs to submit transmission facility outages prior to the Financial Transmission Right (FTR) auctions so that market participants have complete information about market conditions on which to base their FTR bids and PJM can accurately model market conditions.[189]

Table 12-85 Transmission facility outage request received status definition

Planned Duration (Calendar Days)	Request Submitted	Received Status
<=5	Before the first of the month one month prior to the starting month of the outage	On Time
	After or on the first of the month one month prior to the starting month of the outage	Late
> 5 & <=30	Before the first of the month six months prior to the starting month of the outage	On Time
	After or on the first of the month six months prior to the starting month of the outage	Late
>30	Before the earlier of 1) February 1, 2) the first of the month six months prior to the starting month of the outage	On Time
	After or on the earlier of 1) February 1, 2) the first of the month six months prior to the starting month of the outage	Late

183 If a transmission facility is not modeled in the PJM EMS or the facility is not expected to significantly impact PJM system security or congestion management, it is not reportable. See PJM, "Manual 3: Transmission Operations," Rev. 68 (May 21, 2025).
184 See PJM, "Manual 3: Transmission Operations," Rev. 68 (May 21, 2025).
185 See PJM, "Manual 3: Transmission Operations," Rev. 68 (May 21, 2025).
186 The hotline tickets, EMS tripping tickets or test outage tickets were excluded. The analysis includes only the transmission outage tickets submitted by PJM companies which are currently active.

188 See PJM, "Manual 3: Transmission Operations," Rev. 68 (May 21, 2025).
189 See "*Report of PJM Interconnection, L.L.C. on Transmission Oversight Procedures*," Docket No. EL01-122-000 (November 2, 2001).

Table 12-86 shows a summary of requests by received status. In the first four months of the 2025/2026 planning period, 31.0 percent of outage requests received were late. In the 2024/2025 planning period, 40.5 percent of outage requests received were late.

Table 12-86 Transmission facility outage requests by received status: June 2024 through September 2025

	2024/2025 (12 months)				2025/2026 (4 months)			
Planned Duration (Days)	On Time	Late	Total	Percent Late	On Time	Late	Total	Percent Late
<=5	9,558	5,534	15,092	36.7%	5,686	2,257	7,943	28.4%
>5 & <=30	1,684	1,464	3,148	46.5%	1,672	685	2,357	29.1%
>30	706	1,132	1,838	61.6%	863	755	1,618	46.7%
Total	11,948	8,130	20,078	40.5%	8,221	3,697	11,918	31.0%

Once received, PJM processes outage requests in priority order: emergency transmission outage request; transmission outage request submitted on time; and transmission outage request submitted late. Transmission outage requests that are submitted late may be approved if the outage does not affect the reliability of PJM or cause congestion in the system.[190]

Outages with emergency status will be approved even if submitted late after PJM determines that the outage does not result in Emergency Procedures. PJM cancels or withholds approval of any outage that results in Emergency Procedures.[191] Table 12-87 is a summary of outage requests by emergency status. Of all outage requests scheduled to occur in the first four months of the 2025/2026 planning period, 9.4 percent were for emergency outages. Of all outage requests scheduled to occur in the 2024/2025 planning period, 12.1 percent were for emergency outages.

190 See PJM, "Manual 3: Transmission Operations," Rev. 68 (May 21, 2025). The following language was removed from Manual 3 Rev. 50: PJM retains the right to deny all jobs submitted after 8 a.m. three days prior to the requested start date unless the request is an emergency job or an exception request (i.e. a generator tripped and the Transmission Owner is taking advantage of a situation that was not available before the unit trip).

191 PJM, "Manual 3: Transmission Operations," Rev. 68 (May 21, 2025).

Table 12-87 Transmission facility outage requests by emergency: June 2024 through September 2025

	2024/2025 (12 months)				2025/2026 (4 months)			
Planned Duration (Days)	Emergency	Non Emergency	Total	Percent Emergency	Emergency	Non Emergency	Total	Percent Emergency
<=5	1,709	13,383	15,092	11.3%	784	7,159	7,943	9.9%
>5 & <=30	400	2,748	3,148	12.7%	149	2,208	2,357	6.3%
>30	325	1,513	1,838	17.7%	190	1,428	1,618	11.7%
Total	2,434	17,644	20,078	12.1%	1,123	10,795	11,918	9.4%

PJM will approve all transmission outage requests that are submitted on time and do not jeopardize the reliability of the PJM system. PJM will approve all transmission outage requests that are submitted late and are not expected to cause congestion on the PJM system and do not jeopardize the reliability of the PJM system. Each outage is studied and if it is expected to cause a constraint to exceed a limit, PJM will flag the outage ticket as "congestion expected."[192]

After PJM determines that a late request may cause congestion, PJM informs the transmission owner of solutions available to eliminate the congestion. For example, if a generator planned or maintenance outage request is contributing to the congestion, PJM can request that the generation owner defer the outage. If no solutions are available, PJM may require the transmission owner to reschedule or cancel the outage.

Table 12-88 is a summary of outage requests by congestion status. Of all outage requests submitted to occur in the first four months of the 2025/2026 planning period, 7.8 percent were expected to cause congestion. Of all the outage requests that were expected to cause congestion, 3.5 percent (33 out of 935) were denied by PJM in the first four months of the 2025/2026 planning period and 17.0 percent (159 out of 935) were cancelled (Table 12-90). Of all outage requests submitted to occur in the 2024/2025 planning period, 9.0 percent were expected to cause congestion. Of all the outage requests that were expected to cause congestion, 5.2 percent (94 out of 1,813) were denied by PJM in the 2024/2025 planning period and 20.6 percent (373 out of 1,813) were cancelled (Table 12-90).

192 PJM added this definition to Manual 38 in February 2017. PJM, "Manual 38: Operations Planning," Rev. 19 (Jan. 23, 2025).

Table 12-88 Transmission facility outage requests by congestion: June 2024 through September 2025

	2024/2025 (12 months)				2025/2026 (4 months)			
Planned Duration (Days)	Congestion Expected	No Congestion Expected	Total	Percent Congestion Expected	Congestion Expected	No Congestion Expected	Total	Percent Congestion Expected

Total	1,817	18,261	20,078	9.0%	935	10,983	11,918	7.8%

Table 12-89 shows the outage requests summary by received status, congestion status and emergency status. In the first four months of the 2025/2026 planning period, 21.8 percent of requests were submitted late and were nonemergency while 1.2 percent of requests (139 out of 11,918) were late, nonemergency, and expected to cause congestion. In the 2024/2025 planning period, 28.5 percent of requests were submitted late and were nonemergency while 1.6 percent of requests (324 out of 20,078) were late, nonemergency, and expected to cause congestion.

Table 12-89 Transmission facility outage requests by received status, emergency and congestion: June 2024 through September 2025

		2024/2025 (12 months)				2025/2026 (4 months)			
Received Status		Congestion Expected	No Congestion Expected	Total	Percent of Total	Congestion Expected	No Congestion Expected	Total	Percent of Total
Late	Emergency	121	2,286	2,407	12.0%	63	1,031	1,094	9.2%
	Non Emergency	324	5,399	5,723	28.5%	139	2,464	2,603	21.8%

	Non Emergency	1,370	10,551	11,921	59.4%	733	7,459	8,192	68.7%
Total		1,817	18,261	20,078	100.0%	935	10,983	11,918	100.0%

Once PJM processes an outage request, the outage request is labelled as Submitted, Received, Denied, Approved, Cancelled by Company, PJM Admin Closure, Revised, Active or Complete according to the processed stage of a request.[193] Table 12-90 shows the detailed process status for outage requests only for the outage requests that are expected to cause congestion. Status Submitted and status Received are in the In Process category and status Cancelled by Company and status PJM Admin Closure are in the Cancelled category in Table 12-90. Table 12-90 shows that of all the outage requests that were expected to cause congestion, 3.5 percent (33 out of 935) were denied by PJM in the first four months of the 2025/2026 planning period, 43.0 percent were complete and 17.0 percent (159 out of 935) were cancelled. Of all the outage requests that were expected to cause congestion, 5.2 percent (94 out of 1,817) were denied by PJM in the 2024/2025 planning period, 67.3 percent were complete and 20.5 percent (373 out of 1,817) were cancelled.

193 See PJM Markets & Operations, PJM Tools "Outage Information," <http://www.pjm.com/markets-and-operations/etools/oasis/system-information/outage-info.aspx> (2019).

Table 12-90 Transmission facility outage requests by processed status[194]: June 2024 through September 2025

		2024/2025 (12 months)						2025/2026 (4 months)					
Received Status		Cancelled	Complete	In Process	Denied	Congestion Expected	Percent Complete	Cancelled	Complete	In Process	Denied	Congestion Expected	Percent Complete

Total		373	1,222	112	94	1,817	67.3%	159	402	322	33	935	43.0%

There are clear rules defined for assigning On Time or Late status for submitted outage requests in both the PJM tariff and PJM manuals.[195] The On Time or Late status affects the way in which PJM addresses the potential to exceed transmission limits. Table 12-90 shows that in the first four months of the 2025/2026 planning period, 139 nonemergency outage requests were submitted late and expected to cause congestion. The expected impact on congestion and the options for controlling that congestion is the basis for PJM's treatment of late outage requests.

The definition of this congestion analysis in the PJM manuals is about physical limits and not about economic congestion. PJM approves on time outages based solely on whether limits are exceeded and available controlling actions, without regard to the resulting level of economic congestion. The MMU recommends that PJM draft a definition of the congestion analysis required for transmission outage requests and associated triggers, including both the extent of overloaded facilities and the level of economic congestion, to include in PJM manuals after appropriate review with appropriate rules for on time and late outage requests.[196]

194 The number of denied transmission outage requests is lower than calculated by PJM the MMU includes only the transmission outage requests with "Denied" as a final status, while PJM included both transmission outage requests with "Denied" as a final status and transmission outage requests with "Denied" as an intermediate status.

195 OA Schedule 1 § 1.9.2.

196 "PJM Manual 38: Operations Planning," Rev. 19 (Jan. 23, 2025). p 21. Manual 38 states: "The outages are analyzed for reliability and expected off-costs. Each outage is studied and any constraints (actual or facility/contingency pair) trending toward a limit or exceeding a limit is noted in eDART. The trending or exceeding of a limit in the study is referred to as potential "congestion". The limit may be any or a combination of thermal, voltage, or stability issues. If there is an expected constraint, PJM will mark the corresponding eDART ticket as "congestion expected". The "congestion expected" flag is used to indicate a potential issue that may occur in the Day-Ahead Market or in Real-time Operations. If there are non-cost controlling actions, changes to the generation pattern, or changes to system conditions, the noted congestion may not occur in the Day-Ahead Market or in Real-time Operations. For "On-time" outages, PJM ensures the constraint can be mitigated by applying both non-cost and off-cost operations. If there are no limit exceedances as a result, the outage will be approved. For "Late" outages, PJM will apply only non-cost operations."

The treatment by PJM and Dominion Virginia Power of the outage for the Lanexa – Dunnsville Line illustrates some of the issues with the current process. The outage was submitted and delayed more than once. It is not clear that PJM's analysis of expected congestion identified or highlighted the magnitude of the economic impact. Dominion Virginia Power did not stage the outage so as to minimize market disruption and congestion. After high congestion costs of Greys Point - Harmony Village constraint and market participant manipulative behavior caused by the outage were identified by the end of January, on February 11, 2022 Dominion decided to temporarily terminate the outage in March in order to work on upgrading Greys Point, Harmony Village and White Stone path. The Greys Point - Harmony Village Line has not been binding since March 14, 2022. It indicates that if the market impact of the outage was identified during PJM outage analysis process and action was taken because of the analysis result, the high congestion costs and manipulative behavior could have been prevented.

Rescheduling Transmission Facility Outage Requests

A TO can reschedule or cancel an outage after initial submission. Table 12-91 is a summary of all the outage requests planned for the 2024/2025 planning period and the first four months of the 2025/2026 planning period which were approved and then cancelled or rescheduled by TOs at least once. If an outage request was submitted, approved and subsequently rescheduled at least once, the outage request will be counted as Approved and Rescheduled. If an outage request was submitted, approved and subsequently cancelled at least once, the outage request will be counted as Approved and Cancelled.

In the first four months of the 2025/2026 planning period, 17.1 percent of transmission outage requests were approved by PJM and then rescheduled by the TOs, and 7.6 percent of the transmission outages were approved by PJM and subsequently cancelled by the TOs. In the 2024/2025 planning period, 29.4 percent of transmission outage requests were approved by PJM and then rescheduled by the TOs, and 12.3 percent of the transmission outages were approved by PJM and subsequently cancelled by the TOs.[197]

Table 12-91 Rescheduled and cancelled transmission outage requests: June 2024 through September 2025

	2024/2025 (12 months)					2025/2026 (4 months)				
Planned Duration (Days)	Outage Requests	Approved and Rescheduled	Percent Approved and Rescheduled	Approved and Cancelled	Percent Approved and Cancelled	Outage Requests	Approved and Rescheduled	Percent Approved and Rescheduled	Approved and Cancelled	Percent Approved and Cancelled
<=5	15,092	3,028	20.1%	2,129	14.1%	7,943	1,113	14.0%	766	9.6%
>5 & <=30	3,148	1,734	55.1%	250	7.9%	2,357	500	21.2%	88	3.7%
>30	1,838	1,133	61.6%	92	5.0%	1,618	423	26.1%	48	3.0%
Total	20,078	5,895	29.4%	2,471	12.3%	11,918	2,036	17.1%	902	7.6%

If a requested outage is determined to be late and TO reschedules the outage, the outage will be revaluated by PJM again as On Time or Late.

A transmission outage ticket with duration of five days or less with an On Time status can retain its On Time status if the outage is rescheduled within the original scheduled month.[198] This rule allows a TO to reschedule within the same month with very little notice.

A transmission outage ticket with a duration exceeding five days with an On Time status can retain its On Time status if the outage is rescheduled to a future month, and the revision is submitted by the first of the month prior to the revised month in which the outage will occur.[199] This rescheduling rule is much less strict than the rule that applies to the first submission of outage requests with similar duration. When first submitted, the outage request with a duration exceeding five days needs to be submitted before the first of the month six months prior to the month in which the outage was expected to occur. The rescheduling rule allows TOs to avoid the timing requirements associated with outages exceeding five days.

The MMU recommends that PJM reevaluate all transmission outage tickets as on time or late as if they were new requests when an outage is rescheduled, create options for late requests based on the reasons, and apply the modified rules for late submissions to any such outages. The MMU recommends that PJM create options for treatment of late outages. The current rules apply more stringent rules, based on controlling actions, to late outages without distinguishing among reasons for late outages.

Long Duration Transmission Facility Outage Requests

PJM rules (Table 12-85) define a transmission outage request as On Time or Late based on the planned outage duration and the time of submission. The rule has stricter submission requirements for transmission outage requests planned for longer than 30 days. In order to avoid the stricter submission requirement, some transmission owners divided the duration of outage requests longer than 30 days into shorter segments for the same equipment and submitted one request for each segment. The MMU recommends that PJM not permit transmission owners to divide long duration outages into smaller segments to avoid complying with the requirements for long duration outages.

More than one outage request can be submitted for the same transmission equipment. In order to accurately present the results, Table 12-92 shows equipment outages by the equipment instead of by outage request.

Table 12-92 shows that there were 8,332 transmission equipment planned outages in the first four months of the 2025/2026 planning period, of which 1,400 or 16.8 percent were longer than 30 days, and of which 205 or 2.5 percent were scheduled longer than 30 days when the duration of all the outage requests are combined for the same equipment.

197 The number of tickets in each category can change over time. For example, a ticket initially classified as canceled or denied may be resubmitted at a later date for a different date range. Once approved the resubmitted ticket overrides the original ticket dates and details.
198 PJM, "Manual 3: Transmission Operations," Rev. 68 (May 21, 2025).
199 *Id.*

Table 12-92 Transmission equipment outages: June 2024 through September 2025

		2024/2025 (12 months)		2025/2026 (4 months)	
Planned Duration (Days)	Divided into Shorter Periods	Count of Equipment with Planned Outages	Percent of Total	Count of Equipment with Planned Outages	Percent of Total
> 30	No	1,583	12.3%	1,400	16.8%
	Yes	251	1.9%	205	2.5%

Total		12,879	100.0%	8,332	100.0%

Table 12-93 shows the details of long duration (> 30 days) outages when combining the duration of the outage requests for the same equipment.[200] The actual duration of scheduled outages would be longer than 30 days if the duration of the outage requests was appropriately combined for the same equipment. An effective duration was calculated for each piece of equipment by subtracting the start date of the earliest outage request from the end date of the latest outage request of the equipment. In the first four months of the 2025/2026 planning period, with an effective duration greater than a month and shorter than two months, there were 32 outages with a combined duration longer than 30 days.[201]

Table 12-93 Transmission equipment outages by effective duration: June 2024 through September 2025

	2024/2025 (12 months)		2025/2026 (4 months)

Total	251	100.0%	205	100.0%

Transmission Facility Outage Analysis for the FTR Market

Transmission facility outages affect the price and quantity outcomes of FTR Auctions. The purpose of the rules governing outage reporting is to ensure that outages are known with enough lead time prior to FTR Auctions so that market participants can understand market conditions and PJM can accurately model market conditions.

There are Long Term, Annual and Monthly Balance of Planning Period auctions in the FTR Market. For each type of auction, PJM includes a set of outages to be modeled.

Annual FTR Market

The Annual FTR Market includes the Annual ARR Allocation and the Annual FTR Auction. When determining transmission outages to be modeled in the simultaneous feasibility test used in the Annual FTR Market, PJM considers all outages with planned duration longer than or equal to two weeks as an initial list. Then PJM may exercise significant discretion in selecting outages to be modeled in the final model. PJM posts the final FTR outage list to the FTR web page usually at least one week before the auction bidding opening day.[202]

In the first four months of the 2025/2026 planning period, 112 outage requests were included in the annual FTR market outage list and 11,806 outage requests were not included.[203] In the 2024/2025 planning period, 436 outage requests were included in the annual FTR market outage list and 19,642 outage requests were not included. Table 12-94, Table 12-95, Table 12-96 and Table 12-97 show the summary information on the modeled outage requests and Table 12-98 and Table 12-99 show the summary information on outages that were not included in the Annual FTR Market.

Table 12-94 shows that 23.2 percent of the outage requests modeled in the Annual FTR Market for the first four months of the 2025/2026 planning

200 A transmission facility is modeled as equipment in the EMS model. Equipment has three identifiers: location (B1), voltage level (B2) and equipment name (B3). The types of equipment include, for example, lines, transformers, and capacitors. There can be multiple outage requests associated with the same equipment.

201 The length of a planned equipment outage can be modified by editing an existing ticket for the equipment outage or by adding new equipment outage tickets for the same equipment.

202 PJM Financial Transmission Rights, "Annual ARR Allocation and FTR Auction Transmission Outage Modeling," <https://www.pjm.com/-/media/markets-ops/ftr/annual-ftr-auction/2018-2019/2018-2019-annual-outage-modeling.ashx?la=en> (April 5, 2018). There is no documentation on the deadline for when modeling outages should be posted on the PJM website.

203 PJM's treatment of transmission outages in the FTR models is discussed in the *2024 Quarterly State of the Market Report for PJM: January through June*, Section 13: FTRs and ARRs, Supply and Demand.

period had a planned duration of less than two weeks and that 25.9 percent of the outage requests (29 out of 112) modeled in the Annual FTR Market for the planning period were submitted late according to outage submission rules. It also shows that 23.2 percent of the outage requests modeled in the Annual FTR Market for the 2024/2025 planning period had a planned duration of less than two weeks and that 17.9 percent of the outage requests (78 out of 436) modeled in the Annual FTR Market for the planning period were submitted late according to outage submission rules.

Table 12-94 Annual FTR market modeled transmission facility outage requests by received status: June 2024 through September 2025

	2024/2025 (12 months)				2025/2026 (4 months)

	>=2 weeks & <2 months	0	20	20	100.0%	0	2	2	100.0%
	>=2 months	3	47	50	94.0%	2	24	26	92.3%
	Total	3	75	78	96.2%	2	31	33	93.9%

PJM determines expected congestion for both On Time and Late outage requests. A Late outage request may be denied or cancelled if it is expected to cause congestion. Table 12-96 shows a summary of requests by expected congestion and received status. Of all the annual FTR market modeled outages expected to occur in the first four months of the 2025/2026 planning period and submitted late, 20.7 percent (6 out of 29) were expected to cause congestion. Of all the annual FTR market modeled outages expected to occur in the 2024/2025 planning period and submitted late, 19.2 percent (15 out of 78) were expected to cause congestion.

Table 12-96 Annual FTR market modeled transmission facility outage requests by congestion: June 2024 through September 2025

		2024/2025 (12 months)				2025/2026 (4 months)			
Received Status	Planned Duration	Congestion Expected	No Congestion Expected	Total	Percent Congestion Expected	Congestion Expected	No Congestion Expected	Total	Percent Congestion Expected
On Time	<2 weeks	23	70	93	24.7%	7	15	22	31.8%
	>=2 weeks & <2 months	33	109	142	23.2%	22	30	52	42.3%
	>=2 months	32	91	123	26.0%	21	76	97	21.6%
	Total	88	270	358	24.6%	50	121	171	29.2%
Late	<2 weeks	2	6	8	25.0%	1	4	5	20.0%
	>=2 weeks & <2 months	4	16	20	20.0%	2	0	2	100.0%
	>=2 months	9	41	50	18.0%	2	24	26	7.7%
	Total	15	63	78	19.2%	5	28	33	15.2%

Table 12-97 shows that 27.3 percent of outage requests modeled in the annual FTR market for the first four months of the 2025/2026 planning period and with a duration of two weeks or longer but shorter than two months were cancelled after the FTR auction was open, compared to 24.1 percent for the 2024/2025 planning period. Table 12-97 also shows that 16.7 percent of outages requests modeled in the Annual FTR Market for the first four months of the 2025/2026 planning period and with a duration of two months or longer were cancelled, compared to 19.1 percent for the 2024/2025 planning period.

More outage requests were not modeled in the Annual FTR Market than were modeled in the Annual FTR Market. In the first four months of the 2025/2026 planning period, 112 outage requests were modeled and 11,806 outage requests were not modeled in the Annual FTR Market. In the 2024/2025 planning period, 436 outage requests were modeled and 19,640 outage requests were not modeled in the Annual FTR Market.

Table 12-98 shows that 10.0 percent of outage requests not modeled in the Annual FTR Auction with duration longer than or equal to two months, labeled On Time according to the rules, were submitted or rescheduled after the Annual FTR Auction bidding opening date in the 2024/2025 planning period, compared to 20.3 percent in the 2024/2025 planning period.

Table 12-98 Transmission facility outage requests not modeled in Annual FTR Auction: June 2024 through September 2025

Table 12-99 shows that 77.3 percent of late outage requests that were submitted after the Annual FTR Auction bidding opening date, were not modeled in the Annual FTR Auction, and had a duration longer than or equal to two months, were completed in the first four months of the 2025/2026 planning period. It also shows that 90.8 percent of late outage requests which were not modeled in the Annual FTR Auction with duration longer than or equal to two months and submitted after the Annual FTR Auction bidding opening date were active or completed in the 2024/2025 planning period.

Although the definition of late outages was developed in order to prevent outages for the planning period being submitted after the opening of bidding in the Annual FTR Auction, the rules have not functioned effectively because the rule has no direct connection to the date on which bidding opens for the Annual FTR Auction. By requiring all long-duration transmission outages to be submitted before February 1, PJM outage submission rules only prevent long-duration transmission outages from being submitted late. The rule does not address the situation in which long-duration transmission outages are submitted on time, but are rescheduled so that they are late. There is no rule to address the situation in which short-duration outages (duration <= 5 days) are submitted on time, but are changed to long-duration transmission outages after the outages are approved and active. The Annual FTR Auction model may consider transmission outages planned for longer than two weeks but less than two months. Those outages not only include long duration outages but also include outages shorter than 30 days. In those cases, PJM outage submission rules failed to prevent those transmission outages from being submitted late. The MMU recommends that PJM create options for late requests based on the reasons, and modify the rules to reduce or eliminate the approval of late outage requests submitted or rescheduled after the FTR auction opening date, based on those options.

Monthly FTR Market

When determining transmission outages to be modeled in the Monthly Balance of Planning Period FTR Auction, PJM considers all outages with planned duration longer than five days and may consider outages with planned durations less than or equal to five days. PJM exercises significant discretion in selecting outages to be modeled. PJM posts an FTR outage list to the FTR webpage usually at least one week before the auction bidding opening day.[204] Table 12-100 and Table 12-101 show the summary information on outage requests modeled in the Monthly Balance of Planning Period FTR Auction and Table 12-102 and Table 12-103 show the summary information on outage requests not modeled in the Monthly Balance of Planning Period FTR Auction.

Table 12-100 shows that on average, 31.4 percent of the outage requests modeled in the Monthly Balance of Planning Period FTR Auction were submitted late according to outage submission rules in the first four months of the 2025/2026 planning period. On average, 28.8 percent of the outage requests modeled in the Monthly Balance of Planning Period FTR Auction were submitted late according to outage submission rules in the 2024/2025 planning period.

Transmission Facility Outage Analysis in the Day-Ahead Energy Market

Transmission facility outages also affect the energy market. Just as with the FTR market, it is critical that outages that affect the operating day are known prior to the submission of offers in the day-ahead energy market so that market participants can understand market conditions and PJM can accurately model market conditions in the day-ahead market. PJM requires transmission owners to submit changes to outages scheduled for the next two days no later than 09:30 am.[205]

There are three relevant time periods for the analysis of the impact of transmission outages on the energy market: before the day-ahead market is closed; when the day-ahead market save cases are created; and during the operating day. The list of approved or active outage requests before the day-ahead market is closed is available to market participants in eDART. The day-ahead market model uses outages included in the day-ahead market save cases as an input. The outages that actually occurred during the operating day are the outages that affect the real-time market. If the three sets of outages are the same, there is no potential impact on markets. If the three sets of outages differ, there is a potential negative impact on markets. For example, if the list of outages before the day-ahead market was closed was different from the list of outages that included in the day-ahead market save cases, the day-ahead market participant would have inconsistent outage information as what day-ahead market model used.

205 PJM, "Manual 3: Transmission Operations," Rev. 68 (May 21, 2025).

For example for the operating day of June 30, 2025, Figure 12-7 shows that: there were 278 approved or active outages seen by market participants before the day-ahead market was closed; there were 363 outage requests included in the day-ahead market model; there were 344 outage requests included in both sets of outages; there were 85 outage requests approved or active before the day-ahead market was closed but not included as inputs in day-ahead market model; and there were 65 outage requests included in day-ahead market model but not available to market participants prior to the day-ahead market.

Figure 12-7 Illustration of day-ahead market analysis: June 30, 2025

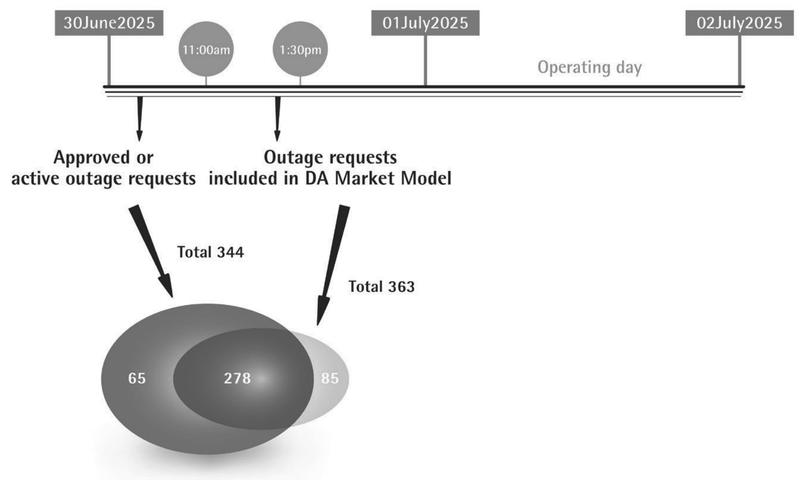

Figure 12-8 compares the weekly average number of active or approved outages available to market participants prior to the close of the day-ahead market with the outages included as inputs to the day-ahead market by PJM.[206] Figure 12-8 shows that the number of outages modeled in the day-ahead market during the spring and fall has increased since 2021 (blue line), but many of these outages were not visible to market participants (gray line).

206 The analysis and figures in this report (Figure 12-8, Figure 12-9, and Figure 12-10) are based on a revised method (relative to the method used in prior State of the Market Reports) that correctly accounts for outages that did not, at the time the outage was active, have an end date specified on the outage ticket.

Figure 12-8 Approved or active outage requests: January 2015 through September 2025

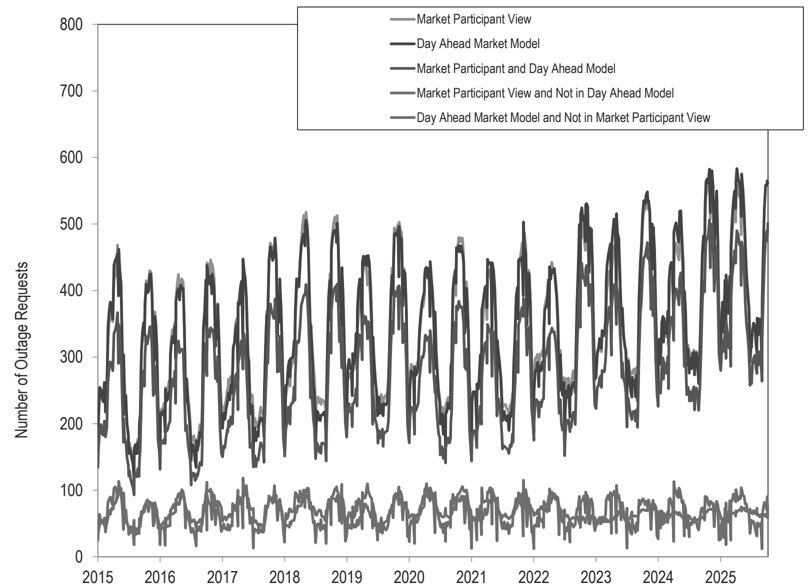

Figure 12-9 compares the weekly average number of outages included in the day-ahead market with the outages that actually occurred during the operating day. Figure 12-9 shows that beginning in 2021, the weekly average number of outages included in the day-ahead market (dark blue line) was higher in the spring and fall than previous years, but many of these outages did not actually occur in the real-time market (gray line). For example, some outages were scheduled to occur in day-ahead based on the information provided in eDART, but were cancelled or rescheduled in real time due to weather, equipment availability, reliability concerns, or the discretion of the transmission owner.

Figure 12-9 Day-ahead market model outages: January 2015 through September 2025

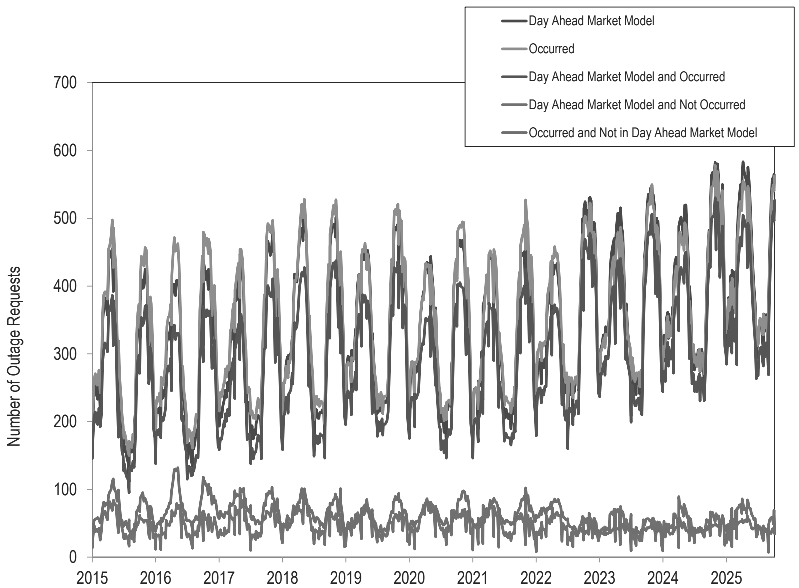

Figure 12-10 Approved or active outage requests: January 2015 through September 2025

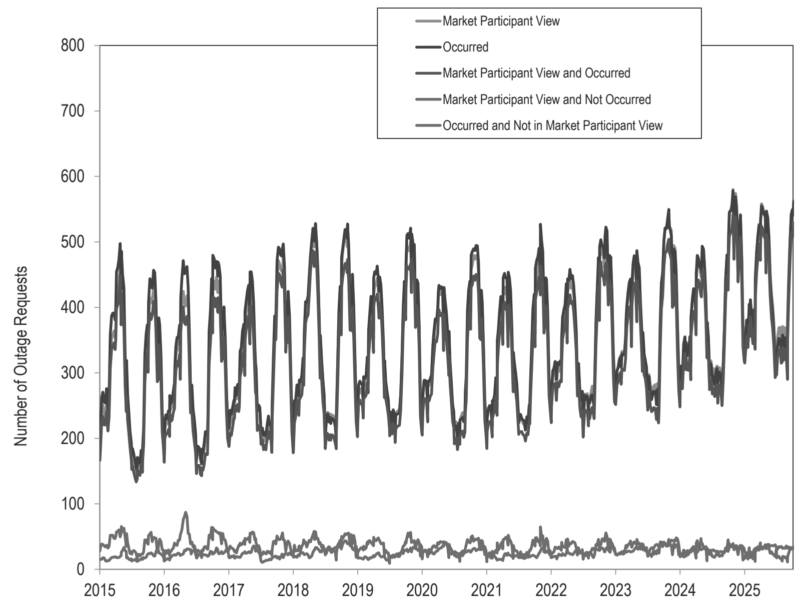

Figure 12-10 compares the weekly average number of active or approved outages for which information was visible to market participants through eDART prior to the close of the day-ahead market with the outages that actually occurred in the real time market during the operating day. Figure 12-10 shows the number of outages visible to market participants in eDART, but not actually occurring in the real time market, varies from less than 10 to over 100 in any given week.

Figure 12-8, Figure 12-9, and Figure 12-10 show that on a weekly average basis, for the full years 2023, 2024, and the first nine months of 2025, the active or approved outages for which information was visible to day-ahead market participants, the outages included as inputs in the day-ahead market model and the outages that actually occurred in real time are not consistent.

Financial Transmission and Auction Revenue Rights

In an LMP market, the lowest cost generation is dispatched to meet the load, but when there are transmission constraints, load pays the high local price for all generation, including the low cost generation serving part of that load. The low cost generation receives payment only for its low local price and does not receive the payment made by load for the output of the low cost generation at the high local price. The result is that load pays the correct local price but pays too much in total for energy because it is paying more for the low cost generation than the low cost generation receives. Load pays the difference between the high local price and the low local price of the low cost generation. That payment is appropriately not made to the low cost generation which is paid its LMP. In an LMP market, load pays more than generation receives. FTRs are the mechanism for returning those excess payments to load. But the current FTR mechanism in PJM does not and cannot return all the excess payments to load. The FTR mechanism in PJM needs a significant redesign in order to achieve that objective. The FTR mechanism has become unduly complicated and has deviated significantly from its original purpose. Return of all the excess payments to load would result in a perfect hedge against congestion. The current FTR mechanism has significantly attenuated the value of the FTR/ARR design as a hedge against congestion for load.

The FTR mechanism should be a simple accounting method for assigning congestion rights to load. But PJM has added increasingly complex rules and regularly intervenes in the FTR mechanism as the PJM FTR design has moved further and further from these economic fundamentals. Some market participants have profited in various ways from these design flaws and those market participants now strongly defend the current design in the PJM stakeholder process and at FERC. The customers who ultimately pay congestion are generally not aware of the current, flawed FTR design and do not understand the extent to which the current design fails to offset their congestion payments compared to a fundamentally correct FTR design that would return congestion to load.

When the lowest cost generation is remote from load centers, the physical transmission system permits that lowest cost generation to be delivered to load, subject to transmission limits. This was true prior to the introduction of LMP markets and continues to be true in LMP markets.

After the introduction of LMP markets in PJM, financial transmission rights (FTRs) were introduced, effective April 1, 1999, for the real-time market and June 1, 2000, for the combined day-ahead and real-time (balancing) markets. FTRs permitted the loads, which pay for the transmission system, to continue to receive the economic benefits of access to either local or remote low cost generation by returning congestion to the load.[1] FTRs and the associated congestion revenues were directly provided to load in recognition of the fact that, as a result of LMP, load was required to pay more for low cost generation than is paid to low cost generation. But there was a flaw built in from the very beginning of the PJM FTR design that had no significant impact initially but which was ultimately the source of all the issues with the FTR mechanism. That flaw was the idea that congestion was based on contract paths in a network system rather than a result of the actual operation of the complex network. Prior to the introduction of LMP markets, payment for the delivery of low cost generation to load was based both on intrazonal generation and intrazonal transmission, both under cost of service rates, and on contracts with specific remote generation outside the local zone and the associated point to point transmission contracts. Most load was served by intrazonal generation. In both cases, customers paid for the physical rights associated with the transmission system used to provide for the delivery of low cost generation to load. There was no congestion revenue because customers paid only the actual cost of the low cost generation. The flawed idea that congestion is based on contract paths was inconsistent with the most basic logic of LMP and the resultant fissure has continued to widen. FTRs were a core part of the LMP design. FTRs ensured that the introduction of locational marginal pricing would not result in overpayments by load. The origin of FTRs was the recognition that the way to hold load harmless from making the excess payments created by the LMP system was to return the excess payments to load. The rights to congestion belong to load. If implemented

1 See 81 FERC ¶ 61,257 at 62,241 (1997).

correctly, FTRs would be the financial equivalent of firm transmission service for load. If implemented correctly, FTRs would be a perfect hedge against congestion for load. The result of the current FTR mechanism is a significant reduction in the value of FTRs as a hedge for load. The current FTR mechanism results in significant wealth transfers from the load that pays congestion to traders of FTRs and traders of virtuals. The current FTR mechanism results in uneven and arbitrary differences in the share of congestion returned to load, depending on location and PJM's assignment of ARRs.

The notion that FTRs exist in order to provide a hedge for generation is a fallacy. In an LMP system, the basic incentive structure for generation derives from the fact that generation is paid the LMP at the generator bus. If generation were to be guaranteed a price at a distant constrained load bus rather than at the generation bus, there would be no incentive for generation to locate where it is needed on the system. In addition, the payment of the price at the generator bus is fundamental to the logic of locational marginal pricing which produces local prices equal to the marginal value of generation at every point. There is no logical or theoretical basis in locational marginal pricing for the assertion that generation at low price nodes is underpaid and should be paid more from congestion dollars. Generation does not pay congestion. Some generation receives a price lower than the system marginal price (SMP) and some generation receives a price greater than SMP, but that does not mean that generation is paying congestion. It means that generation is being paid an LMP that is higher or lower than the system load-weighted average LMP. If a generating unit wants a hedge, it may enter into an arm's length transaction with a willing counter party as a hedge. That is the way hedges work in markets. That is not the purpose of FTRs.

In an LMP system, the only way to ensure that load receives the benefits associated with the use of the transmission system to deliver low cost energy is to use FTRs, or an equivalent mechanism, to pay back to load the difference between the total load payments and the total generation revenues. FTRs are a core theoretical part of the LMP design and were included in the PJM market design to offset the congestion costs that load pays in an LMP market. Congestion revenues are the source of the funds to pay FTRs. Congestion revenues should be assigned to the load that paid them through FTRs.[2] The only way to ensure that load receives the benefits associated with the use of the transmission system to deliver low cost energy is to ensure that all congestion revenues are returned to load or, more precisely, that the rights to all congestion revenues are assigned to load. In order to do that, congestion payments must be defined correctly based on the way that power actually flows in the PJM network and not based on arbitrary contract paths.

Effective April 1, 1999, when FTRs were introduced with the LMP market, there was a real-time market but no day-ahead market, and FTRs returned real-time congestion revenue to load. Effective June 1, 2000, the day-ahead market was introduced and FTRs returned total congestion including day-ahead and real-time (balancing) congestion to load.[3] Congestion is the sum of day-ahead and balancing congestion. Effective June 1, 2003, PJM replaced the direct allocation of FTRs to load with an allocation of Auction Revenue Rights (ARRs). Under the ARR design, the load still owns the rights to congestion revenue, but the ARR design allows load to either claim the FTRs directly (through a process called self scheduling), or to sell the rights to congestion revenue in the FTR auction in exchange for a revenue stream based on the auction clearing prices of the FTRs. Under the ARR design, the right to all congestion revenues should belong to load and load should have the ability to retain or sell the congestion revenue rights on terms that load defines and accepts. The actual ARR implementation produces a very different result and fails to assign all congestion revenue rights to load.

ARRs were an add on concept, defined based on a misunderstanding of FTRs, which had its roots in the assignment of congestion to load using contract paths (generation to load paths) rather than on the calculation of congestion actually paid. Contract paths are a fiction in a network. ARRs used assumed contract paths to assign congestion to load. The use of contract paths for ARRs was a more critical mistake than using contract paths for FTRs because contract paths did not, do not, and cannot account for all congestion. The use of contract paths led to the mistaken conclusion that there was some excess congestion that did not belong to load and could be sold to FTR buyers. The

2 See *id.* at 62, 259–62,260 & n. 123.
3 PJM refers to the combination of the day-ahead and real-time (balancing) markets as a two settlement system.

ARR concept, as it is currently implemented, does not allow the FTR sellers, load, to establish a price at which they are willing to sell, but forces load to accept whatever prices buyers are willing to pay. The revenue from the sale of congestion rights is not even paid in full to ARR holders. Sellers are required to return some of the cleared auction revenue to FTR buyers when FTR payments are less than target allocations. So called surplus revenue is paid to FTR holders to ensure payment, despite the fact that willing FTR buyers paid the revenues in the auction for the rights to an uncertain level of congestion.

The use of generation to load contract paths, rather than the direct calculation of congestion, led to an increased divergence between FTR target allocations on the generation to load contract paths and actual total congestion. This divergence between actual network use and historic contract paths was exacerbated as new zones were added with their own historic generation to load contract paths and as significant numbers of generating units retired and new units were added.[4] Rather than understanding that the divergence resulted from the fact that a contract path based approach did not correctly calculate congestion in a network system, especially as the system grew significantly, the issue was characterized as the existence of excess capacity on the transmission system. But congestion was never about capacity on the transmission system. Prior to the introduction of ARRs, the so called excess congestion that exceeded the congestion on the defined contract paths was returned to load, regardless of its source. There is no such thing as excess congestion. Congestion is congestion. In a well designed LMP/FTR system, all congestion is returned to load, neither more nor less. The overlay of ARRs on the FTR concept did not change the fundamental logic of congestion, but permitted the introduction of a system in which the divergence was formally created between the amount of congestion paid by load and the amount of congestion returned to load. Congestion belongs to the load, by definition. The introduction of ARRs based on the contract path fiction undermined the assignment of all congestion rights to load.

4 For a comprehensive report on capacity retirements and capacity additions in PJM, see: "2020 PJM Generation Capacity and Funding Sources: 2007/2008 through 2021/2022," (September 15, 2020) available at <http://www.monitoringanalytics.com/reports/Reports/2020/Constraint_Based_Congestion_Calculations_20200722.pdf>.

FTR revenue adequacy, like surplus congestion revenue, is a misnomer. FTR revenue adequacy, as defined in PJM rules, is an artifact of the flawed design of the current approach to FTR/ARRs. If FTRs only returned congestion to FTR holders, there could be no such thing as revenue inadequacy. As currently defined in PJM, FTR revenue adequacy simply compares day-ahead congestion revenues to FTR target allocations. (Target allocations are the day-ahead CLMP differences, shadow prices, between the source and sink of the FTR times the MW of the FTR.) There is no reason to expect congestion revenues to equal FTR target allocations under the path based approach. There are systematic differences between FTR target allocations and actual congestion in aggregate and on a path by path basis. Revenue adequacy is not a benchmark for how well the FTR process is working. Target allocations are not congestion. FTR revenue adequacy is not equivalent to the adequacy of ARRs as an offset for load against total congestion. A path specific target allocation is not a guarantee of payment. Yet PJM treats target allocations as a guarantee of payment and takes what is termed surplus auction revenue from ARR holders (load) and gives it to FTR holders when day-ahead congestion revenues are not enough to cover all FTR target allocations.

The contract path fiction is also the source of the incorrect definition of the product that is bought and sold as FTRs, the available supply of the product and the price paid to the buyers of the product. The FTR product is defined as the difference in congestion prices in the day-ahead market only, across specific transmission contract paths (the shadow price), multiplied by the FTR MW position on those paths. That is the definition of FTR target allocation. The difference in congestion prices across contract paths is not congestion and is not equal to congestion revenues when multiplied by the FTR MW position. The MW quantity of the product made available for sale in the FTR auctions is defined as system capability, meaning the capacity of the transmission system to deliver power. But system capability is not actual market flows and system capability is not congestion and system capability is not the difference in congestion prices across transmission contract paths nor the potential for such difference. Congestion is defined as the difference in congestion prices across a path multiplied by the market flow on that path, recognizing both day-ahead and balancing market results. That is the measure of the amount load pays in excess of what generation receives. The definition of ARRs based on contract paths led to the mistaken idea that some transmission system capacity was used by ARRs but some was not and that both the ARR capability and the excess capability was available for sale as FTRs. This fundamental confusion in the design of the market is the source of so called revenue shortfalls, of the redesign of the market to exclude balancing congestion, and of the need for PJM to intervene in the market. PJM has had to regularly intervene in the market because the market as designed cannot reach equilibrium based on the economic fundamentals. The product, the quantity of the product, and the price of the product are all incorrectly defined.

The ARR/FTR design does not serve as an efficient mechanism for returning congestion to load as a result of an FTR design that was flawed from its introduction and as a result of various distortions added to the design since its introduction. The distortions include the definition of target allocations based on day-ahead price differences only, the fact that ARR holders cannot set the sale price for the congestion revenue rights they own, the return of market revenues to FTR buyers when profit targets are not met, the failure to assign all FTR auction revenues to ARR holders, the differences between modeled and actual system capability, the definition and allocation of surplus, and the numerous cross subsidies among participants. The fundamental distortion was the assignment of the rights to congestion revenue based on specific generation to load transmission contract paths. This approach retained the contract path based view of how load is served that is fundamentally inconsistent with the way load is actually served in a network system and therefore inconsistent with the role of FTRs in a nodal, network system with locational marginal pricing.

The cumulative offset of congestion by ARRs for the 2011/2012 planning period through the first four months of the 2025/2026 planning period, using the rules effective for each planning period, was only 68.7 percent. Only 68.7 percent of congestion revenue was returned to load over this period. Load was underpaid by $5.4 billion from the 2011/2012 planning period through the first four months of the 2025/2026 planning period. This is an increase of $0.5 billion in underpayment to load from the end of the 2024/2025 planning period through the first four months of the 2025/2026 planning period.

The overall underassignment of congestion to load includes dramatically different results by zone. Load in some zones receives congestion revenues well in excess of the congestion they pay while the reverse is true for other zones.

If the original PJM FTR approach had been designed to return congestion revenues to load without use of the generation to load contract paths, and if the distortions subsequently introduced into the FTR design had not been added, many of the subsequent issues with the FTR design and complex redesigns would have been avoided. PJM would not have had to repeatedly intervene in the functioning of the FTR system in an effort to meet the artificial and incorrectly defined goal of revenue adequacy. The design should simply have provided for the return of all congestion revenues to load. The design should have also provided for the ability of load to sell the rights to congestion revenue. That sale could be organized as an FTR auction with the product and the price clearly defined. Now is a good time to address the issues of the FTR design and to return the design to its original purpose. This would eliminate much of the complexity associated with ARRs and FTRs and eliminate unnecessary controversy about the appropriate recipients of congestion revenues.

The *2025 Quarterly State of the Market Report for PJM: January through September* focuses on the 2024/2025 planning period as well as the 2025/2026 Long Term and Annual FTR auctions and ARR allocation, specifically covering June 1, 2024, through September 30, 2025. The Market Monitoring Unit (MMU) analyzed measures of market structure, participant conduct and market performance, including market size, concentration, offer behavior, and price. The MMU concludes that the PJM FTR auction market results were partially competitive in the first nine months of 2025.

Table 13-1 The FTR/ARR markets results were partially competitive

Market Element	Evaluation	Market Design
Market Structure	Competitive	
Participant Behavior	Partially Competitive	
Market Performance	**Partially Competitive**	**Flawed**

- Market structure was evaluated as competitive. The ownership of FTR obligations is unconcentrated for the individual years of the 2025/2028 Long Term FTR Auction, the 2025/2026 Annual FTR Auction and each period of the Monthly Balance of Planning Period Auctions for prevailing flow FTRs. The ownership of FTR obligations is unconcentrated or moderately concentrated for each period of the Monthly Balance of Planning Period Auctions for counter flow FTRs. The ownership of FTR options is moderately or highly concentrated for every Monthly FTR Auction period and unconcentrated for the 2025/2026 Annual FTR Auction. Ownership of current FTRs is disproportionately (88.7 percent) by financial participants. The ownership of ARRs is unconcentrated.
- Participant behavior was evaluated as partially competitive because ARR holders who are the sellers of FTRs have no option to set an acceptable sale price and are not permitted to participate in the market clearing in any way and are not assured they will receive 100 percent of auction revenues.
- Market performance was evaluated as partially competitive because of the significant and persistent flaws in the market design. Sellers, the ARR holders, cannot set a sale price. Buyers can reclaim some of their purchase price after the market clears if the product does not meet a profitability target. The market resulted in a substantial shortfall in congestion payments to load and significant and unsupportable disparities among zones in the share of congestion returned to load. FTR purchases by financial entities remain persistently profitable in part as a result of the flaws in the market design.
- Market design was evaluated as flawed because there are significant, fundamental and persistent flaws in the basic ARR/FTR design. The FTR auction market is not actually a market because the sellers have no independent role in the process. ARR holders cannot determine the price at which they are willing to sell rights to congestion revenue. Buyers have the ability to reclaim some of the price paid for FTRs after the market clears and, as a result, sellers are not assured they will receive 100 percent of auction revenues. The market design is not an efficient or effective way to ensure that the rights to all congestion revenues are assigned to load. The product sold to FTR buyers is incorrectly defined as target allocations rather than a share of congestion revenue. ARR holders' rights to congestion revenues are not correctly defined because the contract path based assignment of congestion rights is inadequate and incorrect. The ongoing PJM subjective intervention in the FTR market that affects market fundamentals is also an issue and a symptom of the fundamental flaws in the design. The product, the quantity of the product and the price of the product are all incorrectly defined.
- The fact that load is not able to define its willingness to sell FTRs or to set the prices at which it is willing to sell FTRs and the fact that load is required to return some of the cleared auction revenue to FTR buyers when FTR profits are deemed to be not adequate, means that the FTR design does not actually function as a market and is evidence of basic flaws in the market design.

Overview

Auction Revenue Rights

Market Structure

- **ARR Ownership.** In the 2025/2026 planning period ARRs were allocated to 1,560 individual participants, held by 130 parent companies, up from 1,523 individual parents, held by 126 parent companies in the 2024/2025 planning period. ARR ownership for the 2025/2026 planning period was unconcentrated with an HHI of 600, down from 610 for the 2024/2025 planning period.

Market Behavior

- **Self Scheduled FTRs.** For the 2025/2026 planning period, 25.9 percent of eligible ARRs were self scheduled as FTRs, up from 25.3 percent for the 2024/2025 planning period.

Market Performance

- **ARRs as an Offset to Congestion.** ARRs have not served as an effective mechanism to return all congestion revenues to load. For the first four months of the 2025/2026 planning period, ARRs and self scheduled FTRs offset only 66.6 percent of total congestion. Congestion payments by load in some zones were more than offset and congestion payments in some zones were less than offset. Load has been underpaid congestion revenues by $5.4 billion from the 2011/2012 planning period through the first four months of the 2025/2026 planning period. The cumulative offset for that period was only 68.7 percent of total congestion. If ARR holders had self scheduled all of their allocated FTRs as ARRs for the first four months of the 2025/2026 planning period, the ARR target allocations would have increased the offset from 66.6 percent to 98.7 percent of total congestion.
- **ARR Payments.** For the first four months of the 2025/2026 planning period, the ARR target allocations, which are based on the nodal price differences from the Annual FTR Auction, were $1,859.0 million, while PJM collected $2,088.2 million from the combined Long Term, Annual and Monthly Balance of Planning Period FTR Auctions. For the 2024/2025 planning period, the ARR target allocations were $1,448.1 million while PJM collected $1,664.9 million from the combined Annual and the first four Monthly Balance of Planning Period FTR Auctions.
- **ARR.** For the first four months of the 2025/2026 planning period there was enough total day-ahead congestion to pay FTR target allocations. However, as a result of the monthly settlement logic for FTRs and ARRs, $22.6 million of FTR auction revenue over ARR target allocations was transferred from ARR holders (load) to FTR holders. In the 2024/2025 all $196.2 million of FTR auction revenue over ARR target allocations was transferred from ARR holders to FTR holders. Although PJM refers to this as a surplus, there is no such thing as surplus FTR auction revenue based on market logic. FTR Auction revenue results from the market prices paid by willing FTR buyers, should be paid to ARR holders, and should not be returned to FTR buyers for any reason.
- **Residual ARRs.** Residual ARRs are only available on contract paths prorated in Stage 1 of the annual ARR allocation, are only effective for single, whole months and cannot be self scheduled. Residual ARR clearing prices are based on monthly FTR auction clearing prices. Residual ARRs with negative target allocations are not allocated to participants. Instead they are removed and the model is rerun.

  In the first four months of the 2025/2026 planning period, as a result of transmission capability being returned to service from outages included in the annual model, PJM allocated a total of 16,614.7 MW of residual ARRs, up 8,616.5 MW (a 107.7 percent increase) from 7,998.2 MW, with a total target allocation of $50.5 million, up $45.0 million (an 819.9 percent increase) from $5.5 million in the same period of the 2024/2025 planning period.
- **ARR Deficiency.** In July 2025 there was not enough FTR auction revenue collected from the monthly FTR auction to pay the high target allocations from Residual ARRs. As a result, July ARR funding was deficient for the first time since ARRs were introduced. Deficient ARRs will be funded at the end of the planning period from surplus FTR revenues, if there is an

FTR surplus, or through an uplift charge to FTR holders if there is not an FTR surplus.

- **ARR Reassignment for Retail Load Switching.** There were 16,509 MW of ARRs associated with $385.7 thousand of revenue that were reassigned for the first four months of the 2025/2026 planning period. There were 11,996 MW of ARRs associated with $184.3 thousand of revenue that were reassigned in the same period of the 2024/2025 planning period.

Financial Transmission Rights

Market Design

- **Monthly Balance of Planning Period FTR Auctions.** The design of the Monthly Balance of Planning Period FTR Auctions includes auctions for each remaining month in the planning period.

Market Structure

- **Patterns of Ownership.**[5] For the Monthly Balance of Planning Period Auctions, financial entities purchased 96.4 of all prevailing and counter flow FTRs, including 95.3 percent of prevailing flow and 97.7 percent of counter flow FTRs for the first four months of the 2025/2026 planning period. Financial entities owned 88.7 percent of all prevailing and counter flow FTRs, including 82.5 percent of all prevailing flow FTRs and 95.7 percent of all counter flow FTRs during the first four months of the 2025/2026 planning period. Self scheduled FTRs account for 4.3 percent of all FTR held.
- **Market Concentration.** In the Monthly Balance of Planning Period Auctions for the first four months of the 2025/2026 planning period, ownership of cleared prevailing flow bids was unconcentrated in all periods. Ownership of cleared counter flow bids was unconcentrated in 47.6 percent of periods and moderately concentrated in 52.4 percent of periods.

5 Beginning in the *2025 Quarterly State of the Market Report for PJM: January through March*, the MMU categorizes all participants owning FTRs in PJM as either physical or financial at an account level. In prior reports, participants were categorized as either physical or financial at an organization level.

Market Behavior

- **Sell Offers.** In a given auction, market participants can sell FTRs acquired in preceding auctions or preceding rounds of auctions. In the 2025/2028 Long Term FTR Auction, total participant FTR sell offers were 1,557,455 MW. In the 2025/2026 Annual FTR Auction, total participant FTR sell offers were 1,695,004 MW. In the Monthly Balance of Planning Period FTR Auctions for the first four months of the 2025/2026 planning period, total participant FTR sell offers were 31,730,557 MW.
- **Buy Bids.** In the 2025/2028 Long Term FTR auction, total FTR buy bids were 6,729,000 MW, up 72.0 percent from 5,729,618 MW the previous long term auction. There were 6,658,483 MW of buy and self scheduled bids in the 2025/2026 Annual FTR Auction, up 39.6 percent from 4,770.381 MW the previous planning period. The total FTR buy bids from the Monthly Balance of Planning Period FTR Auctions for the first four months of the 2025/2026 planning period were 48,912,396 MW.
- **FTR Forfeitures.** Total FTR forfeitures were $1,312.2 thousand for the first four months of the 2025/2026 planning period, up 38.0 percent from $951.0 thousand from the same period of the2024/2025 planning period.
- **Credit.** There were no collateral defaults and two payment defaults in the first nine months of 2025.

Market Performance

- **Quantity.** In the 2025/2028 Long Term FTR Auction 923,869 MW (13.7 percent) of buy bids cleared and 168,852 MW (10.8 percent) of sell offers cleared. In the 2025/2026 Annual FTR Auction 1,324,299 MW (19.9 percent) of buy and self scheduled bids cleared, up 28.8 percent from the 2024/2025 Annual FTR Auction, and 183,410 MW (10.8 percent) of sell offers cleared, up 47.6 percent from the 2024/2025 Annual Auction. In the first four months of the 2025/2026 planning period, Monthly Balance of Planning Period FTR Auctions 8,010,114 MW (16.4 percent) of FTR buy bids cleared, up 54.9 percent from the the same period of the 2024/2025 planning period and 5,089,192 MW (16.0 percent) of FTR sell offers cleared, up 36.5 percent from the same period of the 2024/2025 planning period.

- **Price.** The weighted average buy bid FTR price in the 2025/2028 Long Term FTR Auction was $0.09 per MW, up from $0.07 from the 2024/2027 Long Term FTR Auction. The weighted average buy bid FTR price in the Annual FTR Auction for the 2025/2026 planning period was $0.50 per MW, up from $0.30 per MW in the 2024/2025 planning period. The weighted average buy bid cleared FTR price in the Monthly Balance of Planning Period FTR Auctions for all periods in the first four months of the 2025/2026 planning period was $0.36 per MWh, down from $0.42 in the 2024/2025 planning period.
- **Revenue.** The 2025/2028 Long Term FTR Auction generated $162.3 million of net revenue for all FTRs, up 58.2 percent from $102.6 million from the 2024/2027 Long Term FTR Auction. The 2025/2026 Annual FTR Auction generated $1,895.3 million in net revenue, up 28.5 percent from $1,475.3 million for the 2024/2025 Annual FTR Auction. The Monthly Balance of Planning Period FTR Auctions resulted in net revenue of $39.9 million in the first four months of the 2025/2026 planning period, down 20.4 percent from $50.1 million in the same period of the 2024/2025 planning period.
- **"Revenue Adequacy."** For the first four months of the 2025/2026 planning period there was enough total day-ahead congestion revenue to pay FTR target allocations. However, as a result of the monthly settlement logic for FTRs and ARRs, $22.6 million of FTR auction revenue was transferred from ARR holders (load) to FTR holders, and FTRs were paid 100.0 percent of the target allocations for the first four months of the 2025/2026 planning period. Based on market logic, there is no such thing as surplus FTR auction revenue and there is no such thing as revenue inadequacy. FTR Auction revenue results from the market prices paid by willing FTR buyers, should be paid to ARR holders, and should not be returned to FTR buyers for any reason.
- **Profitability.** FTR profitability is the difference between the revenue received directly from holding an FTR plus any revenue from the sale of an FTR, and the cost of buying the FTR. In the first four months of the 2025/2026 planning period, profits for all participants were $445.8 million, up from $351.8 million in profits in the same time period in the 2024/2025 planning period. In the first four months of the 2025/2026 planning period, physical entities received $93.0 million in profits on FTRs purchased directly (not self scheduled), up from $36.4 million profits in the same time period in the 2024/2025 planning period. Financial entities received $352.8 million in profits, up from $315.4 million profits in the same time period in the 2024/2025 planning period.

Markets Timeline

Any PJM member can participate in the Long Term FTR Auction, the Annual FTR Auction and the Monthly Balance of Planning Period FTR Auctions.

Table 13-2 shows the date of first availability and final closing date for all ARR and FTR auctions with bidding days that occur in 2025.

Table 13-2 Annual FTR auction dates

Auction	Initial Open Date	Final Close Date
2024/2025 Monthly	14-May-24	18-Apr-25
2025/2028 Long Term	3-Jun-24	3-Mar-25
2025/2026 ARR	5-Mar-25	22-Mar-24
2025/2026 Annual	9-Apr-25	2-May-25
2026/2029 Long Term	2-Jun-25	04-Mar-26
2025/2026 Monthly	15-May-25	17-Apr-26

Recommendations

Market Design

- The MMU recommends that the current ARR/FTR design be replaced with defined congestion revenue rights (CRRs). A CRR is the right to actual congestion revenue that is paid by physical load at a specific bus, zone or aggregate. (Priority: High. First reported 2015. Status: Not adopted.)

