DATA REQUEST

KPSC PHDR_1	Refer to Direct Testimony of Tanner S. Wolfram (Wolfram Direct Testimony), page 22, line 5 through line 6. Provide a copy of any minutes from the May 28, 2025 meeting of the Mitchell Operating Committee.

RESPONSE

Please see KPCO_R_KPSC_PHDR_1_Attachment1.

Witness: Tanner S. Wolffram

MITCHELL OPERATING COMMITTEE

AGENDA

May 28, 2025

Pursuant to notice, a videoconference meeting of the Operating Committee (the "Committee") of the Mitchell Operating Agreement (the "Agreement") will be held on May 28, 2025, at 1:00 p.m. (Eastern).

Invitees: Operating Representatives: Cynthia Wiseman (Kentucky Power), Aaron Walker (Wheeling Power), Alex Vaughan (Agent)

Other Invitees: John Crespo (Secretary), Jeffrey Newcomb, John Scalzo, Bob Jessee, Keith Fisher, Christen Blend

1. Call to Order

A. Roll Call for Quorum

B. Review of Agenda

2. Kentucky Power Interest in Mitchell Plant

A. Discuss prior orders of the Kentucky and West Virginia Commissions regarding the ownership and operation of the Mitchell Plant after December 31, 2028.

B. Discuss Kentucky Power reinvestment in Mitchell Plant and utilization of capacity and energy from the Mitchell Plant after December 31, 2028.

C. Review the Consent Action adopted by the Committee on September 1, 2022.

D. Discussion of potential Committee actions regarding Kentucky Power reinvestment.

3. Other Business

4. Adjournment

MITCHELL OPERATING COMMITTEE

MINUTES

May 28, 2025

Pursuant to notice, a videoconference meeting of the Operating Committee (the "Committee") of the Mitchell Plant Operating Agreement (the "Agreement") was held on May 28, 2025, at 1:00 p.m. (Eastern).

Operating Representatives Present:

- Aaron Walker, President and Chief Operating Officer, Wheeling Power Company ("Wheeling Power"),
- Cynthia Wiseman, President and Chief Operating Officer, Kentucky Power Company ("Kentucky Power"), and
- Alex Vaughan, Managing Director, Regulated Pricing – Generation and Fuel Strategy, American Electric Power Service Corporation ("AEPSC"),

constituting all the Operating Representatives. Also present were:

- John Scalzo, Vice President, Regulatory and Finance, Wheeling Power
- Jeffrey Newcomb, Vice President, Regulatory and Finance, Kentucky Power
- John Crespo, Dep. Gen. Counsel, Regulatory & Nuclear, AEPSC
- Bob Jessee, Vice President, Generating Assets – East, Appalachian Power
- Christen Blend, Corp. Sec. and Assoc. Gen. Counsel, AEPSC
- Keith Fisher, Senior Counsel, AEPSC

1. Call to Order

Mr. Crespo acted as Secretary of the Committee. Mr. Crespo presented and on motion duly seconded the Operating Representatives of the Owners, comprising the voting members of the Committee, unanimously approved the agenda for the meeting, attached.

2. Kentucky Power Interest in Mitchell Plant

The Operating Representatives discussed the prior orders of the Kentucky and West Virginia Commissions regarding the ownership and operation of the Mitchell Plant after December 31, 2028.

Ms. Wiseman described Kentucky Power's intention to make the appropriate filings pursuant to Kentucky law and the prior orders of the Kentucky Commission to reinvest in the Effluent Limitations Guidelines ("ELG") control equipment and other equipment at the Mitchell Plant for which Kentucky Power has been allocated less than a 50% share of the costs, as set forth in the Consent Action adopted by the Committee on September 1, 2022, and to continue using its 50% share of the capacity and energy of the Mitchell Plant after December 31, 2028. The Operating Representatives and others present engaged in a general discussion of Kentucky Power's reinvestment and its intention to make the appropriate filings with the Kentucky Commission in June 2025.

The Operating Representatives also reviewed the Minutes of the Committee's January 31, 2024 meeting. The Operating Representatives generally observed that Kentucky Power's actions to reinvest in the Mitchell Plant would satisfy the resolutions set forth in those Minutes to better define the Owners' interests in the Mitchell Plant and to form a mutually acceptable resolution of post-2028 plant ownership and operations.

The Operating Representatives further reviewed the Consent Action adopted by the Committee on September 1, 2022. The Operating Representatives and others present engaged in general discussion of the resolutions contained in the Consent Action that would require modification to facilitate Kentucky Power's reinvestment in the Mitchell Plant. The Operating Representatives will continue to review the modifications which may be required to facilitate Kentucky Power's reinvestment in the Mitchell Plant and to obtain the required regulatory approvals.

3. Other Business

Mr. Walker generally described the West Virginia Commission's May 23, 2025 order directing Wheeling Power and Appalachian Power to file an Integrated Resource Plan (IRP) by October 1, 2025 in accordance with IRP requirements recently enacted by the West Virginia Legislature as part of the Power Generation and Consumption Act of 2025.

4. Adjournment

There being no further business, the Committee meeting was adjourned.

DATA REQUEST

KPSC PHDR_2

Refer to Wolfram Direct Testimony, Exhibit TSW-1.

a.: Explain each basis for the premise that Exhibit TSW-1 or any other agreement involving Kentucky Power would require Kentucky Power to give-up its 50 percent share of the Mitchell Plant, or its right to 50 percent of the energy or capacity from the Mitchell Plant, due to Kentucky Power's failure to pay 50 percent of the capital costs for a given project. Identify in your response the provisions of agreements that support that premise and explain why those provisions support that premise.

b.: If the Commission were to approve Kentucky Power's request herein, explain whether it is Kentucky Power's position that the Commission would be required to approve recovery of any capital project approved by the Mitchell Plant Operating Committee and the West Virginia Commission in order for Kentucky Power to retain its 50 percent share of the Mitchell Plant, or its right to 50 percent of the energy or capacity from the Mitchell Plant, and explain each basis for your response.

c.: Explain whether your response to subpart b. would differ in a circumstance in which the Mitchell Plant Operating Committee and the West Virginia Commission approved a future project with a higher capital cost but which had a longer life whereas the Kentucky Commission found that a project with a lower capital cost and a shorter life would be least-cost.

d.: Confirm that Exhibit TSW-1 and other agreements related to Mitchell Plant allow the Commission to review the prudency of operation and maintenance (O&M) expenses at Mitchell Plant and to make adjustments to the extent such adjustments are supported by the evidence, and explain each basis for your response.

e.: Explain whether changes made to Exhibit TSW-1 and other agreements related to Mitchell Plant that allowed Wheeling Power Company (Wheeling Power) to take over direct operation of the Mitchell Plant from Kentucky Power affect the Commission's ability to conduct prudency reviews of O&M expenses at Mitchell Plant and to make adjustments to the extent such adjustments are supported by the evidence.

RESPONSE

a. The premise that Kentucky Power is not currently entitled to energy and capacity from the Mitchell Plant after December 31, 2028, is based on the Commission's prior orders, specifically those referenced and provided in the Company's response to KPSC 1-1, dictating that Kentucky Power was not authorized to make the ELG investment necessary for the Mitchell Plant to continue operating after December 31, 2028. The September 1, 2022 Written Consent Action of the Mitchell Operating Committee, provided in Exhibit TSW-1, reflects the effects of the Commission's orders and provides the cost allocation amongst Kentucky Power and Wheeling Power to ensure costs associated with the Mitchell Plant are allocated consistent with the Commission's orders. There are no explicit provisions within the Mitchell Plant Operating Agreement concerning the disposition of Kentucky Power's 50% ownership interest in the Mitchell Plant, but the aforementioned Commission orders require the Company's interest in the energy and capacity from the Mitchell Plant to terminate after December 31, 2028.

b. Kentucky Power acknowledges that the Commission has the plenary authority and discretion to approve and/or disapprove costs in a manner consistent with its statutory authority, and it is not Kentucky Power's position that the Commission would be "required" to approve the recovery of future capital costs as a result of approving this application. However, while Kentucky Power cannot anticipate all future needs for capital investment, it is possible that there could be future requirements to file CPCNs that could impact each Plant owner's respective entitlement to energy and capacity, similar to the impacts of the Commission's Orders in Case No. 2021-00004 and Case No. 2021-00421 on Kentucky Power's entitlement to capacity and energy from the Mitchell Plant after December 31, 2028.

c. The Company's response does not change in that scenario. However, such an outcome could have similar effects to the Kentucky and West Virginia Commission's orders with respect to the ELG investment, and the Operating Committee would likely need to determine what impacts those approvals or disapprovals would have on Kentucky Power's or Wheeling Power's respective entitlements to the Mitchell Plant's energy and capacity going forward.

d. The Commission retains the right to review the prudency of all costs for which Kentucky Power seeks cost recovery that are within the Commission's jurisdiction and consistent with its statutory authority. Please see, for example, KRS 278.030, KRS 278.040, KRS 278.190. Nothing in the Commission-approved Mitchell Plant Operating Agreement or the Written Consent Action abrogates that plenary authority.

e. Please see the Company’s response to subpart (d).

Witness: Tanner S. Wolffram

DATA REQUEST

KPSC PHDR_3	Refer to Wolfram Direct Testimony, page 24, Figure TSW-4. a.: State whether the full $20,059,165.36 reflected in Figure TSW-4 as Kentucky Power's cost of service through December 2025 will be recovered from Wheeling Power's customers, and explain each basis for your response. b.: If the Commission were to grant a regulatory asset to be recovered in Kentucky Power's rates for the full $20,059,165.36 reflected in Figure TSW-4, explain how the full $20,059,165.36 will be reimbursed to Wheeling Power's customers through the creation and amortization of a regulatory liability, with or without carrying costs. If any portion of the $20,059,165.36 will not be reimbursed to Wheeling Power's customers, identify those portions that will not be reimbursed and explain why they will not be reimbursed e.g. they were not paid by Wheeling Power customers.

RESPONSE

a. Kentucky Power expects that the estimated $20.1 million will be recovered from Wheeling Power Company's customers as that amount was based on information provided by Wheeling Power Company based on its current recovery mechanism for the ELG project costs.

b. Based on conversations with Wheeling Power Company, it is the Company's understanding that the entire amount will be passed back to its customers, but the exact mechanism for how that will be accomplished has not yet been determined by Wheeling Power.

Witness: Tanner S. Wolffram (subpart a)

Witness: Alex E. Vaughan (subpart b)

DATA REQUEST

KPSC PHDR_4	Refer to the Direct Testimony of Joshua D. Snodgrass, page 8, Figure JDS-3, indicating estimated additional future spending for Cooling Tower Reinforcement of $15,852,410 from April 2025 to December 2025. a. Identify what portions of that amount have not been spent to date. b. Identify any other material changes to the amounts reflected in Figure JDS-3, if any, not including the potential projects discussed in the Supplemental Direct Testimony of Alex E. Vaughn.

RESPONSE

a. Based on the amount spent from May 2025 through the end of October 2025, $10,079,739 of the estimated future spending of $15,852,410 has not been spent.

b. The Company is not aware of any other material changes at this time.

Witness: Joshua D. Snodgrass

DATA REQUEST

KPSC PHDR_5	Refer to the final Order in Case No. 2020-00290 in which the Commission noted that it will not issue a certificate of public convenience and necessity (CPCN) for construction that has been completed prior to the filing of an application for the CPCN, but in which the Commission authorized the inclusion of the plant in service associated with such construction in the revenue requirement calculation. Explain whether a decision that denied the CPCN requested in this matter based on that procedural issue but otherwise determined that the costs at issue were recoverable would affect Kentucky Power's ability to retain its 50 percent share of the capacity and energy from Mitchell Plant.

RESPONSE

The Company respectfully disagrees with the premise of the question and therefore cannot speculate about the effect, if any, that such a "procedural issue" would have on Kentucky Power's share of the capacity and energy from the Mitchell Plant.

The case cited (Case No. 2020-00290) is factually distinguishable. In that case, the utility, Bluegrass Water ("BW"), made improvements to several sewer and water systems that it either owned and operated or recently purchased. After construction was completed, BW sought a declaratory order from the Commission that a CPCN was not required because the improvements were extensions in the ordinary course of business, or, in the alternative, for approval of a CPCN. The Commission determined that a CPCN was required for certain improvements and ultimately declined to grant BW a CPCN for some of the improvements. The Commission explained that "work on most of the construction items identified was completed," meaning that BW violated KRS 278.020(1) by "failing to obtain a CPCN before it began construction on those items." Order at 28, *In The Matter Of: Electronic Application Of Bluegrass Water Utility Operating Company, LLC For An Adjustment Of Rates And Approval Of Construction*, Case No. 2020-00290 (Ky. P.S.C. Aug. 2, 2021).

This is factually distinguishable from the CPCN sought by Kentucky Power in this proceeding. Although the ELG Project has already been constructed, the project was constructed exclusively by Wheeling Power and at its exclusive cost. The ELG Project was not constructed in contravention of any Kentucky statute, regulation, or Commission order. In this case, Kentucky Power seeks to continue receiving capacity and energy from the Mitchell Plant, and to do that, Kentucky Power must make the capital investments (both in the ELG Project and otherwise) consistent with its ownership share.

The BW case stands instead for the proposition that a utility cannot construct facilities and later seek cost recovery for them without the requisite Commission pre-approvals, including a CPCN.

The instant proceeding is instead factually and procedurally similar to the 2013 case where the Commission granted Kentucky Power a CPCN to acquire an undivided 50% interest in the Mitchell Plant. *See* Order at 43, *In the Matter of: Application Of Kentucky Power Company For (1) A Certificate Of Public Convenience And Necessity Authorizing the Transfer To The Company Of An Undivided Fifty Percent Interest In The Mitchell Generating Station And Associated Assets; (2) Approval Of The Assumption By Kentucky Power Company Of Certain Liabilities In Connection With The Transfer Of The Mitchell Generating Station; (3) Declaratory Rulings; (4) Deferral Of Costs Incurred In Connection With The Company's Efforts To Meet Federal Clean Air Act And Related Requirements; And (5) All Other Required Approvals And Relief*, Case No. 2012-00578 (Ky. P.S.C. Oct. 7, 2013). The Mitchell Plant was constructed and fully operational prior to the Company's application in that case, and the Company sought a CPCN to make the investments necessary to acquire its 50% undivided interest in the Plant. The Commission's order in that case makes no mention of any procedural issue that would affect the Commission's ability to issue the CPCN requested because the Mitchell Plant had already been constructed. The Commission therefore can and should grant the same approvals in this case.

Respondent: Counsel

DATA REQUEST

KPSC PHDR_6	Refer to the November 18, 2025 Hearing Video Transcript (H.V.T.) at 10:13:15-10:15:00. Provide a copy of Kentucky Power's application, once filed or submitted to the federal government, for grant funds from the amounts recently announced by the Department of Energy for coal plants.

RESPONSE

Please see KPCO_R_KPSC_PHDR_6_ConfidentialAttachment1.

Prime Applicant Eligibility Certification

The prime awardee must meet the applicable eligibility requirements as defined for each Topic below.

Topic Area 1 – Coal Commissioning, Recommissioning, Retrofitting, and Modernization Projects

☐ I am the prime applicant and own or operate the coal-fired generation assets to be constructed or that are currently inactive or scheduled for retirement prior to January 1, 2032.

☒ N/A (I am not applying under this topic area)

Topic Area 2 – Rural Capacity and Energy Affordability Projects

☒ I am the prime applicant and own or operate the coal-fired generation assets to be newly constructed or are otherwise located in rural or remote communities as defined by IIJA §40103(c)(1).

☐ N/A (I am not applying under this topic area)

Name/Title: Scott Osterholt, Managing Director Federal Grants & Broadband
Business Name: American Electric Power
I, the authorized official named above, represent by my signature that I am authorized to certify this information on behalf of the Prime Applicant. I certify under penalty of perjury that the information contained herein is true, accurate, and complete. I understand that false, fictitious, or fraudulent information, misrepresentations, half-truths, or omissions of any material fact , may subject me to criminal, civil, or administrative penalties for fraud, false statements, false claims or others. (18 U.S.C. 1001 and 287, and 31 U.S.C. 3729-.730 and 3801-.3812). I further understand and agree that (1) the statements made herein are material to DOE's eligibility and funding decisions, and (2) I have a responsibility to update this information immediately upon change.

Construction Strategy and Permitting

Mitchell Mechanical Draft Cooling Tower Modernization Project

Site and Permitting Requirements

Wheeling Power Company (WPCo), in collaboration with Kentucky Power Company (KPCo) and Appalachian Power Company (APCo), all subsidiaries of American Electric Power (AEP), proposes to modernize the Mitchell Plant in the rural community of Moundsville, West Virginia. The proposed project will modernize the Mitchell Plant by installing a new, modern mechanical draft cooling tower, replacing the nearly 60-year-old natural draft “Unit 2” cooling tower currently in operation.

The construction strategy for the Mitchell Plant cooling tower upgrade is designed to ensure timely compliance with all federal, state, and local permitting requirements while supporting a safe and efficient construction process. AEP’s environmental team identified potential permits for the project. Possible required permits include:

Permit	Permitting Agency	Estimated Requirements	Review Duration	Estimated Date of Completion
Construction Stormwater General Permit for a Large Construction Activity (disturbing three or more acres)	West Virginia National Pollutant Discharge Elimination System (NPDES)	• Stormwater Pollution Prevention Plan (SWPPP) • Groundwater Protection Plan • Project drawings and topo map • Erosion and sediment (E&S) control plans • Pre- and post-closure drainage maps and calculations • Soil report	6-8 months	Q3 2026
Floodplain Permit	Marshall County	To be determined	6-8 months	Q3 2026
Air Permit	West Virginia Division of Air Quality	To be determined	12 months	Q3 2026

Table 1. Potential permit requirements

Submission dates will be coordinated with the overall project schedule to ensure permits are in place before construction begins. All documents will be prepared in accordance with regulatory guidance. WPCo will track permitting progress using Primavera P6 project management software and take corrective actions, such as providing additional information or revising plans, if permits are delayed or conditions change.

Financing

Mitchell Mechanical Draft Cooling Tower Modernization Project

Pages 2-3 of this document may contain business sensitive, trade secret, proprietary, or otherwise confidential information that is exempt from public disclosure, as indicated by highlight. Such information shall be used or disclosed only for evaluation purposes or in accordance with a financial assistance, loan, or Other Transaction Agreement between the submitter and the Government. The Government may use or disclose any information that is not appropriately marked or otherwise restricted, regardless of source.

Financing Strategy

Wheeling Power Company (WPCo), in collaboration with Kentucky Power Company (KPCo) and Appalachian Power Company (APCo), all subsidiaries of American Electric Power (AEP), proposes to modernize the Mitchell Plant in the rural community of Moundsville, West Virginia. The proposed project will modernize the Mitchell Plant by installing a new, modern mechanical draft cooling tower, replacing the nearly 60-year-old natural draft "Unit 2" cooling tower currently in operation.

Funding provided by the Department of Energy (DOE), covering about 30% of total project costs, is instrumental in de-risking and accelerating the project. DOE funding would alleviate the strain on the internal budget, enabling the timely procurement of essential materials and labor, and minimizing cash flow-related delays. This flexibility would help maintain the project schedule and allow the new cooling tower to come online sooner, ensuring the delivery of reliable and affordable energy to ratepayers while effectively managing cost, performance, and operational risks.

Milestones

The project milestones selected for the Mitchell Plant cooling tower upgrade will track progress toward a fully operational mechanical draft cooling tower capable of reliably sustaining the plant's full generation capacity of 1,600 megawatts (MW) and preventing the potential loss of up to 800 MW of generation capacity. These milestones align with critical technical and construction activities, with certain milestones proposed as cost-shared under this award due to their importance in ensuring project success. Proposed cost-shared milestones include engineering and design, procurement of the mechanical draft cooling tower, and piping for tie-in. These activities represent the most significant and high-risk components of the project, directly impacting the project's performance objectives.

Overall Project Management								
Contingency Costs	Allocated to above phases					[redacted]	[redacted]	
Owner's Indirect Costs				[redacted]	[redacted]	[redacted]	[redacted]	
			[redacted]	[redacted]	[redacted]	[redacted]	[redacted]	[redacted]

*Table 1. Milestone and cost summary. *As described in the Project Narrative, [redacted] of preliminary project costs are not included in the proposed budget as they will take place before the anticipated DOE award date.*

Milestone progress will be tracked by Project Controls using Primavera P6 to monitor schedule adherence, budget spend, and milestone completion. If a milestone is anticipated to be delayed, corrective actions will include reallocating resources, accelerating subsequent activities where possible, and engaging with vendors or contractors to mitigate schedule risks. A detailed milestone payment breakdown and project spend plan are under development and will be finalized by Q1 2026.

Project Cost

WPCo and KPCo will recover the non-federal share of the project costs from customers through their electric service rates, as applicable. WPCo and KPCo, the owners of the Mitchell Plant, will capitalize the balance of the project costs through a combination of debt and equity financing.

Control Number: 3605-1510

Documentation from Potentially Impacted Indian Tribes

Mitchell Mechanical Draft Cooling Tower Modernization Project

Project Description

The proposed initiative aims to modernize a coal power plant in Moundsville, West Virginia, by installing an upgraded mechanical cooling tower to maintain its operational output. Given that this is an existing facility rather than new construction, there are no anticipated impacts on Tribal land or resources.

Project Location

The proposed activities will be conducted at: 8999 Energy Hwy, Moundsville, WV 26041.

Justification for No Impact Determination

The project site is located on private property and falls outside the boundaries of any federally recognized Indian tribal lands (see Figure 1). Based on the project scope and location, no direct, indirect, or cumulative impacts to Tribal lands, resources, or interests are anticipated. The proposed activities will occur entirely on non-Tribal property, involve no ground disturbance, and do not affect known or potential historic or cultural sites. Accordingly, this project is expected to have no impact on Indian Tribes or Tribal resources. The attached map shows the proposed project site overlaid with the Bureau of Indian Affairs' "Indian Lands" GIS dataset, confirming that the site is on non-Tribal land and outside federally recognized trust lands or reservations. Therefore, the project will not impact trust lands or areas of Tribal jurisdiction.

As the activities will only occur on non-Tribal property and will not disturb Tribal lands or affect historic or cultural sites, the project is expected to have no impact on Indian tribes, resources, or subsurface rights.

Washington, DC 20585

Dear Secretary Wright,

As a company deeply invested in the well-being of our local area, I am writing to affirm our commitment to the construction of a mechanical draft cooling tower at Mitchell Power Plant, a coal-fired power plant in the rural community of Moundsville, West Virginia. Our organization recognizes that resilient and reliable energy infrastructure is essential for the prosperity and safety of our community.

The project aims to construct a new mechanical draft cooling tower to replace the compromised natural draft cooling tower currently onsite at the Mitchell Power. This project will allow the plant to continue performing at maximum capacity while generating the needed power in our community. Wheeling Power will lead the project implementation and activities. Our organization will partner with Kentucky Power, Appalachian Power Company, and American Electric Power (AEP) to successfully implement this project.

Key Personnel

Mitchell Plant personnel have various other roles and responsibilities, but they will provide the time commitment necessary to ensure this project's success and provide the grant team with the required information for reporting.

Name, Title	Company	Project Roles and Responsibilities	Expertise	% Time Commitment
Dan Eaton, Maintenance Superintendent Senior	Wheeling Power Company	Technical support	Maintenance and engineering professional with extensive experience in the utility sector; expertise in outage planning and execution, ensuring compliance with safety and regulatory standards	20%
Barb Iverson, Administrative Supervisor Senior	Wheeling Power Company	Monitoring and maintaining budget	Skilled supervisor in receiving, inventory management, invoicing, and catalog management	15%
Jeremy Jackson, Interim Maintenance Supervisor	Wheeling Power Company	Site lead	19 years of experience in power plant maintenance and supervision, managing large teams, and coordinating across facilities	40%
Joshua Snodgrass, Plant Manager, Mitchell Plant	Wheeling Power Company	Staffing and resource management; oversee business plans and site finances	20+ years of experience as a plant manager and supervisor in energy production and maintenance leadership, specializing in operational efficiency, safety initiatives, budgeting, outage coordination, and continuous improvement across multiple AEP facilities	25%

Control Number: 3605-1510

Scott Osterholt, Managing Director, Federal Grants and Broadband (Business Contact)	AEP	Federal funding and grant compliance	30+ years at AEP, securing federal funds to support multi-billion-dollar infrastructure projects; extensive expertise advancing grid modernization, new technology deployment, telecom network operations, and grant management	10%
Grant Patch, Senior Project Manager, Generation and Distribution (Project Lead)	AEP	Site project manager	9+ years of experience in coal-fired power plants, distribution, transmission, right of way, and electrical/lighting wholesale	80%
Dan Pizzino, Director, Civil Engineering	AEP	Project engineering lead	20+ years in civil and structural engineering experience with a strong track record in power generation project development, technical team management, and regulatory compliance	50%
Anthony Null, Site Construction Manager	AEP	Construction planning and supervision	Oversees safe, reliable, compliant, and cost-effective operations of fossil-fueled and hydro assets across multiple plants; coordinates operations, maintenance, engineering, construction, and budgeting with AEP functional groups	80%
Robert Jesse, VP Generation Assets	Appalachian Power Company	Oversight of generation assets	29+ years of Power Generation Industry experience; 15+ years in a leadership role, with responsibility for overseeing and directing the activities of facility employees and contractors	15%
Frank Zeroski, Budget Analyst Staff	Appalachian Power	Operating corporate company budgetary information lead contact responsible for coordinating the budget for both KPCo and WPCo	Extensive expertise in managing multimillion-dollar operations and capital budgets, aligning financial data with regulatory filings, and developing complex reporting tools	25%

Table 2. Key personnel

Past Performance

A previous key initiative with a comparable scope to the proposed project was the Unit 2 Components Upgrade, which took place at the Mitchell Plant in 2021. This project enhanced existing cooling tower infrastructure by upgrading the hot water deck and supports, circumferential and radial basin walls, and splash boxes, including flow control valve, pipe saddles and supports, louvers, louver columns, circumferential girts, fill and grid (partial), ice screens, outer walkway, and canopy deck with crossover bridges. The work was completed in collaboration with contractors SPX Cooling Tech, LLC (a cooling tower vendor) and Worley Parsons (an engineering firm), which the team intends to engage for competitive pricing for the proposed mechanical draft cooling tower project. This Unit 2 upgrade was also executed during a constrained outage. It was completed on time (2021-2022) and within the $10M project budget.

Another significant project with a comparable scope was the Mitchell Coal Combustion Residuals (CCR) and Effluent Limitation Guidelines (ELG) Compliance initiative in 2024, an environmental program implemented to ensure Department of Energy (DOE) compliance. Activities consisted of bottom ash conversion, pond closure and repurposing, and flue-gas desulfurization wastewater treatment. The project team collaborated with several contractors supporting the scope of activities, including Worley Parsons. It was completed on time (2020-2024) and within the $175M project budget.

Engagement with Regulators and Other Relevant Community Stakeholders

AEP will work in collaboration with our local operating companies to manage awarded funds and coordinate with the DOE to ensure that all customers understand the impact the grant award will have on affordability and reliability. Additionally, we may conduct targeted outreach to regulators and policymakers to share information as appropriate. We have celebrated previous grant awards and loan closings, resulting in positive coverage and communication to relevant communities through local media.

Project Narrative

Mitchell Mechanical Draft Cooling Tower Modernization Project

Pages 2-3 and 8 of this document may contain business sensitive, trade secret, proprietary, or otherwise confidential information that is exempt from public disclosure, as indicated by highlight. Such information shall be used or disclosed only for evaluation purposes or in accordance with a financial assistance, loan, or Other Transaction Agreement between the submitter and the Government. The Government may use or disclose any information that is not appropriately marked or otherwise restricted, regardless of source.

Project Concept

Wheeling Power Company (WPCo), in collaboration with Kentucky Power Company (KPCo) and Appalachian Power Company (APCo), proposes to modernize the Mitchell Plant in the rural community of Moundsville, West Virginia. WPCo, KPCo, and APCo—American Electric Power (AEP) subsidiaries—serve approximately 1.25M customers across West Virginia, Kentucky, Virginia, and Tennessee. As a coal-fired generation facility, the Mitchell Plant contributes to the region’s energy resilience and reliable, affordable, and secure generation resources. The plant is equipped with advanced pollution-control technologies, demonstrating the facility’s commitment to reducing emissions and providing reliable energy with improved environmental performance. It also plays a crucial role in sustaining the local economy by providing stable, high-wage employment for 167 full-time staff members in a rural, remote area.

The proposed project will modernize the Mitchell Plant by installing a new, modern mechanical draft cooling tower, replacing the nearly 60-year-old natural draft “Unit 2” cooling tower currently in operation, which requires significant repair and upgrades. This modernization effort is essential to sustain and maintain the plant’s full generation capability of approximately 1,600 megawatts (MW) and to prevent the potential loss of up to 800 MW of capacity if the existing tower fails or becomes inoperable. This critical modernization upgrade will enhance regional grid reliability and significantly reduce outage risk by eliminating reliance on aging infrastructure. Installing a mechanical draft cooling tower provides a robust solution with a lifespan exceeding 25 years, ensuring safe and efficient plant operation, directly improving system reliability and regional energy affordability. Other contemplated options, such as piecemeal upgrades on the aging infrastructure, could ultimately cost customers hundreds of millions of dollars more than the proposed mechanical draft cooling tower and result in the premature closure of the facility.

Project Approach

The project will be executed through a structured, phased approach to ensure timely completion. Phases may overlap when it is feasible to optimize the schedule and maintain project momentum.

Phase 1: Engineering and Design

Preliminary engineering activities will occur prior to the anticipated release of Department of Energy (DOE) grant funding in Q2 2026. Conceptual and functional engineering will begin in Q4 2025 and continue through Q1 2026 to establish project feasibility, scope definition, and baseline design parameters. WPCo anticipates contracting Worley Parsons for engineering, design, and construction support. The proposed project budget does not include these initial costs [redacted]. These early activities will position the project for an efficient transition into DOE-supported phases upon award.

Detailed engineering design, including civil, mechanical, structural, and electrical systems, is scheduled to begin in Q3 2026 and is anticipated to be completed in Q1 2027. The main deliverables for this phase will be construction drawings, revised cost estimates, and a comprehensive project execution plan.

Phase 2: Procurement and Permitting

This phase will focus on environmental and construction permitting, as well as the procurement of long-lead materials and equipment. All major components will be sourced domestically, including the prefabricated mechanical draft cooling tower structure, piping, steel, insulation, electrical components, coatings, and scaffolding.

Phase 3: Construction

This phase will begin with demolition and removal of the out-of-service coal conveyor and coal rail car dumper currently occupying the proposed cooling tower site. All demolition work will be executed in accordance with safety and environmental protocols, ensuring the protection of surrounding infrastructure and personnel. Following demolition, the site will be prepared for installation, and the ground will be taken to grade. This phase will also involve the delivery and staging of tower components, as well as other key materials and equipment. The construction of the new mechanical draft cooling tower will include assembly of prefabricated components, installation of mechanical and electrical systems, piping tie-ins, and integration with existing plant systems. Construction will be conducted by an outside firm utilizing domestic union workers, selected during a request for proposal (RFP) process. The project is expected to generate approximately 50-75 construction jobs, with final staffing levels to be determined by the contractor's execution plan once the project is awarded.

Phase 4: Testing and In-Service

The project will utilize a planned plant outage to complete final tie-in activities, minimizing operational disruptions. The final phase will also include system testing, commissioning, and performance verification to ensure full operational capability. The new mechanical draft cooling tower is scheduled to be placed in service by the end of 2028.

The planned project phases are summarized in the table below.

Phase	Estimated Start Date	Estimated End Date
Engineering and Design	Q2 2026*	Q1 2027
Procurement and Permitting	Q3 2026	Q4 2027
Construction	Q2 2027	Q3 2028
Testing and In-Service	Q2 2028	Q3 2028

*Table 1. Project phases with estimated completion dates. *As described above, preliminary engineering will begin in Q4 2025*

The following table summarizes the proposed total anticipated project costs by major categories.

Cost Category	Justification	Estimated Cost (M)
Personnel / Internal Labor	Labor utilization within AEP	[redacted]
Personnel / Contracted Outside Services	Labor utilization outside AEP	[redacted]
Personnel / Contracted Construction Labor	Third-party companies for specific, project-based construction jobs	[redacted]
Equipment and Supplies	Major items needed in field to complete scope of work	[redacted]
Contingency	About 10-13% of the budget set aside to cover unexpected costs that may arise, which is set to become risk-based as project progresses	[redacted]
Owner's Indirect Costs	General expenses for overhead costs, which are calculated at 18% of non-contingency project costs. Indirect costs are estimated rates published in Q1 each year that AEP uses as the basis for allocations and Allowance for Funds Used During Construction (AFUDC)	[redacted]
	TOTAL	[redacted]

Table 2. Summary of overall project costs. Note that this total includes the estimated $3.5M of pre-award preliminary engineering costs

Project Site

The Mitchell Plant is in Moundsville, WV (population approximately 8,000), with a total generation capacity of approximately 1,600 MW. It consists of multiple generating units, primarily using bituminous coal. Throughout its history, the plant has undergone various upgrades to reduce emissions and comply with environmental standards. This includes coal combustion residuals regulations, effluent limitations guidelines, flue gas desulfurization, selective catalytic reduction, and compliance with the mercury and air toxins standards. See Figure 1 for a detailed schematic of the facility; a full-size image is available upon request.