ARR

- The MMU recommends that the ARR/FTR design be modified to ensure that the rights to all congestion revenues are assigned to load. (Priority: High. First reported 2015. Status: Not adopted.)
- The MMU recommends that all historical generation to load paths be eliminated as a basis for assigning ARRs. The MMU recommends that the current design be replaced with a design in which the rights to actual congestion paid are assigned directly to the load that paid that congestion by node. (Priority: High. First reported 2015. Status: Partially adopted.)
- The MMU recommends that, under the current FTR design, the rights to all congestion revenue be allocated as ARRs prior to sale as FTRs. Reductions in allocated revenue as a contingency for outages and increased system capability should be reserved for ARRs rather than sold in the Long Term FTR Auction. (Priority: High. First reported 2017. Status: Not adopted.)
- The MMU recommends that IARRs be eliminated from PJM's tariff, but that if IARRs are not eliminated, IARRs should be subject to the same proration rules that apply to all other ARR rights. (Priority: Low. First reported 2018. Status: Not adopted.)

FTR

- The MMU recommends that FTR funding be based on total congestion, including both day-ahead and balancing congestion. (Priority: High. First reported 2017. Status: Not adopted.)
- The MMU recommends that bilateral transactions be eliminated and that all FTR transactions occur in the PJM market. (Priority: High. First reported 2022. Status: Not adopted.)[6]
- The MMU recommends a requirement that the details of all bilateral FTR transactions be reported to PJM. (Priority: High. First reported 2020. Status: Not adopted.)
- The MMU recommends that PJM continue to evaluate the bilateral indemnification rules and any asymmetries they may create. (Priority: Low. First reported 2018. Status: Not adopted.)
- The MMU recommends that PJM reduce FTR sales on paths with persistent overallocation of FTRs, including a clear definition of persistent overallocation and how the reduction will be applied. (Priority: High. First reported 2013. Status: Partially adopted, 2014/2015 planning period.)
- The MMU recommends that PJM eliminate generation to generation paths and all other paths that do not represent the delivery of power to load. (Priority: High. First reported 2018. Status: Not adopted.)
- The MMU recommends that the Long Term FTR product be eliminated. If the Long Term FTR product is not eliminated, the Long Term FTR Market should be modified so that the supply of prevailing flow FTRs in the Long Term FTR Market is based solely on counter flow offers in the Long Term FTR Market. (Priority: High. First reported 2017. Status: Not adopted.)
- The MMU recommends that PJM improve transmission outage modeling in the FTR auction models, including the use of probabilistic outage modeling. (Priority: Low. First reported 2013. Status: Not adopted.)

"Surplus"

- The MMU recommends that all FTR auction revenue be distributed to ARR holders monthly, regardless of FTR funding levels. (Priority: High. First reported 2015. Status: Not adopted.)
- The MMU recommends that, under the current FTR design, all congestion revenue in excess of FTR target allocations be distributed to ARR holders on a monthly basis. (Priority: High. First reported 2018. Status: Not adopted.)
- The MMU recommends that FTR auction revenues not be used by PJM to buy counter flow FTRs for the purpose of improving FTR payout ratios.[7] (Priority: High. First reported 2015. Status: Not adopted.)

FTR Subsidies

- The MMU recommends that PJM eliminate portfolio netting to eliminate cross subsidies among FTR market participants. (Priority: High. First reported 2012. Status: Not adopted. Rejected by FERC.)

6 If adopted, this recommendation would replace the next two recommendations.

7 See "PJM Manual 6: Financial Transmission Rights," Rev. 34 (May 21, 2025).

- The MMU recommends that PJM eliminate subsidies to counter flow FTRs by applying the payout ratio to counter flow FTRs in the same way the payout ratio is applied to prevailing flow FTRs. (Priority: High. First reported 2012. Status: Not adopted.)
- The MMU recommends that PJM eliminate geographic cross subsidies. (Priority: High. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM examine the mechanism by which self scheduled FTRs are allocated when load switching among LSEs occurs throughout the planning period. (Priority: Low. First reported 2011. Status: Not adopted.)

FTR Liquidation

- The MMU recommends that the FTR portfolio of a defaulted member be canceled rather than liquidated or allowed to settle as a default cost to the membership. (Priority: High. First reported 2018. Status: Not adopted.)

Credit

- The MMU recommends that PJM's minimum credit requirements be reviewed and updated to appropriately reflect the risk created for the markets and other market participants. The PJM minimum credit requirements (minimum tangible net worth and minimum tangible assets) were set as fixed dollars amounts in 2011 in FERC order 741 based on the specific market participation (FTRs or other). (Priority: Medium. New recommendation. Status: Not adopted.)

Conclusion

Solutions

The annual ARR allocation should be designed to ensure that the rights to all congestion revenues are assigned to load, without requiring contract path or point to point physical or financial transmission rights that are inconsistent with the network based delivery of power and the actual way congestion is generated in PJM's security constrained LMP market. When there are binding transmission constraints and locational price differences, load pays more for energy than generation is paid to produce that energy. The difference is congestion. As a result, congestion belongs to load and should be returned to load.

The current contract path based design should be replaced with a design in which the rights to actual congestion paid are assigned directly to the load that paid that congestion by node. The assigned right should be to the actual difference between load payments, both day-ahead and balancing, and revenues paid to the generation used to serve that load. The load can retain the right to the congestion revenues or sell the rights through auctions. The correct assignment of congestion revenues to load is fully consistent with retaining FTR auctions for the voluntary sale by load of their congestion revenue rights at terms defined by load, recognizing that load has property rights to congestion.

Issues

If the original PJM FTR approach had been designed to return congestion revenues to load without the use of generation to load contract paths, and if the distortions subsequently introduced into the FTR design had not been added, many of the subsequent issues with the FTR design and complex redesigns would have been avoided. PJM would not have had to repeatedly intervene in the functioning of the FTR system in an effort to meet the artificial and incorrectly defined goal of revenue adequacy.

PJM has persistently and subjectively intervened in the FTR market in order to affect the payments to FTR holders. These interventions are not appropriate. For example, in the 2014/2015, 2015/2016 and 2016/2017 planning periods, PJM significantly reduced the allocation of ARR capacity, and FTRs, in order to guarantee full FTR funding. PJM reduced system capability in the FTR auction model by including more outages, reducing line limits and including additional constraints. PJM's modeling changes resulted in significant reductions in Stage 1B and Stage 2 ARR allocations, a corresponding reduction in the available quantity of FTRs, a reduction in congestion revenues assigned to ARRs, and an associated surplus of congestion revenue relative to FTR target allocations. This also resulted in a significant redistribution of ARRs among ARR holders based on differences in allocations between Stage 1A and Stage 1B ARRs. Starting in the 2017/2018 planning period, with the allocation of balancing congestion and M2M payments to load rather than FTRs, PJM increased system capability allocated to Stage 1B and Stage 2 ARRs, but continued to conservatively select outages to manage FTR funding levels.

PJM has intervened aggressively in the FTR market since its inception in order to meet various subjective objectives including so called revenue adequacy. PJM should not intervene in the FTR market to subjectively manage FTR funding. PJM should fix the FTR/ARR design and then should let the market work to return congestion to load and to let FTR values reflect actual congestion.

Load should never be required to subsidize payments to FTR holders, regardless of the reason.[8] The FERC order of September 15, 2016, introduced a subsidy to FTR holders at the expense of ARR holders.[9] The order requires PJM to ignore balancing congestion when calculating total congestion dollars available to fund FTRs. As a result, balancing congestion and M2M payments are assigned to load, rather than to FTR holders, as of the 2017/2018 planning period. When combined with the direct assignment of both surplus day-ahead congestion and surplus FTR auction revenues to FTR holders, the Commission's order shifted substantial revenue from load to the holders of FTRs and further reduced the offset to congestion payments by load. This approach ignores the fact that load pays both day-ahead and balancing congestion, and that actual congestion is the sum of day-ahead and balancing congestion. Eliminating balancing congestion from the FTR revenue calculation requires load to pay twice for congestion. Load pays total congestion and pays negative balancing congestion again. The fundamental reasons that there has been a significant and persistent difference between day-ahead and balancing congestion include inadequate transmission modeling in the FTR auction and the role of UTCs in taking advantage of these modeling differences and creating negative balancing congestion. There is no reason to impose these costs on load.

These changes were made in order to increase the payout to holders of FTRs who are not loads. Increasing the payout to FTR holders at the expense of the load is not a supportable market objective. PJM should implement an FTR design that calculates and assigns congestion rights to load rather than continuing to modify the current, fundamentally flawed, design.

Load was made significantly worse off as a result of the changes made to the FTR/ARR process by PJM based on the FERC order of September 15, 2016. ARR revenues were significantly reduced for the 2017/2018 FTR Auction, the first auction under the new rules. ARRs and self scheduled FTRs offset only 49.5 percent of total congestion costs for the 2017/2018 planning period rather than the 58.0 percent offset that would have occurred under the prior rules, a difference of $101.4 million.

A subsequent rule change was implemented that modified the allocation of what is termed surplus auction revenue to load. Beginning with the 2018/2019 planning period, surplus day-ahead congestion and surplus FTR auction revenue are assigned to FTR holders only up total target allocations, and then distributed to ARR holders.[10] ARR holders will only be allocated this surplus after FTRs are paid 100 percent of their target allocations. While this rule change increased the level of congestion revenues returned to load under some conditions, the rules do not recognize ARR holders' rights to all congestion revenue, and only improves congestion payouts to load when there is a surplus. There was no surplus for the 2020/2021 or 2021/2022 planning years. With this rule in effect for the 2021/2022 planning period, ARRs and self scheduled FTRs offset 31.6 percent of total congestion. There was surplus for the 2022/2023 and the 2023/2024 planning periods. However, FTR auction surplus revenues were taken from load and given to FTR holders because day-ahead congestion revenues were less than target allocations in the 2023/2024 planning period. For the 2024/2025 planning period, there was not enough congestion revenue to fund FTR target allocations and all FTR auction surplus revenues were taken from load and given to FTR holders. Based on market logic, there is no such thing as surplus FTR auction revenue. FTR Auction revenue results from the market prices paid by willing FTR buyers, should be paid to ARR holders, and should not be returned to FTR buyers for any reason. ARRs and self scheduled FTRs offset only 66.6 percent of total congestion paid by load in the first four months of the 2025/2026 planning period. Load

8 Such subsidies have been suggested repeatedly. See FERC Dockets Nos. EL13-47-000 and EL12-19-000.
9 See 156 FERC ¶ 61,180 (2016), *reh'g denied*, 158 FERC ¶ 61,093 (2017).
10 163 FERC ¶ 61,165 (2018).

has been underpaid congestion revenues by $5.4 billion from the 2011/2012 planning period through the first four months of the 2025/2026 planning period. The cumulative offset for that period was only 68.7 percent of total congestion.

The complex process related to what is termed the overallocation of Stage 1A ARRs is entirely an artificial result of reliance on the contract path model in the assignment of FTRs. For example, there is a reason that transmission is not actually built to address the Stage 1A overallocation issue. The Stage 1A overallocation issue is a fiction based on the use of outdated and irrelevant generation to load contract paths to assign Stage 1A rights that have nothing to do with actual power flows.

PJM proposed, and on March 11, 2022, FERC accepted, an increase to Stage 1A ARR allocations from 50 percent of Network Service Base Load (NSBL) to 60 percent of Network Service Peak Load (NSPL).[11] NSBL is a network service customer's contribution to the lowest daily zonal peak load in the prior twelve month period, and NSPL is a network service customer's contribution to the highest daily zonal peak load in the prior twelve month period. PJM's new ARR allocation rules have increased Stage 1A rights at the cost of Stage 1B and Stage 2 ARR allocations. More importantly, PJM's new ARR allocation rules have exacerbated the current misalignment between congestion property rights and the congestion paid by load.

Proposed Design

To address the issues with the current contract path based ARR/FTR market design, the MMU recommends that the current design be replaced with a design in which the rights to actual congestion paid are assigned directly to the load that paid that congestion by node. The assigned right would be the actual difference between load payments, both day-ahead and balancing, and revenues paid to the generation used to serve that load. The load could retain the right to the congestion or sell the right through auctions. The correct assignment of congestion revenues to load is fully consistent with retaining FTR auctions for the voluntary sale by load of their congestion revenue rights at terms defined by load.

With a network assignment of actual congestion, there would be no cross subsidies among rights holders and no over or under allocation of rights relative to actual network market solutions. There would be no revenue shortfalls as congestion payments equal congestion collected. The risk of default would be isolated to the buyer and seller of the right, and any default would not be socialized to other rights holders. In the case of a defaulting buyer, the rights to the congestion revenues would revert to the load. There would be no risk of a network right flipping in value from positive to negative, because congestion is always the positive difference between what load pays for energy and what generation is paid for energy as a result of transmission constraints.

The MMU proposal requires the calculation of constraint specific congestion and the calculation of that specific constraint's congestion related charges to each physical load bus downstream of that constraint. Under the MMU proposal, the constraint specific congestion calculated by hour, from both the day-ahead and balancing market would be paid directly to the physical load as a credit against the associated load serving entity's (LSE) energy bill. This right to the congestion is defined as the congestion revenue right (CRR) that belongs to the physical load at a defined bus, zone or aggregate. The LSE could choose to sell all or a portion of the CRR through auctions.

A CRR is the right to actual, realized network related congestion that is paid by physical load at a specific bus, zone or aggregate. Under the MMU proposal a bus, zone or aggregate specific CRR could be sold as a defined share of the actual congestion. For example, an LSE could sell 50 percent of its congestion revenue right for the planning period to a third party. The third party buyer would then be entitled to 50 percent of the congestion that is credited to that specific bus, zone or aggregate for the planning period. The remaining 50 percent of the congestion credit for the specified bus, zone or aggregate would be paid to the LSE along with the auction clearing price for the 50 percent of the CRR that was sold to the third party. Depending on actual congestion and

11 See 178 FERC ¶ 61,170.

the price paid for a CRR, an LSE selling its congestion revenue rights could be better or worse off than if it retained its rights.

Under the MMU proposal, the LSE would be able to set reservation prices in the auction for the sale of portions or all of its CRR. Third parties would have an opportunity to bid for the offered portions of the CRR, and the market for the congestion revenue associated with the specified bus, zone or aggregate would clear at a price. If the reservation price of an identified portion of the offered CRR was not met at the clearing price, that portion of the offered CRR would remain with the load. Auctions could be annual and/or monthly and/or more frequent.

Under the MMU proposal, point to point rights (FTRs) could exist as a separate, self-funded hedging product based on simultaneously feasible prevailing and counter flows in a PJM managed network based auction. The only supply and the only source of revenues in the point to point market for prevailing flow FTRs would be counter flow offers and direct payments for specific rights.

Auction Revenue Rights

Auction Revenue Rights (ARRs) are the mechanism used to assign congestion rights to load, using an archaic and invalid contract path based approach, and to sell those rights to FTR buyers in various auctions. ARR values are based on nodal price differences established by cleared FTR bids in the Annual FTR Auction. ARR sellers have no opportunity to define a price at which they are willing to sell and must accept the prices set by FTR buyers. ARR revenues are a function of FTR auction participants' expectations of congestion, risk, competition and available supply. But some auction revenues may be returned to FTR buyers as "surplus," despite the fact that FTR buyers willingly paid a defined price for FTRs. There is no surplus. PJM has significant discretion over the level of supply made available to FTR buyers. That discretion is needed only as a result of the flawed design. As long as the current design persists, the goals of that discretion should be significantly limited and defined clearly in the tariff.

ARRs are available only as obligations (not options) and only as a 24 hour product. ARRs are available to the nearest 0.1 MW. The ARR target allocation is equal to the product of the ARR MW and the price difference between the ARR sink and source from the Annual FTR Auction.[12] The value of ARR target allocations is set by the Annual FTR Auction. ARRs would be revenue inadequate if the money collected from the Annual FTR auction is not enough to pay the entirety of Annual ARR target allocations for the planning period which could happen only if there is a modeling difference between the system model used for ARRs and the system model used for FTRs and the FTR MW are reduced. The Annual FTR Auction and ARR target allocations were not the issue in the first four months of the 2025/2026 planning period. The disproportionate increase in Residual ARR target allocations compared to Annual ARR target allocations and FTR Auction Revenue led to the first month with an ARR deficiency in the history of the ARR market. An ARR's target allocation, or value, which is established from the Annual FTR Auction, can be a benefit or liability depending on the price difference between sink and source.

The goal of the ARR/FTR design should be to provide an efficient mechanism to ensure that load receives the rights to all congestion revenues. In the current design, all auction revenues should be paid to ARR holders.

The quantity of the product made available as ARRs or for sale in the FTR auctions is defined as system capability, meaning the capacity of the transmission system to deliver power. But system capability is not congestion and system capability is not the difference in congestion prices across transmission contract paths nor the potential for such difference and system capability is not the market flow across transmission paths. The concept of system capability is not relevant to assigning the rights to congestion revenues to load. The use, or misuse, of the concept of system capability in assigning ARRs is derived entirely from the contract path approach used in the PJM design. The definition of ARRs based on contract paths led to the mistaken idea that some transmission system capacity was used by ARRs but some was not and that both the ARR capability and the excess capability were available for sale as FTRs. Power does not flow on contract paths. In the current approach,

12 These nodal prices are a function of the market participants' annual FTR bids and binding transmission constraints.

system capability available to ARR holders is limited by the system capability made available in PJM's annual FTR transmission system market model. PJM's annual FTR transmission market model represents annual, expected system capability, modified by PJM to achieve PJM's goal of guaranteeing revenue equal to target allocations for FTRs, and subject to the requirement that all Stage 1A ARR requests must be allocated. Stage 1A ARR right requests are guaranteed and system capability necessary to accommodate the rights must be included in PJM's annual FTR transmission system market model despite the fact that there are not real world paths, real world capability, or real world flows that correspond to Stage 1A rights.

Market Design

ARRs have been available to network service and firm, point to point transmission service customers since June 1, 2003, when the annual ARR allocation was first implemented for the 2003/2004 planning period. The initial allocation covered the Mid-Atlantic Region and the APS Control Zone. For the 2006/2007 planning period, the choice of ARRs or direct allocation FTRs was available to eligible market participants in the AEP, DAY, DUQ and DOM Control Zones. For the 2007/2008 and subsequent planning periods through the present, all eligible market participants were allocated ARRs.

Each March, PJM allocates annual ARRs to eligible customers in a three stage process: Stage 1A, Stage 1B and Stage 2B. Stage 1A ARRs are assigned based on historic contract paths and Stage 1A ARRs must be preserved for at least ten planning periods regardless of system or regulatory changes.[13]

The 2022/2023 planning period annual auction was the first auction under PJM's new ARR allocation rules. Under the new rules, Stage 1A ARR allocations increase from 50 percent of Network Service Base Load (NSBL) to 60 percent of Network Service Peak Load (NSPL).[14] NSBL is a network service customer's contribution to the lowest daily zonal peak load in the prior 12 month period, and NSPL is a network service customer's contribution to the highest daily zonal peak load in the prior twelve month period. PJM's new ARR allocation rules have increased Stage 1A rights at the cost of Stage 1B and Stage 2 ARR allocations.

In Stage 1A, LSEs can obtain ARRs, based on their contribution to the network service peak load (NSPL) and based on putative generation to load contract paths, or their qualified replacements if the resource has retired and PJM has replaced it with a different generator regardless of whether there is a contract. The historical reference year is the year in which PJM markets were implemented, which is 1999 for the original zones, or the year in which a zone joined PJM. Firm, point to point transmission service customers can obtain Stage 1A ARRs up to 50 percent of the MW of firm, point to point transmission service provided between the receipt and delivery points for the historical reference year, subject to a cap of 60 percent of the participants total network service peak load for the zone or load aggregation zone that the ARRs are obtained. Effective for the 2023/2024 planning period, network service customers can obtain Stage 1A ARRs based on the MW of firm service provided during the reference year, subject to a cap of 60 percent of the participants total network service peak load for the zone or load aggregation zone that the ARRs are obtained. Stage 1A ARRs cannot be prorated. If Stage 1A ARRs are found to be infeasible, transmission system upgrades must be undertaken to maintain feasibility.[15] However, PJM does not actually upgrade the transmission system to address Stage 1A ARR infeasibility because there is no actual physical infeasibility. The apparent infeasibility is an artificial result based on the fiction that power flows on the unsupported, outdated, fictional and irrelevant generation to load contract paths on which PJM's current and incorrect ARR allocation is based. Stage 1A rights have nothing to do with actual power flows or transmission limits.

In Stage 1B, network transmission service customers can obtain ARRs, up to the difference between their share of network service peak load and Stage 1A allocations. Effective for the 2023/2024 planning period, Stage 1B ARRs can be obtained from historical generation resources, qualified replacement resources, hubs, zones, or interfaces to designated load aggregation zones. Firm, point to point transmission service customers can obtain ARRs based

13 See "PJM Manual 6: Financial Transmission Rights," Rev. 34 (May 21, 2025) at 20.
14 See 178 FERC ¶ 61,170.
15 See "PJM Manual 6: Financial Transmission Rights," Rev. 34 (May 21, 2025)

on the MW of long-term, firm, point to point service provided between the receipt and delivery points for the historical reference year.

In Stage 2, network transmission service customers can obtain ARRs from any hub, control zone, generator bus or interface pricing point to any part of their aggregate load in the control zone, load aggregation zone, or any generator, interface, hub or zone, up to their total peak network load in that zone. Firm, point to point transmission service customers can obtain ARRs consistent with their transmission service as in Stage 1A and Stage 1B.

ARR holders can self schedule ARRs as FTRs during the Annual FTR Auction.[16] When ARR holders self schedule FTRs, the ARR holders choose to be paid based on variable FTR target allocations rather than the fixed ARR value determined in the annual FTR auction. ARRs can be traded between LSEs prior to the first round of the Annual FTR Auction.

Effective for the 2015/2016 planning period, when residual zonal pricing was introduced, ARRs default to sinking at the load settlement point if different than the zone, but the ARR holder may elect to sink their ARR at the zone instead.[17]

In 2016, FERC ordered PJM to remove retired resources from the generation to load contract paths used to allocate Stage 1A ARRs.[18] PJM replaced retired units with operating generators, termed qualified replacement resources (QRRs), regardless of whether there was a corresponding contract.[19] Existing Stage 1A resources retain their current allocations, while ARR allocations to QRRs that replace retired Stage 1A resources are prorated based on the feasibility of these ARRs after existing resources are allocated. As a result of this proration, ARRs for QRRs have lower priority than ARRs from generators that existed in 1998.

Generation to load paths, even from active generators, are based on a contract path model rather than a network model. Generation to load contract paths should not be used as a basis for assigning the rights to congestion revenue. There is no basis for assuming that a contract existed in 1999 or exists currently. Contract paths are a fiction and are not an accurate representation of the reasons that congestion exists or of how load is served in a network and will, by definition, not accurately measure the exposure of load to congestion.

Market Structure

ARRs are allocated on an annual basis. For the 2025/2026 planning period there were 1,560 individual participants and 130 parent companies, up from 1,523 individual participants and 126 parent companies for the 2024/2025 planning period.

The ownership of ARRs by parent company was unconcentrated, with an HHI of 600, for the 2025/2026 planning period compared to 610 for the 2024/2025 planning period.

Market Performance

Volume

Table 13-3 shows the MW of ARR allocations for each round of the 2024/2025 and 2025/2026 planning periods. There was a 3,011 MW increase (1.9 percent) in Network Service Peak Load (NSPL) between the 2024/2025 and 2025/2026 planning period. This increase resulted in an increase in ARR MW requested by load in the annual auction of 1,858 MW (0.9 percent) from the 2024/2025 to the 2025/2026 planning period. The ARR MW actually provided to load decreased by 1,559 MW (1.4 percent) from the 2024/2025 to the 2025/2026 planning period. The cleared volume of Stage 1B ARR MW decreased 3.4 percentage points from 26.5 percent in the 2024/2025 planning period to 23.1 percent in the 2025/2026 planning period.

Table 13-3 Annual ARR allocation volume: 2024/2025 and 2025/2026 planning periods

Planning Period	Stage	Round	Requested Count	Requested Volume (MW)	Cleared Volume (MW)	Cleared Volume	Uncleared Volume (MW)	Uncleared Volume
2024/2025	1A	0	33,729	86,657	86,657	100.0%	0	0.0%
	1B	1	11,182	56,080	14,880	26.5%	41,200	73.5%
	2	2	14,374	31,556	5,691	18.0%	25,865	82.0%
		3	9,552	31,520	7,788	24.7%	23,732	75.3%
		Total	23,926	63,076	13,479	21.4%	49,597	78.6%
	Total		68,837	205,813	115,016	55.9%	90,797	44.1%
2025/2026	1A	0	35,072	89,253	89,245	100.0%	8	0.0%
	1B	1	10,807	55,826	12,919	23.1%	42,907	76.9%
	2	2	9,006	31,316	5,261	16.8%	26,055	83.2%
		3	6,660	31,276	6,032	19.3%	25,244	80.7%
		Total	15,666	62,592	11,293	18.0%	51,299	82.0%
	Total		61,545	207,671	113,457	54.6%	94,214	45.4%

Table 13-4 shows the share of ARR MW, by stage, for ARRs with paths that source inside or outside the zone where the load is located, for the 2025/2026 planning period. Table 13-4 shows that, for the 2025/2026 planning period, 78.6 percent of the ARR MW are based on generation inside the zone where the ARR load is located and 21.4 percent of the ARR MW are based on generation outside the zone where the ARR load is located. In contrast, only 15.5 percent of congestion resulted from constraints inside the zone where load is located and 84.5 percent of congestion resulted from constraints outside the zone where load is located during the 2024/2025 planning period (Table 13-53). This illustrates one of the fundamental issues with the path based approach which originated in a cost of service design where most load was served by generation in the same zone as load. In fact, in the PJM market, which operates as an integrated network, a significant proportion of congestion results from constraints that are not in the same zone as load. The path based approach cannot and does not reflect the actual congestion paid by load.

Table 13-4 Share of ARRs that source in/out of load zone: 2025/2026 planning period

	Stage 1A		Stage 1B		Stage 2		Total	
	Out of Zone	In Zone	Out of Zone	In Zone	Out of Zone	In Zone	Out of Zone	In Zone
ACEC	31.1%	36.3%	4.7%	9.3%	8.3%	10.3%	44.1%	55.9%

Stage 1A Infeasibility

Stage 1A ARRs are allocated for a year, but guaranteed for 10 years, with the ability for a participant to opt out of any planning period within the 10 years. PJM conducts a simultaneous feasibility analysis to determine the transmission upgrades required to ensure that the long term ARRs can remain feasible. The rules provide that if a simultaneous feasibility test violation occurs in any year, PJM will identify or accelerate any transmission upgrades to resolve the violation and these upgrades will be recommended for inclusion in the PJM RTEP process. But such transmission upgrades must pass PJM's RTEP process.

PJM's transmission planning process (RTEP) does not identify a need for new transmission associated with Stage 1A overallocations because there is, in fact, no need for new transmission associated with Stage 1A ARRs. The Stage 1A overallocation issue is a fiction based on the use of outdated and irrelevant generation to load contract paths to assign Stage 1A rights that have nothing to do with actual power flows. This continues to be true even with the replacement of retired generating units.

For the 2024/2025 and 2025/2026 planning periods, Stage 1A of the Annual ARR Allocation was infeasible, resulting in an over allocation of ARRs on the affected facilities. As a result, modeled system capability, in excess of actual system capability, was provided to the Stage 1A ARRs and added to the FTR auction. According to Section 7.4.2 (i) of the OATT, the capability limits of the binding constraints rendering these ARRs infeasible must be increased in the model and these increased limits must be used in subsequent ARR and FTR allocations and auctions for the entire planning period, except in the case of extraordinary circumstances. Stage 1A related over allocations have to be made up elsewhere in PJM's FTR market model, in the form of reduced system capability, in order for PJM to achieve its goal of fully funding FTRs. The need for and use of these artificial and factually incorrect calculations are another illustration of the failure of the FTR/ARR design to meet basic logical standards.

Table 13-5 shows the MW quantity and count of overloaded constraint/contingency pairs and the reasons for the modeled overload for the 2024/2025 and 2025/2026 planning periods. In order to eliminate the infeasibilities for the requested Stage 1A ARR allocations, PJM needed to raise the modeled capacity limits above the actual transmission line limits on 113 constraint/contingency pairs, 84 of which were internal to PJM, a total of 25,565 MW in the 2025/2026 planning period. This is an increase of 15 constraint/contingency pairs (15.3 percent), an increase of 27 constraint/contingency pairs internal to PJM, (47.4 percent), and an increase of 8,691 MW (51.5 percent) compared to the 2024/2025 planning period.[20]

20 *PJM 2023/2024 Stage 1A Over allocation notice*, PJM FTRs, <https://pjm.com/-/media/markets-ops/ftr/annual-arr-allocation/2023-2024/2023-2024-stage-1a-over-allocation-notice.ashx> (March 6, 2023).

Table 13-5 Stage 1A overloaded constraint reasons and MW: 2024/2025 and 2025/2026 planning periods

		2024/2025		2025/2026	
Reason	Type	MW	Count	MW	Count
Network Load	Internal PJM	2,745	5	17	1
Network Load	M2M Flowgate	2,003	26	2,177	23
Transmission Outage	Internal PJM	12,031	57	23,316	84
Transmission Outage	M2M Flowgate	95	10	55	5
Transmission Outage	Tie Line	0	0	0	0
Total		16,874	98	25,565	113

Table 13-6 shows the share of Stage 1A over allocations for the 2024/2025 and 2025/2026 planning periods for ARR allocations that source inside and outside the zone where the over allocated MW sink. The share of over allocations that has a source outside the zone in which it sinks, increased 3.4 percent from 26.8 percent in the 2024/2025 planning period to 27.7 percent in the 2025/2026 planning period. The total MW of overloaded constraint/contingency pairs (Table 13-5) is greater than the total MW of overloaded Stage 1A ARR paths (Table 13-6) because an individual overloaded ARR path can require the modeled capacity limit to be increased for multiple constraint/contingency pairs and multiple contingencies per constraint.

Table 13-6 Stage 1A overloaded paths that sink inside and outside source zone: 2024/2025 and 2025/2026 planning periods

Figure 13-1 shows the predicted and estimated impact of Stage 1A infeasibilities on FTR funding for the 2012/2013 through 2024/2025 planning periods, as well as the predicted impact on funding for the 2025/2026 planning period. The predicted funding is based on the infeasible ARR MW and the nodal price of the source and sink in the Annual FTR Auction. The estimated funding is calculated assuming every infeasible ARR MW is self scheduled, and uses the hourly congestion LMP values of the applicable day-ahead hours. The large estimated funding impact in the 2024/2025 planning period was a result of the relatively large overallocation of Stage 1A ARRs (and related FTRs) relative to expected congestion on Stage 1A related paths (Figure 13-13).

Figure 13-1 Stage 1A Infeasibility funding impact

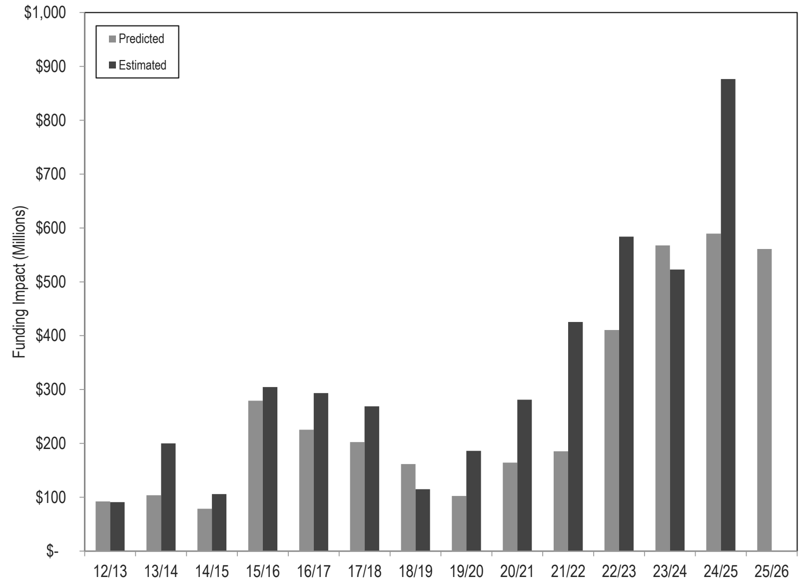

Table 13-7 shows the MW of retired generation sources for Stage 1A ARRs, the Qualified Replacement Resource (QRR) MW assigned by PJM for all resources and the replacement MW that were considered rate based. A rate based unit is a replacement generator that is owned by the ARR holder, or subject to firm energy and capacity supply contracts.[21] The term rate based is a misleading reference to the premarket cost of service regulation paradigm. If PJM does not find such a unit, PJM will use another unit that is close to where the retired unit was located even if it is not owned or under contract.

21 See "PJM Manual 6: Financial Transmission Rights," Rev. 34 (May 21, 2025) at 21.

ARR Reassignment for Retail Load Switching

PJM rules provide that when load switches between LSEs during the planning period, an LSE gaining load in the same control zone is allocated a proportional share of positively valued ARRs and residual ARRs within the control zone based on the shifted load.[22] ARRs are reassigned to the nearest 0.001 MW and may be reassigned multiple times over a planning period. The reassignment of positively valued ARRs supports competition by ensuring that the offset to congestion follows load, thereby removing a barrier to competition among LSEs and, by ensuring that only ARRs with a positive value are reassigned, preventing an LSE from assigning poor ARR choices to other LSEs. However, when ARRs are self scheduled as FTRs, the self scheduled FTRs do not follow load that shifts while the ARRs do follow load that shifts, and this may result in lower value of the ARRs for the receiving LSE compared to the total value held by the original ARR holder.

22 See "PJM Manual 6: Financial Transmission Rights," Rev. 34 (May 21, 2025).

Table 13-8 summarizes ARR MW and associated revenue reassigned for network load in each control zone where changes occurred from June 1, 2024, through September 30, 2025.

There were 16,509 MW of ARRs associated with $385.7 thousand of revenue that were reassigned for the first four months of the 2025/2026 planning period. There were 32,594 MW of ARRs associated with $1,187.6 thousand of revenue that were reassigned for the 2024/2025 planning period.

Table 13-8 ARRs and ARR revenue automatically reassigned for network load changes by control zone: June 2024 through September 2025

	ARRs Reassigned (MW-day)		ARR Revenue Reassigned [Dollars (Thousands) per MW-day]

Revenue

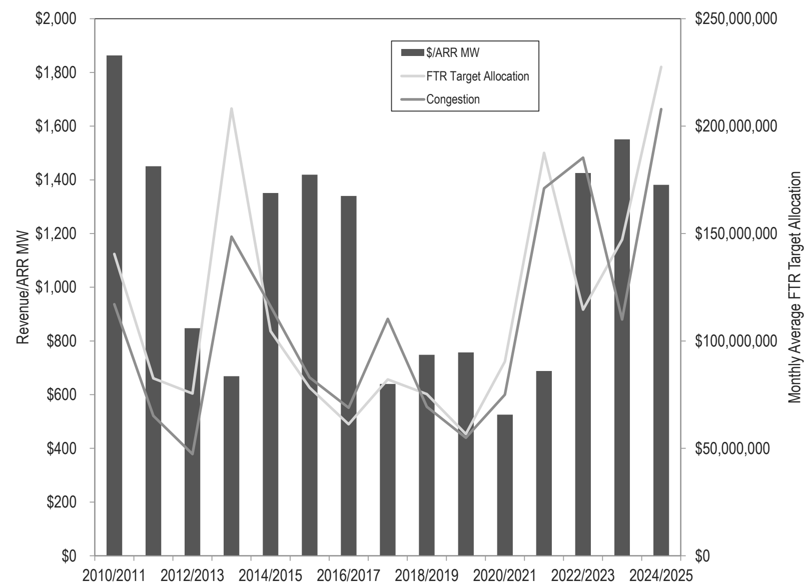
ARRs are allocated to qualifying customers rather than sold, so ARR revenue (target allocation) is different from the revenue that results from the FTR auctions, which generally exceeds the sum of the ARR target allocations.

Figure 13-2 shows the revenue per ARR MW held for each month of the 2010/2011 planning period through the 2024/2025 planning period. The revenue per ARR MW held does not include target allocation related payouts for self scheduled FTRs or surplus revenue, but does include Residual ARRs starting in August 2012.

PJM has had to repeatedly intervene in the functioning of the FTR system in an effort to meet the artificial and incorrectly defined goal of revenue adequacy. FTR prices increased in the 2014/2015 Annual FTR Auction in part as a result of reduced supply caused by PJM's assumption of more outages in the model relative to prior years. The decrease in system capability caused by PJM's more conservative modeling of the FTR market model reduced Stage 1B and Stage 2 ARR allocations. The increased FTR prices resulted in an increase in revenue per ARR MW, but there are fewer ARR MW. For the 2014/2015 planning period, the total dollars per MW of ARR allocation was $11,279, while the previous planning period resulted in revenue per MW of $6,692, a 68.5 percent increase in revenue per allocated ARR MW. Some of the ARR MW lost from proration were provided in the Residual ARR process, but the residual allocations are not comparable to the ARRs awarded in the annual process because residual ARR allocations change each month and cannot be self scheduled as FTRs. For the 2015/2016 and 2016/2017 planning periods, the revenue per MW of ARR allocation was $10,642 and $10,411. During these planning periods PJM chose more restrictive modeling criteria, which did not release the full capacity of the FTR model to account for revenue inadequacies. Beginning in the 2017/2018 planning period, when balancing congestion was removed from FTR funding, PJM reinstated less restrictive modeling criteria, and the revenue per MW of ARR decreased due to an increase in modeled capability. For the 2017/2018 and 2018/2019 planning periods the revenue per MW of ARR was $5,168 and $6,841. For the 2022/2023 planning period, cleared ARR MW decreased significantly (see Table 13-3) from the previous planning period, indicating that PJM again chose more restrictive modeling criteria for the FTR model to improve FTR funding. This results in fewer ARRs being awarded. Due to significant increases in FTR prices in the 2022/2023 planning period, the revenue per MW of ARR was $12,274. For the 2023/2024 planning period, FTR prices decreased compared to the 2022/2023 planning period and the revenue per MW of ARR was $14,463, a 17.8 percent decrease. For the 2024/2025 planning period PJM again used less restrictive modeling criteria in the FTR model, resulting in more ARRs being awarded. The revenue per MW of ARR decreased to $12,058, a 16.6 percent decrease.

Under the current rules, load is required to directly pay balancing congestion costs, not included in Figure 13-2, which reduce the revenue received by ARR holders. There is no support for the assertion made by proponents of shifting balancing congestion to load that higher ARR values would result, and there is no evidence of any kind that load is better off as a result of the arbitrary assignment of balancing congestion to load.

Figure 13-2 Revenue per ARR MW paid to ARR holders compared to congestion and FTR target allocations: 2010/2011 through 2024/2025 planning periods



ARR holders have limited options to pick source points for their ARRs. The holders of Stage 1A rights are limited to specific historical sources (or PJM defined replacement sources when resources retire). Of the stage 1A rights allocated to ARR holders, 58.5 percent were sourced within the ARR holder's zone in the 2024/2025 planning period. Table 13-4 shows that, for the 2025/2026 planning period, 78.6 percent of the ARR MW are based on generation inside the zone where the ARR load is located and 21.4 percent of the ARR MW are based on generation outside the zone where the ARR load is located. In contrast, only 15.5 percent of congestion resulted from constraints inside the zone where load is located and 84.5 percent of congestion resulted from constraints outside the zone where load is located during the 2024/2025 planning period. The primary source of a load zone's actual congestion is the result of transmission constraints that separate that zone from resources external to that zone, not by constraints internal to that zone. The congestion offset revenues per MW of internally sourced Stage 1A ARR rights are less than the revenue per MW of Stage 1A ARR rights from externally sourced resources. Table 13-9 shows the share of ARR revenue, by stage, for ARRs with paths that source inside or outside the zone where the load is located, for the 2025/2026 planning period. While 14.8 percent of all ARR MW are Stage 1A ARRs with sources outside the zone where load is located (see Table 13-4), those ARRs provide 26.2 percent of the total ARR revenues.

This illustrates one of the fundamental issues with the path based approach which originated in a cost of service design where most load was served by, or assumed to be served by, generation in the same zone as load. In fact, in the PJM market, which operates as an integrated network, a significant proportion of congestion is based on constraints that are not in the same zone as load. The path based approach does not and cannot reflect the actual congestion paid by load. The use of the path based approach is the fundamental source of the under assignment of congestion revenue rights to load in the ARR/FTR model.

Table 13-9 Share of ARR revenue that sources in/out of load zone: 2025/2026 planning period

ARR Target Allocations

Table 13-10 shows the monthly ARR target allocations from Annual ARRs and Residual Residual ARRs for the first four months of the 2025/2026 planning period and the entire 2024/2025 planning period. Table 13-10 also shows the FTR auction revenue available to fund ARR target allocations. Annual ARR target allocations (Table 13-10) are based on the nodal clearing prices from FTR obligations in the Annual FTR Auction. The annual ARR target allocation is divided evenly among every day of the planning period. Residual ARR target allocations (Table 13-10) are based on the nodal clearing prices from FTR obligations in the monthly FTR auctions and vary each month.

In the first four months of the 2025/2026 planning period, total ARR target allocations (the sum of annual and residual ARR target allocations) were $664,369,697, up 36.3 percent from $487,592,678 in the same period of the 2024/2025 planning period. Total ARR target allocations in the first four months of the 2025/2026 planning period include $613,835,777 annual ARR target allocations (up 27.3 percent relative the same period of the 2024/2025 planning period) and $50,533,920 Residual ARR target allocations (up 819.0 percent relative to the same period of the 2024/2025 planning period). In the first four months of the 2025/2026 planning period FTR auction revenue available to pay FTR was $702,778,731, up 28.0 percent from $548,979,997 in the same period of the 2024/2025 planning period. The significant and unprecedented increase in Residual ARR target allocations compared to Annual ARR target allocations and FTR Auction Revenue led to the first month with an ARR deficiency in the history of the ARR market. In July 2025 there was a $229,526 deficiency for ARR holders. PJM's monthly auction process does not consider the impact of Residual ARR target allocation when the Monthly FTR Auctions are optimized and cleared.

Table 13-10 Monthly ARR target allocations compared to FTR auction revenue: 2024/2025 and 2025/2026 planning periods

Month	Annual ARR Target Allocations	Residual ARR Target Allocations	Total ARR Target Allocations	FTR Auction Revenue	ARR Surplus or Deficiency
Jun-24	$118,548,955	$1,542,269	$120,091,225	$133,459,438	$13,368,213
Jul-24	$122,500,587	$817,746	$123,318,333	$139,272,100	$15,953,768

Residual ARRs

Introduced August 1, 2012, Residual ARRs are available for eligible ARR holders when a transmission outage was modeled in the Annual ARR Allocation, but the transmission facility returns to service during the planning period. Residual ARRs can only be allocated to participants whose ARRs were prorated in Stage 1B and only to a maximum of the prorated reduction, so not all available Residual ARRs are allocated. Residual ARRs are automatically assigned to eligible participants the month before the effective date, are effective for a single month and cannot be self scheduled. Residual ARR target allocations are based on the clearing prices from FTR obligations for FTRs of the same period purchased the relevant monthly auctions, may not exceed zonal network services peak load or firm transmission reservation levels and are only available up to the prorated ARR MW capacity as allocated in the Annual ARR Allocation. For the following planning period, these Residual

ARRs are available as ARRs in the annual ARR allocation. Residual ARRs are a separate product from incremental ARRs. Beginning with the June 2017 monthly auction, Residual ARRs that would have cleared with a negative target allocation are not assigned to participants.[23] In prior planning periods, PJM's modeling of excess outages in order to manage FTR market outcomes resulted in the allocation of some ARRs that would have been allocated in Stage 1B being allocated as Residual ARRs on a month to month basis without the option to self schedule.

Table 13-11 shows the Residual ARRs allocated to participants and the associated target allocations. The available volume is the total additional capacity available to be allocated as Residual ARRs. The cleared volume is the residual ARR capacity actually allocated to participants with prorated ARRs based on the level of prorated ARRs in Stage 1B and the affected paths. In the first four months of the 2025/2026 planning period, PJM allocated a total of 15,233.8 MW of Residual ARRs with a target allocation of $50.5 million. In the same period of the 2024/2025 planning period, PJM allocated a total of 7,998.2 MW of residual ARRs with a target allocation of $5.5 million. The 819.9 percent increase in target allocations for Residual ARRs without a corresponding increase in monthly FTR auction revenue (See Table 13-43) in the first four months of the 2025/2026 planning period led to the ARR deficiency in July 2025.

Table 13-11 Residual ARR allocation volume and target allocation: 2014/2015 planning period through 2025/2026 planning period

Planning Period	Available Volume (MW)	Cleared Volume (MW)	Cleared Volume	Target Allocation
2014/2015	65,095.3	22,532.9	34.6%	$8,160,918.27
2015/2016	61,807.0	37,042.4	59.9%	$8,620,353.27

23 See FERC Letter Order, Docket No. ER17-1057 (April 5, 2017).

IARRs

In theory, Incremental Auction Revenue Rights (IARRs) are ARRs made available by physical transmission system upgrades from customer funded transmission projects or from merchant transmission or generation interconnection requests. In order for a transmission project to result in IARRs, the project must create simultaneously feasible incremental market flow capability in PJM's ARR market model, over and above all system capability being used by existing allocated ARRs and/or would be used by granting any prorated outstanding ARR requests, in the ARR market model.[24]

There are three sources of IARRs: IARRs based on a specific transmission investment; IARRs based on merchant transmission or generation interconnection projects; and IARRs based on RTEP upgrades. In the case of a specific transmission investment, the participant elects desired IARR MW between a specified source and sink and PJM and the affected transmission owners determine the upgrades necessary to create incremental capability.[25] In the other two cases, the participants paying for the upgrades are assigned IARRs if any are created. IARR requests have resulted in 12 unique source and sink combinations, totaling 1,887.2 MW of IARR paths.

The MMU supports increased competition to provide transmission using market mechanisms. The IARR process is not a viable mechanism for facilitating competitive transmission investments. Maintaining the IARR process impedes the search for real solutions. PJM's process for creating and assigning IARRs is fundamentally flawed and cannot be made consistent with the requirements of Order No. 681 which established IARRs.[26]

Order No. 681 requires that long-term firm transmission rights made feasible by transmission upgrades or expansions be available upon request to the party that pays for such upgrades or expansions.[27] Order No. 681 also requires that the rights granted by upgrades/expansions cannot come at the expense of transmission rights held by others. IARRs are treated as Stage 1A rights,

24 See PJM Incremental Auction Revenue Rights Model Development and Analysis, PJM June 12, 2017. <https://www.pjm.com/~/media/markets-ops/ftr/pjm-iarr-model-development-and-analysis.ashx>.

26 See November 7, 2019 Comments on TranSource, LLC v. PJM, 168 FERC ¶ 61,119 (2019) ("Opinion No. 566").
27 *Long-Term Firm Transmission Rights in Organized Electricity Markets*, Order No. 681, 116 FERC ¶ 61,077 (2006) ("Order No. 681"), *order on reh'g*, Order No. 618-A, 117 FERC ¶ 61,201 (2006), *order on reh'g*, Order No. 681-A, 126 FERC ¶ 61,254 (2009).

which are given first and absolute priority in PJM's annual allocation process. Granting Stage 1A status to IARRs is preferential treatment of IARR rights relative to the ARR rights belonging to load. If the annual market model used to assign existing ARR rights in a given year cannot simultaneously support all Stage 1A ARR requests, the system model is modified so as to make the Stage 1A ARR requests feasible. The result is an over allocation of congestion rights relative to expected congestion. To avoid having FTR target allocations exceed expected congestion, PJM reduces the annual supply (market model system capability) available to non-Stage 1A rights through selective line outages and line rating reductions. The resulting market model artificially supports all the Stage 1A ARR requests and artificially reduces the amount of remaining later tier ARRs from other rights holders. Stage 1A ARRs, including IARRs, are approved at the expense of other preexisting congestion rights. In the case of IARRs, this is in violation of Order No. 681.

The MMU recommends that IARRs be eliminated from the PJM tariff. If IARRs are not eliminated, the MMU recommends that IARRs be subject to prorating like all other ARR rights rather than being exempt from prorating.

Financial Transmission Rights

FTRs are financial instruments that entitle their holders to receive revenue or require them to pay charges based on locational congestion price differences in the day-ahead energy market across specific FTR transmission paths. These day-ahead congestion price differences (shadow prices), multiplied by the FTR position in MW, are termed the FTR target allocations. The FTR target allocations define the maximum, but not guaranteed, payout for FTRs. The target allocation of an FTR reflects the difference in day-ahead congestion prices (CLMPs) rather than the difference in LMPs, which includes both congestion and marginal losses. Negative target allocations require the FTR holder to make payments rather than receive revenues in the FTR market. One of the fundamental flaws in the FTR design is the mismatch between congestion and the differences in day-ahead prices between nodes. The difference in day-ahead congestion prices is not congestion. Target allocations are not congestion. It is this fundamental flaw that creates what PJM refers to as "underfunding" or "revenue inadequacy." If FTRs were the rights to congestion revenue, there could never be revenue inadequacy. Congestion payments to FTR holders would always exactly equal congestion revenues.

Under the current rules, the revenue available to pay FTR holders' target allocations in a given month includes day-ahead congestion, payments by holders of negatively valued FTRs, and FTR auction revenues greater than ARR target allocations. Any such revenue above FTR target allocations from prior months in a planning period are used to pay any current month shortfalls. Payments to FTR holders for each planning period cannot exceed the target allocations because the target allocations define the FTR product purchased. At the end of each planning period, any surplus revenue above the target allocations is distributed to ARR holders.

FTR funding is not on a path specific basis or on an hour to hour basis and treats all FTRs the same. For example, if the payout ratio is less than 1.0 at the end of the planning period, the payments to all FTRs are reduced. Payments are made pro rata based on target allocations. The result is widespread cross subsidies because assignment of path specific FTRs may exceed system capability and affect the payments to FTRs on other paths. FTR auction revenues and excess revenues are carried forward from prior months and distributed back from later months within a planning period. At the end of a planning period, if the total revenue is less than the total target allocations, an uplift charge is collected from any FTR market participants that hold FTRs for the planning period, based on their pro rata share of total net positive FTR target allocations, excluding any charge to FTR holders with a net negative FTR position for the planning period.

Auction market participants may offer to buy FTRs between any eligible pricing nodes on the system, as defined by PJM for each auction. For the Annual FTR Auction and FTRs bought in the monthly auctions, the available FTR source and sink points include hubs, control zones, aggregates, generator buses, load buses and interface pricing points. For the Long Term FTR Auction there is a smaller set of available hubs, control zones, aggregates, generator buses and interface pricing points available. PJM does not allow FTR buy bids to clear with a price of zero unless there is at least one constraint in the auction which affects the FTR path. FTRs are available to the nearest 0.1 MW.

FTRs are bought from supply defined by PJM. The fact that load is selling congestion revenue rights is not recognized in the FTR design, although FTR buyers can resell FTRs at a price they agree to accept. Load has no role in defining the price at which PJM sells FTRs on their behalf. Load has no role in deciding the total FTR MW to be sold. Load has no role in deciding whether to sell load's rights to congestion revenues. PJM's objective in the FTR auctions is to maximize auction revenue, based only on the total set of bid prices and bid MW, but absent reservation prices from load. The failure to allow sellers the ability to decide at what price to sell FTRs is a fundamental flaw in the FTR market. The result is that PJM cannot actually maximize auction net revenue and that the FTR market is not really a market.

Once bought from PJM, FTRs can be bought and sold. Buy bids are bids to buy FTRs in the auctions. Sell offers are offers to sell existing FTRs in the auctions.

Market participants can buy and sell existing FTRs, outside of the auction process, through a voluntary bulletin board, termed the PJM bilateral market. FTRs can also be exchanged bilaterally without using the bulletin board. Prior to June 30, 2024, there was no requirement to report accurate detailed information about bilateral transactions settled through PJM billing systems. Effective June 30, 2024, the Commission accepted PJM's proposed revisions to the rules that required the reporting of bilateral price information and corroborating contract documents of any bilateral change of FTR ownership between participants/accounts that is settled through PJM settlement systems.[28] Bilateral transactions remain dependent on the contract established between the parties. PJM has no knowledge of bilateral transactions, or the terms and risks of bilateral transactions, that are done outside of PJM's bilateral market system.

Supply and Demand

Total FTR supply in each auction as defined by PJM is limited by the definition of the transmission system capacity included in the PJM FTR market model as modified, for example, by PJM assumptions about transmission outages, for which there are no clear rules. PJM may also limit available transmission capacity through subjective judgment exercised without any clear guidelines.

The FTR auction process does not account for the fact that significant transmission outages, which have not been provided to PJM by transmission owners prior to the auction date, will occur during the periods covered by the auctions. Such transmission outages may or may not be planned in advance or may be emergency outages.[29] In addition, it is difficult to model in an annual auction two outages of similar significance and similar duration in different areas which do not overlap in time. The choice of which to model will generally have significant distributional consequences; they will affect different areas very differently. The fact that outages are modeled at significantly lower than historical levels results in selling too much FTR capacity, which creates downward pressure on ARR prices. To address this issue within the existing design, the MMU recommends that PJM use probabilistic outage modeling to better align the supply of ARRs and FTRs with actual expected transmission capacity.

Long Term FTR Auctions

In July 2006, FERC approved Order No. 681 mandating the creation of long term firm transmission rights in transmission organizations with organized electricity markets. FERC's goal was that "load serving entities be able to request and obtain transmission rights up to a reasonable amount on a long-term firm basis, instead of being limited to obtaining exclusively annual rights."[30] Despite that order and inconsistent with the directive in that order, LSEs are not able to request ARRs nor are LSEs guaranteed rights to the revenue from Long Term FTR Auctions in PJM's long term FTR auction market design. Excess system capability in years two and three of the long term FTR auction is never made available to load in the form of ARRs and is only made available to FTR buyers.

PJM conducts the Long Term FTR Auction for the next three consecutive planning periods. The Long Term FTR Auction consists of five rounds beginning in June of the preceding planning period and continuing through March. FTRs

28 *See* 187 FERC ¶ 61,020.

29 See the *2022 Annual State of the Market Report for PJM*, Volume 2, Section 12: Transmission Facility Outages: Transmission Facility Outages Analysis for the FTR Market.

30 Order No. 681 at P 17.

purchased in prior rounds or Long Term Auctions may be offered for sale in subsequent rounds of the long term, annual or monthly FTR auctions. FTRs obtained in the Long Term FTR Auctions have terms of one year. FTR products available in the Long Term Auction include 24 hour, on peak and off peak FTR obligations, with FTR options unavailable in the Long Term FTR Auctions.

Beginning with Round 2 of the 2019/2022 Long Term FTR Auction, PJM implemented revisions to the determination of residual system capability made available in the Long Term FTR Auctions, and eliminated the YRALL product, consistent with the MMU's recommendation. The revisions affect the determination of ARR rights reserved for ARR holders. Rather than simply preserving the ARR cleared capacity from the previous annual allocation, PJM reruns the simultaneous feasibility test for the ARR/FTR market model, without outages, using the previous year's ARR requests, prorated when necessary, and uses the resulting ARRs as the basis for reserving capability for ARR holders in the Long Term FTR Auction. The ARR requests are greater than the previously cleared ARRs. The difference between the requested ARRs and the ARR/FTR market model's transmission system capacity, both without outages, determines the residual capability offered in the Long Term FTR Auction. The revisions provide ARR holders with more congestion rights in the Long Term FTR Auction that will carry into the Annual FTR Auction.

But the revisions do not address the congestion revenue rights sold in years two and three of the Long Term FTR Auction, which remain unavailable to ARRs. As a result, the rights to significant congestion revenues are still assigned to the Long Term FTR Auction without ever having been made available to ARR holders. That outcome is inconsistent with the basic logic of ARRs and inconsistent with the stated intent of the market design which is to return all congestion revenues to load.

Long Term FTR Auction transmission capacity is determined by removing all outages and running an offline model of the previous Annual FTR Auction model with all ARR bids from the prior annual ARR allocation. Any ARR MW that clear in this offline model are reserved for ARR holders in the relevant planning periods, and are removed from the Long Term FTR Auction capability. Even this approach does not, and cannot, preserve all congestion revenues for ARR holders in the first year of the Long Term Auction due to changes in system topology and outage selection between planning periods. PJM outage assumptions are a key factor in determining the supply of ARRs and the related supply of FTRs in the Annual FTR Auction.

Annual FTR Auctions

Annual FTRs are effective for an entire planning period, June 1 through May 31. Outages expected to last two or more months, as well as any outages of a shorter duration that PJM decides would cause FTR revenue inadequacy if not modeled, are included in the determination of the simultaneous feasibility for the Annual FTR Auction.[31] While the full list of outages selected is publicly posted, PJM exercises significant subjective judgment in selecting outages to accomplish FTR revenue adequacy goals and the process by which these outages are selected is not clear, is not defined and is not documented. ARR holders who wish to self schedule must inform PJM prior to round one of the annual auction. Any self scheduled ARR requests clear 25 percent of the requested volume in each round of the Annual FTR Auction as price takers. The Annual FTR Auction consists of four rounds that allow any PJM member to bid for any FTR or to offer for sale any FTR that they currently hold. FTRs in the auctions include obligations and options and 24 hour, peak, off peak, and weekend peak products. FTRs purchased in one round of the Annual FTR Auction can be sold in later rounds or in the Monthly Balance of Planning Period FTR Auctions.

Monthly Balance of Planning Period FTR Auctions

Total Monthly FTR Auction capacity is based on the residual capacity available after the Long Term and Annual FTR auctions are conducted and adjustments are made to outages to reflect anticipated system conditions for the time periods auctioned. Outages expected to last five or more days are included in the determination of the simultaneous feasibility test for the Monthly Balance of Planning Period FTR Auction. These are single round monthly auctions that allow any transmission service customer or PJM member to bid for any FTR or to offer for sale any FTR that they currently hold. Beginning with the 2020/2021 planning period, market participants can bid for or offer monthly

31 See "PJM Manual 6: Financial Transmission Rights," Rev. 34 (May 21, 2025).

FTRs for any of the remaining individual calendar months in the planning period. FTRs in the auctions include obligations and options and 24 hour, peak, off peak, and weekend peak products.[32]

Bilateral Market

Market participants can buy and sell existing FTRs, outside of the auction process, through a voluntary bulletin board, termed the PJM bilateral market. FTRs can also be exchanged bilaterally without using the bulletin board. Bilateral transactions that are not done through PJM can involve parties that are not PJM members. PJM has no knowledge of bilateral transactions, or the terms and risks of bilateral transactions, that are done outside of PJM's bilateral market system. Prior to June 30, 2024, there was no requirement to report accurate detailed information about bilateral transactions settled through PJM billing systems. Effective June 30, 2024, the Commission accepted PJM's proposed revisions to the rules that required the reporting of bilateral price information and corroborating contract documents of any bilateral change of FTR ownership between participants/accounts that is settled through PJM settlement systems.[33] Bilateral transactions remain dependent on the contract established between the parties.

For bilateral trades reported to PJM, the FTR transmission path must remain the same, FTR obligations must remain obligations, and FTR options must remain options. However, an individual FTR may be split up into multiple, smaller FTRs, down to increments of 0.1 MW. Bilateral FTRs reported to PJM can also include more restrictive start and end times, meaning that the start time cannot be earlier than the original FTR start time and the end time cannot be later than the original FTR end time. Once the bilateral transaction is reported to PJM, PJM transfers ownership and adjusts credit requirements accordingly. Participants have used bilateral trades reported to PJM to reduce their credit requirements.

PJM's revised rules related to bilateral contracts fail to address the impact of PJM's indemnification rules. PJM stated that the "maintenance of the assumption of risk and costs is not a continuing interest in the FTR once sold; a continuing interest would be a right or benefit with respect to the subject FTR that survives the bilateral transaction." Contrary to logic, PJM asserts that only positive interests count as interests. Assumption of risks and costs of an FTR is, by definition, assumption of a financial interest in an FTR. When a participant buys an FTR in an auction, they assume the risks and costs of the FTR. Under PJM's indemnification rules the participant that bilaterally trades an FTR retains risks and costs associated with that FTR. Under PJM's indemnification rules, a bilateral seller of an FTR therefore has a continuing direct financial interest in that FTR and a direct financial interest in the credit and collateral of the buyer.

PJM's FTR market is the most transparent of all PJM markets. The facilitation of confidential bilateral transactions undercuts that transparency and therefore the efficiency of the FTR market. The bilateral information would be provided solely to PJM and not to the market. Transparency for PJM alone is not market transparency. The facilitation of confidential bilateral transactions does nothing to advance or improve the basic function of FTR markets.