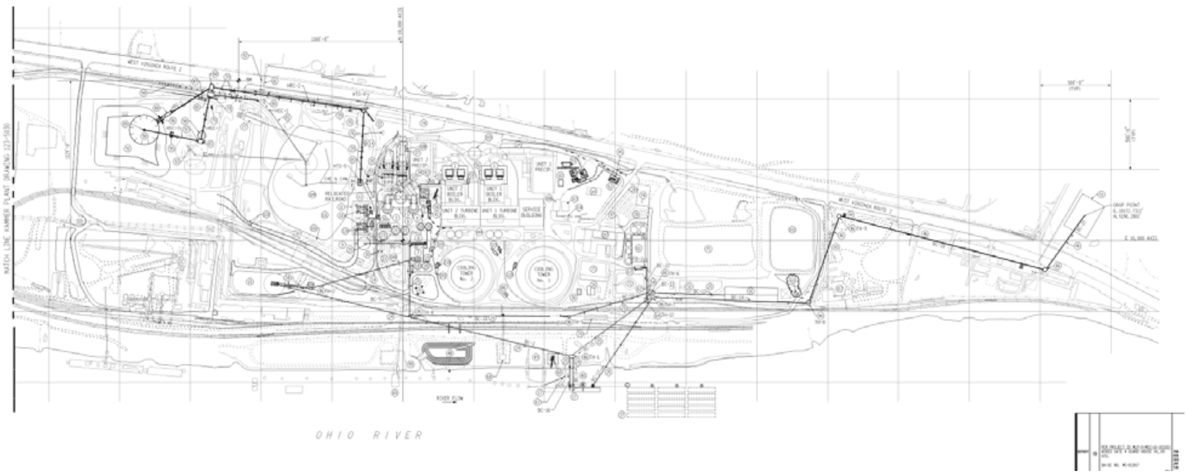

Figure 1. Mitchell plant site plan

WPCo and KPCo are co-owners of the Mitchell Plant, each owning a 50% undivided interest in the plant. Both companies are wholly owned subsidiaries of AEP. As co-owner, WPCo has joint control and management responsibilities over the site.

Technology Selection

The primary technology for this project is a mechanical draft cooling tower, a specialized type of heat exchanger in which air and water are brought into direct contact to reduce the temperature of the circulating water. As this process occurs, a small portion of the water evaporates, extracting heat and cooling the remaining water before it is recirculated.

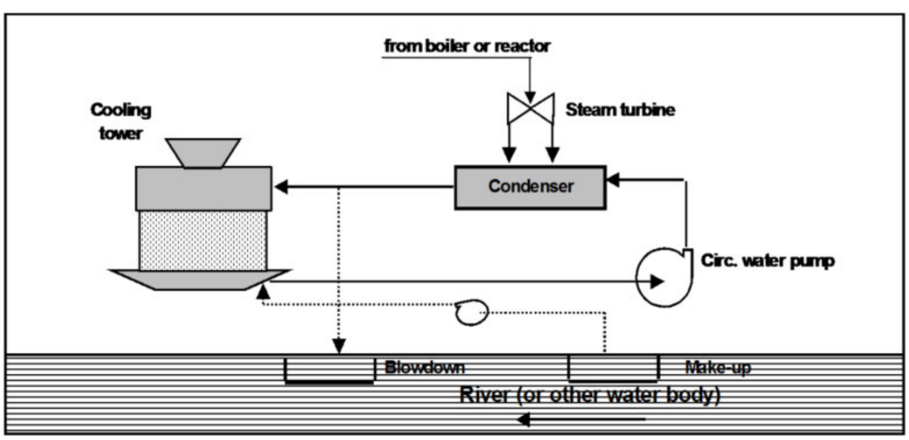

Figure 2. Diagram of the cooling tower as it ties into the rest of the plant

In operation, hot water from the condenser, which carries waste heat from the generating unit, is pumped to the top of the cooling tower. From there, it is distributed across an area known as the “fill,” which is the primary heat transfer medium. The fill is designed to create a large surface area, allowing the water to spread. This design maximizes contact between the water and the airflow moving through the tower, greatly enhancing evaporative cooling efficiency. Mechanical fans draw large volumes of air through the fill and the water, promoting continuous heat and mass transfer. As the air passes through, it absorbs heat and moisture, becoming warmer and more humid before being discharged through the stack at the top of the tower. Once cooled, the water is collected in a basin at the base of the tower and pumped back to the condenser to absorb additional waste heat, completing the cycle. This way, the mechanical draft cooling tower effectively maintains system efficiency by continuously removing waste heat from the power generation process.

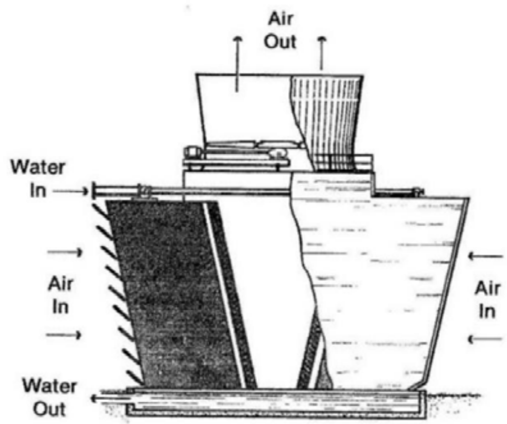

Figure 3. Schematic of a mechanical draft cooling tower

Any power generation facility (e.g., coal, gas, nuclear, biomass) that utilizes a Rankine steam cycle, like the Mitchell Plant, must have a means of condensing steam back into water, which involves transferring a large amount of heat from the steam to another source of water, known as circulating water. The circulating water heats up during the process and must be cooled by discharging it into a large body of water (e.g., a lake, river, or ocean) or a cooling tower. The selection of a cooling tower at the Mitchell Plant minimizes water consumption from the Ohio River and eliminates the need to discharge hot water back into the river, which would potentially have adverse environmental effects.

The new cooling tower will be supplied by a competitively sourced cooling tower industry leader. WPCo has initiated discussions to formalize a contract agreement, which is expected to be completed by Q1 2026. Preliminary specifications for the technology being considered are outlined in the table below.

Design Conditions		Tower Dimensions	
Flow	275,000 gallons per minute (gpm)	Tower Width	78.17 ft
Hot Water	117.5 °F	Tower Length	448.7 ft
Cold Water	91.5 °F	Tower Height	61.58 ft
Wet Bulb	74 °F	Fan Deck Height	47.83 ft

Tower Description		Basin Dimensions	
Model	F674D-20-14	Basin Width	55.5 ft
Number of Cells	14	Basin Length	449 ft
Pump Head	47.41 ft		
Fan Diameter	28 ft		
Motor Size	14 @ 300 Horsepower (Hp)		
Brake Horsepower	14 @ 293.5 Hp		
Evaporation	6,140 gpm		
Drift Rate	0.0010%		

Table 3. Preliminary specifications from a cooling tower industry leader for a mechanical draft cooling tower

Mechanical draft cooling towers are the industry standard for new installations where sufficient water is available to offset evaporation losses—ideal for the Mitchell Plant, which is located along the Ohio River. They are preferred over natural draft towers due to significantly lower capital costs, smaller footprint requirements, and public perception considerations, as natural draft towers are often associated with nuclear facilities. Natural draft towers have not been constructed in the U.S. since the 1980s for these reasons. Additionally, the smaller footprint requirement is a key factor for the Mitchell Plant, given the limited available space on site.

Due to its lower capital cost and sizing advantage, a mechanical draft cooling tower is the most suitable engineering choice for meeting the project's cooling needs.

Organizational Goals

WPCo and AEP are committed to providing reliable, affordable, and environmentally responsible energy to their customers, while adhering strictly to all relevant federal and state energy and environmental regulations. They prioritize modernizing existing infrastructure and integrating advanced technologies to sustain service reliability and manage costs for ratepayers.

The new mechanical draft cooling tower will have an engineered life expectancy of more than 25 years. It will replace the existing hyperbolic cooling tower, which would require significant repairs/upgrades in the near term to allow Mitchell Unit 2 to continue operating, extending its current life by only 10 years. The mechanical draft cooling tower system investment will provide a dependable and efficient cooling solution, supporting plant performance and operational stability. The new tower's projected lifespan of 25+ years will help maintain generation capacity, whether through continued coal combustion or future transitions to alternative or lower-carbon fuels.

Mitchell Plant has consistently demonstrated its commitment to operational excellence and environmental stewardship via significant infrastructure improvements and compliance projects. Notable initiatives include the Coal Combustion Residuals (CCR) and Effluent Limitation

Guidelines (ELG) compliance project, which involved bottom ash conversion, pond closure and repurposing, and flue-gas desulfurization wastewater treatment enhancements.

Through initiatives such as these, WPCo and AEP continue to advance organizational objectives to maintain reliability, minimize environmental impacts, and promote long-term affordability of power generation for customers. The cooling tower upgrade reflects the company's proactive approach, striking a balance between immediate operational needs and long-term energy system resilience and adaptability.

This project also aligns with Governor Morrisey's 25-year energy plan, which prioritizes upgrading existing coal-fired generation to ensure continued delivery of stable, reliable baseload power. By replacing aging infrastructure with a modern mechanical draft cooling tower, the plant will operate more efficiently and economically, supporting the Governor's goal of keeping West Virginia's energy assets online for decades to come.[1] In addition, the project advances the Governor's "Grow West Virginia" economic initiative by ensuring the dependable, affordable power supply needed to attract new businesses and support long-term economic growth across the state.[2]

Economic Competitiveness

A new, modern cooling tower can sustain and potentially improve thermal efficiency, even under suboptimal conditions such as temperature fluctuations and high humidity. By maintaining optimal cooling performance, the new mechanical draft cooling tower will enable more efficient power generation, thereby reducing overall operating costs. Compared to the current natural cooling tower, the new installation is expected to require less maintenance and enable improved operations by using more modern materials, components, and control systems. Investing in a new cooling tower also provides a reliable solution to the existing hyperbolic tower that requires significant repairs and upgrades. This replacement will ensure uninterrupted cooling performance and extend the operational life of the Mitchell Plant, reducing overall costs for AEP and its customers.

Risk Management Plan

The Mitchell Plant project team will implement a comprehensive Risk Management Plan to identify, analyze, monitor, and respond to potential risks throughout the project's lifecycle. The plan will mitigate risks that could impact cost, schedule, technical performance, safety, or regulatory compliance. A Project Risk Register will be established and maintained as a living

[1] Governor Morrisey Provides Details of 25-Year Energy Plan. WV Independent Observer. Sept 11, 2025. https://observerwv.com/governor-morrisey-provides-details-of-25-year-energy-plan/

[2] Governor Patrick Morrisey Announces "Grow West Virginia" Economic Initiative, Makes Targeted Investment in Mettler Packaging to Add 50 New Jobs. West Virginia Office of the Governor. July 10, 2025. https://governor.wv.gov/article/governor-patrick-morrisey-announces-grow-west-virginia-economic-initiative-makes-targeted

document to capture all identified risks, potential impacts, and corresponding mitigation strategies. Each risk will be assessed based on its likelihood of occurrence and the severity of its potential consequences. Risks will be categorized by type—technical, management, schedule, procurement, or financial—and assigned ownership to ensure accountability. The register will also support the development of a risk-based contingency within the project budget. Risks identified as "High" will require a formal written Risk Response Plan, outlining corrective actions, triggers, and mitigation timelines. Initial key risk areas identified in Table 4 include long lead material deliveries, procurement of construction materials, and schedule delays.

Potential Risk	Estimated Probability	Estimated Impact	Mitigation Strategies
Schedule: Potential for schedule delays due to extended permitting, additional engineering requirements, or weather impacts during construction	30%	[redacted]	Implement a detailed project schedule with phase-specific contingency; use a phase-funded approach tied to DOE milestone completion
Procurement and Supply Chain: Potential delays in procurement or delivery of long-lead materials	40%	[redacted]	Prioritize early procurement of critical materials, establish vendor agreements with defined delivery schedules, and maintain buffer inventory where feasible. All materials will be domestically sourced to minimize global supply chain risk
Technical: Potential for unforeseen engineering or integration issues	20%	[redacted]	Conduct comprehensive engineering design reviews and system modeling in Phase 1
Workforce: Availability of skilled construction and technical personnel during peak project phases	15%	[redacted]	Engage early in the RFP process to contract vendors and cross-train internal staff as needed

Table 4. Initial identification of potential risks (Class V estimates)

SUMMARY

Project Management Professional (PMP) with 9+ years of experience in Coal-Fired Power Plants, Distribution, Transmission, Right of Way, and Electrical/Lighting Wholesale. My skills include leadership, planning, executing, scheduling, risk management, and communication. I am seeking to use my work experience, skills, and education to help organizations with their ongoing projects. In my current and previous roles, I have led several multimillion-dollar projects and programs that continue to positively impact AEP's customers.

PROFESSIONAL EXPERIENCE

American Electric Power – Senior Project Manager (ERCOT & APCo) – Generation & Distribution
(November 2022 – present)
Columbus, Ohio

- Managing a first of a kind generator project in order to increase maximum capacity for station needs offsite
- Managing multiple projects within a matrix team environment at Mitchell Power Plant and in ERCOT Distribution
- Providing leadership, direction, and effective communication to initiate, plan, execute, monitor and control, and close projects in a safe, efficient, economical, risk-balanced approach to achieve short and long range goals and to obtain maximum customer satisfaction
- Developing relationships and effectively communicate with all stakeholders including internal customers, external customers, team members, suppliers, contractors, and vendors. This includes groups within AEP Transmission, Distribution, and Generation
- Creating and managing the yearly schedule and cost baselines for projects
- Planning, organizing, directing, coordinating and supervising project activities
- Managing, developing, reviewing and coordinating the project plan, schedule, and budget
- Managing cost and providing timely reallocation of funding as needed
- Leading meetings and providing project updates including stakeholder presentations
- Providing clear and concise monthly reporting on projects up to the SVP level
- Actively managing working relationships with the project team, customers, contractors, vendors, and suppliers
- Providing specific guidance to reduce risk and to improve the project schedule and costs
- Reviewing and approving deliverables to ensure projects are on time and in budget
- Ensuring maximum customer satisfaction and demonstrating effective performance of project work activities
- Supporting and hold employees and contractors accountable for the AEP System Safety Process, ensuring a safe working environment focused on Zero Harm

American Electric Power – Project Manager (I&M) – Transmission Development & Right of Way (December 2019 – November 2022)
New Albany, Ohio

- Ensured that Transmission projects were properly developed to hand-off to the project execution team
- Directed planning meetings and project updates with supportive role in stakeholder presentations
- Developed working relationships with the project team, contractors, vendors, and suppliers
- Provided guidance, instruction, and training to improve design, systems, procedures, schedules, and costs
- Managed the project team in ensuring effective and timely performance and deadlines of project activities
- Assigned as the Right of Way Telecom Lead that tracked permitting for construction on projects
- Led bi-weekly project calls with the project team and vendors
- Prepared and presented right of way kick-off meetings to begin acquisition activities
- Mentored and trained new team members on AEP right of way processes and the project lifecycle
- Reviewed monthly forecasting on assigned capital projects

- Handled negotiations with landowners for the acquisition of land rights
- Settled damage claims with property owners relative to property damage
- Reviewed and interpreted legal documents, surveys, legal descriptions, appraisals, and reports
- Prepared approved legal documents for the acquisition of land rights
- Provided support to other AEP Business Units in regard to questions and procedures in the acquisition of land rights
- Maintained property owner files, maps, drawings, exhibits and detailed progress reports
- Completed estimates & scopes for projects, and managed, developed, and reviewed deliverables from vendors
- Monitored the closeout process and establish any lessons learned for future improvements

Loeb Electric – Project Coordinator – North America Accounts (January 2018 – December 2019)
Columbus, Ohio

- Project scopes included internal and external store lighting retrofits for Walmart, L-Brands, and Meijer
- Processed and performed take-offs with electrical materials that were needed for the desired projects
- Helped create logistical routes across North America to complete jobs by their deadlines
- Created purchase orders and work orders for future jobs
- Presented monthly project updates to the organization's executives
- Provided overall project support for assigned projects for designated Project Manager
- Took and maintained ownership of assigned queues and projects
- Processed material orders for assigned projects and queues
- Completed calls for scheduling, quality, waste pickup, and security to our company's accounts

Loeb Electric – Project Services Specialist – National Accounts (May 2016 – January 2018)
Columbus, Ohio

- Managed accounts throughout North America with stores that requested electrical work
- Built relationships with account managers and technicians
- Made phone calls and emailed regularly to receive updates on current jobs
- Conducted a time study analysis for dispatchers and service coordinators
- Designed a training manual for newly hired service coordinators
- Prepared standard operating procedures for service coordinators daily work
- Worked on different processes within accounts payable and accounts receivable

EDUCATION & CERTIFICATIONS

Franklin University **Master of Business Administration (MBA)**
Project Management Institute **Project Management Professional (PMP)**
Otterbein University **Bachelor of Business Administration (BBA)**
OSHA 30 Outreach Training Program **Construction Safety Certified (DOL card)**

ORGANIZATIONS, GROUPS, & ACCOMPLISHMENTS

Member of the Project Management Institute (PMI)
Member of the International Right of Way Association (IRWA)
AEP 2025 Corporate DEI Liaison for 1RP
Chair of AEP's 2024 Project Solutions DEI Committee
Awardee of AEP's 2023 Project Solutions Community Engagement Award
Member of AEP's 2023-2025 Generation Goldfish Program
Member of AEP's 2023-2025 Project Solutions Mentoring Program
Member of AEP's 2023-2024 Distribution Culture Action Plan Team
Member of AEP's 2022 Transmission SOAR Culture Team (Siting, Outreach, and Right of Way) Member of AEP's 2021 Grid Development Strategic Goal for Diversity & Inclusion Group Member of AEP's 2020 Transmission Safety Group
Graduate of AEP's 2020 Transmission Talent Onboarding Program

[redacted]

Summary

Recognized for establishing, managing, and motivating high-performance teams—practices honed through a commitment to introducing new standards, establishing operational best practices, improving quality, and increasing enterprise value.

Employment

2023-Present — Managing Director, Federal Grants and Broadband

- Tasked with finding, analyzing, seeking alignment, and implementation of federal grant applications and compliance to help keep customer cost impacts low through the acquisition of federal grant funds
- Responsible for seizing opportunities to maximize federal funding within our footprint through grant development utilizing a comprehensive fiber strategy that helps us modernize the electric grid while connecting areas without broadband coverage
- Company's subject matter expert and witness for regulatory proceedings for grid modernization, federal grant and rural broadband pursuits with an associated track record of success

2021-2023 — Director, Broadband and Telecom Business Development

- Responsible for uncovering and extracting additional annual revenue from leveraging existing unutilized dark fiber and Vertical assets
- Tasked with implementation of marketing partners to drive additional revenue from leveraging existing unutilized telecom, transmission, and real estate assets
- Responsible for seizing opportunities to maximize federal funding within our footprint through grant development utilizing a comprehensive fiber strategy that helps us modernize the electric grid while connecting areas without broadband coverage

2016-2021 — Director, GRID Modernization

- Responsible for AEP Ohio's new grid technology including its gridSMART Phase 2 Deployment - $385M capital.
- Regulatory and Filing Leader of AEP Ohio's support of the Smart City / Smart Columbus Project including the proposed AEP Ohio deployment of Smart Lighting, Microgrid and Battery Storage, and Electric Vehicle Charging Infrastructure - $87M capital.
- Responsible for AEP Ohio's Risk Management organization and activities.

Education

1999-2003 — BA, Business Administration, Mount Vernon Nazarene University

Control Number: 3605-1510

[redacted]

[redacted]

Summary

Results-driven maintenance and engineering professional with extensive experience in the utility sector, currently serving as a Maintenance Superintendent Sr. Proven ability to lead and mentor teams while developing and implementing strategies to enhance equipment reliability and performance. Expertise in outage planning and execution, ensuring compliance with safety and regulatory standards. Demonstrated success in project management of multi-discipline engineering projects, conducting audits, and providing training on new technologies. Holds a Bachelor of Science in Electrical and Computer Engineering from The Ohio State University, combining technical knowledge with strong leadership skills to drive operational excellence and cost efficiency.

PROFESSIONAL EXPERIENCE

AMERICAN ELECTRIC POWER, Moundsville, WV
2024 - Present
Maintenance Superintendent Sr

- Supervise and mentor electrical and mechanical maintenance staff, providing guidance and training as needed.
- Develop and implement maintenance strategies to optimize equipment reliability and performance.
- Oversee preventive and corrective maintenance activities, ensuring timely completion of work orders.
- Manage administrative staff, budgets, and resources, tracking expenses and identifying cost-saving opportunities.
- Collaborate with engineering and operations teams to identify maintenance needs and improvements.
- Ensure compliance with all safety programs and regulatory requirements.
- Maintain accurate records of maintenance activities and equipment performance.
- Analyze maintenance data to identify trends and recommend improvements.

AMERICAN ELECTRIC POWER, Moundsville, WV
2023 - 2024
Outage Process Owner

- Responsible for planning and execution of scheduled and/or forced outages, including plant work, RSO, and contract labor work, and coordinating outage activities and operations.
- Establish outage critical path, outage duration, and work schedules.
- Establish work scopes based on previous outage inspection reports, predictive maintenance, preventative maintenance, circular letters, lessons learned, facility health reports, long-range planning, and NDE test results.

- Provide regular updates and reports on work progress, safety performance, schedule adherence, and budget performance.
- Supervise Outage Coordinators in the planning and execution of outage plans.

AMERICAN ELECTRIC POWER, Moundsville, WV
2021 - 2023
Electrical Process Owner

- Responsible for the overall operations and maintenance of electrical process turbine-generator, transformer, and BOP equipment.
- Develop multi-year plans and budgets to ensure Circular Letter compliance.
- Ensure generator-to-line NERC compliance.
- Responsible for outage plans and schedules.
- Responsible for personnel safety on all electrical process equipment.

AMERICAN ELECTRIC POWER, Moundsville, WV
2016 - 2021
Supervising Engineer (2019-2021), Regional Engineer (2016-2019)

- Supervise engineering resources to perform multi-discipline projects utilizing EWC.
- Project manager of DCS/PLC controls upgrades, GSU replacements, and process upgrades, ensuring projects are completed on time, on budget, and without impacting plant operations.
- Perform safety-in-design checks and peer reviews of new installations.
- Provide guidance to Engineers and I&C supervisors to ensure hardware and software maintenance and upgrades are performed as needed.
- Provide training and documentation to energy production personnel on the operation of all new equipment.
- Perform NERC audits to ensure compliance.

EDUCATION

Bachelor of Science in Electrical and Computer Engineering
THE OHIO STATE UNIVERSITY
Columbus, OH May 2016

Qualification

Current U.S. Citizen

ADDITIONAL TRAINING

- API 579-1/ASME FFS-1 Fitness for Service Training.
- SEL protection relay and automation.
- CISCO Networking.
- P6 Professional Scheduling

Control Number: 3605-1510

[redacted]

PROFESSIONAL PROFILE

A hardworking and dedicated individual who is well-organized with an exceptional focus on safety and culture. An exceptional leader in the Supply Chain/Accounting organization. I work diligently to establish relationships across cross-functional teams, enabling us to achieve our goals and fulfill our daily work duties successfully. I am a highly skilled supervisor in receiving, inventory management, invoicing, and catalog management. With this experience, it has developed strong interpersonal and communication skills, and I have become an exceptional trainer. I work very hard alongside my team and colleagues to ensure that they are aware of breakthrough objectives and that we meet or exceed them.

PROFESSIONAL EXPERIENCE

Cabela's Distribution Center

Receiving Coordinator 2004-2008

- Managed day and night shift receiving and shipping, consisting of over 50 employees.
- Maintained and manage budgeted costs within that department.
- Maintained headcount for the department and future needs (ex. during holidays we would have the need to employ temporary employees)
- Fork truck, stacker, long tail, and bobtail trainer.
- Worked closely with human resources department to hire associates that would be the proper fit for the positions that we had open and scheduled interviews.
- Operated training classes held to keep up with the OSHA standard for the entire warehouse. Our safety record was exceptional, considering we were in the construction phase of the center.
- Moved across departments to broaden my understanding of distribution processes.

American Electric Power

Stores Attendant 2008-2010

- Carried out the day-to-day functions of a storeroom attendant.

Stores Attendant Senior 2010-2013

- Day-to-day responsibilities of a senior storeroom attendant.
- Worked closely with the catalog department and the vendors to complete the u-3 FGD parts setup.
- Managed the project to complete re-organization of the open stock area at each of the outer warehouses.
- Daily duties included work with the plant to acquire material/get quotes/set up delivery/plan the outage material needed, etc.

Kentucky Power Co Mitchell Plant Stores, Moundsville, WV

NE Storeroom Supervisor 2013-2021

- Supervised attendants to service business partners during times that we are really needed and assigned work as necessary.
- Participate in lean events, a trainer for the MAXIMO implementation, a trainer for HPI Tools and concepts for the 2021 HPI initiative, participating in the CORE visit assessment standardization assessment.
- Meet and exceed KPI's that are attainable.
- Safety focus with over an 11-year incident-free record.
- Administer PAT test for new employees and other storerooms on the East Coast.
- Maintain stock and work closely with our suppliers.

Regional Supply Chain Supervisor 2021-2025

- Oversight of multiple facilities in the Northeastern area.
- Cascaded tasks, budgets, and duties down to employees at the facility.
- Communicated information to employees pertaining to invoicing, procuring, transportation, cataloging, and many other areas of operation within the company.
- Hired and trained staff.
- Set performance goals while collaborating with upper management to secure the goals that align with the company.
- Site visits to assess compliance, address questions, and support the local team.

Administrative Supervisor Senior 2025-Present

- Monitored and worked to maintain the budget for Mitchell plant.
- Guide both the storeroom and the accounting department to make sure that we remain in SOX compliance in invoicing, payroll, purchase order, storage, and work orders.
- Working to achieve clear guidelines and expectations within both departments.

EDUCATION

West Liberty University, West Liberty, WV
Bachelor of Science
Business Administration, with specialization in Computer Information Systems

ADDITIONAL SKILLS

- PAT (physical ability test) administrator
- LEAN green belt – lean administrator
- Certified fork truck trainer
- Certified MAXIMO trainer
- Proficient in Microsoft – WORD, EXCEL, POWERPOINT, LOTUS NOTES, OUTLOOK
- Proficient in PeopleSoft expense
- Proficient in Asset Suite
- Proficient in Maximo
- PASS fuel delivery certification
- Exceptional driving record
- HPI trainer
- OSHA 30 certification
- SMITH SYSTEM driving certification

Control Number: 3605-1510

Experience:

FGD Process Supervisor SR 2025-Present

- Manage, plan, and direct process maintenance for FGD
- Develop short- and long-range plans based on equipment run time and circular letter compliance
- Develop, update, and maintain 10-year projected budget.
- Oversee a 20-person team of exempt and hourly employees.

Maintenance Supervisor SR. 2021-2025

- Supervise the work of other employees in executing plant maintenance responsibilities to achieve efficient, safe, and reliable operation of plant equipment.
- Maintain and ensure safe working conditions.
- Supervise, coordinate, plan direct, and/or organize plant maintenance activities.
- Coordinate the planning for maintenance support for plant outages. Develop workflow charts and critical paths, analyzing and overseeing requisitioning of material and equipment needs.

Planner Prin. Mitchell Power Plant, 2017- 2021

- Daily and outage maintenance planner
- Schedule and plan crews for the upkeep of facility
- Utilize Maximo and PASTA work management systems.
- Work with ICE and Operations to schedule equipment for servicing.
- Solicit quotes and procure various parts and equipment.
- Fill in for crew and Maintenance Supervisor SR. as needed.

Planner SR. RSO zone 3, 2016-2017

- Daily and outage maintenance planner
- Scheduled and planned crews for the upkeep of facilities
- Worked between Cardinal, Mitchell, and Dresden plants for planning purposes.
- Filled in as crew supervisor as needed.

Turbine Mechanic SR. AEP RSO zone 3, 2006-2016

- Performed daily and outage tasks for Northern and Southern regions of AEP.
- Repaired/Rebuilt coal and gas-powered steam turbines and generators.
- Performed preventative and corrective maintenance as directed.

Education:

United States Air Force
- 504 hours of on-the-job training Sheppard AFB Texas
- Airman Leadership School
- Air Force Trainers Course
- Maintenance Qualification Training
- Flight line Engine Operation
- Aircraft Advanced Troubleshooting
- Multipoint Refueling Systems
- Certified Physical Training Leader

Belmont Technical College
- Welding and Fabrication
- Completed 51 credit hours in Oxyacetylene, Shielded Arc, MIG, and TIG welding.
- Weld testing, Welding problems and solutions, and welding fabrication

Training:

- Weld Checker, Red Dye
- Power Up & Lead
- Front Line Leadership training
- OSHA 30hr training
- Root Cause Analysis (LCA- Failsafe)
- JSA/JHA courses
- HPI Tool Training
- Clearance Permit System Training & Annual Refreshers
- Excavation Safety for Competent Person

Current U.S. Citizen

EDUCATION

2001-2005 Marshall University
Lewis College of Business
Graduated May of 2005
Bachelor's Degree in Accounting
Minors: History and Economics

EMPLOYMENT

Jan 2024 - Present Plant Manager - Mitchell Plant
Job Description: Focusing on achieving Zero Harm through utilization of HPI tools, Staffing/Resource Management, Business Plans, Oversee all aspects of the business site finances, Operation of the facility via Operations, Material Handling and the Lab, & Site Maintenance Program. Promote a Continuous Improvement program.

Jan 2018 - June 2021 Energy Production Supt Sr - Mitchell Plant
Job Description: Focusing on achieving Zero Harm through utilization of HPI tools, Staffing/Resource Management, Business Plans, Oversee Operation of the facility via Operations, Material Handling and the Lab, Plant Health Report, HR/Labor Relation/Union Grievances/Messages, PMRs/ Developmental Plans for direct & indirect reports, Promote Lean & Achieving Excellence & much more

Jan 2018 - Dec 2019 Maintenance Supervisor - John Amos Plant
Job Description: Focusing on achieving Zero Harm, implementing lean ideas, completing Gap Action Plans, controlling the facility budget, reviewing emergent work, PM compliance & schedule compliance.

Feb 2017 - Jan 2018 Maintenance Supervisor (Outage Coordinator FO/SO) – John Amos Plant
Job Description: coordinating work with contractors and plant maintenance, helped to create Operations Outage Priority sheet which is now a key focus in our outage efforts, performing planning/travelers for Forced and scheduled outage, getting directly involved in our Long Range Plan, working with the scheduler to improve our pre-fabricating process for our outages which has led to availability for work scope increase during the outages. Developing a new Plant Health Report

Jul 2015 - Jan 2017 Maintenance Supervisor – John Amos Plant
Job Description: Completed CI upgrade project on AOD/Urea systems - installed all new valves, piping, etc, Upgraded Urea System to improve pump efficiencies, installed new strainers to prevent pump failures, focused on improving leaks, ventilation, etc to allow building entry without respirators, implemented Intent Based Leadership at John Amos, focused on Unit 3 steam process planning and forced outage work planning/coordination

Jan 2015 - July 2015 Plant System Owner I (Operations Supervisor) - Big Sandy Plant AEP
Job Description: Check completion of routine operator rounds, job briefs, crew time entry, work requests, assist with clearance system and perform safety meetings/implement HPI tools

Jan 2014 - Dec 2014 Plant System Owner I (Maintenance Supervisor) - Big Sandy Plant AEP
Job Description: Run Maintenance Crew, Identify weekly work plans, Clearance Request/Discussions, Review pertinent JHAs/SIBs, Job Briefs, Implement HPI Tools, Work Requests, & Delivered all Corporate messages/initiatives directly to crew.

Jan 2013 - Dec 2013 Plant System Owner I (Coal Yard Evening Shift Supervisor) - Big Sandy Plant AEP
Job Description: Control Fuels Budget, CY Outages, Job Briefs, Implement HPI Tools, Checking Equipment, Work Requests, CY Clearances & Organize Contract Labor

Oct 2012-Dec 2012 Labor Gang Supervisor- Big Sandy Plant AEP
Job Description: Manpower contract labor crew - housekeeping, combustible dust cleaning, i.e., using a vacuum truck in the unit, washing coal conveyors & outage cleaning

2010-2012 Administrative Supervisor- Big Sandy Plant AEP
Job Description: Budgeting, front-line leadership of the plant accounting department, housekeeping, & LITA (IT Rep)

2008-2010 Administrator III – Kanawha River Plant- AEP
Job Description: Budgeting, LITA representative, NERC Lead, capital work orders, security, assist/direct admin department, housekeeping & materials coordinator

2005-2008 Administrative Associate - Kanawha River Plant- AEP
Job Description: Process invoices, contracts, coal entry/pricing & ash entry/billing

Training:

- Generation Targeted Leadership Development Program 2015
- HPI Tool Training
- Clearance Permit System Training & Annual Refreshers
- JSA/JHA courses
- NERC CIP training
- Root Cause Analysis (LCA- Failsafe)
- Business Financial Accounting Online Training- AEP Specific
- OSHA 30hr training
- Front Line Leadership training-
- Power Up & Lead
- Business/Technical Writing Course
- Business Objects/Cognos Training
- Scaffold Competency
- Vibration Analysis
- Oil Analysis
- Weld Checker
- Red Dye (2)
- Weld Checker Planner (2)
- Intent Based Leadership Plant Facilitator

Control Number: 3605-1510

WORK EXPERIENCE
American Electric Power, Columbus, Ohio | April 2011 - Present
Director – Civil Engineering | Dec 2024 - Present

- Lead technical team of Civil, Structural and Geotechnical engineers supporting both existing and new generating facilities.

Director / Manager – New Generation & Project Engineering | Aug 2019 - Dec 2024

- Led multidisciplinary teams in the development and execution of Wind, Solar, Battery, and Gas generation projects.
- Directed bid strategy and self-development processes to deliver competitive proposals for new generation initiatives.
- Oversaw procurement and engineering design for gas turbine equipment and plant siting studies.
- Collaborated with internal and external stakeholders to align generation deployment strategies and execution plans.
- Presented project outcomes to executive leadership and advanced Shared Services strategy for major initiatives.
- Mentored engineering staff and drove organizational culture initiatives to enhance team performance and engagement

Supervisor / Engineer, Civil Engineering | April 2011 - Aug 2019

- Supported Civil Engineering projects at existing power plants.
- Managed capital and retirement projects at existing power plants, including ELG retrofits and CCR closures.
- Led engineering efforts for hydro facilities and wind repower projects
- Developed and oversaw environmental and Dam Safety compliance programs (CCR & ELG).
- Conducted risk assessments for coal ash and cooling lake infrastructure.
- Contributed to O&M strategy development for renewable assets within cross-functional teams.

EMH&T Inc, Columbus, Ohio | April 2004 - April 2011
Design Engineer

- Performed engineering and led team for large utility, industrial, municipal, and commercial projects

LICENSURE & CERTIFICATIONS

- Registered Professional Engineer in the State of Ohio since 2008

EDUCATION

The Ohio State University, Columbus, Ohio

B.S. Civil Engineering, June 2003

Control Number: 3605-1510

CAREER SUMMARY	Continue building trusting relationships with various organizations throughout AEP, while utilizing my leadership, knowledge, and abilities to successfully and safely complete projects.	
CERTIFICATIONS, TRAINING & EDUCATION	• OSHA 510 and 500 • Certified Rigging Instructor • Over 60 Welding Certifications from SMAW-GTAW • 2000 Graduate Apprentice	
SKILLS	• Can manage multiple projects simultaneously, meeting schedule dates and customer expectations • Building a teamwork atmosphere with all parties involved in project processes	• Time management • Proficient in multiple AEP programs/software
WORK HISTORY	**SITE CONSTRUCTION MANAGER – AEP SS CONSTRUCTION SVCS** 07/2024 – Present Responsible for the management, coordination, and supervision of one or more AEP construction projects. Direct and administer the planning, scheduling, QA/QC, contract administration, coordination, and supervision of all construction work activities in a safe, efficient, and economical manner. Provide leadership, communication, and develop partnerships with internal (plant management teams) and external customers, labor contractors, suppliers, vendors, and governmental agencies • Mitchell Cooling Tower Shell Reinforcement • Mitchell Haul Road • Mitchell Waste Water Treatment Facility **CONSTRUCTION COORDINATOR SR – AEP PS CONSTRUCTION SVCS** 06/2017 – 07/2024 Coordinate assigned construction projects located in AEP service territory. Participate in planning, scheduling, and coordination of all construction work activities in a safe, efficient, and economical manner. Collaborate with Plant management teams and external customers, labor, contractors, suppliers, vendors, and governmental agencies. • Amos CCR/ELG • Rockport DSI • Amos U3 Air Heater Upgrades • Wilkes Reheat/Superheat/Outlet Header Change Out • Welsh Rail Car Dumper Replacement • Welsh U2 Precipitator Demo • Welsh Pulse Jet Fabric Filter	

Control Number: 3605-1510

[redacted]

Leadership

29+ years of Power Generation Industry experience; 15+ years in a leadership role with responsibility for overseeing and directing the activities of facility employees and contractors in a safe, compliant, reliable, and economical manner, including electric power production, maintenance, engineering, construction, accounting, procurement, materials management, human resources, public affairs, and compliance with regulating agencies. This responsibility also includes developing strategic and tactical plans to ensure that performance and budget are aligned with asset management expectations. Additionally, establishing and maintaining two-way communication with employees, managers, and the public, as well as providing leadership and managing change through the development of a culture that promotes/supports teamwork, process improvement activities, employee development, and proper recognition and reward.

Experience

01/2024 – Present
VP Generation Assets • Appalachian Power Company • Charleston, WV

04/2022 – 01/2024
Managing Director Generation & Indiana & Michigan Power, Kentucky Power • Rockport, IN

12/2020 – 04/2022
Plant Manager Rockport Plant • AEP • Rockport, IN

05/2018– 12/12/20
Plant Manager Clinch River • AEP • Cleveland, VA

01/2017– 05/2018
Plant Manager – Gavin Plant • Lightstone Generation LLC • Gallipolis, OH

08/2015 – 01/2017
Plant Manager – Gavin Plant • AEP • Gallipolis, OH

05/2011 – 08/2015
Facility Manager – Waterford & Wind Generation • AEP • Waterford, OH / Abilene, TX / Iraan, TX

08/1996 – 05/2011
Various roles – Clinch River & Sporn • AEP • Cleveland, VA / New Haven, WV

Education

Bachelor of Science, Mechanical Engineering / Virginia Tech, Blacksburg, VA

Control Number: 3605-1510

[redacted]

My goal is to steadily obtain more challenging and fulfilling roles that utilize my strong analytical skills and ability to improve the performance of those around me.

EXPERIENCE

2022 - PRESENT
BUDGET ANALYST STAFF, AEP – APPALACHIAN POWER BUSINESS OPERATIONS
Manage operations and maintenance (O&M) budgets and Capital budgets for Appalachian Power (APCo), Wheeling Power, and Kentucky Power generating assets which total $300M annually and include jointly owned facilities and facilities with concurrent cost recovery requiring special handling. Provide Generation data and help build testimony for base rate cases, various filings, and discovery questions. Data includes, but not limited to: O&M expenses, fuel costs, capital expenditures, plant in service activity, and operational data. Coordinate with Regulatory team and witnesses to ensure data is telling the same story as the associated testimony. Build, schedule, and maintain Cognos reports, often joining many different data sources, for users throughout AEP.

2021- 2022
BUDGET ANALYST SENIOR, AEP – APPALACHIAN POWER BUSINESS OPERATIONS
Assisted budgeting O&M and Capital for APCo Distribution and aligned Distribution's project work plan with the budget. Provided Distribution data for various filings and discovery questions. Created, managed, and closed major storm and mutual assistance work orders.

2019 - 2021
ADMINISTRATIVE SUPV, AEP - MITCHELL PLANT
Managed the accounting operations at the Mitchell Plant, which included budgeting, variance reporting, invoice processing, contract requisitions, capital work order processing, Sarbanes-Oxley compliance, document retention, ad-hoc reporting, and managing direct reports. Self-taught Cognos and supported the eastern Generation fleet by creating dozens of Cognos reports for various business needs and facilitated several group and one-on-one Cognos training sessions via WebEx.

2018 - 2019
ADMINISTRATIVE SUPT/ACCOUNTING AND BUSINESS SYSTEM PROCESS OWNER,
CARDINAL OPERATING COMPANY - CARDINAL PLANT

Successfully managed the transition of the accounting, procurement, and inventory management functions from AEP to Buckeye Power in March 2018. Owned the Asset Suite application and integrations with other systems (ComTrac, Dynamics GP, Oracle, and ADP), developed numerous new work processes, and worked with ABB to develop Power BI reporting cubes and subsequent reports on Asset Suite data.

2013 - 2018

ADMINISTRATIVE SUPV/SUPT, AEP/AEP GENERATION RESOURCES - CARDINAL PLANT

Managed the accounting operations at the Cardinal Plant, which included budgeting and variance reporting separately for each owner, invoice processing, contracting, capital work order processing, Sarbanes-Oxley compliance, document retention, ad-hoc reporting, and managing direct reports. Completed Generation Resource's leadership development program, attended Lean Green Belt training facilitated by Bescorp, and facilitated the financial module for Front Line Leader Training several times.

2007 - 2013

COAL EQUIPMENT OPERATOR, AEP - CARDINAL PLANT

Safely operated heavy equipment and conveyor belts to reclaim, stockpile, and load out coal, limestone, and gypsum. Facilitated aerial lift training and served as step up supervisor. Installed water lines along coal conveyors for cleaning and executed other process improvement ideas.

EDUCATION

2005

B.A. MATHEMATICS AND ECONOMICS, OHIO UNIVERSITY

4.0 GPA, Summa Cum Laude, Phi Beta Kappa member

2001

HIGH SCHOOL DIPLOMA, BUCKEYE LOCAL HIGH SCHOOL

4.0 GPA, Valedictorian, 2-time National Spelling Bee participant

SKILLS

- Strong analytical skills
- Excellent coach and mentor
- Self-motivated
- Cognos, Power BI, and Business Objects
- Asset Suite, Maximo, and Storms
- Ability to quickly learn new processes
- Synthesizing process improvement ideas
- Constant pursuit of excellence
- Microsoft Office suite
- PeopleSoft, ComTrac, PowerPlan, MSC

Techno-Economic Analysis
Mitchell Mechanical Draft Cooling Tower Modernization Project

Notice of Restriction on Use and Disclosure of Information: *All pages of this document may contain business sensitive, trade secret, proprietary, or otherwise confidential information that is exempt from public disclosure, as indicated by highlight. Such information shall be used or disclosed only for evaluation purposes or in accordance with a financial assistance, loan, or Other Transaction Agreement between the submitter and the Government. The Government may use or disclose any information that is not appropriately marked or otherwise restricted, regardless of source.*

The Company requires a capital investment in Unit 2's cooling tower to ensure the continued safe and reliable operation of the Mitchell Plant for its customers.

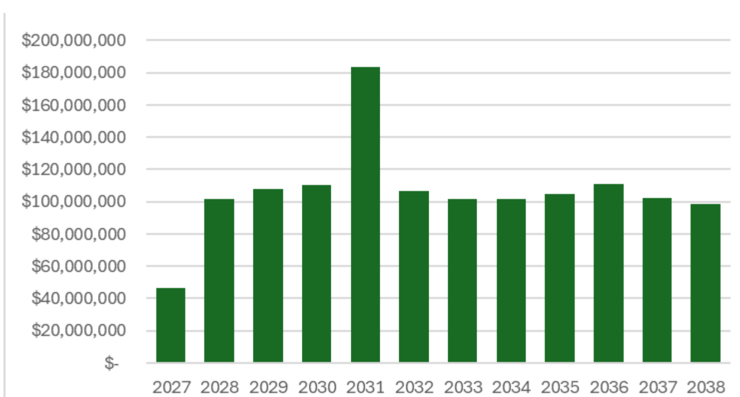
Alternatives Considered

Four options were evaluated to address the Unit 2 cooling tower at the Mitchell Plant. Option 1 was to expand and extend the exterior shell reinforcement project. Option 2 was to retire Unit 2 and partially demolish the existing Unit 2 cooling tower. Option 3 was to construct a new mechanical draft cooling tower and partially demolish the existing Unit 2 cooling tower. Option 4 was to reduce the height of the existing Unit 2 cooling tower and continue with a reduced scope of exterior shell reinforcement.

Economic Analysis

In this type of analysis, the Company aims to find the most cost-effective option for its customers. The Company examined the Present Value (PV) of the Revenue Requirements (RRs) from 2027-2038 and the Average Yearly Revenue Requirements. RR is the focus of the economic analysis, as this is what the customer will ultimately pay through their bills for the project. The Company works to provide safe, reliable power to customers through the least costly option.

Option 2 – retiring the unit – is the least viable, as it would lead to a capacity and energy shortfall beginning in 2026, and result in high costs for customers. This shortfall, along with further economic analysis of replacing the capacity provided through market purchases and building a new generation resource, led to the option not being pursued or recommended. [redacted],



[redacted]

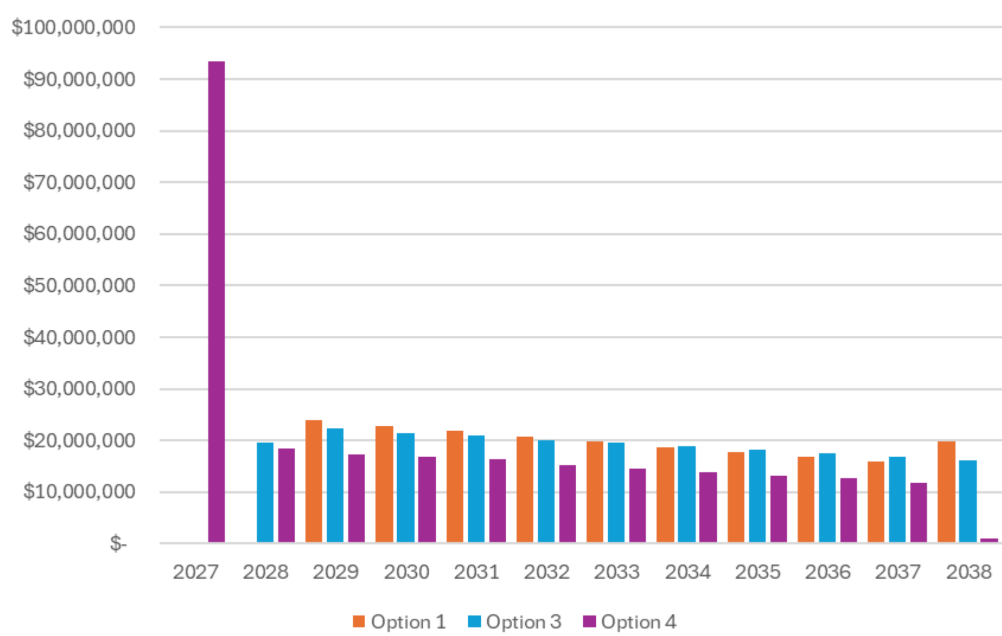
[redacted] However, if Option 3 were not available to the Company, this option would have to be reconsidered, given the high-risk profile of Options 1 and 4. The results of the PV Revenue Requirement and Average Revenue Requirement were as follows:

	Option 2
PV RR 2027 - 2038	[redacted]
Average RR 2027-2038	[redacted]

Discount Rate for PV calculation: 6.95%

The other options were deemed more viable, and an economic analysis was conducted to determine the least costly option for customers, while also evaluating the qualitative benefits and risks associated with each option. The analysis considered the capital costs of the options and determined the revenue requirement that would be collected from customers. Other inputs into the economic analysis included the option's life, when the option could be placed in service, whether an outage would be required for construction, and any lost energy margins due to derates (decreases in capacity) of the unit. The results of the PV RR and Average RR were as follows for Options 1, 3, and 4:

	Option 1	**Option 3**	**Option 4**
PV RR 2027-2038	[redacted]	[redacted]	[redacted]
Average RR 2027-2038	[redacted]	[redacted]	[redacted]



[redacted]

The economics for customers only improve if the Company were to be granted $50 million for the project, as it would reduce the cost to customers by roughly $6 million per year.

	Option 3 with Grant
PV RR 2027 - 2038	[redacted]
Average RR 2027-2038	[redacted]

Years with zero revenue requirement (due to the timing of when the project can go into service) were omitted from the Average RR calculation so as not to skew the results.
Discount rate for PV calculations: 6.95%.

Ultimately, Option 3 was selected for the construction of a new mechanical draft tower. This option provides the lowest average cost to customers – 80% cheaper than retiring the unit – and increases optionality for the future of Mitchell Plant operations due to the longer life of the new mechanical draft tower.

DATA REQUEST

KPSC PHDR_7	Refer to the November 18, 2025 H.V.T. at 11:39:05 discussing the completion of an annual 10 year capital budget for Mitchell Plant. Provide a copy of the most recent capital budget prepared for the Mitchell Plant.

RESPONSE

Please see KPCO_R_KPSC_PHDR_7_ConfidentialAttachment1 for the 10-year capital budget for the Mitchell Plant.

Witness: Joshua D. Snodgrass

KPCO_R_KPSC_PHDR_7_ConfidentialAttachment1 is redacted in its entirety.

DATA REQUEST

KPSC PHDR_8	Refer to the November 18, 2025 H.V.T. at 11:32:05. a. Explain the frequency of monitoring recommended by engineers for the cooling tower at Mitchell Unit 2. b. Explain the criteria, if any, that engineers are looking for in the inspections and what circumstances, if any, would necessitate an immediate or emergency repair to keep Mitchell Unit 2 operational.

RESPONSE

a. The monitoring program is comprised of four key elements: continuous structural monitoring, annual drone inspections, bi-annual LiDAR assessments, and Wind Weather monitoring. Below is a description of each component:

Continuous Structural Monitoring: This involves the use of three automated laser Total Station survey devices strategically positioned around the tower to provide full coverage. These devices continuously measure survey prisms affixed to the tower. In total, there are 121 prisms installed on the shell, which are being monitored continuously around the clock for structural movement. In the event that any unusual movement is detected, a notification is promptly sent to AEP. Additionally, the collected data is reviewed monthly by an engineer to ensure ongoing safety and structural integrity.

Drone Assessment: This process involves deploying a drone around the tower to capture images and identify areas of concrete distress conditions. A 3D model of the structure is then created from the stitched together images to assess the tower's condition. This will be conducted annually.

LiDAR Assessment: This assessment utilizes laser scanning equipment to produce a comprehensive 3D scan of the tower. New scans will be compared to previous scans to identify any changes in the tower's shape. This evaluation will be conducted bi-annually.

Wind Weather Monitoring: This system consists of eight weather stations located around the tower. If excessive wind is detected, AEP will be alerted. A visual inspection can then be performed and an engineering assessment completed if needed.

b. Engineers will utilize the monitoring techniques described above to identify any unusual movements, signs of concrete distress such as cracking or spalling, and changes to the overall shape of the tower. Should any anomalies be detected, an engineering assessment will be conducted to evaluate the need for immediate actions or repairs.

Q3

State of the Market Report for PJM

January through September

Monitoring Analytics, LLC

Independent
Market Monitor
for PJM

11.13.2025

2025

Preface

The PJM Market Monitoring Plan provides:

> The Market Monitoring Unit shall prepare and submit contemporaneously to the Commission, the State Commissions, the PJM Board, PJM Management and to the PJM Members Committee, annual state-of-the-market reports on the state of competition within, and the efficiency of, the PJM Markets, and quarterly reports that update selected portions of the annual report and which may focus on certain topics of particular interest to the Market Monitoring Unit. The quarterly reports shall not be as extensive as the annual reports. In its annual, quarterly and other reports, the Market Monitoring Unit may make recommendations regarding any matter within its purview. The annual reports shall, and the quarterly reports may, address, among other things, the extent to which prices in the PJM Markets reflect competitive outcomes, the structural competitiveness of the PJM Markets, the effectiveness of bid mitigation rules, and the effectiveness of the PJM Markets in signaling infrastructure investment. These annual reports shall, and the quarterly reports may include recommendations as to whether changes to the Market Monitoring Unit or the Plan are required.[1]

Accordingly, Monitoring Analytics, LLC, which serves as the Market Monitoring Unit (MMU) for PJM Interconnection, L.L.C. (PJM), and is also known as the Independent Market Monitor for PJM (IMM), submits this *2025 Quarterly State of the Market Report for PJM: January through September*.[2] [3]

1 PJM Open Access Transmission Tariff (OATT) Attachment M (PJM Market Monitoring Plan) § VI.A. Capitalized terms used herein and not otherwise defined have the meaning provided in the OATT, PJM Operating Agreement, PJM Reliability Assurance Agreement (RAA), the Consolidated Transmission Owners Agreement (CTOA) or other tariffs that PJM has on file with the Federal Energy Regulatory Commission (FERC or Commission).
2 OATT Attachment M.
3 All references to this report should refer to the source as Monitoring Analytics, LLC, and should include the complete name of the report: *2025 Quarterly State of the Market Report for PJM: January through September*.

Table of Contents

Introduction

Q3 2025 in Review

Reliability is a core goal of PJM. Maintaining and improving competitive markets should also be a core goal of PJM. The goal of competition in PJM is to provide customers reliable wholesale power at the lowest possible price, but no lower. The PJM energy markets have done that. The PJM markets work, even if not perfectly. The results of PJM markets were reliable in the first nine months of 2025. The results of the energy market were competitive in the first nine months of 2025. The results of the 2025/2026 and 2026/2027 capacity markets were not competitive. The PJM markets bring customers the benefits of competition when the market rules allow competition to work and prevent the exercise of market power.

The PJM energy and capacity markets are components of the PJM market; both are essential to providing reliable energy to customers at the lowest possible price. The energy market results incorporate immediate short term conditions including weather, unit availability, actual load, transmission limitations, and fuel availability and costs. The capacity market results incorporate load forecasts and the response of investors in resources to expected market conditions. The energy market and the capacity market face interrelated challenges. There are interactive effects between the incentives in the energy market and the incentives in the capacity market.

There are clear warning signs for the capacity market. The capacity market was short of meeting its reliability objective in the most recent capacity auction for the 2026/2027 BRA. PJM was also short of meeting its IRM target as of June 1, 2025, on an ICAP and a UCAP basis. The amount that PJM is short capacity is relatively small, around 200 MW in both the BRA and the actual available capacity. The price impacts have been very large and will be even larger in the near term even if the issues are addressed in a timely manner.

Data center load growth is the primary reason for recent and expected capacity market conditions, including total forecast load growth, the tight supply and demand balance, and high prices. But for data center growth, both actual and forecast, the capacity market would not have seen the same tight supply demand conditions, the same high prices observed in the 2025/2026 BRA and the 2026/2027 BRA, and the currently expected tight supply conditions and high prices for subsequent capacity auctions.

Holding aside all the other issues associated with the 2026/2027 BRA, existing and forecast data center load by itself resulted in a significant increase in the 2026/2027 BRA revenues. Based on actual auction clearing prices and quantities and uplift MW, inclusion of existing and forecast data center load in the peak load forecast for 2026 resulted in a $7,271,197,971 or an 82.1 percent increase in capacity market revenues for the 2026/2027 RPM Base Residual Auction. Inclusion of existing and forecast data center load growth resulted in a combined total increase in capacity market revenues for the 2025/2026 BRA and the 2026/2027 BRA of $16,603,301,829. This total will continue to grow until the issues associated with the additions of large data center loads are addressed. The impact will increase significantly in the 2028/2029 BRA currently scheduled for June 2026, when the maximum and minimum prices defined by the Agreement are no longer effective.

The impact on the 2026/2027 BRA revenues would have been higher had PJM not used the restricted VRR curve.[1] If the 2026/2027 BRA had been run with an unrestricted VRR curve, total revenues would have been $19,294,286,100, an increase of $3,169,915,210, or 19.7 percent, compared to the actual auction results. Without the restricted VRR curve, including existing and forecast data center load in the 2026 peak load forecast would have resulted in capacity market revenues of $19,294,286,100, a $14,189,483,234 or a 278.0 percent increase in capacity market revenues for the 2026/2027 RPM BRA compared to what RPM revenues would have been without the impact of data center load.

Large data center load additions have already had a significant impact and will have additional significant impacts on other customers as a result of

1 On December 30, 2024, in Docket No. EL25-46-000, Governor Josh Shapiro and the Commonwealth of Pennsylvania filed a complaint against PJM asserting that the maximum price for PJM's capacity auctions is unjust and unreasonable. The Governor and PJM reached an Agreement. On February 20, 2025, in Docket No. ER25-1357-000, pursuant to FPA section 205, PJM submitted proposed revisions to its Tariff to establish a specific maximum price and minimum price for all RPM auctions for the 2026/2027 and 2027/2028 Delivery Years, consistent with the Agreement. The resultant VRR curve is termed the restricted VRR curve.

higher transmission costs, higher energy market prices and higher capacity market prices.

In order to address these issues related to the addition of large new data center loads, the PJM Board of Managers created a Critical Issue Fast Path (CIFP) stakeholder process that began on August 18, 2025, and is expected to conclude on November 19, 2025.

Markets cannot solve all problems and it is not enough to simply assert that the market will solve all these problems. The wholesale power markets created by FERC need rules and include rules. FERC relies on competitive markets to be a more effective substitute for economic regulation. FERC's rules about market design and rules governing demand and supply are essential to creating the conditions under which markets can work, in significant part because there is endemic structural market power in the capacity market. The decisions about the interconnection of large new data center loads when there is not enough capacity to maintain system reliability are public, regulatory decisions because they are about competitive outcomes that are in the interests of all market participants. PJM markets are not laissez faire markets.

It is clear that continuing to simply accept the interconnection of large data center loads that cannot be served reliably because there is not adequate dispatchable capacity, is not a reasonable path forward and is not a market solution and is not a solution of any kind. That path leads to continued shortfalls, increased reliability issues, continued maximum prices, and continued calls to abandon markets and return to cost of service regulation. The calls to return to cost of service regulation have continued to grow from the regulated transmission owners and from sectors of the supply community that prefer customer subsidies to markets. The question is how to serve large new data center loads without imposing the related costs and risks on other customers.

The current supply of capacity in PJM is not adequate to meet the demand from large data center loads and will not be adequate in the foreseeable future. This is a simple factual issue. There is not enough capacity currently to meet the data center load. The solution is not to create reliability issues and wealth transfer issues by clearing the capacity market at the maximum price and at a quantity less than the reliability requirement by allowing the ongoing interconnection of large data center loads without adequate generation to serve them.

The market solution is to establish a queue for the addition of large new data center loads which would not be interconnected until there is adequate capacity to serve them. The market solution would create an expedited fast track load and generation interconnection process for large new data center loads that bring their own new generation with locational and temporal characteristics reasonably matched to their load profile. This solution to the issues created by the addition of unprecedented amounts of large data center load does not require a massive wealth transfer. It is essential to have a pragmatic market solution that is consistent with and sustains efficient and competitive PJM markets rather than to create the conditions for a return to cost of service regulation.

All loads should be served. All loads should be served reliably. The process for adding large data center loads should be transparent. All loads should benefit from competitive markets. All loads should have equal access to the transmission system. All loads should be treated as full transmission customers. All loads and generation are and should be on the grid and the grid is highly interconnected.

There are a number of other approaches to address the current capacity market conditions at the wholesale level. In addition to general agreement that load forecasts should be more accurate, the approaches include features that fall into two broad categories: allow bilateral contracts to remove existing capacity to serve data center loads, and allow data centers to be treated as demand side resources. These proposals exacerbate reliability issues and customer cost issues and fail to directly address the real issue.

The temptation to create regulatory fictions that would permit the interconnection of large new data center loads without matching capacity should be resisted. The simple fact is that if significant new loads are added without adding new capacity, PJM markets will be less reliable and more costly. New capacity is needed to serve the new loads.

The proposals to allow data center loads to remove existing capacity from the market and dedicate it to the data centers would simply shift the costs of serving data center load to all other customers. The assertion that this is a solution to the issues is a regulatory fiction. This approach includes proposals to declare that resources would retire but for such a bilateral contract and to define an existing resource as new based on investment in the existing resource. Both arguments would serve as a rationale for removing existing capacity resources from the market and dedicating them to data centers. As with the co-location proposals, the result would be chaos in the PJM markets. It would not be possible to serve existing customers reliably until matching amounts of new generation are built. The impacts on capacity and energy market prices would exceed the demonstrated impacts to date.

The assertion that large new data center loads can be demand side resources and do not require new capacity is a regulatory fiction. The unintended consequences would be overwhelming, given the very large level of such loads. Holding aside the impacts on energy prices and reliability, the direct impact of adding a MW of demand side resources for every MW of data center load would be to increase capacity market prices.

If 20,000 MW of new data center load were added and all 20,000 MW of this load were offered in the capacity market as emergency demand side resources, the MMU estimates that the increased cost of capacity would be around $396 million per year to existing customers.[2] If 20,000 MW of new data center load were added and 90 percent or less of this load were offered in the capacity market as emergency demand side resources, the IMM estimates that the increased cost of capacity would be around $5.48 billion per year to existing customers.[3] There would be comparable impacts on the cost of capacity for any proposal that results in an equivalent or smaller level of emergency demand resources in UCAP terms, e.g. from lower ELCC derating factors. The impact on energy market prices of adding data center load without new generation would also be in the billions of dollars annually. The additional load without new generation affects energy prices directly by requiring generation from more expensive resources on the supply curve and by increasing the probability of shortage pricing. Emergency demand resources also directly affect clearing prices based on the offered strike prices which can be as high as $1,849 per MWh.

In addition to the immediate increase in both capacity and energy costs, there are significant issues with actually expanding the role of emergency demand side resources in a massive way. Demand side response when called is effectively voluntary based on the relatively weak incentives to respond, despite the fact that the tariff states that reductions are required. If demand side resources do not respond when called, any actual performance penalties can be overridden by test results, if the performance issue is not during a PAI event. PJM does not have the authority to enforce reductions in load from emergency demand resources. Given the 99.999 percent reliability requirements of data centers, the option to interrupt these customers is not a viable solution from the data centers' or the other customers' perspective unless the conditions for interruption are so limited as to impose only a small probability of interruption. The actual rules for exactly when PJM calls emergency demand resources are not clear. There is no fixed order of emergency procedures. Many of the proposals for the demand side option in the CIFP stakeholder process would significantly limit the number and duration of calls on the emergency demand resources. Those limits are not consistent with the actual impact of the large new data center loads on the system which will require frequent and potentially long reductions in load as a result of the extremely high level of such loads. Under these proposals, PJM would rely on demand side resources for all of its reserve margin and more.

In addition, the proposals that include the demand side option in place of adding actual generation capacity do not make the demand side option a mandatory condition for interconnection and do not provide a mechanism

2 The MMU estimated the impact by clearing the 2026/2027 BRA without maximum and minimum prices, with 20,000 MW additional peak load, and 20,000 ICAP MW of additional demand resources offered at $0 per MW-day in the Rest of the RTO and comparing it against the 2026/2027 BRA results without maximum and minimum prices. For this sensitivity analysis, the MMU used the 2027/2028 FPR (0.926) for the additional 20,000 MW of data center load and the 2027/2028 ELCC based AUCAP factor (0.92) for the additional demand resources offered, while holding everything else the same as the 2026/2027 BRA without maximum and minimum prices.

3 Adding data center load that is not fully offset by demand response resources is equivalent to increasing the demand for capacity. The MMU sensitivity analysis shows that the additional load would result in increasing the cost of capacity to existing customers through higher capacity market clearing prices.

for PJM to enforce such demand side offers from new data center loads. As a result, the demand side option is voluntary and effectively equivalent to the status quo that has already increased the costs to PJM customers by about $16.6 billion over the last two capacity auctions, in addition to the impact on energy costs.

PJM's initial non capacity backed load (NCBL) option was the only demand side proposal that could actually work, even in theory. PJM's NCBL proposal would have made interruptions mandatory when PJM needed the capacity to serve the load that had actually paid for the capacity. However, even PJM's proposal was not enforceable. PJM does not have the authority to curtail loads of specific customers. Even the strongest and cleanest approach to treating large new data center loads as emergency capacity market demand resources cannot work. The other such proposals are also unworkable and unenforceable and will result in the shift of significant costs and risks to the other PJM customers.

Implementing a load queue for large new data center loads is the only enforceable way to address the impacts of such loads and to require large new data center loads to pay for a significant part of the costs and risks that they would otherwise impose on other customers. The load queue provides strong and enforceable incentives to bring new capacity to the market, which is the point.

One of the benefits of competitive power markets is that changes in input prices and changes in the balance of supply and demand are reflected immediately in energy prices for both price decreases and price increases. Energy prices increased in the first nine months of 2025 from the first nine months of 2024. The real-time load-weighted average LMP in the first nine months of 2025 increased $16.20 per MWh, or 47.2 percent from the first nine months of 2024, from $34.31 per MWh to $50.51 per MWh. The PJM energy market met new winter and summer peak loads in the first nine months of 2025.

Of the $16.20 per MWh increase, $9.85 per MWh (60.8 percent) was in the fuel and consumables cost components of LMP, $2.07 per MWh (12.8 percent) was in the transmission constraint penalty factor component of LMP, $0.85 per MWh (5.2 percent) was in the market power components of LMP, -$0.16 per MWh (-1.0 percent) was in the emissions cost components of LMP, and $1.14 per MWh (7.0 percent) was in the scarcity component of LMP. The strike prices of pre-emergency demand response called on by PJM during the hot weather days in June and July increased the LMP by $0.89 per MWh, 5.5 percent of the increase in LMP.

The total cost of wholesale power increased in the first nine months of 2025, from the first nine months of 2024. Energy (61.3 percent), capacity (13.5 percent) and transmission (23.1 percent) are the three largest components of the total cost of wholesale power, comprising 97.9 percent of the total cost per MWh in the first nine months of 2025. The total cost of wholesale power increased $24.10 per MWh, or 43.7 percent, from $55.18 per MWh in the first nine months of 2024 to $79.28 per MWh in the first nine months of 2025. Of the $24.10 increase, the total cost of energy increased by $15.91 per MWh, 48.7 percent, the total cost of capacity increased by $7.13 per MWh, 200.8 percent, and the total cost of transmission increased by $0.94 per MWh, 5.4 percent.

In the first nine months of 2025, generation from coal units increased 16.1 percent, generation from natural gas units decreased 1.6 percent, generation from oil units increased 25.8 percent, generation from wind units increased 1.8 percent, and generation from solar units increased 46.4 percent compared to the first nine months of 2024.

Energy market net revenues are significantly affected by energy prices and fuel prices. Energy prices, gas prices and coal prices increased in the first nine months of 2025 compared to the first nine months of 2024. The net effects were that in the first nine months of 2025, average energy market theoretical net revenues increased by 30 percent for a new combustion turbine (CT), increased by 35 percent for a new combined cycle (CC), increased by 148 percent for a new coal plant (CP), increased by 46 percent for a new nuclear plant, increased by 279 percent for a new diesel (DS), increased by 52 percent for a new onshore wind installation, increased by 49 percent for a new offshore wind installation and increased by 42 percent for a new solar installation.