There is no reason to continue to permit bilateral transactions outside the PJM FTR market. The MMU recommends that the bilateral FTR transactions market be eliminated and that all FTR transactions should take place in the FTR auctions, in order to provide full transparency, effective price discovery, and to minimize risk to market participants and PJM members.[34] The bilateral FTR market provides a PJM facilitated mechanism that undermines transparency for market participants and for loads whose congestion revenues fund FTRs. Bilateral FTR trading outside of PJM's transparent FTR market is inefficient, inconsistent with the basic structure and purpose of the PJM FTR market, and creates unnecessary credit risk.

Market Structure

In order to evaluate the ownership of FTRs, the MMU categorizes all participants owning FTRs in PJM as either physical or financial. The MMU modified the method for categorizing participants as physical and financial participants. Prior to the *2025 Quarterly State of the Market Report for PJM: January*

32 See "PJM Manual 6: Financial Transmission Rights," Rev. 34 (May 21, 2025).
33 *See* 187 FERC ¶ 61,020.
34 See Protest of the Independent Market Monitor for PJM, Docket No. ER24-374-000 (November 30, 2023); Comments of the Independent Market Monitor for PJM, Docket No. ER24-374-000 (February 6, 2024).

through March, participants were defined as either physical or financial at an organization level. Under the modified approach, physical entities are defined as individual accounts in PJM's settlement systems that take physical positions in PJM markets and typically include utilities and customers. Financial entities are defined as individual accounts in PJM's settlement systems that take financial positions in PJM markets and typically include banks and trading firms. International market participants that primarily take financial positions in PJM markets are generally considered to be financial entities even if they are utilities in their own countries.

Table 13-12 shows the 2025/2028 Long Term FTR Auction market cleared FTRs by trade type, organization type and FTR direction. The results show that financial entities purchased 92.7 percent of prevailing flow buy bid FTRs and 96.8 percent of counter flow buy bid FTRs with the result that financial entities purchased 94.7 percent of all long term FTR auction cleared buy bids. Physical entities purchased 5.3 percent of all cleared long term FTRs in the 2025/2028 Long Term FTR Auction, down 1.0 percentage points from the previous Long Term FTR Auction.

Table 13-12 Long term FTR auction patterns of ownership by FTR direction: 2025/2028 auction

		FTR Direction		
Trade Type	Organization Type	Prevailing Flow	Counter Flow	All
Buy Bids	Physical	7.3%	3.2%	5.3%
	Financial	92.7%	96.8%	94.7%
	Total	100.0%	100.0%	100.0%
Sell Offers	Physical	0.2%	0.2%	0.2%
	Financial	99.8%	99.8%	99.8%
	Total	100.0%	100.0%	100.0%

Table 13-13 shows the HHI for the individual periods in the 2017/2020 through 2025/2028 Long Term FTR Auctions and the entire auction. The YRALL auction was highly concentrated until its removal in the 2020/2023 Long Term Auction. The individual annual auctions are unconcentrated with the exception of years two and three of the 2017/2020 Auction and year three of the 2023/2026 Auction.

Table 13-13 Long term HHIs by auction

Auction	YR1	YR2	YR3	YRALL	Entire Auction

Table 13-14 shows the annual FTR auction cleared FTRs for the 2025/2026 planning period by trade type, organization type and FTR direction. In the Annual FTR Auction for the 2025/2026 planning period, financial entities purchased 89.6 percent of prevailing flow FTRs, down 0.9 percentage points, and 97.8 percent of counter flow FTRs, up 0.5 percentage points, with the results that financial entities purchased 93.0 percent, unchanged, of all annual FTR auction cleared buy bids for the 2025/2026 planning period.

Table 13-14 Annual FTR Auction patterns of ownership by FTR direction: 2025/2026 planning period

			FTR Direction		
Trade Type	Organization Type	Self-Scheduled FTRs	Prevailing Flow	Counter Flow	All

	Total		100.0%	100.0%	100.0%

Table 13-15 shows the HHI values for cleared buy and self scheduled bids for the 2016/2017 through 2025/2026 Annual FTR Auctions. Obligation buy bids are consistently unconcentrated, while Option buy bids are unconcentrated to moderately concentrated. Cleared self scheduled bids are always highly concentrated.

Table 13-15 Annual auction HHIs by auction

Auction	Offset Type	Trade Type	HHI

Total	100.0%	100.0%	100.0%

Market Performance

Volume

PJM regularly intervenes in the FTR market based on subjective judgment which is not based on clear or documented guidelines. Such intervention in the FTR market, or any market, is not appropriate and not consistent with the operation of competitive markets. In an apparent effort to manage FTR revenues, PJM may adjust normal transmission limits in the FTR auction model. If, in PJM's judgment, the normal transmission limit is not consistent with revenue adequacy goals and simultaneous feasibility, then transmission limits are reduced pro rata based on the MW of Stage 1A infeasibility and the availability of auction bids for counter flow FTRs.[36] PJM may also remove or reduce infeasibilities caused by transmission outages by clearing counter flow bids without being required to clear the corresponding prevailing flow bids.[37] The use of both of these procedures is contingent on the conditions that: PJM actions not affect the revenue adequacy of allocated ARRs; all requested self scheduled FTRs clear; and net FTR auction revenue is positive.

Long Term FTR Auction

In the 2025/2028 Long Term FTR Auction, 465,963 MW (23.5 percent of bid volume; 50.4 percent of total FTR volume) of counter flow FTR buy bids cleared, an increase from 304,456 MW and an increase from 47.7 percent of total FTR volume. In the same auction, prevailing flow FTR buy bids cleared 457,906 MW (9.6 percent of bid volume; 49.6 percent of total FTR volume) an increase from 334,216 MW and a decrease from 52.3 percent of total FTR volume. In the 2025/2028 Long Term FTR Auction, 57,108 MW (8.5 percent) of counter flow sell offers and 111,744 MW (12.6 percent) of prevailing flow sell offers cleared.

Figure 13-3 shows the percent of FTR MW cleared, and bid and cleared volume, by direction, for each round of the Long Term FTR Auction from the 2015/2018 through the 2025/2028 auctions.

36 See "PJM Manual 6: Financial Transmission Rights," Rev. 34 (May 21, 2025).
37 See *id.*

Figure 13-3 Long Term FTR Auction bid and cleared volume by round and direction

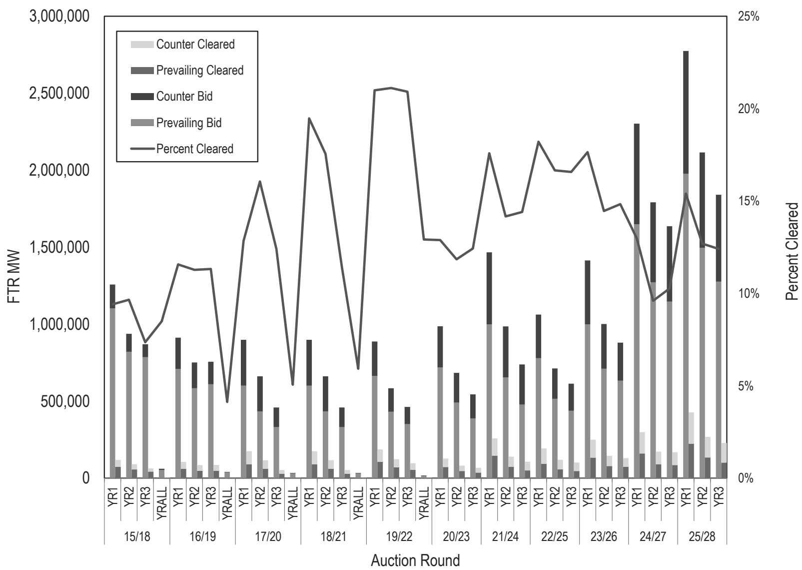

Table 13-21 compares cleared FTR obligations (not options) acquired in the Long Term FTR Auctions to the total cleared FTR obligations from the Annual FTR Auction, for FTRs in the 2014/2015 through 2025/2026 planning periods. A three year FTR is distributed to each individual planning period during its three year effective period. Long term FTRs that are effective in a single planning period were an average of 39.9 percent of total FTR volume in the 2014/2015 through 2025/2026 planning periods.

Table 13-21 Long Term and Annual Auction total cleared FTR MW

	Long Term FTR Product (Including YRALL)			Obligation Volume (MW)		
Effective Planning Period	YR3	YR2	YR1	Total Long Term	Annual (including self scheduled)	Long Term Percent of Total Cleared
2014/2015	81,666	86,754	131,911	300,330	356,522	45.7%
2015/2016	89,419	99,329	123,400	312,148	355,682	46.7%

Annual FTR Auction

Table 13-23 shows the annual FTR auction market volume for the 2025/2026 Annual FTR Auction. Total FTR buy bids were 6,628,872 MW, up 39.8 percent from 4,741,013 MW for the previous Annual FTR Auction. For the 2025/2026 Annual FTR Auction 1,294,688 MW (19.5 percent) of buy bids cleared, up 29.6 percent from 999,108 MW (21.1 percent) for the previous Annual FTR Auction. There were 1,695,004 MW of sell offers, up 44.5 percent from 1,172,749 for the previous Annual FTR Auction. For the 2025/2026 Annual FTR Auction 183,410 MW (10.8 percent) of sell offers cleared, up 47.6 percent from 124,227 for the previous Annual FTR Auction. The total volume of cleared buy and self scheduled bids was 1,324,299 MW, up 28.8 percent from 1,028,420 MW in the previous Annual FTR Auction.

Figure 13-4 shows the percent of FTR MW cleared and bid and cleared volume, by direction, for each round of the Annual FTR Auction from the 2015/2016 planning period through the 2025/2026 planning period.

Figure 13-4 Annual FTR Auction bid and cleared volume by round and direction

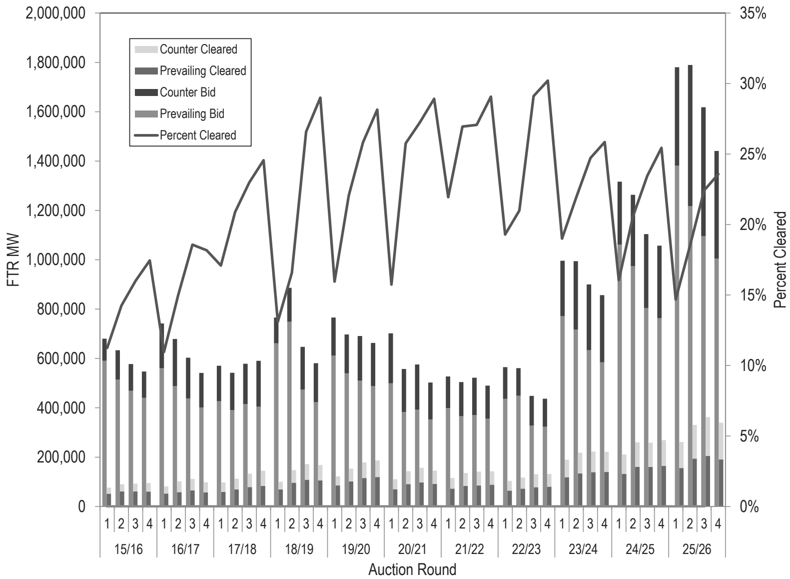

Figure 13-5 shows the proportion of ARRs self scheduled as FTRs for the last sixteen planning periods. The maximum possible level of self scheduled FTRs is equal to total ARRs. Eligible participants self scheduled 29,611MW (25.9 percent) of ARRs as FTRs for the 2025/2026 planning period, compared to 29,312 MW (25.3 percent) in the previous planning period.

Figure 13-5 Comparison of self scheduled FTRs: 2009/2010 through 2025/2026 planning periods

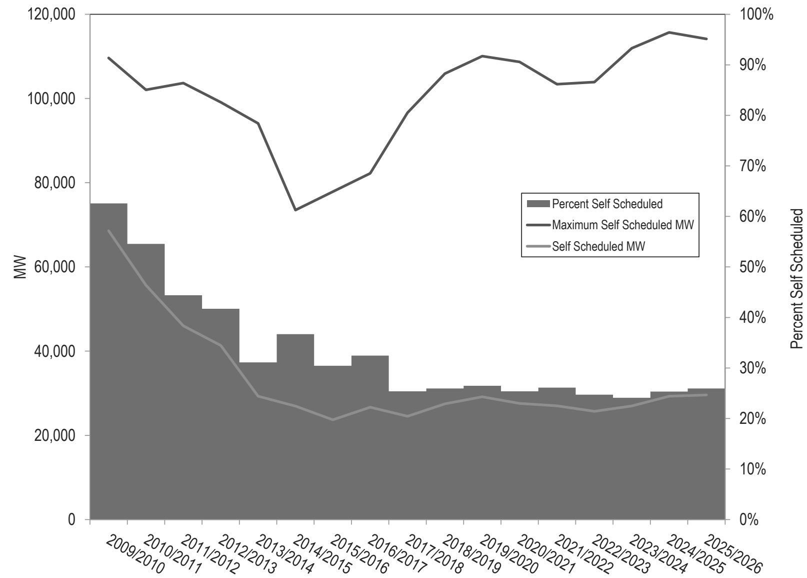

Table 13-24 shows the MW proportion of FTRs by source and sink node type for cleared buy and self scheduled bids in the 2025/2026 Annual FTR Auction.

Generator to generator FTRs comprise 60.1 percent of all cleared FTR buy and self scheduled bids in the 2025/20265 Annual Auction, up 2.4 percentage points from the previous planning period. Generator to generator FTRs make up a disproportionate share of total FTRs. Congestion results from load paying more for generation than generators receive. By definition, congestion is between generator sources and load sinks. Generator to generator paths do not represent the delivery of generation to load. FTRs between generators simply create a speculative opportunity because they can be a low cost or zero cost FTR in the current design with a significant payoff if there is a price difference between the two nodes.

The MMU recommends that PJM examine the source and sink node combinations available in the FTR market and eliminate generation to generation paths and all other paths that do not represent the delivery of power to load.

Table 13-24 Annual auction FTR node type matrix by proportion of MW: 2025/2026 auction

Monthly Balance of Planning Period Auctions

Table 13-25 provides the monthly balance of planning period FTR auction market volume for the first four months of the 2025/2026 and entire 2024/2025 planning periods. There were 35,598,375 MW of FTR obligation buy bids and 38,689,011 MW of FTR obligation sell offers for all bidding periods in the first four months of the 2025/2026 planning period.[38] The monthly balance of planning period FTR auction cleared 7,547,143 (21.8 percent) of FTR obligation buy bids and 4,481,377 MW (15.6 percent) of FTR obligation sell offers.

There were 14,314,021 MW of FTR option buy bids and 3,041,545 MW of FTR option sell offers for all bidding periods in the Monthly Balance of Planning Period FTR Auctions for the first four months of the 2025/2026 planning period. The monthly balance of planning period FTR auction auctions cleared 462,972 MW (3.2 percent) of FTR option buy bids and 607,814 MW (20.0 percent) of FTR option sell offers.

38 The term obligation is used only to distinguish FTRs from options.

Table 13-25 Monthly Balance of Planning Period FTR Auction market volume: June 2025 through September 2025

Monthly Auction	Type	Trade Type	Bid and Requested Count	Bid and Requested Volume (MW)	Cleared Volume (MW)	Cleared Volume	Uncleared Volume (MW)	Uncleared Volume
Jun-25	Obligations	Buy bids	1,524,117	10,459,179	1,857,497	17.8%	8,601,683	82.2%
		Sell offers	1,672,291	7,831,025	1,599,672	20.4%	6,231,353	79.6%

*Shows 12 months for 2024/2025 **Shows 4 months for 2025/2026

Figure 13-6 shows the bid volume from each monthly auction for each period of the Monthly Balance of Planning Period FTR Auctions of the first four months of the 2025/2026 planning period. The prompt month is the final month for which FTRs for a specific month are sold. For example, June is the prompt month for June FTRs sold in the June auction, which occurs in May. The bid volume for the non-prompt months is significantly lower than for the prompt months. On average, the non-prompt month bid volume is 58.8 percent of the prompt month bid volume.

Figure 13-6 Monthly Balance of Planning Period FTR Auction bid volume (MW per period): June 2025 through September 2025 Auction

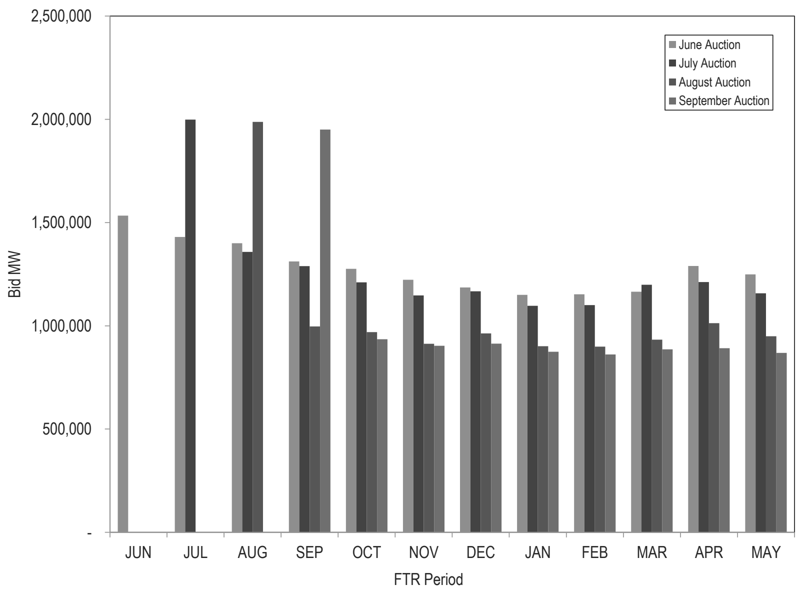

Figure 13-7 Monthly Balance of Planning Period FTR Auction cleared volume (MW per period): June 2025 through September 2025 Auction

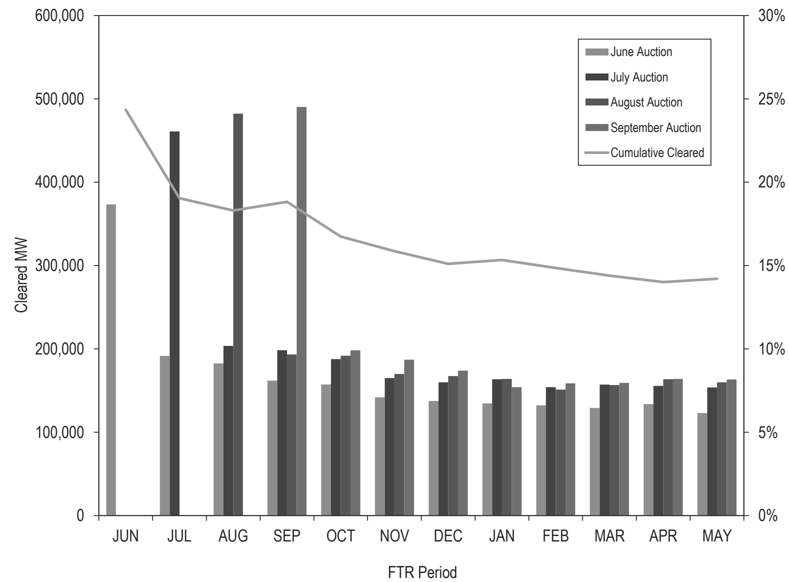

Figure 13-7 shows the cleared volume from each monthly auction for each period of the Monthly Balance of Planning Period FTR Auctions of the first four months of the 2025/2026 planning period. The cleared volume for non-prompt months is also significantly lower than in prompt months. On average, the non-prompt months cleared volume is 36.5 percent of the prompt month cleared volume.

Figure 13-8 shows the FTR bid, net bid and cleared volume from June 2003 through September 2025 for Long Term, Annual and Monthly Balance of Planning Period Auctions. Cleared volume includes FTR buy and sell offers that were accepted. The net bid volume includes the total buy, sell and self scheduled offers, counting sell offers as a negative volume. The bid volume is the total of all bid and self scheduled offers, excluding sell offers. Following the implementation of the Historical Simulation Initial Margining (HSIM) analysis model in the September 2022 Monthly Auction, bid and net bid volumes have increased significantly. On average in the first four months of the 2025/2026 planning period there was a 47.7 percent increase in bid volume and a 66.3 percent increase in net bid volume compared to the same month in the previous planning period.

Figure 13-8 Long Term, Annual and Monthly FTR Auction bid and cleared volume: June 2003 through September 2025

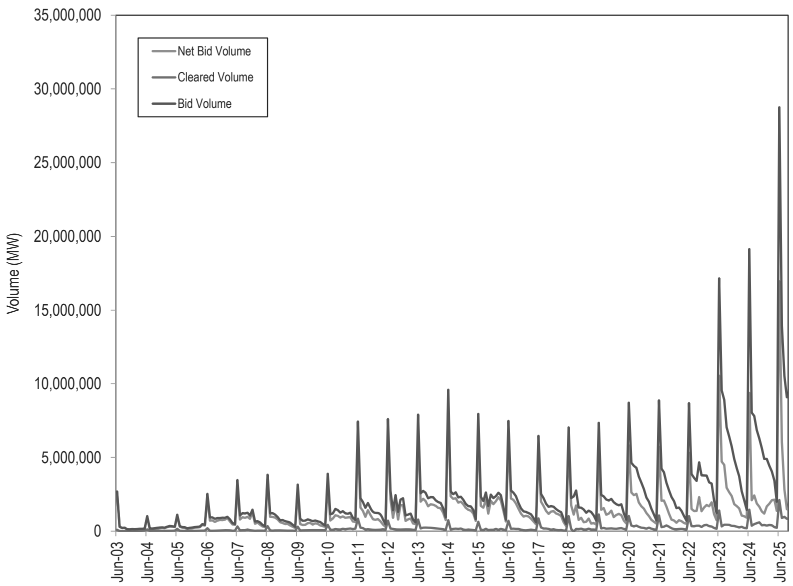

Figure 13-9 Cleared auction volume (MW) as a percent of total FTR cleared volume by calendar month: June 2004 through September 2025

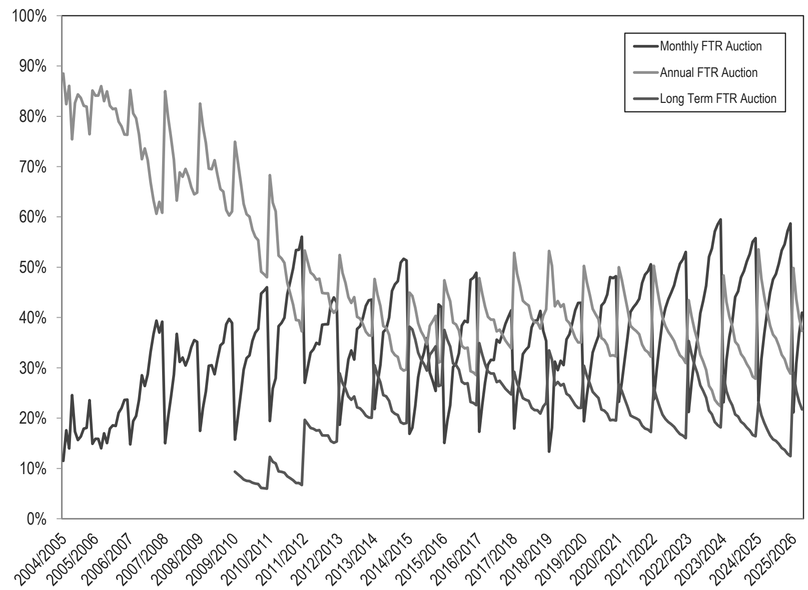

Figure 13-9 shows cleared auction volumes by auction type as a percent of the total FTR cleared volume by calendar months for June 2004 through September 2025. FTR volumes are included in the calendar month they are effective, with long term and annual FTR auction volumes spread equally to each month in the relevant planning period. Over the course of each planning period an increasing number of Monthly Balance of Planning Period FTRs are purchased, resulting in a greater share of total FTRs. When the Annual FTR Auction occurs, FTRs purchased in previous Monthly Balance of Planning Period Auctions, other than the current June auction, are no longer effective, resulting in a smaller share for monthly and a greater share for annual FTRs.

Bilateral Market

Table 13-26 provides the PJM registered secondary bilateral FTR market volume for the first four months of the 2025/2026 and the entire 2024/2025 planning periods. Market participants can buy and sell existing FTRs, outside of the auction process, through a voluntary bulletin board, termed the PJM bilateral market. FTRs can also be exchanged bilaterally without using the bulletin board. Prior to June 30, 2024, there was no requirement to report accurate detailed information about bilateral transactions settled through PJM billing systems. Effective June 30, 2024, the Commission accepted PJM's proposed revisions to the rules that required the reporting of bilateral price information and corroborating contract documents of any bilateral change of FTR ownership between participants/accounts that is settled through

PJM settlement systems.[39] Bilateral transactions remain dependent on the contract established between the parties. PJM has no knowledge of bilateral transactions, or the terms and risks of bilateral transactions, that are done outside of PJM's bilateral market system. As a result, the bilateral data are not a reliable basis for evaluating actual bilateral activity in PJM FTRs.

In the first four months of the 2025/2026 planning period there were no bilateral transactions for FTRs that were originally acquired in the 2025/2026 Auction or the Monthly Balance of Planning Period auctions. In the 2024/2025 planning period, there were eight total pairs of bilateral trading participants, three pairs of unaffiliated participants and 121 total bilateral FTR transactions.

Table 13-26 Secondary bilateral FTR market volume: 2024/2025 and 2025/2026 planning periods[40]

Planning Period	Type	Class Type	Volume (MW)
2024/2025	Obligation	24-Hour	1,196.4

*First four months of 2025/2026

39 *See* 187 FERC ¶ 61,020.
40 The 2024/2025 planning period covers bilateral FTRs that are effective for any time between June 1, 2024 through May 31, 2025, which originally had been purchased in a Long Term FTR Auction, Annual FTR Auction or Monthly Balance of Planning Period FTR Auction.

Price

Table 13-27 shows the cleared, weighted average prices by trade type, FTR direction, period type and class type for the 2025/2028 Long Term FTR Auction. Only FTR obligation products (no options) are available in the Long Term FTR Auctions. In this auction, weighted average buy bid counter flow and prevailing flow FTR prices were -$0.82 and $0.99, compared to -$0.55 and $0.64 from the 2024/2027 Long Term FTR Auction. Weighted average sell bid counter flow and prevailing flow FTR prices were -$0.79 and $0.73, compared to -$0.66 for counter flow FTRs and $0.64 for prevailing flow FTRs for the 2024/2027 Long Term FTR Auction.

Table 13-27 Long Term FTR Auction: weighted average cleared prices (Dollars per MW): 2025/2028 auction

			Class Type				
Trade Type	FTR Direction	Period Type	24-Hour	On Peak	Weekend On Peak	Daily Off Peak	All
Buy bids	Counter Flow	Year 1	($2.93)	($0.36)	($0.74)	($0.60)	($0.82)

		Total	$2.02	$2.21	$1.48	$0.98	$1.68

Table 13-29 shows the cleared buy bid volume, cleared buy bid revenue and cleared revenue/cleared MW for the last twelve planning periods. In the 2014/2015 planning period the $/MW increased significantly from the 2013/2014 planning period due to PJM's decisions to limit capacity through conservative modeling. In the 2017/2018 Annual FTR Auction, the $/MW decreased to lower than 2013/2014 levels, due in part to the partial relaxation of PJM's conservative modeling practices due to the reassignment of balancing congestion and M2M payments to load and exports. This reduction continued into the 2019/2020 planning period. Due to the more restrictive modeling for the 2022/2023 planning period (relative to the 2021/2022 planning period), quantities and revenue were similar to 2016/2017 levels, when PJM was restricting the FTR market to account for balancing congestion. The reassignment of balancing congestion and M2M payments to load did not increase the per MW value of ARRs.

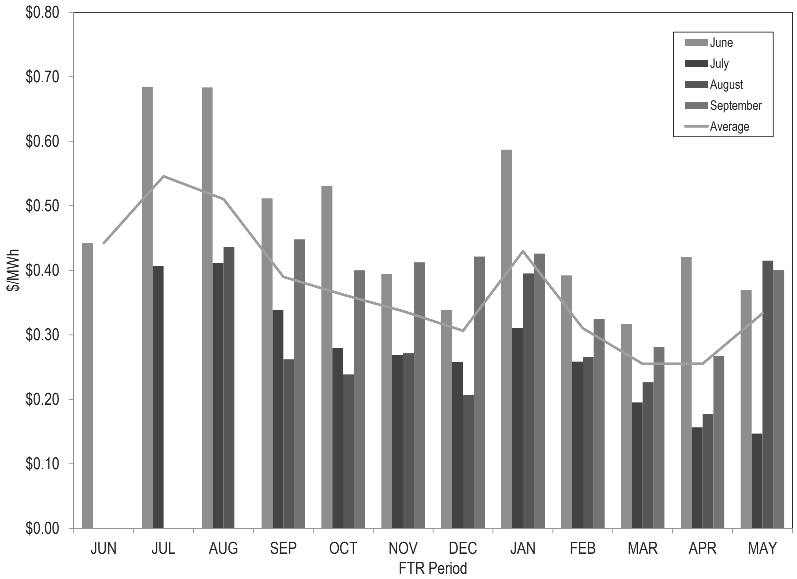
The 2023/2024 Annual FTR Auction was the first Annual FTR Auction to use the HSIM model. Following the high revenue from the 2022/2023 planning period, and the implementation of the HSIM model, the 2023/2024 Annual FTR Auction cleared buy bid volume increased by 75.9 percent. For the 2023/2024 Annual FTR Auction, the cleared buy bid volume increased 75.9 percent, total buy bid revenue decreased 12.6 percent, and buy bid revenue per MW decreased 50.1 percent. For the 2024/2025 Annual FTR Auction, cleared buy bid volume increased 17.4 percent, total buy bid revenue decreased 1.7 percent, and buy bid revenue per MW decreased 16.3 percent. In the 2025/2026 Annual FTR Auction, cleared buy bid volume increased by 29.6 percent, and buy bid revenue increased by 34.2 percent compared to the previous annual FTR auction.

Table 13-29 Cleared volume, revenue and $/MW: 2012/2013 through 2025/2026 Annual FTR Auction

	Buy Bid Volume	Cleared Buy Bid Volume	Percent Cleared	Buy Bid Revenue (millions)	Buy Bid Revenue ($/MW)
2012/2013	2,520,119	329,578	13.1%	$389.1	$1,181
2013/2014	3,245,033	391,148	12.1%	$382.5	$978
2014/2015	3,243,346	338,879	10.4%	$506.3	$1,494
2015/2016	2,437,964	354,630	14.5%	$620.5	$1,750
2016/2017	2,565,494	393,509	15.3%	$615.8	$1,565
2017/2018	2,281,534	488,734	21.4%	$406.5	$832
2018/2019	2,880,105	587,628	20.4%	$635.7	$1,082
2019/2020	2,787,716	611,878	21.9%	$649.0	$1,061
2020/2021	2,336,551	556,034	23.8%	$449.6	$809
2021/2022	2,043,408	535,277	26.2%	$519.0	$970
2022/2023	1,984,377	483,988	24.4%	$1,096.3	$2,265
2023/2024	3,746,935	851,248	22.7%	$957.9	$1,125
2024/2025	4,741,013	999,108	21.1%	$941.4	$942
2025/2026	6,628,872	1,294,688	19.5%	$1,263.6	$976

Figure 13-10 shows the weighted average cleared buy bid price of obligations in the Monthly Balance of Planning Period FTR Auctions by bidding period for the first four months of the 2025/2026 planning period and the average price per MWh for each of the FTR periods. The average price per MWh across all bidding periods for the first four months of the 2025/2026 planning period was $0.36.

Figure 13-10 Monthly Balance of Planning Period FTR Auction cleared weighted-average buy bid price per period (Dollars per MWh): 2025/2026 planning period



Profitability

FTR profitability is the difference between the revenue received directly from holding an FTR plus any revenue from the sale of an FTR, and the cost of the FTR. FTR profitability is relevant only to participants purchasing FTRs and is not relevant to self scheduled FTRs. For a prevailing flow FTR, the FTR revenue is the actual revenue that an FTR holder is paid as the target allocation plus the auction price from the sale of the FTR, if relevant, and the FTR cost is the auction price. For a counter flow FTR, the FTR revenue is the auction price that an FTR holder is paid to take the FTR plus the positive auction price from the sale of the FTR, if relevant, and the FTR cost is the target allocation that the FTR holder must pay plus the negative auction price from the sale of the FTR, if relevant. Profits include the payment of surplus to FTRs. Bilateral transactions are excluded from the profit calculations. Bilateral profits and losses net to zero in market total profits and losses. ARR holders that self schedule FTRs receive congestion revenues but do not receive profits from those FTRs because ARR holders are assigned the rights to congestion revenues which they choose to take directly as the congestion payments associated with the corresponding FTRs.

Profits in the first four months of the 2025/2026 planning period include the auction cost and revenue from both buying and selling FTRs that were effective from June 2025 through September 2025. This includes FTRs from the 2023/2026, 2024/2027 and 2025/2028 Long Term auctions, the 2025/2026 Annual auction, and the Monthly auctions from June 2025 through September 2025. The costs and revenues of the yearly FTR products are prorated based on the period of the FTRs. Any revenues or costs related to bilateral transactions are not included in profits.

Hourly FTR profits are the sum of the hourly revenues minus the hourly costs for each FTR. The hourly revenues equal any positive hourly FTR target allocations, adjusted by the payout ratio plus any hourly auction revenues from the sale and/or the purchase of the FTR. The hourly auction costs equal any negative hourly FTR target allocations plus any hourly auction costs from the purchase and/or the sale of the FTR. The hourly auction costs and auction revenues are the product of the FTR MW and the auction price divided by the period of the FTR in hours. The FTR revenues do not include after the fact adjustments which are very small and do not occur in every month.

The surplus includes surplus day-ahead congestion revenue and FTR auction surplus. The surplus is first allocated to FTR holders to cover any shortfall in paying FTR target allocations for the current month or prior months in the planning period. A negative surplus (shortfall) at the end of the planning period is a deficiency that is charged as FTR uplift to FTR holders. The end of planning period surplus or uplift was distributed to FTR holders prorata based on FTR positive target allocations through the 2017/2018 planning period. Beginning with the 2018/2019 planning period, any surplus is given to FTR holders only up to FTR target allocations within the planning period, and, after any surplus assigned to FTRs, the net surplus at the end of the planning period is distributed to ARR holders. Profits include any surplus distribution or uplift payments that was used to satisfy any shortfall in FTR target allocations.

The fact that FTR profits in each planning period have been positive for financial entities as a group, regardless of the payout ratio, raises questions about the competitiveness of the market. FTR profits for financial entities were not positive in the 2019/2020 planning period when accounting for GreenHat losses, but were positive otherwise. FTR profits for financial entities without GreenHat losses were positive in every planning period from 2012/2013 through 2025/2026 except the 2016/2017 planning period, and were positive if summed over the entire period. Financial entities have been much more profitable than physical and physical ARR entities combined except for the 2015/2016 and the 2016/2017 planning periods (Table 13-33). It is not clear, in a competitive market, why FTRs remain persistently profitable for financial entities and much more profitable for financial entities than for other participants. In a competitive market, it is be expected that profits would be competed to zero.

Table 13-30 lists FTR profits, and the congestion returned through self scheduled FTRs, by organization type and FTR direction in the first four months of the 2025/2026 planning period. All physical participants who were assigned ARRs are classified as physical. Some participants that are not eligible for ARRs are classified as physical because they are physical participants, for example companies that own only generation.

In the first four months of the 2025/2026 planning period, physical participants, including physical ARR and IARR participants, received $93.0 million in profits on FTRs purchased directly (not self scheduled), up from $36.4 million profits in the same time period in the 2024/2025 planning period. Financial participants, including financial IARR participants, received $352.8 million in profits, up from $315.4 million in profits in the same time period in the 2024/2025 planning period.[41] Some IARRs owned by financial participants were self scheduled as FTRs, which lost $18,821. Self scheduled FTRs have zero cost. Physical ARR holders who self scheduled FTRs received $413.1 million in congestion revenues, up from $191.9 million in revenue in the same time period in the 2024/2025 planning period. Revenues from self scheduled FTRs are a return of congestion to the load that paid the congestion and are not profits. Since the revenue from self scheduled FTRs is not profit it is excluded from the other tables in the profitability section.

41 There are financial participants who hold IARRs. The IARRs held by the financial participants were originally assigned to transmission upgrades associated with generation interconnection projects where the participant subsequently sold the associated physical assets (generation units) but kept the associated IARRs. Since these participants have not offered MW into the physical energy or capacity market and currently only hold financial positions, they are currently classified as financial participants.

Table 13-30 FTR profits and revenues by organization type and FTR direction: June through September, 2025/2026

	Purchased FTRs Profit			Self Scheduled FTRs Revenue Returned		
Organization Type	Prevailing Flow	Counter Flow	Total	Prevailing Flow	Counter Flow	Total
Financial	$330,428,744	$22,395,055	$352,823,799	($18,821)		($18,821)
Physical	$52,812,454	$2,427,098	$55,239,552			
Physical ARR	$47,419,767	($9,700,744)	$37,719,023	$412,987,270	$102,401	$413,089,670
Total	$430,660,964	$15,121,410	$445,782,374	$412,968,448	$102,401	$413,070,849

Table 13-31 compares the revenue from self scheduled FTRs and the ARR target allocation if the self scheduled FTRs were held as ARRs. Table 13-31 shows whether the self scheduled FTR holders were better off by self scheduling compared with holding ARRs. In the first four months in the 2025/2026 planning period, the total revenue returned to self scheduled FTRs was $413.1 million. If the self scheduled FTRs were held as ARRs, they would have received $251.2 million in ARR target allocation, or only 60.8 percent of the revenue received from self scheduled FTRs. One self scheduled FTR holder accounted for $336.9 million, or 81.6 percent, of the total revenue received by all self scheduled FTRs in the first four months of the 2025/2026 planning period.

Table 13-31 Self scheduled FTR revenues and unrealized ARR target allocation: June – September 2025/2026

	Self Scheduled FTRs Revenue Returned			Unrealized ARR Target Allocation		
Organization Type	Prevailing Flow	Counter Flow	Total	Prevailing Flow	Counter Flow	Total
Financial	($18,821)		($18,821)	$85,131		$85,131
Physical						
Physical ARR	$412,987,270	$102,401	$413,089,670	$251,163,661	($33,951)	$251,129,709
Total	$412,968,448	$102,401	$413,070,849	$251,248,791	($33,951)	$251,214,840

Table 13-32 lists the monthly FTR profits for the 2024/2025 planning period and the first four months of the 2025/2026 planning period by organization type. In the first four months of the 2025/2026 planning period, profits for all participants were $445.8 million, up from $351.8 million in profits in the same time period in the 2024/2025 planning period and the highest level of profits since the 2012/2013 planning period. The increase in profits is due to the increase in FTR volume. July had the largest monthly profit in the first four months of the 2025/2026 planning period, $221.5 million. August had the smallest monthly profit, $30.4 million. The largest month to month increase in profits in the first four months of the 2025/2026 planning period was in June, an increase of $76.4 million. Among organization types, financial organizations' profits were the largest, $352.8 million, or 79.1 percent of the market's total profits. Physical ARR organizations had the largest increase in profits, $37.7 million, up from a loss of $9.9 million, although their profits were the smallest among organization types.

Table 13-32 Monthly FTR profits by organization type: 2024/2025 through September 2025/2026

	Organization Type			
Month	Financial	Physical	Physical ARR	Total
Jun-24	$47,118,337	($625,023)	($6,496,086)	$39,997,228

Summary for Planning Period 2025/2026				
Total	$352,823,799	$55,239,552	$37,719,023	$445,782,374

Table 13-33 lists the historical profits by planning period by organization type beginning in the 2012/2013 planning period for purchased FTRs. (Profits do not include congestion revenue to self scheduled FTRs.) The rules governing the allocation of surplus are described later in this section.

Table 13-33 FTR profits by organization type: 2012/2013 through 2025/2026

		2012/2013	2013/2014	2014/2015	2015/2016	2016/2017	2017/2018	2018/2019	2019/2020	2020/2021	2021/2022	2022/2023	2023/2024	2024/2025	2025/2026

* The first four months of the 2025/2026 planning period

Table 13-34 shows the profits and losses of the five most and the five least profitable participants by ownership type. Total MWh is the sum of all MWh by ownership type regardless of profitability. The Top 5 Profit is the sum of the profits of the five most profitable participants by ownership type. The Top 5 Profit/MWh is the Top 5 Profit divided by the sum of the MWh of the top 5 participants by ownership type. The Top 5 Market Share of MWh is the sum of the MWh of the top 5 participants by ownership type divided by Total MWh of that ownership type. The Top 5 Profit Share Among Profitable Participants is the Top 5 Profit divided by the sum of the profits of all profitable participants by ownership type. The same logic applies for the statistics related to the Bottom 5 participants. The All row considers all ownership types when selecting the Top 5 and Bottom 5 participants.

The sum of the Top 5 financial participants' profits was the largest of all the ownership types, $142.6 million, while the sum of the Top 5 physical ARR participants' profits (excluding self-scheduled FTRS) was the smallest, $47.9 million. While having the smallest sum of profits, the Top 5 physical ARR's sum of profit increased the most by $39.0 million, or 437.7 percent increase. Each of the ownership type's top 5 profit increased in the first four months of the 2025/2026 planning period compared with the same time period in the 2024/2025 planning period. The Bottom 5 financial participants' sum of losses was the largest while their loss per MWh was the smallest. Only the Bottom 5 physical ARR participants' sum of losses decreased in the first four months of the 2025/2026 planning period compared with the same time period in the 2024/2025 planning period. When all participants across ownership types are considered, three of the Top 5 participants and three of the bottom 5 participants were financial participants. Overall, the five most profitable participants' profits and profits per MWh increased and the five least profitable participants' losses and losses per MWh decreased in the first four months of the 2025/2026 planning period compared with the same time period in the 2024/2025 planning period.

There are participants who have had persistent losses for multiple years. It is possible for PJM FTR participants to have complementary positions in other trading platforms such as the Intercontinental Exchange (ICE) or Nodal Exchange or in other products in the PJM market.

Table 13-34 Top 5 and bottom 5 FTR profits by ownership type: June through September, 2025/2026

Organization Type	Total MWh	Top 5 Profit	Top 5 Profit/MWh	Top 5 Market Share in MWh	Top 5 Profit Share Among Profitable Participants	Bottom 5 Loss	Bottom 5 Loss/MWh	Bottom 5 Market Share in MWh	Bottom 5 Loss Share Among Unprofitable Participants
Financial	1,952,886,625	$142,646,228	$0.56	13.2%	38.3%	($10,227,620)	($0.05)	9.9%	51.2%
Physical	61,364,232	$56,436,089	$1.61	57.1%	92.4%	($5,129,464)	($1.22)	6.8%	88.0%
Physical ARR	108,475,404	$47,936,960	$0.69	64.0%	96.3%	($7,028,377)	($0.27)	23.6%	58.4%
All	2,122,726,261	$170,150,104	$0.70	11.4%	35.2%	($12,231,326)	($0.08)	7.0%	32.3%

Table 13-35 shows the shares of profitable and unprofitable participants by ownership type weighted by FTR MW in the first four months of the 2025/2026 planning period. There were more profitable participants than unprofitable participants for each organization type and for market total. Compared with the same time period in the 2024/2025 planning period, in the first four months of the 2025/2026 planning period, the share of profitable participants decreased by 8.7 percentage points from 89.6 percent to 80.8 percent. Physical ARR organizations were the only organization type whose share of profitable participants increased.

Table 13-35 Share of participants MWh by profitability by ownership type: June through September, 2025/2026

Organization Type	Unprofitable	Profitable
Financial	18.6%	81.4%
Physical	21.1%	78.9%
Physical ARR	28.6%	71.4%
Total	19.2%	80.8%

Table 13-36 shows the profits by source and sink node type in the first four months of the 2025/2026 planning period. The sink total row is the sum of all profits and losses of FTRs that have the same sink node type. The source total column is the sum of all profits and losses of FTRs that have the same source node type. The profits of generator to generator FTRs were the largest, $108.6 million in the first four months of the 2025/2026 planning period. However, the profits of generator to generator FTRs had the largest decrease in profits ($43.6 million decrease) compared with the same time period in the 2024/2025 planning period. The losses of hub to hub FTRs were the largest, a loss of $19.7 million, in the first four months of the 2025/2026 planning period.

Table 13-36 Profits by node type matrix: June through September, 2025/2026

	Sink Type								
Source Type	Aggregate	EHVAGG	Generator	Hub	Interface	Load	Residual Metered Aggregate	Zone	Source Total

Table 13-37 shows the profit per MWh by source and sink node type in the first four months of the 2025/2026 planning period. The sink total row represents the average profit per MWh of FTRs that have the same sink type. The source total column shows the average profit per MWh of FTRs that have the same source type. Interface to load FTRs had the highest profit per MWh, $11.30 per MWh. Interface to zone FTRs had the largest loss per MWh, -$2.37 per MWh. Profit per MWh of generator to generator FTRs was $0.11 per MWh, below the market average of $0.21 per MWh.

Revenue

Long Term FTR Auction Revenue

Table 13-38 shows the Long Term FTR Auction revenue data by trade type, FTR direction, period type and class type. The 2025/2028 Long Term FTR Auction netted $162,279,258 million in revenue, $59,642,543 million less (58.1 percent) than the previous Long Term FTR Auction. Buyers paid $276,421,108 million, up $86.7 million (45.7 percent), and sellers received $114,141,850 million, up $27.1 million (31.1 percent) over the previous Long Term FTR Auction.

Table 13-38 Long Term FTR Auction Revenue: 2025/2028 auction

			Class Type				
Trade Type	FTR Direction	Period Type	24-Hour	On Peak	Weekend On Peak	Daily Off Peak	All

Annual FTR Auction Revenue

Table 13-39 shows the Annual FTR Auction revenue by trade type, type, FTR direction and class type. The Annual FTR Auction for the 2025/2026 planning period generated $1,895.3 million, up 28.5 percent from $1,475.3 million in the 2024/2025 Annual FTR Auction. Counter flow FTR holders received $701.0 million, up 116.8 percent from the previous Annual FTR Auction and prevailing flow FTR holders paid $2,596.4 million, up 44.4 percent from the previous planning period.

FTRs sold in Long Term FTR Auctions are sold at a substantial discount to the same FTRs sold in Annual FTR Auctions. Table 13-40 shows the increase in total auction revenue that would have resulted for the 2014/2015 through 2025/2026 planning periods if long term FTRs were sold at annual auction clearing prices.

Long Term FTR Auction MW are determined by removing all outages and running an offline model of the previous Annual FTR Auction model with all ARR bids from the prior annual ARR allocation. Any ARR MW that clear in this offline model are reserved for ARR holders in the relevant planning periods, and are removed from the Long Term FTR Auction. But even this approach does not, and cannot, preserve all the capacity for ARR holders in the first year of the Long Term Auction. The MW purchased in the Long Term FTR Auction are made available to FTR holders before ARR holders have access to them. The result is that MW are reserved, inappropriately and for unexplained reasons, in future auctions for FTR holders. This difference provides an estimate of the value of the MW made available in the Long Term FTR Auction that are not made available to ARR holders. These MW should be made available to ARR holders in the Annual FTR Auctions where they are the most valuable. Under the current market rules, MW made available in the Long Term FTR auction are not available to ARR holders as ARRs. The MMU recommends that the Long Term FTR product be eliminated. If the Long Term FTR product is not eliminated, the Long Term FTR Market should be modified so that the supply of prevailing flow FTRs in the Long Term FTR Market is based solely on counter flow offers in the Long Term FTR Market, and not projected residual system capability based on a snapshot of prior ARR requests.

Table 13-40 Estimated additional Long Term FTR Auction revenue at Annual FTR Auction prices

	Long Term FTR Product				
Planning Period	YR3	YR2	YR1	YRALL	Total Difference
2014/2015	$59,598,642	$30,284,173	$52,030,909	$926,989	$142,840,713

Monthly Balance of Planning Period FTR Auction Revenue

Table 13-41 shows monthly balance of planning period FTR auction revenue by trade type, type and class type for the first four months of the 2025/2026 and the entire 2024/2025 planning periods. The Monthly Balance of Planning Period FTR Auctions for the first four months of the 2025/2026 planning period netted $39.9 million in revenue, the difference between buyers paying $448.4 million and sellers receiving $408.6 million. For the entire 2024/2025 planning period, the Monthly Balance of Planning Period FTR Auctions netted $79.6 million in revenue with buyers paying $671.2 million and sellers receiving $591.6 million. Revenue from obligation buy bids for the first four months of the 2025/2026 planning period was 18.0 percent compared to the same period of the 2024/2025 planning period. Revenue from obligation sell offers in the first four months of the 2025/2026 planning period was up 13.4 percent compared to the same period of the 2024/2025 planning period.

*Shows twelve months for 2024/2025 **Shows four months for 2025/2026

Table 13-42 shows the monthly balance of planning period FTR auction revenue by FTR direction and trade type for FTRs effective in each month. For example, June 2025 shows FTR auction revenue for FTRs that are effective in June that were sold in the June 2025 Auction. July 2025 shows FTR auction revenue for FTRs that are effective in July that were sold in the June 2025 Auction and the July 2025 Auction. Table 13-42 also shows the monthly Residual ARR target allocations. Residual ARR target allocations in a month should be fully funded by FTR auction revenue from FTRs that are effective in the same month.

Auction revenue from monthly FTRs effective in the first four months of the 2025/2026 plannning period was $18,138,911, down 5.0 percent from $19,102,401 in the same period of the 2024/2025 planning period. However, Residual ARR target allocations in the first four months of the 2025/2026 planinng period were $50,533,920, up 819.9 percent from $5,493,683 in the same period of the 2024/2025 planning period.

While total auction revenue from monthly FTRs effective in the first four months of the 2025/2026 planning period was down 5.0 percent, the results by FTR direction (prevailing versus counterflow) and by trade type (buy versus sell) were different. Negative auction revenue from buy bids for counter flow FTRs effective in the first four months of the 2025/2026 planning period was $241,552,054, up 95.5 percent from $123,550,174 in the same period of the 2024/2025 planing period. Positive auction revenue from sell bids for counter flow FTRs effective in the first four months of the 2025/2026 planning period was $92,257,662, up 73.1 percent from $53,298,619 in the same period of the 2024/2025 planning period. Positive auction revenue from buy bids for prevailing flow FTRs effective in the first four months of the 2025/2026 planning period was $437,190,572, up 58.2 percent from $276,368,421 in the same period of the 2024/2025 planning period. Negative auction revenue from sell bids for prevailing flow FTRs effective in the first four months of the 2025/2026 planning period was $269,757,269, up 44.2 percent from $187,014,465 in the same period of the 2024/2025 planning period. The disproportionate increase in negative auction revenue from counter flow FTRs effective in the first four months of the planning period contributed to the first ARR deficiency in the history of the ARR market in July 2025 (See Table 13-10). If PJM had sold fewer counter flow FTRs effective in July 2025, there would not have been an ARR deficiency.

Table 13-42 Monthly Balance of Planning Period FTR Auction revenue by FTR period compared to Residual ARR target allocations: 2024/2025 and 2025/2026

	Revenue From Monthly FTR Auctions By Period					
Month	Counter Flow Buy Bids	Counter Flow Sell Bids	Prevailing Flow Buy Bids	Prevailing Flow Sell Bids	All	Residual ARR Target Allocations

*First four months of the 2025/2026 planning period

FTR Target Allocations

FTR target allocations were examined separately by source and sink contribution. Hourly FTR target allocations were divided into those that were benefits and liabilities and summed by sink and by source. Figure 13-11 shows the 10 largest positive and negative FTR target allocations, summed by sink, for the first four months of the 2025/2026 planning period. The top 10 sinks that produced financial benefit accounted for 24.2 percent of total positive target allocations with the Dominion Residual Aggregate accounting for 8.8 percent of all positive target allocations. The top 10 sinks that created liability accounted for 9.8 percent of total negative target allocations with PPL accounting for 1.7 percent of all negative target allocations.

Figure 13-11 Ten largest positive and negative FTR target allocations summed by sink: June through September, 2025/2026

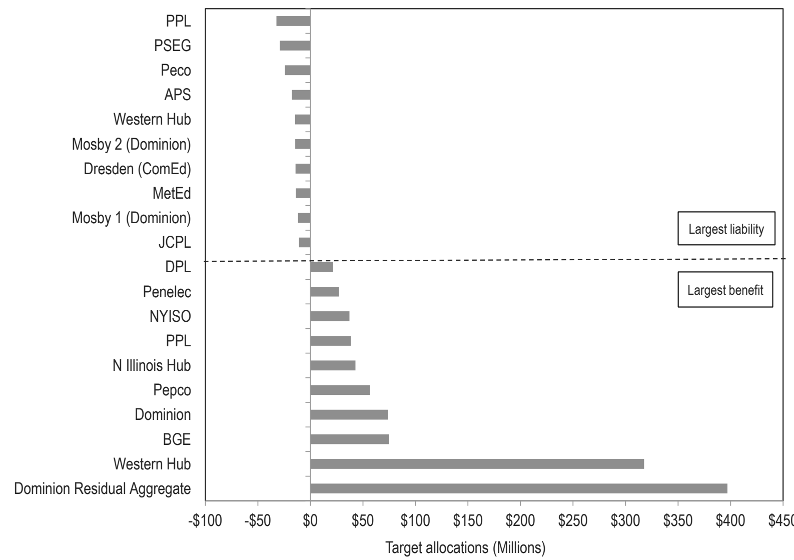

Figure 13-12 shows the 10 largest positive and negative FTR target allocations, summed by source, for the first four months of the 2025/2026 planning period. The top 10 sources with a positive target allocation accounted for 12.9 percent of total positive target allocations with Western Hub accounting for 2.5 percent of total positive target allocations. The top 10 sources with a negative target allocation accounted for 13.9 percent of all negative target allocations, with the Western Hub accounting for 8.1 percent of total negative target allocations.

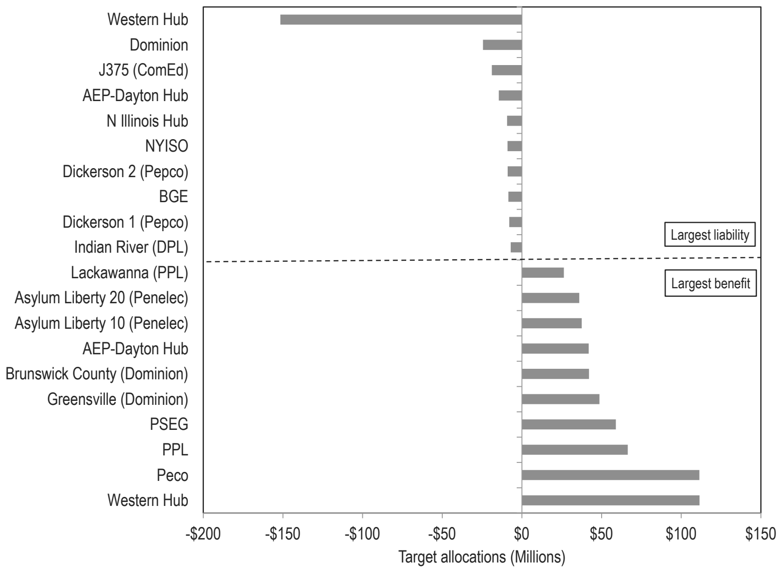
Figure 13-12 Ten largest positive and negative FTR target allocations summed by source: June through September, 2025/2026



The Effect of Fast Start Pricing on FTR Target Allocations

PJM implemented fast start pricing on September 1, 2021, and as a result, PJM produces separate dispatch and pricing market solutions. The dispatch run results in dispatch instructions and matching prices, termed dispatch run locational marginal prices, or DLMP. The DLMP prices are the prices that would have been the LMPs prior to fast start pricing. The pricing run results in the final prices used in settlements and for FTR target allocations, termed pricing run locational marginal prices, or PLMP. The two runs result in different sets of target allocations for the same FTR paths. Table 13-43 compares the target allocations that result from the pricing and dispatch runs for both self scheduled and all other FTRs for the 2021/2022 planning period through the first four months of the 2025/2026 planning period. The difference indicates whether the target allocations were increased or decreased as a result of fast start pricing.

Table 13-43 Pricing run and dispatch run FTR Target Allocations: 2021/2022 through 2025/2026 planning periods

Planning Period		Pricing Run	Dispatch Run	Difference	Percent Difference
2021/2022*	Not Self Scheduled	$1,499,077,738	$1,497,963,895	$1,113,844	0.1%
	Self Scheduled	$429,271,338	$430,800,598	($1,529,260)	(0.4%)
	Total	$1,928,349,076	$1,928,764,493	($415,416)	(0.0%)
2022/2023	Not Self Scheduled	$1,641,324,421	$1,586,284,502	$55,039,919	3.4%
	Self Scheduled	$622,535,802	$668,468,552	($45,932,751)	(7.4%)

** first four months of the 2025/2026 planning period

Surplus Congestion Revenue

Surplus congestion revenue is a misnomer. There is no such thing as surplus congestion revenue. The rights to all congestion revenue belong to load. Surplus congestion revenue, as defined in PJM rules, is an artifact of the flawed design of the current approach to FTR/ARRs. In the current design, surplus congestion revenue should be allocated to ARR holders because such revenue is part of total congestion revenues.

Based on market logic, there is no such thing as surplus FTR auction revenue. FTR Auction revenue results from the market prices paid by willing FTR buyers, should be paid to ARR holders who are the sellers, and should not be returned to FTR buyers for any reason.

Under the existing PJM rules, surplus day-ahead congestion is defined as the difference between the day-ahead congestion paid and FTR target allocations. Under the existing PJM rules, surplus FTR auction revenue is defined as the difference between the sum of monthly FTR auction revenue from the Long Term, Annual and monthly auctions, and ARR target allocations. Surplus FTR auction revenue can result from high prices in the FTR auctions, and from FTR capacity sold in excess of assigned ARR capacity on specific paths, and FTR capacity sold on paths not available to ARR holders.

Under the existing PJM rules, surplus congestion revenue is defined as the sum of the surplus day-ahead congestion revenue and the surplus FTR auction revenue at the end of each month.[42] Beginning with the 2014/2015 planning period, PJM may use surplus FTR auction revenue to pay for the clearing of counter flow FTRs as part of the auction clearing process.[43] The remaining surplus is first used to ensure that ARR target allocations in the month are fully funded. Any remaining surplus is used to pay any negative difference between day-ahead congestion revenue and FTR target allocations for the current month or prior months in the planning period. Any remaining surplus is used to pay any negative difference between day-ahead congestion revenue and FTR target allocations for the entire planning period at the end of the planning period. Any remaining surplus after that is distributed to ARR holders.[44]

If, at the end of the planning period, all the surplus congestion revenue has been provided to FTR holders and target allocations for the year are not covered, an uplift charge is assigned to FTR holders to cover the net planning period deficiency. An individual participant's uplift charge allocation is the ratio of their share of net positive target allocations to the total net positive target allocations.

Figure 13-13 shows the monthly composition of total surplus, by surplus FTR auction revenue and surplus congestion revenue from June 2017 through September 2025 as if FTRs were settled monthly, based on the congestion and FTR auction revenue in each individual month. In only two of the first four months of the 2025/2026 planning period (June and July) the day ahead congestion in that month alone was enough to pay FTR target allocations for the month. In July 2025 there was no auction surplus and ARR holders were not paid the full target allocations for the month. Months with ARR deficiencies will be funded at the end of the planning period from surplus FTR revenues if there is an FTR surplus or through an uplift charge to FTR holders if there is not an FTR surplus. Figure 13-13 shows the extent to which FTRs are funded by the auction surplus. As part of the illogic of the FTR/ARR construct and as an illustration that it is unlike any actual market, FTR buyers pay ARR holders for the rights to congestion but FTR buyers may reclaim part of their payment if actual congestion is less than they expected and not enough to cover target allocations.

The market rules should recognize that ARR holders have the right to all surplus FTR auction revenue, not just the remainder after guaranteeing that FTRs are paid target allocations. The surplus FTR auction revenue results from the prices that FTR buyers willingly paid for the rights to price differences across specific paths. The MMU recommends that all FTR auction revenue be distributed to ARR holders monthly, regardless of FTR funding levels. The MMU recommends that, under the current FTR design, all congestion revenue

42 Prior to the 2017/2018 planning period, the surplus congestion revenue was not the simple sum of the surplus FTR auction revenue and surplus day-ahead congestion because there were various cross market charges subtracted from FTR revenue, including M2M and competing use charges, which reduced available surplus congestion revenue.
43 *See* "PJM Manual 6: Financial Transmission Rights," Rev. 34 (May 21, 2025).

44 On May 31, 2018, a rule change was implemented. Effective for the 2018/2019 planning period, surplus day-ahead congestion charges and surplus FTR auction revenue that remain at the end of the Planning Period allocated to ARR holders, rather than to FTR holders. 163 FERC ¶ 61,165 (2018).

in excess of FTR target allocations be distributed to ARR holders on a monthly basis. Under the MMU recommendation, the amount represented by each bar in Figure 13-14 would be assigned to ARR holders in every month.

Figure 13-13 Monthly surplus auction revenue and surplus congestion revenue: June 2017 through September 2025[45]

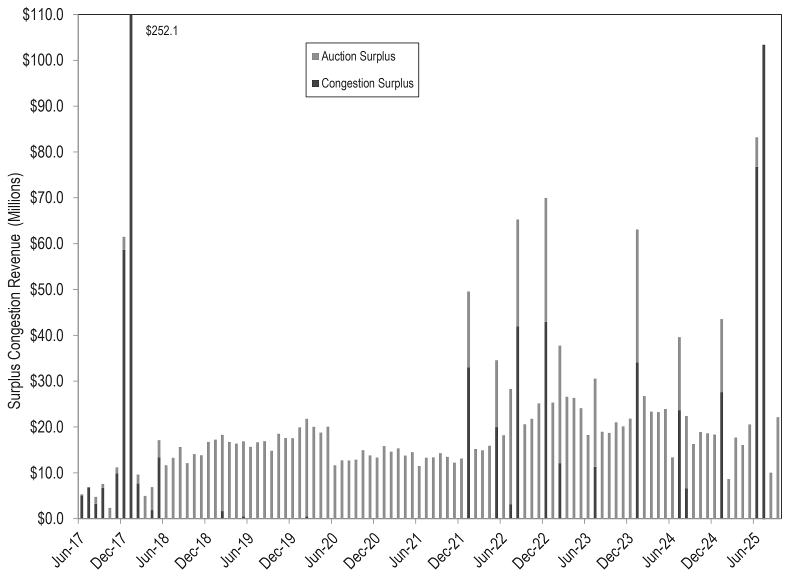

Figure 13-14 shows the increase or decrease in total accrued surplus for the planning period for each month (orange line). In Figure 13-14, if the FTR payments from the auction surplus are positive in a month (blue line above zero), that means that FTR payments in that month were dependent on FTR auction surplus from that month to cover the FTR target allocations in that month. If the change in the total accrued surplus for a month is positive, that means that there was surplus revenue (equal to the height of the orange bar) left over after paying FTR target allocations in that month from congestion or from auction revenue. This net surplus is carried until the end of the planning period and used to backfill FTR target allocations as needed before distributing to ARR holders. If the change in total accrued surplus for a month is negative, that means that were insufficient revenues, including the auction surplus, to pay FTR target allocations in that month. If the net surplus is negative at the end of the planning period, total revenue paid to FTRs will be lower than total FTR target allocations. Under the current rules, FTRs are made whole using surplus revenue from other months within the same planning period or by an uplift charge to all FTR holders at the end of the planning period. The final settlements are not known until the end of the planning period.

45 The bar for January 2018 is truncated.

In the 2024/2025 planning period there was not enough revenue from congestion plus auction surplus to pay FTR target allocations, resulting in a reduction to the entire planning period surplus of $196.2 million. ARR holders were required to subsidize FTR holders because congestion revenues were less than FTR target allocations.

In the first four months of the 2025/2026 planning period, $22.6 million of surplus auction revenue was transferred to FTR holders that would have been paid to ARR holders under the MMU's recommendation to distribute all FTR auction revenue to ARR holders every month, regardless of FTR funding levels. Day-ahead congestion increased by $548.9 million, 60.2 percent, from $912.0 million in the first four months of the 2024/2025 planning period to $1,460.9 million in the first four months of the 2025/2026 planning period. Target allocations increased by $378.6 million, 40.7 percent, from $931.2 million in the first four months of the 2024/2025 planning period to $1,309.8 million in the first four months of the 2025/2026 planning period. The actual day-ahead congestion ($1,460.9 million) was greater than the target allocations ($1,309.8 million) in the first four months of the 2025/2026 planning period. In July 2025, there was a large increase in Residual ARR target allocations without a corresponding increase in Monthly FTR Auction revenue, resulting in the first month with an ARR deficiency in the history of the ARR market. This disconnect between the ARR and FTR markets is a result of the fact that congestion is incorrectly defined as target allocations, i.e. the property rights for congestion in the current ARR/FTR market design are not correctly defined.

Figure 13-14 Monthly ARR surplus: June 2017 through September 2025[46]

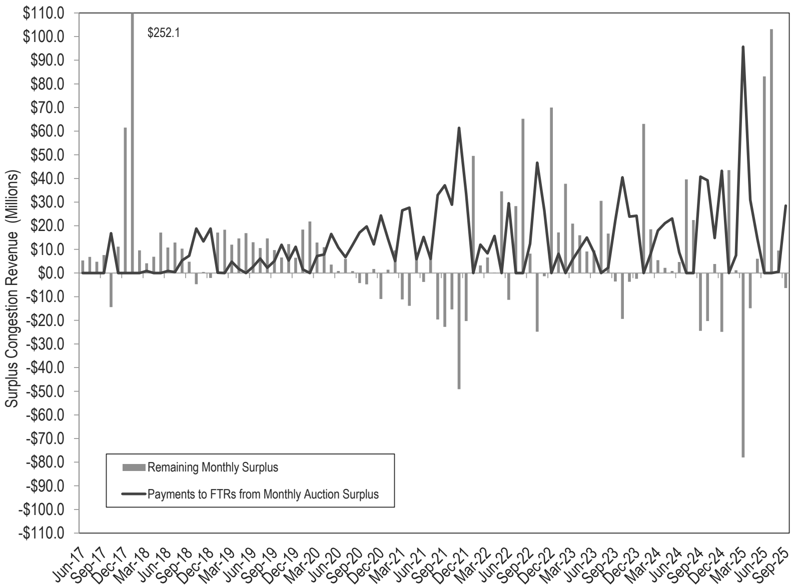

Figure 13-15 shows the surplus FTR auction revenue from the 2011/2012 planning period through the first four months of the 2025/2026 planning period. Each new planning period introduces a new FTR model, including outages and PJM's discretionary adjustments for revenue adequacy. The differences in the assumptions in the market model can result in large differences in FTR auction surplus and ARR revenue from one planning period to another. Payments to FTRs have relied on payments from the surplus rather than from day-ahead congestion. The persistent mismatch between target allocations and day-ahead congestion and the use of the surplus are another illustration of the internal illogic and incoherence of the PJM FTR/ARR design.

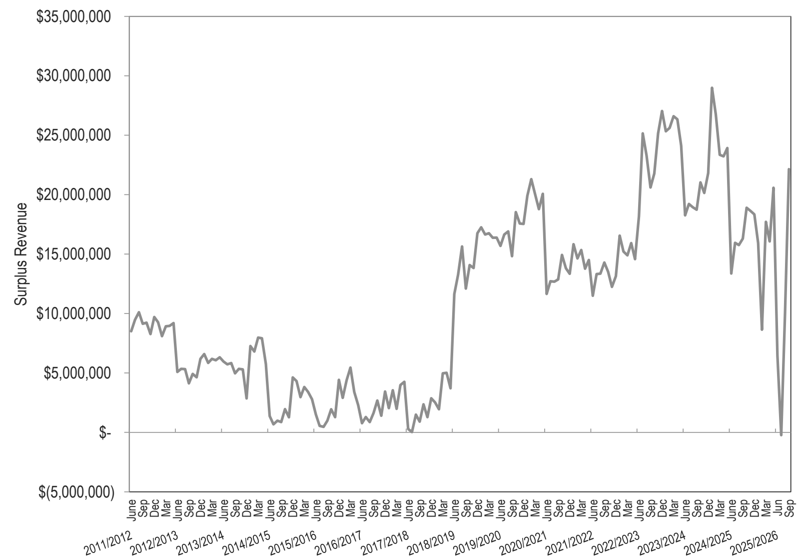
FTR auction revenue is the value that FTR buyers assign to congestion rights that belong to ARR holders. There is no logical or market based reason to assign any part of that auction revenue back to the FTR buyers. It is inconsistent with the operation of a market that sellers are required to return some of the purchase price to buyers if the purchase is less profitable for buyers than expected. Auction revenue from the sale of FTRs should be distributed directly and completely to ARR holders.

Figure 13-15 Monthly FTR auction surplus: 2011/2012 through 2025/2026 planning period



46 The bar for January 2018 is truncated.

Table 13-44 shows the surplus FTR auction revenue, surplus day-ahead congestion revenue and surplus congestion revenue for planning periods 2010/2011 through the first four months of the 2025/2026 planning period.

Table 13-44 Surplus FTR Auction Revenue: 2010/2011 through 2025/2026 planning period[47]

Planning Period	Surplus FTR Auction Revenue (Millions)	Surplus Day-Ahead Congestion (Millions)	Surplus Congestion Revenue (Millions)
2010/2011	$29.7	($1,218.7)	($449.3)
2011/2012	$108.9	($460.3)	($192.5)

"Revenue Adequacy"

FTR revenue adequacy, like surplus congestion revenue, is a misnomer. FTR revenue adequacy, as defined in PJM rules, is an artifact of the flawed design of the current approach to FTR/ARRs. If FTRs only returned congestion to FTR holders, there could be no such thing as revenue inadequacy.

As currently defined in PJM, FTR revenue adequacy simply compares day-ahead congestion revenues to FTR target allocations. (Target allocations are the day-ahead CLMP differences, shadow prices, between the source and sink of the FTR times the MW of the FTR. Congestion revenues are the day-ahead CLMP differences, shadow prices, between sources and sinks times the MW flow on the lines.) There is no reason to expect congestion revenues to equal FTR target allocations under the path based approach. There are systematic differences between FTR target allocations and actual congestion in aggregate and on a path by path basis. Revenue adequacy is not a benchmark for how well the FTR process is working. Target allocations are not congestion. FTR revenue adequacy is not equivalent to the adequacy of ARRs as an offset for load against total congestion. A path specific target allocation is not a guarantee of payment. Yet PJM treats target allocations as a guarantee of payment and takes what is termed surplus auction revenue from ARR holders (load) and gives it to FTR holders when day-ahead congestion revenues are not enough to cover all FTR target allocations.

Actual day-ahead congestion revenues are not a result of PJM's decisions about the FTR auction model, but result from the operation of the day-ahead energy market. As a result, the fewer FTRs sold, the higher the probability that congestion will exceed the sum of the FTR target allocations. For example, PJM's subjective decision to reduce available ARR/FTR supply in the ARR/FTR market model through outage selection for the 2014/2015 through 2016/2017 planning periods resulted in actual day-ahead congestion exceeding target allocations at the expense of a reduction in available ARRs and associated FTRs. PJM's decisions have included the arbitrary use of higher outage levels and the decision to include additional constraints (closed loop interfaces) both of which reduced the FTRs made available for sale in FTR auctions. PJM's

47 Total congestion surplus not equal to the sum of the columns in years prior to the 2017/2018 planning period because other charges were subtracted from the congestion surplus.

actions have led to a significant reduction in the allocation of Stage 1B and Stage 2 ARRs and therefore a reduction in available FTRs.

PJM's arbitrary decision to increase outages in the ARR allocation and in the Annual FTR Auction did not address the Stage 1A ARR over allocation issue directly because Stage 1A ARR allocations cannot be prorated. Instead, PJM's actions for the 2014/2015 through 2016/2017 planning periods resulted in decreased Stage 1B ARR allocations, decreased Stage 2 ARR allocations and decreased FTR capability. The direct assignment of balancing congestion (generally negative) and M2M payments to load beginning in the 2017/2018 planning period arbitrarily decreased congestion available for load and increased the congestion revenue available to pay FTR holders. PJM reduced the number of outages taken in the ARR allocation and in the Annual FTR Auction, increasing the supply of ARRs and FTRs. The current ARR/FTR design does not serve as an efficient way to ensure that load receives all the congestion revenues or has the ability to receive the auction revenues associated with all the potential congestion revenues. There are several reasons for the disconnect between congestion revenues and ARR/FTR revenues in the current design. The reasons include: the use of generation to load paths rather than a measure of total congestion to assign congestion revenue rights; the failure to provide to ARR holders the full system capability that is provided to FTR purchasers in the Long Term FTR Auction; unavoidable modeling differences such as emergency outages; avoidable modeling differences such as outage modeling decisions; and cross subsidies among and between FTR participants and ARR holders.

Revenue adequacy for ARRs is, for practical purposes, a meaningless concept. Revenue adequacy for ARRs means that FTR buyers collectively pay more than zero for FTRs in FTR auctions, and that those payments were received by ARR holders. For that reason, ARRs have unsurprisingly been defined to be revenue adequate for every auction to date. ARR revenue adequacy has nothing to do with the adequacy of ARRs as an offset to total congestion. ARRs can be revenue adequate at the same time that ARRs return only half of congestion to load, or even much less.

Total net FTR auction revenue for the 2024/2025 planning period, before accounting for self scheduling, load shifts or residual ARRs, was $1,664.9 million. For the first four months of the 2025/2026 planning period, total net FTR auction revenue was $1,859.0 million.

Table 13-45 presents the PJM FTR revenue detail for the 2024/2025 planning period and the first four months of the 2025/2026 planning period. This includes ARR target allocations from the Annual ARR Allocation and net revenue sources from the Long Term, Annual and Monthly Balance of Planning Period FTR Auctions.[48] In this table, under the balancing congestion and M2M payment rules, any net negative congestion revenue is from day-ahead congestion and does not include balancing congestion. Any remaining surplus will be distributed to ARR holders at the end of the planning period, while any remaining deficiency will be charged to all FTR holders as FTR uplift at the end of the planning period. The actual surplus or deficiency for the planning period is not known until the end of the planning period. In the 2024/2025 planning period and the first four months of the 2025/2026 planning period, FTRs were paid part of the ARR auction surplus to ensure the payment of the FTR target allocations.

48 The final ARR values may change if load shifts.

Table 13-45 Total annual ARR and FTR revenue detail (Dollars (Millions)): 2024/2025 and 2025/2026 planning periods

Accounting Element	2024/2025	2025/2026*
ARR Information		
ARR Target Allocations	$1,448.1	$1,859.0
ARR Credits	$1,448.1	$1,859.0

Remaining Surplus	$0.0	$189.8

*First four months of the 2025/2026 planning period

FTR target allocations are defined based on hourly CLMP differences in the day-ahead energy market for FTR paths. FTR credits are paid to FTR holders and, depending on market conditions, can be less than the target allocations but are capped at target allocations. Table 13-46 lists the FTR revenues, target allocations, credits, payout ratios, congestion credit deficiencies and excess congestion charges by month for the 2024/2025 planning period and the first four months of the 2025/2026 planning period. FTR revenues include congestion and surplus FTR auction revenue.

The total row in Table 13-46 is not the sum of each of the monthly rows because the monthly rows may include excess revenues carried forward from prior months and excess revenues distributed back from later months.

Table 13-46 Monthly FTR accounting summary (Dollars (Millions)): 2024/2025 and 2025/2026 planning periods

Period	FTR Revenues	FTR Target Allocations	FTR Payout Ratio (original)	FTR Credits (with adjustments)	FTR Payout Ratio (with adjustments)	Monthly Credits Surplus (with adjustments)	Monthly Credits Deficiency (with adjustments)

* First four months of the 2025/2026 planning period

Figure 13-16 shows the original PJM reported FTR payout ratio by month, excluding excess revenue distribution, for January 2004 through September 2025. The months with payout ratios above 100 percent have congestion revenue greater than the target allocations and the months with payout ratios under 100 percent have congestion revenue that is less than the target allocations. Figure 13-16 also shows the payout ratio after distributing surplus congestion revenue across months within the planning period. The payout ratio for months with a payout ratio less than 100 percent in the current planning period may change if surplus congestion revenue is collected in the remainder of the planning period and assigned to prior months.

Figure 13-16 FTR payout ratio by month, excluding and including excess revenue distribution: January 2004 through September 2025

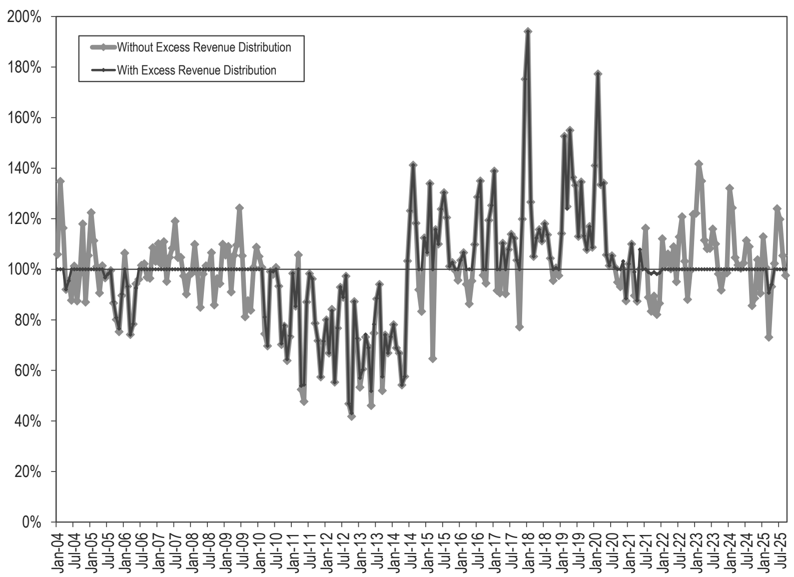

Table 13-47 shows the FTR payout ratio by planning period from the 2003/2004 planning period forward. The 2013/2014 planning period includes the additional revenue from unallocated congestion charges from Balancing Operating Reserves. Beginning with the 2018/2019 planning period payments to FTRs are limited to 100 percent of the target allocations.

The first four months of the 2025/2026 planning period had a payout ratio of 100.0 percent.

Table 13-47 Reported FTR payout ratio by planning period[49]

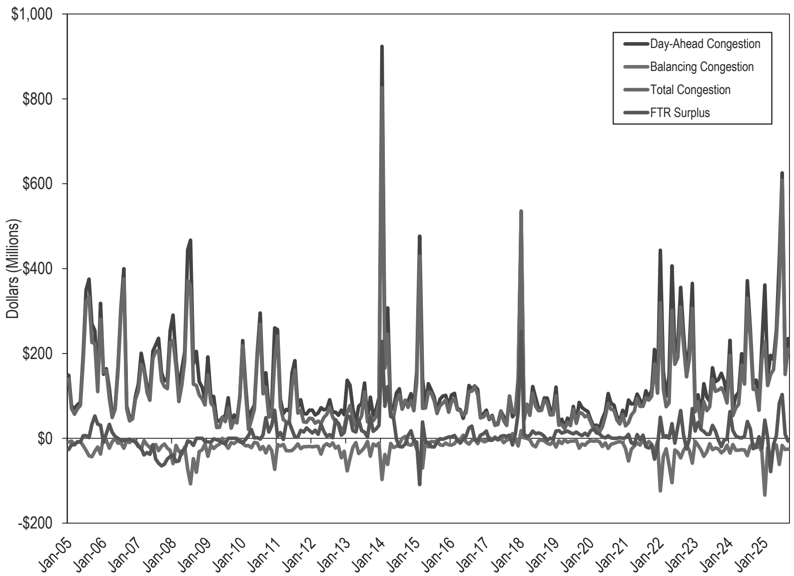
Planning Period	FTR Payout Ratio
2003/2004	97.7%
2004/2005	100.0%
2005/2006	90.7%
2006/2007	100.0%
2007/2008	100.0%
2008/2009	100.0%
2009/2010	96.9%
2010/2011	85.0%
2011/2012	80.6%
2012/2013	67.8%
2013/2014	72.8%
2014/2015	116.2%
2015/2016	106.8%
2016/2017	112.6%
2017/2018	138.5%
2018/2019	100.0%
2019/2020	100.0%
2020/2021	98.7%
2021/2022	99.0%
2022/2023	100.0%
2023/2024	100.0%
2024/2025	98.8%
2025/2026*	100.0%

*First four months of 2025/2026

49 The actual payout ratios for the 2006/2007, 2007/2008, and 2008/2009 planning periods may have exceeded 100 percent.

Figure 13-17 shows the day-ahead balancing, total congestion and the FTR surplus from 2005 through September 2025.

Figure 13-17 FTR surplus and day-ahead, balancing and total congestion: 2005 through September 2025



Target Allocations and Congestion by Constraint Do Not Match

The path based ARR/FTR market design does not align with congestion based on actual network use. A comparison of the FTR target allocations for individual constraints to the day-ahead and total congestion by constraint provides evidence of this misalignment. Total congestion is the sum of day-ahead and balancing congestion. If FTR target allocations on some paths are significantly greater than actual congestion and FTR target allocations on other paths are significantly less than actual congestion, this is evidence of a serious flaw in the design. It is evidence of a mismatch between the definition of target allocations paid to FTR holders and the congestion that is the purported source of those payments.

FTR target allocations are the result of constraints on day-ahead paths in the energy market. Any specific FTR path may be affected by multiple constraints. Constraints that result in FTR target allocations greater than the congestion that results from those constraints mean that the FTR target allocations are greater than the actual congestion. Figure 13-18 shows the constraints that are the top 10 sources of positive FTR target allocations, for first four months of the 2025/2026 planning period. Figure 13-18 also shows the corresponding day-ahead congestion and total congestion that result from the identified constraints. Constraints for which FTR target allocations were greater than total congestion resulted in $276.1 million of excess target allocations not funded by actual congestion. Such constraints include constraints in Figure 13-18, such as Lenox – North Meshoppen, which resulted in FTR target allocations that were 1.7 times larger than the corresponding total congestion. In order to pay FTRs their target allocations on these constraints, congestion from other constraints where congestion exceeds target allocations and auction surplus are used as the source. This is not consistent with an efficient market either for other FTR holders or for load.

Figure 13-18 Top ten constraint sources of positive FTR target allocations: June 2025 through September 2025

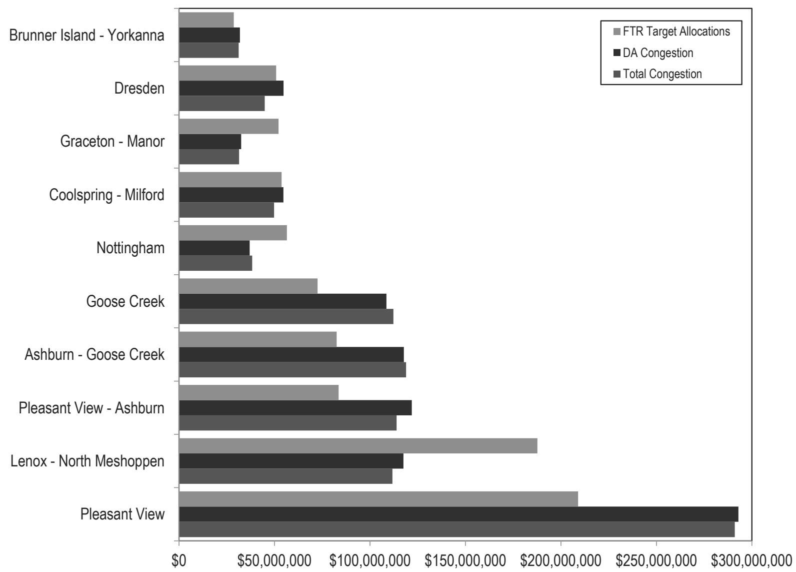


Figure 13-19 shows the hourly FTR target allocations, day-ahead congestion and balancing congestion for the Lenox – North Meshoppen constraint for the first four months of the 2025/2026 planning period. The Lenox – North Meshoppen constraint was the largest source of FTR target allocations during this period. The significant and variable difference between constraint specific FTR target allocations and constraint specific day ahead congestion provides evidence of the misalignment and over allocation of the path based FTR congestion rights relative to the actual network use of the physical energy market.

The Lenox – North Meshoppen constraint was a significant component of the overallocation of FTRs. FTRs routinely receive more target allocations than the congestion collected from the system because of the misalignment and over allocation of the path based FTR congestion rights relative to the actual network use of the physical energy market. The misalignment and overallocation of path based FTRs is exacerbated when line outages reduce the physical system capability between generation and load (the source of congestion revenue) relative to system capability assumed in the FTR market model. Figure 13-19 shows a large deviation between FTR target allocations and congestion for the Lenox – North Meshoppen constraint in December 2024. The main contributing factor for the deviation was the outage of the Grover – Scotch Hollow line.

Figure 13-19 Hourly FTR target allocations, total congestion, day-ahead congestion and balancing congestion for the Lenox – North Meshoppen constraint: June 2025 through September 2025

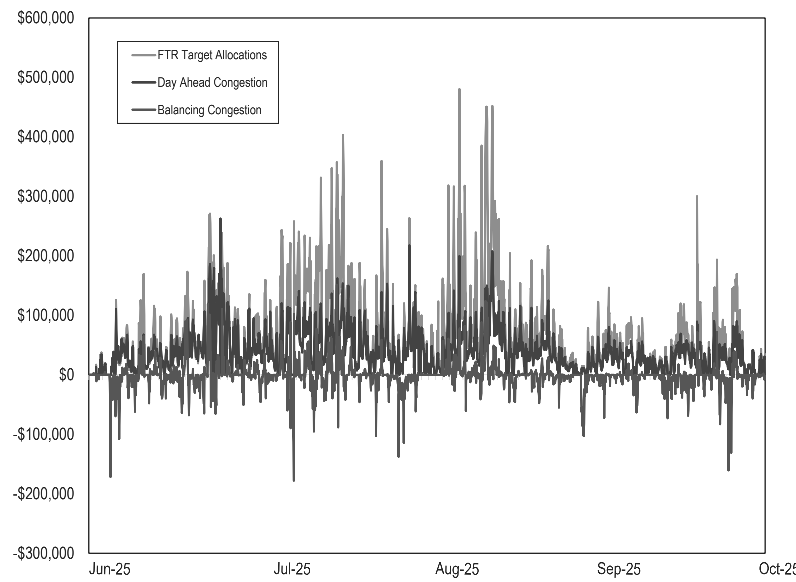

Figure 13-20 shows the constraints that are the top 10 sources of negative FTR target allocations (counter flow) for the first four months of the 2025/2026 planning period. Figure 13-20 also shows the corresponding day-ahead congestion and total congestion that result from the identified constraints.

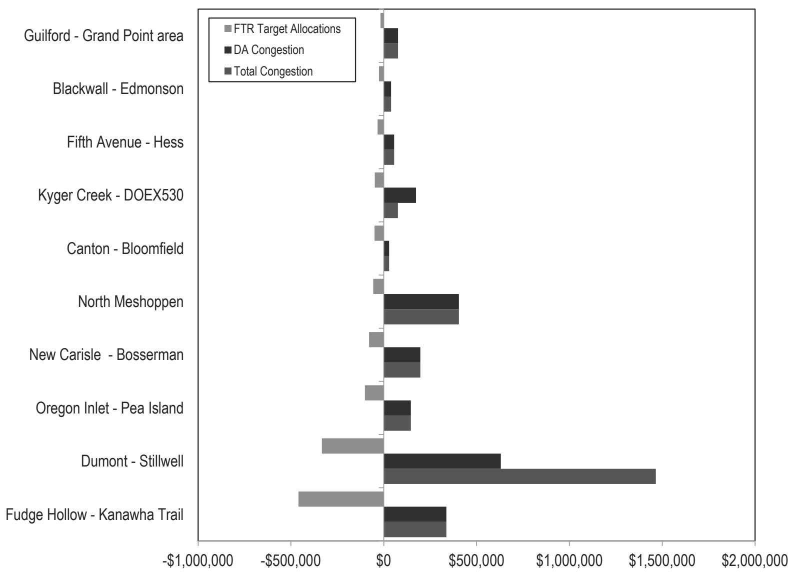
In the first four months of the 2025/2026 planning period, there were 29 constraints that were sources of negative target allocations. All of the 29 constraints that were sources of negative target allocations resulted in positive actual total congestion. Constraints that contribute positive congestion revenues and have negative FTR target allocations are a source of funds used in the settlement process to pay for FTR target allocations on FTR paths that are overallocated relative to actual congestion.

Figure 13-20 Top ten constraint sources of negative FTR target allocations: June 2025 through September 2025[50]



ARRs as an Offset to Congestion for Load

Load pays 100 percent of congestion revenues. FTRs, and later ARRs, were intended to return congestion revenues to load to offset an unintended consequence of locational marginal pricing. With the implementation of the current, path based FTR/ARR design, the purpose of FTRs has been subverted. The inconsistencies between actual network solutions used to serve load and path based rights available to load cause a misalignment of congestion paid by load and the congestion paid to load, in aggregate and on a specific load basis. These inconsistencies between actual network use and path based rights cause cross subsidies between ARR holders and FTR holders and among ARR holders. One result of this misalignment is that individual zones have very different offsets due to the location of their path based ARRs compared to their actual congestion costs from actual network use.

Table 13-48 shows the ARR and FTR revenue paid to load, the congestion offset available to load with and without allocating balancing congestion to load and the congestion offset when surplus congestion revenue is allocated to load. The highlighted offsets are the actual offsets based on the rules that were effective in that planning period. The pre 2017/2018 offset is calculated as the ARR credits and the FTR credits excluding balancing congestion and M2M payments, divided by the total day-ahead congestion and the load share of balancing and M2M payments.

Total ARR and self scheduled FTR revenue offset only 66.6 percent of total congestion costs for the first four months of the 2025/2026 planning period.

50 New Carisle – Bosserman is the spelling provided in PJM data, rather than New Carlisle – Bosserman.

Table 13-48 ARR and self scheduled FTR total congestion offset (in millions) for ARR holders: 2011/2012 through 2025/2026 planning periods

*First four months of the 2025/2026 planning period

Table 13-48 illustrates the inadequacies of the ARR/FTR design. The goal of the design should be to give the rights to 100 percent of the congestion revenues to the load.

Table 13-49 shows the cumulative offset and shortfall using the rules that were effective in the given planning period to calculate the ARR/FTR revenue. The cumulative offset, beginning in the 2011/2012 planning period, is the sum of the revenue received for that planning period and all previous planning periods divided by the total congestion for that planning period and all previous planning periods. The cumulative shortfall is the cumulative difference between the ARR holders' revenue and the congestion they paid, for each planning period and the planning periods prior to each planning period.

From the 2011/2012 planning period through the first four months of the 2025/2026 planning period, the cumulative offset, the cumulative return of congestion to load, was only 68.7 percent based on the total congestion and the effective offset rules that were in place for each planning period. Load has been underpaid by $5.4 billion from the 2011/2012 planning period through the first four months of the 2025/2026 planning period. This is an increase of $0.5 billion from the $4.9 billion that load had been underpaid for the 2011/2012 planning period through the 2024/2025 planning period. The $5.4 billion is the difference between the total congestion column ($17.2 billion) and the total offset column ($11. billion) in Table 13-48.

Table 13-49 ARR and self scheduled FTR cumulative offset for ARR holders: 2011/2012 through 2025/2026 planning periods

Planning Period	Cumulative Offset	Cumulative Shortfall (Millions)
2011/2012	103.4%	$25.3
2012/2013	102.4%	$31.2
2013/2014	67.8%	($1,012.9)
2014/2015	66.7%	($1,498.3)
2015/2016	70.9%	($1,589.2)
2016/2017	75.0%	($1,556.9)
2017/2018	71.0%	($2,156.7)
2018/2019	72.7%	($2,215.4)
2019/2020	76.3%	($2,030.2)
2020/2021	74.4%	($2,357.2)
2021/2022	68.0%	($3,459.1)
2022/2023	69.5%	($3,818.7)
2023/2024	70.7%	($4,036.8)
2024/2025	68.8%	($4,928.5)
2025/2026*	68.7%	($5,370.9)

*First four months of the 2025/2026 planning period

Zonal ARR Congestion Offset

Zonal ARR congestion offsets vary significantly across zones. There is no good reason that this should be the result of a system designed to return congestion to load. PJM has offered no explanation for this result. This outcome is a direct result of the flawed definition of congestion and of the method for assigning rights to congestion to ARR holders. The results show that path based ARR assignments in the current path based ARR/FTR design are not aligned with actual network use by load, and are therefore not aligned with how congestion is actually paid by load on actual network usage. Due to this misalignment of ARR rights relative to actual network usage, individual loads cannot claim the congestion they paid through assigned ARRs. One result of the misalignment of path based ARR rights are cross subsidies among ARR holders.

ARRs are allocated to zonal load based on historical generation to load transmission contract paths, in many cases based on 1999 contract paths. ARRs are allocated within zones based on zonal base load (Stage 1A) and zonal peak loads (other stages). ARR revenue is the result of the prices that result from the sale of FTRs through the FTR auctions. ARR revenue for each zone is the revenue for the ARRs that sink in each zone.

Congestion paid by load in a zone is the total difference between what the zonal load pays in congestion charges net of payments to the generation that serves the zonal load, including generation in the zone and outside the zone.[51]

Table 13-50 shows the day-ahead congestion and balancing congestion and M2M charges paid by load in each zone along with the congestion offsets paid to load: FTR auction revenue; self scheduled FTR revenue adjusted by the payout ratio for FTRs if below 100 percent; and the allocation of end of planning period surplus.[52] The offset for the first four months of the 2025/2026 planning period assigns the current surplus revenue at the end of the quarter to ARR holders. Table 13-50 also shows payments by load for balancing congestion and M2M payments. The total congestion offset paid to load is the sum of all of those credits and charges.

The zonal offset percentage shown in Table 13-50 is the sum of the congestion related revenues (offset) paid to load in each zone divided by the total congestion payment made by load in each zone.

The total congestion offset paid to loads in the first four months of the 2025/2026 planning period was 66.6 percent of congestion costs. The results vary significantly by zone. Loads in some zones, like BGE and DOM, receive substantially more in offsets than their total congestion payments. Loads in other zones, like EKPC, receive substantially less in offsets than their total congestion payments. Loads in some zones, like MEC, have higher balancing congestion and M2M charges than the load is able to offset with ARRs and FTRs, resulting in a negative total offset. The offsets are a function of the assignment of ARRs and the valuation of ARRs in the FTR auctions.

The amount and proportion of the offset that can be realized by load serving entities via their ARR allocations varies by planning period. The offsets are a function of the assignment of ARRs relative actual network sources of congestion paid, the valuation of ARRs in the FTR auctions and the congestion revenue from self scheduled ARRs. If the prices for FTRs are high relative to realized congestion, the offset provided by ARR is increased relative to cases where the prices for FTRs are low relative to realized congestion. While the amount of congestion that is returned to the load varies by planning period, PJM's ARR/FTR design has consistently failed to return the congestion revenues to the load that paid it. It is not possible for load to recover all of the congestion that they pay under the current design in which the rights to congestion revenues are assigned based on fictitious contract paths.

Offset If All ARRs Are Held As ARRs

Table 13-51 shows the total congestion offset that would be available to ARR holders via allocated ARRs, by zone, if the ARRs holders held all their allocated ARRs in the 2023/2024, 2024/2025, and the first four months of the 2025/2026 planning periods and did not self schedule any. If ARR holders held all their allocated ARRs for the first four months of the 2025/2026 planning period, the ARR Target Allocations would have offset 39.9 percent of the congestion paid by load. However, the offset that would be received by individual zones varies widely, from -5.1 percent for MEC to 124.0 percent for BGE.

* First four months of the 2025/2026 planning period

Offset If All ARRs Are Self Scheduled

Table 13-52 shows the total congestion offset that would be available to ARR holders via allocated ARRs, by zone, if the ARR holders self scheduled all their ARRs received in the annual auction process as FTRs in the 2023/2024, 2024/2025, and the first four months of the 2025/2026 planning periods. Market rules allow ARRs available in the annual auction process to be self scheduled as FTRs. Any ARRs awarded monthly as residual ARRs cannot be self scheduled but provide ARR revenue based on monthly auction results. The calculated self scheduled FTR target allocations assume a 100 percent payout ratio. Residual ARRs cannot be self scheduled and are included in addition to the self scheduled FTR target allocations. If ARR holders had self scheduled all their allocated ARRs to FTRs for the first four months of the 2025/2026 planning period, the ARR Target Allocations would have offset 98.7 percent of the congestion paid by load. The results show that the recovery of congestion varies significantly by zone and that the load in some zones recovers more than the congestion paid and the load in other zones recovers less. This result is not consistent with a rational FTR/ARR design under which all load would be returned their congestion, but no more and no less.

* First four months of the 2025/2026 planning period

ARR Allocation and Congestion In and Out of Zone

Table 13-53 shows the share of ARR MW for the 2023/2024, 2024/2025, and 2025/2026 planning periods with paths that source inside and outside the zone where the ARR load is located (see Table 13-4) and the proportion of congestion that results from constraints that are inside and outside the zone for the 2023/2024, 2024/2025 and the first four months of the 2025/2026 planning periods. Table 13-53 allows a comparison of externally sourced ARRs with the congestion that results from external constraints. For example, 94.6 percent of ACEC congestion in the the first four months of the 2025/2026 planning period results from constraints that are outside of the zone, but only 55.9 percent of ACEC ARRs originate outside the zone for the 2025/2026 planning period ARR allocations.

Table 13-53 illustrates one of the fundamental issues with the contract path based approach to ARR/FTR design. In the PJM market, which operates as an integrated network, a significant proportion of congestion results from constraints that are not in the same zone as load, but the assignment of ARRs is inconsistent with that fact. This inconsistency makes it impossible for load to match ARRs with the actual sources of congestion.

*first four months of the 2025/2026 planning period for congestion

Credit

There were two payment defaults and no collateral defaults in the first nine months of 2025. The two payment defaults were from the same member and have not been cured. The total payment defaults were $30,537.03.

On December 21, 2021, PJM submitted a change to the credit rules to FERC.[53] PJM proposed to replace the current credit calculation, which is largely based on a weighted average historical FTR value, with an initial margin based on a risk confidence interval from an Historical Simulation Initial Margining (HSIM) analysis model. PJM's proposal included the use of a 97 percent confidence interval, meaning a 97 percent probability that the initial margin collected would cover potential default costs.

On February 28, 2022, FERC rejected PJM's filing recommending a 97 percent confidence interval because the record did not support 97 percent.[54] FERC instituted a Section 206 proceeding, but recognized that PJM could propose revisions through a Section 205 filing. On June 3, 2022, PJM submitted the same change to the credit rules as the December 21, 2021, filing to FERC.[55] The June 3, 2022, filing included a cost /enefit analysis for the proposed use of a 97 percent confidence interval compared to the use of a 99 percent confidence interval. The MMU objected to PJM's filing and proposed a 99 percent confidence interval, with a transition to a 100 percent confidence interval.[56] On September 21, 2023, FERC directed PJM to use a 99 percent confidence level in the HSIM model.[57]

The most fundamental point is that if costs are shifted from FTR buyers to other market participants, no logical cost-benefit analysis can show that the other market participants benefit in any way. Under the current default rules, the cost of default is socialized to all market participants, not just those participating in the FTR market. The 99 percent confidence interval places more of the risk where it belongs, on the FTR market participants that are engaged in the risky behavior, than the 97 percent confidence interval. The goal of internalizing as much of the risk to the FTR participants as possible, where it belongs, could be more directly addressed either by using 100 percent or by directly assigning the risk to those in the FTR market rather than all market participants.

The PJM minimum credit requirements (minimum tangible net worth and minimum tangible assets) were set as fixed dollar amounts in 2011 in FERC Order No. 741 based on whether the market participant held FTRs. PJM has been reviewing the minimum credit requirements in the Risk Management Committee. The MMU and PJM developed a joint package to increase the fixed minimum credit requirements to be consistent with updated risks. The proposal was approved by the Risk Management Committee on October 22, 2025.[58]

Treatment of Defaulted Portfolios

Under the method applied to the GreenHat default, when an FTR participant defaults on their positions, their portfolio remains in the FTR market and continues to accrue revenues and/or charges and must be reconciled. Under this method, PJM leaves the participant's positions unchanged, lets the positions settle at day-ahead prices, and charges any net losses to the default allocation assessment. This method exposes all members in PJM to an uncertain charge for the default allocation assessment that will not be known until those FTRs settle.

The MMU recommends that the defaulted FTRs be canceled rather than holding or liquidating them.[59] Canceling the FTRs would release the FTRs to the FTR market. The market would then decide the value of the capacity released and the timing of its release. There would be no discretion necessary to settle the defaulted position and the losses would be contained within the ARR/FTR market.

Cancellation of a defaulting portfolio does not change congestion. Cancellation of a defaulting portfolio can affect ARR/FTR funding as a result of changes in auction revenue, changes in the net target allocations, and potential

simultaneous feasibility violations, while any collateral collected from the defaulted participant is available to offset losses from the cancelled FTRs. However, PJM can and does address similar issues routinely. PJM has tools available, such as the counter flow buyback and Stage 1A over allocation rules, and uses them regularly in the Annual FTR Auction, to improve funding as well as address feasibility concerns. Cancellation of FTRs would isolate the costs of the default to those participating in and benefitting from the FTR market.

FTR Forfeitures

By order issued January 19, 2017, the Commission determined that the FTR forfeiture rule is just and reasonable and "...serves to deter such manipulation" related to virtual transaction cross product manipulation.[60] The Commission identified four main tenets with which the Forfeiture Rule must comply, including that it: deter manipulation, provide transparency allowing participants to modify their behavior, base forfeitures on an individual participant's actions and is not punitive.[61]

The point of the FTR forfeiture rule is to avoid an inefficient and costly market power mitigation process and to establish an objective rule that prevents manipulation of the FTR market. The FTR forfeiture rule is designed to remove the incentive to engage in manipulation. The rule does not result in findings of manipulation.[62]

The FTR forfeiture rule considers the impact of a participant's net virtual transaction portfolio on all constraints.[63] If a participant's net virtual portfolio impacts a constraint by the greater of 0.1 MW or 10 percent or more of the constraint line limit, and that constraint affects an individual FTR's target allocation by $0.01 or more, the participant's net virtual portfolio increased the value of the FTR, and the FTR is subject to FTR forfeiture. The FTR forfeiture also requires that congestion on the FTR path in the day ahead market be greater than congestion on that path in the real time market.

61 See *id.* at P 62.
62 *See* "Protest and Motion for Rejection of the Independent Market Monitor for PJM," Docket No. EL20-41 (June 1, 2020).
63 A modified FTR forfeiture rule was implemented effective January 19, 2017. See *2019 Annual State of the Market Report for PJM*, Volume 2, Section 13: Financial Transmission Rights for the full history.

The FTR forfeiture rule does not require FTR holders to pay penalties. The FTR forfeiture rule does not affect the profits or losses of virtual activity. The FTR forfeiture rule, if triggered by a participant's virtual portfolio, results in forfeiting only FTR profits and only in the specific hours for which the rule is violated. The profit is calculated as the hourly FTR target allocation minus the FTR's hourly cost. Even when FTR profits are forfeited, the value that the buyer assigned to congestion in the FTR auction (the price paid) is not affected. For example, if a buyer paid $5.00/MWh for congestion and congestion was $5.00/MWh, the forfeiture would be zero. If congestion were $7.00/MWh, the forfeiture would be $2.00/MWh. Market participants understand the relationship between FTR and virtual positions in detail and can avoid violating the FTR forfeiture rule if they choose to do so.

The FTR forfeiture rule is less effective than initially intended as a result of the element of the rule requiring that day-ahead congestion on the FTR path be greater than real-time congestion the same path. As a result of model differences, there is a significant opportunity for virtual participants to profit from differences between day-ahead and real-time prices without driving the prices together, termed false arbitrage. As a result, FTR holders can use virtual positions to make their FTR positions more valuable without violating the rule.

The FTR forfeiture rule has not reduced participation in the PJM FTR market or participation in virtual activity. There has been an increase in the number of participants in the FTR market since the implementation of the new FTR forfeiture rule, and a decrease in the number of participants with forfeitures.

On June 24, 2019, PJM implemented a new method to calculate the hourly cost of an FTR only for hours in which it is effective.[64] Beginning with the September 2019 bill, PJM began billing using the correct hourly cost calculation. For the 2020/2021 planning period, total FTR forfeitures were $4.6 million.

On May 20, 2021, FERC issued an order ruling the $0.01 definition of an increase in the value of an FTR unjust and unreasonable, but upheld the other

64 *See* "Minor modification to Tariff Language for FTR Forfeiture Rule," Docket No. ER19-2240 (June 24, 2019).

parts of PJM's forfeiture rule.[65] In this order, FERC required PJM to modify the FTR forfeiture rule and submit a compliance filing. As a result, there was no FTR forfeiture rule in place from May 21, 2021 until February 1, 2022. These months have zero forfeiture in Figure 13-21.

On June 21, 2021, PJM filed a request for clarification, or alternatively rehearing.[66] PJM asked that FERC clarify the status of the forfeitures that were assessed over the four years between the initial FERC order for a compliance filing, and their order rejecting PJM's compliance filing. On July 19, 2021, PJM made a compliance filing to address FERC's concerns with the $0.01 element of the FTR forfeiture rule.[67] PJM's compliance filing eliminated that element and replaced it with a constraint based FTR forfeiture. The forfeiture is based on the increased value of each constraint that violates the rule, determined by the shadow price multiplied by the net dfax on that constraint. This change meets FERC's previously established criteria established under the initial FERC order and creates a more precise FTR forfeiture value, to meet the criteria established under the new FERC order.

On January 31, 2022, FERC accepted PJM's July 19, 2021 compliance filing to implement FTR forfeitures using a constraint based method, effective February 1, 2022.[68]

Figure 13-21 shows the monthly FTR forfeitures under the FTR forfeiture rules in effect from January 19, 2017, through September 30, 2025. As required by the FERC order, PJM began retroactively billing FTR forfeitures with the September 2017 bill. In the period from January 2017 through September 2017, participants did not have good information about the level of their FTR forfeitures, so they could not accurately modify their bidding behavior to avoid FTR forfeitures. After September 2017, participants received more timely information on their FTR forfeitures. Calculations of forfeitures under the new constraint specific rule from February 1, 2022, through September 30, 2025, are included in Figure 13-21.

Figure 13-21 Monthly FTR forfeitures for physical and financial participants: January 2017 through September 2025

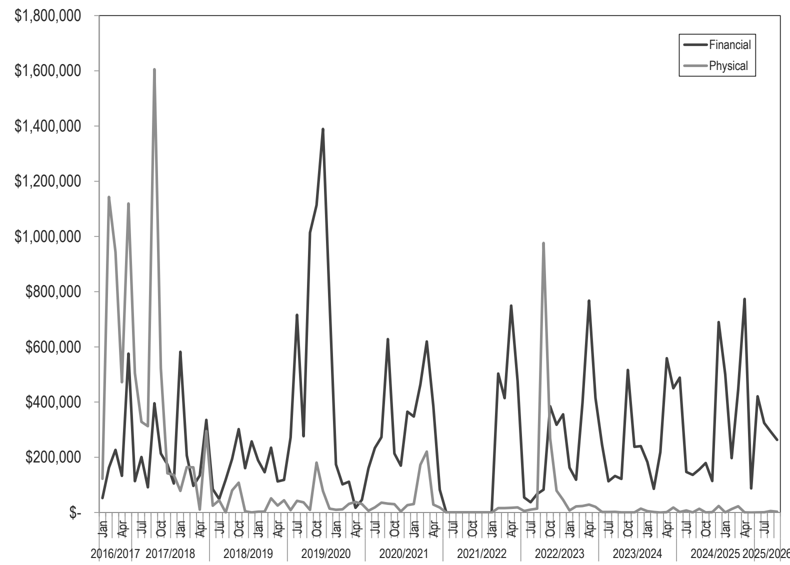

Table 13-54 shows the monthly FTR forfeitures by organization type for the 2024/2025 planning period and the first four months of the 2025/2026 planning period. For the first four months of the 2025/2026 planning period there were $1,312,218 in FTR forfeitures, up 38.0 percent from $951,033 in the same period of the 2024/2025 planning period.

Table 13-54 Monthly FTR forfeitures by organization type: June 2024 through September 2025

	Organization Type		
Month	Physical	Financial	Total
Jun-24	$2,062.39	$488,478.10	$490,540.49
Jul-24	$7,263.55	$147,024.31	$154,287.86
Aug-24	$265.40	$136,407.60	$136,672.99
Sep-24	$13,609.35	$155,922.29	$169,531.63
Oct-24	$153.22	$179,545.06	$179,698.29
Nov-24	$1,159.23	$114,091.82	$115,251.06
Dec-24	$23,393.12	$689,808.14	$713,201.26
Jan-25	$538.39	$500,477.32	$501,015.71
Feb-25	$12,543.78	$197,063.07	$209,606.85
Mar-25	$22,717.56	$446,139.20	$468,856.76
Apr-25	$638.34	$773,771.75	$774,410.09
May-25	$17.41	$87,239.94	$87,257.35
Summary for 2024/2025 Planning Period			
Total	$84,361.73	$3,915,968.60	$4,000,330.34
Jun-25	$615.50	$420,868.10	$421,483.61
Jul-25	$1,055.22	$324,455.09	$325,510.31
Aug-25	$5,596.14	$293,350.91	$298,947.05
Sep-25	$3,094.75	$263,182.16	$266,276.91
Summary For 2025/2026 Planning Period*			
Total	$10,361.61	$1,301,856.26	$1,312,217.87

State of the Market Report for PJM

Volume 2: Detailed Analysis

Monitoring Analytics, LLC

Independent Market Monitor for PJM

2021

3.10.2022

Preface

The PJM Market Monitoring Plan provides:

> The Market Monitoring Unit shall prepare and submit contemporaneously to the Commission, the State Commissions, the PJM Board, PJM Management and to the PJM Members Committee, annual state-of-the-market reports on the state of competition within, and the efficiency of, the PJM Markets, and quarterly reports that update selected portions of the annual report and which may focus on certain topics of particular interest to the Market Monitoring Unit. The quarterly reports shall not be as extensive as the annual reports. In its annual, quarterly and other reports, the Market Monitoring Unit may make recommendations regarding any matter within its purview. The annual reports shall, and the quarterly reports may, address, among other things, the extent to which prices in the PJM Markets reflect competitive outcomes, the structural competitiveness of the PJM Markets, the effectiveness of bid mitigation rules, and the effectiveness of the PJM Markets in signaling infrastructure investment. These annual reports shall, and the quarterly reports may include recommendations as to whether changes to the Market Monitoring Unit or the Plan are required.[1]

Accordingly, Monitoring Analytics, LLC, which serves as the Market Monitoring Unit (MMU) for PJM Interconnection, L.L.C. (PJM), and is also known as the Independent Market Monitor for PJM (IMM), submits this *2021 Annual State of the Market Report for PJM.*[2] [3]

1 PJM Open Access Transmission Tariff (OATT) Attachment M (PJM Market Monitoring Plan) § VI.A. Capitalized terms used herein and not otherwise defined have the meaning provided in the OATT, PJM Operating Agreement, PJM Reliability Assurance Agreement (RAA), the Consolidated Transmission Owners Agreement (CTOA) or other tariffs that PJM has on file with the Federal Energy Regulatory Commission (FERC or Commission).

2 OATT Attachment M.

TABLE OF CONTENTS

Introduction

2021 in Review

Reliability is a core goal of PJM. Maintaining and improving competitive markets should also be a core goal of PJM. The goal of competition in PJM is to provide customers reliable wholesale power at the lowest possible price, but no lower. The PJM markets have done that. The PJM markets work, even if not perfectly. The results of PJM markets were reliable in 2021. The results of the energy market were competitive in 2021. The results of the 2021/2022 and 2022/2023 base capacity auctions were not competitive, but the Commission resolved the core underlying issue, the overstated market seller offer cap in the capacity market, prior to the 2023/2024 base capacity auction. The PJM markets bring customers the benefits of competition.

Markets provide incentives for innovation and efficiency. Organized, competitive wholesale power markets are the best way to facilitate the least cost path to decarbonization. Renewables can compete, without guaranteed long term contracts. Innovation will occur in renewable technologies in unpredictable and beneficial ways. But the PJM markets are not perfect. Significant changes to the core market design continue, including some that improve markets and some that do not. Significant issues with the core market design remain. It is not guaranteed that the market design will successfully adapt to the changing realities, including the role of renewable and intermittent resources, the role of distributed resources, the role of regulated EDCs in competitive wholesale power markets, and the role of states in subsidizing resources.

One of the benefits of competitive power markets is that changes in input prices and changes in the balance of supply and demand are reflected immediately in energy prices for both price decreases and price increases. Energy prices increased significantly in 2021 from the very low levels in 2020. The real-time load-weighted average LMP in 2021 increased 82.8 percent from 2020, from $21.77 per MWh to $39.78 per MWh, the largest annual percent increase since the start of PJM markets in 1999, although not the largest dollar per MWh increase. Of the $18.02 per MWh increase, 72.7 percent was a direct result of higher fuel and emission costs, particularly higher natural gas prices. The real-time hourly average load in 2021 increased by 3.6 percent from 2020, from 84,584 MWh to 87,606 MWh.

The total price of wholesale power increased from $44.59 per MWh in 2020 to $65.14 per MWh in 2021, an increase of 46.1 percent. Energy, capacity and transmission charges are the three largest components of the total price of wholesale power, comprising 97.5 percent of the total price per MWh in 2021. Starting in the third quarter of 2019, for the first time since the start of the RPM capacity market design in 2007, the cost of transmission per MWh of wholesale power is higher than the cost of capacity.

Higher gas costs and higher power prices changed the relative economics of coal and gas units in 2021. Coal generation increased 17.8 percent and gas generation decreased 2.4 percent in 2021 compared to 2020. The changes in relative fuel prices slowed but did not change the long term decline in the share of coal and the increase in the share of gas. The share of total PJM energy produced from coal was 22.2 percent in 2021, down from 54.9 percent in 2008, and the share of energy produced from natural gas was 37.7 percent, greater than any other fuel source, up from 7.4 percent in 2008. The role of gas fired generation highlights the importance of ensuring that PJM has real time, detailed and complete information on the gas supply arrangements of all generators and that PJM consider rules requiring capacity resources to have firm fuel supplies. It is also essential that FERC consider and address the implications of the inconsistencies between the gas pipeline business model and the power producer business model and the issue of market power in the gas commodity market under extreme weather conditions.

Net revenue is a key measure of overall market performance as well as a measure of the incentive to invest in new generation to serve PJM markets. Theoretical net revenues from the energy market increased for all unit types in 2021 compared to 2020. Theoretical energy net revenues increased by 76 percent for a new combustion turbine, 78 percent for a new combined cycle, 642 percent (from a level near zero in 2020) for a new coal unit, and 86 percent for a new nuclear plant. In 2021, most units did not achieve full recovery of avoidable costs through net revenue from energy markets alone, illustrating the critical role of the capacity market in providing incentives for continued operation and investment. In 2021, capacity revenues were sufficient to cover the shortfall between energy revenues and avoidable costs for the majority of units and technology types in PJM, with the exception of some coal units. In 2021, a theoretical new combined cycle plant would have received sufficient net revenue to cover levelized total costs in 14 of the 20 PJM zones. But no theoretical new combustion turbine, coal plant, nuclear plant, or diesel plant would have received sufficient net revenue to cover levelized total costs in any zone.

Changes in forward energy market prices significantly affect the expected profitability of nuclear plants in PJM. Based on forward prices as of January 3, 2022, for energy, and known forward prices for capacity, all the nuclear plants in PJM are expected to cover their annual avoidable costs in 2022, based on NEI average costs. None of the currently subsidized nuclear plants in PJM need a subsidy for 2022 in order to cover their avoidable costs.

If more PJM states decide that carbon is a pollutant with a negative value, a market approach to carbon is preferred to an inefficient technology or unit specific subsidy approach or inconsistent RPS rules that in some cases subsidize carbon emitting resources. Delaware, Maryland, New Jersey and Virginia were members of RGGI in 2021. Virginia joined RGGI on January 1, 2021. Pennsylvania had planned to join RGGI on January 1, 2022 but has been delayed due to actions by the Pennsylvania legislature. Implementation of a carbon price is a market approach which would let market participants respond in efficient and innovative ways to the price signal rather than relying on planners to identify specific technologies or resources to be subsidized. Implementation of a carbon price using RGGI or a similar market mechanism by the states would mean that the states control the carbon price and that no FERC approval would be required and no PJM rule changes would be required. The carbon price would become part of the marginal costs of power plants and the impacts on production and consumption decisions would be market based. States would control the resulting revenues. This is the case regardless of the number of PJM states that join RGGI or a similar market.

The MMU continues to recommend that PJM provide a full analysis of the impact of carbon pricing on PJM generating units and carbon pricing revenues to all PJM states in order to permit states to consider the development of a multistate framework that could benefit all states: for REC market design; for potential agreement on carbon pricing; for potential agreement on the distribution of carbon pricing revenues; and for coordination with PJM wholesale markets.

A number of PJM states are pursuing direct approaches to environmental issues including mandating the closure of emitting resources and capping emissions.

RECs (renewable energy credits) are an important mechanism used by PJM states to implement environmental policy. RECs affect prices in the PJM wholesale power market. Some resources are not economic except for the ability to sell RECs. RECs provide out of market payments to qualifying renewable resources, primarily wind and solar.

In the absence of a PJM market carbon price, a single, transparent PJM market for RECs would contribute significantly to market efficiency and to the procurement of renewable resources in a least cost manner. Ideally, there would be a single PJM operated forward market for RECs, for a single product based on a common set of state definitions of renewable technologies, with a single clearing price, trued up to real time delivery. States would continue to have the option to create separate RECs for additional products that did not fit the product definition, e.g. waste coal, trash incinerators, or black liquor. Such a market would provide better information for market participants about supply and demand and prices and contribute to a more efficient and competitive market and to better price formation. The market could also facilitate entry by renewable resources by reducing the risks associated with lack of transparent market data and ensuring competitive prices.

Despite suggestions that PJM needs a flexibility product, the PJM fleet already includes the flexibility needed to offset the fluctuations in output assumed to be inherent in renewable energy. But it should not simply be assumed that renewable resources require flexible resources to offset their output fluctuations. PJM markets should provide incentives, especially in the capacity market, for renewable resources to provide higher quality capacity and more stable output by creating hybrid resources. For example, if the ELCC calculations reflected the relatively low marginal value of standalone renewables, as they should, and the significantly higher marginal value of hybrids, there would be a strong incentive to combine resources into hybrids. There would be a related incentive to invest in longer duration hybrids over shorter duration hybrids. PJM does not need a flexibility product. PJM needs to provide incentives to existing and new entrant resources to unlock the significant flexibility potential that already exists and to stop creating incentives for inflexibility. This means enforcing parameter limited schedules, enforcing must offer requirements, enhancing generator modelling to support combined cycle resources, and requiring resources to follow PJM's dispatch instructions in order to be eligible for uplift payments. There is no reason to consider a new flexibility product until the existing rules are enforced and refined, including the elimination of current incentives to be inflexible.

PJM interventions in the market have substantial effects on energy market outcomes. For example, transmission line ratings, transmission penalty factors, load forecast bias, hydro resource schedules, and unit ramp rate adjustments change the dispatch of the system, affect prices, and can create significant price increases through transmission line limit violations or restrictions on the resources available to resolve constraints. PJM interventions to reduce line ratings unnecessarily trigger transmission constraint penalty factors and significantly increase prices. In 2021, 7.2 percent of the total load-weighted LMP was the result of the transmission constraint violation penalty factors. PJM reduced transmission line ratings in almost all of these cases, increasing the number and impact of such penalties. PJM also increased the constraint penalty factor from $2,000 per MWh to $3,000 per MWh in some cases, for reasons that are not clear. PJM should limit its interventions in the market and provide greater transparency about the reasons and impacts, if any such interventions continue, in order to enhance market efficiency.

Fast start pricing significantly increases energy market prices in ways not consistent with competitive markets. Fast start pricing, implemented on September 1, 2021, creates an inefficient wedge between the competitive price and the actual price paid to generators and charged to customers. Fast start pricing increased average real-time energy market prices by 5.5 percent. This is a significant increase to energy prices given that it does not result from any change to the underlying market supply and demand fundamentals.

Changes to the operating reserve demand curve (ORDC), previously approved by FERC and planned for implementation in 2022, were reversed by the Commission in an order issued on December 22, 2021. The changes, if implemented, would have increased the price for reserve quantities less than the reserve requirement to $2,000 per MWh, and prices beyond the reserve requirement to levels that were based on an extended downward sloping ORDC, and the price cap would have been removed. The MMU had opposed those changes. While Commission's order maintains the current levels of emergency pricing, rather than PJM's higher proposed levels, there remain possible scenarios in which prolonged and excessively high administrative pricing in the energy market under the current tariff provisions would impose inefficient wealth transfers. Inefficient wealth transfers from load to generation, among generators, or from physical to financial market participants occur when administrative pricing creates arbitrarily high price signals to which participants cannot respond. While appropriate shortage pricing is important, there is no demonstrated benefit to imposing extreme prices for either long term generation incentives to invest in reliable capacity or customer incentives to curtail usage during an emergency.

On September 29, 2021, PJM's filing to revise the Minimum Offer Price Rule (MOPR) was made effective by operation of law. The MMU's filing in response to PJM's proposal was clear. The PJM markets would be better off, more competitive, and more efficient with no MOPR than with PJM's proposed approach. PJM's proposal would effectively eliminate the MOPR while creating a confusing and inefficient administrative process that effectively makes it both unnecessary and impossible to prove buyer side market power as PJM has defined it.

The competitiveness of energy market prices cannot be taken for granted. Despite low average marginal unit markups in 2021, 4.7 percent of marginal units set price with positive markups, in some cases over $150 per MWh, despite failing the Three Pivotal Supplier (TPS) test for market power in the real-time energy market. This was the result of documented flaws in the application of offer capping when units fail the TPS test. PJM also schedules and pays uplift to units that fail the TPS test without requiring that units use flexible operating parameters, an issue that FERC raised in a June 17, 2021, Order to Show Cause. In addition to the existing issues with market power mitigation, the definition of a competitive energy offer is overstated through the inclusion of major maintenance costs which do not vary in the short run with energy output and are not short run marginal costs. Further, the use of and applicability of fuel cost policies have been undermined. Fuel cost policies ensure that the costs in generator offers are clearly defined and are verifiable and systematic. Fuel cost policies are required for effective and accurate market power mitigation. Some generation owners prefer to not have clearly defined costs in order to exercise market power and in order to avoid taking responsibility for the accuracy of their offers.