The real-time hourly average load in the first nine months of 2025 increased by 3.0 percent from the first nine months of 2024, from 90,917 MWh to 93,683 MWh.

While there are multiple centrifugal forces acting on PJM markets, there are still options available to maintain well functioning markets. Steps that can and should be taken immediately to offset those forces include: define and implement a queue for the addition of large new data center loads; implement a bring your own new generation option for the interconnection of large new data center loads; improve the ELCC/CP capacity market design; clarify the goals and design of the PJM reserve products; clarify the rules for advance commitment of generation for extreme weather; identify the availability of firm gas supply; ensure transparent information from pipelines; identify the need for dual fuel capacity; modify the RMR process; add comprehensive expedited queue options under PJM control to replace retiring resources and address immediate reliability issues; ensure integrated PJM transmission and reliability planning; ensure that large new loads are not subsidized or given preferential treatment; ensure that market power mitigation measures are strengthened and clarified, not eroded; facilitate more competition for transmission projects; and include direct comparisons between generation and transmission options to address reliability issues.

The evolution of wholesale power markets is far from complete. The PJM markets need rules in order to provide reliable energy through competition. The foundational principle of using markets, with rules to prevent the exercise of market power and provide competitive results, is essential. Private investors, regardless of technology or subsidies, will put capital at risk and earn compensatory returns in markets that are not skewed in favor of any specific technology and in markets that are stable and that do not add risk and volatility. The core elements of the PJM market design remain robust. The use of locational marginal prices (LMP) in the energy market and partially locational prices in the capacity market continue to be essential to getting the price signals right. Technological and policy changes do not require that the core elements change. However, the market design can and must be improved and made more reliable and more efficient and more competitive. The current PJM ELCC capacity market design adds unnecessary risk and volatility that are not part of the market fundamentals. The ELCC approach needs to be applied on a unit specific basis, incorporate hourly supply and demand matching, and pay resources based on actual availability and performance rather than on assumed performance derived from a very limited data set of misinterpreted performance results based on unrepresentative extreme historical weather and specific PJM commitment and dispatch decisions. The capacity market also needs to eliminate artificial PAI risk that leads to uneconomic retirements and exits from PJM. The basic logic of market power mitigation in both energy and capacity markets needs to be restored. The queue process should allow for a comprehensive, expedited process to resolve identified reliability issues. There should be a load queue for the addition of large new data center loads. The queue process should include an expedited process for large data center load additions that bring their own generation. The markets will also need support from regulators whose decisions create and/or limit the options available to investors in PJM resources. Competition to build transmission, to implement dynamic line ratings (DLR) and to add grid enhancing technologies (GETs) should be expanded.

In the interests of all market participants, PJM, its current and potential market participants and stakeholders, PJM states, and the FERC will need to continue to work constructively to refine the competitive market design and to ensure the continued effectiveness of PJM markets in providing customers wholesale power at the lowest possible price, but no lower.

PJM Market Summary Statistics

Table 1-1 shows selected summary statistics describing PJM markets.

Table 1-1 PJM market summary statistics: January through September, 2024 and 2025[4]

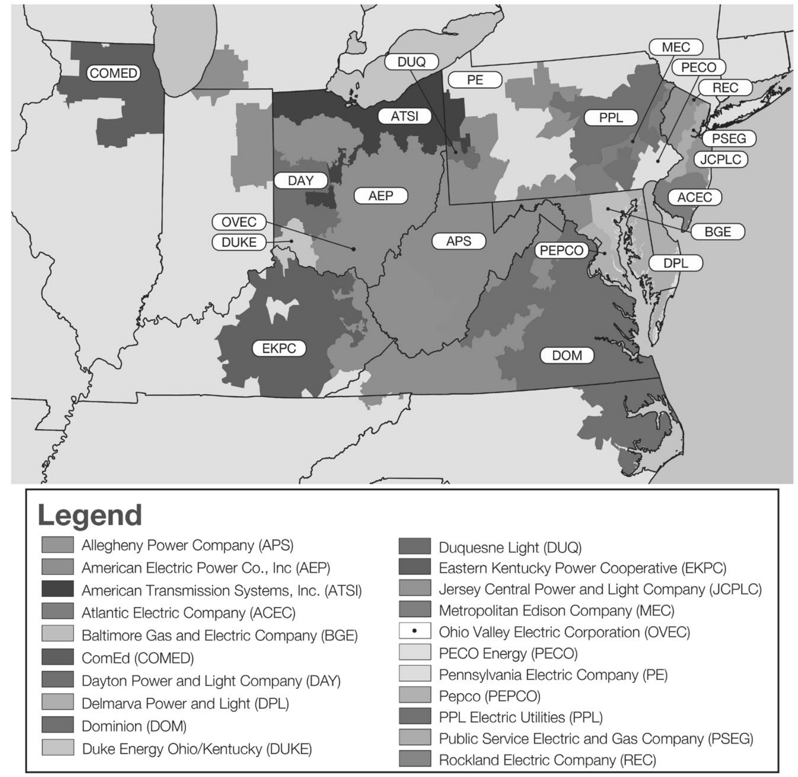
	2024 (Jan-Sep)	2025 (Jan-Sep)	Percent Change
Average Hourly Load Plus Exports (MWh)	96,746	100,114	3.5%
Average Hourly Generation Plus Imports (MWh)	98,593	102,018	3.5%
Peak Load Plus Net Export (MWh)	149,398	158,789	6.3%
Peak Load Excluding Export (MWh)	148,890	156,256	4.9%
Installed Capacity at September 30 (MW)	177,032	181,729	2.7%
Load Weighted Average Real Time LMP ($/MWh)	$34.31	$50.51	47.2%
Total Congestion Costs ($ Million)	$1,385.80	$2,233.80	61.2%
Total Uplift Credits ($ Million)	$218.5	$660.6	202.3%
Total PJM Billing ($ Billion)	$39.07	$57.77	47.9%

PJM Market Background

The PJM Interconnection, L.L.C. (PJM) operates a centrally dispatched, competitive wholesale electric power market that, as of September 30, 2025, had installed generating capacity of 181,729 megawatts (MW) and 1,102 members including market buyers, sellers and traders of electricity in a region including more than 67 million people in 21 control zones and all or parts of 13 states (Delaware, Illinois, Indiana, Kentucky, Maryland, Michigan, New Jersey, North Carolina, Ohio, Pennsylvania, Tennessee, Virginia, West Virginia) and the District of Columbia (Figure 1-1).[5] [6] [7]

As part of the market operator function, PJM coordinates and directs the operation of the transmission grid and plans transmission expansion improvements to maintain grid reliability in this region.

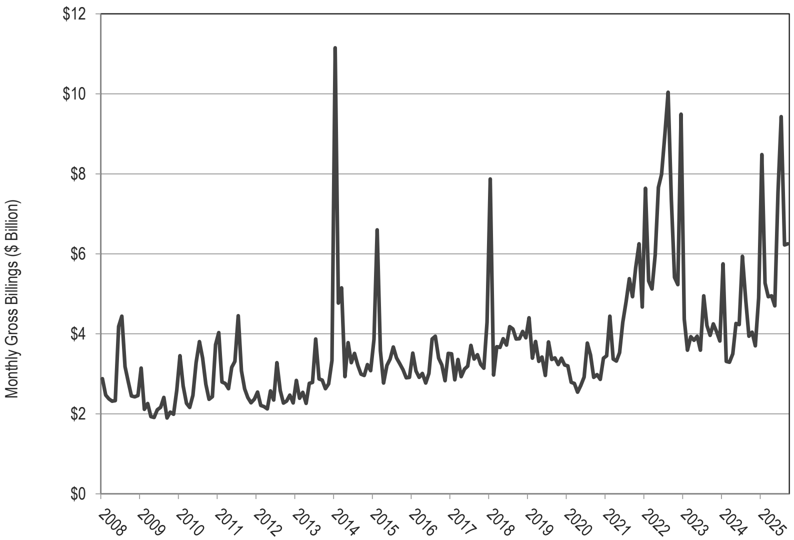
Figure 1-1 PJM's footprint and its 21 control zones



4 In Table 1-1, the MMU used the total PJM billing values provided by PJM through 2018. Starting in 2019, the total PJM billing values in Table 1-1 are modified by the MMU, to more accurately reflect PJM total billing. The total PJM billing shown in Table 1-1 is different from the total cost shown in Table 1-9. The total PJM billing in Table 1-1 represents the total dollars (charges) that pass through the PJM settlement process, while the total cost shown in Table 1-9 represents the portion of the total billing associated with the cost to load and includes additional costs to load accounted for outside the PJM settlement process.
5 See PJM. "Member List," which can be accessed at: <http://pjm.com/about-pjm/member-services/member-list.aspx>.
6 See PJM. "Who We Are," which can be accessed at: <http://pjm.com/about-pjm/who-we-are.aspx>.
7 See the *2024 Annual State of the Market Report for PJM*, Volume 2, Appendix A: "PJM Overview" for maps showing the PJM footprint and its evolution prior to 2024.

In the first nine months of 2025, PJM had gross billings of $57.77 billion, an increase of 47.9 percent from $39.07 billion in the first nine months of 2024. (Figure 1-2).

Figure 1-2 Monthly PJM billings ($ Billion): January 2008 through September 2025[8]



PJM operates the day-ahead energy market, the real-time energy market, the capacity market, the regulation market, the synchronized reserve market, the secondary reserve market and the financial transmission rights (FTRs) markets.

PJM introduced energy pricing with cost-based offers and market-clearing nodal prices on April 1, 1998, and market-clearing nodal prices with market-based offers on April 1, 1999. PJM introduced the Daily Capacity Market on January 1, 1999, and the Monthly and Multimonthly Capacity Markets for the January through May 1999 period. PJM implemented FTRs on May 1, 1999. PJM implemented the day-ahead energy market and the regulation market on June 1, 2000. PJM modified the regulation market design and added a market in Synchronized Reserve on December 1, 2002. PJM introduced an Auction Revenue Rights (ARR) allocation process and an associated Annual FTR Auction effective June 1, 2003. PJM introduced the RPM capacity market effective June 1, 2007. PJM implemented the DASR market on June 1, 2008, and eliminated it on October 1, 2022. PJM introduced the Capacity Performance capacity market design effective on August 10, 2015, with the Base Residual Auction for 2018/2019.[9] [10]

8 In Figure 1-2, the MMU used the total PJM billing values provided by PJM through 2018. Starting in 2019, the total PJM billing values in Figure 1-2 are modified by the MMU, to more accurately reflect PJM total billing. The total PJM billing shown in Figure 1-2 is different from the total cost shown in Table 1-9. The total PJM billing in Figure 1-2 represents the total dollars (charges) that pass through the PJM settlement process, while the total cost shown in Table 1-9 represents the portion of the total billing associated with the cost to load and includes additional costs to load accounted for outside the PJM settlement process.

9 See also the *2024 Annual State of the Market Report for PJM*, Appendix A: "PJM Overview."

10 Analysis of 2025 market results requires comparison to prior years. During calendar years 2004 and 2005, PJM conducted the phased integration of five control zones: COMED, American Electric Power (AEP), The Dayton Power & Light Company (DAY), Duquesne Light Company (DUQ) and Dominion (DOM). In June 2011, PJM integrated the American Transmission Systems, Inc. (ATSI) Control Zone. In January 2012, PJM integrated the Duke Energy Ohio/Kentucky (DUKE) Control Zone. In June 2013, PJM integrated the Eastern Kentucky Power Cooperative (EKPC). In December 2018, PJM integrated the Ohio Valley Electric Corporation (OVEC.) By convention, control zones bear the name of a large utility service provider working within their boundaries. The nomenclature applies to the geographic area, not to any single company. For additional information on the integrations, their timing and their impact on the footprint of the PJM service territory prior to 2025, see *2024 Annual State of the Market Report for PJM*, Appendix A: "PJM Overview."

Conclusions

This report assesses the competitiveness of the markets managed by PJM in the first nine months of 2025, including market structure, participant behavior and market performance. This report was prepared by and represents the analysis of the Independent Market Monitor for PJM, also referred to as the IMM, the Market Monitoring Unit or the MMU.

For each PJM market, the market structure is evaluated as competitive or not competitive, and participant behavior is evaluated as competitive or not competitive. Most important, the outcome of each market, market performance, is evaluated as competitive or not competitive.

The MMU also evaluates the market design for each market. The market design serves as the vehicle for translating participant behavior within the market structure into market performance. This report evaluates the effectiveness of the market design of each PJM market in providing market performance consistent with competitive results.

Market structure refers to the cost, demand, and ownership structure of the market. The three pivotal supplier (TPS) test is the most relevant measure of market structure because it accounts for the ownership of assets and the relationship among the pattern of ownership, the resource costs, and the market demand using actual market conditions with both temporal and geographic granularity. Market shares and the related Herfindahl-Hirschman Index (HHI) are also measures of market structure.

Participant behavior refers to the actions of individual market participants, also sometimes referred to as participant conduct.

Market performance refers to the outcomes of the market. Market performance results from the behavior of market participants within a market structure, mediated by market design.

Market design means the rules under which the entire relevant market operates, including the software that implements the market rules. Market rules include the definition of the product, the definition of short run marginal cost, rules governing offer behavior, market power mitigation rules, and the definition of demand. Market design is characterized as effective, mixed or flawed. An effective market design provides incentives for competitive behavior and permits competitive outcomes. A mixed market design has significant issues that constrain the potential for competitive behavior to result in competitive market outcomes, and does not have adequate rules to mitigate market power or incent competitive behavior. A flawed market design produces inefficient outcomes which cannot be corrected by competitive behavior.

Energy Market Conclusion

The Market Monitoring Unit (MMU) analyzed measures of market structure, participant conduct and market performance, including market size, concentration, pivotal suppliers, offer behavior, markup, and price. The MMU concludes that the PJM energy market results were competitive in the first nine months of 2025.

Table 1-2 The energy market results were competitive

Market Element	Evaluation	Market Design
Market Structure: Aggregate Market	Partially Competitive	
Market Structure: Local Market	Not Competitive	
Participant Behavior	Competitive	
Market Performance	Competitive	Effective

- The aggregate market structure was evaluated as partially competitive because the aggregate market power test based on pivotal suppliers indicates that the aggregate day-ahead market structure was not competitive on 94.1 percent of the days in the first nine months of 2025. The hourly HHI (Herfindahl-Hirschman Index) results indicate that the PJM aggregate energy market in the first nine months of 2025 was, on average, unconcentrated by FERC HHI standards. The average HHI was 686 with a minimum of 511 and a maximum of 988. The baseload segment of the supply curve was unconcentrated. The intermediate segment of the supply curve was unconcentrated on average. The peaking segment of the supply curve was highly concentrated. The fact that the average HHI is in the unconcentrated range does not mean that the aggregate market was competitive in all hours. As demonstrated for the day-ahead market, it is possible to have pivotal suppliers in the aggregate market even when the HHI level is not in the highly concentrated range. It is possible to have an exercise of market power even when the HHI level is not in the highly concentrated range. The number of pivotal suppliers in the energy market is a more precise measure of structural market power than the HHI. The HHI is not a definitive measure of structural market power.

- The local market structure was evaluated as not competitive due to the highly concentrated ownership of supply in local markets created by transmission constraints and local reliability issues. The results of the three pivotal supplier (TPS) test, used to test local market structure, indicate the existence of market power in local markets created by transmission constraints. The local market performance is competitive as a result of the application of the TPS test. Transmission constraints create the potential for the exercise of local market power. The goal of PJM's application of the three pivotal supplier test is to identify local market power and offer cap to competitive offers, correcting for structural issues created by local transmission constraints. There are, however, identified issues with the definition of cost-based offers and the application of market power mitigation to resources whose owners fail the TPS test that need to be addressed because unit owners can exercise market power even when they fail the TPS test.
- Participant behavior was evaluated as competitive because the analysis of markup shows that marginal units generally make offers at, or close to, their marginal costs in both the day-ahead and real-time energy markets, although the behavior of some participants both routinely and during periods of high demand represents economic withholding. The ownership of marginal units is concentrated. The markups of pivotal suppliers in the aggregate market and of many pivotal suppliers in local markets remain unmitigated due to the lack of aggregate market power mitigation and the flawed implementation of offer caps for resources that fail the TPS test. The markups of those participants affected LMP.
- Market performance was evaluated as competitive because market results in the energy market reflect the outcome of a competitive market, as PJM prices are set, on average, by marginal units operating at, or close to, their marginal costs in both day-ahead and real-time energy markets, although high markups for some marginal units did affect prices.
- Market design was evaluated as effective because the analysis shows that the PJM energy market resulted in competitive market outcomes. In general, PJM's energy market design provides incentives for competitive behavior and results in competitive outcomes. In local markets, where market power is an issue, the market design identifies market power and causes the market to provide competitive market outcomes in most cases although issues with the implementation of market power mitigation and development of cost-based offers remain. The role of UTCs in the day-ahead energy market continues to cause concerns. Market design implementation issues, including inaccuracies in modeling of the transmission system and of generator capabilities as well as inefficiencies in price formation, undermine market efficiency in the energy market. The implementation of fast start pricing on September 1, 2021, undermined market efficiency by setting inefficient prices that are inconsistent with the dispatch signals.

PJM markets are designed to promote competitive outcomes derived from the interaction of supply and demand in each of the PJM markets. Market design itself is the primary means of achieving and promoting competitive outcomes in PJM markets. One of the MMU's core functions is to identify actual or potential market design flaws.[11] The approach to market power mitigation in PJM has focused on market designs that promote competition (a structural basis for competitive outcomes) and on mitigating market power in instances where the market structure is not competitive and thus where market design alone cannot mitigate market power. FERC relies on effective market power mitigation when it approves market sellers to participate in the PJM market at market based rates.[12] In the PJM energy market, market power mitigation occurs primarily in the case of local market power. When a transmission constraint creates the potential for local market power, PJM applies a structural test to determine if the local market is competitive, applies a behavioral test to determine if generator offers exceed competitive levels and applies a market

11 OATT Attachment M (PJM Market Monitoring Plan).
12 See *Refinements to Horizontal Market Power Analysis for Sellers in Certain Regional Transmission Organization and Independent System Operator Markets*, Order No. 861, 168 FERC ¶ 61,040 (2019); *order on reh'g*, Order No. 861-A; 170 FERC ¶ 61,106 (2020).

performance test to determine if such generator offers would affect the market price.[13] There are, however, identified issues with the application of market power mitigation to resources whose owners fail the TPS test that can result in the exercise of local market power even when market power mitigation rules are applied. These issues need to be addressed, but, so far, PJM and FERC have failed to address them.[14] [15] [16] Some units with market power have positive markups and some have inflexible parameters, which means that the cost-based offer was not used and that the process for offer capping units that fail the TPS test does not consistently result in competitive market outcomes in the presence of market power. There are issues related to the definition of gas costs includable in energy offers that need to be addressed. There are issues related to the level of maintenance expense includable in energy offers that need to be addressed. There are currently no market power mitigation rules in place that limit the ability to exercise market power when aggregate market conditions are tight and there are pivotal suppliers in the aggregate market. Aggregate market power needs to be addressed. Market design must reflect appropriate incentives for competitive behavior, the application of local market power mitigation needs to be fixed, the definition of a competitive offer needs to be fixed, and aggregate market power mitigation rules need to be developed. The importance of these issues is amplified by the rules permitting cost-based offers in excess of $1,000 per MWh.

Capacity Market Conclusion

The Market Monitoring Unit (MMU) analyzed market design, market structure, participant conduct and market performance in the PJM Capacity Market, including supply, demand, concentration ratios, pivotal suppliers, volumes, prices, outage rates and reliability.[17] The conclusions are a result of the MMU's evaluation of the 2026/2027 Base Residual Auction.[18] [19] [20] [21] [22] [23] [24] [25]

Table 1-3 The capacity market results were not competitive

Market Element	Evaluation	Market Design
Market Structure: Aggregate Market	Not Competitive	
Market Structure: Local Market	Not Competitive	
Participant Behavior	Not Competitive	
Market Performance	**Not Competitive**	**Mixed**

- The aggregate market structure was evaluated as not competitive. For almost all auctions held from 2007 to the present, the PJM capacity market failed the three pivotal supplier test (TPS), which is conducted at the time of the auction.[26] Structural market power is endemic to the capacity market.
- The local market structure was evaluated as not competitive. For almost every auction held, all LDAs have failed the TPS test, which is conducted at the time of the auction.[27]
- Participant behavior was evaluated as not competitive in the 2026/2027 BRA. Effective with the 2026/2027 Delivery Year, the market seller offer cap definition was modified to include unit specific standalone Capacity

13 The market performance test means that offer capping is not applied if the offer does not exceed the competitive level and therefore market power would not affect market performance.
14 175 FERC ¶ 61,231 (2021).
15 185 FERC ¶ 61,158 (2023).
16 189 FERC ¶ 61,060 (2024).

17 The values stated in this report for the RTO and LDAs refer to the aggregate level including all nested LDAs unless otherwise specified. For example, RTO values include the entire PJM market and all LDAs. Rest of RTO values are RTO values net of nested LDA values.

24 See "Analysis of the 2025/2026 RPM Base Residual Auction - Part G Revised," (June 3, 2025) <https://www.monitoringanalytics.com/reports/Reports/2025/IMM_Analysis_of_the_20252026_RPM_Base_Residual_Auction_Part_G_20250603_Revised.pdf>.
25 See "Analysis of the 2026/2027 RPM Base Residual Auction - Part A," (October 1, 2025) <https://www.monitoringanalytics.com/reports/Reports/2025/IMM_Analysis_of_the_20262027_RPM_Base_Residual_Auction_Part_A_20251001.pdf>.
26 In the 2008/2009 RPM Third Incremental Auction, 18 participants in the RTO market passed the TPS test. In the 2018/2019 RPM Second Incremental Auction, 35 participants in the RTO market passed the test. In the 2023/2024 RPM Third Incremental Auction, 36 participants in the RTO passed the TPS test.
27 In the 2012/2013 RPM Base Residual Auction, six participants included in the incremental supply of EMAAC passed the TPS test. In the 2014/2015 RPM Base Residual Auction, seven participants in the incremental supply in MAAC passed the TPS test. In the 2021/2022 RPM First Incremental Auction, two participants in the incremental supply in EMAAC passed the TPS test. In the 2021/2022 RPM Second Incremental Auction, two participants in the incremental supply in EMAAC passed the TPS test. In the 2023/2024 RPM Third Incremental Auction, eight participants in MAAC passed the TPS test.

Performance Quantifiable Risk (CPQR) and segmented unit specific offer caps.[28] The offers in the 2026/2027 BRA included those based on standalone CPQR offer caps. Market power mitigation measures were applied when the capacity market seller failed the market power test for the auction, the submitted sell offer exceeded the defined offer cap, and the submitted sell offer, absent mitigation, would increase the market clearing price.

- Market performance was evaluated as not competitive based on the 2026/2027 Base Residual Auction as a result of the flaws in the Effective Load Carrying Capability (ELCC) design including the failure to correctly define the reliability contribution of thermal resources in the winter, and the failure to recognize and address the role of large data center loads is a direct cause of higher prices and will continue to result in even higher prices unless the related issues are addressed.
- Market design was evaluated as mixed because while there are many positive features of the capacity market design and some of the MMU's recommendations were implemented in the 2026/2027 BRA, there are several features of the RPM design which still threaten competitive outcomes. These include the lack of a queue for the addition of large new data center loads, details of PJM's ELCC implementation, the definition of market seller offer caps, the failure to apply the RPM must offer requirement to demand resources, the inclusion of performance assessment interval (PAI) penalties, the use of gross CONE as the maximum price on the VRR curve, the definition of DR which permits inferior products to substitute for capacity, the replacement capacity issue, the definition of unit offer parameters, and the inclusion of imports which are not substitutes for internal capacity resources.[29]

28 190 FERC ¶ 61,117 (2025).

29 While PJM filed for and FERC accepted the inclusion of RMR resources Brandon Shores and Wagner plants in the 2026/2027 BRA and 2027/2028 BRA, that does not require that RMR resources be included in capacity market auction clearing in future auctions for these or other RMR resources. See Letter Order, FERC Docket No. ER25-682-001 (April 29, 2025).

Synchronized Reserve Market Conclusion

- The MMU analyzed measures of market structure, conduct and performance for the PJM Synchronized Reserve Market for the first nine months of 2025.

Table 1-4 The synchronized reserve market results were not competitive

Market Element	Evaluation	Market Design
Market Structure: Regional Markets	Not Competitive	
Participant Behavior	Competitive	
Market Performance	**Not Competitive**	**Flawed**

- The synchronized reserve market structure was evaluated as not competitive due to supplier concentration. The RTO Reserve Zone was unconcentrated in the day-ahead market and unconcentrated in the real-time market. The MAD Reserve Subzone was moderately concentrated in the day-ahead market and moderately concentrated in the real-time market.
- Participant behavior was evaluated as competitive because the market rules require all available reserves to offer at cost-based offers.
- Market performance was evaluated as not competitive because the interaction of participant behavior with the market design does not result in competitive prices as a result of PJM's changes to the operating reserve demand curve (ORDC). In an attempt to counter poor unit specific synchronized reserve performance, PJM unilaterally and inappropriately extended the first step of the ORDC for synchronized reserve, known as the synchronized reserve reliability requirement, in May 2023, raising prices for synchronized reserves, nonsynchronized reserves and energy.
- Market design was evaluated as flawed based on PJM's modifications to the ORDC. PJM previously adopted reforms, including several based on MMU recommendations, removing both physical and economic withholding from the market.
- Significant communications technology issues when calling resources during synchronized reserve events have resulted in slow response from resources. On December 17, 2024, PJM implemented an electronic

deployment of reserves via an augmented dispatch signal, but PJM does not require that resources be able to receive this signal.

Nonsynchronized Reserve Market Conclusion

The MMU analyzed measures of market structure, conduct and performance for the PJM Nonsynchronized Reserve Market for the first nine months of 2025.

Table 1-5 The nonsynchronized reserve market results were not competitive

Market Element	Evaluation	Market Design
Market Structure: Regional Markets	Not Competitive	
Participant Behavior	Competitive	
Market Performance	**Not Competitive**	**Flawed**

- The nonsynchronized reserve market structure was evaluated as not competitive due to supplier concentration for primary reserve. The RTO Reserve Zone was unconcentrated in the day-ahead market and unconcentrated in the real-time market. The MAD Reserve Subzone was moderately concentrated in the day-ahead market and moderately concentrated in the real-time market.
- Participant behavior was evaluated as competitive because all available reserves are included by the PJM markets software, so withholding is not possible.
- Market performance was evaluated as not competitive because the interaction of participant behavior with the market design does not result in competitive prices as a result of PJM's changes to the operating reserve demand curve (ORDC). In an attempt to counter poor unit specific synchronized reserve performance, PJM unilaterally and inappropriately extended the first step of the ORDC for synchronized reserve, known as the synchronized reserve reliability requirement, in May 2023. Because the first step of the ORDC for primary reserve, known as the primary reserve reliability requirement, is based on the synchronized reserve reliability requirement, the primary reserve reliability requirement was consequently also extended, raising prices for synchronized reserves, nonsynchronized reserves, and energy.
- Market design was evaluated as flawed based on PJM's modifications to the first step of the ORDC.

Secondary Reserve Market Conclusion

The MMU analyzed measures of market structure, conduct and performance for the PJM Secondary Reserve Market for the first nine months of 2025.

Table 1-6 The secondary reserve market results were competitive

Market Element	Evaluation	Market Design
Market Structure	Competitive	
Participant Behavior	Competitive	
Market Performance	**Competitive**	**Effective**

- The secondary reserve market structure was evaluated as competitive due to the lack of supplier concentration for 30-minute reserve. The RTO Reserve Zone was unconcentrated in the day-ahead market and unconcentrated in the real-time market.
- Participant behavior was evaluated as competitive because all available reserves are included by the PJM software, so withholding is not possible.
- Market performance was evaluated as competitive because the combination of a competitive market structure and competitive participation resulted in competitive market outcomes.
- The market design was evaluated as effective because the market rules ensure competitive market offers and require repayment of offline cleared secondary reserves that are not available when called on to provide energy in 30 minutes.

Regulation Market Conclusion

The MMU analyzed measures of market structure, conduct and performance for the PJM Regulation Market for the first nine months of 2025.

Table 1-7 The regulation market results were not competitive

Market Element	Evaluation	Market Design
Market Structure	Not Competitive	
Participant Behavior	Competitive	
Market Performance	**Not Competitive**	**Flawed**

- The regulation market structure was evaluated as not competitive because the PJM Regulation Market failed the three pivotal supplier (TPS) test in 94.2 percent of the hours in the first nine months of 2025.
- Participant behavior in the PJM Regulation Market was evaluated as competitive in the first nine months of 2025 because market power mitigation requires competitive offers when the three pivotal supplier test is failed, although the inclusion of a positive margin is not consistent with competitive offers.
- Market performance was evaluated as not competitive, because all units are not paid the same price on an equivalent MW basis.
- Market design was evaluated as flawed. The market design has failed to correctly incorporate a consistent implementation of the marginal benefit factor in optimization, pricing and settlement. The market results continue to include the incorrect definition of opportunity cost. The result is significantly flawed market signals to existing and prospective suppliers of regulation.

FTR Auction Market Conclusion

The *2025 Quarterly State of the Market Report for PJM: January through September* focuses on the 2024/2025 planning period as well as the 2025/2026 Long Term and Annual FTR auctions and ARR allocation, specifically covering June 1, 2024, through September 30, 2025. The Market Monitoring Unit (MMU) analyzed measures of market structure, participant conduct and market performance, including market size, concentration, offer behavior, and price. The MMU concludes that the PJM FTR auction market results were partially competitive in the first nine months of 2025.

Table 1-8 The FTR auction markets results were partially competitive

Market Element	Evaluation	Market Design
Market Structure	Competitive	
Participant Behavior	Partially Competitive	
Market Performance	**Partially Competitive**	**Flawed**

- Market structure was evaluated as competitive. The ownership of FTR obligations is unconcentrated for the individual years of the 2025/2028 Long Term FTR Auction, the 2025/2026 Annual FTR Auction and each period of the Monthly Balance of Planning Period Auctions for prevailing flow FTRs. The ownership of FTR obligations is unconcentrated or moderately concentrated for each period of the Monthly Balance of Planning Period Auctions for counter flow FTRs. The ownership of FTR options is moderately or highly concentrated for every Monthly FTR Auction period and unconcentrated for the 2025/2026 Annual FTR Auction. Ownership of current FTRs is disproportionately (88.7 percent) by financial participants. The ownership of ARRs is unconcentrated.
- Participant behavior was evaluated as partially competitive because ARR holders who are the sellers of FTRs have no option to set an acceptable sale price and are not permitted to participate in the market clearing in any way and are not assured they will receive 100 percent of auction revenues.
- Market performance was evaluated as partially competitive because of the significant and persistent flaws in the market design. Sellers, the ARR holders, cannot set a sale price. Buyers can reclaim some of their purchase price after the market clears if the product does not meet a profitability target. The market resulted in a substantial shortfall in congestion payments to load and significant and unsupportable disparities among zones in the share of congestion returned to load. FTR purchases by financial entities remain persistently profitable in part as a result of the flaws in the market design.

- Market design was evaluated as flawed because there are significant, fundamental and persistent flaws in the basic ARR/FTR design. The FTR auction market is not actually a market because the sellers have no independent role in the process. ARR holders cannot determine the price at which they are willing to sell rights to congestion revenue. Buyers have the ability to reclaim some of the price paid for FTRs after the market clears and, as a result, sellers are not assured they will receive 100 percent of auction revenues. The market design is not an efficient or effective way to ensure that the rights to all congestion revenues are assigned to load. The product sold to FTR buyers is incorrectly defined as target allocations rather than a share of congestion revenue. ARR holders' rights to congestion revenues are not correctly defined because the contract path based assignment of congestion rights is inadequate and incorrect. The ongoing PJM subjective intervention in the FTR market that affects market fundamentals is also an issue and a symptom of the fundamental flaws in the design. The product, the quantity of the product and the price of the product are all incorrectly defined.
- The fact that load is not able to define its willingness to sell FTRs or to set the prices at which it is willing to sell FTRs and the fact that load is required to return some of the cleared auction revenue to FTR buyers when FTR profits are deemed to be not adequate, means that the FTR design does not actually function as a market and is evidence of basic flaws in the market design.

Role of MMU

FERC assigns three core functions to MMUs: reporting, monitoring and market design.[30] These functions are interrelated and overlap. The PJM Market Monitoring Plan establishes these functions, providing that the MMU is responsible for monitoring: compliance with the PJM Market Rules; actual or potential design flaws in the PJM Market Rules; structural problems in the PJM Markets that may inhibit a robust and competitive market; the actual or potential exercise of market power or violation of the market rules by a Market Participant; PJM's implementation of the PJM Market Rules or operation of the PJM Markets; and such matters as are necessary to prepare reports.[31]

Reporting

The MMU performs its reporting function primarily by issuing and filing annual and quarterly state of the market reports; regular reports on market issues, such as RPM auction reports; reports responding to requests from regulators and other authorities; and ad hoc reports on specific topics. The state of the market reports provide a comprehensive analysis of market structure, participant conduct and market performance for the PJM markets. State of the market reports and other reports are intended to inform PJM, the PJM Board, FERC, other regulators, other authorities, market participants, stakeholders and the general public about how well PJM markets achieve the competitive outcomes necessary to realize the goals of regulation through competition, and how the markets can be improved.

The MMU presents reports directly to PJM stakeholders, PJM staff, FERC staff, state commission staff, state commissions, other regulatory agencies and the general public. Report presentations provide an opportunity for interested parties to ask questions, discuss issues, and provide feedback to the MMU.

Monitoring

To perform its monitoring function, the MMU screens and monitors the conduct of Market Participants under the MMU's broad purview to monitor,

30 18 CFR § 35.28(g)(3)(ii); see also *Wholesale Competition in Regions with Organized Electric Markets*, Order No. 719, FERC Stats. & Regs. ¶31,281 (2008) ("Order No. 719"), *order on reh'g*, Order No. 719-A, FERC Stats. & Regs. ¶31,292 (2009), *reh'g denied*, Order No. 719-B, 129 FERC ¶ 61,252 (2009).
31 OATT Attachment M § IV; 18 CFR § 1c.2.

investigate, evaluate and report on the PJM Markets.[32] The MMU has direct, confidential access to FERC.[33] The MMU may also refer matters to the attention of state commissions.[34]

The MMU monitors market behavior for violations of FERC Market Rules and PJM Market Rules, including the actual or potential exercise of market power.[35] The MMU will investigate and refer "Market Violations," which refer to any of "a tariff violation, violation of a Commission-approved order, rule or regulation, market manipulation, or inappropriate dispatch that creates substantial concerns regarding unnecessary market inefficiencies…"[36] [37] [38] The MMU also monitors PJM for compliance with the rules, in addition to market participants.[39]

An important component of the monitoring function is the review of inputs to mitigation. The actual or potential exercise of market power is addressed in part through *ex ante* mitigation rules incorporated in PJM's market clearing software for the energy market, the capacity market and the regulation market. If a market participant fails the TPS test in any of these markets its offer is set to the lower of its price-based or cost-based offer. This prevents the exercise of market power and ensures competitive pricing, provided that the cost-based offer accurately reflects short run marginal cost.

32 OATT Attachment M § IV.
33 OATT Attachment M § IV.K.3.
34 OATT Attachment M § IV.H.
35 OATT § I.1 ("FERC Market Rules" mean the market behavior rules and the prohibition against electric energy market manipulation codified by the Commission in its Rules and Regulations at 18 CFR §§ 1c.2 and 35.37, respectively; the Commission-approved PJM Market Rules and any related proscriptions or any successor rules that the Commission from time to time may issue, approve or otherwise establish… "PJM Market Rules" mean the rules, standards, procedures, and practices of the PJM Markets set forth in the PJM Tariff, the PJM Operating Agreement, the PJM Reliability Assurance Agreement, the PJM Consolidated Transmission Owners Agreement, the PJM Manuals, the PJM Regional Practices Document, the PJM-Midwest Independent Transmission System Operator Joint Operating Agreement or any other document setting forth market rules.")
36 FERC defines manipulation as engaging "in any act, practice, or course of business that operates or would operate as a fraud or deceit upon any entity." 18 CFR § 1c.2(a)(3). Manipulation may involve behavior that is consistent with the letter of the rules, but violates their spirit. An example is market behavior that is economically meaningless, such as equal and opposite transactions, which may entitle the transacting party to a benefit associated with volume. Unlike market power or rule violations, manipulation must be intentional. The MMU must build its case, including an inference of intent, on the basis of market data.
37 OATT § I.1.
38 The MMU has no prosecutorial or enforcement authority. The MMU notifies FERC when it identifies a significant market problem or market violation. OATT Attachment M § IV.I.1. If the problem or violation involves a market participant, the MMU discusses the matter with the participant(s) involved and analyzes relevant market data. If that investigation produces sufficient credible evidence of a violation, the MMU prepares a formal referral and thereafter undertakes additional investigation of the specific matter only at the direction of FERC staff. *Id.* If the problem involves an existing or proposed law, rule or practice that exposes PJM markets to the risk that market power or market manipulation could compromise the integrity of the markets, the MMU explains the issue, as appropriate, to FERC, state regulators, stakeholders or other authorities. The MMU may also initiate, participate as a party or provide information or testimony in regulatory or other proceedings.
39 OATT Attachment M § IV.C.

If cost-based offers do not accurately reflect short run marginal cost, the market power mitigation process does not ensure competitive pricing in PJM markets. The MMU evaluates the fuel cost policy for every unit as well as the other inputs to cost-based offers. PJM Manual 15 does not clearly or accurately describe the short run marginal cost of generation. Manual 15 should be replaced with a straightforward description of the components of cost offers based on short run marginal costs and the correct calculation of cost offers. The MMU evaluates every offer cap in each capacity market (RPM) auction using data submitted to the MMU through web-based data input systems developed by the MMU.[40]

The MMU also reviews operational parameter limits included with unit offers, evaluates compliance with the requirement to offer into the energy and capacity markets, evaluates the economic basis for unit retirement requests and evaluates and compares offers in the day-ahead and real-time energy markets.[41] [42] [43] [44]

The MMU reviews offers and inputs in order to evaluate whether those offers raise market power concerns. Market participants, not the MMU, determine and take responsibility for offers that they submit and the market conduct that those offers represent. If the MMU has a concern about an offer, the MMU may raise that concern with FERC or other regulatory authorities. FERC and other regulators have enforcement and regulatory authority that they may exercise with respect to offers submitted by market participants. PJM also reviews offers, but it does so in order to determine whether offers comply with the PJM tariff and manuals. PJM, in its role as the market operator, may reject an offer that fails to comply with the market rules. The respective reviews performed by the MMU and PJM are separate and non-sequential.

The PJM markets monitored by the MMU include market related procurement processes conducted by PJM, such as for Black Start resources included in the PJM system restoration plan.[45] [46]

40 OATT Attachment M–Appendix § II.E.
41 OATT Attachment M–Appendix § II.B.
42 OATT Attachment M–Appendix § II.C.
43 OATT Attachment M–Appendix § IV.
44 OATT Attachment M–Appendix § VII.
45 OATT Attachment M–Appendix § II(p).
46 OATT Attachment M–Appendix § III.

The MMU also monitors transmission planning, interconnections and rules for vertical market power issues, and with the introduction of competitive transmission development policy in Order No. 1000, horizontal market power issues.[47]

Market Design

In order to perform its role in PJM market design, the MMU evaluates existing and proposed PJM Market Rules and the design of the PJM Markets.[48] The MMU initiates and proposes changes to the design of such markets or the PJM Market Rules in stakeholder or regulatory proceedings.[49] In support of this function, the MMU engages in discussions with stakeholders, State Commissions, PJM Management, and the PJM Board; participates in PJM stakeholder meetings or working groups regarding market design matters; publishes proposals, reports or studies on such market design issues; and makes filings with the Commission on market design, market rules and market rule implementation issues, including complaints or petitions.[50] The MMU also recommends changes to the PJM Market Rules to the staff of the Commission's Office of Energy Market Regulation, State Commissions, and the PJM Board.[51] The MMU may provide in its annual, quarterly and other reports "recommendations regarding any matter within its purview."[52]

New Recommendations

Consistent with its core function to "[e]valuate existing and proposed market rules, tariff provisions and market design elements and recommend proposed rule and tariff changes," the MMU recommends specific enhancements to existing market rules and implementation of new rules that are required for competitive results in PJM markets and for continued improvements in the functioning of PJM markets.[53]

In this *2025 Quarterly State of the Market Report for PJM: January through September*, the MMU includes three new recommendations.

New Recommendations from Section 6, Demand Response

- The MMU recommends that DER aggregations that clear in a capacity auction not be permitted to change status from homogeneous demand response to any other status for any additional auctions for the same delivery year, or for the delivery year. (Priority: High. New recommendation. Status: Not adopted.)
- The MMU recommends that PRD be required to respond during a PAI, regardless of whether the real-time LMP at the applicable location meet or exceeds the PRD strike price, to be consistent with all CP resources. (Priority: Medium. New recommendation. Status: Not adopted.)

New Recommendation from Section 13, Financial Transmission Rights and Auction Revenue Rights

- The MMU recommends that PJM's minimum credit requirements be reviewed and updated to appropriately reflect the risk created for the markets and other market participants. The PJM minimum credit requirements (minimum tangible net worth and minimum tangible assets) were set as fixed dollars amounts in 2011 in FERC order 741 based on the specific market participation (FTRs or other). (Priority: Medium. New recommendation. Status: Not adopted.)

53 18 CFR § 35.28(g)(3)(ii)(A); see also OATT Attachment M § IV.D.

Total Cost of Wholesale Power

The total cost of wholesale power is the average total cost per MWh of wholesale electricity in PJM markets.[54] The costs of each component and subcomponent may vary by location and time period. The total costs are the sum of the total charges for the individual billing line items in each category divided by real time load, even when a specific category is not charged on that basis. The total cost of wholesale power and the components of that cost are presented for informational purposes and should not be used to calculate the costs of any specific market activity in PJM. The total cost includes the cost of energy, capacity, transmission service, ancillary services, and administrative fees billed through PJM systems. Table 1-9 shows the total cost, by component, for the first nine months of 2024 and 2025.

The total costs shown in Table 1-9 equal the total cost per MWh, by category, multiplied by the total real time load. The total costs are different from the total billing values that PJM reports as shown in Figure 1-2. PJM's reported total billing values represent the total dollars (charges) that pass through the PJM settlement process.

Each of the components in Table 1-9 is defined in PJM's Open Access Transmission Tariff (OATT) and PJM Operating Agreement and each is collected through PJM's settlement process.[55]

Table 1-9 shows that energy, capacity and transmission charges are the three largest components of the total cost per MWh of wholesale power, comprising 97.9 percent of the total cost per MWh in the first nine months of 2025. The total cost of energy per MWh increased by $15.91 from $32.69 in the first nine months of 2024 to $48.60 in the first nine months of 2025, an increase of 48.7 percent. The total cost of capacity per MWh increased by $7.13 from $3.55 in the first nine months of 2024 to $10.69 in the first nine months of 2025, an increase of 200.8 percent. The total cost of transmission per MWh increased by $0.94 from $17.37 in the first nine months of 2024 to $18.31 in the first nine months of 2025, an increase of 5.4 percent. The total cost per MWh of wholesale power increased by $24.10 from $55.18 in the first nine months of 2024 to $79.28 in the first nine months of 2025, an increase of 43.7 percent.

54 Accounting load is used in the calculation of total price because accounting load is the load customers pay for in PJM settlements. The use of accounting load with losses before June 1, 2007 and without losses after June 1, 2007, is consistent with PJM's calculation of LMP. Before June 1, 2007, transmission losses were included in accounting load. After June 1, 2007, transmission losses were excluded from accounting load and losses were addressed through the inclusion of marginal loss pricing in LMP.
55 For more information on the calculation of the total cost of wholesale power, see Monitoring Analytics, "*Total Cost of Wholesale Power Calculation Documentation*," <https://www.monitoringanalytics.com/data/docs/Total_Cost_of_Wholesale_Power_Calculation.pdf>.

Table 1-9 Total cost per MWh by category: January through September, 2024 and 2025[56][57][58]

Category	2024 (Jan-Sep) $/MWh	2024 (Jan-Sep) ($ Millions)	2024 (Jan-Sep) Percent of Total	2025 (Jan-Sep) $/MWh	2025 (Jan-Sep) ($ Millions)	2025 (Jan-Sep) Percent of Total	Percent Change
Energy	$32.69	$19,541	59.2%	$48.60	$29,826	61.3%	48.7%
Day Ahead Energy	$33.47	$20,005	60.6%	$49.31	$30,263	62.2%	47.3%
Balancing Energy	$0.61	$365	1.1%	$1.06	$650	1.3%	73.5%
ARR Credits	($1.23)	($734)	(2.2%)	($1.63)	($1,001)	(2.1%)	32.8%
Self Scheduled FTR Credits	($0.53)	($319)	(1.0%)	($1.29)	($792)	(1.6%)	141.5%

Administration	$0.66	$393	1.2%	$0.65	$402	0.8%	(0.5%)
PJM Administrative Fees	$0.61	$364	1.1%	$0.61	$373	0.8%	(0.1%)
NERC/RFC	$0.04	$25	0.1%	$0.04	$26	0.1%	1.0%
RTO Startup and Expansion	$0.00	$0	0.0%	$0.00	$0	0.0%	0.0%
Other	$0.01	$5	0.0%	$0.00	$3	0.0%	(41.8%)
Total Price	$55.18	$32,987	100.0%	$79.28	$48,655	100.0%	43.7%
Total Day Ahead Load (GWh)	591,116			605,190			2.4%
Total Balancing Load (GWh)	(6,667)			(8,528)			27.9%
Total Real Time Load (GWh)	597,782			613,718			2.7%
Total Cost ($ Billions)	$32.99			$48.65			47.5%

56 Note: The totals in this table include after the fact billing adjustments and may not match totals presented in past reports.
57 The total cost in this table does not match the PJM reported total billing due to differences in calculation methods. The total prices in this table are load-weighted average system prices per MWh by category, even if each category is not charged on a per MWh basis. PJM's reported total billing represents the total dollars (charges) that pass through the PJM settlement process.
58 The MMU publishes monthly detail of the total cost of wholesale power. See <http://www.monitoringanalytics.com/data/pjm_price.shtml>.

Table 1-10 shows the inflation adjusted average cost, by component, for the first nine months of 2024 and 2025. To calculate the inflation adjusted average costs, the individual components' costs are deflated using the US Consumer Price Index for all items, Urban Consumers (with a base period of January 1998).[59]

Table 1-10 Inflation adjusted total cost per MWh by category: January through September, 2024 and 2025[60 61]

Category	2024 (Jan-Sep) $/MWh	2024 (Jan-Sep) ($ Millions)	2024 (Jan-Sep) Percent of Total	2025 (Jan-Sep) $/MWh	2025 (Jan-Sep) ($ Millions)	2025 (Jan-Sep) Percent of Total	Percent Change

59 US Consumer Price Index for all items, Urban Consumers (base period: January 1998), published by *Bureau of Labor Statistics*. <http://download.bls.gov/pub/time.series/cu/cu.data.1.AllItems> (October 24, 2025).
60 The totals in the Transmission section of this table include corrections to previously reported totals which did not include a full accounting of Transmission Enhancement Cost Recovery costs.
61 Note: The totals in this table include after the fact billing adjustments and may not match totals presented in past reports.

Figure 1-3 shows the total cost of wholesale power in the first nine months of 2024 and 2025.

Figure 1-3 Total cost per MWh by category: January through September, 2024 and 2025

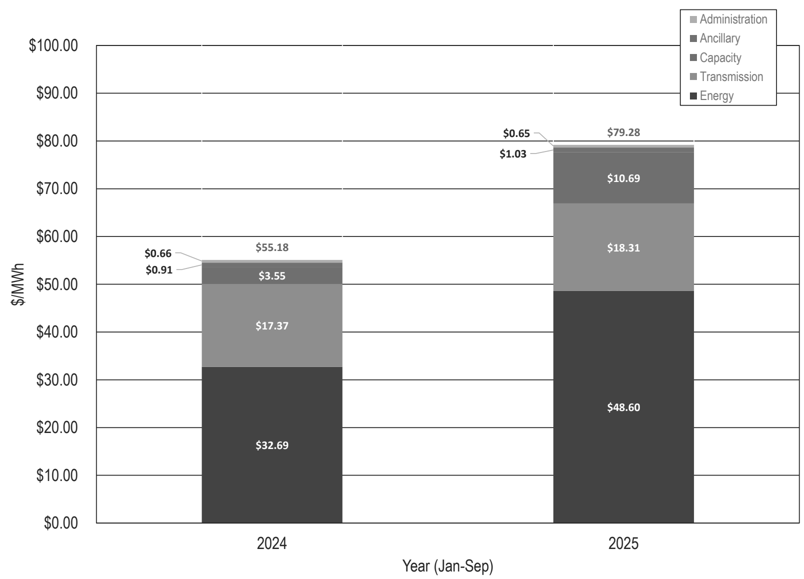

Figure 1-4 shows the contributions of the energy, capacity and transmission service components of the total cost of wholesale power for each quarter since 2001. In the third quarter of 2019, the cost of transmission per MWh of wholesale power exceeded the cost of capacity for the first time. In the third quarter of 2025, significant increases in capacity market prices resulted in the cost of capacity per MWh of wholesale power increasing above the cost of transmission.

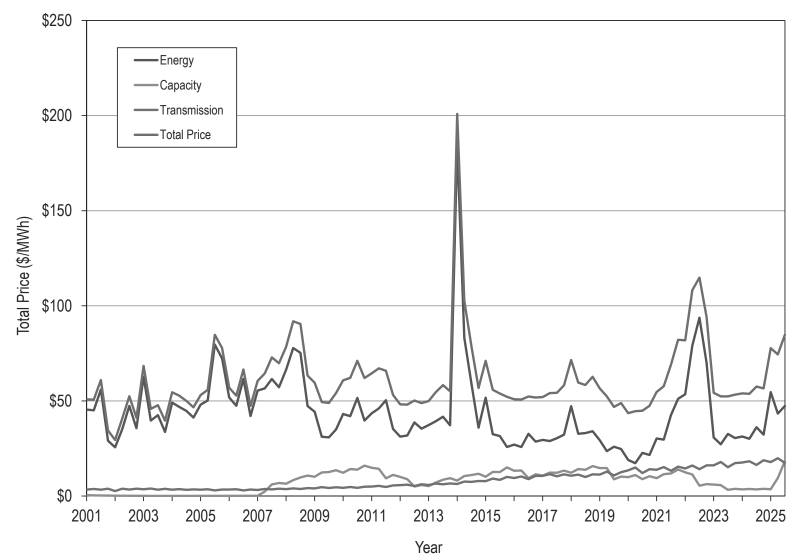
Figure 1-4 Top three components of quarterly total cost ($/MWh): January 2001 through September 2025[62]



62 Note: The totals presented in this figure include after the fact billing adjustments and may not match totals presented in past reports.

Table 1-11 shows the total cost, by component of the total wholesale power cost per MWh, for calendar years 2001 through 2024.

Section Overviews

Overview: Section 3, Energy Market

Supply and Demand

Market Structure

- **Supply.** In the first nine months of 2025, 2,756 MW of new resources were added in the energy market, and 982 MW of resources were retired.
- The real-time hourly on peak average offered supply in the first nine months of 2025 increased by 1.4 percent, from the first nine months of 2024, from 140,934 MWh to 142,851 MWh.
- The day-ahead hourly average offered supply in the first nine months of 2025 decreased by 1.5 percent, from the first nine months of 2024, from 153,603 MWh to 151,275 MWh.
- The real-time hourly average cleared generation in the first nine months of 2025 increased by 3.3 percent from the first nine months of 2024, from 96,954 MWh to 100,136 MWh.
- The day-ahead hourly average cleared supply in the first nine months of 2025, including INCs and UTCs, increased by 1.9 percent from the first nine months of 2024 from 112,192 MWh to 114,328 MWh.
- **Demand.** The real-time hourly peak load without exports in the first nine months of 2025 was 156,256 MWh (158,789 MWh with net exports) in the HE 1800 (EPT) on June 23, 2025, higher than the PJM peak load in the first nine months of 2024, which was 144,245 MWh (149,398 MWh with net exports) in the HE 1800 (EPT) on June 21, 2024.
- The real-time hourly average load in the first nine months of 2025 increased by 3.0 percent from the first nine months of 2024, from 90,917 MWh to 93,683 MWh.
- The day-ahead hourly average cleared demand in the first nine months of 2025, including DECs and UTCs, increased by 1.4 percent from the first nine months of 2024, from 106,355 MWh to 107,864 MWh.

Market Behavior

- **Virtual Offers and Bids.** Any market participant in the PJM Day-Ahead Energy Market can use increment offers, decrement bids, up to congestion transactions, import transactions and export transactions as financial instruments that do not require physical generation or load. The hourly average submitted increment offer MW increased by 4.6 percent and the cleared increment MW increased by 8.4 percent in the first nine months of 2025 compared to the first nine months of 2024. The hourly average submitted decrement bid MW increased by 17.7 percent and the cleared decrement MW decreased by 2.6 percent in the first nine months of 2025 compared to the first nine months of 2024. The hourly average submitted up to congestion bid MW decreased by 2.1 percent and the cleared up to congestion bid MW decreased by 8.2 percent in the first nine months of 2025 compared to the first nine months of 2024.

Market Performance

- **Generation Fuel Mix.** In the first nine months of 2025, generation from coal units increased 16.1 percent, generation from natural gas units decreased 1.6 percent, generation from oil units increased 25.8 percent, generation from wind units increased 1.8 percent, and generation from solar units increased 46.4 percent compared to the first nine months of 2024.
- **Fuel Diversity.** The fuel diversity of energy generation in the first nine months of 2025, measured by the fuel diversity index for energy (FDI_e), increased 2.5 percent compared to the first nine months of 2024.
- **Marginal Resources.** In the PJM Real-Time Energy Market in the first nine months of 2025, coal units were 7.6 percent, natural gas units were 77.9 percent and wind units were 10.3 percent of marginal resources. In the first nine months of 2024, coal units were 11.0 percent, natural gas units were 74.8 and wind units were 11.9 percent of marginal resources.
- **Prices.** The real-time load-weighted average LMP in the first nine months of 2025 increased $16.20 per MWh, or 47.2 percent from the first nine months of 2024, from $34.31 per MWh to $50.51 per MWh.

- The day-ahead load-weighted average LMP for the first nine months of 2025 increased $16.03 or 47.4 percent from the first nine months of 2024, from $33.85 per MWh to $49.88 per MWh.
- **Fast Start Pricing.** The real-time load-weighted average PLMP was $50.51 per MWh for the first nine months of 2025, which is 9.0 percent, $4.17 per MWh, higher than the real-time load-weighted average DLMP of $46.34 per MWh.
- **Components of Real-Time LMP.** In the PJM Real-Time Energy Market in the first nine months of 2025, 7.2 percent of the real-time load-weighted LMP was the result of coal costs, 43.4 percent was the result of gas costs, 4.3 percent was the result of the cost of emission allowances, and 10.5 percent was the result of transmission constraint violation penalty factors.
- **Components of Day-Ahead LMP.** In the PJM Day-Ahead Energy Market in the six months between April and September of 2025, 7.2 percent of the day-ahead load-weighted LMP was the result of coal costs, 12.2 percent was the result of gas costs, 33.2 percent was the result of the decrement bids, and 18.5 percent was the result of increment offers.
- **Changes in Real-Time LMP.** Of the $16.20 per MWh increase in the real-time load-weighted average LMP, $9.85 per MWh (60.8 percent) was the fuel and consumables cost components of LMP, -$0.16 per MWh (-1.0 percent) was the emissions cost components of LMP, $0.85 per MWh (5.2 percent) was the sum of the markup, maintenance, and ten percent adder components of LMP, $2.07 per MWh (12.8 percent) was the transmission constraint penalty factor component of LMP, and $1.14 per MWh (7.0 percent) was the scarcity component of LMP. The pre-emergency demand response called on by PJM during the hot weather days in June and July increased the LMP by $0.89 per MWh, 5.5 percent of the increase in LMP. The LMP increase would have been higher if PJM had not imposed a $3,700.00 per MWh administrative cap. The administrative cap reduced the LMP by $0.11 per MWh, a 0.7 percent decrease.
- **Price Convergence.** Hourly and daily price differences between the day-ahead and real-time energy markets fluctuate continuously and substantially from positive to negative. The average difference between day-ahead and real-time average prices was $0.38 per MWh in the first nine months of 2025, and $0.41 per MWh in the first nine months of 2024. The difference between day-ahead and real-time average prices, by itself, is not a measure of the competitiveness or effectiveness of the day-ahead energy market.

Scarcity

- **Shortage Intervals.** There were 130 intervals with five minute shortage pricing on 22 days in the first nine months of 2025. Of the 130 intervals, 79 occurred during the June 2025 heatwave, for which PJM issued several emergency warnings and actions. Seven of the 130 intervals of shortage overlapped with synchronized reserve events.
- **SCED Shortage Intervals.** In the first nine months of 2025, there were 4,082 five minute intervals, or 5.2 percent of all five minute intervals, for which at least one RT SCED solution showed a shortage of reserves. In the first nine months of 2025, there were 1,368 five minute intervals, or 1.7 percent of all five minute intervals, for which more than one RT SCED solution showed a shortage of reserves. In the first nine months of 2025, PJM triggered shortage pricing for 130 five minute intervals, or 0.2 percent of all five minute intervals.

Competitive Assessment

Market Structure

- **Aggregate Pivotal Suppliers.** The PJM energy market, at times, requires generation from pivotal suppliers to meet load, resulting in aggregate market power even when the HHI level indicates that the aggregate market is unconcentrated. Three suppliers were jointly pivotal in the day-ahead market on 257 days, 94.1 percent of the days, in the first nine months of 2025 and 138 days, 50.4 percent of the days, in the first nine months of 2024.
- **Local Market Power.** In the first nine months of 2025, in the real-time market, the 500 kV system, 13 zones, and the PJM/MISO interface experienced congestion resulting from one or more constraints binding for 75 or more hours. For seven out of the top 10 congested facilities (by

real-time binding hours) in the first nine months of 2025, the average number of suppliers providing constraint relief was three or fewer. There was a high level of concentration within the local markets for providing relief to the most congested facilities in the PJM Real-Time Energy Market. The local market structure was not competitive.

Market Behavior

- **Offer Capping for Local Market Power.** PJM offer caps units when the local market structure is noncompetitive. Offer capping is an effective means of addressing local market power when the rules are designed and implemented properly. Offer capping levels have historically been low in PJM. In the day-ahead energy market, for units committed to provide energy for local constraint relief, offer-capped unit hours decreased from 2.0 percent in the first nine months of 2024 to 1.9 percent in the first nine months of 2025. In the real-time energy market, for units committed to provide energy for local constraint relief, offer-capped unit hours decreased from 1.5 percent in the first nine months of 2024 to 1.4 percent in the first nine months of 2025. While overall offer capping levels have been low, there are a significant number of units with persistent structural local market power that would have had a significant impact on prices in the absence of local market power mitigation.

  The analysis of the application of the TPS test to local markets demonstrates that it is working to identify pivotal owners when the market structure is noncompetitive and to ensure that owners are not subject to offer capping when the market structure is competitive. There are, however, identified issues with the application of market power mitigation to resources whose owners fail the TPS test that can result in the exercise of local market power. These issues need to be addressed.

- **Offer Capping for Reliability.** PJM also offer caps units that are committed for reliability reasons, including for reactive support. In the day-ahead energy market, for units committed for reliability reasons, offer-capped unit hours decreased from 0.18 percent in the first nine months of 2024 to 0.10 percent in the first nine months of 2025. In the real-time energy market, for units committed for reliability reasons, offer-capped unit hours decreased from 0.23 percent in the first nine months of 2024 to 0.12 percent in the first nine months of 2025. The low offer cap percentages for reliability commitments, relative to offer capping for transmission constraints, do not mean that units committed for reliability reasons do not have market power. All units manually committed for reliability have market power and all are treated consistent with that fact.

- **Parameter Mitigation.** PJM applies operating parameter limits (PLS) to units that fail the TPS test and to all units during hot and cold weather alerts. In the first nine months of 2025, 29.3 percent of unit hours for units that failed the TPS test in the day-ahead market were committed on price-based schedules that were less flexible than their cost-based schedules. On days when cold weather alerts and hot weather alerts were declared, 31.2 percent of unit hours in the day-ahead energy market were committed on price-based schedules that were less flexible than their price PLS schedules.

- **Frequently Mitigated Units (FMU) and Associated Units (AU).** In the first nine months of 2025, no units qualified for an FMU adder. In 2024, 2023 and 2022, no units qualified for an FMU adder. In 2021, one unit qualified for an FMU adder.

- **Markup Index.** The markup index is a summary measure of participant offer behavior for individual marginal units. While the average markup index in the real-time market was -$0.07 when using unadjusted cost-based offers in the first nine months of 2025, some marginal units did have substantial markups. The highest markup for any marginal unit in the real-time market in the first nine months of 2025 was more than $900 per MWh and the highest markup in the first nine months of 2024 was more than $900 per MWh, using unadjusted cost-based offers.

  While the average markup index in the day-ahead market was $0.23 per MWh in the six months between April and September of 2025, some marginal units did have substantial markups. The highest markup for any marginal unit in the day-ahead market in the six months between April and September of 2025 was more than $550 per MWh.

- **Markup.** The markup frequency distributions show that a significant proportion of units make price-based offers less than the cost-based offers permitted under the PJM market rules. This behavior means that competitive price-based offers reveal actual unit marginal costs and that PJM market rules permit the inclusion of costs in cost-based offers that are not short run marginal costs.

  The markup frequency distributions also show that a significant proportion of units were offered with high markups, consistent with the exercise of market power.

Market Performance

- **Markup.** The markup conduct of individual owners and units has an identifiable impact on market prices. Markup is a key indicator of the competitiveness of the energy market.

  In the PJM Real-Time Energy Market in the first nine months of 2025, the unadjusted markup component (net of positive and negative markup components) of LMP was -$0.09 per MWh or -0.2 percent of the PJM load-weighted average LMP. July had the highest unadjusted peak markup component, $2.74 per MWh, or 3.5 percent of the real-time peak hour load-weighted average LMP for July.

  In the PJM Day-Ahead Energy Market in the six months between April and September of 2025, the unadjusted markup component (net of positive and negative markup components) of LMP was $2.64 per MWh or 12.2 percent of the PJM load-weighted average LMP. July had the highest unadjusted peak markup component, $7.59 per MWh, or 8.59 percent of the day-ahead peak hour load-weighted average LMP for July.

  Participant behavior was evaluated as competitive because the analysis of markup shows that marginal units generally make offers at, or close to, their marginal costs in both the day-ahead and real-time energy markets, although the behavior of some participants represents economic withholding.

- **Markup and Local Market Power.** Comparison of the markup behavior of marginal units with TPS test results shows that for 3.0 percent of all real-time marginal unit intervals in the first nine months of 2025, the marginal unit had both local market power as determined by the TPS test and a positive markup. The fact that units with market power had a positive markup means that the cost-based offer was not used, that a higher price-based offer was used, and that the process for offer capping units that fail the TPS test does not consistently result in competitive market outcomes in the presence of market power.

- **Markup and Aggregate Market Power.** In the first nine months of 2025, pivotal suppliers in the aggregate market, committed in the day-ahead market and identified as one of three day-ahead aggregate pivotal suppliers, set real-time market prices with markups over $100 per MWh on 117 days, compared to 76 days in the first nine months of 2024.[65] Some of the marginal units had local market power, but were not offer capped due to issues with the method that PJM uses to select offer schedules for units that fail the TPS test. Some of the marginal units had aggregate market power, for which there is no offer capping, and some had both local and aggregate market power.

Section 3 Recommendations

Market Power

- The MMU recommends that the market rules explicitly require that offers in the energy market be competitive, where competitive is defined to be the short run marginal cost of the units. The short run marginal cost should reflect opportunity cost when appropriate. The MMU recommends that the level of incremental costs includable in cost-based offers per the PJM Operating Agreement not exceed the short run marginal cost of the unit. (Priority: Medium. First reported 2009. Status: Not adopted.)

Fuel Cost Policies

- The MMU recommends that PJM require that all fuel cost policies be algorithmic, verifiable, and systematic, and accurately reflect short

65 The number of days reported in the 2025 Quarterly State of the Market Report for PJM: January through March and the 2025 Quarterly State of the Market Report for PJM: January through June were understated, and have been correctly calculated in this 2025 Quarterly State of the Market Report for PJM: January through September.

run marginal costs. (Priority: Medium. First reported 2016. Status: Not adopted.)

- The MMU recommends that the temporary cost method be removed and that all units that submit nonzero cost-based offers be required to have an approved fuel cost policy. (Priority: Low. First reported 2020. Status: Not adopted.)
- The MMU recommends that the penalty exemption provision be removed and that all units that submit nonzero cost-based offers be required to follow their approved fuel cost policy. (Priority: Medium. First reported 2020. Status: Not adopted.)

Cost-Based Offers

- The MMU recommends removal of all use of FERC System of Accounts in the Cost Development Guidelines. (Priority: Medium. First reported 2016. Status: Not adopted.)
- The MMU recommends the removal of all use of cyclic starting and peaking factors from the Cost Development Guidelines. (Priority: Medium. First reported 2016. Status: Not adopted.)
- The MMU recommends the removal of all maintenance costs from the Cost Development Guidelines. (Priority: Medium. First reported 2019. Status: Not adopted.)
- The MMU recommends, given that maintenance costs are currently allowed in cost-based offers, that market participants be permitted to include only variable maintenance costs, linked to verifiable operational events and that can be supported by clear and unambiguous documentation of the operational data (e.g. run hours, MWh, MMBtu) that support the maintenance cycle of the equipment being serviced/replaced. (Priority: Medium. First reported 2020. Status: Partially adopted 2023.)
- The MMU recommends explicitly accounting for soak costs and changing the definition of the start heat input for combined cycles to include only the amount of fuel used from first fire to the first breaker close in the Cost Development Guidelines. (Priority: Medium. First reported 2016. Status: Partially adopted.)
- The MMU recommends that soak costs, soak time and the MWh produced during soaking be modeled separately. This will ensure that the time required for units to reach a dispatchable level is known and used in the unit commitment process instead of only being communicated verbally between dispatchers and generators. Separating soak costs from start costs and modeling the MWh produced during soaking allows for a better representation of the costs because it eliminates the need to simply assume the price paid for those MWh. (Priority: Medium. First reported 2022. Status: Not adopted.)
- The MMU recommends the removal of nuclear fuel and nonfuel operations and maintenance costs that are not short run marginal costs from the Cost Development Guidelines. (Priority: Medium. First reported 2016. Status: Not adopted.)
- The MMU recommends revising the pumped hydro fuel cost calculation to include day-ahead and real-time power purchases. (Priority: Low. First reported 2016. Status: Not adopted.)