If PJM markets are going to continue to be sustainable, it is essential that the basic structure of the current capacity market remain, including the single definition of reliability for the PJM market, the incorporation of transmission constraints and locational supply and demand fundamentals, and a clear definition of capacity and the contribution of capacity to reliability. The basic structure of the capacity market includes a must offer and a must buy requirement that are essential and have been demonstrated to be essential to limiting market power and operating a competitive market. The PJM Capacity Market has never been nor was it ever intended to be a residual market, as evidenced by the must buy and must sell provisions of the market rules. Reliability is only definable at the level of the entire PJM market, including locational differences based on transmission constraints. The market reflects the interactions across free flowing ties throughout the entire network. There are transmission constraints that prevent the lowest cost capacity from providing reliability in constrained areas. Locational prices reflect the combination of transmission constraints and local supply and demand conditions.

Purely bilateral markets are characterized by a lack of transparency, a corresponding asymmetry in access to information that favors market sellers, and the resultant ability of sellers to exercise market power. Transparent clearing markets are the best way to facilitate bilateral contracts. PJM had only a bilateral capacity market at its inception. That bilateral market was replaced in 1999, at the request of the Pennsylvania Public Utility Commission, by PJM's first transparent, mandatory capacity clearing market, the precursor to the current design. The problem with the bilateral market was that reliance on voluntary bilateral sales and purchases facilitated the exercise of market power by incumbents and served as a barrier to entry to retail competitors, because the new entrant had to purchase capacity from the utilities with which it was competing for retail load.

It is also essential that the contribution of different types of capacity be calculated in a comparable manner. The contribution of one MW of a solar or wind resource is not the same as the contribution of one MW of a gas fired combined cycle resource. Capacity must be defined in a homogeneous manner so that the clearing price is the same for all MW of capacity that provide the same contribution to reliability. Capacity should be offered and cleared in the capacity market only at a MW level that reflects its contribution to reliability. For most wind and solar resources that means a capacity value appropriately derated from the nameplate capability.

In order for the capacity market to provide competitive price signals, particularly with more renewable and intermittent resources, the ELCC values must be accurate. PJM has replaced default derating factors by technology type with the Effective Load Carrying Capability (ELCC) approach. PJM's approach to calculating ELCC values by technology is badly flawed. Fixing the PJM approach to ELCC is a manageable task if there is a shared goal of letting markets reflect the actual, marginal contribution of all types of capacity (including fossil resources) to reliability without assumptions that arbitrarily favor some resource types.

Derating factors and ELCC values are used in capacity auctions to convert the nameplate capacity of intermittent and storage resources into MW of capacity equivalent to resources that can produce for any of the 8,760 hours in a year. Both the capacity derating factors applied to intermittent nameplate capacity in the 2022/2023 BRA and the ELCC calculations to be used for future capacity auctions are based on the assumption that the intermittent resources provide reliable output in excess of their CIRs. But that output is not deliverable when needed for reliability because it is in excess of the defined deliverability rights (CIRs) and therefore should not be included in the definition of intermittent capacity. The definition of intermittent capacity is thus not consistent with the way that capacity is defined. This results in an overstatement of the supply of capacity and reduces the clearing price in the capacity market. Intermittent resources, including storage, should not be permitted to offer capacity MW based on energy delivery that exceeds their defined deliverability rights (CIRs).

Renewable energy was a relatively small share of PJM total energy and capacity in 2021 but many renewable projects are under development. While renewables currently make up the majority of both projects and nameplate MW in the interconnection queue, historical completion rates and derating factors must be accounted for when evaluating the share of capacity resources that are likely to be contributed by renewables and by thermal resources. Of the 18,707.9 MW of combined cycle projects in the queue, 11,128.3 MW (59.5 percent) are expected to go in service based on historical completion rates as of December 31, 2021, providing both energy and capacity at that level. Of the 191,372.4 MW of renewable projects in the queue, only 24,300.6 MW (12.7 percent) are expected to go in service based on historical completion rates and be available to supply energy. Of those 24,300.6 MW, only 9,871.6 MW (5.1 percent of the total) are expected to be capacity resources, based on the average derate factors for wind and solar.

PJM has regularly procured excess capacity in excess of the reserve requirement at significant cost to customers, both as a result of over forecasted demand and the shape and location of the capacity market demand (VRR) curve. But the quality and significance of PJM reserves needs to be analyzed carefully.

The level of cleared demand resources (8,710.3 MW) is greater than the entire level of excess capacity cleared in the auction (7,660.2 MW). This is consistent with PJM effectively not relying on demand response for reliability in actual operations. The excess is a result of the flawed rules permitting the participation of inferior demand side resources in the capacity market. Maintaining the persistent excess has meant that PJM markets have never experienced the results of reliance on demand side resources as part of the required reserve margin, rather than as excess above the required reserve margin. PJM markets have never experienced the implications of the definition of demand side resources as a purely emergency capacity resource that triggers a PAI whenever called. If DR were part of the required reserves and there were no excess capacity, the probability of PAI would increase, potentially significantly.

In addition, the sum of cleared MW that were considered categorically exempt from the capacity market must offer requirement is 8,113.0 MW, or 48.5 percent of the required reserves and 33.3 percent of total reserves. The sum of cleared MW that did not have a must offer requirement and the cleared MW of DR is 16,823.3 MW, or 100.7 percent of required reserves and 69.0 percent of total reserves.

These results suggest that the required reserve margin and the actual reserve margin be considered carefully along with the obligations of the resources that the reserve margin assumes will be available.

The evolution of wholesale power markets is far from complete. The market design can be improved and made more efficient and more competitive. PJM and its market participants will need to continue to work constructively to refine the competitive market design and to ensure the continued effectiveness of PJM markets in providing customers wholesale power at the lowest possible price, but no lower.

PJM Market Summary Statistics

Table 1-1 shows selected summary statistics describing PJM markets.

Table 1-1 PJM market summary statistics: 2020 and 2021[1]

	2020	2021	Percent Change
Average Hourly Load Plus Exports (MW)	90,059	92,774	3.0%
Average Hourly Generation Plus Imports (MW)	91,674	94,501	3.1%
Peak Load (MW)	148,996	151,680	1.8%
Installed Capacity at December 31 (MW)	184,237	186,593	1.3%
Load Weighted Average Real Time LMP ($/MWh)	$21.77	$39.78	82.8%
Total Congestion Costs ($ Million)	$528.7	$995.3	88.3%
Total Uplift Credits ($ Million)	$90.9	$178.3	96.1%
Total PJM Billing ($ Billion)	$36.28	$54.13	49.2%

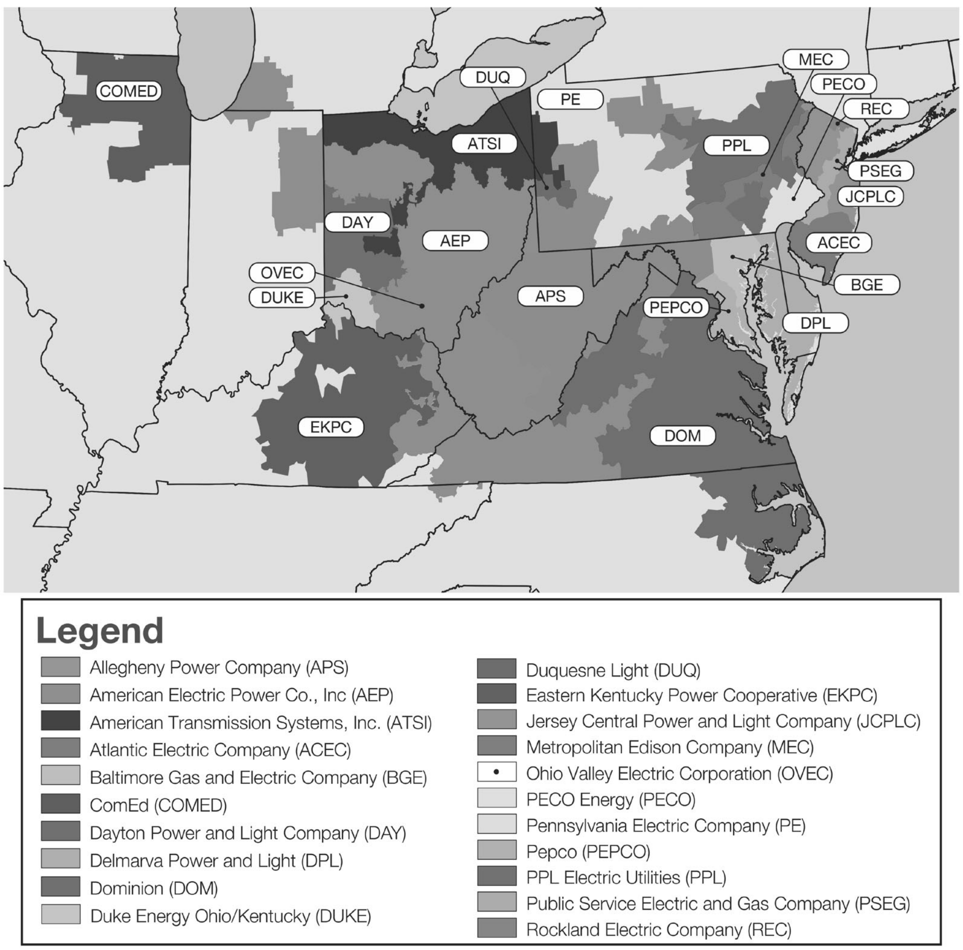
1 In Table 1-1, the MMU uses Total PJM Billing values provided by PJM. For 2019 and after, the Total PJM Billing calculation was modified to better reflect PJM total billing through the PJM settlement process.

PJM Market Background

The PJM Interconnection, L.L.C. (PJM) operates a centrally dispatched, competitive wholesale electric power market that, as of December 31, 2021, had installed generating capacity of 186,593 megawatts (MW) and 1,045 members including market buyers, sellers and traders of electricity in a region including more than 65 million people in all or parts of 13 states (Delaware, Illinois, Indiana, Kentucky, Maryland, Michigan, New Jersey, North Carolina, Ohio, Pennsylvania, Tennessee, Virginia, West Virginia) and the District of Columbia (Figure 1-1).[2 3 4]

As part of the market operator function, PJM coordinates and directs the operation of the transmission grid and plans transmission expansion improvements to maintain grid reliability in this region.

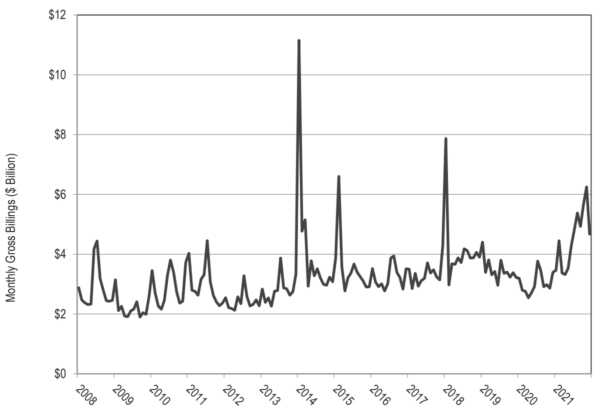
Figure 1-1 PJM's footprint and its 21 control zones



2 See PJM. "Member List," which can be accessed at: <http://pjm.com/about-pjm/member-services/member-list.aspx>.
3 See PJM. "Who We Are," which can be accessed at: <http://pjm.com/about-pjm/who-we-are.aspx>.
4 See the *2021 State of the Market Report for PJM*, Volume II, Appendix A: "PJM Overview" for maps showing the PJM footprint and its evolution prior to 2021.

In 2021, PJM had net gross billings of $54.13 billion, an increase of 49.2 percent from $36.28 billion in 2020, and the largest annual billing since 2014. (Figure 1-2).[5]

Figure 1-2 PJM reported monthly billings ($ Billion): 2008 through 2021[6]



PJM operates the day-ahead energy market, the real-time energy market, the Reliability Pricing Model (RPM) capacity market, the regulation market, the synchronized reserve market, the day-ahead scheduling reserve (DASR) market and the financial transmission rights (FTRs) markets.

PJM introduced energy pricing with cost-based offers and market-clearing nodal prices on April 1, 1998, and market-clearing nodal prices with market-based offers on April 1, 1999. PJM introduced the Daily Capacity Market on January 1, 1999, and the Monthly and Multimonthly Capacity Markets for the January through May 1999 period. PJM implemented FTRs on May 1, 1999. PJM implemented the day-ahead energy market and the regulation market on June 1, 2000. PJM modified the regulation market design and added a market in Synchronized Reserve on December 1, 2002. PJM introduced an Auction Revenue Rights (ARR) allocation process and an associated Annual FTR Auction effective June 1, 2003. PJM introduced the RPM capacity market effective June 1, 2007. PJM implemented the DASR market on June 1, 2008. PJM introduced the Capacity Performance capacity market design effective on August 10, 2015, with the Base Residual Auction for 2018/2019.[7] [8]

Conclusions

This report assesses the competitiveness of the markets managed by PJM in 2021, including market structure, participant behavior and market performance. This report was prepared by and represents the analysis of the Independent Market Monitor for PJM, also referred to as the Market Monitoring Unit or MMU.

For each PJM market, the market structure is evaluated as competitive or not competitive, and participant behavior is evaluated as competitive or not competitive. Most important, the outcome of each market, market performance, is evaluated as competitive or not competitive.

The MMU also evaluates the market design for each market. The market design serves as the vehicle for translating participant behavior within the market structure into market performance. This report evaluates the effectiveness of the market design of each PJM market in providing market performance consistent with competitive results.

Market structure refers to the cost, demand, and ownership structure of the market. The three pivotal supplier (TPS) test is the most relevant measure of market structure because it accounts for the ownership of assets and the relationship among the pattern of ownership, the resource costs, and the market demand using actual market conditions with both temporal and geographic granularity. Market shares and the related Herfindahl-Hirschman Index (HHI) are also measures of market structure.

Participant behavior refers to the actions of individual market participants, also sometimes referred to as participant conduct.

5 The MMU uses Total PJM Billing values provided by PJM. For 2019 and after, the Total PJM Billing calculation was modified to better reflect PJM total billing through the PJM settlement process..

6 In Figure 1-2, the MMU uses Total PJM Billing values provided by PJM. For 2019 and after, the Total PJM Billing calculation was modified to better reflect PJM total billing through the PJM settlement process.

7 See also the *2021 State of the Market Report for PJM*, Volume II, Appendix A: "PJM Overview."

8 Analysis of 2021 market results requires comparison to prior years. During calendar years 2004 and 2005, PJM conducted the phased integration of five control zones: ComEd, American Electric Power (AEP), The Dayton Power & Light Company (DAY), Duquesne Light Company (DUQ) and Dominion. In June 2011, PJM integrated the American Transmission Systems, Inc. (ATSI) Control Zone. In January 2012, PJM integrated the Duke Energy Ohio/Kentucky (DUKE) Control Zone. In June 2013, PJM integrated the Eastern Kentucky Power Cooperative (EKPC). In December 2018, PJM integrated the Ohio Valley Electric Corporation (OVEC.) By convention, control zones bear the name of a large utility service provider working within their boundaries. The nomenclature applies to the geographic area, not to any single company. For additional information on the integrations, their timing and their impact on the footprint of the PJM service territory prior to 2020, see *2019 State of the Market Report for PJM*, Volume 2, Appendix A: "PJM Overview."

Market performance refers to the outcomes of the market. Market performance results from the behavior of market participants within a market structure, mediated by market design.

Market design means the rules under which the entire relevant market operates, including the software that implements the market rules. Market rules include the definition of the product, the definition of short run marginal cost, rules governing offer behavior, market power mitigation rules, and the definition of demand. Market design is characterized as effective, mixed or flawed. An effective market design provides incentives for competitive behavior and permits competitive outcomes. A mixed market design has significant issues that constrain the potential for competitive behavior to result in competitive market outcomes, and does not have adequate rules to mitigate market power or incent competitive behavior. A flawed market design produces inefficient outcomes which cannot be corrected by competitive behavior.

Energy Market Conclusion

The Market Monitoring Unit (MMU) analyzed measures of market structure, participant conduct and market performance, including market size, concentration, pivotal suppliers, offer behavior, markup, and price. The MMU concludes that the PJM energy market results were competitive in 2021.

Table 1-2 The energy market results were competitive

Market Element	Evaluation	Market Design
Market Structure: Aggregate Market	Partially Competitive	
Market Structure: Local Market	Not Competitive	
Participant Behavior	Competitive	
Market Performance	**Competitive**	**Effective**

- The aggregate market structure was evaluated as partially competitive because the aggregate market power test based on pivotal suppliers indicates that the aggregate day-ahead market structure was not competitive on every day. The hourly HHI (Herfindahl-Hirschman Index) results indicate that the PJM aggregate energy market in 2021 was, on average, unconcentrated by FERC HHI standards. Average HHI was 742 with a minimum of 532 and a maximum of 1115 in 2021. The intermediate segment was moderately concentrated. The peaking segment of supply was highly concentrated. The fact that the average HHI is in the unconcentrated range does not mean that the aggregate market was competitive in all hours. As demonstrated for the day-ahead market, it is possible to have pivotal suppliers in the aggregate market even when the HHI level is not in the highly concentrated range. It is possible to have an exercise of market power even when the HHI level is not in the highly concentrated range. The number of pivotal suppliers in the energy market is a more precise measure of structural market power than the HHI. The HHI is not a definitive measure of structural market power.
- The local market structure was evaluated as not competitive due to the highly concentrated ownership of supply in local markets created by transmission constraints and local reliability issues. The results of the three pivotal supplier (TPS) test, used to test local market structure, indicate the existence of market power in local markets created by transmission constraints. The local market performance is competitive as a result of the application of the TPS test. While transmission constraints create the potential for the exercise of local market power, PJM's application of the three pivotal supplier test identified local market power and resulted in offer capping to require competitive offers, correcting for structural issues created by local transmission constraints. There are, however, identified issues with the definition of cost-based offers and the application of market power mitigation to resources whose owners fail the TPS test that need to be addressed because unit owners can exercise market power even when they fail the TPS test.
- Participant behavior was evaluated as competitive because the analysis of markup shows that marginal units generally make offers at, or close to, their marginal costs in both the day-ahead and real-time energy markets, although the behavior of some participants both routinely and during periods of high demand represents economic withholding. The ownership of marginal units is concentrated. The markups of pivotal suppliers in the aggregate market and of many pivotal suppliers in local markets remain unmitigated due to the lack of aggregate market power mitigation and the flawed implementation of offer caps for resources that fail the TPS test. The markups of those participants affected LMP.

- Market performance was evaluated as competitive because market results in the energy market reflect the outcome of a competitive market, as PJM prices are set, on average, by marginal units operating at, or close to, their marginal costs in both day-ahead and real-time energy markets, although high markups for some marginal units did affect prices.
- Market design was evaluated as effective because the analysis shows that the PJM energy market resulted in competitive market outcomes. In general, PJM's energy market design provides incentives for competitive behavior and results in competitive outcomes. In local markets, where market power is an issue, the market design identifies market power and causes the market to provide competitive market outcomes in most cases although issues with the implementation of market power mitigation and development of cost-based offers remain. The role of UTCs in the day-ahead energy market continues to cause concerns. Market design implementation issues, including inaccuracies in modeling of the transmission system and of generator capabilities as well as inefficiencies in real-time dispatch and price formation, undermine market efficiency in the energy market. PJM resolved the problems with real-time dispatch and pricing on November 1, 2021. The implementation of fast start pricing on September 1, 2021 undermined market efficiency by setting inefficient prices that are inconsistent with the dispatch signals.

PJM markets are designed to promote competitive outcomes derived from the interaction of supply and demand in each of the PJM markets. Market design itself is the primary means of achieving and promoting competitive outcomes in PJM markets. One of the MMU's core functions is to identify actual or potential market design flaws.[9] The approach to market power mitigation in PJM has focused on market designs that promote competition (a structural basis for competitive outcomes) and on mitigating market power in instances where the market structure is not competitive and thus where market design alone cannot mitigate market power. FERC relies on effective market power mitigation when it approves market sellers to participate in the PJM market at market based rates.[10] In the PJM energy market, market power mitigation occurs primarily in the case of local market power. When a transmission constraint creates the potential for local market power, PJM applies a structural test to determine if the local market is competitive, applies a behavioral test to determine if generator offers exceed competitive levels and applies a market performance test to determine if such generator offers would affect the market price.[11] There are, however, identified issues with the application of market power mitigation to resources whose owners fail the TPS test that can result in the exercise of local market power even when market power mitigation rules are applied. These issues need to be addressed. FERC recognized these issues in its June 17, 2021 order.[12] Some units with market power have positive markups and some have inflexible parameters, which means that the cost-based offer was not used and that the process for offer capping units that fail the TPS test does not consistently result in competitive market outcomes in the presence of market power. There are issues related to the definition of gas costs includable in energy offers that need to be addressed. There are issues related to the level of maintenance expense includable in energy offers that need to be addressed. There are currently no market power mitigation rules in place that limit the ability to exercise market power when aggregate market conditions are tight and there are pivotal suppliers in the aggregate market. Aggregate market power needs to be addressed. Market design must reflect appropriate incentives for competitive behavior, the application of local market power mitigation needs to be fixed, the definition of a competitive offer needs to be fixed, and aggregate market power mitigation rules need to be developed. The importance of these issues is amplified by the rules permitting cost-based offers in excess of $1,000 per MWh.

Capacity Market Conclusion

The Market Monitoring Unit (MMU) analyzed market structure, participant conduct and market performance in the PJM Capacity Market, including supply, demand, concentration ratios, pivotal suppliers, volumes, prices,

9 OATT Attachment M (PJM Market Monitoring Plan).

10 See *Refinements to Horizontal Market Power Analysis for Sellers in Certain Regional Transmission Organization and Independent System Operator Markets*, Order No. 861, 168 FERC ¶ 61,040 (2019); *order on reh'g*, Order No. 861-A; 170 FERC ¶ 61,106 (2020).

11 The market performance test means that offer capping is not applied if the offer does not exceed the competitive level and therefore market power would not affect market performance.

12 175 FERC ¶ 61,231 (2021).

outage rates and reliability.[13] The conclusions are a result of the MMU's evaluation of the 2022/2023 Base Residual Auction.

Table 1-3 The capacity market results were not competitive

Market Element	Evaluation	Market Design
Market Structure: Aggregate Market	Not Competitive	
Market Structure: Local Market	Not Competitive	
Participant Behavior	Not Competitive	
Market Performance	**Not Competitive**	**Mixed**

- The aggregate market structure was evaluated as not competitive. For almost all auctions held from 2007 to the present, the PJM region failed the three pivotal supplier test (TPS), which is conducted at the time of the auction.[14] Structural market power is endemic to the capacity market.
- The local market structure was evaluated as not competitive. For almost every auction held, all LDAs have failed the TPS test, which is conducted at the time of the auction.[15]
- Participant behavior was evaluated as not competitive in the 2022/2023 RPM Base Residual Auction. Market power mitigation measures were applied when the capacity market seller failed the market power test for the auction, the submitted sell offer exceeded the defined offer cap, and the submitted sell offer, absent mitigation, would increase the market clearing price. But the Net CONE times B offer cap under the capacity performance design exceeds the competitive level. In the 2022/2023 RPM Base Residual Auction, some participants' offers were above the competitive level. The MMU recognizes that these market participants followed the capacity market rules by offering at less than the stated offer cap of Net CONE times B. But Net CONE times B is not a competitive offer when the expected number of performance assessment intervals is zero or a very small number and the nonperformance charge rate is defined as Net CONE/30, and the other strong CP assumptions are also not correct. Under these circumstances, a competitive offer is net ACR. That is the way in which most market participants offered in this and prior capacity performance auctions. The Commission recognized this issue and issued an order correcting the PJM tariff, eliminating the prior offer cap and establishing a competitive market seller offer cap set at net ACR, effective September 2, 2021. But the 2022/2023 BRA was conducted with the previous default MSOC of Net CONE times B.[16]
- Market performance was evaluated as not competitive based on the 2022/2023 RPM Base Residual Auction. Although structural market power exists in the capacity market, a competitive outcome can result from the application of market power mitigation rules. The outcome of the 2022/2023 RPM Base Residual Auction was not competitive as a result of participant behavior which was not competitive, specifically offers which exceeded the competitive level.
- Market design was evaluated as mixed because while there are many positive features of the Reliability Pricing Model (RPM) design and the capacity performance modifications to RPM, there are several features of the RPM design which still threaten competitive outcomes. These include the definition of DR which permits inferior products to substitute for capacity, the replacement capacity issue, the definition of unit offer parameters, and the inclusion of imports which are not substitutes for internal capacity resources.
- As a result of the fact that the capacity market design was found to be not just and reasonable by FERC and a final market design had not been approved, the 2022/2023 Base Residual Auction was delayed and held in May 2021, and for a number of additional reasons, the 2023/2024 Base Residual Auction is delayed and scheduled for June 2022, and first and second incremental auctions for the 2022/2023 through 2026/2027 Delivery Years are canceled if within 10 months of the revised BRA schedule.[17]

13 The values stated in this report for the RTO and LDAs refer to the aggregate level including all nested LDAs unless otherwise specified. For example, RTO values include the entire PJM market and all LDAs. Rest of RTO values are RTO values net of nested LDA values.

14 In the 2008/2009 RPM Third Incremental Auction, 18 participants in the RTO market passed the TPS test. In the 2018/2019 RPM Second Incremental Auction, 35 participants in the RTO market passed the test.

15 In the 2012/2013 RPM Base Residual Auction, six participants included in the incremental supply of EMAAC passed the TPS test. In the 2014/2015 RPM Base Residual Auction, seven participants in the incremental supply in MAAC passed the TPS test. In the 2021/2022 RPM First Incremental Auction, two participants in the incremental supply in EMAAC passed the TPS test. In the 2021/2022 RPM Second Incremental Auction, two participants in the incremental supply in EMAAC passed the TPS test.

16 176 FERC ¶ 61,137 (September 2, 2021).

17 174 FERC ¶ 61,036 (2021), 177 FERC ¶ 61,050 (2021), 177 FERC ¶ 61,209 (2021).

Tier 2 Synchronized Reserve Market Conclusion

The MMU analyzed measures of market structure, conduct and performance for the PJM Synchronized Reserve Market for 2021.

Table 1-4 The tier 2 synchronized reserve market results were competitive

Market Element	Evaluation	Market Design
Market Structure: Regional Markets	Not Competitive	
Participant Behavior	Competitive	
Market Performance	**Competitive**	**Mixed**

- The tier 2 synchronized reserve market structure was evaluated as not competitive because of high levels of supplier concentration.
- Participant behavior was evaluated as competitive because the market rules require cost-based offers.
- Market performance was evaluated as competitive because the interaction of participant behavior with the market design results in competitive prices.
- Market design was evaluated as mixed. Market power mitigation rules result in competitive outcomes despite high levels of supplier concentration. However, tier 1 reserves are inappropriately overcompensated when the nonsynchronized reserve market clears with a nonzero price.

Day-Ahead Scheduling Reserve Market Conclusion

The MMU analyzed measures of market structure, conduct and performance for the PJM DASR Market for 2021.

Table 1-5 The day-ahead scheduling reserve market results were competitive

Market Element	Evaluation	Market Design
Market Structure	Not Competitive	
Participant Behavior	Mixed	
Market Performance	**Competitive**	**Mixed**

- The DASR market structure was evaluated as not competitive because the DASR market failed the three pivotal supplier (TPS) test in 94 percent of the intervals in which the price was greater than $0.01 per MWh.
- Participant behavior was evaluated as mixed because while most offers were equal to marginal costs, a significant proportion of offers reflected economic withholding.
- Market performance was evaluated as competitive because there were adequate offers in every hour to satisfy the requirement and the clearing prices reflected those offers, although there is concern about offers above the competitive level affecting prices. The day-ahead scheduling reserve market clearing price was above $0 in 16.9 percent of hours in 2021. In 98.6 percent of hours when the clearing price was above $0, the clearing price was the offer price of the marginal unit. In the remaining 1.4 percent of hours, the price included lost opportunity cost.
- Market design was evaluated as mixed because the DASR product does not include performance obligations. Offers should be based on opportunity cost only, to ensure competitive outcomes and that market power cannot be exercised.

Regulation Market Conclusion

The MMU analyzed measures of market structure, conduct and performance for the PJM Regulation Market for 2021.

Table 1-6 The regulation market results were not competitive

Market Element	Evaluation	Market Design
Market Structure	Not Competitive	
Participant Behavior	Competitive	
Market Performance	**Not Competitive**	**Flawed**

- The regulation market structure was evaluated as not competitive because the PJM Regulation Market failed the three pivotal supplier (TPS) test in 85.9 percent of the hours in 2021.
- Participant behavior in the PJM Regulation Market was evaluated as competitive in 2021 because market power mitigation requires competitive offers when the three pivotal supplier test is failed, although the inclusion of a positive margin raises questions.
- Market performance was evaluated as not competitive, because all units are not paid the same price on an equivalent MW basis.
- Market design was evaluated as flawed. The market design has failed to correctly incorporate a consistent implementation of the marginal benefit factor in

optimization, pricing and settlement. The market results continue to include the incorrect definition of opportunity cost. The result is significantly flawed market signals to existing and prospective suppliers of regulation.

FTR Auction Market Conclusion

The *2021 State of the Market Report for PJM* focuses on the 2020/2021 Monthly Balance of Planning Period FTR Auctions, specifically covering January 1, 2021, through December 31, 2021. The Market Monitoring Unit (MMU) analyzed measures of market structure, participant conduct and market performance, including market size, concentration, offer behavior, and price. The MMU concludes that the PJM FTR auction market results were partially competitive in 2021.

Table 1-7 The FTR auction markets results were partially competitive

Market Element	Evaluation	Market Design
Market Structure	Competitive	
Participant Behavior	Partially Competitive	
Market Performance	**Partially Competitive**	**Flawed**

- Market structure was evaluated as competitive. The ownership of FTR obligations is unconcentrated for the individual years of the 2021/2024 Long Term FTR Auction, the 2021/2022 Annual FTR Auction and each period of the Monthly Balance of Planning Period Auctions. The ownership of FTR options is moderately or highly concentrated for every Monthly FTR Auction period and moderately concentrated for the 2020/2021 Annual FTR Auction. Ownership of FTRs is disproportionately (76.2 percent) by financial participants. The ownership of ARRs is unconcentrated.
- Participant behavior was evaluated as partially competitive because ARR holders who are the sellers of FTRs are not permitted to participate in the market clearing.
- Market performance was evaluated as partially competitive because of the flaws in the market design. Sellers, the ARR holders, cannot set a sale price. Buyers can reclaim some of their purchase price after the market clears if the product does not meet a profitability target. The market resulted in a substantial shortfall in congestion payments to load and significant and unsupportable disparities among zones in the share of congestion returned to load. FTR purchases by financial entities remain persistently profitable in part as a result of the flaws in the market design.
- Market design was evaluated as flawed because there are significant and fundamental flaws with the basic ARR/FTR design. The FTR auction market is not actually a market because the sellers have no independent role in the process. ARR holders cannot determine the price at which they are willing to sell rights to congestion revenue. Buyers have the ability to reclaim some of the price paid for FTRs after the market clears. The market design is not an efficient or effective way to ensure that the rights to all congestion revenues are assigned to load. The product sold to FTR buyers is incorrectly defined as target allocations rather than a share of congestion revenue. ARR holders' rights to congestion revenues are not correctly defined because the contract path based assignment of congestion rights is inadequate and incorrect. Ongoing PJM subjective intervention in the FTR market that affects market fundamentals is also an issue and a symptom of the fundamental flaws in the design. The product, the quantity of the product and the price of the product are all incorrectly defined.
- The fact that load is not able to define its willingness to sell FTRs or the prices at which it is willing to sell FTRs and the fact that sellers are required to return some of the cleared auction revenue to FTR buyers when FTR profits are not adequate, means that the FTR design does not actually function as a market and is evidence of basic flaws in the market design.

Role of MMU

FERC assigns three core functions to MMUs: reporting, monitoring and market design.[18] These functions are interrelated and overlap. The PJM Market Monitoring Plan establishes these functions, providing that the MMU is responsible for monitoring: compliance with the PJM Market Rules; actual or potential design flaws in the PJM Market Rules; structural problems in the PJM Markets that may inhibit a robust and competitive market; the actual or potential exercise of market power or violation of the market rules by a Market Participant;

18 18 CFR § 35.28(g)(3)(ii); see also *Wholesale Competition in Regions with Organized Electric Markets*, Order No. 719, FERC Stats. & Regs. ¶31,281 (2008) ("Order No. 719"), *order on reh'g*, Order No. 719-A, FERC Stats. & Regs. ¶31,292 (2009), *reh'g denied*, Order No. 719-B, 129 FERC ¶ 61,252 (2009).

PJM's implementation of the PJM Market Rules or operation of the PJM Markets; and such matters as are necessary to prepare reports.[19]

Reporting

The MMU performs its reporting function primarily by issuing and filing annual and quarterly state of the market reports; regular reports on market issues, such as RPM auction reports; reports responding to requests from regulators and other authorities; and ad hoc reports on specific topics. The state of the market reports provide a comprehensive analysis of market structure, participant conduct and market performance for the PJM markets. State of the market reports and other reports are intended to inform PJM, the PJM Board, FERC, other regulators, other authorities, market participants, stakeholders and the general public about how well PJM markets achieve the competitive outcomes necessary to realize the goals of regulation through competition, and how the markets can be improved.

The MMU presents reports directly to PJM stakeholders, PJM staff, FERC staff, state commission staff, state commissions, other regulatory agencies and the general public. Report presentations provide an opportunity for interested parties to ask questions, discuss issues, and provide feedback to the MMU.

Monitoring

To perform its monitoring function, the MMU screens and monitors the conduct of Market Participants under the MMU's broad purview to monitor, investigate, evaluate and report on the PJM Markets.[20] The MMU has direct, confidential access to FERC.[21] The MMU may also refer matters to the attention of state commissions.[22]

The MMU monitors market behavior for violations of FERC Market Rules and PJM Market Rules, including the actual or potential exercise of market power.[23] The MMU will investigate and refer "Market Violations," which refer to any of "a tariff violation, violation of a Commission-approved order, rule or regulation, market manipulation, or inappropriate dispatch that creates substantial concerns regarding unnecessary market inefficiencies..."[24] [25] [26] The MMU also monitors PJM for compliance with the rules, in addition to market participants.[27]

An important component of the monitoring function is the review of inputs to mitigation. The actual or potential exercise of market power is addressed in part through *ex ante* mitigation rules incorporated in PJM's market clearing software for the energy market, the capacity market and the regulation market. If a market participant fails the TPS test in any of these markets its offer is set to the lower of its price-based or cost-based offer. This prevents the exercise of market power and ensures competitive pricing, provided that the cost-based offer accurately reflects short run marginal cost.

If cost-based offers do not accurately reflect short run marginal cost, the market power mitigation process does not ensure competitive pricing in PJM markets. The MMU evaluates the fuel cost policy for every unit as well as the other inputs to cost-based offers. PJM Manual 15 does not clearly or accurately describe the short run marginal cost of generation. Manual 15 should be replaced with a straightforward description of the components of cost offers based on short run marginal costs and the correct calculation of cost offers. The MMU evaluates every offer in each capacity market (RPM) auction using data submitted to the MMU through web-based data input systems developed by the MMU.[28]

The MMU also reviews operational parameter limits included with unit offers, evaluates compliance with

19 OATT Attachment M § IV; 18 CFR § 1c.2.
20 OATT Attachment M § IV.
21 OATT Attachment M § IV.K.3.
22 OATT Attachment M § IV.H.
23 OATT § I.1 ("FERC Market Rules" mean the market behavior rules and the prohibition against electric energy market manipulation codified by the Commission in its Rules and Regulations at 18 CFR §§ 1c.2 and 35.37, respectively; the Commission-approved PJM Market Rules and any related proscriptions or any successor rules that the Commission from time to time may issue, approve or otherwise establish… "PJM Market Rules" mean the rules, standards, procedures, and practices of the PJM Markets set forth in the PJM Tariff, the PJM Operating Agreement, the PJM Reliability Assurance Agreement, the PJM Consolidated Transmission Owners Agreement, the PJM Manuals, the PJM Regional Practices Document, the PJM-Midwest Independent Transmission System Operator Joint Operating Agreement or any other document setting forth market rules.")
24 FERC defines manipulation as engaging "in any act, practice, or course of business that operates or would operate as a fraud or deceit upon any entity." 18 CFR § 1c.2(a)(3). Manipulation may involve behavior that is consistent with the letter of the rules, but violates their spirit. An example is market behavior that is economically meaningless, such as equal and opposite transactions, which may entitle the transacting party to a benefit associated with volume. Unlike market power or rule violations, manipulation must be intentional. The MMU must build its case, including an inference of intent, on the basis of market data.
25 OATT § I.1.
26 The MMU has no prosecutorial or enforcement authority. The MMU notifies FERC when it identifies a significant market problem or market violation. OATT Attachment M § IV.I.1. If the problem or violation involves a market participant, the MMU discusses the matter with the participant(s) involved and analyzes relevant market data. If that investigation produces sufficient credible evidence of a violation, the MMU prepares a formal referral and thereafter undertakes additional investigation of the specific matter only at the direction of FERC staff. *Id.* If the problem involves an existing or proposed law, rule or practice that exposes PJM markets to the risk that market power or market manipulation could compromise the integrity of the markets, the MMU explains the issue, as appropriate, to FERC, state regulators, stakeholders or other authorities. The MMU may also initiate, participate as a party or provide information or testimony in regulatory or other proceedings.
27 OATT Attachment M § IV.C.
28 OATT Attachment M–Appendix § II.E.

the requirement to offer into the energy and capacity markets, evaluates the economic basis for unit retirement requests and evaluates and compares offers in the day-ahead and real-time energy markets.[29] [30] [31] [32]

The MMU reviews offers and inputs in order to evaluate whether those offers raise market power concerns. Market participants, not the MMU, determine and take responsibility for offers that they submit and the market conduct that those offers represent. If the MMU has a concern about an offer, the MMU may raise that concern with FERC or other regulatory authorities. FERC and other regulators have enforcement and regulatory authority that they may exercise with respect to offers submitted by market participants. PJM also reviews offers, but it does so in order to determine whether offers comply with the PJM tariff and manuals. PJM, in its role as the market operator, may reject an offer that fails to comply with the market rules. The respective reviews performed by the MMU and PJM are separate and non-sequential.

The PJM markets monitored by the MMU include market related procurement processes conducted by PJM, such as for Black Start resources included in the PJM system restoration plan.[33] [34]

The MMU also monitors transmission planning, interconnections and rules for vertical market power issues, and with the introduction of competitive transmission development policy in Order No. 1000, horizontal market power issues.[35]

Market Design

In order to perform its role in PJM market design, the MMU evaluates existing and proposed PJM Market Rules and the design of the PJM Markets.[36] The MMU initiates and proposes changes to the design of such markets or the PJM Market Rules in stakeholder or regulatory proceedings.[37] In support of this function, the MMU engages in discussions with stakeholders, State Commissions, PJM Management, and the PJM Board; participates in PJM stakeholder meetings or working groups regarding market design matters; publishes proposals, reports or studies on such market design issues; and makes filings with the Commission on market design, market rules and market rule implementation issues, including complaints or petitions.[38] The MMU also recommends changes to the PJM Market Rules to the staff of the Commission's Office of Energy Market Regulation, State Commissions, and the PJM Board.[39] The MMU may provide in its annual, quarterly and other reports "recommendations regarding any matter within its purview."[40]

New Recommendations

Consistent with its core function to "[e]valuate existing and proposed market rules, tariff provisions and market design elements and recommend proposed rule and tariff changes," the MMU recommends specific enhancements to existing market rules and implementation of new rules that are required for competitive results in PJM markets and for continued improvements in the functioning of PJM markets.[41]

In this *2021 State of the Market Report for PJM*, the MMU includes 20 new recommendations made for 2021, 13 of which are new in this 2021 annual report.[42] [43]

New Recommendations from Section 3, Energy Market

- The MMU recommends that PJM stop capping the system marginal price in RT SCED and instead limit the sum of violated reserve constraint shadow prices used in LPC to $1,700 per MWh. (Priority: Medium. First reported Q1, 2021. Status: Not adopted.)
- The MMU recommends, if PJM implements extended downward sloping ORDCs, that PJM calculate the probability of reserves falling below the minimum reserve requirement (MRR) based on ten minute rather than 30 minute forecast error, and on forced outages in the ten minute rather than the 30 minute

39 *Id.*
40 OATT Attachment M § VI.A.
41 18 CFR § 35.28(g)(3)(ii)(A); see also OATT Attachment M § IV.D.
42 New recommendations include all MMU recommendations that were reported for the first time in the *2021 State of the Market Report for PJM* or in any of the three quarterly state of the market reports that were published in 2021.
43 For a complete list of MMU recommendations, see the *2021 State of the Market Report for PJM*, Vol II, Section 2, Recommendations.

look ahead window to model the uncertainty in the inputs to RT SCED. (Priority: Medium. First reported Q2, 2021. Status: Not adopted.)

- The MMU recommends, in order to ensure effective market power mitigation and to ensure that capacity resources meet their obligations to be flexible, that capacity resources be required to use flexible parameters in all offers at all times. (Priority: High. First reported Q3, 2021. Status: Not adopted.)
- The MMU recommends that PJM require generators that violate their approved turn down ratio (by either using the fixed gen option or increasing their economic minimum) to use the temporary parameter exception process that requires market sellers to demonstrate that the request is based on a physical and actual constraint. (Priority: Medium. New recommendation. Status: Not adopted.)
- The MMU recommends that PJM adjust the ORDCs during spin events to reduce the reserve requirement for synchronized and primary reserves by the amount of the reserves deployed. (Priority: Medium. New recommendation. Status: Not adopted.)
- The MMU recommends that PJM clearly document the calculation of shortage prices and implementation of reserve price caps in the PJM Manuals, including defining all the components of reserve prices, and all the constraints whose shadow prices are included in reserve prices. (Priority: High. New recommendation. Status: Not adopted.)

New Recommendation from Section 4, Energy Uplift

- The MMU recommends that units not be paid lost opportunity cost uplift when PJM directs a unit to reduce output based on a transmission constraint or other reliability issue. There is no lost opportunity because the unit is required to reduce for the reliability of the unit and the system. (Priority: High. First reported Q2, 2021. Status: Not adopted.)

New Recommendations from Section 5, Capacity Market

- The MMU recommends that the value of CTRs should be defined by the total MW cleared in the capacity market, the internal MW cleared and the imported MW cleared, and not redefined later prior to the delivery year. (Priority: Medium. First reported Q3, 2021. Status: Not adopted.)
- The MMU recommends that intermittent resources, including storage, not be permitted to offer capacity MW based on energy delivery that exceeds their defined deliverability rights (CIRs). Only energy output for such resources below the designated CIR/deliverability level should be recognized in the definition of capacity. (Priority: High. New recommendation. Status: Not adopted.)
- The MMU recommends that the must offer rule in the capacity market apply to all capacity resources. There is no reason to exempt intermittent and storage resources, including hydro. The purpose of the must offer rule, which has been in place since the beginning of the capacity market in 1999, is to prevent the exercise of market power via withholding. (Priority: High. New recommendation. Status: Not adopted.)
- The MMU recommends that PJM reevaluate the shape of the VRR curve. The shape of the VRR curve directly results in load paying substantially more for capacity than load would pay with a vertical demand curve. (Priority: High. New recommendation. Status: Not adopted.)
- The MMU recommends that the market clearing results be used in settlements rather than the reallocation process currently used, or that the process of modifying the obligations to pay for capacity be reviewed. (Priority: Medium. New recommendation. Status: Not adopted.)
- The MMU recommends that PJM improve the clarity and transparency of its CETL calculations. The MMU also recommends that CETL for capacity imports into PJM be based on the ability to import capacity only where PJM capacity exists and where that capacity has a must offer requirement in the PJM Capacity Market. (Priority: Medium. New recommendation. Status: Not adopted.)
- The MMU recommends using the lower of the cost or price-based energy market offer to calculate energy costs in the calculation of the historical net revenues which are an offset to gross ACR in the calculation of unit specific capacity resource offer caps based on net ACR. (Priority: Medium. New recommendation. Status: Not adopted.)

- The MMU recommends that any combined seasonal resources be required to be in the same LDA and preferably at the same location, in order for the energy market and capacity market to remain synchronized and reliability metrics correctly calculated. (Priority: Medium. New recommendation. Status: Not adopted.)

New Recommendations from Section 6, Demand Response

- The MMU recommends that EDCs not be allowed to participate in markets as DER aggregators in addition to their EDC role. (Priority: High. New recommendation. Status: Not adopted.)
- The MMU recommends that PJM include a 5 MW maximum size cap on DER aggregations. (Priority: Medium. New recommendation. Status: Not adopted.)

New Recommendation from Section 8, Environmental and Renewable Regulations

- The MMU recommends that renewable energy credit markets based on state renewable portfolio standards be brought into PJM markets as they are an increasingly important component of the wholesale energy market. The MMU recommends that there be a single PJM operated forward market for RECs, for a single product based on a common set of state definitions of renewable technologies, with a single clearing price, trued up to real time delivery. (Priority: High. First reported 2010. Status: Not adopted.)[44]

New Recommendation from Section 10, Ancillary Services

- The MMU recommends that the $12.00 margin adder be eliminated from the definition of the cost based regulation offer because it is a markup and not a cost. (Priority: Medium. First reported Q1, 2021. Status: Not adopted.)

New Recommendation from Section 13, Financial Transmission Rights and Auction Revenue Rights

- The MMU recommends the use of a 99 percent confidence interval when calculating initial margin requirements for FTR market participants, in order to assign the cost of managing risk to the FTR holders who benefit or lose from their FTR positions. (Priority: High. New recommendation. Status: Not adopted.)

Total Price of Wholesale Power

The total price of wholesale power is the total price per MWh of wholesale electricity in PJM markets.[45] The total price is an average price. Prices vary by location and time period. The total price includes the price of energy, capacity, transmission service, ancillary services, and administrative fees, regulatory support fees and uplift charges billed through PJM systems. Table 1-8 shows the average price, by component, for 2020 and 2021.

The total costs for each year shown in Table 1-8 equal the total price per MWh, by category, multiplied by the total load. The total costs are different from the total billing values that PJM reports as shown in Figure 1-2. PJM's reported total billing values represent the total dollars that pass through the PJM settlement process.

Each of the components in Table 1-8 is defined in PJM's Open Access Transmission Tariff (OATT) and PJM Operating Agreement and each is collected through PJM's billing system.

Components of Total Price

- The Energy component is the real-time load weighted average PJM locational marginal price (LMP).
- The Capacity component is the average price per MWh of Reliability Pricing Model (RPM) payments.
- The Transmission Service Charges component is the average price per MWh of network integration

44 This recommendation was first reported in 2010, but has been enhanced in the *2021 State of the Market Report for PJM.*

45 Accounting load is used in the calculation of total price because accounting load is the load customers pay for in PJM settlements. The use of accounting load with losses before June 1, and without losses after June 1, 2007, is consistent with PJM's calculation of LMP. Before June 1, 2007, transmission losses were included in accounting load. After June 1, 2007, transmission losses were excluded from accounting load and losses were addressed through the incorporation of marginal loss pricing in LMP.

charges, and firm and nonfirm point to point transmission service.[46]

- The Energy Uplift (Operating Reserves) component is the average price per MWh of day-ahead and balancing operating reserves and synchronous condensing charges.[47]
- The Reactive component is the average cost per MWh of reactive supply and voltage control from generation and other sources.[48]
- The Regulation component is the average cost per MWh of regulation procured through the PJM Regulation Market.[49]
- The PJM Administrative Fees component is the average cost per MWh of PJM's monthly expenses for a number of administrative services, including Advanced Control Center (AC^2) and OATT Schedule 9 funding of FERC, OPSI, CAPS and the MMU.
- The Transmission Enhancement Cost Recovery component is the average cost per MWh of PJM billed (and not otherwise collected through utility rates) costs for transmission upgrades and projects, including annual recovery for the TrAIL and PATH projects.[50]
- The Capacity (FRR) component is the average cost per MWh under the Fixed Resource Requirement (FRR) Alternative for an eligible LSE to satisfy its Unforced Capacity obligation.[51]
- The Emergency Load Response component is the average cost per MWh of the PJM Emergency Load Response Program.[52]
- The Day-Ahead Scheduling Reserve component is the average cost per MWh of Day-Ahead scheduling reserves procured through the day-ahead scheduling reserve market.[53]
- The Transmission Owner (Schedule 1A) component is the average cost per MWh of transmission owner scheduling, system control and dispatch services charged to transmission customers.[54]
- The Synchronized Reserve component is the average cost per MWh of synchronized reserve procured through the Synchronized Reserve Market.[55]
- The Black Start component is the average cost per MWh of black start service.[56]
- The RTO Startup and Expansion component is the average cost per MWh of charges to recover AEP, ComEd and DAY's integration expenses.[57]
- The NERC/RFC component is the average cost per MWh of NERC and RFC charges, plus any reconciliation charges.[58]
- The Economic Load Response component is the average cost per MWh of day-ahead and real-time economic load response program charges to LSEs.[59]
- The Transmission Facility Charges component is the average cost per MWh of Ramapo Phase Angle Regulators charges allocated to PJM Mid-Atlantic transmission owners.[60]
- The Nonsynchronized Reserve component is the average cost per MWh of non-synchronized reserve procured through the Non-Synchronized Reserve Market.[61]
- The Emergency Energy component is the average cost per MWh of emergency energy.[62]

46 OATT §§ 13.7, 14.5, 27A & 34.
47 OA Schedules 1 §§ 3.2.3 & 3.3.3.
48 OATT Schedule 2 and OA Schedule 1 § 3.2.3B. The line item in Table 1-8 includes all reactive services charges.
49 OA Schedules 1 §§ 3.2.2, 3.2.2A, 3.3.2, & 3.3.2A; OATT Schedule 3.
50 OATT Schedule 12.
51 RAA Schedule 8.1.
52 OATT PJM Emergency Load Response Program.

55 OA Schedule 1 § 3.2.3A.01; PJM OATT Schedule 6.
56 OATT Schedule 6A. The line item in Table 1-8 includes all Energy Uplift (Operating Reserves) charges for Black Start.
57 OATT Attachments H-13, H-14 and H-15 and Schedule 13.
58 OATT Schedule 10-NERC and OATT Schedule 10-RFC.
59 OA Schedule 1 § 3.6.
60 OA Schedule 1 § 5.3b.
61 OA Schedule 1 § 3.2.3A.001.
62 OA Schedule 1 § 3.2.6.

Table 1-8 shows that energy, capacity and transmission charges are the three largest components of the total price per MWh of wholesale power, comprising 97.5 percent of the total price per MWh in 2021. The total price per MWh of wholesale power increased from $44.59 in 2020 to $65.14 in 2021, an increase of 46.1 percent. Starting in the third quarter of 2019, for the first time since the start of the PJM RPM Capacity Market in 2007, the cost of transmission has been a larger share of the total price per MWh of wholesale power than the cost of capacity.

Table 1-8 Total price per MWh by category: 2020 and 2021[63 64 65]

Category	2020 $/MWh	2020 ($ Millions)	2020 Percent of Total	2021 $/MWh	2021 ($ Millions)	2021 Percent of Total	Percent Change
Load Weighted Energy	$21.77	$16,171	48.8%	$39.78	$30,532	61.1%	82.8%

Total Load (GWh)	742,987			767,425			3.3%
Total Cost ($ Billions)	$33.13			$49.99			50.9%

63 Note: The totals in this table include after the fact billing adjustments and may not match totals presented in past reports.
64 The total cost in this table does not match the PJM reported total billing due to differences in calculation methods. The total prices in this table are load weighted average system prices per MWh by category, even if each category is not charged on a per MWh basis. PJM's reported total billing represents the total dollars that pass through the PJM settlement process.
65 The MMU publishes monthly detail of these components of PJM price. See <http://www.monitoringanalytics.com/data/pjm_price.shtml>.

Table 1-9 shows the inflation adjusted average price, by component, for 2020 and 2021. To calculate the inflation adjusted average prices, the individual components' prices are deflated using the US Consumer Price Index for all items, Urban Consumers (with a base period of January 1998).[66]

Table 1-9 Inflation adjusted total price per MWh by category: 2020 and 2021[67]

Category	2020 $/MWh	2020 ($ Millions)	2020 Percent of Total	2021 $/MWh	2021 ($ Millions)	2021 Percent of Total	Percent Change

Section Overviews

Overview: Section 3, Energy Market

Supply and Demand

Market Structure

- **Supply.** In 2021, 3,990 MW of new resources were added in the energy market, and 1,308 MW of resources were retired.

  The real-time hourly on peak average offered supply was 139,027 MW in 2020, and 136,184 MW in 2021. The day-ahead hourly on peak average offered supply was 158,253 MW in 2020, and 155,811 MW in 2021.

  The real-time hourly average cleared generation in 2021 increased by 3.0 percent from 2020, from 90,938 MWh to 93,644 MWh.

  The day-ahead hourly average supply in 2021, including INCs and UTCs, decreased by 8.1 percent from 2020, from 111,470 MWh to 102,431 MWh.

68 Note: The totals presented in this figure include after the fact billing adjustments and may not match totals presented in past reports.

69 US Consumer Price Index for all items, Urban Consumers (base period: January 1998), published by *Bureau of Labor Statistics*. <http://download.bls.gov/pub/time.series/cu/cu.data.1.AllItems> (January 12, 2022).

70 Note: The totals presented in this figure include after the fact billing adjustments and may not match totals presented in past reports.

71 US Consumer Price Index for all items, Urban Consumers (base period: January 1998), published by *Bureau of Labor Statistics*. <http://download.bls.gov/pub/time.series/cu/cu.data.1.AllItems> (January 12, 2022).

72 Note: The totals presented in this figure include after the fact billing adjustments and may not match totals presented in past reports.

- **Demand.** The real-time hourly peak load plus exports in 2021 was 151,680 MWh (145,561 MWh of load plus 6,120 MWh of gross exports) in the HE 1800 on August 24, 2021, which was 1.8 percent, 2,684 MWh, higher than the PJM peak load plus exports in 2020, which was 148,996 MWh in the HE 1800 on July 20, 2020.

  The real-time hourly average load in 2021 increased by 3.6 percent from 2020, from 84,584 MWh to 87,606 MWh.

  The day-ahead hourly average demand in 2021, including DECs and UTCs, decreased by 8.2 percent from 2020, from 106,209 MWh to 97,537 MWh.

Market Behavior

- **Virtual Offers and Bids.** Any market participant in the PJM Day-Ahead Energy Market can use increment offers, decrement bids, up to congestion transactions, import transactions and export transactions as financial instruments that do not require physical generation or load. The hourly average submitted increment offer MW decreased by 12.1 percent and cleared MW decreased by 4.5 percent in 2021 compared to 2020. The hourly average submitted decrement bid MW increased by 12.0 percent and cleared MW decreased by 2.4 percent in 2021 compared to 2020. The hourly average submitted up to congestion bid MW decreased by 58.2 percent and cleared MW decreased by 61.4 percent in 2021 compared to 2020.

Market Performance

- **Generation Fuel Mix.** In 2021, generation from coal units increased 17.8 percent, generation from natural gas units decreased 2.3 percent, and generation from oil increased 11.5 percent compared to 2020. Wind and solar output rose by 15.7 percent compared to 2020, supplying 4.2 percent of PJM energy in 2021.

- **Fuel Diversity.** The fuel diversity of energy generation in 2021, measured by the fuel diversity index for energy (FDI_e), increased 1.8 percent compared to 2020.

- **Marginal Resources.** In the PJM Real-Time Energy Market in 2021, coal units were 14.1 percent and natural gas units were 71.7 percent of marginal resources. In 2020, coal units were 17.5 percent and natural gas units were 72.6 percent of marginal resources.

  In the PJM Day-Ahead Energy Market in 2021, UTCs were 35.2 percent, INCs were 17.9 percent, DECs were 27.1 percent, and generation resources were 19.5 percent of marginal resources. In 2020, UTCs were 51.4 percent, INCs were 13.2 percent, DECs were 18.8 percent, and generation resources were 16.5 percent of marginal resources.

- **Prices.** The real-time load-weighted average LMP in 2021 increased 82.8 percent from 2020, from $21.77 per MWh to $39.78 per MWh.

  The day-ahead load-weighted average LMP in 2021 increased 84.0 percent from 2020, from $21.40 per MWh to $39.37 per MWh.

- **Fast Start Pricing.** The real-time load-weighted average PLMP was $52.20 per MWh for September 1, 2021, through December 31, 2021, which is 5.5 percent, $2.73 per MWh, higher than the real-time load-weighted average DLMP of $49.47 per MWh.

- **Components of LMP.** In the PJM Real-Time Energy Market in 2021, 10.2 percent of the load-weighted LMP was the result of coal costs, 53.9 percent was the result of gas costs and 3.2 percent was the result of the cost of emission allowances. In 2021, 8.3 percent of load-weighted LMP was the result of the transmission constraint violation penalty factor due to an increased frequency of transmission constraint violations, especially on the 500 kV system. PJM implemented Fast Start Pricing on September 1, 2021, which explicitly allowed commitment costs to affect LMPs. In the first four months of the fast start pricing in PJM, 3.4 percent of the real-time load-weighted average LMP was the result of commitment costs.

  In the PJM Day-Ahead Energy Market in 2021, 25.9 percent of the load-weighted LMP was the result of gas costs, 11.2 percent was the result of coal costs, 29.7 percent was the result of DEC bids, 17.2 percent was the result of INC offers, 5.7 percent was the result of positive markup, and 0.8 percent was the result of UTCs. In the first four months of fast start pricing in PJM, 0.4 percent of the day-ahead load-weighted average LMP was the result of commitment costs.

- **Price Convergence.** Hourly and daily price differences between the day-ahead and real-time energy markets fluctuate continuously and substantially from positive to negative. The difference between day-ahead and real-time average prices was $0.42 per MWh in 2021, and $0.33 per MWh in 2020. The difference between day-ahead and real-time average prices, by itself, is not a measure of the competitiveness or effectiveness of the day-ahead energy market.

Scarcity

- There were 28 intervals with five minute shortage pricing in 2021. There were no emergency actions that resulted in Performance Assessment Intervals in 2021.
- There were 5,590 five minute intervals, or 5.3 percent of all five minute intervals, in 2021 for which at least one RT SCED solution showed a shortage of reserves, and 1,572 five minute intervals, or 1.5 percent of all five minute intervals, in 2021 for which more than one RT SCED solution showed a shortage of reserves. PJM triggered shortage pricing for 28 five minute intervals.

Competitive Assessment

Market Structure

- **Aggregate Pivotal Suppliers.** The PJM energy market, at times, requires generation from pivotal suppliers to meet load, resulting in aggregate market power even when the HHI level indicates that the aggregate market is unconcentrated. Three suppliers were jointly pivotal in the day-ahead market on 301 days in 2020 and 286 days in 2021.
- **Local Market Power.** In 2021, 11 control zones experienced congestion resulting from one or more constraints binding for 100 or more hours. For three out of the top 10 congested facilities (by real-time binding hours) in 2021, the average number of suppliers providing constraint relief was three or less. There is a high level of concentration within the local markets for providing relief to the most congested facilities in the PJM Real-Time Energy Market. The local market structure is not competitive.

Market Behavior

- **Offer Capping for Local Market Power.** PJM offer caps units when the local market structure is noncompetitive. Offer capping is an effective means of addressing local market power when the rules are designed and implemented properly. Offer capping levels have historically been low in PJM. In the day-ahead energy market, for units committed to provide energy for local constraint relief, offer-capped unit hours remained at 1.6 percent in 2020 and 2021. In the real-time energy market, for units committed to provide energy for local constraint relief, offer-capped unit hours increased from 1.0 percent in 2020 to 1.5 percent in 2021. While overall offer capping levels have been low, there are a significant number of units with persistent structural local market power that would have a significant impact on prices in the absence of local market power mitigation.

  The analysis of the application of the TPS test to local markets demonstrates that it is working to identify pivotal owners when the market structure is noncompetitive and to ensure that owners are not subject to offer capping when the market structure is competitive. There are, however, identified issues with the application of market power mitigation to resources whose owners fail the TPS test that can result in the exercise of local market power. These issues need to be addressed.
- **Offer Capping for Reliability.** PJM also offer caps units that are committed for reliability reasons, including for reactive support. In the day-ahead energy market, for units committed for reliability reasons, offer-capped unit hours increased from 0.00 percent in 2020 to 0.02 percent in 2021. In the real-time energy market, for units committed for reliability reasons, offer-capped unit hours increased from 0.00 percent in 2020 to 0.03 percent in 2021. The low offer cap percentages do not mean that units manually committed for reliability reasons do not have market power. All units manually committed for reliability have market power and all are treated as if they had market power. These units are not capped to their cost-based offers because they tend to offer with a negative markup in their price-based offers, particularly at the economic minimum level, which means that PJM's offer capping process results in the use of the price-based

offer for commitment even if it has less flexible operating parameters.