Market Power: TPS Test and Offer Capping

- The MMU recommends that the rules governing the application of the TPS test be clarified and documented. The TPS test application in the day-ahead energy market is not documented. (Priority: High. First reported 2015. Status: Partially adopted.)[66]
- The MMU recommends that PJM modify the process of applying the TPS test in the day-ahead energy market to ensure that all local markets created by binding constraints are tested for market power and to ensure that market sellers with market power are appropriately mitigated to their competitive offers. (Priority: High. First reported 2022. Status: Not adopted.)
- The MMU recommends, in order to ensure effective market power mitigation when the TPS test is failed, that offer capping be applied to units that fail the TPS test in the real-time market that were not offer capped at the time of commitment in the day-ahead market or at a prior

66 The real-time market formula for determining the lowest cost schedule is documented. The day-ahead market formula for determining the lowest cost schedule is not documented.

time in the real-time market. (Priority: High. First reported 2020. Status: Not adopted.)

- The MMU recommends, in order to ensure effective market power mitigation and to ensure that capacity resources meet their obligations to be flexible, that capacity resources be required to use flexible parameters in all offers at all times. (Priority: High. First reported 2021. Status: Not adopted.)
- The MMU recommends, in order to ensure effective market power mitigation, PJM always use cost-based offers for units that fail the TPS test, and always use flexible parameters for all cost-based and all price-based offers during high load conditions such as cold and hot weather alerts and emergency conditions. (Priority: High. First reported 2015. Status: Not adopted.)
- The MMU recommends that PJM require every market participant to make available at least one cost schedule based on the same hourly fuel type(s) and parameters at least as flexible as their offered price schedule. (Priority: Medium. First reported 2015. Status: Not adopted.)
- The MMU recommends, in order to ensure effective market power mitigation when the TPS test is failed, that markup be consistently positive or negative across the full MWh range of price and cost-based offers. (Priority: High. First reported 2015. Status: Not adopted.)
- The MMU recommends, in order to ensure effective market power mitigation, that PJM commit all resources that fail the TPS test on their cost-based offers, that the Market Seller designate the cost-based offer if there is more than one, and that PJM implement this solution as soon as possible. (Priority: High. First reported Q3 2024. Status: Not adopted.)
- The MMU recommends that PJM retain the $1,000 per MWh offer cap in the PJM energy market except when cost-based offers exceed $1,000 per MWh, and retain other existing rules that limit incentives to exercise market power. (Priority: High. First reported 1999. Status: Partially adopted, 1999, 2017.)
- The MMU recommends the elimination of FMU and AU adders. FMU and AU adders no longer serve the purpose for which they were created and interfere with the efficient operation of PJM markets. (Priority: Medium. First reported 2012. Status: Partially adopted, 2014.)[67]

Offer Behavior

- The MMU recommends that resources not be allowed to violate the ICAP must offer requirement. The MMU recommends that PJM enforce the ICAP must offer requirement by assigning a forced outage to any unit that is derated in the energy market below its committed ICAP without an outage that reflects the derate. (Priority: Medium. First reported 2020. Status: Not adopted.)
- The MMU recommends that storage resources be subject to an enforceable ICAP must offer rule in the day-ahead and real-time energy markets that reflects the limitations of these resources. (Priority: Medium. First reported 2020. Status: Not adopted.)
- The MMU recommends that capacity resources not be allowed to offer any portion of their capacity market obligation as maximum emergency energy. (Priority: Medium. First reported 2012. Status: Not adopted.)
- The MMU recommends that PJM integrate all the outage reporting tools in order to enforce the ICAP must offer requirement, ensure that outages are reported correctly and eliminate reporting inconsistencies. Generators currently submit availability in three different tools that are not integrated, Markets Gateway, eDART and eGADS. (Priority: Medium. First reported 2022. Status: Not adopted.)
- The MMU recommends that gas generators be required to check with pipelines throughout the operating day to confirm that nominations are accepted beyond the NAESB deadlines, that gas generators be required to inform PJM about whether they have gas, and that gas generators be required to place their units on forced outage until the time that pipelines allow nominations to consume gas at a unit. (Priority: Medium. First reported 2022. Status: Not adopted.)

67 The applicability of the FMU and AU adders is limited by the rule implemented in 2014 requiring that net revenues must fall below avoidable costs, but the possibility of FMU and AU adders is still part of the PJM Market Rules.

Capacity Resources

- The MMU recommends that capacity resources be held to the OEM operating parameters of the capacity market CONE reference resource for performance assessment and energy uplift payments and that this standard be applied to all technologies on a uniform basis. (Priority: Medium. First reported 2015. Status: Not adopted.)
- The MMU recommends that the parameters which determine nonperformance charges and the amounts of uplift payments should reflect the flexibility goals of the capacity market design. The operational parameters used by generation owners to indicate to PJM operators what a unit is capable of during the operating day should not determine capacity resource performance assessment or uplift payments. (Priority: Medium. First reported 2015. Status: Partially adopted.)[68]
- The MMU recommends that PJM clearly define the business rules that apply to the unit specific parameter adjustment process, including PJM's implementation of the tariff rules in the PJM manuals to ensure market sellers know the requirements for their resources. (Priority: Low. First reported 2018. Status: Not adopted.)
- The MMU recommends that PJM update the tariff to clarify that all generation resources are subject to unit specific parameter limits on their cost-based offers using the same standard and process as capacity resources. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that resources not be paid the daily capacity payment when unable to operate to their unit specific parameter limits. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that PJM not approve temporary exceptions that are based on pipeline tariff terms that are not enforced at the time, or are based on inferior transportation service procured by the generator. (Priority: Medium. First reported 2019. Status: Not adopted.)
- The MMU recommends that PJM require generators that violate their approved turn down ratio (by either using the fixed gen option or increasing their economic minimum) to use the temporary parameter exception process that requires market sellers to demonstrate that the request is based on a physical and actual constraint. (Priority: Medium. First reported 2021. Status: Not adopted.)
- The MMU recommends: that gas generators be required to confirm, regularly during the operating day, that they can obtain gas if requested to operate at their economic maximum level; that gas generators provide that information to PJM during the operating day; and that gas generators be required to be on forced outage if they cannot obtain gas during the operating day to meet their must offer requirement as a result of pipeline restrictions, and they do not have backup fuel. As part of this, the MMU recommends that PJM collect data on each individual generator's fuel supply arrangements at least annually or when such arrangements change, and analyze the associated locational and regional risks to reliability. (Priority: Medium. First reported 2022. Status: Not adopted.)

Accurate System Modeling

- The MMU recommends that PJM explicitly state its policy on the use of transmission penalty factors including: the level of the penalty factors; the triggers for the use of the penalty factors; the appropriate line ratings to trigger the use of penalty factors; the allowed duration of the violation and when the transmission penalty factors will be used to set the shadow price. The MMU recommends that PJM end the practice of manual and automated discretionary reductions in the control limits on transmission constraint line ratings used in the market clearing software (SCED) and included in LMP. (Priority: Medium. First reported 2015. Status: Partially adopted 2020.)[69]
- The MMU recommends that PJM routinely review all transmission facility ratings and any changes to those ratings to ensure that the normal, emergency and load dump ratings used in modeling the transmission

68 Flexible parameter standards are in place for combined cycle and combustion turbine resources when operating on a parameter limited schedule, but not for other schedules or generating technologies.

69 PJM created a more transparent process for transmission constraint penalty factors and added it to the tariff in 2020. Policies on reductions in control limits and the duration of violations remain discretionary and undocumented in the PJM Market Rules.

system are accurate and reflect standard ratings practice. (Priority: Low. First reported 2013. Status: Not adopted.)

- The MMU recommends that PJM not use closed loop interface or surrogate constraints to artificially override nodal prices based on fundamental LMP logic in order to: accommodate rather than resolve the inadequacies of the demand side resource capacity product; address the inability of the power flow model to incorporate the need for reactive power; accommodate rather than resolve the flaws in PJM's approach to scarcity pricing; or for any other reason. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM update the outage impact studies, the reliability analyses used in RPM for capacity deliverability, and the reliability analyses used in RTEP for transmission upgrades to be consistent with the more conservative emergency operations (post contingency load dump limit exceedance analysis) in the energy market that were implemented in June 2013.[70] (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM include in the tariff or appropriate manual an explanation of the initial creation of hubs, the process for modifying hub definitions and a description of how hub definitions have changed.[71] [72] (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends that all buses with a net withdrawal be treated as load for purposes of calculating load and load-weighted LMP, even if the MW are settled to the generator. The MMU recommends that during hours when a load bus shows a net injection, the energy injection be treated as generation, not negative load, for purposes of calculating generation and load-weighted LMP, even if the injection MW are settled to the load serving entity. (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM identify and collect data on available behind the meter generation resources, including nodal location information and relevant operating parameters. (Priority: Low. First reported 2013. Status: Partially adopted.)
- The MMU recommends that PJM document how LMPs are calculated when demand response is marginal. (Priority: Low. First reported 2014. Status: Not adopted.)
- The MMU recommends that PJM not allow nuclear generators which do not respond to prices or which only respond to manual instructions from the operator to set the LMPs in the real-time market. (Priority: Low. First reported 2016. Status: Not adopted.)
- The MMU recommends that PJM increase the coordination of outage and operational restrictions data submitted by market participants via eDART/eGADs and offer data submitted via Markets Gateway. (Priority: Low. First reported 2017. Status: Not adopted.)
- The MMU recommends that PJM model generators' operating transitions, including soak time for units with a steam turbine, configuration transitions for combined cycles, and peak operating modes. (Priority: Medium. First reported 2019. Status: Not adopted.)
- The MMU recommends that PJM clarify, modify and document its process for dispatching reserves and energy when SCED indicates that supply is less than total demand including forecasted load and reserve requirements. The modifications should define: a SCED process to economically convert reserves to energy; a process for the recall of energy from capacity resources; and the minimum level of synchronized reserves that would trigger load shedding. (Priority: Medium. First reported 2020. Status: Not adopted.)
- The MMU recommends that PJM stop capping the system marginal price in RT SCED and LPC and instead limit the sum of violated reserve constraint shadow prices that are included in the determination of LMP in LPC to $1,700 per MWh. While PJM no longer caps prices in RT SCED, PJM continues to apply a cap to the system marginal price in the pricing

70 This recommendation was the result of load shed events in September, 2013. For detailed discussion, please see *2013 Annual State of the Market Report for PJM*, Volume 2: Section 3 at 114 – 116.
71 According to minutes from the first meeting of the Energy Market Committee (EMC) on January 28, 1998, the EMC unanimously agreed to be responsible for approving additions, deletions and changes to the hub definitions to be published and modeled by PJM. Since the EMC has become the Market Implementation Committee (MIC), the MIC now appears to be responsible for such changes.
72 There is currently no PJM documentation in the tariff or manuals explaining how hubs are created and how their definitions are changed. The general definition of a hub can be found in the PJM.com Glossary <http://www.pjm.com/Glossary.aspx>.

run (LPC) under fast start pricing. (Priority: Medium. First reported 2021. Status: Not adopted.)

- The MMU recommends that PJM adjust the ORDCs during spin events to reduce the reserve requirement for synchronized and primary reserves by the amount of the reserves deployed. (Priority: Medium. First reported 2021. Status: Not adopted.)

Transparency

- The MMU recommends that PJM clearly document the calculation of shortage prices and implementation of reserve price caps in the PJM manuals, including defining all the components of reserve prices, and all the constraints whose shadow prices are included in reserve prices. (Priority: High. First reported 2021. Status: Not adopted.)
- The MMU recommends that PJM allow generators to report fuel type on an hourly basis in their offer schedules and to designate schedule availability on an hourly basis. (Priority: Medium. First reported 2015. Status: Partially adopted.)[73]
- The MMU recommends that PJM define clear criteria for operator approval of RT SCED cases, including shortage cases, that are used to send dispatch signals to resources, and for pricing, to minimize discretion. (Priority: High. First reported 2018. Status: Partially adopted.)[74]

Virtual Bids and Offers

- The MMU recommends eliminating up to congestion (UTC) bidding at pricing nodes that aggregate only small sections of transmission zones with few physical assets. (Priority: Medium. First reported 2020. Status: Not adopted.)
- The MMU recommends eliminating INC, DEC, and UTC bidding at pricing nodes that allow market participants to profit from modeling issues. (Priority: Medium. First reported 2020. Status: Not adopted.)

73 Fuel type is reported by offer schedule, but it can be inaccurate on an hourly basis.
74 The PJM Market Rules clarify that shortage case approval will be based on RT SCED, but does not address RT SCED case choice or load bias.

Section 3 Conclusion

The MMU analyzed key elements of PJM energy market structure, participant conduct and market performance in the first nine months of 2025, including aggregate supply and demand, concentration ratios, aggregate pivotal supplier results, local three pivotal supplier test results, offer capping, markup, marginal units, participation in demand response programs, virtual bids and offers, loads and prices.

Prices are a key outcome of markets. Prices vary across hours, days and years for multiple reasons. Price is an indicator of the level of competition in a market. In a competitive market, prices are directly related to input prices, the marginal cost to serve load. In the first nine months of 2025, LMP increased by $16.20 per MWh compared to the first nine months of 2024. The fuel cost components of LMP (the sum of gas, coal, oil, landfill gas, and consumables) increased $9.85 per MWh, 60.8 percent of the increase in LMP. The emissions cost components of LMP, including opportunity costs for emissions limited resources, decreased by $0.16 per MWh, -1.0 percent of the increase in LMP. The transmission constraint penalty factor component increased by $2.07 per MWh, 12.8 percent of the increase in LMP, primarily as a result of PJM actions to reduce the line limits applied in SCED (control limits) below the actual line limits. The pre-emergency demand response called on by PJM during the hot weather days in June and July increased the LMP by $0.89 per MWh, 5.5 percent of the increase in LMP. The LMP increase would have been higher if PJM had not imposed a $3,700.00 per MWh administrative cap. The administrative cap reduced the LMP by $0.11 per MWh, a 0.7 percent decrease.

The pattern of prices within days and across months and years illustrates how prices are directly related to supply and demand conditions and illustrates the potential significance of the impact of the price elasticity of demand on prices. Energy market results in the first nine months of 2025 generally reflected supply-demand fundamentals, although the behavior of some participants both routinely and during high demand periods represents economic withholding. Economic withholding occurs when generator offers are greater than competitive levels. In the first nine months of 2025, the sum of the markup, ten percent adder, and maintenance cost (not short run marginal cost) components increased by $0.85 per MWh or 5.2 percent of the increase in LMP. In addition, PJM actions in the form of transmission constraint penalty factors, significantly increased prices.

The potential for prolonged and excessively high administrative pricing in the energy market due to reserve penalty factors and transmission constraint penalty factors remains an issue that needs to be addressed.[75] There also continue to be significant issues with PJM's scarcity pricing rules, including the absence of a clear trigger based on accurately estimated reserve levels. For example, PJM approved 21.9 percent of solved shortage cases in June 2025, but only 3.2 percent for the first nine months of 2025. Six of the other eight months had a higher percent of shortage cases solved, but fewer approved. The pattern of shortage case approvals indicates that PJM considers factors that are not documented in the tariff when deciding whether to approve shortage cases. The application of shortage pricing should not involve operator discretion. As directed by FERC Order No. 825, PJM should approve shortage cases based on market software results alone.[76]

With or without a capacity market, energy market design must permit scarcity pricing when such pricing is consistent with market conditions and constrained by reasonable rules to ensure that market power is not exercised and to ensure no scarcity pricing when such pricing is not consistent with market conditions. Scarcity pricing for revenue adequacy, as in PJM's 2019 ORDC proposal that would have created administrative scarcity pricing, is not consistent with a competitive market design. Scarcity pricing for price signals that reflect market conditions during periods of scarcity is consistent with a competitive market design. Scarcity pricing is part of an appropriate incentive structure facing both load and generation owners in a working wholesale electric power market design. Scarcity pricing must be designed to ensure that market prices reflect actual market conditions, that scarcity pricing occurs with transparent triggers based on measured reserve levels and transparent prices, that scarcity pricing only occurs when scarcity exists, that scarcity pricing not be excessive or punitive, and that there are strong incentives for competitive behavior and strong disincentives to exercise market power. Such administrative scarcity pricing is a key link between energy and capacity markets.

PJM defined inputs to the dispatch tools, particularly RT SCED, have substantial effects on energy market outcomes. Transmission line ratings in SCED, transmission constraint penalty factors, load forecast bias, hydro resource schedules, fast start pricing, and the treatment of demand resources change the dispatch of the system, affect prices, and can create significant price increases, particularly through transmission constraint penalty factors. PJM operator interventions to reduce the control limits on transmission constraint line ratings in RT SCED unnecessarily trigger transmission constraint penalty factors and significantly increase prices. In the first nine months of 2025, the control limit used in RT SCED for 85 percent of violated transmission constraint intervals was less than 100 percent of the actual line limit, with an average reduction of 5.1 percent. If the control limits had not been artificially reduced for PJM transmission constraints and everything else remained unchanged, the transmission constraint penalty factor's contribution to the load-weighted average LMP in the first nine months of 2025 would have decreased by 99.4 percent from $5.31 to $0.03 per MWh. PJM should evaluate its interventions in the market, including the unnecessary imposition of transmission constraint penalty factors, reconsider whether the interventions are appropriate, and provide greater transparency to enhance market efficiency.

Fast start pricing, implemented on September 1, 2021, has disconnected pricing from dispatch instructions and despite the stated goal of reducing overall uplift, created a greater reliance on uplift rather than price as an incentive to follow PJM's instructions. The objective of efficient short run price signals is to minimize system production costs, not to minimize uplift. Repricing the market to reflect commitment costs using fast start pricing prioritizes minimizing uplift over minimizing production costs.[77] The tradeoff exists because when commitment costs are included in prices, the price signal no longer equals the short run marginal cost and therefore no longer provides the correct signal for efficient behavior for market participants making decisions on the margin, whether resources, load, interchange transactions, or virtual traders. Units that start in one hour are not actually fast start units, and their commitment

75 177 FERC ¶ 61,209 (2021).
76 155 FERC ¶ 61,276 at P 161 (2016) ("shortage pricing is required only when a shortage of energy or operating reserves is indicated by the RTO's/ISO's software").
77 See 173 FERC ¶ 61,244 (2020).

costs are not marginal in a five minute market. The differences between the actual LMP and the fast start LMP distort the incentive for market participants to behave competitively and to follow PJM's dispatch instructions. PJM is paying uplift in an attempt to counter the distorted incentives inherent in fast start pricing. PJM is also using the pricing run to implement administrative pricing rules that are not related to fast start pricing. Specifically, PJM uses lower transmission constraint penalty factors in the day-ahead pricing run than in the dispatch run and implements system marginal price capping in the pricing run. Every difference between the dispatch run and the pricing run introduces another inefficiency in the market. In the four years since fast start pricing was introduced, the market has not responded with new entry of fast start units despite consistently higher LMPs when a fast start unit sets price.

The energy market requires more flexible operation of the dispatchable fleet as wind and solar resource penetration grows. Since 2018, PJM has argued that the way to incent investment in flexible units is to increase reserve requirements and to increase the administrative prices defined in the ORDCs. In fact, PJM's ORDCs would benefit inflexible units. Providing windfall gains to all generation through higher LMPs during more frequent reserve shortages is not an effective incentive for flexibility.

The question of how to provide market incentives for investment in flexibility, and for operating to the full capability of that flexibility should be addressed directly. Are units inflexible because they are old and inefficient, because owners have not invested in increased flexibility or because they serve as a mechanism for the exercise of market power? Are units inflexible because the PJM software does not model combined cycle transitions?

A direct solution would include improved modelling of generator capabilities, so that PJM can send more targeted dispatch signals that generators are consistently capable of following. A direct solution would include targeted reforms to PJM software, like multi-interval dispatch and combined cycle modelling would directly address PJM energy market performance. A direct solution would include stronger standards in the PJM Market Rules for performance of resources to their actual physical parameters. These reforms would be more efficient and effective than simply raising prices across the board.

The relationship between supply and demand is referred to as the supply-demand fundamentals, or economic fundamentals, or market structure. The market structure of the PJM aggregate energy market is partially competitive because aggregate market power does exist for a significant number of hours. The HHI is not a definitive measure of structural market power. The number of pivotal suppliers in the energy market is a more precise measure of structural market power than the HHI. It is possible to have pivotal suppliers in the aggregate market even when the HHI level is not in the highly concentrated range. Even a low HHI may be consistent with the exercise of market power with a low price elasticity of demand. The current market power mitigation rules for the PJM energy market rely on the assumption that the ownership structure of the aggregate market ensures competitive outcomes at all times. This assumption requires that the total demand for energy can be met without the supply from any individual supplier or the supply from a small group of suppliers. This assumption is not correct. There are pivotal suppliers in the aggregate energy market with increasing frequency. High markups for some units demonstrate the potential to exercise market power both routinely and during high demand conditions. The existing market power mitigation measures do not address aggregate market power. The MMU is developing an aggregate market power test and will propose market power mitigation rules to address aggregate market power.

The three pivotal supplier test is applied by PJM on an ongoing basis for local energy markets in order to determine whether offer capping is required for transmission constraints.[78] However, there are issues with the application of market power mitigation in the day-ahead energy market and the real-time energy market when market sellers fail the TPS test. The Commission recognized some of these issues in its order issued on June 17, 2021, but failed to address them in its November 30, 2023 order.[79] [80] Many of these issues can be resolved by simple rule changes. PJM filed and, on October 25, 2024, FERC accepted a proposal that would require that sellers that fail the TPS test will be

78 The MMU reviews PJM's application of the TPS test and brings issues to the attention of PJM.
79 See 175 FERC ¶ 61,231 (2021).
80 185 FERC ¶ 61,158 (2023).

offer capped at their cost-based offers and that operating parameters will be mitigated.[81] That order has no current effect because FERC approved the PJM filing that linked, for no logical reason, implementing the improved rules to PJM's adoption of an improved combined cycle model with no defined date. The flawed rules remain in place. There is no reason to delay implementation of the FERC approved rules until PJM addresses combined cycle modelling. The changes would decrease the solution time for the day-ahead market and enhance market efficiency. The approved approach should be implemented as soon as possible to help ensure effective market power mitigation.

The enforcement of market power mitigation rules is undermined if the definition of a competitive offer is not correct. A competitive offer is equal to short run marginal costs. The significance of competition metrics like markup is also undermined if the definition of a competitive offer is not correct. The definition of a competitive offer, under the PJM Market Rules, is not currently correct. The definition, that all costs that are related to electric production are short run marginal costs, is not clear or correct. All costs and investments for power generation are related to electric production. Under this definition, some unit owners include costs in cost-based energy offers that are not short run marginal costs in offers, especially maintenance costs. This issue can be resolved by simple rule changes to incorporate a clear and accurate definition of short run marginal costs. This rule also had unintended consequences for market seller offer caps in the capacity market. Maintenance costs includable in energy offers cannot be included in capacity market offer caps based on avoidable costs. As a result, capacity market offer caps based on net avoidable costs were lower than they would have been if maintenance costs had been correctly included in avoidable costs rather than incorrectly defined to be part of short marginal costs of producing energy and includable in energy offers.

A competitive power market will result in higher prices when fuel costs increase and lower prices when fuel costs decrease. A competitive market will not result in higher prices when markups increase based on market power, or when PJM selects a price-based offer including a markup rather than a cost-based offer in the presence of local market power, or when PJM artificially triggers transmission constraint penalty factors. The overall energy market results support the conclusion that energy prices in PJM are set, generally, by marginal units operating at, or close to, their marginal costs, although this was not always the case in the first nine months of 2025 or prior years. Given the structure of the energy market which can permit the exercise of aggregate and local market power, some participants' offer behavior is a source of concern in the energy market and provides a reason to use correctly defined short run marginal cost as the sole basis for cost-based offers and a reason for implementing an aggregate market power test and correcting the offer capping process for resources with local market power. In addition, PJM's extensive administrative interventions in the energy market should be reduced. The MMU concludes that the PJM energy market results were competitive in the first nine months of 2025.

81 189 FERC ¶ 61,060 (2024).

Overview: Section 4, Energy Uplift

Energy Uplift Credits

- **Energy uplift credits.** Total energy uplift credits increased by $442.1 million, or 202.3 percent, in the first nine months of 2025 compared to the first nine months of 2024, from $218.5 million to $660.6 million.
- **Types of energy uplift credits.** In the first nine months of 2025, total energy uplift credits included $181.5 million in day-ahead generator credits, $447.7 million in balancing generator credits, $28.9 million in lost opportunity cost credits. Dispatch differential lost opportunity credits, which are a subset of balancing operating reserves, were implemented as part of fast start pricing on September 1, 2021, and were $2.0 million in the first nine months of 2025.
- **Types of units.** In the first nine months of 2025, steam coal units received 9.1 percent of day-ahead generator credits, and combustion turbines received 53.5 percent of balancing generator credits and 64.8 percent of lost opportunity cost credits. Combined cycle units and combustion turbines received 36.3 percent of dispatch differential lost opportunity credits, and hydro units received 47.5 percent of dispatch differential lost opportunity credits

- **Concentration of energy uplift credits.** In the first nine months of 2025, the top 10 units receiving energy uplift credits received 37.5 percent of all credits and the top 10 organizations received 70.3 percent of all credits.
- **Lost opportunity cost credits.** Lost opportunity cost credits increased by $3.2 million, or 12.3 percent, in the first nine months of 2025, compared to the first nine months of 2024, from $25.7 million to $28.9 million.

  Some combustion turbines and diesels are scheduled day-ahead but not requested in real time, and receive day-ahead lost opportunity cost credits as a result. This was the source of 65.2 percent of the $29.0 million of lost opportunity costs.
- **Following dispatch.** Some units are incorrectly paid uplift despite not meeting uplift eligibility requirements, including not following dispatch, not having the correct commitment status, or not operating with PLS offer parameters. Since 2018, the MMU has made cumulative resettlement requests for the most extreme overpaid units of $17.9 million, of which PJM has resettled only $3.9 million, or 22.0 percent.

Energy Uplift Charges

- **Energy Uplift Charges.** In the first nine months of 2025, total energy uplift charges increased by $443.1 million, or 203.8 percent, compared to the first nine months of 2024, from $217.4 million to $660.6 million.
- **Types of Energy Uplift Charges.** In the first nine months of 2025, total uplift charges included $181.4 million in day-ahead operating reserve charges, $478.1 million in balancing generator charges, $0.6 million in reactive charges, and $0.4 million in black start services.

Section 4 Recommendations

- The MMU recommends that uplift be paid only based on operating parameters that reflect the flexibility of the benchmark new entrant unit (CONE unit) in the PJM Capacity Market. (Priority: High. First reported 2018. Status: Not adopted.)
- The MMU recommends that PJM not pay uplift to units not following dispatch, including uplift related to fast start pricing, and require refunds where it has made such payments. This includes units whose offers are flagged for fixed generation in Markets Gateway because such units are not dispatchable. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that PJM pay uplift based on the offer at the lower of the actual unit output or the dispatch signal MW. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends eliminating intraday segments from the calculation of uplift payments and returning to calculating the need for uplift based on the entire 24 hour operating day. (Priority: High. First reported 2018. Status: Not adopted.)
- The MMU recommends the elimination of day-ahead uplift to ensure that units receive an energy uplift payment based on their real-time output and not their day-ahead scheduled output. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that units not be paid lost opportunity cost uplift credits when PJM directs a unit to reduce output based on a transmission constraint or other reliability issue. There is no lost opportunity because the unit is required to reduce for the reliability of the unit and the system. (Priority: High. First reported 2021. Status: Not adopted.)
- The MMU recommends reincorporating the use of net regulation revenues as an offset in the calculation of balancing generator credits. (Priority: Medium. First reported 2009. Status: Not adopted.)
- The MMU recommends that self scheduled units not be paid energy uplift credits for their startup cost when the units are scheduled by PJM to start before the self scheduled hours. (Priority: Low. First reported 2013. Status: Not adopted.)

- The MMU recommends three modifications to the energy lost opportunity cost calculations:
  - The MMU recommends calculating LOC based on 24 hour daily periods for combustion turbines and diesels scheduled in the day-ahead energy market, but not committed in real time. (Priority: Medium. First reported 2014. Status: Not adopted.)
  - The MMU recommends that units scheduled in the day-ahead energy market and not committed in real time should be compensated for LOC based on their real-time desired and achievable output, not their scheduled day-ahead output. (Priority: Medium. First reported 2015. Status: Not adopted.)
  - The MMU recommends that only flexible fast start units (startup plus notification times of 10 minutes or less) and units with short minimum run times (one hour or less) be eligible by default for the LOC compensation to units scheduled in the day-ahead energy market and not committed in real time. Other units should be eligible for LOC compensation only if PJM explicitly cancels their day-ahead commitment. (Priority: Medium. First reported 2015. Status: Not adopted.)
- The MMU recommends that up to congestion (UTC) transactions be required to pay energy uplift charges for both the injection and the withdrawal sides of the UTC. (Priority: High. First reported 2011. Status: Partially adopted.)
- The MMU recommends allocating the energy uplift credits paid to units scheduled by PJM as must run in the day-ahead energy market for reasons other than voltage/reactive or black start services as a reliability charge to real-time load, real-time exports and real-time wheels. (Priority: Medium. First reported 2014. Status: Not adopted. Stakeholder process.)
- The MMU recommends that the total cost of providing reactive support be categorized and allocated as reactive services. Reactive services credits should be calculated consistent with the balancing generator credit calculation. (Priority: Medium. First reported 2012. Status: Not adopted. Stakeholder process.)
- The MMU recommends including real-time exports and real-time wheels in the allocation of the cost of providing reactive support to the 500 kV system or above, in addition to real-time load. (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends modifications to the calculation of lost opportunity costs credits paid to wind units. The lost opportunity costs credits paid to wind units should be based on the lesser of the desired output, the estimated output based on actual wind conditions and the capacity interconnection rights (CIRs). The MMU recommends that PJM require wind units to request CIRs based on the maximum output used in the ELCC calculation for wind units. (Priority: Low. First reported 2012. Status: Partially adopted.)
- The MMU recommends that PJM clearly identify and classify all reasons for incurring uplift in the day-ahead and the real-time energy markets and the associated uplift charges in order to make all market participants aware of the reasons for these costs and to help ensure a long term solution to the issue of how to allocate the costs of uplift. (Priority: Medium. First reported 2011. Status: Partially adopted.)
- The MMU recommends that PJM revise the current uplift confidentiality rules in order to allow the disclosure of complete information about the level of uplift by unit and the detailed reasons for the level of uplift credits by unit in the PJM region. (Priority: High. First reported 2013. Status: Partially adopted.)[82]

Section 4 Conclusion

Competitive market outcomes result from energy offers equal to short run marginal costs that incorporate flexible operating parameters. When PJM permits a unit to include inflexible operating parameters in its offer and pays uplift based on those inflexible parameters, there is an incentive for the unit to remain inflexible. The rules regarding operating parameters should be implemented in a way that creates incentives for flexible operations rather than inflexible operations. The standard for paying uplift should be the maximum

82 On September 7, 2018, PJM made a compliance filing for FERC Order No. 844 to publish unit specific uplift credits. The compliance filing was accepted by FERC on June 21, 2019. 166 FERC ¶ 61,210 (2019). PJM began posting unit specific uplift reports on May 1, 2019. 167 FERC ¶ 61,280 (2019).

achievable flexibility, based on OEM standards for the benchmark new entrant unit (CONE unit) in the PJM Capacity Market demand (VRR) curve. Applying a weaker standard effectively subsidizes inflexible units by paying them based on inflexible parameters that result from lack of investment and that could be made more flexible. The result inflates uplift costs, suppresses energy prices, and is an incentive to inflexibility.

It is not appropriate to accept that inflexible units should be paid uplift based on inflexible offers. The question of why units make inflexible offers should be addressed directly. Are units inflexible because they are old and inefficient, because owners have not invested in increased flexibility or because they serve as a mechanism for the exercise of market power? The question of why the inflexible unit was built, whether it was built under cost of service regulation and whether it is efficient to retain the unit should be answered directly. The question of how to provide market incentives for investment in flexible units and for investment in increased flexibility of existing units should be addressed directly. The question of whether inflexible units should be paid uplift at all should be addressed directly. Marginal cost pricing without paying uplift to inflexible units would create incentives for market participants to provide flexible solutions including replacing inefficient units with flexible, efficient units.

Implementing combined cycle modeling, to permit the energy market model optimization to take advantage of the versatility and flexibility of combined cycle technology in commitment and dispatch, would provide significant flexibility without requiring a distortion of the market rules. Such modeling should not be used as an excuse to eliminate market power mitigation or an excuse to permit inflexible offers to be paid uplift. There are defined steps that could and should be taken immediately to improve the modeling of combined cycle plants that do not require investment in combined cycle modeling software, including modeling soak time, and accurately accounting for transition times to power augmentation offer segments.

The reduction of uplift payments should not be a goal to be achieved at the expense of the fundamental logic of the LMP system. For example, the use of closed loop interfaces to reduce uplift should be eliminated because it is not consistent with LMP fundamentals and constitutes a form of subjective price setting. The same is true of fast start pricing. The same is true of PJM's proposals to modify the ORDC in order to increase energy prices and reduce uplift.