- **Parameter Mitigation.** In 2021, 28.0 percent of unit hours for units that failed the TPS test in the day-ahead market were committed on price-based schedules that were less flexible than their cost-based schedules. In 2021, on days when hot weather and cold weather alerts were declared, 32.6 percent of unit hours in the day-ahead energy market were committed on price-based schedules that were less flexible than their price PLS schedules.
- **Frequently Mitigated Units (FMU) and Associated Units (AU).** In 2020, five units qualified for an FMU adder in at least one month. In 2021, one unit qualified for an FMU adder, in January.
- **Markup Index.** The markup index is a summary measure of participant offer behavior for individual marginal units. While the average markup index in the real-time market was -0.01 in 2021, some marginal units did have substantial markups. The highest markup for any marginal unit in the real-time market in 2021 was more than $450 per MWh when using unadjusted cost-based offers.

  While the average markup index in the day-ahead market was 0.07 in 2021, some marginal units did have substantial markups. The highest markup for any marginal unit in the day-ahead market in 2021 was more than $140 per MWh when using unadjusted cost-based offers.
- **Markup.** The markup frequency distributions show that a significant proportion of units make price-based offers less than the cost-based offers permitted under the PJM market rules. This behavior means that competitive price-based offers reveal actual unit marginal costs and that PJM market rules permit the inclusion of costs in cost-based offers that are not short run marginal costs.

  The markup behavior shown in the markup frequency distributions also shows that a substantial number of units were offered with high markups, consistent with the exercise of market power.

Market Performance

- **Markup.** The markup conduct of individual owners and units has an identifiable impact on market prices. Markup is a key indicator of the competitiveness of the energy market.

  In the PJM Real-Time Energy Market in 2021, the unadjusted markup component of LMP was $1.69 per MWh or 4.2 percent of the PJM load-weighted average LMP. August had the highest unadjusted peak markup component, $6.68 per MWh, or 11.8 percent of the real-time peak hour load-weighted average LMP for August.

  In the PJM Day-Ahead Energy Market, INCs, DECs and UTCs have zero markups. In 2021, the unadjusted markup component of LMP was $1.22 per MWh or 3.1 percent of the PJM day-ahead load-weighted average LMP. October had the highest unadjusted peak markup component, $8.06 per MWh, or 12.0 percent of the day-ahead peak hour load-weighted average LMP for October.

  Participant behavior was evaluated as competitive because the analysis of markup shows that marginal units generally make offers at, or close to, their marginal costs in both the day-ahead and real-time energy markets, although the behavior of some participants represents economic withholding.
- **Markup and Local Market Power.** Comparison of the markup behavior of marginal units with TPS test results shows that for 4.7 percent of all real-time marginal unit intervals in 2021, the marginal unit had both local market power as determined by the TPS test and a positive markup. The fact that units with market power had a positive markup means that the cost-based offer was not used, that a higher price-based offer was used, and that the process for offer capping units that fail the TPS test does not consistently result in competitive market outcomes in the presence of market power.
- **Markup and Aggregate Market Power.** In 2021, pivotal suppliers in the aggregate market set prices with high markups for some real-time market intervals.

Section 3 Recommendations

Market Power

- The MMU recommends that the market rules explicitly require that offers in the energy market be competitive, where competitive is defined to be the short run marginal cost of the units. The short run marginal cost should reflect opportunity cost when and where appropriate. The MMU recommends that the level of incremental costs includable in cost-based offers not exceed the short run marginal cost of the unit. (Priority: Medium. First reported 2009. Status: Not adopted.)

Fuel Cost Policies

- The MMU recommends that PJM require that all fuel cost policies be algorithmic, verifiable, and systematic, and accurately reflect short run marginal costs. (Priority: Medium. First reported 2016. Status: Not adopted.)
- The MMU recommends that the temporary cost method be removed and that all units that submit nonzero cost-based offers be required to have an approved fuel cost policy. (Priority: Low. First reported 2020. Status: Not adopted.)
- The MMU recommends that the penalty exemption provision be removed and that all units that submit nonzero cost-based offers be required to follow their approved fuel cost policy. (Priority: Medium. First reported 2020. Status: Not adopted.)

Cost-Based Offers

- The MMU recommends that Manual 15 (Cost Development Guidelines) be replaced with a straightforward description of the components of cost-based offers based on short run marginal costs and the correct calculation of cost-based offers. (Priority: Medium. First reported 2016. Status: Not adopted.)
- The MMU recommends removal of all use of FERC System of Accounts in the Cost Development Guidelines. (Priority: Medium. First reported 2016. Status: Not adopted.)
- The MMU recommends the removal of all use of cyclic starting and peaking factors from the Cost Development Guidelines. (Priority: Medium. First reported 2016. Status: Not adopted.)
- The MMU recommends the removal of all labor costs from the Cost Development Guidelines. (Priority: Medium. First reported 2016. Status: Not adopted.)
- The MMU recommends the removal of all maintenance costs from the Cost Development Guidelines. (Priority: Medium. First reported 2019. Status: Not adopted.)
- The MMU recommends that market participants be required to document the amount and cost of consumables used when operating in order to verify that the total operating cost is consistent with the total quantity used and the unit characteristics. (Priority: Medium. First reported 2020. Status: Not adopted.)
- The MMU recommends, given that maintenance costs are currently allowed in cost-based offers, that market participants be permitted to include only variable maintenance costs, linked to verifiable operational events and that can be supported by clear and unambiguous documentation of the operational data (e.g. run hours, MWh, MMBtu) that support the maintenance cycle of the equipment being serviced/replaced. (Priority: Medium. First reported 2020. Status: Not adopted.)
- The MMU recommends explicitly accounting for soak costs and changing the definition of the start heat input for combined cycles to include only the amount of fuel used from first fire to the first breaker close in the Cost Development Guidelines. (Priority: Medium. First reported 2016. Status: Not adopted.)
- The MMU recommends the removal of nuclear fuel and nonfuel operations and maintenance costs that are not short run marginal costs from the Cost Development Guidelines. (Priority: Medium. First reported 2016. Status: Not adopted.)
- The MMU recommends revising the pumped hydro fuel cost calculation to include day-ahead and real-time power purchases. (Priority: Low. First reported 2016. Status: Not adopted.)

Market Power: TPS Test and Offer Capping

- The MMU recommends that the rules governing the application of the TPS test be clarified and documented. The TPS test application in the day-ahead energy market is not documented. (Priority: High. First reported 2015. Status: Partially adopted.)
- The MMU recommends, in order to ensure effective market power mitigation and to ensure that capacity resources meet their obligations to be flexible, that capacity resources be required to use flexible parameters in all offers at all times. (Priority: High. First reported Q3 2021. Status: Not adopted.)
- The MMU recommends, if the preferred recommendation is not implemented, that in order to ensure effective market power mitigation, PJM always enforce parameter limited values when the

TPS test is failed and during high load conditions such as cold and hot weather alerts and emergency conditions. (Priority: High. First reported 2015. Status: Not adopted.)

- The MMU recommends that PJM require every market participant to make available at least one cost schedule based on the same hourly fuel type(s) and parameters at least as flexible as their offered price schedule. (Priority: Medium. First reported 2015. Status: Not adopted.)
- The MMU recommends, in order to ensure effective market power mitigation when the TPS test is failed, that markup be consistently positive or negative across the full MWh range of price and cost-based offers. (Priority: High. First reported 2015. Status: Not adopted.)
- The MMU recommends, in order to ensure effective market power mitigation when the TPS test is failed, that offer capping be applied to units that fail the TPS test in the real-time market that were not offer capped at the time of commitment in the day-ahead market or at a prior time in the real-time market. (Priority: High. First reported 2020. Status: Not adopted.)
- The MMU recommends that PJM retain the $1,000 per MWh offer cap in the PJM energy market except when cost-based offers exceed $1,000 per MWh, and retain other existing rules that limit incentives to exercise market power. (Priority: High. First reported 1999. Status: Partially adopted, 1999, 2017.)
- The MMU recommends the elimination of FMU and AU adders. FMU and AU adders no longer serve the purpose for which they were created and interfere with the efficient operation of PJM markets. (Priority: Medium. First reported 2012. Status: Partially adopted, 2014.)

Offer Behavior

- The MMU recommends that resources not be allowed to violate the ICAP must offer requirement. The MMU recommends that PJM enforce the ICAP must offer requirement by assigning a forced outage to any unit that is derated in the energy market below its committed ICAP without an outage that reflects the derate. (Priority: Medium. First reported 2020. Status: Not adopted.)
- The MMU recommends that storage and intermittent resources be subject to an enforceable ICAP must offer rule that reflects the limitations of these resources. (Priority: Medium. First reported 2020. Status: Not adopted.)
- The MMU recommends that capacity resources not be allowed to offer any portion of their capacity market obligation as maximum emergency energy. (Priority: Medium. First reported 2012. Status: Not adopted.)

Capacity Performance Resources

- The MMU recommends that capacity performance resources be held to the OEM operating parameters of the capacity market CONE reference resource for performance assessment and energy uplift payments and that this standard be applied to all technologies on a uniform basis. (Priority: Medium. First reported 2015. Status: Not adopted.)
- The MMU recommends that the parameters which determine nonperformance charges and the amounts of uplift payments should reflect the flexibility goals of the capacity performance construct. The operational parameters used by generation owners to indicate to PJM operators what a unit is capable of during the operating day should not determine capacity performance assessment or uplift payments. (Priority: Medium. First reported 2015. Status: Partially adopted.)
- The MMU recommends, if the capacity market seller offer cap were to be calculated using the historical average balancing ratio, that PJM not include the balancing ratios calculated for localized Performance Assessment Intervals (PAIs), and only include those events that trigger emergencies at a defined zonal or higher level. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that PJM clearly define the business rules that apply to the unit specific parameter adjustment process, including PJM's implementation of the tariff rules in the PJM manuals to ensure market sellers know the requirements for their resources. (Priority: Low. First reported 2018. Status: Not adopted.)
- The MMU recommends that PJM update the tariff to clarify that all generation resources are subject to unit specific parameter limits on their cost-based

offers using the same standard and process as capacity performance capacity resources. (Priority: Medium. First reported 2018. Status: Not adopted.)

- The MMU recommends that resources not be paid the daily capacity payment when unable to operate to their unit specific parameter limits. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that PJM not approve temporary exceptions that are based on pipeline tariff terms that are not routinely enforced, and based on inferior transportation service procured by the generator. (Priority: Medium. First reported 2019. Status: Not adopted.)
- The MMU recommends that PJM require generators that violate their approved turn down ratio (by either using the fixed gen option or increasing their economic minimum) to use the temporary parameter exception process that requires market sellers to demonstrate that the request is based on a physical and actual constraint. (Priority: Medium. New recommendation. Status: Not adopted.)

Accurate System Modeling

- The MMU recommends that PJM approve one RT SCED case for each five minute interval to dispatch resources during that interval using a five minute ramp time, and that PJM calculate prices using LPC for that five minute interval using the same approved RT SCED case. (Priority: High. First reported 2019. Status: Adopted 2021.)
- The MMU recommends that PJM explicitly state its policy on the use of transmission penalty factors including: the level of the penalty factors; the triggers for the use of the penalty factors; the appropriate line ratings to trigger the use of penalty factors; the allowed duration of the violation; the use of constraint relaxation logic; and when the transmission penalty factors will be used to set the shadow price. (Priority: Medium. First reported 2015. Status: Partially adopted 2020.)
- The MMU recommends that PJM routinely review all transmission facility ratings and any changes to those ratings to ensure that the normal, emergency and load dump ratings used in modeling the transmission system are accurate and reflect standard ratings practice. (Priority: Low. First reported 2013. Status: Partially adopted.)
- The MMU recommends that PJM not use closed loop interface or surrogate constraints to artificially override nodal prices based on fundamental LMP logic in order to: accommodate rather than resolve the inadequacies of the demand side resource capacity product; address the inability of the power flow model to incorporate the need for reactive power; accommodate rather than resolve the flaws in PJM's approach to scarcity pricing; or for any other reason. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM not use CT price setting logic to modify transmission line limits to artificially override the nodal prices that are based on fundamental LMP logic in order to reduce uplift. (Priority: Medium. First reported 2015. Status: Not adopted.)
- The MMU recommends that if PJM believes it appropriate to implement CT price setting logic, PJM first initiate a stakeholder process to determine whether such modification is appropriate. PJM should file any proposed changes with FERC to ensure review. Any such changes should be incorporated in the PJM tariff. (Priority: Medium. First reported 2016. Status: Not adopted.)
- The MMU recommends that PJM update the outage impact studies, the reliability analyses used in RPM for capacity deliverability, and the reliability analyses used in RTEP for transmission upgrades to be consistent with the more conservative emergency operations (post contingency load dump limit exceedance analysis) in the energy market that were implemented in June 2013. (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM include in the tariff or appropriate manual an explanation of the initial creation of hubs, the process for modifying hub definitions and a description of how hub definitions have changed.[73] [74] (Priority: Low. First reported 2013. Status: Not adopted.)

73 According to minutes from the first meeting of the Energy Market Committee (EMC) on January 28, 1998, the EMC unanimously agreed to be responsible for approving additions, deletions and changes to the hub definitions to be published and modeled by PJM. Since the EMC has become the Market Implementation Committee (MIC), the MIC now appears to be responsible for such changes.

74 There is currently no PJM documentation in the tariff or manuals explaining how hubs are created and how their definitions are changed. The general definition of a hub can be found in the PJM.com Glossary <http://www.pjm.com/Glossary.aspx>.

- The MMU recommends that all buses with a net withdrawal be treated as load for purposes of calculating load and load-weighted LMP, even if the MW are settled to the generator. The MMU recommends that during hours when a load bus shows a net injection, the energy injection be treated as generation, not negative load, for purposes of calculating generation and load-weighted LMP, even if the injection MW are settled to the load serving entity. (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM identify and collect data on available behind the meter generation resources, including nodal location information and relevant operating parameters. (Priority: Low. First reported 2013. Status: Partially adopted.)
- The MMU recommends that PJM document how LMPs are calculated when demand response is marginal. (Priority: Low. First reported 2014. Status: Not adopted.)
- The MMU recommends that PJM not allow nuclear generators which do not respond to prices or which only respond to manual instructions from the operator to set the LMPs in the real-time market. (Priority: Low. First reported 2016. Status: Not adopted.)
- The MMU recommends that PJM increase the coordination of outage and operational restrictions data submitted by market participants via eDART/eGADs and offer data submitted via Markets Gateway. (Priority: Low. First reported 2017. Status: Not adopted.)
- The MMU recommends that PJM model generators' operating transitions, including soak time for units with a steam turbine, configuration transitions for combined cycles, and peak operating modes. (Priority: Medium. First reported 2019. Status: Not adopted.)
- The MMU recommends that PJM clarify, modify and document its process for dispatching reserves and energy when SCED indicates that supply is less than total demand including forecasted load and reserve requirements. The modifications should define: a SCED process to economically convert reserves to energy; a process for the recall of energy from capacity resources; and the minimum level of synchronized reserves that would trigger load shedding. (Priority: Medium. First reported 2020. Status: Not adopted.)
- The MMU recommends that PJM stop capping the system marginal price in RT SCED and instead limit the sum of violated reserve constraint shadow prices used in LPC to $1,700 per MWh. (Priority: Medium. First reported Q1, 2021. Status: Not adopted.)
- The MMU recommends, if PJM implements extended downward sloping ORDCs, that PJM calculate the probability of reserves falling below the minimum reserve requirement (MRR) based on ten minute rather than 30 minute forecast error, and on forced outages in the ten minute rather than the 30 minute look ahead window to model the uncertainty in the inputs to RT SCED. (Priority: Medium. First reported Q2, 2021. Status: Not adopted.)
- The MMU recommends that PJM adjust the ORDCs during spin events to reduce the reserve requirement for synchronized and primary reserves by the amount of the reserves deployed. (Priority: Medium. New recommendation. Status: Not adopted.)

Transparency

- The MMU recommends that PJM clearly document the calculation of shortage prices and implementation of reserve price caps in the PJM Manuals, including defining all the components of reserve prices, and all the constraints whose shadow prices are included in reserve prices. (Priority: High. New recommendation. Status: Not adopted.)
- The MMU recommends that PJM allow generators to report fuel type on an hourly basis in their offer schedules and to designate schedule availability on an hourly basis. (Priority: Medium. First reported 2015. Status: Partially adopted.)
- The MMU recommends that PJM define clear criteria for operator approval of RT SCED cases, including shortage cases, that are used to send dispatch signals to resources, and for pricing, to minimize discretion. (Priority: High. First reported 2018. Status: Partially adopted.)

Virtual Bids and Offers

- The MMU recommends eliminating up to congestion (UTC) bidding at pricing nodes that aggregate only small sections of transmission zones with few physical assets. (Priority: Medium. First reported 2020. Status: Not adopted.)

- The MMU recommends eliminating INC, DEC, and UTC bidding at pricing nodes that allow market participants to profit from modeling issues. (Priority: Medium. First reported 2020. Status: Not adopted.)

Section 3 Conclusion

The MMU analyzed key elements of PJM energy market structure, participant conduct and market performance in 2021, including aggregate supply and demand, concentration ratios, aggregate pivotal supplier results, local three pivotal supplier test results, offer capping, markup, marginal units, participation in demand response programs, virtual bids and offers, loads and prices.

PJM real-time hourly average load in 2021 increased by 3.6 percent from 2020, from 84,584 MWh to 87,606 MWh. The relationship between supply and demand, regardless of the specific market, along with market concentration and the extent of pivotal suppliers, is referred to as the supply-demand fundamentals or economic fundamentals or market structure. The market structure of the PJM aggregate energy market is partially competitive because aggregate market power does exist for a significant number of hours. The HHI is not a definitive measure of structural market power. The number of pivotal suppliers in the energy market is a more precise measure of structural market power than the HHI. It is possible to have pivotal suppliers in the aggregate market even when the HHI level is not in the highly concentrated range. Even a low HHI may be consistent with the exercise of market power with a low price elasticity of demand. The current market power mitigation rules for the PJM energy market rely on the assumption that the ownership structure of the aggregate market ensures competitive outcomes. This assumption requires that the total demand for energy can be met without the supply from any individual supplier or without the supply from a small group of suppliers. This assumption is not correct. There are pivotal suppliers in the aggregate energy market at times. High markups for some units demonstrate the potential to exercise market power both routinely and during high demand conditions. The existing market power mitigation measures do not address aggregate market power. The MMU is developing an aggregate market power test and will propose market power mitigation rules to address aggregate market power.

The three pivotal supplier test is applied by PJM on an ongoing basis for local energy markets in order to determine whether offer capping is required for transmission constraints.[75] However, there are some issues with the application of market power mitigation in the day-ahead energy market and the real-time energy market when market sellers fail the TPS test. The Commission recognized some of these issues in its order issued on June 17, 2021.[76] PJM continues to ignore the evidence cited by the Commission and denies the prevalence of these issues, instead of ensuring that market power mitigation works as intended and results in efficient market outcomes.[77] Many of these issues can be resolved by simple rule changes. The MMU proposed these rule changes in its response submitted on October 15, 2021, and continues to recommend them.[78]

The enforcement of market power mitigation rules is undermined if the definition of a competitive offer is not correct. A competitive offer is equal to short run marginal costs. The significance of competition metrics like markup is also undermined if the definition of a competitive offer is not correct. The definition of a competitive offer, under the PJM Market Rules, is not currently correct. The definition, that all costs that are related to electric production are short run marginal costs, is not clear or correct. All costs and investments for power generation are related to electric production. Under this definition, some unit owners include costs that are not short run marginal costs in offers, especially maintenance costs. This issue can be resolved by simple rule changes to incorporate a clear and accurate definition of short run marginal costs. This rule also had unintended consequences for market seller offer caps in the capacity market. Maintenance costs includable in energy offers cannot be included in capacity market offer caps based on avoidable costs. As a result, capacity market offer caps based on net avoidable costs were lower than they would have been if maintenance costs had been correctly included in avoidable costs rather than incorrectly defined to be part of short marginal

75 The MMU reviews PJM's application of the TPS test and brings issues to the attention of PJM.
76 See 175 FERC ¶ 61,231 (2021).

costs of producing energy and includable in energy offers.

Prices are a key outcome of markets. Prices vary across hours, days and years for multiple reasons. Price is an indicator of the level of competition in a market. In a competitive market, prices are directly related to the marginal cost to serve load at a given time. The pattern of prices within days and across months and years illustrates how prices are directly related to supply and demand conditions and thus also illustrates the potential significance of the impact of the price elasticity of demand on prices. Energy market results in 2021 generally reflected supply-demand fundamentals, although the behavior of some participants both routinely and during high demand periods represents economic withholding. Economic withholding occurs when generator offers are greater than competitive levels. There are additional issues in the energy market including the uncertainties about the pricing and availability of natural gas, the way that generation owners incorporate natural gas costs in offers, and the lack of adequate incentives for unit owners to take all necessary actions to acquire fuel, staff their units, and operate rather than economically withhold or physically withhold.

Prices in PJM are the result of input prices, consistent with a competitive market. Low natural gas prices were a primary cause of low PJM energy market prices from 2017 to 2020. Higher natural gas prices are a primary cause of higher prices in 2021. There is no evidence to support significant changes to the calculation of LMP, such as fast start pricing or the extended ORDC. Fast start pricing, implemented on September 1, 2021, has disconnected pricing from dispatch instructions and created a greater reliance on uplift rather than price as an incentive to follow PJM's instructions. The extended ORDCs would have created shortage pricing when no reserve shortages exist and, in emergency situations, would have resulted in unjustifiable wealth transfers due to extreme high pricing with no demonstrable market benefit. These changes are unnecessary and distort, rather than improve, price formation. PJM appropriately and directly addressed price formation with the changes that went into effect on November 1, 2021, to resolve the timing mismatch between pricing (LPC) and dispatch instructions (RT SCED). Other potential areas for improvements in price formation include shortage pricing, operator actions and the design of reserve markets. FERC's December 22, 2021, order reversed its prior approval of PJM's proposed extended ORDCs, but accepted other changes to the reserve market design, including the consolidation of tier 1 and tier 2 synchronized reserves and the addition of a day-ahead reserve market. The potential for prolonged and excessively high administrative pricing in the energy market due to reserve penalty factors and transmission constraint penalty factors remains an issue that needs to addressed.[79] There are also continue to be significant issues with PJM's scarcity pricing rules, including the absence of a clear trigger based on accurately estimated reserve levels (the current triggers are based on estimates that result from inaccurate generator modeling, and PJM's administrative overrides on eligibility of units to provide reserves) and the lack of adequate locational scarcity pricing options.

The PJM defined inputs to the dispatch tools, particularly the RT SCED, have substantial effects on energy market outcomes. Transmission line ratings, transmission penalty factors, load forecast bias, hydro resource schedules, and unit ramp rate adjustments change the dispatch of the system, affect prices, and can create significant price increases, particularly through transmission line limit violations. The automated adjustment of ramp rates by PJM, called Degree of Generator Performance (DGP), modified the values offered by generators and limits the MW available to the RT SCED through the first 10 months of 2021.[80] Rather than sending dispatch signals consistent with resource offers and holding resources accountable when they fail to follow them, DGP accommodated resources that did not follow dispatch. PJM operator interventions to reduce line ratings unnecessarily trigger transmission constraint penalty factors and significantly increase prices. PJM should evaluate its interventions in the market, consider whether the interventions are appropriate, and provide greater transparency to enhance market efficiency.

The objective of efficient short run price signals is to minimize system production costs, not to minimize uplift. Repricing the market to reflect commitment costs using fast start pricing prioritizes minimizing uplift over minimizing production costs.[81] The tradeoff exists because when commitment costs are included in prices,

79 177 FERC ¶ 61,209 (2021).
80 DGP in the calculation of energy dispatch was removed as of November 1, 2021.
81 See 173 FERC ¶ 61,244 (2020).

the price signal no longer equals the short run marginal cost and therefore no longer provides the correct signal for efficient behavior for market participants making decisions on the margin, whether resources, load, interchange transactions, or virtual traders.

Units that start in one hour are not actually fast start units, and their commitment costs are not marginal in a five minute market. The differences between the actual LMP and the fast start LMP will distort the incentive for market participants to behave competitively and to follow PJM's dispatch instructions. PJM is paying new forms of uplift in an attempt to counter the distorted incentives inherent in fast start pricing. While the magnitude of the new payments was small in 2021, their effects on behavior are not clear yet.

PJM's arguments for changing energy market price formation asserted that fast start pricing and the extended ORDC would price flexibility in the market, but instead they will benefit inflexible units. The fast start pricing and extended ORDC solutions would undercut LMP logic rather than directly addressing the underlying issues. The solution is not to accept that the inflexible CT should be paid or set price based on its commitment costs rather than its short run marginal costs. The question of why units make inflexible offers should be addressed directly. Are units inflexible because they are old and inefficient, because owners have not invested in increased flexibility or because they serve as a mechanism for the exercise of market power? The question of why the unit was built, whether it was built under cost of service regulation and whether it is efficient to retain the unit should be answered directly. The question of how to provide market incentives for investment in flexible units, for investment in increased flexibility of existing units, and for operating at the full extent of existing flexibility should be addressed directly. The question of whether inflexible units should be paid uplift at all should be addressed directly. Marginal cost pricing without paying excess uplift to inflexible units would create incentives for market participants to provide flexible solutions including replacing inefficient units with flexible, efficient units.

With or without a capacity market, energy market design must permit scarcity pricing when such pricing is consistent with market conditions and constrained by reasonable rules to ensure that market power is not exercised and ensure no scarcity pricing when such pricing is not consistent with market conditions. Scarcity pricing can serve two functions in wholesale power markets: revenue adequacy and price signals. Scarcity pricing for revenue adequacy, as in PJM's ORDC proposal, is not required in PJM. Scarcity pricing for price signals that reflect market conditions during periods of scarcity is required in PJM. Scarcity pricing is also part of an appropriate incentive structure facing both load and generation owners in a working wholesale electric power market design. Scarcity pricing must be designed to ensure that market prices reflect actual market conditions, that scarcity pricing occurs with transparent triggers based on measured reserve levels and transparent prices, that scarcity pricing only occurs when scarcity exists, and that there are strong incentives for competitive behavior and strong disincentives to exercise market power. Such administrative scarcity pricing is a key link between energy and capacity markets. Administrative scarcity pricing that establishes scarcity pricing in about 85 percent of hours, as PJM's ORDC proposal would have done, is not scarcity pricing but simply a revenue enhancement mechanism, which could have unintended consequences in an emergency, as was the case in ERCOT in February 2021. The Commission recognized that PJM's ORDC changes were not consistent with efficient market design and were just a revenue enhancement mechanism.

The overall energy market results support the conclusion that energy prices in PJM are set, generally, by marginal units operating at, or close to, their marginal costs, although this was not always the case in 2021 or prior years. In 2021, marginal units were predominantly combined cycle gas generators. The frequency of combined cycle gas units as the marginal unit type has risen rapidly, from 31.2 percent in 2016 to 71.7 percent in 2021. Overdue improvements in generator modeling in the energy market would allow PJM to more efficiently commit and dispatch combined cycle plants and to fully reflect the flexibility of these units. New combined cycle units have placed competitive pressure on less efficient generators, and the market has reliably served load with less congestion, less uplift, and less markup as a result. This is evidence of generally competitive behavior and competitive market outcomes, although the behavior of some participants represents economic withholding. Given the structure of the energy market which can permit the exercise of aggregate and local market power, the change in some participants' behavior is a source of concern in the energy market and provides a reason to use correctly defined short run marginal cost as the sole basis for cost-based offers and a reason for implementing an aggregate market power test and correcting the offer capping process for resources with local market power. The MMU concludes that the PJM energy market results were competitive in 2021.

Overview: Section 4, Energy Uplift

Energy Uplift Charges

- **Energy Uplift Charges.** Total energy uplift charges increased by $87.4 million, or 96.2 percent, in 2021 compared to 2020, from $90.9 million to $178.3 million.
- **Energy Uplift Charges Categories.** The increase of $87.4 million in 2021 was comprised of a $4.4 million increase in day-ahead operating reserve charges, an $82.5 million increase in balancing operating reserve charges, and a $0.5 million increase in reactive services charges.
- **Average Effective Operating Reserve Rates in the Eastern Region.** Day-ahead load, exports, DECs and UTCs paid $0.016 per MWh in the Eastern Region. Real-time load and exports paid $0.084 per MWh. Deviations (which include deviations from load, imports, exports, generators, INCs, DECs and UTCs) paid $0.467 per MWh in the Eastern Region.
- **Average Effective Operating Reserve Rates in the Western Region.** Day-ahead load, exports, DECs and UTCs paid $ 0.210 per MWh in the Western Region. Real-time load and exports paid $0.073 per MWh. Deviations (which include deviations from load, imports, exports, generators, INCs, DECs and UTCs) paid $0.416 per MWh in the Western Region.
- **Reactive Services Rates.** PPL and COMED were the two zones with the highest local reactive services (voltage support) rates, excluding reactive capability payments. PPL had a rate of $0.017 per MWh and COMED had a rate of $0.002 per MWh.

Energy Uplift Credits

- **Types of credits.** In 2021, energy uplift credits were $178.3 million, including $13.7 million in day-ahead generator credits, $127.5 million in balancing generator credits, $30.3 million in lost opportunity cost credits, and $4.8 million in local constraint control credits. Dispatch differential lost opportunity credits, implemented as part of fast start pricing on September 1, 2021, were $0.7 million.
- **Types of units.** In 2021, coal units received 72.0 percent of day-ahead generator credits, and combustion turbines received 92.8 percent of balancing generator credits and 95.6 percent of lost opportunity cost credits. Since September 1, 2021, combined cycle units and combustion turbines have received 66.6 percent of dispatch differential lost opportunity credits.
- **Economic and Noneconomic Generation.** In 2021, 89.5 percent of the day-ahead generation eligible for operating reserve credits was economic and 65.9 percent of the real-time generation eligible for operating reserve credits was economic.
- **Day-Ahead Unit Commitment for Reliability.** In 2021, 0.2 percent of the total day-ahead generation MWh was scheduled as must run for reliability by PJM, of which 50.6 percent received energy uplift payments.
- **Concentration of Energy Uplift Credits.** In 2021, the top 10 units receiving energy uplift credits received 41.6 percent of all credits and the top 10 organizations received 87.3 percent of all credits. The HHI for day-ahead operating reserves was 7876, the HHI for balancing operating reserves was 2637 and the HHI for lost opportunity cost was 5728, all of which are classified as highly concentrated.
- **Lost Opportunity Cost Credits.** Lost opportunity cost credits increased by $11.0 million or 56.8 percent, in 2021 compared to 2020, from $19.3 million to $30.3 million.
- Some combustion turbines and diesels are scheduled day-ahead but not requested in real time, and receive day-ahead lost opportunity cost credits as a result. This was the source of 96.7 percent of the $17.2 million. The day-ahead generation paid LOC credits for this reason decreased by 718.3 GWh or 55.7 percent during 2021, compared to 2020, from 1,288.7 GWh to 570.4 GWh.
- **Following Dispatch.** Some units are incorrectly paid uplift despite not meeting uplift eligibility requirements, including not following dispatch, not having the correct commitment status, or not

operating with PLS offer parameters. Since 2018, the MMU has made cumulative resettlement requests for the most extreme overpaid units of $14.8 million, of which PJM has resettled $1.5 million, or 9.9 percent.

- **Daily Uplift.** In 2021, balancing operating reserve charges would have been $27.0 million or 21.2 percent lower if they had been calculated on a daily basis rather than a segmented basis. In 2020, balancing operating reserve credits would have been $10.7 million or 18.5 percent lower if they had been calculated on a daily basis rather than a segmented basis. Uplift was designed to be charged on a daily basis and not on an intraday segmented basis.

Geography of Charges and Credits

- In 2021, 88.9 percent of all uplift charges allocated regionally (day-ahead operating reserves and balancing operating reserves) were paid by transactions at control zones, 4.3 percent by transactions at hubs and aggregates, and 6.7 percent by transactions at interchange interfaces.
- In 2021, generators in the Eastern Region received 38.7 percent of all balancing generator credits, including lost opportunity cost and canceled resources credits.
- In 2021, generators in the Western Region received 58.0 percent of all balancing generator credits, including lost opportunity cost and canceled resources credits.
- In 2021, external generators received 3.8 percent of all balancing generator credits, including lost opportunity cost and canceled resources credits.

Section 4 Recommendations

- The MMU recommends that uplift be paid only based on operating parameters that reflect the flexibility of the benchmark new entrant unit (CONE unit) in the PJM Capacity Market. (Priority: High. First reported 2018. Status: Not adopted.)
- The MMU recommends that PJM initiate an analysis of the reasons why a significant number of combustion turbines and diesels scheduled in the day-ahead energy market are not called in real time when they are economic. (Priority: Medium. First Reported 2012. Status: Partially adopted, 2019.)
- The MMU recommends that PJM not pay uplift to units not following dispatch, including uplift related to fast start pricing, and require refunds where it has made such payments. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that PJM pay uplift based on the offer at the lower of the actual unit output or the dispatch signal MW. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that PJM designate units whose offers are flagged for fixed generation in Markets Gateway as not eligible for uplift. Units that are flagged for fixed generation are not dispatchable. Following dispatch is an eligibility requirement for uplift compensation. (Priority: Medium. First reported 2020. Status: Not adopted.)
- The MMU recommends eliminating intraday segments from the calculation of uplift payments and returning to calculating the need for uplift based on the entire 24 hour operating day. (Priority: High. First reported 2018. Status: Not adopted.)
- The MMU recommends the elimination of day-ahead uplift to ensure that units receive an energy uplift payment based on their real-time output and not their day-ahead scheduled output. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends enhancing the current energy uplift allocation rules to reflect the recommended elimination of day-ahead uplift, the timing of commitment decisions and the commitment reasons. (Priority: High. First reported 2012. Status: Not adopted.)
- The MMU recommends that units not be paid lost opportunity cost uplift when PJM directs a unit to reduce output based on a transmission constraint or other reliability issue. There is no lost opportunity because the unit is required to reduce for the reliability of the unit and the system. (Priority: High. First reported Q2, 2021. Status: Not adopted.)
- The MMU recommends reincorporating the use of net regulation revenues as an offset in the calculation of balancing operating reserve credits. (Priority: Medium. First reported 2009. Status: Not adopted.)
- The MMU recommends that self scheduled units not be paid energy uplift for their startup cost when the

units are scheduled by PJM to start before the self scheduled hours. (Priority: Low. First reported 2013. Status: Not adopted.)

- The MMU recommends three modifications to the energy lost opportunity cost calculations:
  - The MMU recommends calculating LOC based on 24 hour daily periods for combustion turbines and diesels scheduled in the day-ahead energy market, but not committed in real time. (Priority: Medium. First reported 2014. Status: Not adopted.)
  - The MMU recommends that units scheduled in the day-ahead energy market and not committed in real time should be compensated for LOC based on their real-time desired and achievable output, not their scheduled day-ahead output. (Priority: Medium. First reported 2015. Status: Not adopted.)
  - The MMU recommends that only flexible fast start units (startup plus notification times of 10 minutes or less) and units with short minimum run times (one hour or less) be eligible by default for the LOC compensation to units scheduled in the day-ahead energy market and not committed in real time. Other units should be eligible for LOC compensation only if PJM explicitly cancels their day-ahead commitment. (Priority: Medium. First reported 2015. Status: Not adopted.)
- The MMU recommends that up to congestion transactions be required to pay energy uplift charges for both the injection and the withdrawal sides of the UTC. (Priority: High. First reported 2011. Status: Partially adopted.)
- The MMU recommends allocating the energy uplift payments to units scheduled as must run in the day-ahead energy market for reasons other than voltage/reactive or black start services as a reliability charge to real-time load, real-time exports and real-time wheels. (Priority: Medium. First reported 2014. Status: Not adopted. Stakeholder process.)
- The MMU recommends that the total cost of providing reactive support be categorized and allocated as reactive services. Reactive services credits should be calculated consistent with the balancing operating reserve credit calculation. (Priority: Medium. First reported 2012. Status: Not adopted. Stakeholder process.)
- The MMU recommends including real-time exports and real-time wheels in the allocation of the cost of providing reactive support to the 500 kV system or above, in addition to real-time load. (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends modifications to the calculation of lost opportunity costs credits paid to wind units. The lost opportunity costs credits paid to wind units should be based on the lesser of the desired output, the estimated output based on actual wind conditions and the capacity interconnection rights (CIRs). The MMU recommends that PJM allow wind units to request CIRs that reflect the maximum output wind units want to inject into the transmission system at any time. (Priority: Low. First reported 2012. Status: Not adopted.)
- The MMU recommends that PJM clearly identify and classify all reasons for incurring uplift in the day-ahead and the real-time energy markets and the associated uplift charges in order to make all market participants aware of the reasons for these costs and to help ensure a long term solution to the issue of how to allocate the costs of uplift. (Priority: Medium. First reported 2011. Status: Partially adopted.)
- The MMU recommends that PJM revise the current uplift (operating reserve) confidentiality rules in order to allow the disclosure of complete information about the level of uplift (operating reserve charges) by unit and the detailed reasons for the level of operating reserve credits by unit in the PJM region. (Priority: High. First reported 2013. Status: Partially adopted.[82])
- The MMU recommends that PJM eliminate the exemption for CTs and diesels from the requirement to follow dispatch. The performance of these resources should be evaluated in a manner consistent with all other resources (Priority: Medium. First reported 2018. Status: Not adopted.)

82 On September 7, 2018, PJM made a compliance filing for FERC Order No. 844 to publish unit specific uplift credits. The compliance filing was accepted by FERC on March 21, 2019. 166 FERC ¶ 61,210 (2019). PJM began posting unit specific uplift reports on May 1, 2019. 167 FERC ¶ 61,280 (2019).

Section 4 Conclusion

Competitive market outcomes result from energy offers equal to short run marginal costs that incorporate flexible operating parameters. When PJM permits a unit to include inflexible operating parameters in its offer and pays uplift based on those inflexible parameters, there is an incentive for the unit to remain inflexible. The rules regarding operating parameters should be implemented in a way that creates incentives for flexible operations rather than inflexible operations. The standard for paying uplift should be the maximum achievable flexibility, based on OEM standards for the benchmark new entrant unit (CONE unit) in the PJM Capacity Market. Applying a weaker standard effectively subsidizes inflexible units by paying them based on inflexible parameters that result from lack of investment and that could be made more flexible. The result both inflates uplift costs and suppresses energy prices.

It is not appropriate to accept that inflexible units should be paid or set price based on short run marginal costs plus start up and no load costs. The question of why units make inflexible offers should be addressed directly. Are units inflexible because they are old and inefficient, because owners have not invested in increased flexibility or because they serve as a mechanism for the exercise of market power? The question of why the inflexible unit was built, whether it was built under cost of service regulation and whether it is efficient to retain the unit should be answered directly. The question of how to provide market incentives for investment in flexible units and for investment in increased flexibility of existing units should be addressed directly. The question of whether inflexible units should be paid uplift at all should be addressed directly. Marginal cost pricing without paying uplift to inflexible units would create incentives for market participants to provide flexible solutions including replacing inefficient units with flexible, efficient units.

Implementing combined cycle modeling, to permit the energy market model optimization to take advantage of the versatility and flexibility of combined cycle technology in commitment and dispatch, would provide significant flexibility without requiring a distortion of the market rules.

The reduction of uplift payments should not be a goal to be achieved at the expense of the fundamental logic of the LMP system. For example, the use of closed loop interfaces to reduce uplift should be eliminated because it is not consistent with LMP fundamentals and constitutes a form of subjective price setting. The same is true of what PJM terms its CT price setting logic. The same is true of fast start pricing. The same is true of PJM's proposal to modify the ORDC in order to increase energy prices and reduce uplift.

Accurate short run price signals, equal to the short run marginal cost of generating power, provide market incentives for cost minimizing production to all economically dispatched resources and provide market incentives to load based on the marginal cost of additional consumption. The objective of efficient short run price signals is to minimize system production costs, not to minimize uplift. Repricing the market to reflect commitment costs will create a tradeoff between minimizing production costs and reduction of uplift. The tradeoff will exist because when commitment costs are included in prices, the price signal no longer equals the short run marginal cost and therefore no longer provides the correct signal for efficient behavior for market participants making decisions on the margin, whether resources, load, interchange transactions, or virtual traders. This tradeoff now exists based on PJM's recently implemented fast start pricing proposal (limited convex hull pricing). Fast start pricing was approved by FERC and implemented on September 1, 2021.[83] Fast start pricing affects uplift calculations by introducing a new category of uplift in the balancing market, and changing the calculation of uplift in the day-ahead market.

When units receive substantial revenues through energy uplift payments, these payments are not fully transparent to the market, in part because of the current confidentiality rules. As a result, other market participants, including generation and transmission developers, do not have the opportunity to compete to displace them. As a result, substantial energy uplift payments to a concentrated group of units and organizations have persisted. FERC Order No. 844 authorized the publication of unit specific uplift payments for credits incurred after July 1, 2019.[84]

83 See 173 FERC ¶ 61,244 (2020).
84 On March 21, 2019, FERC accepted PJM's Order No. 844 compliance filing. 166 FERC ¶ 61,210 (2019). The filing stated that PJM would begin posting unit specific uplift reports on May 1, 2019. On April 8, 2019, PJM filed for an extension on the implementation date of the zonal uplift reports and unit specific uplift reports to July 1, 2019. On June 28, 2019, FERC accepted PJM's request for extension of effective dates. 167 FERC ¶ 61,280 (2019).

However, Order No. 844 failed to require the publication of unit specific uplift credits for the largest units receiving significant uplift payments, inflexible steam units committed for reliability in the day-ahead market.

One part of addressing the level and allocation of uplift payments is to eliminate all day-ahead operating reserve credits. It is illogical and unnecessary to pay units day-ahead operating reserve credits because units do not incur any costs to run and any revenue shortfalls are addressed by balancing operating reserve credits.

On July 16, 2020, following its investigation of the issue, the Commission ordered PJM to revise its rules so that UTCs are required to pay uplift on the withdrawal side (DEC) only.[85] The uplift payments for UTCs began on November 1, 2020.[86] This had been a longstanding recommendation of the MMU.

PJM needs to pay substantially more attention to the details of uplift payments including accurately tracking whether units are following dispatch, identifying the actual need for units to be dispatched out of merit and determining whether local reserve zones or better definitions of constraints would be a more market based approach. PJM pays uplift to units even when they do not operate as requested by PJM, i.e. they do not follow dispatch. PJM uses dispatcher logs as a primary screen to determine if units are eligible for uplift regardless of how they actually operate or if they followed the PJM dispatch signal. The reliance on dispatcher logs for this purpose is impractical, inefficient, and incorrect. PJM needs to define and implement rules for determining when units are following dispatch as a primary screen for eligibility for uplift payments. PJM should not pay uplift to units that do not follow dispatch.

The MMU notifies PJM and generators of instances in which, based on the PJM dispatch signal and the real-time output of the unit, it is clear that the unit did not operate as requested by PJM. The MMU sends requests for resettlements to PJM to make the units with the most extreme overpayments ineligible for uplift credits. Since 2018, the MMU has requested that PJM require the return of $14.8 million of incorrect uplift credits.

85 See 172 FERC ¶ 61,046 (2020).
86 On October 17, 2017, PJM filed a proposed tariff change at FERC to allocate uplift to UTC transactions in the same way uplift is allocated to other virtual transactions, as a separate injection and withdrawal deviation. FERC rejected the proposed tariff change. See 162 FERC ¶ 61,019 (2018).

While energy uplift charges are an appropriate part of the cost of energy, market efficiency would be improved by ensuring that the level and variability of these charges are as low as possible consistent with the reliable operation of the system and consistent with pricing at short run marginal cost. The goal should be to minimize the total incurred energy uplift charges and to increase the transactions over which those charges are spread in order to reduce the impact of energy uplift charges on markets. The result would be to reduce the level of per MWh charges, to reduce the uncertainty associated with uplift charges and to reduce the impact of energy uplift charges on decisions about how and when to participate in PJM markets. The result would also be to increase incentives for flexible operation and to decrease incentives for the continued operation of inflexible and uneconomic resources. PJM does not need a flexibility product. PJM needs to provide incentives to existing and new entrant resources to unlock the significant flexibility potential that already exists and to stop creating incentives for inflexibility.

Overview: Section 5, Capacity Market

RPM Capacity Market

Market Design

The Reliability Pricing Model (RPM) Capacity Market is a forward-looking, annual, locational market, with a must offer requirement for Existing Generation Capacity Resources and mandatory participation by load, with performance incentives, that includes clear market power mitigation rules and that permits the direct participation of demand-side resources.[87]

Under RPM, capacity obligations are annual.[88] Base Residual Auctions (BRA) are held for delivery years that are three years in the future. First, Second and Third Incremental Auctions (IA) are held for each delivery year.[89] First, Second, and Third Incremental Auctions are conducted 20, 10, and three months prior to the delivery year.[90] A Conditional Incremental Auction may be held if there is a need to procure additional capacity resulting from a delay in a planned large transmission upgrade

87 The terms *PJM Region*, *RTO Region* and *RTO* are synonymous in this report and include all capacity within the PJM footprint.
88 Effective for the 2020/2021 and subsequent delivery years, the RPM market design incorporated seasonal capacity resources. Summer period and winter period capacity must be matched either through commercial aggregation or through the optimization in equal MW amounts in the LDA or the lowest common parent LDA.
89 See 126 FERC ¶ 61,275 at P 86 (2009).
90 See Letter Order, FERC Docket No. ER10-366-000 (January 22, 2010).

that was modeled in the BRA for the relevant delivery year.[91]

The 2021/2022 RPM Third Incremental Auction and the 2022/2023 RPM Base Residual Auction were conducted in 2021.

RPM prices are locational and may vary depending on transmission constraints and local supply and demand conditions.[92] Existing generation capable of qualifying as a capacity resource must be offered into RPM auctions, except for resources owned by entities that elect the fixed resource requirement (FRR) option. Participation by LSEs is mandatory, except for those entities that elect the FRR option. There is an administratively determined demand curve that defines scarcity pricing levels and that, with the supply curve derived from capacity offers, determines market prices in each BRA. RPM rules provide performance incentives for generation, including the requirement to submit generator outage data and the linking of capacity payments to the level of unforced capacity, and the performance incentives have been strengthened significantly under the Capacity Performance modifications to RPM. Under RPM there are explicit market power mitigation rules that define the must offer requirement, that define structural market power based on the marginal cost of capacity, that define offer caps, that define the minimum offer price, and that have flexible criteria for competitive offers by new entrants. Market power mitigation is effective only when these definitions are up to date and accurate. Demand resources and energy efficiency resources may be offered directly into RPM auctions and receive the clearing price without mitigation.

Market Structure

- **RPM Installed Capacity.** In 2021, RPM installed capacity increased 2,348.4 MW or 1.3 percent, from 184,245.0 MW on January 1, to 186,593.4 MW on December 31. Installed capacity includes net capacity imports and exports and can vary on a daily basis.
- **Reserves.** The sum of cleared MW that did not have a must offer requirement and the cleared MW of DR is 16,823.3 MW, or 100.7 percent of required reserves and 69.0 percent of total reserves. These results suggest that the required reserve margin and the actual reserve margin be considered carefully along with the obligations of the resources that the reserve margin assumes will be available.
- **RPM Installed Capacity by Fuel Type.** Of the total installed capacity on December 31, 2021, 46.3 percent was gas; 26.0 percent was coal; 17.3 percent was nuclear; 4.7 percent was hydroelectric; 3.0 percent was oil; 1.4 percent was wind; 0.3 percent was solid waste; and 1.0 percent was solar.
- **Market Concentration.** In the 2021/2022 RPM Third Incremental Auction and the 2022/2023 RPM Base Residual Auction all participants in the total PJM market as well as the LDA RPM markets failed the three pivotal supplier (TPS) test.[93] Offer caps were applied to all sell offers for resources which were subject to mitigation when the capacity market seller did not pass the test, the submitted sell offer exceeded the defined offer cap, and the submitted sell offer, absent mitigation, increased the market clearing price.[94] [95] [96]
- **Imports and Exports.** Of the 1,558.0 MW of imports in the 2022/2023 RPM Base Residual Auction, 1,558.0 MW cleared. Of the cleared imports, 954.9 MW (61.3 percent) were from MISO.
- **Demand-Side and Energy Efficiency Resources.** Capacity in the RPM load management programs was 12,115.9 MW for June 1, 2021, as a result of cleared capacity for demand resources and energy efficiency resources in RPM auctions for the 2021/2022 Delivery Year (16,233.9 MW) less purchases of replacement capacity (4,118.0 MW).

Market Conduct

- **2021/2022 RPM Third Incremental Auction.** Of the 481 generation resources that submitted Capacity Performance offers, the MMU calculated unit

91 See 126 FERC ¶ 61,275 at P 88 (2009). There have been no Conditional Incremental Auctions.

92 Transmission constraints are local capacity import capability limitations (low capacity emergency transfer limit (CETL) margin over capacity emergency transfer objective (CETO)) caused by transmission facility limitations, voltage limitations or stability limitations.

93 There are 27 Locational Deliverability Areas (LDAs) identified to recognize locational constraints as defined in "Reliability Assurance Agreement Among Load Serving Entities in the PJM Region," Schedule 10.1. PJM determines, in advance of each BRA, whether the defined LDAs will be modeled in the given delivery year using the rules defined in OATT Attachment DD § 5.10(a)(ii).

94 See OATT Attachment DD § 6.5.

95 Prior to November 1, 2009, existing DR and EE resources were subject to market power mitigation in RPM Auctions. See 129 FERC ¶ 61,081 at P 30 (2009).

96 Effective January 31, 2011, the RPM rules related to market power mitigation were changed, including revising the definition for Planned Generation Capacity Resource and creating a new definition for Existing Generation Capacity Resource for purposes of the must offer requirement and market power mitigation, and treating a proposed increase in the capability of a generation capacity resource the same in terms of mitigation as a Planned Generation Capacity Resource. See 134 FERC ¶ 61,065 (2011).

specific offer caps for zero generation resources (0.0 percent).

- **2022/2023 RPM Base Residual Auction.** Of the 1,083 generation resources that submitted Capacity Performance offers, the MMU calculated unit specific offer caps for zero generation resources (0.0 percent).

Market Performance

- The 2021/2022 RPM Third Incremental Auction and 2022/2023 RPM Base Residual Auction were conducted in 2021.[97] The weighted average capacity price for the 2020/2021 Delivery Year is $111.07 per MW-day, including all RPM auctions for the 2020/2021 Delivery Year. The weighted average capacity price for the 2021/2022 Delivery Year is $147.33 per MW-day, including all RPM auctions for the 2021/2022 Delivery Year.
- For the 2021/2022 Delivery Year, RPM annual charges to load are $9.4 billion.
- In the 2022/2023 RPM Base Residual Auction, the market performance was determined to be not competitive as a result of noncompetitive offers that affected market results.

Reliability Must Run Service

- Of the seven companies (23 units) that have provided RMR service, two companies (seven units) filed to be paid for RMR service under the deactivation avoidable cost rate (DACR), the formula rate. The other five companies (16 units) filed to be paid for RMR service under the cost of service recovery rate. PJM has indicated to another plant that RMR service will be required in 2022.

Generator Performance

- **Forced Outage Rates.** The average PJM EFORd in 2021 was 7.3 percent, an increase from 6.3 percent in 2020.[98]
- **Generator Performance Factors.** The PJM aggregate equivalent availability factor in 2021 was 81.7 percent, a decrease from 84.7 percent in 2020.

Section 5 Recommendations[99]

Definition of Capacity

- The MMU recommends the enforcement of a consistent definition of capacity resource. The MMU recommends that the requirement to be a physical resource be enforced and enhanced. The requirement to be a physical resource should apply at the time of auctions and should also constitute a commitment to be physical in the relevant delivery year. The requirement to be a physical resource should be applied to all resource types, including planned generation, demand resources and imports.[100] [101] (Priority: High. First reported 2013. Status: Not adopted.)
- The MMU recommends that DR providers be required to have a signed contract with specific customers for specific facilities for specific levels of DR at least six months prior to any capacity auction in which the DR is offered. (Priority: High. First reported 2016. Status: Not adopted.)
- The MMU recommends that energy efficiency resources (EE) not be included on the supply side of the capacity market, because PJM's load forecasts now account for future EE, unlike the situation when EE was first added to the capacity market. EE should not be part of the capacity market. If EE is not included on the supply side, there is no reason to have an addback mechanism. If EE remains on the supply side, the MMU recommends that the implementation of the EE addback mechanism be modified to ensure that market clearing prices are not affected.[102] (Priority: Medium. First reported 2016. Status: Not adopted.)

97 FERC granted PJM's request for waiver of its Open Access Transmission Tariff to delay the 2022/2023 RPM Base Residual Auction from May 2019 to August 2019. See 164 FERC ¶ 61,153 (2018). FERC subsequently denied PJM's motion seeking clarification of the June 29, 2018, Order (163 FERC ¶ 61,236) and directed PJM not to run the 2022/2023 BRA in August 2019. See 168 FERC ¶ 61,051 (2019).

98 The generator performance analysis includes all PJM capacity resources for which there are data in the PJM generator availability data systems (GADS) database. Data was downloaded from the PJM GADS database on January 24, 2022. EFORd data presented in state of the market reports may be revised based on data submitted after the publication of the reports as generation owners may submit corrections at any time with permission from PJM GADS administrators.

99 The MMU has identified serious market design issues with RPM and the MMU has made specific recommendations to address those issues. These recommendations have been made in public reports. See Table 5-2.

100 See also Comments of the Independent Market Monitor for PJM, Docket No. ER14-503-000 (December 20, 2013).

101 See "Analysis of Replacement Capacity for RPM Commitments: June 1, 2007 to June 1, 2019," <http://www.monitoringanalytics.com/reports/Reports/2019/IMM_Analysis_of_Replacement_Capacity_for_RPM_Commitments_June_1_2007_to_June_1_2019_20190913.pdf> (September 13, 2019).

102 Based on an Issue Charge introduced by the MMU, PJM has updated the EE addback rules effective with the 2023/2024 Delivery Year, to address this issue. "PJM Manual 18: PJM Capacity Market," § 2.4.5 Adjustments to RPM Auction Parameters for EE Resources, Rev. 51 (Oct. 20, 2021).

- The MMU recommends that intermittent resources, including storage, not be permitted to offer capacity MW based on energy delivery that exceeds their defined deliverability rights (CIRs). Only energy output for such resources below the designated CIR/deliverability level should be recognized in the definition of capacity. (Priority: High. New recommendation. Status: Not adopted.)
- The MMU recommends that the must offer rule in the capacity market apply to all capacity resources. There is no reason to exempt intermittent and storage resources, including hydro. The purpose of the must offer rule, which has been in place since the beginning of the capacity market in 1999, is to prevent the exercise of market power via withholding. (Priority: High. New recommendation. Status: Not adopted.)

Market Design and Parameters

- The MMU recommends that PJM reevaluate the shape of the VRR curve. The shape of the VRR curve directly results in load paying substantially more for capacity than load would pay with a vertical demand curve. (Priority: High. New recommendation. Status: Not adopted.)
- The MMU recommends that the maximum price on the VRR curve be defined as net CONE. (Priority: Medium. First reported 2019. Status: Not adopted.)
- The MMU recommends that the test for determining modeled Locational Deliverability Areas (LDAs) in RPM be redefined. A detailed reliability analysis of all at risk units should be included in the redefined model. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM clear the capacity market based on nodal capacity resource locations and the characteristics of the transmission system consistent with the actual electrical facts of the grid. Absent a fully nodal capacity market clearing process, the MMU recommends that PJM use a non-nested model with all LDAs modeled including VRR curves for all LDAs. Each LDA requirement should be met with the capacity resources located within the LDA and exchanges from neighboring LDAs up to the transmission limit. LDAs should be allowed to price separate if that is the result of the LDA supply curves and the transmission constraints between LDAs. (Priority: Medium. First reported 2017. Status: Not adopted.)
- The MMU recommends that the net revenue calculation used by PJM to calculate the Net Cost of New Entry (CONE) VRR parameter reflect the actual flexibility of units in responding to price signals rather than using assumed fixed operating blocks that are not a result of actual unit limitations.[103] [104] The result of reflecting the actual flexibility is higher net revenues, which affect the parameters of the RPM demand curve and market outcomes. (Priority: High. First reported 2013. Status: Adopted 2021.)
- The MMU recommends that PJM reduce the number of incremental auctions to a single incremental auction held three months prior to the start of the delivery year and reevaluate the triggers for holding conditional incremental auctions. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM not sell back any capacity in any IA, at much lower prices, procured in a BRA. If PJM continues to sell back capacity, the MMU recommends that PJM offer to sell back capacity in incremental auctions only at the BRA clearing price for the relevant delivery year. (Priority: Medium. First reported 2017. Status: Not adopted.)
- The MMU recommends changing the RPM solution method to explicitly incorporate the cost of uplift (make whole) payments in the objective function. (Priority: Medium. First reported 2014. Status: Not adopted.)
- The MMU recommends that the Fixed Resource Requirement (FRR) rules, including obligations and performance requirements, be revised and updated to ensure that the rules reflect current market realities and that FRR entities do not unfairly take advantage of those customers paying for capacity in the PJM capacity market. (Priority: Medium. First reported 2019. Status: Not adopted.)
- The MMU recommends that the value of CTRs should be defined by the total MW cleared in the capacity market, the internal MW cleared and the imported MW cleared, and not redefined later prior to the

103 See PJM Interconnection, L.L.C., Docket No. ER12-513-000 (December 1, 2011) ("Triennial Review").
104 See the *2019 State of the Market Report for PJM*, Volume 2, Section 7: Net Revenue.

delivery year. (Priority: Medium. First reported Q3 2021. Status: Not adopted.)

- The MMU recommends that the market clearing results be used in settlements rather than the reallocation process currently used, or that the process of modifying the obligations to pay for capacity be reviewed. (Priority: Medium. New recommendation. Status: Not adopted.)
- The MMU recommends that PJM improve the clarity and transparency of its CETL calculations. The MMU also recommends that CETL for capacity imports into PJM be based on the ability to import capacity only where PJM capacity exists and where that capacity has a must offer requirement in the PJM Capacity Market. (Priority: Medium. New recommendation. Status: Not adopted.)

Offer Caps, Offer Floors, and Must Offer

- The MMU recommends using the lower of the cost or price-based energy market offer to calculate energy costs in the calculation of the historical net revenues which are an offset to gross ACR in the calculation of unit specific capacity resource offer caps based on net ACR. (Priority: Medium. New recommendation. Status: Not adopted.)
- The MMU recommends use of the Sustainable Market Rule (SMR) in order to protect competition in the capacity market from nonmarket revenues.[105] (Priority: High. First reported 2016. Status: Not adopted.)
- The MMU recommends that, as part of the MOPR unit specific standard of review, all projects be required to use the same basic modeling assumptions. That is the only way to ensure that projects compete on the basis of actual costs rather than on the basis of modeling assumptions.[106] (Priority: High. First reported 2013. Status: Not adopted.)
- The MMU recommends that modifications to existing resources be subject to market power related offer caps or MOPR offer floors and not be treated as new resources and therefore exempt. (Priority: Low. First reported 2012. Status: Not adopted.)
- The MMU recommends that the RPM market power mitigation rule be modified to apply offer caps in all cases when the three pivotal supplier test is failed and the sell offer is greater than the offer cap. This will ensure that market power does not result in an increase in uplift (make whole) payments for seasonal resources. (Priority: Medium. First reported 2017. Status: Not adopted.)
- The MMU recommends that any combined seasonal resources be required to be in the same LDA and preferably at the same location, in order for the energy market and capacity market to remain synchronized and reliability metrics correctly calculated. (Priority: Medium. New recommendation. Status: Not adopted.)
- The MMU recommends that the offer cap for capacity resources be defined as the net avoidable cost rate (ACR) of each unit so that the clearing prices are a result of such net ACR offers, consistent with the fundamental economic logic for a competitive offer of a CP resource. (Priority: High. First reported 2017. Status: Adopted, 2021.)
- The MMU recommends that capacity market sellers be required to explicitly request and support the use of minimum MW quantities (inflexible sell offer segments) and that the requests only be permitted for defined physical reasons. (Priority: Medium. First reported 2018. Status: Not adopted.)

Performance Incentive Requirements of RPM

- The MMU recommends that any unit not capable of supplying energy equal to its day-ahead must offer requirement (ICAP) be required to reflect an appropriate outage. (Priority: Medium. First reported 2009. Status: Not adopted.)
- The MMU recommends that retroactive replacement transactions associated with a failure to perform during a PAI not be allowed and that, more generally, retroactive replacement capacity transactions not be permitted. (Priority: Medium. First reported 2016. Status: Not adopted.)