Accurate short run price signals, equal to the short run marginal cost of generating power, provide market incentives for cost minimizing production to all economically dispatched resources and provide market incentives to load based on the marginal cost of additional consumption. The objective of efficient short run price signals is to minimize system production costs, not to minimize uplift. Repricing the market to reflect commitment costs creates a tradeoff between minimizing production costs and reduction of uplift. The tradeoff exists because when commitment costs are included in prices, the price signal no longer equals the short run marginal cost and therefore no longer provides the correct signal for efficient behavior for market participants making decisions on the margin, whether resources, load, interchange transactions, or virtual traders. This tradeoff now exists based on PJM's recently implemented fast start pricing approach.[83] Fast start pricing affects uplift calculations by introducing a new category of uplift in the balancing market, and changing the calculation of uplift in the day-ahead market.

When units routinely receive substantial revenues through energy uplift payments, these payments are not fully transparent to the market, in part because of the current confidentiality rules. As a result, other market participants, including generation and transmission developers, do not have the opportunity to compete to displace them. As a result, substantial energy uplift payments to a concentrated group of units and organizations have persisted. FERC Order No. 844 authorized the publication of unit specific uplift payments for credits incurred after July 1, 2019.[84] However, Order No. 844 failed to require the publication of unit specific uplift credits for the largest units receiving significant uplift payments, inflexible steam units committed for reliability by PJM in the day-ahead market.

83 Fast start pricing was approved by FERC and implemented on September 1, 2021. See 173 FERC ¶ 61,244 (2020).
84 On June 21, 2019, FERC accepted PJM's Order No. 844 compliance filing. 166 FERC ¶ 61,210 (2019). The filing stated that PJM would begin posting unit specific uplift reports on May 1, 2019. On April 8, 2019, PJM filed for an extension on the implementation date of the zonal uplift reports and unit specific uplift reports to July 1, 2019. On June 28, 2019, FERC accepted PJM's request for extension of effective dates. 167 FERC ¶ 61,280 (2019).

Uplift payments could be significantly reduced by reversing many of the changes that have been made to the original basic uplift rules. The goal of uplift is to ensure that competitive energy and ancillary service market outcomes do not require efficient resources operating for the PJM system, at the direction of PJM, to operate at a loss. In the original PJM design, uplift was calculated on a daily basis, including all costs and net revenues. But that rule was changed to use only segments of the day. The result is to overstate uplift payments because units may be paid uplift for a day in which their net revenues exceed their costs. In the original PJM design, all net revenues from energy and ancillary services were an offset to uplift payments. That rule was changed to eliminate net revenue from the regulation market. The result is to overstate uplift payments, for no logical reason.

Uplift payments could also be significantly reduced to a more efficient level by eliminating all day-ahead operating reserve credits. It is illogical and unnecessary to pay units day-ahead operating reserve credits because units do not incur any costs to run and any revenue shortfalls are addressed by balancing generator credits.

PJM needs to pay substantially more attention to the details of uplift payments including accurately tracking whether units are following dispatch, identifying the actual need for units to be dispatched out of merit and determining whether better definitions of constraints would be a more market based approach. PJM pays uplift to units even when they do not operate as requested by PJM, i.e. when units do not follow dispatch. PJM uses dispatcher logs as a primary screen to determine if units are eligible for uplift regardless of how they actually operate or if they followed the PJM dispatch signal. The reliance on dispatcher logs for this purpose is impractical, inefficient, and incorrect. PJM needs to define and implement systematic and verifiable rules for determining when units are following dispatch as a primary screen for eligibility for uplift payments. PJM should not pay uplift to units that do not follow dispatch. PJM continues to pay uplift to units that do not follow dispatch. PJM and the MMU are actively working together to revise the definition of following dispatch to address these issues.

The MMU notifies PJM and generators of instances in which, based on the PJM dispatch signal and the real-time output of the unit, it is clear that the unit did not operate as requested by PJM. The MMU sends requests for resettlements to PJM to make the units with the most extreme overpayments ineligible for uplift credits. Since 2018, the MMU has requested that PJM require the return of $17.9 million of incorrect uplift credits of which PJM has agreed and resettled only $3.9 million over the last two years, or 22.0 percent. In addition, PJM has refused to accept the return of incorrectly paid uplift credits by generators when the MMU has identified such cases and generators offer to repay the credits.

While energy uplift charges are an appropriate part of the cost of energy, market efficiency would be improved by ensuring that the level and variability of these charges are as low as possible consistent with the reliable operation of the system and consistent with pricing at short run marginal cost. The goal should be to minimize the total incurred energy uplift charges and to increase the transactions over which those charges are spread in order to reduce the impact of energy uplift charges on markets. The result would be to reduce the level of per MWh charges, to reduce the uncertainty associated with uplift charges and to reduce the impact of energy uplift charges on decisions about how and when to participate in PJM markets. The result would also be to increase incentives for flexible operation and to decrease incentives for the continued operation of inflexible and uneconomic resources. PJM does not need a new flexibility product. PJM needs to provide incentives to existing and new entrant resources to unlock the significant flexibility potential that already exists, to end incentives for inflexibility and to stop creating new incentives for inflexibility.

Polar Vortex 2025 resulted in 51.3 percent of uplift credits in the first nine months of 2025. This level of uplift was consistent with the efficient operation of a reliable market. In anticipation of the cold weather and to avoid a repetition of the poor performance during Winter Storm Elliott, PJM made out of market commitments to mitigate generation performance risks associated with cold temperatures and natural gas commodity illiquidity over the weekend and intraday. PJM took conservative measures to ensure reliability by scheduling resources well in advance of the day-ahead energy market. As there is no multiday market, out of market actions taken before the market starts generally result in uplift. While the results of the Polar Vortex 2025 vindicated PJM's strategy, the rules governing PJM's actions should be more transparent and clearly documented. The results of Polar Vortex 2025 are preferred to Winter Storm Elliott and increased uplift is the expected result. Nonetheless, the uplift rules need significant improvement. In addition, the process of conservative operations and advanced commitments needs to be improved, formalized, and made as market based as possible in order to minimize uplift.

Overview: Section 5, Capacity Market

RPM Capacity Market

Market Design

The Reliability Pricing Model (RPM) Capacity Market is a three year forward looking, annual, locational market, with a must offer requirement for Existing Generation Capacity Resources and a must buy requirement for load, with performance incentives, that includes clear market power mitigation rules and that permits the direct participation of demand side resources.[85] PJM introduced the Capacity Performance design for the 2017/2018 BRA. PJM introduced a new ELCC method for defining capacity MW offered in the 2025/2026 BRA.[86]

Under RPM, capacity obligations are annual.[87] By design, Base Residual Auctions (BRA) are held for delivery years that are three years in the future despite recent auction delays. First, Second and Third Incremental Auctions (IA) are held for each delivery year.[88] First, Second, and Third Incremental Auctions are conducted 20, 10, and three months prior to the delivery year although some incremental auctions have not been held as a result of delays in holding BRAs.[89] A Conditional Incremental Auction may be held if there is a need to procure additional capacity resulting from a delay in a planned large transmission upgrade that was modeled in the BRA for the relevant delivery year.[90] A Reliability Backstop Auction may be conducted if tariff defined criteria are met to resolve reliability criteria violations caused by lack of sufficient capacity procured through RPM auctions.[91] If the installed reserve margin resulting from the total UCAP committed through self supply or BRAs for three consecutive years is more than one percentage point lower than the approved PJM installed reserve margin, PJM will make a filing with FERC to conduct a Reliability Backstop Auction. If the total UCAP committed for all base load generation resources in BRAs for three consecutive years is less than the forecasted minimum hourly load, PJM will make a filing with FERC to conduct a Reliability Backstop Auction.

The 2025/2026 RPM Third Incremental Auction and the 2026/2027 RPM Base Residual Auction were conducted in the first nine months of 2025.

Market Structure

- **RPM Installed Capacity.** In the first nine months of 2025, RPM installed capacity increased 2,072.3 MW or 1.2 percent, from 179,656.2 MW on January 1, to 181,728.5 MW on June 30. Installed capacity includes net capacity imports and exports and can vary on a daily basis.
- **Reserves.** Total reserves on June 1, 2025, were 19,999.9 MW, which is 205.1 MW (UCAP) short of the required reserve level of 20,205.0 MW (UCAP). On June 1, 2025, the target installed reserve margin was 17.8 percent, and the actual reserve margin was only 17.6 percent.
- **RPM Installed Capacity by Fuel Type.** Of the total installed capacity on September 30, 2025, 48.9 percent was gas; 20.7 percent was coal; 17.7 percent was nuclear; 4.5 percent was hydroelectric; 2.2 percent was oil; 1.2 percent was wind; 0.3 percent was solid waste; and 4.4 percent was solar.
- **Market Concentration.** In the 2025/2026 RPM Third Incremental Auction and the 2026/2027 RPM Base Residual Auction, all participants in the total PJM market as well as the LDA RPM markets failed the three pivotal

85 The terms *PJM Region*, *RTO Region* and *RTO* are synonymous in this report and include all capacity within the PJM footprint.
86 See 186 FERC ¶ 61,080 (2024), *reh'g order*, 189 FERC ¶ 61,043 (2024).
87 Effective for the 2020/2021 and subsequent delivery years, the RPM market design incorporated seasonal capacity resources. Summer period and winter period capacity must be matched either through commercial aggregation or through the optimization in equal MW amounts in the LDA or the lowest common parent LDA.
88 See 126 FERC ¶ 61,275 at P 86 (2009).
89 See Letter Order, FERC Docket No. ER10-366-000 (January 22, 2010).
90 See 126 FERC ¶ 61,275 at P 88 (2009). There have been no Conditional Incremental Auctions.
91 See OATT Attachment DD § 16.

supplier (TPS) test.[92] Offer caps were applied to all sell offers for resources which were subject to mitigation when the capacity market seller did not pass the test, the submitted sell offer exceeded the defined offer cap, and the submitted sell offer, absent mitigation, increased the market clearing price.[93] [94] [95]

- **Imports and Exports.** Of the 1,281.7 MW of imports offered in the 2026/2027 RPM Base Residual Auction, 1,281.7 MW cleared. Of the cleared imports, 697.4 MW (54.4 percent) were from MISO.
- **Demand Resources.** Committed DR was 5,782.9 MW for June 1, 2025, as a result of cleared capacity for demand resources in RPM auctions for the 2025/2026 Delivery Year (6,265.9 MW) less replacement capacity (483.0 MW).
- **Energy Efficiency Resources.** EE is not a capacity resource but is paid the capacity market clearing price as a subsidy through the 2025/2026 Delivery Year. Committed EE was 1,481.6 MW for June 1, 2025, as a result of MW offered at a price less than or equal to the RPM auction clearing price in RPM auctions for the 2025/2026 Delivery Year (1,493.2 MW) less replacement MW (11.6 MW).

Market Conduct

- **2025/2026 RPM Third Incremental Auction.** Of the 307 generation resources that submitted Capacity Performance offers, unit specific offer caps were calculated for two generation resources (0.7 percent).
- **2026/2027 RPM Base Residual Auction.** Of the 1,293 generation resources that submitted Capacity Performance offers, unit specific offer caps were calculated for 82 generation resources (6.3 percent).

92 There are 27 Locational Deliverability Areas (LDAs) identified to recognize locational constraints as defined in "Reliability Assurance Agreement Among Load Serving Entities in the PJM Region," Schedule 10.1. PJM determines, in advance of each BRA, whether the defined LDAs will be modeled in the given delivery year using the rules defined in OATT Attachment DD § 5.10(a)(ii).
93 See OATT Attachment DD § 6.5.
94 Prior to November 1, 2009, existing DR and EE resources were subject to market power mitigation in RPM Auctions. See 129 FERC ¶ 61,081 at P 30 (2009).
95 Effective January 31, 2011, the RPM rules related to market power mitigation were changed, including revising the definition for Planned Generation Capacity Resource and creating a new definition for Existing Generation Capacity Resource for purposes of the must offer requirement and market power mitigation, and treating a proposed increase in the capability of a generation capacity resource the same in terms of mitigation as a Planned Generation Capacity Resource. See 134 FERC ¶ 61,065 (2011).

Market Performance

- The 2025/2026 RPM Third Incremental Auction and the 2026/2027 RPM Base Residual Auction were conducted in the first nine months of 2025. The weighted average capacity price for the 2025/2026 Delivery Year is $296.98 per MW-day, including all RPM auctions for the 2025/2026 Delivery Year. The weighted average capacity price for the 2026/2027 Delivery Year is $329.17 per MW-day, including all RPM auctions for the 2026/2027 Delivery Year.
- For the 2025/2026 Delivery Year, RPM annual charges to load are $14.8 billion.
- In the 2026/2027 RPM Base Residual Auction, the market performance was determined to be not competitive.

Part V Reliability Service (RMR)

- Of the nine companies (28 units) that have provided service following deactivation requests, two companies (seven units) filed to be paid under the deactivation avoidable cost rate (DACR), the formula rate. The other seven companies (21 units) filed to be paid under the cost of service recovery rate.

Generator Performance

- **Forced Outage Rates.** The average PJM EFORd in the first nine months of 2025 was 6.6 percent, an increase from 4.5 percent in the first nine months of 2024.[96]
- **Generator Performance Factors.** The PJM aggregate equivalent availability factor in the first nine months of 2025 was 83.7 percent, a decrease from 86.3 percent in the first nine months of 2024.

96 The generator performance analysis includes all PJM capacity resources for which there are data in the PJM generator availability data systems (GADS) database. Data was downloaded from the PJM GADS database on October 22, 2025. EFORd data presented in state of the market reports may be revised based on data submitted after the publication of the reports as generation owners may submit corrections at any time with permission from PJM GADS administrators.

Section 5 Recommendations[97]

Definition of Capacity

- The MMU recommends elimination of the key remaining components of the CP model because they interfere with competitive outcomes in the capacity market and create unnecessary complexity and risk. (Priority: High. First reported 2022. Status: Not adopted.)
- The MMU recommends the enforcement of a consistent definition of capacity resources. The MMU recommends that the tariff requirement to be a physical resource be enforced and enhanced. The requirement to be a physical resource should apply at the time of auctions and should also constitute a commitment to be physical in the relevant delivery year. The requirement to be a physical resource should be applied to all resource types, including planned generation, demand resources, and imports.[98] [99] (Priority: High. First reported 2013. Status: Not adopted.)
- The MMU recommends that DR providers be required to have a signed contract with specific customers for specific facilities for specific levels of DR at least six months prior to any capacity auction in which the DR is offered. (Priority: High. First reported 2016. Status: Not adopted.)
- The MMU recommends that Energy Efficiency Resources (EE) not be included in the capacity market construct because PJM's load forecasts have accounted for EE since the 2016 load forecast for the 2019/2020 Delivery Year. EE is not a capacity resource as defined in the tariff, and there is no reason to continue to pay large subsidies to EE providers.[100] (Priority: Medium. First reported 2016. Status: Adopted 2024.)[101]
- The MMU recommends that PJM require all market participants to meet their deliverability requirements under the same rules. PJM should end the practice of giving away winter CIRs to intermittent resources that appear to exist because other resources paid for the supporting network upgrades. (Priority: High. First reported 2017. Status: Not adopted.)[102]
- The MMU recommends that the must offer rule in the capacity market apply to all capacity resources. There is no reason to exempt intermittent and capacity storage resources, including hydro, and demand resources from the must offer requirement. The same rules should apply to all capacity resources in order to ensure open access to the transmission system and prevent the exercise of market power through withholding. (Priority: High. First reported 2021. Status: Partially adopted.)
- The MMU recommends that PJM require all market sellers of proposed generation capacity resources, including thermal and intermittent, to submit a binding notice of intent to offer at least six months prior to the base residual auction. This is consistent with the overall MMU recommendation that all capacity resources have a must offer obligation in the capacity market auctions. (Priority: High. First reported 2023. Status: Partially adopted.)
- The MMU recommends that PJM's application of the ELCC approach be replaced with an ELCC approach that is based on the actual hourly availability of all individual generators for accreditation and for payment. The MMU recommends short term modifications to PJM's approach to include hourly data that would permit unit specific ELCC ratings, to weight summer and winter risk in a more balanced manner, to eliminate PAI risks, and to pay for actual hourly performance rather than based on inflexible class capacity accreditation ratings derived from a small number of nonrepresentative hours of poor performance from PV1 and WSE. (Priority: High. First reported 2023. Status: Not adopted.)

Market Design and Parameters

- The MMU recommends that PJM establish a load queue for large new data center loads to ensure that such loads are not added until there is adequate generation capacity to serve them. The MMU recommends that an expedited queue option that would permit both the load and the

97 The MMU has identified serious market design issues with RPM and the MMU has made specific recommendations to address those issues. These recommendations have been made in public reports. See Table 5-2.

98 See also Comments of the Independent Market Monitor for PJM, Docket No. ER14-503-000 (December 20, 2013).

99 See "Analysis of Replacement Capacity for RPM Commitments: June 1, 2007 to June 1, 2019," <http://www.monitoringanalytics.com/reports/Reports/2019/IMM_Analysis_of_Replacement_Capacity_for_RPM_Commitments_June_1_2007_to_June_1_2019_20190913.pdf> (September 13, 2019).

100 "PJM Manual 19: Load Forecasting and Analysis," § 3.2 Development of the Forecast, Rev. 37 (Dec. 18, 2024).

101 See 189 FERC ¶ 61,095 (2024).

102 This recommendation was first made in the 2020/2021 BRA report in 2017. See the "Analysis of the 2020/2021 RPM Base Residual Auction," <http://www.monitoringanalytics.com/reports/Reports/2017/IMM_Analysis_of_the_20202021_RPM_BRA_20171117.pdf> (November 11, 2017).

generation to be added without delays be available to large data centers if they bring their own new generation with locational and temporal characteristics reasonably matched to their load profile. (Priority: High. First reported Q2, 2025. Status: Not adopted.)

- The MMU recommends that PJM reevaluate the shape of the VRR curve. The shape of the VRR curve directly results in load paying substantially more for capacity than load would pay with a vertical demand curve. More specifically, the MMU recommended that the VRR curve be rotated half way towards the vertical demand curve at the reliability requirement in the 2022 Quadrennial Review. (Priority: High. First reported 2021. Status: Partially adopted.)
- The MMU recommends that the maximum price on the VRR curve be defined as 1.5 times Net CONE, capped at Gross CONE. (Priority: Medium. First reported 2019. Status: Not adopted.)
- The MMU recommends that the reference resource be a CT rather than a CC. The MMU recommends that the ELCC value used to convert the gross CONE in ICAP terms for a CT to the gross CONE in UCAP terms be the ELCC based on winter ratings. (Priority: High. First reported 2024. Status: Adopted 2025.)
- The MMU recommends that the test for determining modeled Locational Deliverability Areas (LDAs) in RPM be redefined. A detailed reliability analysis of all at risk units should be included in the redefined model including transmission constraints inside LDAs. The market design should clear and pay units that are needed for reliability per PJM's transmission reliability analysis in order to forestall RMRs. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM clear the capacity market based on nodal capacity resource locations and the characteristics of the transmission system inside and outside LDAs consistent with the actual electrical facts of the grid. Absent a fully nodal capacity market clearing process, the MMU recommends that PJM use a non-nested model with all LDAs modeled including VRR curves for all LDAs. Each LDA requirement should be met with the capacity resources located within the LDA and exchanges from neighboring LDAs up to the transmission limit. LDAs should be allowed to price separate if that is the result of the LDA supply curves and the transmission constraints between LDAs. (Priority: Medium. First reported 2017. Status: Not adopted.)
- The MMU recommends that the net revenue offset calculation used by PJM to calculate the net Cost of New Entry (CONE) and net ACR be based on a forward looking calculation of expected energy and ancillary services net revenues using historical net revenues that are scaled based on forward prices for energy and fuel. (Priority: High. First reported 2014. Status: Not adopted.)[103]
- The MMU recommends that PJM reduce the number of incremental auctions to a single incremental auction held three months prior to the start of the delivery year and reevaluate the triggers for holding conditional incremental auctions. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM not sell back any capacity in any IA procured in a BRA. If PJM continues to sell back capacity, the MMU recommends that PJM offer to sell back capacity in incremental auctions only at the BRA clearing price for the relevant delivery year. (Priority: Medium. First reported 2017. Status: Not adopted.)
- The MMU recommends that PJM not buy any capacity in any IA if PJM has already procured excess reserves. (Priority: Medium. First reported 2023. Status: Not adopted.)
- The MMU recommends changing the RPM solution method to explicitly incorporate the cost of uplift (make whole) payments in the objective function. (Priority: Medium. First reported 2014. Status: Not adopted.)
- The MMU recommends that the Fixed Resource Requirement (FRR) rules, including obligations and performance requirements, be revised and updated to ensure that the rules reflect current market realities and that FRR entities do not unfairly take advantage of those customers paying for capacity in the PJM capacity market. (Priority: Medium. First reported 2019. Status: Not adopted.)

103 This recommendation was first made during the Quadrennial Review in 2014, including the PJM Capacity Senior Task Force (CSTF), the MRC and the MC. <https://www.pjm.com/committees-and-groups/closed-groups/cstf>.

- The MMU recommends that the value of CTRs be defined by the total MW cleared in the capacity market, the internal MW cleared and the imported MW cleared, and not redefined later prior to the delivery year. (Priority: Medium. First reported 2021. Status: Not adopted.)
- The MMU recommends that the market clearing results be used in settlements rather than the reallocation process currently used, or that the process of modifying the obligations to pay for capacity be reviewed. (Priority: Medium. First reported 2021. Status: Not adopted.)[104]
- The MMU recommends that PJM improve the clarity and transparency of its CETL calculations. The MMU also recommends that CETL for capacity imports into PJM be based on the ability to import capacity only where PJM capacity exists and where that capacity has a must offer requirement in the PJM Capacity Market. (Priority: Medium. First reported 2021. Status: Partially adopted 2022.)

Offer Caps, Offer Floors, and Must Offer

- The MMU recommends using the lower of the cost or price-based energy market offer to calculate energy costs in the calculation of the historical net revenues which are an offset to gross ACR in the calculation of unit specific capacity resource offer caps based on net ACR. (Priority: Medium. First reported 2021. Status: Not adopted.)
- The MMU recommends that modifications to existing resources, including relatively small proposed increases in the capability of a Generation Capacity Resource be treated as an existing resource and subject to the corresponding market power mitigation rules and no longer be treated as planned and exempt from offer capping. (Priority: Medium. First reported 2012. Status: Not adopted.)[105]
- The MMU recommends that the RPM market power mitigation rules be modified to apply offer caps in all cases when the three pivotal supplier test is failed and the sell offer is greater than the offer cap. This will ensure that market power does not result in an increase in uplift (make whole) payments for seasonal products. (Priority: Medium. First reported 2017. Status: Not adopted.)
- The MMU recommends that any combined seasonal resources be required to be in the same LDA and at the same location, in order for the energy market and capacity market to remain synchronized and reliability metrics correctly calculated. (Priority: Medium. First reported 2021. Status: Not adopted.)
- The MMU recommends that the definition of avoidable costs in the tariff be corrected to be consistent with the economic definition. Avoidable costs are costs that are neither short run marginal costs, like fuel or consumables, nor fixed costs like depreciation and rate of return. Avoidable costs are the marginal costs of capacity and therefore the competitive offer level for capacity resources and therefore the market seller offer cap. Avoidable costs are the marginal costs of capacity for both new resources and existing resources. (Priority: Medium. First reported 2017. Status: Not adopted.)[106]
- The MMU recommends that major maintenance costs be included in the definition of avoidable costs and removed from energy offers because such costs are avoidable costs and not short run marginal costs. (Priority: High. First reported 2019. Status: Not adopted.)
- The MMU recommends that capacity market sellers be required to explicitly request and support the use of minimum MW quantities (inflexible sell offer segments) and that the requests only be permitted for defined physical reasons. (Priority: Medium. First reported 2018. Status: Not adopted.)

104 This recommendation was first made in the 2023/2024 BRA report in 2022. See "Analysis of the 2023/2024 RPM Base Residual Auction Revised," <http://www.monitoringanalytics.com/reports/Reports/2022/IMM_Analysis_of_the_20232024_RPM_Base_Residual_Auction_20221028.pdf> (October 28, 2022).

105 This recommendation was first made in the 2014/2015 BRA report in 2012. See "Analysis of the 2014/2015 RPM Base Residual Auction," <http://www.monitoringanalytics.com/reports/Reports/2012/Analysis_of_2014_2015_RPM_Base_Residual_Auction_20120409.pdf> (April 9, 2012).

106 This recommendation was first made in the 2023/2024 BRA report in 2022. See "Analysis of the 2023/2024 RPM Base Residual Auction Revised," <http://www.monitoringanalytics.com/reports/Reports/2022/IMM_Analysis_of_the_20232024_RPM_Base_Residual_Auction_20221028.pdf> (October 28, 2022).

- The MMU recommends that, as part of the MOPR unit specific standard of review, all projects be required to use the same basic modeling assumptions. That is the only way to ensure that projects compete on the basis of actual costs rather than on the basis of modeling assumptions.[107] (Priority: High. First reported 2013. Status: Not adopted.)

Performance Incentive Requirements of RPM

- The MMU recommends that any unit not capable of supplying energy equal to its day-ahead must offer requirement (ICAP) be required to reflect an appropriate outage and associated performance penalty. (Priority: Medium. First reported 2009. Status: Not adopted.)
- The MMU recommends that retroactive replacement transactions associated with a failure to perform during a PAI not be allowed and that, more generally, retroactive replacement capacity transactions not be permitted. (Priority: Medium. First reported 2016. Status: Not adopted.)
- The MMU recommends that there be an explicit requirement that capacity resource offers in the day-ahead energy market be competitive, where competitive is defined to be the short run marginal cost of the units, including flexible operating parameters. (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends that Capacity Performance resources be required to perform without excuses. Resources that do not perform should not be paid regardless of the reason for nonperformance. (Priority: High. First reported 2019. Status: Not adopted.)
- The MMU recommends that PJM require actual seasonal tests as part of the Summer/Winter Capability Testing rules, that the number of tests be limited, and that the ambient conditions under which the tests are performed be defined to reflect seasonal extreme conditions. (Priority: Medium. First reported 2022. Status: Not adopted.)

107 See 143 FERC ¶ 61,090 (2013) ("We encourage PJM and its stakeholders to consider, for example, whether the unit-specific review process would be more effective if PJM requires the use of common modeling assumptions for establishing unit-specific offer floors while, at the same time, allowing sellers to provide support for objective, individual cost advantages. Moreover, we encourage PJM and its stakeholders to consider these modifications to the unit-specific review process together with possible enhancements to the calculation of Net CONE."); see also, Comments of the Independent Market Monitor for PJM, Docket No. ER13-535-001 (March 25, 2013); Complaint of the Independent Market Monitor for PJM v. Unnamed Participant, Docket No. EL12-63-000 (May 1, 2012); Motion for Clarification of the Independent Market Monitor for PJM, Docket No. ER11-2875-000, et al. (February 17, 2012); Protest of the Independent Market Monitor for PJM, Docket No. ER11-2875-002 (June 2, 2011); Comments of the Independent Market Monitor for PJM, Docket Nos. EL11-20 and ER11-2875 (March 4, 2011).

- The MMU recommends that PJM select the time and day that a unit undergoes Net Capability Verification Testing, not the unit owner, and that this information not be communicated in advance to the unit owner. (Priority: Medium. First reported 2022. Status: Not adopted.)

Capacity Imports and Exports

- The MMU recommends that all capacity imports be required to be deliverable to PJM load in an identified LDA, zonal or subzonal, or defined combinations of specific zones, e.g. MAAC, prior to the relevant delivery year to ensure that they are full substitutes for internal, physical capacity resources. Pseudo ties alone are not adequate to ensure deliverability to PJM load. (Priority: High. First reported 2016. Status: Not adopted.)
- The MMU recommends that all costs incurred as a result of a pseudo tied unit be borne by the unit itself and included as appropriate in unit offers in the capacity market. (Priority: High. First reported 2016. Status: Not adopted.)

Deactivations/Retirements

- The MMU recommends that the notification requirement for deactivations be extended from the current one quarter prior (See Table 5-29) to 12 months prior to an auction in which the unit will not be offered due to deactivation; and no less than 12 months prior to the date of deactivation (Priority: Low. First reported 2012. Status: Partially adopted.)
- The MMU recommends that the same reliability standard be used in capacity auctions as is used by PJM transmission planning. One result of the current design is that a unit may fail to clear in a BRA, decide to retire as a result, but then be found to be needed for reliability by PJM planning and paid under Part V of the OATT (RMR) to remain in service while transmission upgrades are made. (Priority: High. First reported 2023. Status: Not adopted.)
- The MMU recommends elimination of both the cost of service recovery rate option and the deactivation avoidable cost rate option for providing Part V reliability service (RMR), and their replacement with clear language that provides for the recovery of 100 percent of the actual incremental

costs required to operate to provide the service plus a defined incentive. (Priority: High. First reported 2017. Status: Not adopted.)

- The MMU recommends that units recover all and only the incremental costs, including incremental investment costs without a cap, required to provide Part V reliability service (RMR service) that the unit owner would not have incurred if the unit owner had deactivated its unit as it proposed, plus a defined incentive payment. Customers should bear no responsibility for paying previously incurred (sunk) costs, including a return on or of prior investments. (Priority: High. First reported 2010. Status: Not adopted.)
- The MMU recommends that if units that are paid under Part V of the OATT (RMR) are included in the calculation of CETO and/or reliability in the relevant LDA, the capacity of the RMR resources should also be included in capacity market supply at zero cost, but without all the obligations of a capacity resource, in order to ensure that the capacity market price signal reflects the appropriate supply and demand conditions. (Priority: High. First reported 2023. Status: Partially adopted.)
- The MMU recommends that units that are paid under Part V of the OATT (RMR) not be included in the calculation of CETO or reliability in the relevant LDA, in order to ensure that the capacity market price signal reflects the appropriate supply and demand conditions, until a decision is made to build transmission as a replacement, and then should be included. (Priority: High. First reported 2023. Status: Not adopted.)
- The MMU recommends that all CIRs be returned to the pool of available interconnection capability on the retirement date of generation resources in order to facilitate timely and competitive entry into the PJM markets, open access to the transmission system and maintain the priority order defined by the queue process. (Priority: High. First reported 2023. Status: Not adopted.)

Section 5 Conclusion

The analysis of the PJM Capacity Market begins with market design and market structure, which provide the framework for the actual behavior or conduct of market participants. The analysis examines participant behavior within that market design and market structure. Regardless of the ownership structure of a market, the market design can result in noncompetitive outcomes. In a good market design and a competitive market structure, market participants are constrained to behave competitively. In a market with endemic structural market power like the PJM Capacity Market, effective market power mitigation rules are required in order to constrain market participants to behave competitively. The analysis examines market performance, measured by price and the relationship between price and marginal cost, that results from the interaction of market structure and participant behavior. The analysis also examines the impact of market design choices on market performance.

The MMU concludes that the results of the 2026/2027 RPM Base Residual Auction were significantly affected by flawed market design elements including the lack of a queue for the addition of large new data center loads, by the performance assessment interval (PAI) penalties that are part of the CP design, by PJM's ELCC approach, by the definition of market seller offer caps, by the failure to extend the RPM must offer requirement to demand resources, and by the product definition and lack of market power mitigation for demand resources. The BRA prices do not reflect supply and demand fundamentals but reflect, in significant part, PJM decisions about the definition of supply and demand. PJM filed changes that were approved by FERC and included in the 2026/2027 BRA to adopt two of the MMU's recommendations, the inclusion of specific RMR resources as supply in the next two BRAs and the elimination of the categorical exemption to the RPM must offer requirement for all but demand resources.[108] [109]

The capacity market is, by design, always tight in the sense that total supply is generally only slightly larger than demand. While the market may be long at times, that is not the equilibrium state. Market power is and will remain endemic to the structure of the PJM Capacity Market. Nonetheless, a competitive outcome can be assured by appropriate market power mitigation rules within an effective market design. Detailed market power mitigation rules are included in the PJM Open Access Transmission Tariff (OATT or

108 See Letter Order, FERC Docket No. ER25-682-001 (April 29, 2025).
109 190 FERC ¶ 61,117 (2025).

Tariff). Reliance on the RPM design for competitive outcomes means reliance on the market power mitigation rules.

The basic conclusion of Part A of the MMU's analysis of the 2026/2027 BRA is that data center load growth is the primary reason for recent and expected capacity market conditions, including total forecast load growth, the tight supply and demand balance, and high prices. But for data center growth, both actual and forecast, the PJM Capacity Market would not have seen the same tight supply demand conditions, the same high prices observed in the 2025/2026 BRA and 2026/2027 BRA or the currently expected tight supply conditions and high prices for subsequent capacity auctions. The combined total increase in capacity market revenues resulting from data center load, both actual and forecast, for the 2025/2026 BRA and the 2026/2027 BRA was $16,603,301,829.[110] [111] This total will continue to grow until the issues associated with the additions of large data center loads are addressed. The impact will increase significantly in the 2028/2029 BRA currently scheduled for June 2026, when the maximum and minimum prices defined by the Agreement are no longer effective.

It is misleading to assert that the capacity market results are simply just a reflection of supply and demand. The current conditions are not the result of organic load growth. The current conditions in the capacity market are almost entirely the result of large load additions from data centers, both actual historical and forecast. The growth in data center load and the expected future growth in data center load are unique and unprecedented and uncertain and require a different approach than simply asserting that it is just supply and demand.