105 Brief of the Independent Market Monitor for PJM, Docket No. EL16-49, ER18-1314-000,-001; EL18-178 (October 2, 2018).

106 See 143 FERC ¶ 61,090 (2013) ("We encourage PJM and its stakeholders to consider, for example, whether the unit-specific review process would be more effective if PJM requires the use of common modeling assumptions for establishing unit-specific offer floors while, at the same time, allowing sellers to provide support for objective, individual cost advantages. Moreover, we encourage PJM and its stakeholders to consider these modifications to the unit-specific review process together with possible enhancements to the calculation of Net CONE."); see also, Comments of the Independent Market Monitor for PJM, Docket No. ER13-535-001 (March 25, 2013); Complaint of the Independent Market Monitor for PJM v. Unnamed Participant, Docket No. EL12-63-000 (May 1, 2012); Motion for Clarification of the Independent Market Monitor for PJM, Docket No. ER11-2875-000, et al. (February 17, 2012); Protest of the Independent Market Monitor for PJM, Docket No. ER11-2875-002 (June 2, 2011); Comments of the Independent Market Monitor for PJM, Docket Nos. EL11-20 and ER11-2875 (March 4, 2011).

- The MMU recommends that there be an explicit requirement that capacity resource offers in the day-ahead energy market be competitive, where competitive is defined to be the short run marginal cost of the units. (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends that Capacity Performance resources be required to perform without excuses. Resources that do not perform should not be paid regardless of the reason for nonperformance. (Priority: High. First reported 2019. Status: Not adopted.)
- The MMU recommends that the market data posting rules be modified to allow the disclosure of expected performance, actual performance, shortfall and bonus MW during a PAI by area without the requirement that more than three market participants' data be aggregated for posting. (Priority: Low. First reported 2019. Status: Not adopted.)

Capacity Imports and Exports

- The MMU recommends that all capacity imports be required to be deliverable to PJM load in an identified LDA prior to the relevant delivery year to ensure that they are full substitutes for internal, physical capacity resources. Pseudo ties alone are not adequate to ensure deliverability to PJM load. (Priority: High. First reported 2016. Status: Not adopted.)
- The MMU recommends that all costs incurred as a result of a pseudo tied unit be borne by the unit itself and included as appropriate in unit offers in the capacity market. (Priority: High. First reported 2016. Status: Not adopted.)
- The MMU recommends clear, explicit and detailed rules that define the conditions under which PJM will and will not recall energy from PJM capacity resources and prohibit new energy exports from PJM capacity resources. The MMU recommends that those rules define the conditions under which PJM will purchase emergency energy while at the same time not recalling energy exports from PJM capacity resources. PJM has modified these rules, but the rules need additional clarification and operational details. (Priority: Low. First reported 2010. Status: Partially adopted.)

Deactivations/Retirements

- The MMU recommends that the notification requirement for deactivations be extended from 90 days prior to the date of deactivation to 12 months prior to the date of deactivation and that PJM and the MMU be provided 60 days rather than 30 days to complete their reliability and market power analyses. (Priority: Low. First reported 2012. Status: Not adopted.)
- The MMU recommends that RMR units recover all and only the incremental costs, including incremental investment costs, required by the RMR service that the unit owner would not have incurred if the unit owner had deactivated its unit as it proposed. Customers should bear no responsibility for paying previously incurred costs, including a return on or of prior investments. (Priority: Low. First reported 2010. Status: Not adopted.)
- The MMU recommends elimination of the cost of service recovery rate in OATT Section 119, that RMR service should be provided under the deactivation avoidable cost rate in Part V, and that the revenue cap under the avoidable cost rate option be eliminated. The MMU also recommends specific improvements to the DACR provisions. (Priority: Medium. First reported 2017. Status: Not adopted.)

Section 5 Conclusion

The analysis of PJM Capacity Markets begins with market structure, which provides the framework for the actual behavior or conduct of market participants. The analysis examines participant behavior within that market structure. In a competitive market structure, market participants are constrained to behave competitively. The analysis examines market performance, measured by price and the relationship between price and marginal cost, that results from the interaction of market structure and participant behavior.

The capacity market is, by design, always tight in the sense that total supply is generally only slightly larger than demand. The PJM Capacity Market is a locational market and local markets can and do have different supply demand balances than the aggregate market. While the market may be long at times, that is not the equilibrium state. Capacity in excess of demand is not sold and, if it does not earn or does not expect to earn adequate revenues in future capacity markets, or in other markets, or does not have value as a hedge, may be expected to retire, provided the market sets appropriate price signals to reflect the availability of excess supply. The demand for capacity includes expected peak load plus a reserve margin, and points on the demand curve, called the Variable Resource Requirement (VRR) curve, exceed peak load plus the reserve margin. The shape of the VRR curve results in the purchase of excess capacity and higher payments by customers. The impact of the VRR curve shape used in the 2022/2023 BRA compared to a vertical demand curve was significant. The defined reliability goal is to have total supply greater than or equal to the defined demand for capacity. The level of purchased demand under RPM has generally exceeded expected peak load plus the target reserve margin, resulting in reserve margins that exceed the target. Demand for capacity is almost entirely inelastic because the market rules require loads to purchase their share of the system capacity requirement. The small level of elasticity incorporated in the RPM demand curve is not adequate to modify this conclusion. The result is that any supplier that owns more capacity than the typically small difference between total supply and the defined demand is individually pivotal and therefore has structural market power. Any supplier that, jointly with two other suppliers, owns more capacity than the difference between supply and demand either in aggregate or for a local market is jointly pivotal and therefore has structural market power.

The level of cleared demand resources (8,710.3 MW) is greater than the entire level of excess capacity cleared in the auction (7,660.2 MW). This is consistent with PJM effectively not relying on demand response for reliability in actual operations. The excess is a result of the flawed rules permitting the participation of inferior demand side resources in the capacity market. Maintaining the persistent excess has meant that PJM markets have never experienced the results of reliance on demand side resources as part of the required reserve margin, rather than as excess above the required reserve margin. PJM markets have never experienced the implications of the definition of demand side resources as a purely emergency capacity resource that triggers a PAI whenever called.

The market design for capacity leads to structural market power in the capacity market. The capacity market is unlikely ever to approach a competitive market structure in the absence of a substantial and unlikely structural change that results in much greater diversity of ownership. Market power is and will remain endemic to the structure of the PJM Capacity Market. Nonetheless a competitive outcome can be assured by appropriate market power mitigation rules. Detailed market power mitigation rules are included in the PJM Open Access Transmission Tariff (OATT or Tariff). Reliance on the RPM design for competitive outcomes means reliance on the market power mitigation rules. Attenuation of those rules means that market participants are not able to rely on the competitiveness of the market outcomes. The market power rules applied in the 2021/2022 BRA and the 2022/2023 BRA were significantly flawed, as illustrated by the results of the 2021/2022 BRA and the 2022/2023 BRA.[107] Competitive outcomes require continued improvement of the rules and ongoing monitoring of market participant behavior and market performance. The incorrect definition of the offer caps in the 2021/2022 BRA and the 2022/2023 BRA resulted in noncompetitive offers and a noncompetitive outcome. The market power rules were corrected by the Commission in an order issued on September 2, 2021, (September 2nd Order) but the modified market power rules were not implemented in the 2022/2023 BRA.[108] [109] The result was that capacity market prices were above the competitive level. In addition, the inclusion of offers that were not consistent with the defined terms of the Minimum Offer Price Rule (MOPR) based on the MMU's review, but were accepted by PJM, had a significant impact on the auction results.

In the capacity market, as in other markets, market power is the ability of a market participant to increase the market price above the competitive level or to decrease the market price below the competitive level. In order to evaluate whether actual prices reflect the exercise of market power, it is necessary to evaluate whether market offers are consistent with competitive offers.

The definition of the market seller offer cap was changed with the introduction of the Capacity Performance (CP) rules. But the CP market seller offer cap was based on

107 See "Analysis of the 2021/2022 RPM Base Residual Auction - Revised," <http://www.monitoringanalytics.com/reports/Reports/2018/IMM_Analysis_of_the_20212022_RPM_BRA_Revised_20180824.pdf> (August 24, 2018).
108 Complaint of the Independent Market Monitor for PJM, Docket No. EL19-47, February 21, 2019s ("IMM MSOC Complaint").
109 176 FERC ¶ 61,137 (September 2nd Order).

strong assumptions that are not correct. The CP market seller offer cap was significantly overstated as a result. For units that could profitably provide energy under the Capacity Performance design even without a capacity payment because their expected CP bonus payments exceed their net ACR, based on expected unit specific performance, expected balancing ratio, expected performance assessment intervals (PAI) and expected penalty payments, the competitive, profit maximizing offer was defined to be Net CONE times B, where B is the expected average balancing ratio. This was the default offer cap for such units only under strong, defined assumptions.[110] Those assumptions included: there are expected PAI; the number of PAI used in the calculation of the nonperformance charge rate is the same as the expected PAI (360); penalties are imposed by PJM for all cases of noncompliance as defined in the tariff and there are no excuses; the bonus payments equal the penalties; and capacity resources have the ability to costlessly switch between energy only status and capacity resource status.

But those assumptions were not even close to being correct for the 2022/2023 BRA and Net CONE times B was not the correct offer cap as a result. The Capacity Performance paradigm has not worked as anticipated in PJM and is not expected to work, in part because the assumptions are never likely to be correct. In addition, PAI is an endogenous variable. The expected number of PAI is a function of the level of capacity resources which is a function of offers and the resultant clearing prices. The correct definition of a competitive offer is net ACR, where ACR includes an explicit accounting for the costs of mitigating risk, including the risk associated with capacity market nonperformance penalties.

The MMU concludes that the results of the 2022/2023 RPM Base Residual Auction were not competitive as a result of economic withholding by resources that used offers that were consistent with the Net CONE times B offer cap but not consistent with competitive offers based on the correctly calculated offer cap. The MMU recognizes that these market participants followed the capacity market rules by offering at less than the stated offer cap of Net CONE times B. A competitive offer in the capacity market is equal to net ACR.[111] That is the way in which most market participants offered in this and prior capacity performance auctions. The ACR values used in this analysis were based on data provided by the participants and were consistent with competitive offers for the relevant capacity and were consistent with PJM's posted default ACR values for the referenced technology.

The MMU also concludes that market prices were significantly affected by other flaws in the capacity market rules and in the application of the capacity market rules by PJM, including the shape of the VRR curve, the overstatement of the capacity of intermittent resources, the treatment of DR, the MOPR rules, the inclusion of EE, and the EE addback rules.

The MMU also concludes that, although a much smaller issue in the 2022/2023 auction, the rules permitted the exercise of market power without mitigation for seasonal resources through uplift payments for noncompetitive offers, rather than through higher prices.[112] Although the impact was small in the 2022/2023 auction, the issue should be addressed immediately in order to prevent the impact from increasing and because the solution is simple.

The recent changes to the capacity market design have addressed some but not all of the significant recommendations made by the MMU in prior reports. The MMU had recommended the elimination of the 2.5 percent demand adjustment (Short-Term Resource Procurement Target). The MMU had recommended that the performance incentives in the capacity market design be strengthened. The MMU had recommended that generation capacity resources pay penalties if they fail to produce energy when called upon during any of the hours defined as critical. The MMU had recommended that the net revenue calculation used by PJM to calculate the net Cost of New Entry (CONE) VRR parameter reflect the actual flexibility of units in responding to price signals rather than using assumed fixed operating blocks that are not a result of actual unit limitations. The MMU had recommended that all capacity imports be required to be pseudo tied in order to ensure that imports are as close to full substitutes

110 For a detailed derivation, *see* Errata to February 25, 2015 Answer and Motion for Leave to Answer of the Independent Market Monitor for PJM Interconnection, L.L.C., Docket No. ER15-623, et al. (February 27, 2015).

111 See 174 FERC ¶ 61,212 at P 65 ("March 18th Order").

112 PJM uses various terms for uplift including make whole payments (often used in the capacity market) and operating reserve payments (often used in the energy market). The term uplift is used in this report to refer to out of market payments made by PJM to market participants in addition to market revenues.

for internal, physical capacity resources as possible. The MMU had recommended that the definition of demand side resources be modified in order to ensure that such resources are full substitutes for and provide the same value in the capacity market as generation resources, although this recommendation has not been incorporated in PJM rules. The MMU had recommended that both the Limited and the Extended Summer DR products be eliminated and that the restrictions on the availability of Annual DR be eliminated in order to ensure that the DR product has the same unlimited obligation to provide capacity year round as Generation Capacity Resources. The MMU had recommended that the default Avoidable Cost Rate (ACR) escalation method be modified in order to ensure accuracy and eliminate double counting.

The MMU is required to identify market issues and to report them to the Commission and to market participants. The Commission decides on any action related to the MMU's findings.

The MMU has identified serious market design issues with RPM and the MMU has made specific recommendations to address those issues.[113] [114] [115] [116] [117] [118] In 2020 and 2021, the MMU prepared a number of RPM related reports and testimony, shown in Table 5-2.

The PJM markets have worked to provide incentives to entry and to retain capacity. PJM had excess reserves of 7,828.5 ICAP MW on June 1, 2021, and will have excess reserves of 8,065.8 ICAP MW on June 1, 2022, based on current positions.[119] A majority of capacity investments in PJM were financed by market sources.[120] Of the 42,969.5 MW of additional capacity that cleared in RPM auctions for the 2007/2008 through 2021/2022 Delivery Years, 31,509.2 MW (73.3 percent) were based on market funding. Of the 6,587.3 MW of additional capacity that cleared in RPM auctions for the 2022/2023 through 2023/2024 Delivery Years, 4,924.2 MW (74.8 percent) were based on market funding. Those investments were made based on the assumption that markets would be allowed to work and that inefficient units would exit.

It is essential that any approach to the PJM markets incorporate a consistent view of how the preferred market design is expected to provide competitive results in a sustainable market design over the long run. A sustainable market design means a market design that results in appropriate incentives to competitive market participants to retire units and to invest in new units over time such that reliability is ensured as a result of the functioning of the market.

A sustainable competitive wholesale power market must recognize three salient structural elements: state nonmarket revenues for renewable energy; a significant level of generation resources subject to cost of service regulation; and the structure and performance of the existing market based generation fleet.

In order to attract and retain adequate resources for the reliable operation of the energy market, revenues from PJM energy, ancillary services and capacity markets must be adequate for those resources. That adequacy requires a capacity market. The capacity market plays the essential role of equilibrating the revenues necessary to incent competitive entry and exit of the resources needed for reliability, with the revenues from the energy market that are directly affected by nonmarket sources.

Price suppression below the competitive level in the capacity market should not be acceptable and is not consistent with a competitive market design. Harmonizing means that the integrity of each paradigm is maintained and respected. Harmonizing permits nonmarket resources to have an unlimited impact on energy markets and energy prices. Harmonizing means designing a capacity market to account for these energy market impacts, clearly limiting the impact of nonmarket revenues on the capacity market and ensuring competitive outcomes in the capacity market and thus in the entire market.

Overview: Section 6, Demand Response

- **Demand Response Activity.** Demand response activity includes economic demand response (economic resources), emergency and pre-emergency demand response (demand resources), synchronized reserves and regulation. Economic demand response participates in the energy market. Emergency and pre-emergency demand response participates in the capacity market and energy market.[121] Demand response resources participate in the synchronized reserve market. Demand response resources participate in the regulation market.

  Total demand response revenue increased by $155.9 million, 43.4 percent, from $359.2 million in 2020 to $515.1 million in 2021. Emergency demand response revenue accounted for 97.9 percent of all demand response revenue, economic demand response for 0.1 percent, demand response in the synchronized reserve market for 1.5 percent and demand response in the regulation market for 0.4 percent.

  Total emergency demand response revenue increased by $149.4 million, 42.1 percent, from $355.1 million in 2020 to $504.4 million in 2021.[122]

  Economic demand response revenue increased by $0.4 million, 128.4 percent, from $0.3 million in 2020 to $0.8 million in 2021.[123] Demand response revenue in the synchronized reserve market increased by $5.2 million, 215.1 percent, from $2.4 million in 2020 to $7.6 million in2021. Demand response revenue in the regulation market increased by $1.0 million, 70.8 percent, from $1.4 million in 2020 to $2.3 million in 2021.

- **Demand Response Energy Payments are Uplift.** Energy payments to emergency and economic demand response resources are uplift. LMP does not cover energy payments although emergency and economic demand response can and does set LMP. Energy payments to emergency demand resources are paid by PJM market participants in proportion to their net purchases in the real-time market. Energy payments to economic demand resources are paid by real-time exports from PJM and real-time loads in each zone for which the load-weighted, average real-time LMP for the hour during which the reduction occurred is greater than or equal to the net benefits test price for that month.[124]

- **Demand Response Market Concentration.** The ownership of economic load response resources was highly concentrated in 2020 and 2021. The HHI for economic resource reductions decreased by 539 points from 9065 for 2020 to 8526 in 2021. The ownership of emergency load response resources was highly concentrated in 2020. The HHI for emergency load response committed MW was 2523 for the 2020/2021 Delivery Year. In the 2020/2021 Delivery Year, the four largest CSPs owned 88.4 percent of all committed demand response UCAP MW. The HHI for emergency demand response committed MW is 2584 for the 2021/2022 Delivery Year. In the 2021/2022 Delivery Year, the four largest CSPs own 89.0 percent of all committed demand response UCAP MW.

- **Limited Locational Dispatch of Demand Resources.** With full implementation of the Capacity Performance rules in the capacity market in the 2020/2021 Delivery Year, PJM should be able to individually dispatch any capacity performance resource, including demand resources. But PJM cannot dispatch demand resources by node with the current rules because demand resources are not registered to a node. Demand resources can be dispatched by subzone only if the subzone is defined before dispatch. Aggregation rules allow a demand resource that incorporates many small end use customers to span an entire zone, which is inconsistent with nodal dispatch.

Section 6 Recommendations

- The MMU recommends, as a preferred alternative to including demand resources as supply in the capacity market, that demand resources be on the demand side of the markets, that customers be able to avoid capacity and energy charges by not using capacity and energy at their discretion, that customer payments be determined only by metered load, and that PJM forecasts immediately

121 Emergency demand response refers to both emergency and pre-emergency demand response. With the implementation of the Capacity Performance design, there is no functional difference between the emergency and pre-emergency demand response resource.

122 The total credits and MWh numbers for demand resources were downloaded as of January 10, 2022 and may change as a result of continued PJM billing updates.

123 Economic credits are synonymous with revenue received for reductions under the economic load response program.

124 "PJM Manual 28: Operating Agreement Accounting," § 11.2.2, Rev. 85 (Sep. 1, 2021).

incorporate the impacts of demand side behavior. (Priority: High. First reported 2014. Status: Not adopted.)

- The MMU recommends that the option to specify a minimum dispatch price (strike price) for demand resources be eliminated and that participating resources receive the hourly real-time LMP less any generation component of their retail rate. (Priority: Medium. First reported 2010. Status: Not adopted.)
- The MMU recommends that the maximum offer for demand resources be the same as the maximum offer for generation resources. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that the demand resources be treated as economic resources, responding to economic price signals like other capacity resources. The MMU recommends that demand resources not be treated as emergency resources, not trigger a PJM emergency and not trigger a Performance Assessment Interval. (Priority: High. First reported 2012. Status: Not adopted.)
- The MMU recommends that the Emergency Program Energy Only option be eliminated because the opportunity to receive the appropriate energy market incentive is already provided in the economic program. (Priority: Low. First reported 2010. Status: Not adopted.)
- The MMU recommends that, if demand resources remain in the capacity market, a daily energy market must offer requirement apply to demand resources, comparable to the rule applicable to generation capacity resources.[125] (Priority: High. First reported 2013. Status: Not adopted.)
- The MMU recommends that demand resources be required to provide their nodal location, comparable to generation resources. (Priority: High. First reported 2011. Status: Not adopted.)
- The MMU recommends that PJM require nodal dispatch of demand resources with no advance notice required or, if nodal location is not required, subzonal dispatch of demand resources with no advance notice required. The MMU recommends that, if PJM continues to use subzones for any purpose, PJM clearly define the role of subzones in the dispatch of demand response. (Priority: High. First reported 2015. Status: Not adopted.)
- The MMU recommends that PJM not remove any defined subzones and maintain a public record of all created and removed subzones. (Priority: Low. First reported 2016. Status: Not adopted.)
- The MMU recommends that PJM eliminate the measurement of compliance across zones within a compliance aggregation area (CAA). The multiple zone approach is less locational than the zonal and subzonal approach and creates larger mismatches between the locational need for the resources and the actual response. (Priority: High. First reported 2015. Status: Not adopted.)
- The MMU recommends that measurement and verification methods for demand resources be modified to reflect compliance more accurately. (Priority: Medium. First reported 2009. Status: Not adopted.)
- The MMU recommends that compliance rules be revised to include submittal of all necessary hourly load data, and that negative values be included when calculating event compliance across hours and registrations. (Priority: Medium. First reported 2012. Status: Not adopted.)
- The MMU recommends that PJM adopt the ISO-NE five-minute metering requirements in order to ensure that operators have the necessary information for reliability and that market payments to demand resources be calculated based on interval meter data at the site of the demand reductions.[126] (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends demand response event compliance be calculated on a five minute basis for all capacity performance resources and that the penalty structure reflect five minute compliance. (Priority: Medium. First reported 2013. Status: Partially adopted.)
- The MMU recommends that load management testing be initiated by PJM with limited warning to CSPs in order to more accurately represent the

125 See "Complaint and Motion to Consolidate of the Independent Market Monitor for PJM," Docket No. EL14-20-000 (January 27, 2014) at 1.

126 See ISO-NE Tariff, Section III, Market Rule 1, Appendix E1 and Appendix E2, "Demand Response," <http://www.iso-ne.com/regulatory/tariff/sect_3/mr1_append-e.pdf>. (Accessed October 17, 2017) ISO-NE requires that DR have an interval meter with five-minute data reported to the ISO and each behind the meter generator is required to have a separate interval meter. After June 1, 2017, demand response resources in ISO-NE must also be registered at a single node.

conditions of an emergency event. (Priority: Low. First reported 2012. Status: Not adopted.)

- The MMU recommends that shutdown cost be defined as the cost to curtail load for a given period that does not vary with the measured reduction or, for behind the meter generators, be the start cost defined in Manual 15 for generators. (Priority: Low. First reported 2012. Status: Not adopted.)
- The MMU recommends that the Net Benefits Test be eliminated and that demand response resources be paid LMP less any generation component of the applicable retail rate. (Priority: Low. First reported 2015. Status: Not adopted.)
- The MMU recommends that the tariff rules for demand response clarify that a resource and its CSP, if any, must notify PJM of material changes affecting the capability of the resource to perform as registered and must terminate or modify registrations that are no longer capable of responding to PJM dispatch directives at defined levels because load has been reduced or eliminated, as in the case of bankrupt and/or out of service facilities. (Priority: Medium. First reported 2015. Status: Not adopted.)
- The MMU recommends that there be only one demand response product in the capacity market, with an obligation to respond when called for any hour of the delivery year. (Priority: High. First reported 2011. Status: Partially adopted.[127])
- The MMU recommends that the lead times for demand resources be shortened to 30 minutes with an hour minimum dispatch for all resources. (Priority: Medium. First reported 2013. Status: Partially adopted.)
- The MMU recommends setting the baseline for measuring capacity compliance under winter compliance at the customers' PLC, similar to GLD, to avoid double counting. (Priority: High. First reported 2010. Status: Partially adopted.)
- The MMU recommends the Relative Root Mean Squared Test be required for all demand resources with a CBL. (Priority: Low. First reported 2017. Status: Partially adopted.)
- The MMU recommends that PRD be required to respond during a PAI to be consistent with all CP resources. (Priority: High. First reported 2017. Status: Not adopted.)
- The MMU recommends that the limits imposed on the pre-emergency and emergency demand response share of the synchronized reserve market be eliminated. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that 30 minute pre-emergency and emergency demand response be considered to be 30 minute reserves. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that energy efficiency MW not be included in the PJM Capacity Market and that PJM should ensure that the impact of EE measures on the load forecast is incorporated immediately rather than with the existing lag. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that demand reductions based entirely on behind the meter generation be capped at the lower of economic maximum or actual generation output. (Priority: High. First reported 2019. Status: Not adopted.)
- The MMU recommends that all demand resources register as Pre-Emergency Load Response and that the Emergency Load Response Program be eliminated. (Priority: High. First reported 2020. Status: Not adopted.)
- The MMU recommends that EDCs not be allowed to participate in markets as DER aggregators in addition to their EDC role. (Priority: High. New recommendation. Status: Not adopted.)
- The MMU recommends that PJM include a 5 MW maximum size cap on DER aggregations. (Priority: Medium. New recommendation. Status: Not adopted.)

Section 6 Conclusion

A fully functional demand side of the electricity market means that end use customers or their designated intermediaries will have the ability to see real-time energy price signals in real time, will have the ability to react to real-time prices in real time and will have the ability to receive the direct benefits or costs of changes in real-time energy use. In addition, customers or their designated intermediaries will have the ability to see current capacity prices, will have the ability to react to

127 PJM's Capacity Performance design requires resources to respond when called for any hour of the delivery year, but demand resources still have a limited mandatory compliance window.

capacity prices and will have the ability to receive the direct benefits or costs of changes in the demand for capacity in the same year in which demand for capacity changes. A functional demand side of these markets means that customers will have the ability to make decisions about levels of power consumption based both on how customers value the power and on the actual cost of that power.

In the energy market, if there is to be a demand side program, demand resources should be paid the value of energy, which is LMP less any generation component of the applicable retail rate. There is no reason to have the net benefits test. The necessity for the net benefits test is an illustration of the illogical approach to demand side compensation embodied in paying full LMP to demand resources. The benefit of demand side resources is not that they suppress market prices, but that customers can choose not to consume at the current price of power, that individual customers benefit from their choices and that the choices of all customers are reflected in market prices. If customers face the market price, customers should have the ability to not purchase power and the market impact of that choice does not require a test for appropriateness.

If demand resources are to continue competing directly with generation capacity resources in the PJM Capacity Market, the product must be defined such that it can actually serve as a substitute for generation. This is a prerequisite to a functional market design. Demand resources do not have a must offer requirement into the day-ahead energy market, are able to offer above $1,000 per MWh without providing a fuel cost policy, or any rationale for the offer. PJM automatically, and inappropriately, triggers a PAI when demand resources are dispatched and demand resources do not have telemetry requirements similar to other Capacity Performance resources.

In order to be a substitute for generation, demand resources should be defined in PJM rules as an economic resource, as generation is defined. Demand resources should be required to offer in the day-ahead energy market and should be called when the resources are required and prior to the declaration of an emergency. Demand resources should be available for every hour of the year. The fact that PJM currently defines demand resources as emergency resources and the fact that calling on demand resources triggers a performance assessment interval (PAI) under the Capacity Performance design, both serve as a significant disincentive to calling on demand resources and mean that demand resources are underused. Demand resources should be treated as economic resources like any other capacity resource. Demand resources should be called when economic and paid the LMP rather than an inflated strike price up to $1,849 per MWh that is set by the seller.

In order to be a substitute for generation, demand resources (DR) should be subject to robust measurement and verification techniques to ensure that transitional DR programs incent the desired behavior. The methods used in PJM programs today are not adequate to determine and quantify deliberate actions taken to reduce consumption.

In order to be a substitute for generation, demand resources should provide a nodal location and should be dispatched nodally to enhance the effectiveness of demand resources and to permit the efficient functioning of the energy market. Both subzonal and multi-zone compliance should be eliminated because they are inconsistent with an efficient nodal market.

In order to be a substitute for generation, compliance by demand resources with PJM dispatch instructions should include both increases and decreases in load. The current method applied by PJM simply ignores increases in load and thus artificially overstates compliance.

In order to be a substitute for generation, reductions should be calculated hourly for dispatched DR. The current rules use the average reduction for the duration of an event. The average reduction across multiple hours does not provide an accurate metric for each hour of the event and is inconsistent with the measurement of generation resources. Measuring compliance hourly would provide accurate information to the PJM system. Under the new CP rules, the performance of demand response during Performance Assessment Interval (PAI) will be measured on a five-minute basis.

In order to be a substitute for generation, any demand resource and its Curtailment Service Provider (CSP), should be required to notify PJM of material changes affecting the capability of the resource to perform as registered and to terminate or modify registrations that are no longer capable of responding to PJM dispatch directives at the specified level, such as in the case of bankrupt and out of service facilities. Generation resources are required to inform PJM of any change in availability status, including outages and shutdown status.

As a preferred alternative to being a substitute for generation in the capacity and energy markets, demand response resources should be on the demand side of the capacity market rather than on the supply side. Rather than detailed demand response programs with their attendant complex and difficult to administer rules, customers would be able to avoid capacity and energy charges by not using capacity and energy at their discretion and the level of usage paid for would be defined by metered usage rather than a complex and inaccurate measurement protocol.

The MMU peak shaving proposal at the Summer-Only Demand Response Senior Task Force (SODRSTF) is an example of how to create a demand side product that is on the demand side of the market and not on the supply side.[128] The MMU proposal was based on the BGE load forecasting program and the Pennsylvania Act 129 Utility Program.[129] [130] Under the MMU proposal, participating load would inform PJM prior to an RPM auction of the MW participating, the months and hours of participation and the temperature humidity index (THI) threshold at which load would be reduced. PJM would reduce the load forecast used in the RPM auction based on the designated reductions. Load would agree to curtail demand to at or below a defined FSL, less than the customer PLC, when the THI exceeds a defined level or load exceeds a specified threshold. By relying on metered load and the PLC, load can reduce its demand for capacity and that reduction can be verified without complicated and inaccurate metrics to estimate load reductions. Under PJM's weakened version of the program, performance will be measured under the current economic demand response CBL rules which means relying on load estimates rather than actual metered load.[131] PJM's proposal includes only a THI curtailment trigger and not an overall load curtailment trigger.

The long term appropriate end state for demand resources in the PJM markets should be comparable to the demand side of any market. Customers should use energy as they wish, accounting for market prices in any way they like, and that usage will determine the amount of capacity and energy for which each customer pays. There would be no counterfactual measurement and verification.

Under this approach, customers that wish to avoid capacity payments would reduce their load during expected high load hours. Capacity costs would be assigned to LSEs and by LSEs to customers, based on actual load on the system during these critical hours. Customers wishing to avoid high energy prices would reduce their load during high price hours. Customers would pay for what they actually use, as measured by meters, rather than relying on flawed measurement and verification methods. No measurement and verification estimates are required. No promises of future reductions which can only be verified by inaccurate and biased measurement and verification methods are required. To the extent that customers enter into contracts with CSPs or LSEs to manage their payments, measurement and verification can be negotiated as part of a bilateral commercial contract between a customer and its CSP or LSE. But the system would be paid for actual, metered usage, regardless of which contractual party takes that obligation.

This approach provides more flexibility to customers to limit usage at their discretion. There is no requirement to be available year round or every hour of every day. There is no 30 minute notice requirement. There is no requirement to offer energy into the day-ahead market. All decisions about interrupting are up to the customers only and they may enter into bilateral commercial arrangements with CSPs at their sole discretion. Customers would pay for capacity and energy depending solely on metered load.

A transition to this end state should be defined in order to ensure that appropriate levels of demand side

128 See the MMU package within the *SODRSTF Matrix*, <http://www.pjm.com/-/media/committees-groups/task-forces/sodrstf/20180802/20180802-item-04-sodrstf-matrix.ashx>.

129 *Advance signals that can be used to foresee demand response days*, BGE, <https://www.pjm.com/-/media/committees-groups/task-forces/sodrstf/20180309/20180309-item-05-bge-load-curtailment-programs.ashx> (Accessed March 6, 2019).

130 *Pennsylvania ACT 129 Utility Program*, CPower, <https://www.pjm.com/-/media/committees-groups/task-forces/sodrstf/20180413/20180413-item-03-pa-act-129-program.ashx> (Accessed March 6, 2019).

131 The PJM proposal from the SODRSTF weakened the proposal but was approved at the October 25, 2018 Members Committee meeting and PJM filed Tariff changes on December 7, 2018. See "Peak Shaving Adjustment Proposal," Docket No. ER19-511-000 (December 7, 2018).

response are incorporated in PJM's load forecasts and thus in the demand curve in the capacity market. That transition should be defined by the PRD rules, modified as proposed by the MMU.

This approach would work under the CP design in the capacity market. This approach is entirely consistent with the Supreme Court decision in *EPSA* as it does not depend on whether FERC has jurisdiction over the demand side.[132] This approach will allow FERC to more fully realize its overriding policy objective to create competitive and efficient wholesale energy markets. The decision of the Supreme Court addressed jurisdictional issues and did not address the merits of FERC's approach. The Supreme Court's decision has removed the uncertainty surrounding the jurisdictional issues and created the opportunity for FERC to revisit its approach to demand side.

Overview: Section 7, Net Revenue

Net Revenue

- Energy market net revenues are significantly affected by energy prices and fuel prices. Energy prices and gas prices were significantly higher in 2021 than in 2020.
- In 2021, average energy market net revenues increased by 76 percent for a new combustion turbine (CT), 78 percent for a new combined cycle (CC), 642 percent for a new coal plant (CP), 86 percent for a new nuclear plant, 129 percent for a new diesel (DS), 67 percent for a new onshore wind installation, 83 percent for a new offshore wind installation and 77 percent for a new solar installation compared to 2020.
- The price of natural gas increased by significantly more than the price of coal in 2021. As a result, the marginal costs of a new CC and a new CT were greater than the marginal cost of a new CP in February 2021 and the marginal costs of a new CT were greater than the marginal cost of a new CP from July through November 2021 as a result of higher gas prices.
- Based on Western Hub prices, the spark spread in 2021 increased by 63 percent, the spark spread standard deviation increased by 104 percent, the dark spread increased by 208 percent, and the dark spread standard deviation increased by 112 percent.
- In 2021, capacity market revenue accounted for 52 percent of total net revenues for a new CT, 38 percent for a new CC, 83 percent for a new CP, 14 percent for a new nuclear plant, 85 percent for a new DS, 7 percent for a new onshore wind installation, 11 percent for a new offshore wind installation and 8 percent for a new solar installation.
- In 2021, a new CC would have received sufficient net revenue to cover levelized total costs in 14 zones. No new CT, CP, nuclear, or DS units would have received sufficient net revenue to cover levelized total costs in any zone.
- In 2021, a new entrant onshore wind installation would not have received sufficient net revenue to cover levelized total costs in any of the four zones analyzed. Net revenues would have covered between 45 and 51 percent of levelized total costs of a new entrant onshore wind installation in AEP, APS, COMED and PE. Renewable energy credits accounted for at least 28 percent of the total net revenue of an onshore wind installation.
- In 2021, a new entrant offshore wind installation would not have received sufficient net revenue to cover levelized total costs in any of the three zones analyzed. Net revenues would have covered between 28 and 32 percent of levelized total costs. Renewable energy credits accounted for 26 percent of the total net revenue of an offshore wind installation.
- In 2021, a new entrant solar installation would have covered more than 100 percent of levelized total costs in all five of the five zones analyzed. Renewable energy credits accounted for at least 59 percent of the total net revenue of a solar installation.
- In 2021, most units did not achieve full recovery of avoidable costs through net revenue from energy markets alone, illustrating the critical role of the PJM Capacity Market in providing incentives for continued operation and investment. In 2021, capacity revenues were sufficient to cover the shortfall between energy revenues and avoidable costs for the majority of units and technology types in PJM, with the exception of some coal units.

132 577 U.S. 260 (2016).

- All existing PJM nuclear plants more than covered their avoidable costs from energy and capacity market revenues in 2021 and are expected to more than cover their avoidable costs from energy and capacity market revenues in 2022.
- Using a forward analysis, a total of 2,230 MW of CT, diesel, and oil fired capacity are at risk of retirement, in addition to the units that are currently planning to retire or are expected to retire as a result of state and federal environmental regulations.

Section 7 Recommendations

- The MMU recommends that the net revenue calculation used by PJM to calculate the net Cost of New Entry (CONE) and net ACR be based on a forward looking estimate of expected energy and ancillary services net revenues using forward prices for energy and fuel. (Priority: Medium. First reported 2019. Status: Not adopted.)

Section 7 Conclusion

Wholesale electric power markets are affected by externally imposed reliability requirements. A regulatory authority external to the market makes a determination as to the acceptable level of reliability which is enforced through a requirement to maintain a target level of installed or unforced capacity. The requirement to maintain a target level of installed capacity can be enforced via a variety of mechanisms, including government construction of generation, full-requirement contracts with developers to construct and operate generation, state utility commission mandates to construct capacity, or capacity markets of various types. Regardless of the enforcement mechanism, the exogenous requirement to construct capacity in excess of what is constructed in response to energy market signals has an impact on energy markets. The reliability requirement results in maintaining a level of capacity in excess of the level that would result from the operation of an energy market alone. The result of that additional capacity is to reduce the level and volatility of energy market prices and to reduce the duration of high energy market prices. This, in turn, reduces net revenue to generation owners which reduces the incentive to invest. The exact level of both aggregate and locational excess capacity is a function of the calculation methods used by RTOs and ISOs.

Overview: Section 8, Environmental and Renewables

Federal Environmental Regulation

- **MATS.** The U.S. Environmental Protection Agency's (EPA) Mercury and Air Toxics Standards rule (MATS) applies the Clean Air Act (CAA) maximum achievable control technology (MACT) requirement to new or modified sources of emissions of mercury and arsenic, acid gas, nickel, selenium and cyanide.[133] On May 22, 2020, the EPA published its determination that MATS is not appropriate and necessary based on a cost-benefit analysis.[134] The list of coal steam units subject to MATS, however, remains in place.[135] All coal steam units in PJM are compliant with the state and federal emissions limits established by MATS. The EPA's May 22, 2020, finding is under review pursuant to Executive Order 13990.
- **Air Quality Standards (NO_x and SO_2 Emissions).** The CAA requires each state to attain and maintain compliance with fine particulate matter (PM) and ozone national ambient air quality standards (NAAQS). The CAA also requires that each state prohibit emissions that significantly interfere with the ability of another state to meet NAAQS.[136] On March 15, 2021, the EPA finalized decreases to allowable emissions under the Cross-State Air Pollution Rule (CSAPR) and the 2008 ozone NAAQS for 10 PJM states.[137]
- **NSR.** On August 1, 2019, the EPA proposed to reform the New Source Review (NSR) permitting program.[138] NSR requires new projects and existing projects receiving major overhauls that significantly increase emissions to obtain permits. Recent EPA proposals would reduce the number of projects that require permits.

133 *National Emission Standards for Hazardous Air Pollutants From Coal and Oil-Fired Electric Utility Steam Generating Units and Standards of Performance for Fossil Fuel Fired Electric Utility, Industrial-Commercial-Institutional, and Small Industrial-Commercial-Institutional Steam Generating Units*, EPA Docket No. EPA-HQ-OAR-2009-0234, 77 Fed. Reg. 9304 (Feb. 16, 2012).

134 *See National Emission Standards for Hazardous Air Pollutants: Coal- and Oil-Fired Electric Utility Steam Generating Units—Reconsideration of Supplemental Finding and Residual Risk and Technology Review*, Docket No. EPA–HQ–OAR–2018–0794, 85 Fed. Reg. 31286.

135 *Id.* at 31291.

136 CAA § 110(a)(2)(D)(i)(I).

137 *Revised Cross-State Air Pollution Rule Update for the 2008 Ozone NAAQS*, Docket No. EPA–HQ–OAR–2020–0272; FRL–10013–42– OAR, 85 Fed. Reg. 23054 (Apr. 30, 2021).

138 *Prevention of Significant Deterioration (PSD) and Nonattainment New Source Review (NNSR): Project Emissions Accounting*, EPA Docket No. EPA–HQ–OAR–2018–0048; FRL–9997–95–OAR, 84 Fed. Reg. 39244 (Aug. 9, 2019).

- **RICE.** Stationary reciprocating internal combustion engines (RICE) are electrical generation facilities like diesel engines typically used for backup, emergency or supplemental power. RICE must be tested annually.[139] RICE do not have to meet the same emissions standards if they are emergency stationary RICE. Environmental regulations allow emergency stationary RICE participating in demand response programs to operate for up to 100 hours per calendar year when providing emergency demand response when there is a PJM declared NERC Energy Emergency Alert Level 2 or there are five percent voltage/frequency deviations.

  PJM does not prevent emergency stationary RICE that cannot meet its capacity market obligations as a result of EPA emissions standards from participating in PJM markets as DR. Some emergency stationary RICE that cannot meet its capacity market obligations as a result of emissions standards are now included in DR portfolios. Emergency stationary RICE should be prohibited from participation as DR either when registered individually or as part of a portfolio if it cannot meet its capacity market obligations as a result of emissions standards.

- **Greenhouse Gas Emissions.** On January 19, 2021, the U.S. Court of Appeals for the District of Columbia Circuit vacated the EPA's Affordable Clean Energy (ACE) rule which would have permitted more CO_2 emissions than under the Clean Power Plan (CPP), which ACE had replaced.[140] Neither the ACE nor CPP is currently effective.

- **Cooling Water Intakes.** An EPA rule implementing Section 316(b) of the Clean Water Act (CWA) requires that cooling water intake structures reflect the best technology available for minimizing adverse environmental impacts.[141]

- **Waters of the United States.** On November 18, 2021, EPA and the Department the Army announced the signing of a proposed rule to revise the definition of "waters of the United States" to restore the pre 2015 definition of "waters of the United States." The proposed rule, if adopted, would make permanent the pre 2015 regulatory regime for interpreting WOTUS that is now effective.

- **Effluents.** Under the CWA, the EPA regulates (National Pollutant Discharge Elimination System (NPDES)) discharges from and intakes to power plants, including water cooling systems at steam electric power generating stations. The EPA has recently been strengthening certain discharge limits applicable to steam generating units, and some plant owners have already indicated an intent to close certain generating units as a result.

- **Coal Ash.** The EPA administers the Resource Conservation and Recovery Act (RCRA), which governs the disposal of solid and hazardous waste.[142] The EPA has adopted significant changes to the implementing regulations that will require closing non compliant impoundments, and, potentially, the host power plant. EPA is implementing a process for extensions to as late as October 17, 2028. EPA is reviewing applications received from PJM plant owners. So far, the EPA has proposed to reject applications for Gavin and Clifty Creek, and proposed to grant, with conditions, an application from Spurlock.

State Environmental Regulation

- **Regional Greenhouse Gas Initiative (RGGI).** The Regional Greenhouse Gas Initiative (RGGI) is a CO_2 emissions cap and trade agreement among Connecticut, Delaware, Maine, Maryland, Massachusetts, New Hampshire, New Jersey, New York, Rhode Island, Vermont and Virginia that applies to power generation facilities. New Jersey rejoined on January 1, 2020.[143] Virginia joined RGGI on January 1, 2021, and Pennsylvania is preparing to join.[144] [145] The auction price in the December 1, 2021, auction was at the administrative price cap (Cost Containment Reserve (CCR) trigger price) of $13.00 per short ton, or $14.33 per metric tonne.

- **Illinois Climate and Equitable Jobs Act (CEJA).** On September 16, 2021, the Climate and Equitable

139 See 40 CFR § 63.6640(f).

145 Executive Order–2019-07. Commonwealth Leadership in Addressing Climate Change through Electric Sector Emissions Reductions, Tom Wolf, Governor, October 3, 2019, <https://www.governor.pa.gov/newsroom/executive-order-2019-07-commonwealth-leadership-in-addressing-climate-change-through-electric-sector-emissions-reductions/>.

Jobs Act (CEJA) became effective. CEJA created an expanded nuclear subsidy program. CEJA mandates that all fossil fuel plants close by 2045. CEJA established emissions caps for investor owned, gas-fired units with three years of operating history, effective October 1, 2021, on a rolling 12 month basis going forward. More than 10,000 MW of capacity are currently affected.

- **Carbon Price.** If the price of carbon were $50.00 per metric tonne, short run marginal costs would increase by $24.52 per MWh or 65.0 percent for a new combustion turbine (CT) unit, $16.71 per MWh or 65.5 percent for a new combined cycle (CC) unit and $43.15 per MWh or 119.8 percent for a new coal plant (CP) for 2021.

State Renewable Portfolio Standards

- **RPS.** In PJM, ten of 14 jurisdictions have enacted legislation requiring that a defined percentage of retail suppliers' load be served by renewable resources, for which definitions vary. These are typically known as renewable portfolio standards, or RPS. As of December 31, 2021, Delaware, Illinois, Maryland, Michigan, New Jersey, North Carolina, Ohio, Pennsylvania, Virginia and Washington, DC have renewable portfolio standards. Virginia had a voluntary RPS in 2020, but a new mandatory RPS became effective on January 1, 2021. Indiana has voluntary renewable portfolio standards. Kentucky, Tennessee and West Virginia do not have renewable portfolio standards.
- **RPS Cost.** The cost of complying with RPS, as reported by the states, is $5.6 billion over the six year period from 2014 through 2019, an average annual RPS compliance cost of $936.7 million. The compliance cost for 2019, the most recent year with almost complete data, was $1.2 billion.[146]

Emissions Controls in PJM Markets

- **Regulations.** Environmental regulations affect decisions about emission control investments in existing units, investment in new units and decisions to retire units. As a result of environmental regulations and agreements to limit emissions, many PJM units burning fossil fuels have installed emission control technology.
- **Emissions Controls.** In PJM, as of December 31, 2021, 93.5 percent of coal steam MW had some type of flue-gas desulfurization (FGD) technology to reduce SO_2 emissions, while 99.8 percent of coal steam MW had some type of particulate control, and 94.6 percent of fossil fuel fired capacity had NO_X emission control technology. All coal steam units in PJM are compliant with the state and federal emissions limits established by MATS.

Renewable Generation

- **Renewable Generation.** Wind and solar generation was 4.2 percent of total generation in PJM in 2021. RPS Tier I generation was 5.7 percent of total generation in PJM and RPS Tier II generation was 2.2 percent of total generation in PJM in 2021. Only Tier I generation is defined to be renewable but Tier 1 includes some carbon emitting generation.

Section 8 Recommendations

- The MMU recommends that renewable energy credit markets based on state renewable portfolio standards be brought into PJM markets as they are an increasingly important component of the wholesale energy market. The MMU recommends that there be a single PJM operated forward market for RECs, for a single product based on a common set of state definitions of renewable technologies, with a single clearing price, trued up to real time delivery. (Priority: High. First reported 2010. Status: Not adopted.)
- The MMU recommends that PJM provide a full analysis of the impact of carbon pricing on PJM generating units and carbon pricing revenues to the PJM states in order to permit the states to consider a potential agreement on the development of a multistate framework for carbon pricing and the distribution of carbon revenues. (Priority: High. First reported 2018. Status: Not adopted.)
- The MMU recommends that jurisdictions with a renewable portfolio standard make the price and quantity data on supply and demand more transparent. (Priority: Low. First reported 2018. Status: Not adopted.)

146 The 2019 compliance cost value for PJM states does not include Illinois, Michigan or North Carolina. Based on past data these states generally account for 3.0 percent of the total RPS compliance cost of PJM states.

- The MMU recommends that the Commission reconsider its disclaimer of jurisdiction over RECs markets because, given market changes since that decision, it is clear that RECs materially affect jurisdictional rates. (Priority: Low. First reported 2018. Status: Not adopted.)
- The MMU recommends that load and generation located at separate nodes be treated as separate resources in order to ensure that load and generation face consistent incentives throughout the markets. (Priority: High. First reported 2019. Status: Not adopted.)
- The MMU recommends that emergency stationary RICE be prohibited from participation as DR either when registered individually or as part of a portfolio if it cannot meet the capacity market requirements to be DR as a result of emissions standards that impose environmental run hour limitations. (Priority: Medium. First reported 2019. Status: Not adopted.)

Section 8 Conclusion

Environmental requirements and renewable energy mandates at both the federal and state levels have a significant impact on the cost of energy and capacity in PJM markets.

Environmental requirements and initiatives at both the federal and state levels, and state renewable energy mandates and associated incentives have resulted in the construction of substantial amounts of renewable capacity in the PJM footprint, especially wind and solar resources and the retirement of emitting resources. Renewable energy credit (REC) markets created by state programs, and federal tax credits have significant impacts on PJM wholesale markets. But state renewables programs in PJM are not coordinated with one another, are generally not consistent with the PJM market design or PJM prices, have widely differing objectives, including supporting some emitting resources, have widely differing implied prices of carbon and are not transparent on pricing and quantities. The effectiveness of state renewables programs would be enhanced if they were coordinated with one another and with PJM markets, and if they increased transparency. States could evaluate the impacts of a range of carbon prices if PJM would provide a full analysis of the impact of carbon pricing on PJM generating units and carbon pricing revenues to the PJM states in order to permit the states to consider a potential agreement on the development of a multistate framework for carbon pricing and the distribution of carbon revenues. A single carbon price across PJM, established by the states, would be the most efficient way to reduce carbon output, if that is the goal.

But in the absence of a PJM market carbon price, a single PJM market for RECs would contribute significantly to market efficiency and to the procurement of renewable resources in a least cost manner. Ideally, there would be a single PJM operated forward market for RECs, for a single product based on a common set of state definitions of renewable technologies, with a single clearing price, trued up to real-time delivery. States would continue to have the option to create separate RECs for additional products that did not fit the product definition, e.g. waste coal, trash incinerators, or black liquor.

RECs are an important mechanism used by PJM states to implement environmental policy. RECs clearly affect prices in the PJM wholesale power market. Some resources are not economic except for the ability to purchase or sell RECs. RECs provide out of market payments to qualifying renewable resources, primarily wind and solar. The credits provide an incentive to make negative energy offers and more generally provide an incentive to enter the market, to remain in the market and to operate whenever possible. These subsidies affect the offer behavior and the operational behavior of these resources in PJM markets and in some cases the existence of these resources and thus the market prices and the mix of clearing resources.

RECs markets are, as an economic fact, integrated with PJM markets including energy and capacity markets, but are not formally recognized as part of PJM markets. It would be preferable to have a single, transparent market for RECs operated by the PJM RTO on behalf of the states that would meet the standards and requirements of all states in the PJM footprint. This would provide better information for market participants about supply and demand and prices and contribute to a more efficient and competitive market and to better price formation. This could also facilitate entry by qualifying renewable resources by reducing the risks associated with lack of transparent market data.

Existing REC markets are not consistently or adequately transparent. Data on REC prices, clearing quantities and markets are not publicly available for all PJM states. The economic logic of RPS programs and the associated REC and SREC prices is not always clear. The price of carbon implied by REC prices ranges from $11.33 per tonne in Washington, DC to $20.48 per tonne in Maryland. The price of carbon implied by SREC prices ranges from $69.30 per tonne in Pennsylvania to $867.85 per tonne in Washington, DC. The effective prices for carbon compare to the RGGI clearing price in December 2021 of $14.33 per tonne and to the social cost of carbon which is estimated in the range of $50 per tonne.[147] The impact on the cost of generation from a new combined cycle unit of a $50 per tonne carbon price would be $16.71 per MWh.[148] The impact of an $800 per tonne carbon price would be $267.30 per MWh. This wide range of implied carbon prices is not consistent with an efficient, competitive, least cost approach to the reduction of carbon emissions.

In addition, even the explicit environmental goals of RPS programs are not clear. While RPS is frequently considered to target carbon emissions, Tier 1 resources include some carbon emitting generation and Tier 2 resources include additional carbon emitting generation.

PJM markets provide a flexible mechanism for incorporating the costs of environmental controls and meeting environmental requirements in a cost effective manner. Costs for environmental controls are part of offers for capacity resources in the PJM Capacity Market. The costs of emissions credits are included in energy offers. PJM markets also provide a flexible mechanism that incorporates renewable resources and the impacts of renewable energy credit markets, and ensures that renewable resources have access to a broad market. PJM markets provide efficient price signals that permit valuation of resources with very different characteristics when they provide the same product.

If the states chose this policy option, PJM markets could also provide a flexible mechanism to limit carbon output, for example by incorporating a consistent carbon price in unit offers which would be reflected in PJM's economic dispatch. If there is a social decision to limit carbon output, a consistent carbon price would be the most efficient way to implement that decision. The states in PJM could agree, if they decided it was in their interests, with the appropriate information, on a carbon price and on how to allocate the revenues from a carbon price that would make all states better off. A mechanism like RGGI leaves all decision making with the states. The carbon price would not be FERC jurisdictional or subject to PJM decisions. The MMU continues to recommend that PJM provide a full analysis of the impact of carbon pricing on PJM generating units and carbon pricing revenues to the PJM states in order to permit the states to consider a potential agreement on the development of a multistate framework for carbon pricing and the distribution of carbon revenues. The results of the analysis would include the impact on the dispatch of every unit, the impact on energy prices and the carbon pricing revenues that would flow to each state.

For example, states receiving high levels of revenue could shift revenue to states disproportionately hurt by a carbon price if they believed that all states would be better off as a result. A carbon price would also be an alternative to specific subsidies to individual nuclear power plants and to the current wide range of implied carbon prices embedded in RPS programs and instead provide a market signal to which any resource could respond. The imposition of specific and prescriptive environmental dispatch rules would, in contrast, pose a threat to economic dispatch and efficient markets and create very difficult market power monitoring and mitigation issues. The provision of subsidies to individual units creates a discriminatory regime that is not consistent with competition. The use of inconsistent implied carbon prices by state is also inconsistent with an efficient market and inconsistent with the least cost approach to meeting state environmental goals.

The annual average cost of complying with RPS over the six year period from 2014 through 2019 for the nine jurisdictions that had RPS was $936.7 million, or a total of $5.6 billion over six years. The RPS compliance cost for 2019, the most recent year for which there is almost

147 "Technical Update of the Social Cost of Carbon for Regulatory Impact Analysis – Under Executive Order 12899," Interagency Working Group on the Social Cost of Greenhouse Gases, United States Government, (Aug. 2016), <https://19january2017snapshot.epa.gov/sites/production/files/2016-12/documents/sc_co2_tsd_august_2016.pdf>.

148 The cost impact calculation assumes a heat rate of 6.296 MMBtu per MWh and a carbon emissions rate of 0.053070 tonne per MMBtu. The $800 per tonne carbon price represents the approximate upper end of the carbon prices implied by the 2019 REC and SREC prices in the PJM jurisdictions with RPS. Additional cost impacts are provided in Table 8-7.

complete data, was $1.2 billion.[149] RPS costs are payments by customers to the sellers of qualifying resources. The revenues from carbon pricing flow to the states.

If all the PJM states participated in a regional carbon market, the estimated revenue returned to the states/customers from selling carbon allowances would be approximately $3.7 billion per year if the carbon price were $13.00 per short ton and emissions levels were five percent below 2021 emission levels. If all the PJM states participated in a regional carbon market, the estimated revenue returned to the states/customers from selling carbon allowances would be approximately $14.1 billion if the carbon price were $50 per short ton and emission levels were five percent below 2021 levels. If only the current RPS states participated in a regional carbon market, the estimated revenue returned to the states/customers from selling carbon allowances at $13.00 per short ton would be about $2.4 billion. The costs of a carbon price are the impact on energy market prices, net of the revenue returned to states/customers.

Overview: Section 9, Interchange Transactions

Interchange Transaction Activity

- **Aggregate Imports and Exports in the Real-Time Energy Market.** In 2021, PJM was a monthly net exporter of energy in the real-time energy market in all months.[150] In 2021, the real-time net interchange was -37,766.5 GWh. The real-time net interchange in 2020 was -41,630.2 GWh.
- **Aggregate Imports and Exports in the Day-Ahead Energy Market.** In 2021, PJM was a monthly net exporter of energy in the day-ahead energy market in all months. In 2021, the total day-ahead net interchange was -25,538.8 GWh. The day-ahead net interchange in 2020 was -15,414.6 GWh.
- **Aggregate Imports and Exports in the Day-Ahead and the Real-Time Energy Market.** In 2021, gross imports in the day-ahead energy market were 99.8 percent of gross imports in the real-time energy market (538.7 percent in 2020). In 2021, gross exports in the day-ahead energy market were 73.0 percent of the gross exports in the real-time energy market (104.4 percent in 2020).
- **Interface Imports and Exports in the Real-Time Energy Market.** In 2021, there were net scheduled exports at 14 of PJM's 19 interfaces in the real-time energy market.
- **Interface Pricing Point Imports and Exports in the Real-Time Energy Market.** In 2021, there were net scheduled exports at six of PJM's nine interface pricing points eligible for real-time transactions in the real-time energy market.[151]
- **Interface Imports and Exports in the Day-Ahead Energy Market.** In 2021, there were net scheduled exports at 15 of PJM's 19 interfaces in the day-ahead energy market.
- **Interface Pricing Point Imports and Exports in the Day-Ahead Energy Market.** In 2021, there were net scheduled exports at seven of PJM's nine interface pricing points eligible for day-ahead transactions in the day-ahead energy market.[152]
- **Up To Congestion Interface Pricing Point Imports and Exports in the Day-Ahead Energy Market.** In 2021, up to congestion transactions were net exports at three of PJM's nine interface pricing points eligible for day-ahead transactions in the day-ahead energy market.[153]
- **Inadvertent Interchange.** In 2021, net scheduled interchange was -37,767 GWh and net actual interchange was -37,813 GWh, a difference of 47 GWh. In 2020, the difference was 86 GWh. This difference is inadvertent interchange.
- **Loop Flows.** In 2021, the Northern Indiana Public Service (NIPS) Interface had the largest loop flows of any interface with -1,637 GWh of net scheduled interchange and -10,972 GWh of net actual interchange, a difference of 9,336 GWh. In 2021, the SouthIMP interface pricing point had the largest loop flows of any interface pricing point with 1,769 GWh of net scheduled interchange and 10,298 GWh of net actual interchange, a difference of 8,529 GWh.

149 The 2019 compliance cost value for PJM states does not include Illinois, Michigan or North Carolina. Based on past data these states generally account for 3.0 percent of the total RPS compliance cost of PJM states.

150 Calculated values shown in Section 9, "Interchange Transactions," are based on unrounded, underlying data and may differ from calculations based on the rounded values in the tables.

151 On June 1, 2021, PJM consolidated the SouthIMP and SouthEXP interface pricing points to one new SOUTH interface pricing point. This reduces the number of real-time interface pricing points to eight.

152 On April 15, 2021, PJM retired the Southeast interface pricing point from the day-ahead market. The Southeast interface pricing point can still be assigned to transactions under the VACAR reserve sharing agreement in the Real-Time Market. On June 1, 2021, PJM consolidated the SouthIMP and SouthEXP interface pricing points to one new SOUTH interface pricing point. This reduces the number of day-ahead interface pricing points to seven.

153 Id.

Interactions with Bordering Areas

PJM Interface Pricing with Organized Markets

- **PJM and MISO Interface Prices.** In 2021, the direction of the hourly flow was consistent with the real-time hourly price differences between the PJM/MISO Interface and the MISO/PJM Interface in 59.9 percent of the hours.
- **PJM and New York ISO Interface Prices.** In 2021, the direction of the hourly flow was consistent with the real-time hourly price differences between the PJM/NYIS Interface and the NYISO/PJM proxy bus in 56.6 percent of the hours.
- **Neptune Underwater Transmission Line to Long Island, New York.** In 2021, the hourly flow (PJM to NYISO) was consistent with the real-time hourly price differences between the PJM Neptune Interface and the NYISO Neptune bus in 74.8 percent of the hours.
- **Linden Variable Frequency Transformer (VFT) Facility.** In 2021, the hourly flow (PJM to NYISO) was consistent with the real-time hourly price differences between the PJM Linden Interface and the NYISO Linden bus in 76.8 percent of the hours.
- **Hudson DC Line.** In 2021, the hourly flow (PJM to NYISO) was consistent with the real-time hourly price differences between the PJM Hudson Interface and the NYISO Hudson bus in 69.9 percent of the hours.

Interchange Transaction Issues

- **PJM Transmission Loading Relief Procedures (TLRs).** PJM issued two TLRs of level 3a or higher in 2021, and two such TLRs in 2020.
- **Up To Congestion.** The average number of up to congestion bids submitted in the day-ahead energy market decreased by 46.6 percent, from 48,618 bids per day in 2020 to 25,965 bids per day in 2021. The average cleared volume of up to congestion bids submitted in the day-ahead energy market decreased by 61.4 percent, from 438,170 MWh per day in 2020, to 169,201 MWh per day in 2021.

Section 9 Recommendations

- The MMU recommends that PJM implement rules to prevent sham scheduling. The MMU recommends that PJM apply after the fact market settlement adjustments to identified sham scheduling segments to ensure that market participants cannot benefit from sham scheduling. (Priority: High. First reported 2012. Status: Not adopted.)
- The MMU recommends that PJM implement a validation method for submitted transactions that would prohibit market participants from breaking transactions into smaller segments to defeat the interface pricing rule by concealing the true source or sink of the transaction. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM implement a validation method for submitted transactions that would require market participants to submit transactions on paths that reflect the expected actual power flow in order to reduce unscheduled loop flows. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM end the practice of maintaining outdated definitions of interface pricing points, eliminate the NIPSCO, Southeast and Southwest interface pricing points from the day-ahead and real-time energy markets and, with VACAR, assign the transactions created under the reserve sharing agreement to the SOUTH interface pricing point. (Priority: High. First reported 2013. Status: Partially adopted, Q2 2020.)[154]
- The MMU recommends that transactions sourcing in the Western Interconnection be priced at either the MISO interface pricing point or the SOUTH interface pricing point based on the locational price impact of flows between the DC tie line point of connection with the Eastern Interconnection and PJM. (Priority: High. First reported Q1, 2020. Status: Not adopted.)
- The MMU recommends that PJM eliminate the IMO interface pricing point, and assign the transactions that originate or sink in the IESO balancing authority to the MISO interface pricing point.

154 The grandfathered agreements associated with the Southwest interface pricing point expired in 2012. The Southwest interface pricing point is no longer an eligible pricing point in the day-ahead or real-time energy markets. Effective June 1, 2020, PJM retired the NIPSCO interface pricing point.

(Priority: Medium. First reported 2013. Status: Not adopted.)

- The MMU recommends that PJM monitor, and adjust as necessary, the weights applied to the components of the interfaces to ensure that the interface prices reflect ongoing changes in system conditions. The MMU also recommends that PJM review the mappings of external balancing authorities to individual interface pricing points to reflect changes to the impact of the external power source on PJM tie lines as a result of system topology changes. The MMU recommends that this review occur at least annually. (Priority: Low. First reported 2009. Status: Not adopted.)
- The MMU recommends that, in order to permit a complete analysis of loop flow, FERC and NERC ensure that the identified data are made available to market monitors as well as other industry entities determined appropriate by FERC. (Priority: Medium. First reported 2003. Status: Not adopted.)
- The MMU recommends that PJM explore an interchange optimization solution with its neighboring balancing authorities that would remove the need for market participants to schedule physical transactions across seams. Such a solution would include an optimized, but limited, joint dispatch approach that uses supply curves and treats seams between balancing authorities as constraints, similar to other constraints within an LMP market. (Priority: Medium. First reported 2014. Status: Not adopted.)
- The MMU recommends that PJM permit unlimited spot market imports as well as unlimited nonfirm point to point willing to pay congestion imports and exports at all PJM interfaces in order to improve the efficiency of the market. (Priority: Medium. First reported 2012. Status: Not adopted.)
- The MMU recommends that the emergency interchange cap be replaced with a market based solution. (Priority: Low. First reported 2015. Status: Not adopted.)
- The MMU recommends that the submission deadline for real-time dispatchable transactions be modified from 1800 on the day prior, to three hours prior to the requested start time, and that the minimum duration be modified from one hour to 15 minutes. These changes would give PJM a more flexible product that could be used to meet load in the most economic manner. (Priority: Medium. First reported 2014. Status: Partially adopted, 2015.)
- The MMU recommends modifications to the FFE calculation to ensure that FFE calculations reflect the current capability of the transmission system as it evolves. The MMU recommends that the Commission set a deadline for PJM and MISO to resolve the FFE freeze date and related issues. (Priority: Medium. First reported 2019. Status: Not adopted.)

Section 9 Conclusion

Transactions between PJM and multiple balancing authorities in the Eastern Interconnection are part of a single energy market. While some of these balancing authorities are termed market areas and some are termed nonmarket areas, all electricity transactions are part of a single energy market. Nonetheless, there are significant differences between market and nonmarket areas. Market areas, like PJM, include essential features of an energy market including locational marginal pricing, financial congestion offsets (FTRs and ARRs in PJM) and transparent, least cost, security constrained economic dispatch for all available generation. Nonmarket areas do not include these features. Pricing in the market areas is transparent and pricing in the nonmarket areas is not transparent.

The MMU's recommendations related to transactions with external balancing authorities all share the goal of improving the economic efficiency of interchange transactions. The standard of comparison is an LMP market. In an LMP market, redispatch based on LMP and competitive generator offers results in an efficient dispatch and efficient prices. The goal of designing interface transaction rules should be to match the outcomes that would exist in an LMP market across the interfaces.

It is not appropriate to have special pricing agreements between PJM and any external entity. The same market pricing should apply to all transactions. External entities wishing to receive the benefits of the PJM LMP market should join PJM.

In 2020, PJM terminated a number of interface pricing points, consistent with longstanding MMU recommendations. Following the termination of the Northwest pricing point on October 1, 2020, PJM failed to correctly map the pricing points to transactions that had been mapped to the Northwest pricing point to pricing points that are consistent with electrical impacts on the PJM system. The MMU recommends that transactions sourcing in the Western Interconnection be priced at either the MISO interface pricing point or the SOUTH interface pricing point based on the electrical impact of flows between the DC tie line point of connection with the Eastern Interconnection and PJM. The MMU continues to recommend the termination of the Southeast interface pricing point and the Ontario interface pricing point. The Southeast pricing point is inappropriately used to support a special agreement and the Ontario interface pricing point is noncontiguous to the PJM footprint that creates opportunities for market participants to engage in sham scheduling activities.

Overview: Section 10, Ancillary Services

Primary Reserve

PJM's primary reserves are made up of resources, both synchronized and nonsynchronized, that can provide energy within 10 minutes. Primary reserve is PJM's implementation of the NERC 15-minute contingency reserve requirement.[155]

PJM determines the primary reserve requirement based on the most severe single contingency plus 190 MW in every approved RT SCED case. Every real-time market solution calculates the available tier 1 synchronized reserve. The required synchronized reserve and nonsynchronized reserve are calculated and dispatched in every real-time market solution, and there are associated clearing prices (SRMCP and NSRMCP) assigned every five minutes. Scheduled resources are credited based on a dispatched assignment and a five minute clearing price.

Market Structure

- **Supply.** Primary reserve is satisfied by both synchronized reserve (generation or demand response currently synchronized to the grid and available within 10 minutes), and nonsynchronized reserve (generation currently off line but available to start and provide energy within 10 minutes).
- **Demand.** The PJM primary reserve requirement is 150 percent of the most severe single contingency plus 190 MW. In 2021, the average primary reserve requirement was 2,449.6 MW in the RTO Zone and 2,436.4 in the MAD Subzone.

Tier 1 Synchronized Reserve

Synchronized reserve is provided by generators and demand response resources synchronized to the grid and capable of increasing output or decreasing load within 10 minutes in response to a PJM declared synchronized reserve event. Synchronized reserve consists of tier 1 and tier 2 synchronized reserves.

Tier 1 synchronized reserve is the capability of online resources following economic dispatch to ramp up in 10 minutes from their current output in response to a synchronized reserve event. There is no formal market for tier 1 synchronized reserve.

- **Supply.** No offers are made for tier 1 synchronized reserves. The market solution estimates tier 1 synchronized reserve as available 10 minute ramp from the energy dispatch. In 2021, there was an average hourly supply of 1,563.7 MW of tier 1 available in the RTO Zone and an average hourly supply of 788.2 MW of tier 1 synchronized reserve available within the MAD Subzone.
- **Demand.** The synchronized reserve requirement is calculated for each real-time dispatch solution as the most severe single contingency plus 190 MW within both the RTO Zone and the MAD Subzone.
- **Tier 1 Synchronized Reserve Event Response.** Tier 1 synchronized reserve is paid when a synchronized reserve event occurs and it responds. When a synchronized reserve event is called, all tier 1 response is paid for increasing its output (or reducing load for demand response) at the rate of $50 per MWh in addition to LMP.[156] This is the Synchronized Energy Premium Price.
- **Issues.** The competitive offer for tier 1 synchronized reserves is zero, as there is no incremental cost associated with the ability to ramp up from

155 See PJM. "Manual 10: Pre-Scheduling Operations," § 3.1.1 Day-ahead Scheduling (Operating Reserve, Rev. 40 (Dec. 15, 2021).

156 See PJM. "Manual 11: Energy & Ancillary Services Market Operations,"§ 4.2.10 Settlements, Rev. 117 (Nov. 1, 2021).

the current economic dispatch point and the appropriate payment for responding to an event is the synchronized energy premium price of $50 per MWh. The tariff requires payment of the tier 2 synchronized reserve market clearing price to tier 1 resources whenever the nonsynchronized reserve market clearing price rises above zero. This requirement is unnecessary and inconsistent with efficient markets. This rule has a significant impact on the cost of tier 1 synchronized reserves, resulting in a windfall payment of $89,719,045 to tier 1 resources in 2014, $34,397,441 in 2015, $4,948,084 in 2016, $2,197,514 in 2017, $4,732,025 in 2018, $3,217,178 in 2019, $3,320,726 in 2020, and $7,354,224 in 2021. The nonsynchronized reserve market clearing price was above $0 in 2,015 intervals (1.9 percent of intervals) in 2020, none of which were during a spinning event. In 2021, the nonsynchronized reserve market clearing price was above $0 in 2.9 percent of all intervals resulting in a net payment of $7,364,936.

Tier 2 Synchronized Reserve Market

Tier 2 synchronized reserve is part of primary reserve and is comprised of resources that are synchronized to the grid, that may incur costs to be synchronized, and that have an obligation to respond to PJM declared synchronized reserve events. Tier 2 synchronized reserve is penalized for failure to respond to a PJM declared synchronized reserve event. In PJM the required amount of synchronized reserve is defined to be no less than the largest single contingency, and 10 minute primary reserve as no less than 150 percent of the largest single contingency, plus 190 MW. This is stricter than the NERC standard of the greater of 80 percent of the largest single contingency or 900 MW.[157]

When the synchronized reserve requirement cannot be met with tier 1 synchronized reserve, PJM uses the tier 2 synchronized reserve market to satisfy the balance of the requirement. The tier 2 synchronized reserve market includes the PJM RTO Reserve Zone and a subzone, the Mid-Atlantic Dominion Reserve Subzone (MAD).

Market Structure

- **Supply.** In 2021, the supply of daily offered and eligible tier 2 synchronized reserve was 36,355.7 MW in the RTO Zone of which 4,606.9 MW was located in the MAD Subzone.
- **Demand.** The average hourly synchronized reserve requirement was 1,697.1 MW in the RTO Reserve Zone and 1,696.5 in the Mid-Atlantic Dominion Reserve Subzone. The hourly average cleared tier 2 synchronized reserve was 274.1 MW in the MAD Subzone and 720.5 MW in the RTO.
- **Market Concentration.** Both the Mid-Atlantic Dominion Subzone Tier 2 Synchronized Reserve Market and the RTO Synchronized Reserve Zone Market were characterized by structural market power in 2021.

  The average HHI for tier 2 synchronized reserve in the RTO Zone was 3460 which is classified as highly concentrated.

Market Conduct

- **Offers.** There is a must offer requirement for tier 2 synchronized reserve. All nonemergency generation capacity resources are required to submit a daily offer for tier 2 synchronized reserve, unless the unit type is exempt. Tier 2 synchronized reserve offers from generating units are subject to an offer cap of marginal cost plus $7.50 per MW, plus opportunity cost which is calculated by PJM. PJM automatically enters an offer of $0 for tier 2 synchronized reserve when an offer is not entered by the owner. Demand resources offering into the tier 2 market are also subject to an offer cap of $7.50 plus costs. Cost may include shutdown costs for demand response.[158]

Market Performance

- **Price.** The weighted average price for tier 2 synchronized reserve for all cleared hours in the MAD subzone was $7.32 per MW in 2021. The weighted average price for tier 2 synchronized reserve for all cleared intervals in the RTO Synchronized Reserve Zone was $8.87 per MW in 2021.

157 NERC (June 2, 2020) <NERC Reliability Standard BAL 002-2 Glossary_of_Terms.pdf>.

158 Ref. PJM. "Manual 11: Energy & Ancillary Services Market Operations," Rev. 117 (Nov. 1, 2021), para. 4.2.1, p. 92

Nonsynchronized Reserve Market

Nonsynchronized reserve is part of primary reserve and includes the RTO Reserve Zone and the Mid-Atlantic Dominion Reserve Subzone (MAD). Nonsynchronized reserve is comprised of nonemergency energy resources not currently synchronized to the grid that can provide energy within 10 minutes. Nonsynchronized reserve is available to fill the primary reserve requirement above the synchronized reserve requirement. Generation owners do not submit supply offers for nonsynchronized reserve. PJM defines the demand curve for nonsynchronized reserve and PJM defines the supply curve based on nonemergency generation resources that are available to provide energy and can start in 10 minutes or less (based on offer parameters), and on the resource opportunity costs calculated by PJM.

Market Structure

- **Supply.** In 2021, the average supply of eligible and available nonsynchronized reserve was 1,414.6 MW in the RTO Zone.
- **Demand.** Demand for nonsynchronized reserve equals the primary reserve requirement minus the tier 1 synchronized reserve estimate and minus the scheduled tier 2 synchronized reserve.[159]
- **Market Concentration.** The MMU calculates that the three pivotal supplier test would have been failed in 99.96 percent of intervals where the price was above $0.01 in 2021.

Market Conduct

- **Offers.** Generation owners do not submit supply offers. Nonemergency generation resources that are available to provide energy and can start in 10 minutes or less are considered available for nonsynchronized reserves by the market solution software. PJM calculates the associated offer prices based on PJM calculations of resource specific opportunity costs.

Market Performance

- **Price.** The nonsynchronized reserve price is determined by the opportunity cost of the marginal nonsynchronized reserve unit. The nonsynchronized reserve weighted average price for all intervals in the RTO Reserve Zone was $0.31 per MW in 2021.

Secondary Reserve (DASR)

There is no NERC standard for secondary reserve. PJM defines secondary reserve in the day-ahead market as reserves (online or offline available for dispatch) that can be converted to energy in 30 minutes. PJM defines a secondary reserve requirement but is not required to maintain this level of secondary reserve in real time.

PJM maintains a day-ahead, offer-based market for 30 minute day-ahead secondary reserve. The PJM Day-Ahead Scheduling Reserve Market (DASR) has no performance obligations except that a unit which clears the DASR market may not be on an outage in real time.[160] If DASR units are on an outage in real time or cleared DASR MW are not available, the DASR payment is not made.

Market Structure

- **Supply.** The DASR market is a must offer market. Any resources that do not make an offer have their offer set to $0.00 per MW. DASR is calculated by the day-ahead market solution as the lesser of the 30 minute energy ramp rate or the economic maximum MW minus the day-ahead dispatch point for all resources that can provide energy within 30 minutes of a request from PJM Dispatch.
- **Demand.** The DASR requirement is the sum of the PJM requirement and the Dominion requirement based on the VACAR reserve sharing agreement. It is calculated every year for the period November 1 through October 31. For November 1, 2020, through October 31, 2021, the DASR requirement was 4.75 percent of peak load forecast. For November 1, 2021, through October 31, 2022, the DASR requirement is 4.40 percent of peak load forecast. The average hourly DASR MW purchased in 2021 was 4,389.5 MW, a reduction from the 4,611.6 hourly MW in 2020.

Market Conduct

- **Withholding.** Economic withholding remains an issue in the DASR Market. The direct marginal

159 See PJM. "Manual 11: Energy & Ancillary Services Market Operations," § 4b.2.2 Non-Synchronized Reserve Zones and Levels, Rev. 117 (Nov. 1, 2021). "Because Synchronized Reserve may be utilized to meet the Primary Reserve requirement, there is no explicit requirement for non-synchronized reserves. "

160 See PJM, "Manual 11: Energy & Ancillary Services Market Operations," § 11.2.7 Day-Ahead Scheduling Reserve Performance, Rev. 117 (Nov. 1, 2021).

cost of providing DASR is zero. PJM calculates the opportunity cost for each resource. All offers by resource owners greater than zero constitute economic withholding. In 2021, 45.3 percent of daily unit offers were above $0.00 and 17.8 percent of daily unit offers were above $5.

- **DR.** Demand resources are eligible to participate in the DASR Market. Some demand resources have entered offers for DASR. No demand resources cleared the DASR market in 2021.

Market Performance

- **Price.** In 2021, the MW weighted average DASR price for all hours when the DASRMCP was above $0.00 was $1.27. The MW weighted average for all hours including hours when the price was $0 was $0.24.

Regulation Market

The PJM Regulation Market is a real-time market. Regulation is provided by generation resources and demand response resources that qualify to follow one of two regulation signals, RegA or RegD. PJM jointly optimizes regulation with synchronized reserve and energy to provide all three products at least cost. The PJM regulation market design includes three clearing price components: capability; performance; and opportunity cost. The RegA signal is designed for energy unlimited resources with physically constrained ramp rates. The RegD signal is designed for energy limited resources with fast ramp rates. In the regulation market RegD MW are converted to effective MW using a marginal rate of technical substitution (MRTS), called a marginal benefit factor (MBF). Correctly implemented, the MBF would be the marginal rate of technical substitution (MRTS) between RegA and RegD, holding the level of regulation service constant. The current market design is critically flawed as it has not properly implemented the MBF as an MRTS between RegA and RegD resource MW and the MBF has not been consistently applied in the optimization, clearing and settlement of the regulation market.

Market Structure

- **Supply.** In 2021, the average hourly offered supply of regulation for nonramp hours was 740.8 performance adjusted MW (744.9 effective MW). This was an increase of 19.9 performance adjusted MW (an increase of 23.7 effective MW) from 2020. In 2021, the average hourly offered supply of regulation for ramp hours was 1,066.4 performance adjusted MW (1,094.9 effective MW). This was an increase of 49.0 performance adjusted MW (an increase of 36.0 effective MW) from 2020, when the average hourly offered supply of regulation was 1,017.4 performance adjusted MW (1,058.9 effective MW).

- **Demand.** The hourly regulation demand is 525.0 effective MW for nonramp hours and 800.0 effective MW for ramp hours.

- **Supply and Demand.** The nonramp regulation requirement of 525.0 effective MW was provided by a combination of RegA and RegD resources equal to 481.6 hourly average performance adjusted actual MW in 2021. This is an increase of 10.4 performance adjusted actual MW from 2020, when the average hourly total regulation cleared performance adjusted actual MW for nonramp hours were 492.0 performance adjusted actual MW. The ramp regulation requirement of 800.0 effective MW was provided by a combination of RegA and RegD resources equal to 707.3 hourly average performance adjusted actual MW in 2021. This is an increase of 4.9 performance adjusted actual MW from 2020, where the average hourly regulation cleared MW for ramp hours were 702.5 performance adjusted actual MW.

  The ratio of the average hourly offered supply of regulation to average hourly regulation demand (performance adjusted cleared MW) for ramp hours was 1.51 in 2021 (1.45 in 2020). The ratio of the average hourly offered supply of regulation to average hourly regulation demand (performance adjusted cleared MW) for nonramp hours was 1.54 in 2021 (1.47 in 2020).

- **Market Concentration.** In 2021, the three pivotal supplier test was failed in 85.9 percent of hours. In 2021, the actual MW weighted average HHI of RegA resources was 2215 which is highly concentrated and the weighted average HHI of RegD resources was 1585 which is moderately concentrated. The weighted average HHI of all resources was 1205, which is moderately concentrated.

Market Conduct

- **Offers.** Daily regulation offer prices are submitted for each unit by the unit owner. Owners are required to submit a cost-based offer and may submit a price-based offer. Offers include both a capability offer and a performance offer. Owners must specify which signal type the unit will be following, RegA or RegD.[161] In 2021, there were 237 resources following the RegA signal and 53 resources following the RegD signal.

Market Performance

- **Price and Cost.** The weighted average clearing price for regulation was $26.00 per MW of regulation in 2021, an increase of $12.45 per MW, or 91.9 percent, from the weighted average clearing price of $13.55 per MW in 2020. The weighted average cost of regulation in 2021 was $31.49 per MW of regulation, an increase of 88.2 percent, from the weighted average cost of $16.73 per MW in 2020.
- **Prices.** RegD resources continue to be incorrectly compensated relative to RegA resources due to an inconsistent application of the marginal benefit factor in the optimization, assignment and settlement processes. If the regulation market were functioning efficiently and competitively, RegD and RegA resources would be paid the same price per effective MW.
- **Marginal Benefit Factor.** The marginal benefit factor (MBF) is intended to measure the operational substitutability of RegD resources for RegA resources. The marginal benefit factor is incorrectly defined and applied in the PJM market clearing. The current incorrect and inconsistent implementation of the MBF has resulted in the PJM Regulation Market over procuring RegD relative to RegA in most hours and in an inefficient market signal about the value of RegD in every hour.

Black Start Service

Black start service is required for the reliable restoration of the grid following a blackout. Black start service is the ability of a generating unit to start without an outside electrical supply, or is the demonstrated ability of a generating unit to automatically remain operating at reduced levels when disconnected from the grid (automatic load rejection or ALR).[162]

In 2021, total black start charges were $68.0 million, including $67.6 million in revenue requirement charges and $0.3 million in uplift charges. Black start revenue requirements consist of fixed black start service costs, variable black start service costs, training costs, fuel storage costs, and an incentive payment. Black start uplift charges are paid to units scheduled in the day-ahead energy market or committed in real time to provide black start service under the ALR option or for black start testing. Black start zonal charges in 2021 ranged from $43,630 in the BGE Zone to $19,803,649 in the AEP Zone.

CRF values are a key determinant of total payments to black start units. The CRF values in PJM tariff tables should have been changed for both black start and the capacity market when the tax laws changed in December 2017. As a result, CRF values have overcompensated black start units since the changes to the tax code.

Reactive

Reactive service, reactive supply and voltage control are provided by generation and other sources of reactive power (measured in MVAr). Reactive power helps maintain appropriate voltage levels on the transmission system and is essential to the flow of real power (measured in MW). The same equipment provides both MVAr and MW. The current rules permit double recovery of some fixed costs.

Reactive capability charges are based on FERC approved filings that permit recovery based on an outdated cost of service approach.[163] All capacity costs of generators should be incorporated in the capacity market. The nonmarket cost of service approach to reactive capability payments should be eliminated. Reactive service charges are paid to units that operate in real time outside of their normal range at the direction of PJM for the purpose of providing reactive service. Total reactive charges increased 6.19 percent from $346.4 million in 2020 to $367.8 million in 2021. Reactive capability charges increased 6.06 percent from $346.0 million in 2020 to $367.0 million in 2021. Total reactive service charges

161 See the *2019 State of the Market Report for PJM*, Vol. II, Appendix F "Ancillary Services Markets."

162 OATT Schedule 1 § 1.3BB. There are no ALR units currently providing black start service.

163 OATT Schedule 2.

in 2021 ranged from $0 in the REC and OVEC Zones, to $49.2 million in the AEP Zone.

Frequency Response

On February 15, 2018, the Commission issued Order No. 842, which modified the pro forma large and small generator interconnection agreements and procedures to require newly interconnecting generating facilities, both synchronous and nonsynchronous, to include equipment for primary frequency response capability as a condition to receive interconnection service.[164] PJM filed revisions in compliance with Order No. 842 that incorporated the pro forma agreements into its market rules.[165]

The PJM Tariff requires that all new generator interconnection customers (Nuclear Regulatory Commission regulated facilities are exempt from this provision) have hardware and/or software that provides frequency responsive real power control with the ability to sense changes in system frequency and autonomously adjust real power output in a direction to correct for frequency deviations. This includes a governor or equivalent controls capable of operating with a maximum five percent droop and a +/- 0.036 deadband.[166] In addition to resource capability, resource owners must comply by setting control systems to autonomously adjust real power output in a direction to correct for frequency deviations.

The response of generators within PJM to NERC identified frequency events remains under evaluation. A frequency event is declared when the frequency goes outside 60 Hz +/- 40 mHz for 60 continuous seconds. The NERC BAL-003-2 requirement for balancing authorities (PJM is a balancing authority) uses a threshold value (L_{10}) equal to -259.3 MW/0.1 Hz and has selected twelve frequency events between December 1, 2020, and November 30, 2021, to evaluate.

As a balancing authority, PJM requires all generators to be capable of providing primary frequency response and to operate with primary frequency response controls enabled. PJM does monitor primary frequency response during NERC identified frequency events for all resources 50 MW or greater. Exclusions to PJM monitoring include nuclear plants, offline units, units with no available headroom, units assigned to regulation, and units with a current outage ticket in eDART.

Market Procurement of Real Time Ancillary Services

PJM uses market mechanisms to varying degrees in the procurement of ancillary services, including primary reserves and regulation. Ideally, all ancillary services would be procured taking full account of the interactions with the energy market. When a resource is used for an ancillary service instead of providing energy in real time, the cost of removing the resource, either fully or partially, from the energy market should be weighed against the benefit the ancillary service provides. The degree to which PJM markets account for these interactions depends on the timing of the product clearing and software limitations and the accuracy of unit parameters and offers.

The synchronized reserve market clearing is more integrated with the energy market clearing than the other ancillary services. Resources categorized as flexible tier 2 reserve, those that can provide reserves by backing down according to their ramp rate, are jointly cleared along with energy in every real-time market solution. Given the joint clearing of energy and flexible tier 2, the synchronized reserve market clearing price should always cover the opportunity cost of providing flexible tier 2. PJM should never need to pay uplift to flexible tier 2. The uplift paid to flexible tier 2 results from issues with the dispatch and pricing software timing. Inflexible tier 2 reserves, provided by resources that require longer notice to take actions to prepare for reserve deployment, are not cleared along with energy in the real-time market solution. Inflexible tier 2 reserves are cleared hourly by the Ancillary Service Optimizer (ASO). The ASO uses forward looking information about the energy market, flexible tier 2, tier 1, and regulation to estimate the costs and benefits of using a resource for inflexible tier 2 synchronized reserves.

Nonsynchronized reserves are cleared with every real-time energy market solution, but their costs are not fully known by the real-time energy market software (RT SCED) because the resources are offline. PJM uses an estimate of the cost of using a resource for nonsynchronized

164 See 157 FERC ¶ 61,122 (2016).
165 See 164 FERC ¶ 61,224 (2018).
166 OATT Attachment O § 4.7.2 (Primary Frequency Response).

reserve instead of energy from a previously solved IT SCED solution. IT SCED runs every 15 minutes looking ahead at target dispatch times up to two hours in the future. The energy commitment decisions for the offline resources have already been made when the RT SCED clears the nonsynchronized reserve market. RT SCED compares the IT SCED estimated cost of nonsynchronized reserve clearing to the RT SCED determined cost of synchronized reserve clearing in satisfying the primary reserve requirement. Nonsynchronized reserve clearing indirectly interacts with energy clearing through both products' substitutability with synchronized reserves.

Prices for the regulation and reserve markets are set by the pricing calculator (LPC), which is uses the RT SCED solution as an input. The RT SCED is partially, but not fully clearing the reserve market. The software determining the prices is not clearing the regulation market. With fast start pricing implementation on September 1, 2021, the pricing calculations in LPC are not the same prices that result from the market clearing in RT SCED.

Section 10 Recommendations

- The MMU recommends that all data necessary to perform the regulation market three pivotal supplier test be saved by PJM so that the test can be replicated. (Priority: Medium. First reported 2016. Status: Not adopted.)
- The MMU recommends that the total regulation (TReg) signal sent on a fleet wide basis be eliminated and replaced with individual regulation signals for each unit. (Priority: Low. First reported 2019. Status: Not adopted.)
- The MMU recommends that the ability to make dual offers (to make offers as both a RegA and a RegD resource in the same market hour) be removed from the regulation market. (Priority: High. First reported 2019. Status: Not adopted.)
- The MMU recommends that the regulation market be modified to incorporate a consistent application of the marginal benefit factor (MBF) throughout the optimization, assignment and settlement process. The MBF should be defined as the Marginal Rate of Technical Substitution (MRTS) between RegA and RegD. (Priority: High. First reported 2012. Status: Not adopted. FERC rejected.[167])
- The MMU recommends that the lost opportunity cost in the ancillary services markets be calculated using the schedule on which the unit was scheduled to run in the energy market. (Priority: High. First reported 2010. Status: Not adopted.[168] FERC rejected.[169])
- The MMU recommends that the lost opportunity cost calculation used in the regulation market be based on the resource's dispatched energy offer schedule, not the lower of its price or cost offer schedule. (Priority: Medium. First reported 2010. Status: Not adopted. FERC rejected.[170])
- The MMU recommends that, to prevent gaming, there be a penalty enforced in the regulation market as a reduction in performance score and/or a forfeiture of revenues when resource owners elect to deassign assigned regulation resources within the hour. (Priority: Medium. First reported 2016. Status: Not adopted. FERC rejected.[171])
- The MMU recommends enhanced documentation of the implementation of the regulation market design. (Priority: Medium. First reported 2010. Status: Not adopted. FERC rejected.[172])
- The MMU recommends that PJM be required to save data elements necessary for verifying the performance of the regulation market. (Priority: Medium. First reported 2010. Status: Not adopted.)
- The MMU recommends that the $12.00 margin adder be eliminated from the definition of the cost based regulation offer because it is a markup and not a cost. (Priority: Medium. First reported Q1, 2021. Status: Not adopted.)
- The MMU recommends that PJM replace the static MidAtlantic/Dominion Reserve Subzone with a reserve zone structure consistent with the actual deliverability of reserves based on current transmission constraints. (Priority: High. First reported 2019. Status: Not adopted.)

167 162 FERC ¶ 61,295 (2018), *reh'g denied*, 170 FERC ¶ 61,259 (2020).
168 This recommendation was adopted by PJM for the energy market. Lost opportunity costs in the energy market are calculated using the schedule on which the unit was scheduled to run. In the regulation market, this recommendation has not been adopted, as the LOC continues to be calculated based on the lower of price or cost in the energy market offer.
169 162 FERC ¶ 61,295 (2018), *reh'g denied*, 170 FERC ¶ 61,259 (2020).
170 *Id.*
171 *Id.*
172 *Id.*

- The MMU recommends that the $7.50 margin be eliminated from the definition of the cost of tier 2 synchronized reserve because it is a markup and not a cost. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that the variable operating and maintenance cost be eliminated from the definition of the cost of tier 2 synchronized reserve and that the calculation of synchronized reserve variable operations and maintenance costs be removed from Manual 15. (Priority: Medium. First reported 2019. Status: Not adopted.)
- The MMU recommends that the components of the cost-based offers for providing regulation and synchronous condensing be defined in Schedule 2 of the Operating Agreement. (Priority: Low. First reported 2019. Status: Not adopted.)
- The MMU recommends that the rule requiring that tier 1 synchronized reserve resources be paid the tier 2 price when the nonsynchronized reserve price is above zero be eliminated immediately and that, under the current rule, tier 1 synchronized reserve resources not be paid the tier 2 price when they do not respond. (Priority: High. First reported 2013. Status: Not adopted.)
- The MMU recommends that the tier 2 synchronized reserve must offer requirement be enforced on a daily and hourly basis. The MMU recommends that PJM define a set of acceptable reasons why a unit can be made unavailable daily or hourly and require unit owners to select a reason in Markets Gateway whenever making a unit unavailable either daily or hourly or setting the offer MW to 0 MW. (Priority: Medium. First reported 2013. Status: Partially adopted.)
- The MMU recommends that, for calculating the penalty for a tier 2 resource failing to meet its scheduled obligation during a spinning event, the penalty should be based on the actual time since the last spinning event of 10 minutes or longer during which the resource performed because performance is only measured for events 10 minutes or longer. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that aggregation not be permitted to offset unit specific penalties for failure to respond to a synchronized reserve event. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that PJM eliminate the use of Degree of Generator Performance (DGP) in the synchronized reserve market solution and improve the actual tier 1 estimate. If PJM continues to use DGP, DGP should be documented in PJM's manuals. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that the details of VACAR Reserve Sharing Agreement (VRSA) be made public, including any responsibilities assigned to PJM and including the amount of reserves that Dominion commits to meet its obligations under the VRSA. (Priority: Medium. First reported 2020. Status: Not adopted.)
- The MMU recommends that the VRSA be terminated and, if necessary, replaced by a reserve sharing agreement between PJM and VACAR South, similar to agreements between PJM and other bordering areas. (Priority: Medium. First reported 2020. Status: Not adopted.)
- The MMU recommends that a reason code be attached to every hour in which PJM market operations adds additional DASR MW. (Priority: Medium. First reported 2015. Status: Not adopted.)
- The MMU recommends that PJM modify the DASR market to ensure that all resources cleared incur a real-time performance obligation. (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends that, in order to mitigate market power, offers in the DASR market be based on opportunity cost only. (Priority: Low. First reported 2009. Modified, 2018. Status: Not adopted.)
- The MMU recommends that all resources, new and existing, have a requirement to include and maintain equipment for primary frequency response capability as a condition of interconnection service. The PJM capacity and energy markets already compensate resources for frequency response capability and any marginal costs. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that new CRF rates for black start units, incorporating current tax code changes, be implemented immediately. The new CRF rates should apply to all black start units. The black start

units should be required to commit to providing black start service for the life of the unit. (Priority: High. First reported 2020. Status: Not adopted.)

- The MMU recommends for oil tanks shared with other resources that only a proportionate share of the minimum tank suction level (MTSL) be allocated to black start service. The MMU further recommends that the PJM tariff be updated to clearly state how the MTSL will be calculated for black start units sharing oil tanks. (Priority: Medium. First reported 2017. Status: Adopted 2021.)
- The MMU recommends that separate cost of service payments for reactive capability be eliminated and the cost of reactive capability be recovered in the capacity market. (Priority: Medium. First reported 2016. Status: Not adopted.)
- The MMU recommends that payments for reactive capability, if continued, be based on the 0.90 power factor that PJM has determined is necessary. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that, if payments for reactive are continued, fleet wide cost of service rates used to compensate resources for reactive capability be eliminated and replaced with compensation based on unit specific costs. (Priority: Low. First reported 2019.[173] Status: Partially adopted.)
- The MMU recommends that Schedule 2 to OATT be revised to state explicitly that only generators that provide reactive capability to the transmission system that PJM operates and has responsibility for are eligible for reactive capability compensation. Specifically, such eligibility should be determined based on whether a generation facility's point of interconnection is on a transmission line that is a Monitored Transmission Facility as defined by PJM and is on a Reportable Transmission Facility as defined by PJM.[174] (Priority: Medium. First reported 2020. Status: Not adopted.)

Section 10 Conclusion

The design of the PJM Regulation Market is significantly flawed.[175] The market design does not correctly incorporate the marginal rate of technical substitution (MRTS) in market clearing and settlement. The market design uses the marginal benefit factor (MBF) to incorrectly represent the MRTS and uses a mileage ratio instead of the MBF in settlement. This failure to correctly and consistently incorporate the MRTS into the regulation market design has resulted in both underpayment and overpayment of RegD resources and in the over procurement of RegD resources in all hours. The market results continue to include the incorrect definition of opportunity cost. These issues are the basis for the MMU's conclusion that the regulation market design is flawed.

To address these flaws, the MMU and PJM developed a joint proposal which was approved by the PJM Members Committee on July 27, 2017, and filed with FERC on October 17, 2017.[176] The PJM/MMU joint proposal addresses issues with the inconsistent application of the marginal benefit factor throughout the optimization and settlement process in the PJM Regulation Market. FERC rejected the joint proposal on March 30, 2018, as being noncompliant with Order No. 755.[177] The MMU and PJM separately filed requests for rehearing, which were denied by order issued March 26, 2020.[178]

The structure of the tier 2 synchronized reserve market has been evaluated and the MMU has concluded that these markets are not structurally competitive as they are characterized by high levels of supplier concentration and inelastic demand. As a result, these markets are operated with market clearing prices and with offers based on the marginal cost of producing the product plus a margin. As a result of these requirements, the conduct of market participants within these market structures has been consistent with competition, and the market performance results have been competitive. However, the $7.50 margin is not a cost. The margin is effectively a rule-based form of economic withholding and is therefore not consistent with a competitive outcome. The $7.50 margin should be eliminated. The

173 The MMU has discussed this recommendation in state of the market reports since 2016 but Q3, 2019 was the first time it was reported as a formal MMU recommendation.

174 *See* PJM Transmission Facilities (note that this requires you first log into a PJM Tools account. If you do not, then the link sends you to an Access Request page, <https://pjm.com/markets-and-operations/ops-analysis/transmission-facilities>.

175 The current PJM regulation market design that incorporates two signals using two resource types was a result of FERC Order No. 755 and subsequent orders. Order No. 755, 137 FERC ¶ 61,064 at PP 197–200 (2011).

176 18 CFR § 385.211.

177 162 FERC ¶ 61,295 (2018).

178 170 FERC ¶ 61,259 (2020).

variable operating and maintenance component of the synchronized reserve offer should also be eliminated. All variable operating and maintenance costs are incurred to provide energy and to make units available to provide energy. There are no variable operating and maintenance costs associated with providing synchronized reserve. Reserve market design changes approved by FERC and scheduled for implementation in October 2022 will eliminate the $7.50 per MW margin and the variable operations and maintenance costs.[179]

Participant performance has not been adequate for tier 2 synchronized reserve. Compliance with calls to respond to actual synchronized reserve events remains significantly less than 100 percent. Actual participant performance means that the penalty structure is not an adequate incentive for performance. The October 2022 reserve market design changes do not respond to the MMU's recommendations to increase the penalties for nonperformance. All synchronized reserves should also have the same obligation to perform, but the proposed changes will mean that not all cleared reserves will be called on to perform during synchronized reserve events.[180]

The rule that requires payment of the tier 2 synchronized reserve price to tier 1 synchronized reserve resources when the nonsynchronized reserve price is greater than zero, is inefficient and results in a substantial windfall payment to the holders of tier 1 synchronized reserve resources. Tier 1 resources have no obligation to perform and pay no penalties if they do not perform, and tier 1 resources do not incur any costs when they are part of the tier 1 estimate in the market solution. Tier 1 resources are already paid for their response if they do respond to a synchronized reserve event. Tier 1 resources require no additional payment. If tier 1 resources wish to be paid as tier 2 resources, the rules provide the opportunity to make competitive offers in the tier 2 market and take on the associated obligations. Overpayment of tier 1 resources based on this rule has added more than $100 million to the cost of primary reserve since 2014. The reserve market design changes approved by FERC and scheduled for implementation in 2022 will consolidate Tier 1 and Tier 2 reserves into a single synchronized reserve product, with a stronger must offer requirement and a single clearing price.[181] This will eliminate the payment of Tier 1 based on the nonzero nonsynchronized reserve price.

The benefits of markets are realized under these approaches to ancillary service markets. Even in the presence of structurally noncompetitive markets, there can be transparent, market clearing prices based on competitive offers that account explicitly and accurately for opportunity cost. This is consistent with the market design goal of ensuring competitive outcomes that provide appropriate incentives without reliance on the exercise of market power and with explicit mechanisms to prevent the exercise of market power.

The MMU concludes that the regulation market results were not competitive, and the market design is significantly flawed. The MMU concludes that the synchronized reserve market results were competitive, although the $7.50 margin should be removed. The MMU concludes that the DASR market results were competitive, although offers above the competitive level continue to affect prices.

Overview: Section 11, Congestion and Marginal Losses

Congestion Cost

- **Total Congestion.** Total congestion costs increased by $466.6 million or 88.2 percent, from $528.7 million in 2020 to $995.3 million in 2021.
- **Day-Ahead Congestion.** Day-ahead congestion costs increased by $563.7 million or 85.1 percent, from $662.5 million in 2020 to $1,226.2 million in 2021.
- **Balancing Congestion.** Negative balancing congestion costs increased by $97.1 million, from -$133.8 million in 2020 to -$230.9 million in 2021. Negative balancing explicit charges increased by $23.1 million, from -$77.6 million in 2020 to -$100.7 million in 2021.
- **Real-Time Congestion.** Real-time congestion costs increased by $706.7 million, from $749.3 million in 2020 to $1,456.0 million in 2021.

179 See FERC Docket No. EL19-58.

180 See PJM, "Intelligent Reserve Deployment – PJM Package (SRDTF)," Presentation to the Members Committee (January 26, 2022), <https://pjm.com/-/media/committees-groups/committees/mc/2022/20220126/20220126-cac-1-synchronous-reserve-deployment-presentation.ashx>.

181 See FERC Docket No. EL19-58.

- **Monthly Congestion.** Monthly total congestion costs in 2021 ranged from $29.1 million in January to $175.3 million in November.
- **Geographic Differences in CLMP.** Differences in CLMP among eastern control zones in PJM were primarily a result of binding on the Three Mile Island Transformer, the Nottingham Series Reactor, the Cumberland - Juniata Line, the Conastone Transformer, and the Brighton Circuit Breaker.
- **Congestion Frequency.** Congestion frequency continued to be significantly higher in the day-ahead energy market than in the real-time energy market in 2021. The number of congestion event hours in the day-ahead energy market was about twice the number of congestion event hours in the real-time energy market.

  Day-ahead congestion frequency decreased by 27.9 percent from 78,239 congestion event hours in 2020 to 56,425 congestion event hours in 2021.

  Real-time congestion frequency increased by 4.9 percent from 21,984 congestion event hours in 2020 to 23,068 congestion event hours in 2021.
- **Congested Facilities.** The monthly average of daily day-ahead congestion event hours decreased in November 2020 as a result of decreased UTC activity due to a FERC order issued effective November 1, 2020, directing PJM to charge uplift to up to congestion transactions.[182] Day-ahead, congestion event hours decreased on all types of facilities except flowgates.

  The Three Mile Island Transformer was the largest contributor to congestion costs in 2021. With $88.2 million in total congestion costs, it accounted for 8.9 percent of the total PJM congestion costs in 2021.
- **CT Price Setting Logic and Closed Loop Interface Related Congestion.** PJM's use of CT pricing logic officially ended with the implementation of fast start pricing on September 1, 2021. CT Price Setting Logic caused -$0.3 million of day-ahead congestion in 2021 and -$6.0 million of balancing congestion in 2021. While CT pricing logic was officially discontinued by PJM on September 1, 2021, PJM continued to use a related logic to force inflexible units to be on the margin in both real time and day ahead. These results have been included in the CT Pricing Logic totals. None of the closed loop interfaces were binding in 2021 or 2020.
- **Zonal Congestion.** AEP had the highest zonal congestion costs among all control zones in 2021. AEP had $163.1 million in zonal congestion costs, comprised of $198.2 million in day-ahead congestion costs and -$35.1 million in balancing congestion costs.

Marginal Loss Cost

- **Total Marginal Loss Costs.** Total marginal loss costs increased by $476.3 million or 99.5 percent, from $478.5 million in 2020 to $954.8 million in 2021. The loss MWh in PJM increased by 953.8 GWh or 6.7 percent, from 14,317.2 GWh in 2020 to 15,271.0 GWh in 2021. The loss component of real-time LMP in 2021 was $0.02, compared to $0.01 in 2020.
- **Day-Ahead Marginal Loss Costs.** Day-ahead marginal loss costs increased by $461.6 million or 87.7 percent, from $526.3 million in 2020 to $987.9 million in 2021.
- **Balancing Marginal Loss Costs.** Negative balancing marginal loss costs decreased by $14.7 million or 30.7 percent, from -$47.7 million in 2020 to -$33.1 million in 2021.
- **Total Marginal Loss Surplus.** The total marginal loss surplus increased by $170.8 million or 107.1 percent, from $159.6 million in 2020, to $330.4 million in 2021.
- **Monthly Total Marginal Loss Costs.** Monthly total marginal loss costs in 2021 ranged from $42.5 million in April to $112.8 million in August.

System Energy Cost

- **Total System Energy Costs.** Total system energy costs decreased by $305.8 million or 96.4 percent, from -$317.4 million in 2020 to -$623.2 million in 2021.
- **Day-Ahead System Energy Costs.** Day-ahead system energy costs decreased by $276.8 million or 68.9 percent, from -$401.4 million in 2020 to -$678.2 million in 2021.
- **Balancing System Energy Costs.** Balancing system energy costs decreased by $29.3 million or 35.9

182 172 FERC ¶ 61,046 (2020).

percent, from $81.6 million in 2020 to $52.3 million in 2021.

- **Monthly Total System Energy Costs.** Monthly total system energy costs in 2021 ranged from -$77.3 million in November to -$28.4 million in April.

Section 11 Conclusion

Congestion is defined as the total payments by load in excess of the total payments to generation, excluding marginal losses. The level and distribution of congestion reflects the underlying characteristics of the power system, including the nature and capability of transmission facilities, the offers and geographic distribution of generation facilities, the level and geographic distribution of incremental bids and offers and the geographic and temporal distribution of load.

Total congestion costs increased by $466.6 million or 88.2 percent, from $528.7 million in 2020 to $995.3 million in 2021.

The monthly total congestion costs ranged from $29.1 million in January to $175.3 million in November in 2021.

The implementation of fast start pricing caused day-ahead congestion to increase by $1.3 million and caused negative balancing congestion to increase by $2.8 million over the September through December, 2021 period.

The current ARR/FTR design does not serve as an efficient way to ensure that load receives the rights to all congestion revenues. The congestion offset for the first seven months of the 2021/2022 planning period was 44.8 percent. The cumulative offset of congestion by ARRs for the 2011/2012 planning period through the first seven months of the 2021/2022 planning period, using the rules effective for each planning period, was 72.2 percent. Load has been underpaid by $2.7 billion from the 2011/2012 planning period through the first seven months of the 2021/2022 planning period.

Overview: Section 12, Planning

Generation Interconnection Planning

Existing Generation Mix

- As of December 31, 2021, PJM had a total installed capacity of 199,195.3 MW, of which 49,074.4 MW (24.6 percent) are coal fired steam units, 52,094.7 MW (26.2 percent) are combined cycle units and 33,452.6 MW (16.8 percent) are nuclear units. This measure of installed capacity differs from capacity market installed capacity because it includes energy only units, excludes all external units, and uses nameplate values for solar and wind resources.
- Of the 199,195.3 MW of installed capacity, 72,821.7 MW (36.6 percent) are from units older than 40 years, of which 37,643.4 MW (51.7 percent) are coal fired steam units, 191.0 MW (0.3 percent) are combined cycle units and 17,342.6 MW (23.8 percent) are nuclear units.

Generation Retirements[183]

- There are 48,406.2 MW of generation that have been, or are planned to be, retired between 2011 and 2024, of which 37,420.2 MW (77.3 percent) are coal fired steam units. Coal unit retirements are primarily a result of the inability of coal units to compete with efficient combined cycle units burning low cost natural gas.
- In 2021, 1,307.8 MW of generation retired. The largest generators that retired in 2021 were the 667.0 MW Chalk Point Unit 1 and 2 coal fired steam units located in the PEPCO Zone. Of the 1,307.8 MW of generation that retired, 669.4 MW (51.2 percent) were located in the PEPCO Zone.
- As of December 31, 2021, there are 7,081.0 MW of generation that have requested retirement after December 31, 2021, of which 1,300.0 MW (18.4 percent) are located in the DUKE Zone. Of the generation requesting retirement in the DUKE Zone, all 1,300.0 MW (100.0 percent) are coal fired steam units.

183 See PJM. Planning. "Generator Deactivations," (Accessed on December 31, 2021) <http://www.pjm.com/planning/services-requests/gen-deactivations.aspx>.

Generation Queue[184]

- There were 173,182.4 MW in generation queues, in the status of active, under construction or suspended, at the end of 2020. In 2021, the AG2 and AH1 queue windows closed, and the AH2 queue window opened. As projects move through the queue process, projects can be removed from the queue due to incomplete or invalid data, withdrawn by the market participant or placed in service. On December 31, 2021, there were 254,914.6 MW in generation queues, in the status of active, under construction or suspended, an increase of 81,732.2 MW (47.2 percent) from the end of 2020.[185]
- As of December 31, 2021, 7,143 projects, representing 761,657.5 MW, have entered the queue process since its inception in 1998. Of those, 1,007 projects, representing 76,511.8 MW, went into service. Of the projects that entered the queue process, 3,269 projects, representing 430,231.1 MW (56.5 percent of the MW) withdrew prior to completion. Such projects may create barriers to entry for projects that would otherwise be completed by taking up queue positions, increasing interconnection costs and creating uncertainty.
- As of December 31, 2021, 254,914.6 MW were in generation request queues in the status of active, under construction or suspended. Based on historical completion rates, 41,074.4 MW (16.1 percent) of new generation in the queue are expected to go into service.
- The number of queue entries has increased during the past several years, primarily renewable projects. Of the 4,491 projects entered from January 2015 through December 2021, 3,344 projects (74.5 percent) were renewable. Of the 1,301 projects entered in 2021, 956 projects (73.5 percent) were renewable. Renewable projects make up 76.0 percent of all projects in the queue and those projects account for 75.1 percent of the nameplate MW currently active, suspended or under construction in the queue as of December 31, 2021.

  But of the 191,352.4 MW of renewable projects in the queue, only 9,781.6 MW (5.1 percent) of capacity resources are expected to go into service, based on both historical completion rates and average derate factors for wind and solar.

Regional Transmission Expansion Plan (RTEP)

Market Efficiency Process

- There are significant issues with PJM's cost/ benefit analysis that should be addressed prior to approval of additional projects. PJM's cost/benefit analysis does not correctly account for the costs of increased congestion associated with market efficiency projects.
- Through December 31, 2021, PJM has completed four market efficiency cycles under Order No. 1000.[186]

PJM MISO Interregional Market Efficiency Process (IMEP)

- PJM and MISO developed a process to facilitate the construction of interregional projects in response to the Commission's concerns about interregional coordination along the PJM-MISO seam. This process, called the Interregional Market Efficiency Process (IMEP), operates on a two year study schedule and is designed to address forward looking congestion.

  But the use of an inaccurate cost/benefit method by PJM and the correct method by MISO results in an over allocation of the costs associated with joint PJM/MISO projects to PJM participants and in some cases approval of projects that do not pass an accurate cost-benefit test.

PJM MISO Targeted Market Efficiency Process (TMEP)

- PJM and MISO developed the Targeted Market Efficiency Process (TMEP) to facilitate the resolution of historic congestion issues that could be addressed through small, quick implementation projects.

184 See PJM. Planning. "New Services Queue," (Accessed on December 31, 2021) <https://www.pjm.com/planning/services-requests/interconnection-queues.aspx>.

185 The queue totals in this report are the winter net MW energy for the interconnection requests ("MW Energy") as shown in the queue.

186 See *Transmission Planning and Cost Allocation by Transmission Owning and Operating Public Utilities*, Order No. 1000, FERC Stats. & Regs. ¶ 31,323 (2011) (Order No. 1000), *order on reh'g*, Order No. 1000-A, 139 FERC ¶ 61,132 (2012).

Supplemental Transmission Projects

- Supplemental projects are defined to be "transmission expansions or enhancements that are not required for compliance with PJM criteria and are not state public policy projects according to the PJM Operating Agreement. These projects are used as inputs to RTEP models, but are not required for reliability, economic efficiency or operational performance criteria, as determined by PJM."[187] Supplemental projects are exempt from the competitive planning process.
- The average number of supplemental projects in each expected in service year increased by 770.0 percent, from 20 for years 1998 through 2007 (pre Order No. 890[188]) to 174 for years 2008 through 2021 (post Order 890).

End of Life Transmission Projects

- An end of life transmission project is a project submitted for the purpose of replacing existing infrastructure that is at, or is approaching, the end of its useful life. End of life transmission projects should be included in the RTEP process and should be subject to a transparent, robust and clearly defined mechanism to permit competition to build the project. Under the current approach, end of life projects are excluded from competition.

Board Authorized Transmission Upgrades

- The Transmission Expansion Advisory Committee (TEAC) reviews internal and external proposals to improve transmission reliability throughout PJM. These proposals, which include reliability baseline, network, market efficiency and targeted market efficiency projects, as well as scope changes and project cancellations, but exclude supplemental and end of life projects, are periodically presented to the PJM Board of Managers for authorization.[189] In 2021, the PJM Board approved $1.11 billion in upgrades. As of December 31, 2021, the PJM Board has approved $38.9 billion in system enhancements since 1999.

187 See PJM. "Transmission Construction Status," (Accessed on December 31, 2021) <http://www.pjm.com/planning/rtep-upgrades-status/construct-status.aspx>.

188 See *Preventing Undue Discrimination and Preference in Transmission Service*, Order No. 890, 118 FERC ¶ 61,119, *order on reh'g*, Order No. 890-A, 121 FERC ¶ 61,297 (2007), *order on reh'g*, Order No. 890-B, 123 FERC ¶ 61,299 (2008), *order on reh'g*, Order No. 890-C, 126 FERC ¶ 61,228, *order on clarification*, Order No. 890-D, 129 FERC ¶ 61,126 (2009).

189 Supplemental Projects, including the end of life subset of supplemental projects, do not require PJM Board of Managers authorization.

Transmission Competition

- The MMU makes several recommendations related to the competitive transmission planning process. The recommendations include improved process transparency, incorporation of competition between transmission and generation alternatives and the removal of barriers to competition from nonincumbent transmission. These recommendations would help ensure that the process is an open and transparent process that results in the most competitive solutions.
- On May 24, 2018, the PJM Markets and Reliability Committee (MRC) approved a motion that required PJM, with input from the MMU, to develop a comparative framework to evaluate the quality and effectiveness of competitive transmission proposals with binding cost containment proposals compared to proposals from incumbent and nonincumbent transmission companies without cost containment provisions.

Qualifying Transmission Upgrades (QTU)

- A Qualifying Transmission Upgrade (QTU) is an upgrade to the transmission system that increases the Capacity Emergency Transfer Limit (CETL) into an LDA and can be offered into capacity auctions as capacity. Once a QTU is in service, the upgrade is eligible to continue to offer the approved incremental import capability into future RPM Auctions. As of December 31, 2021, no QTUs have cleared a Base Residual Auction or an Incremental Auction.

Transmission Facility Outages

- PJM maintains a list of reportable transmission facilities. When the reportable transmission facilities need to be taken out of service, PJM transmission owners are required to report planned transmission facility outages as early as possible. PJM processes the transmission facility outage requests according to rules in PJM's Manual 3 to decide if the outage is on time or late and whether or not they will allow the outage.[190]
- There were 10,753 transmission outage requests submitted in the first seven months of the 2021/2022

190 See "PJM Manual 03: Transmission Operations," Rev. 60 (November 17, 2021).

planning period. Of the requested outages, 74.8 percent of the requested outages were planned for less than or equal to five days and 9.9 percent of requested outages were planned for greater than 30 days. Of the requested outages, 43.6 percent were late according to the rules in PJM's Manual 3.

Section 12 Recommendations

Generation Retirements

- The MMU recommends that the question of whether Capacity Interconnection Rights (CIRs) should persist after the retirement of a unit be addressed. The rules need to ensure that incumbents cannot exploit control of CIRs to block or postpone entry of competitors.[191] (Priority: Low. First reported 2013. Status: Partially adopted, 2012.)

Generation Queue

- The MMU recommends that barriers to entry be addressed in a timely manner in order to help ensure that the capacity market will result in the entry of new capacity to meet the needs of PJM market participants and reflect the uncertainty and resultant risks in the cost of new entry used to establish the capacity market demand curve in RPM. (Priority: Low. First reported 2012. Status: Not adopted.)
- The MMU recommends improvements in queue management including that PJM establish a review process to ensure that projects are removed from the queue if they are not viable, as well as a process to allow commercially viable projects to advance in the queue ahead of projects which have failed to make progress, subject to rules to prevent gaming. (Priority: Medium. First reported 2013. Status: Partially adopted.)
- The MMU recommends continuing analysis of the study phase of PJM's transmission planning to reduce the need for postponements of study results, to decrease study completion times, and to improve the likelihood that a project at a given phase in the study process will successfully go into service. (Priority: Medium. First reported 2014. Status: Partially adopted.)
- The MMU recommends outsourcing interconnection studies to an independent party to avoid potential conflicts of interest. Currently, these studies are performed by incumbent transmission owners under PJM's direction. This creates potential conflicts of interest, particularly when transmission owners are vertically integrated and the owner of transmission also owns generation. (Priority: Low. First reported 2013. Status: Not adopted.)

Market Efficiency Process

- The MMU recommends that the market efficiency process be eliminated because it is not consistent with a competitive market design. (Priority: Medium. First reported 2019. Status: Not adopted.)
- The MMU recommends that, if the market efficiency process is retained, PJM modify the rules governing cost/benefit analysis, the evaluation process for selecting among competing market efficiency projects and cost allocation for economic projects in order to ensure that all costs, including increased congestion costs and the risk of project cost increases, in all zones are included in order to ensure that the correct metrics are used for defining benefits. (Priority: Medium. First reported 2018. Status: Not adopted.)

Comparative Cost Framework

- The MMU recommends that PJM modify the project proposal templates to include data necessary to perform a detailed project lifetime financial analysis. The required data includes, but is not limited to: capital expenditure; capital structure; return on equity; cost of debt; tax assumptions; ongoing capital expenditures; ongoing maintenance; and expected life. (Priority: Medium. First reported 2020. Status: Not adopted.)

Transmission Competition

- The MMU recommends, to increase the role of competition, that the exemption of supplemental projects from the Order No. 1000 competitive process be terminated and that the basis for all such exemptions be reviewed and modified to ensure that the supplemental project designation is not used to exempt transmission projects from a transparent, robust and clearly defined mechanism to permit competition to build such projects or to effectively

191 See Comments of the Independent Market Monitor for PJM, Docket No. ER12-1177-000 (March 12, 2012) <http://www.monitoringanalytics.com/Filings/2012/IMM_Comments_ER12-1177-000_20120312.PDF>.

replace the RTEP process. (Priority: Medium. First reported 2017. Status: Not adopted. Rejected by FERC.)[192]

- The MMU recommends, to increase the role of competition, that the exemption of end of life projects from the Order No. 1000 competitive process be terminated and that end of life transmission projects be included in the RTEP process and should be subject to a transparent, robust and clearly defined mechanism to permit competition to build such projects. (Priority: Medium. First reported 2019. Status: Not adopted. Rejected by FERC.)[193]
- The MMU recommends that PJM enhance the transparency and queue management process for nonincumbent transmission investment. Issues related to data access and complete explanations of cost impacts should be addressed. The goal should be to remove barriers to competition from nonincumbent transmission providers. (Priority: Medium. First reported 2015. Status: Not adopted.)
- The MMU recommends that PJM continue to incorporate the principle that the goal of transmission planning should be the incorporation of transmission investment decisions into market driven processes as much as possible. (Priority: Low. First reported 2001. Status: Not adopted.)
- The MMU recommends the creation of a mechanism to permit a direct comparison, or competition, between transmission and generation alternatives, including which alternative is less costly and who bears the risks associated with each alternative. (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM establish fair terms of access to rights of way and property, such as at substations, in order to remove any barriers to entry and permit competition between incumbent transmission providers and nonincumbent transmission providers in the RTEP. (Priority: Medium. First reported 2014. Status: Not adopted.)
- The MMU recommends that rules be implemented to permit competition to provide financing for transmission projects. This competition could reduce the cost of capital for transmission projects and significantly reduce total costs to customers. (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends that storage resources not be includable as transmission assets for any reason. (Priority: High. First reported 2020. Status: Not adopted.)

Cost Allocation

- The MMU recommends a comprehensive review of the ways in which the solution based dfax is implemented. The goal for such a process would be to ensure that the most rational and efficient approach to implementing the solution based dfax method is used in PJM. Such an approach should allocate costs consistent with benefits and appropriately calibrate the incentives for investment in new transmission capability. No replacement approach should be approved until all potential alternatives, including the status quo, are thoroughly reviewed. (Priority: Medium. First reported 2020. Status: Not adopted.)
- The MMU recommends consideration of changing the minimum distribution factor in the allocation from 0.01 to 0.00 and adding a threshold minimum usage impact on the line.[194] (Priority: Medium. First reported 2015. Status: Not adopted.)

Transmission Line Ratings

- The MMU recommends that all PJM transmission owners use the same methods to define line ratings and that all PJM transmission owners implement dynamic line ratings (DLR), subject to NERC standards and guidelines, subject to review by NERC, PJM and the MMU, and approval by FERC. (Priority: Medium. First reported 2019. Status: Not adopted.)

Transmission Facility Outages

- The MMU recommends that PJM reevaluate all transmission outage tickets as on time or late as if they were new requests when an outage is rescheduled, and apply the standard rules for late

192 The FERC accepted tariff provisions that exclude supplemental projects from competition in the RTEP. 162 FERC ¶ 61,129 (2018), *reh'g denied*, 164 FERC ¶ 61,217 (2018).

193 In recent decisions addressing competing proposals on end of life projects, the Commission accepted a transmission owner proposal excluding end of life projects from competition in the RTEP process, 172 FERC ¶ 61,136 (2020), *reh'g denied*, 173 FERC ¶ 61,225 (2020), and rejected a proposal from PJM stakeholders that would have included end of life projects in competition in the RTEP process, 173 FERC ¶ 61,242 (2020).

194 See *2015 State of the Market Report for PJM*, Volume II, Section 12: Generation and Transmission Planning, at 463, Cost Allocation Issues.

submissions to any such outages. (Priority: Low. First reported 2014. Status: Not adopted.)

- The MMU recommends that PJM draft a clear definition of the congestion analysis required for transmission outage requests to include in Manual 3 after appropriate review. (Priority: Low. First reported 2015. Status: Not adopted.)
- The MMU recommends that PJM modify the rules to reduce or eliminate the approval of late outage requests submitted or rescheduled after the FTR auction bidding opening date. (Priority: Low. First reported 2015. Status: Not adopted.)
- The MMU recommends that PJM not permit transmission owners to divide long duration outages into smaller segments to avoid complying with the requirements for long duration outages. (Priority: Low. First reported 2015. Status: Not adopted.)

Section 12 Conclusion

The goal of PJM market design should be to enhance competition and to ensure that competition is the driver for all the key elements of PJM markets. But transmission investments have not been fully incorporated into competitive markets. The construction of new transmission facilities has significant impacts on the energy and capacity markets. But when generating units retire or load increases, there is no market mechanism in place that would require or even permit direct competition between transmission and generation to meet loads in the affected area. In addition, despite FERC Order No. 1000, there is not yet a transparent, robust and clearly defined mechanism to permit competition to build transmission projects, to ensure that competitors provide a total project cost cap, or to obtain least cost financing through the capital markets.