It is equally misleading to assert that the PJM Capacity Market does not work as a result of the impact of existing and forecast large data center load additions. Despite all the issues with PJM's changes to the capacity market design, the PJM Capacity Market would have provided for reliability at prices consistent with organic load growth and the cost of new capacity were it not for the paradigm shift represented by the almost inexhaustible demand for power from data centers.

Data center load growth is the core reliability issue facing PJM markets at present. There is still time to address the issue but failure to do so will result in very high costs for other PJM customers and could also result in a switch from competitive markets to cost of service regulation. Customers are already bearing billions of dollars in higher costs as a direct result of existing and forecast data center load as the Market Monitor demonstrated in Part G of the 2025/2026 BRA Analysis report and Part A of the 2027/2027 BRA Analysis Report.[112] [113]

PJM should not continue to interconnect large new data center load if it cannot be served reliably. The goal should be to serve all load that can be served reliably. The MMU recommends that PJM establish a load queue for large new data center loads to ensure that such loads are not added until there is adequate generation capacity to serve them. The MMU recommends that an expedited queue option that would permit both the load and the generation to be added without delays be available to large data centers if they bring their own new generation with locational and temporal characteristics reasonably matched to their load profile

For the first time since the introduction of the RPM capacity market design, the 2026/2027 BRA used a VRR curve with both a defined maximum price and a defined minimum price. The maximum and minimum prices were based on the Agreement between Governor Shapiro of Pennsylvania and PJM that was incorporated in a PJM filing with FERC.[114] That VRR curve with the defined maximum and minimum price is referred to in this report as the restricted VRR curve. The VRR curve that would have been used absent the Agreement is referred in this report as the unrestricted VRR curve.

113 See "Analysis of the 2026/2027 RPM Base Residual Auction - Part A," (October 1, 2025) <https://www.monitoringanalytics.com/reports/Reports/2025/IMM_Analysis_of_the_20262027_RPM_Base_Residual_Auction_Part_A_20251001.pdf>.

114 On December 30, 2024, in Docket No. EL25-46-000, Governor Josh Shapiro and the Commonwealth of Pennsylvania filed a complaint against PJM asserting that the maximum price for PJM's capacity auctions is unjust and unreasonable. The Governor and PJM reached an Agreement. On February 20, 2025, in Docket No. ER25-1357-000, pursuant to FPA section 205, PJM submitted proposed revisions to its Tariff to establish a specific maximum price and minimum price for all RPM auctions for the 2026/2027 and 2027/2028 delivery years, consistent with the Agreement.

The Agreement resulted in a reduction of BRA revenues of $3,169,915,210, or 16.4 percent, compared to the revenues that would have resulted from the unrestricted VRR curve, holding everything else constant. If the 2026/2027 BRA had been run with an unrestricted VRR curve, total revenues would have been $19,294,286,100, an increase of $3,169,915,210, or 19.7 percent, compared to the actual auction revenues of $16,124,370,889 (Scenario 1).

The demand for capacity includes expected peak load plus a reserve margin, and points on the demand curve, called the Variable Resource Requirement (VRR) curve, exceed peak load plus the reserve margin. The maximum price on the VRR curve has a significant impact on market prices particularly when the market is tight. The shape of the VRR curve results in the purchase of excess capacity and higher payments by customers. The VRR curves used in the 2025/2026 BRA included a maximum price equal to gross CONE for most LDAs that resulted in a significant increase in customer payments for load as a result of paying a price above the competitive level. Demand for capacity is almost entirely inelastic because the market rules require loads to purchase their share of the system capacity requirement. The VRR demand curve is everywhere inelastic. The result is that any supplier that owns more capacity than the typically small difference between total supply and the defined demand is individually pivotal and therefore has structural market power.

For the 2026/2027 RPM Base Residual Auction, total reserves were 21,353.2 MW, which is 208.7 MW (UCAP) short of the required reserve level of 21,561.9 MW (UCAP). The level of committed demand resources in the 2026/2027 BRA was 5,530.6 MW, meaning the PJM markets will rely on demand resources as part of the required reserve margin, rather than as excess above the required reserve margin. This is not consistent with the defined obligations of DR compared to other capacity resources. DR capacity resources do not have a must offer obligation in the energy market. DR capacity resources do not have a must offer obligation in the capacity market. The definition of performance for DR is not to provide a defined incremental level of MW when called but is only to be at a defined level of demand. DR capacity resources do not have a defined market seller offer cap. PJM markets for the first time in the 2025/2026 and 2026/2027 Delivery Years will rely on demand response resources as part of the required reserve margin, rather than as excess above the required reserve margin. PJM markets for the first time in the 2025/2026 and 2026/2027 Delivery Years will experience the implications of the definition of demand resources as a purely emergency capacity resource, when demand resources are a significant share of required reserves. Nonetheless, as another significant flaw in the market design, PJM does not include DR in its definition of primary or secondary reserves in the energy market. DR, for all these reasons, is an inferior resource in the capacity market. PJM does not have clear rules defining when the operators must call on DR.

There are currently two important gaps in the market power rules for the PJM Capacity Market related to demand resources. The RPM must offer requirement is not applied to demand resources. There are no market power mitigation rules that apply to demand resources.

For the 2026/2027 BRA, all participants to which the three pivotal supplier (TPS) test was applied (in the RTO RPM market) failed the three pivotal supplier test. The result was that offer caps were applied to all sell offers for Existing Generation Capacity Resources when the capacity market seller did not pass the test, the submitted sell offer exceeded the tariff defined offer cap, and the submitted sell offer, absent mitigation, would have resulted in a higher market clearing price.[115] [116]

The correct definition of a competitive offer in the capacity market is the marginal cost of capacity, net ACR, where ACR includes an explicit accounting for the costs of mitigating risk, including the risk associated with mitigating rational capacity market nonperformance penalties, and the relevant costs of acquiring fuel, including natural gas.

The MMU recommends elimination of the key remaining components of the CP model because they interfere with competitive outcomes in the capacity market and create unnecessary complexity and risk. The use of Net CONE as the basis for the PAI penalty rate is unsupported by economic logic. The use

115 Prior to November 1, 2009, existing DR and EE were subject to market power mitigation in RPM Auctions. See 129 FERC ¶ 61,081 (2009) at P 30.

116 Effective January 31, 2011, the RPM rules related to market power mitigation were changed, including revising the definition for Planned Generation Capacity Resource and creating a new definition for Existing Generation Capacity Resource for purposes of the must-offer requirement and market power mitigation, and treating a proposed increase in the capability of a Generation Capacity Resource the same in terms of mitigation as a Planned Generation Capacity Resource. See 134 FERC ¶ 61,065 (2011).

of Net CONE to establish penalties is a form of arbitrary administrative pricing that creates arbitrarily high risk for generators, creates complexity in the calculation of CPQR and increases CPQR above rational levels, and ultimately raises the price of capacity above the competitive level. Given PJM's recent decision to rely on conservative operations during tight market conditions as evidenced during Polar Vortex 2025 in January 2025, the probability of a PAI is extremely small. In addition, PJM tightened the definition of a PAI and capped the total annual penalty at 1.5 times the resource's capacity market BRA clearing price. As a result, there is no effective performance incentive remaining in the capacity market.

Rather than penalizing capacity resources at extremely high levels for nonperformance only during PAI events, capacity resources should be paid the daily price of capacity only to the extent that they are available to produce energy or provide reserves, as required by PJM on a daily/hourly basis, based on their cleared capacity (ICAP). This is a positive performance incentive based on the market price of capacity rather than a penalty based on an arbitrary assumption. This would mean that capacity resources are paid to provide energy and reserves based on their full ICAP and are not paid a bonus for doing so. The reduced payments for capacity would directly reduce customers' bills for capacity. This would also end the pretense that there will be penalty payments to fund bonus payments. This would also end the need for complex CPQR calculations based on the penalty rate and assumptions about the number and timing of PAI events. CP has not worked as the theory suggested. PAI events are high impact, low probability events. The failure of the PAI incentives to prevent a very high level of outages during Winter Storm Elliott illustrates the weakness of incentives based on this type of event. In addition, the actual performance standards were unacceptably weakened in the CP model. The standard of performance in the CP model is (B) * (ELCC accredited UCAP factor for a unit), where B is the balancing ratio and the ELCC accredited UCAP factor is the derating factor. For example, if B were 80 percent, the actual required performance for a unit with an 80 percent ELCC accredited UCAP factor would be only 64 percent of ICAP (.80 * .80). For units with low ELCC accredited UCAP factors, the required performance is even lower. The obligation to perform should equal the full ICAP value of a unit, consistent with the associated must offer obligation in the energy market for capacity resources.

The MMU is required to identify market issues and to report them to the Commission and to market participants. The Commission decides on any action related to the MMU's findings.

The MMU has identified serious market design issues with RPM and the MMU has made specific recommendations to address those issues.[117] [118] [119] [120] [121] [122] [123] [124] [125] [126] [127] [128] [129] In the first nine months of 2025, the MMU prepared a number of RPM related reports and testimony, shown in Table 5-2.

The PJM markets have worked to provide incentives to entry and to retain capacity. A majority of capacity investments in PJM were financed by market sources. Of the 57,618.3 MW of additional capacity that cleared in RPM auctions for the 2007/2008 through 2024/2025 Delivery Years, 43,653.8 MW (76.0 percent) were based on market funding. Of the 5,661.6 MW of additional capacity that cleared in RPM auctions for the 2025/2026 and 2026/2027 Delivery Years, 4,487.6 MW (79.3 percent) were based on market funding. Those investments were made based on the assumption that markets would be allowed to work and that inefficient units would exit.

It is essential that any approach to the PJM markets incorporate a consistent view of how the preferred market design is expected to provide competitive results in a sustainable market design over the long run. A sustainable market design means a market design that results in appropriate incentives to competitive market participants to retire units and to invest in new units over time such that reliability is ensured as a result of the functioning of the market.

In order to attract and retain adequate resources for the reliable operation of the energy market, revenues from PJM energy, ancillary services and capacity markets must be adequate for those resources. That adequacy requires a capacity market. The capacity market plays the essential role of equilibrating the revenues necessary to incent competitive entry and exit of the resources needed for reliability, with the revenues from the energy market that are directly affected by nonmarket sources.

Overview: Section 6, Demand Response

- **Demand Response Activity.** Demand response resources include economic demand response (energy market demand resources), emergency demand response, pre-emergency demand response and price responsive demand (PRD) (capacity market demand resources), synchronized reserves and regulation.[130]

  Total demand response revenue increased by $221.8 million, 194.2 percent, from $114.2 million in the first nine months of 2024 to $336.0 million in the first nine months of 2025, primarily due to increases in capacity market revenue. Emergency demand response revenue accounted for 85.9 percent of all demand response revenue, economic demand response for 6.1 percent, demand response in the synchronized reserve market for 4.2 percent and demand response in the regulation market for 3.8 percent.

  Total emergency demand response revenue increased by $201.5 million, 231.5 percent, from $87.0 million in the first nine months of 2024 to $288.5 million in the first nine months of 2025.[131] This increase was primarily a result of higher capacity market prices and capacity market revenue.

  Economic demand response revenue increased by $11.8 million, 134.4 percent, from $8.7 million in the first nine months of 2024 to $20.5 million in the first nine months of 2025.[132] Demand response revenue in the synchronized reserve market increased by $5.9 million, 70.7 percent, from $8.3 million in the first nine months of 2024 to $14.2 million in the first nine months of 2025. Demand response revenue in the regulation market increased by $2.7 million, 26.5 percent, from $10.1 million in the first nine months of 2024 to $12.8 million in the first nine months of 2025.

- **Demand Response Energy Payments are Uplift.** Energy payments to emergency and economic demand response resources are uplift. LMP does not cover energy payments to demand response resources although emergency demand response and economic demand response can and do set LMP. Energy payments to emergency demand resources are paid by PJM market participants in proportion to their net purchases in the real-time energy market. Energy payments to economic demand resources are paid by real-time exports from PJM and real-time loads in each zone for which the load-weighted, average real-time LMP for the hour during which the reduction occurred is greater than or equal to the net benefits test price for that month.[133]

- **Demand Response Market Concentration.** The ownership of economic demand response resources was highly concentrated in the first nine months of 2024 and 2025. The HHI for economic demand response resource reductions decreased by 46 points from 8846 in the first nine months of 2024 to 8800 in the first nine months of 2025.

  The ownership of emergency demand response resources is highly concentrated. The HHI for emergency demand response resources committed MW was 2387 for the 2024/2025 Delivery Year. In the 2024/2025 Delivery Year, the four largest CSPs owned 88.5 percent of all committed emergency demand response UCAP MW. The HHI for

130 Emergency demand response refers to both emergency and pre-emergency demand response.
131 The total credits and MWh numbers for demand resources were downloaded as of October 14, 2025, and may change as a result of continued PJM billing updates.
132 Economic credits are synonymous with revenue received for reductions under the economic load response program.
133 "PJM Manual 28: Operating Agreement Accounting," § 11.2.2, Rev. 102 (Oct. 1, 2025).

emergency demand response committed MW is 2517 for the 2025/2026 Delivery Year. In the 2025/2026 Delivery Year, the four largest CSPs own 86.7 percent of all committed demand response UCAP MW.

- **Limited Locational Dispatch of Demand Resources.** With full implementation of the Capacity Performance rules in the capacity market in the 2020/2021 Delivery Year, PJM should be able to individually dispatch any capacity performance resource, including demand resources. PJM cannot dispatch demand resources by node with the current rules because demand resources are not registered to a node. In addition, aggregation rules allow a demand resource that incorporates many small End Use Customers to span an entire zone, which is inconsistent with nodal dispatch.
- **Energy Efficiency.** Energy efficiency payments have been eliminated from PJM markets effective June 1, 2026. Energy efficiency resources are not capacity resources in PJM and do not clear in the capacity market. The total MW of energy efficiency resources paid decreased by 80.6 percent, from 7,716.0 MW in the 2024/2025 Delivery Year to 1,493.2 MW in the 2025/2026 Delivery Year. In the 2025/2026 Delivery Year, payments to EE are $148 million.
- **Energy Efficiency Payments are a Subsidy and Uplift.** Payments from the buyers of capacity to energy efficiency providers are a subsidy and uplift. Energy efficiency is not a capacity resource and does not contribute to reliability.
- **Energy Efficiency Market Concentration.** The HHI for energy efficiency on an aggregate market basis shows that ownership is highly concentrated. The four largest companies own 90 percent or more of all paid Energy Efficiency MW. The HHI for Energy Efficiency resources also shows that ownership is highly concentrated for the 2025/2026 Delivery Year, with an HHI value of 2804. In the 2025/2026 Delivery Year, the four largest companies own 96.0 percent of all paid Energy Efficiency MW.

Section 6 Recommendations

- The MMU recommends that PJM report the response of emergency demand response resources to dispatch by PJM as the actual change in load rather than simply the difference between the amount of capacity purchased by the customer and the actual metered load. The current approach significantly overstates the expected response to PJM dispatch. (Priority: High. First reported 2023. Status: Not adopted.)
- The MMU recommends that emergency demand response resources offering as supply in the capacity market be required to offer a guaranteed load drop (GLD) below their PLC to ensure that demand resources provide an identifiable MW resource to PJM when called. (Priority: High. First reported 2023. Status: Not adopted.)
- The MMU recommends, as an alternative to including emergency demand response resources as supply in the capacity market, that demand resources have the option to be on the demand side of the markets, that customers be able to avoid capacity and energy charges by not using capacity and energy at their discretion, that customer payments be determined only by metered load, and that PJM forecasts immediately incorporate the impacts of demand side behavior. (Priority: High. First reported 2014. Status: Not adopted.)
- The MMU recommends that the option to specify a minimum dispatch price (strike price) for emergency demand response resources be eliminated and that participating resources receive the hourly real-time LMP less any generation component of their retail rate.[134] (Priority: Medium. First reported 2010. Status: Not adopted.)
- The MMU recommends that the maximum offer for emergency demand response resources and price response demand resources be the same as the maximum offer for generation resources and that the same cost verification rules applied to generation resources apply to demand resources. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that the emergency demand response resources be treated as economic resources, responding to economic price signals like

134 See "Complaint and Motion to Consolidate of the Independent Market Monitor for PJM," Docket No. EL14-20-000 (January 28, 2014), "Comments of the Independent Market Monitor for PJM," Docket No. ER15-852-000 (February 13, 2015).

other capacity resources. The MMU recommends that emergency demand response resources not be treated as emergency resources. The MMU recommends that emergency demand response resources be available for every hour of the year. (Priority: High. First reported 2012. Status: Partially adopted.)

- The MMU recommends that the Emergency Program Energy Only option be eliminated because the opportunity to receive the appropriate energy market prices is already provided in the economic program. (Priority: Low. First reported 2010. Status: Not adopted.)
- The MMU recommends that, if emergency demand response resources remain in the capacity market, a daily energy market must offer requirement apply to emergency demand response resources, comparable to the rule applicable to generation capacity resources.[135] (Priority: High. First reported 2013. Status: Not adopted.)
- The MMU recommends that emergency demand response resources be required to provide their nodal location, comparable to generation resources. (Priority: High. First reported 2011. Status: Not adopted.)
- The MMU recommends that PJM require nodal dispatch of emergency demand response resources with no advance notice required or, if nodal location is not required, subzonal dispatch of demand resources with no advance notice required. The MMU recommends that, if PJM continues to use subzones for any purpose, PJM clearly define the role of subzones in the dispatch of demand response. (Priority: High. First reported 2015. Status: Not adopted.)
- The MMU recommends that PJM not remove any defined subzones and maintain a public record of all created and removed subzones. (Priority: Low. First reported 2016. Status: Not adopted.)
- The MMU recommends that PJM eliminate the measurement of compliance across zones within a compliance aggregation area (CAA). The multiple zone approach is less locational than the zonal and subzonal approach and creates larger mismatches between the locational need for the resources and the actual response. (Priority: High. First reported 2015. Status: Not adopted.)
- The MMU recommends that measurement and verification methods for all demand resources be modified to reflect compliance more accurately. (Priority: Medium. First reported 2009. Status: Not adopted.)
- The MMU recommends that compliance rules be revised to include submittal of all necessary hourly load data, and that negative values be included when calculating event compliance across hours and registrations. (Priority: Medium. First reported 2012. Status: Not adopted.)
- The MMU recommends that PJM adopt the ISO-NE five-minute metering requirements in order to ensure that operators have the necessary information for reliability and that market payments to demand resources be calculated based on interval meter data at the site of the demand reductions.[136] (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends demand response event compliance be calculated on a five minute basis for all emergency demand response resources and that the penalty structure reflect five minute compliance. (Priority: Medium. First reported 2013. Status: Partially adopted.)
- The MMU recommends that demand response testing be initiated by PJM with advance notice to CSPs identical to the actual lead time required in an emergency in order to accurately represent the conditions of an emergency event. (Priority: Low. First reported 2012. Status: Partially adopted.)
- The MMU recommends that shutdown cost be defined as the cost to curtail load for a given period that does not vary with the measured reduction or, for behind the meter generators, be the start cost defined in Manual 15 for generators. (Priority: Low. First reported 2012. Status: Not adopted.)
- The MMU recommends that the Net Benefits Test be eliminated and that economic demand response resources be paid LMP less any generation

135 See "Complaint and Motion to Consolidate of the Independent Market Monitor for PJM," Docket No. EL14-20-000 (January 27, 2014) at 1.

136 See ISO-NE Tariff, Section III, Market Rule 1, Appendix E1 and Appendix E2, "Demand Response," <http://www.iso-ne.com/regulatory/tariff/sect_3/mr1_append-e.pdf>. (Accessed October 17, 2017) ISO-NE requires that DR have an interval meter with five-minute data reported to the ISO and each behind the meter generator is required to have a separate interval meter. After June 1, 2017, demand response resources in ISO-NE must also be registered at a single node.

component of the applicable retail rate. (Priority: Low. First reported 2015. Status: Not adopted.)

- The MMU recommends that the tariff rules for emergency demand response resources clarify that a resource and its CSP, if any, must notify PJM of material changes affecting the capability of the resource to perform as registered and must terminate or modify registrations that are no longer capable of responding to PJM dispatch directives at defined levels because load has been reduced or eliminated, as in the case of bankrupt and/or out of service facilities. (Priority: Medium. First reported 2015. Status: Not adopted.)
- The MMU recommends that there be only one demand response product in the capacity market, with an obligation to respond when called for any hour of the delivery year. (Priority: High. First reported 2011. Status: Partially adopted.[137])
- The MMU recommends that all demand resources register as Pre-Emergency and that the Emergency Program be eliminated. (Priority: High. First reported 2020. Status: Not adopted.)
- The MMU recommends that the lead times for emergency demand response resources be shortened to 30 minutes with a one hour minimum dispatch for all resources. (Priority: Medium. First reported 2013. Status: Partially adopted.)
- The MMU recommends setting the baseline for measuring capacity compliance under winter compliance at the customers' PLC, similar to GLD, to avoid double counting. (Priority: High. First reported 2010. Status: Partially adopted.)
- The MMU recommends the Relative Root Mean Squared Test be required for all demand resources with a CBL. (Priority: Low. First reported 2017. Status: Partially adopted.)
- The MMU recommends that 30 minute pre-emergency and emergency demand response be considered to be 30 minute reserves. (Priority: Medium. First reported 2018. Status: Not adopted.)

137 PJM's Capacity Performance design requires resources to respond when called for any hour of the delivery year, but demand resources still have a limited mandatory compliance window.

- The MMU recommends that energy efficiency resources (EE) not be included in the capacity market mechanism and that PJM should ensure that the impact of EE measures on the load forecast is incorporated immediately. (Priority: Medium. First reported 2018. Status: Adopted 2024.)[138] [139]
- The MMU recommends that demand reductions based entirely on behind the meter generation be capped at the lower of economic maximum or actual generation output. (Priority: High. First reported 2019. Status: Not adopted.)
- The MMU recommends that DER aggregations that clear in a capacity auction not be permitted to change status from homogeneous demand response to any other status for any additional auctions for the same delivery year, or for the delivery year. (Priority: High. New recommendation. Status: Not adopted.)
- The MMU recommends that EDCs not be allowed to participate in markets as DER aggregators in addition to their EDC role. (Priority: High. First reported 2021. Status: Not adopted.)
- The MMU recommends that PJM include a 5.0 MW maximum size cap on DER aggregations. (Priority: Medium. First reported 2021. Status: Not adopted.)
- The MMU recommends that PJM use a nodal approach for DER participation in PJM markets that excludes multinodal aggregation. (Priority: Medium. First reported 2022. Status: Partially adopted.)
- The MMU recommends that the Commission require PJM to include in OATT Attachment M the explicit statement that the Market Monitor's role includes the right to collect information from EDCs and DERA related to actions taken on the distribution system related to DERs. (Priority: Medium. First reported 2023. Status: Not adopted.)
- The MMU recommends that net metering resources be prohibited from participating in wholesale ancillary services markets if they are

138 See 189 FERC ¶ 61,095.
139 Originally incorporated with auctions conducted in 2016 for the 2016/2017 Delivery Year and forward. The mechanics of the EE addback mechanism were modified beginning with the 2023/2024 Delivery Year.

compensated for the service at the retail level. (Priority: Medium. First reported Q2, 2025. Status: Not adopted.)

- The MMU recommends that PJM revise the requirements for reporting expected real time energy load reductions by CSPs to PJM to improve the accuracy and usefulness to PJM's system operators. (Priority: Medium. First reported 2023. Status: Not adopted.)
- The MMU recommends that PJM define when operators can and should call on demand resources, given that a call on demand resources no longer triggers a PAI. The MMU recommends that PJM revise the performance requirements for demand resources to include an event specific measurement for dispatch occurring outside of Performance Assessment Events and penalties for nonperformance. (Priority: Medium. First reported 2023. Status: Not adopted.)
- The MMU recommends that PRD be required to respond during a PAI, regardless of whether the real-time LMP at the applicable location meet or exceeds the PRD strike price, to be consistent with all CP resources. (Priority: Medium. New recommendation. Status: Not adopted.)

Section 6 Conclusion

A fully functional demand side of the electricity market means that End Use Customers or their designated intermediaries will have the ability to see real-time energy price signals in real time, will have the ability to react to real-time prices in real time and will have the ability to receive the direct benefits or costs of changes in real-time energy use. In addition, customers or their designated intermediaries will have the ability to see current capacity prices, will have the ability to react to capacity prices and will have the ability to receive the direct benefits or costs of changes in the demand for capacity in the same year in which demand for capacity changes. A functional demand side of these markets means that customers will have the ability to make decisions about levels of power consumption based both on how customers value the power and on the actual cost of that power.

In the energy market, if there is to be a demand side program, demand resources should be paid the value of energy, which is LMP less any generation component of the applicable retail rate. There is no reason to have the net benefits test. The necessity for the net benefits test is an illustration of the illogical approach to demand side compensation embodied in paying full LMP to demand resources. The benefit of demand side resources is not that they suppress market prices, but that customers can choose not to consume at the current price of power, that individual customers benefit from their choices and that the choices of all customers are reflected in market prices. If customers face the market price, customers should have the ability to not purchase power and the market impact of that choice does not require a test for appropriateness.

If demand resources are to continue competing directly with generation capacity resources in the PJM Capacity Market, the product must be defined such that it can actually serve as a substitute for generation. This is a prerequisite to a functional market design. Demand resources do not have a must offer requirement into the day-ahead energy market, are able to offer above $1,000 per MWh without providing a fuel cost policy, or any rationale for the offer. Demand resources do not have telemetry requirements similar to other Capacity Performance resources. Until July 30, 2023, including Winter Storm Elliott, PJM automatically, and inappropriately, triggered a PAI when demand resources were dispatched.

In order to be a substitute for generation, demand resources offering as supply in the capacity market should be required to offer a guaranteed load drop (GLD) below their PLC to ensure that demand resources provide an identifiable MW resource to PJM when called.

In order to be a substitute for generation, the ELCC for demand resources should be based on data about actual reductions in demand during high expected loss of load hours, like other capacity resources. The current DR ELCC is significantly overstated because the DR ELCC value is based on the unsupported assumption that the full amount of capacity sold will respond when called rather than on actual response data. In other words, the actual response is assumed to be perfect. The amount of capacity sold equals the PLC – the FSL for the resource. PJM has proposed to make this problem worse rather than to correct it, by increasing the ELCC of demand resources based on assumptions rather than actual performance data.

In order to be a substitute for generation, demand resources should be defined in PJM rules as an economic resource, as generation is defined. Demand resources should be required to offer in the day-ahead energy market and should be called when the resources are required and prior to the declaration of an emergency. Demand resources should be available for every hour of the year. The fact that demand resources are only obligated to respond for defined time periods meant that PJM could not fully use demand resources during Winter Storm Elliott (Elliott). Demand resources should be treated as economic resources like any other capacity resource. Demand resources should be called whenever economic and paid the LMP rather than an inflated strike price up to $1,849 per MWh that is set by the seller.

In order to be a substitute for generation, demand resources should be subject to robust measurement and verification techniques to ensure that transitional DR programs incent the desired behavior. The methods used in PJM programs today are not adequate to determine and quantify deliberate actions taken to reduce consumption.

In order to be a substitute for generation, demand resources should provide a nodal location and should be dispatched nodally to enhance the effectiveness of demand resources and to permit the efficient functioning of the energy market. Both subzonal and multi-zone compliance should be eliminated because they are inconsistent with an efficient nodal market.

In order to be a substitute for generation, compliance by demand resources with PJM dispatch instructions should include both increases and decreases in load. Compliance of demand resources for capacity purposes during a Performance Assessment Event is measured relative to either Peak Load Contribution or Winter Peak Load, which are static values. If a demand resource's metered load increases above these reference values during a PAI, the current method applied by PJM simply ignores increases in load and thus artificially overstates compliance.[140]

140 See PJM. MC Webinar, Market Monitor Report <https://pjm.com/-/media/committees-groups/committees/mc/2023/20230620-webinar/item-04---imm-report.ashx> (June 20, 2023).

In order to be a substitute for generation, Actual Performance of demand resources during a Performance Assessment Event should be determined consistent with that of generation and should not be netted across the Emergency Action Area (EAA). The Capacity Market Seller's Performance Shortfalls for Demand Resources in the EAA are netted to determine a net EAA Performance Shortfall for the Performance Assessment Interval. Any net positive EAA Performance Shortfall is allocated to the Capacity Market Seller's demand resources that under complied within the EAA on a prorata basis based on the under compliance MW, and such seller's demand resources will be assessed a Performance Shortfall for the Performance Assessment Interval. Any net negative EAA Performance Shortfall is allocated to the Market Seller's Demand Resources that over complied within the EAA on a prorata basis based on over compliance MW, and such Market Seller's Demand Resources will be assessed Bonus Performance. Netting of performance of Demand Resources across the EAA is inconsistent with the performance measurement of other Capacity Performance resources.

In order to be a substitute for generation, any demand resource and its Curtailment Service Provider (CSP), should be required to notify PJM of material changes affecting the capability of the resource to perform as registered and to terminate or modify registrations that are no longer capable of responding to PJM dispatch directives at the specified level, such as in the case of bankrupt and out of service facilities. Generation resources are required to inform PJM of any change in availability status, including outages and shutdown status.

As an alternative to being a substitute for generation in the capacity market, demand response resources should have the option to be on the demand side of the capacity market rather than on the supply side. Rather than detailed demand response programs with their attendant complex and difficult to administer rules, customers would be able to avoid capacity and energy charges by not using capacity and energy at their discretion and the level of usage paid for would be defined by metered usage rather than a complex and inaccurate measurement protocol, and PJM forecasts would immediately incorporate the impacts of demand side behavior.

The MMU peak shaving proposal at the Summer-Only Demand Response Senior Task Force (SODRSTF) is an example of how to create a demand side product that is on the demand side of the market and not on the supply side.[141] The MMU proposal was based on the BGE load forecasting program and the Pennsylvania Act 129 Utility Program.[142] [143] Under the MMU proposal, participating load would inform PJM prior to an RPM auction of the MW participating, the months and hours of participation and the temperature humidity index (THI) threshold at which load would be reduced. PJM would reduce the load forecast used in the RPM auction based on the designated reductions. Load would agree to curtail demand to at or below a defined FSL, less than the customer PLC, when the THI exceeds a defined level or load exceeds a specified threshold. By relying on metered load and the PLC, load can reduce its demand for capacity and that reduction can be verified without complicated and inaccurate metrics to estimate load reductions. Under PJM's weakened version of the program, performance is measured under the current economic demand response CBL rules which means relying on load estimates rather than actual metered load.[144] PJM's proposal includes only a THI curtailment trigger and not an overall load curtailment trigger.

The long term appropriate end state for demand resources in the PJM markets should be comparable to the demand side of any market. Customers should use energy as they wish, accounting for market prices in any way they like, and that usage will determine the amount of capacity and energy for which each customer pays. There would be no counterfactual measurement and verification.

Under this approach, customers that wish to avoid capacity payments would reduce their load during expected high load hours, not limited to a small number of peak hours. Capacity costs would be assigned to LSEs and by LSEs to customers, based on actual load on the system during these hours. Customers wishing to avoid high energy prices would reduce their load during high price hours. Customers would pay for what they actually use, as measured by meters, rather than relying on flawed measurement and verification methods. No measurement and verification estimates are required. No promises of future reductions which can only be verified by inaccurate and biased measurement and verification methods are required. To the extent that customers enter into contracts with CSPs or LSEs to manage their payments, measurement and verification can be negotiated as part of a bilateral commercial contract between a customer and its CSP or LSE. But the system would be paid for actual, metered usage, regardless of which contractual party takes that obligation.

This approach provides more flexibility to customers to limit usage at their discretion. There is no requirement to be available year round or every hour of every day. There is no 30 minute notice requirement. There is no requirement to offer energy into the day-ahead market. All decisions about interrupting are up to the customers only and they may enter into bilateral commercial arrangements with CSPs at their sole discretion. Customers would pay for capacity and energy depending solely on metered load.

A transition to this end state should be defined in order to ensure that appropriate levels of demand side response are incorporated in PJM's load forecasts and thus in the demand curve in the capacity market. That transition should be defined by the rules proposed by the MMU.

This approach would work under the CP design in the capacity market. This approach is entirely consistent with the Supreme Court decision in EPSA as it does not depend on whether FERC has jurisdiction over the demand side.[145] This approach will allow FERC to more fully realize its overriding policy objective to create competitive and efficient wholesale energy markets. The decision of the Supreme Court addressed jurisdictional issues and did not address the merits of FERC's approach. The Supreme Court's decision has removed the uncertainty surrounding the jurisdictional issues and created the opportunity for FERC to revisit its approach to demand side.

141 See the MMU package within the *SODRSTF Matrix*, <http://www.pjm.com/-/media/committees-groups/task-forces/sodrstf/20180802/20180802-item-04-sodrstf-matrix.ashx>.

142 *Advance signals that can be used to foresee demand response days*, BGE, <https://www.pjm.com/-/media/committees-groups/task-forces/sodrstf/20180309/20180309-item-05-bge-load-curtailment-programs.ashx> (March 9, 2018).

143 *Pennsylvania ACT 129 Utility Program*, CPower, <https://www.pjm.com/-/media/committees-groups/task-forces/sodrstf/20180413/20180413-item-03-pa-act-129-program.ashx> (April 13, 2018).

144 The PJM proposal from the SODRSTF weakened the proposal but was approved at the October 25, 2018 Members Committee meeting and PJM filed Tariff changes on December 7, 2018. See "Peak Shaving Adjustment Proposal," Docket No. ER19-511-000 (December 7, 2018).

145 577 U.S. 260 (2016).

Any discussion of demand resource performance during a PAI must recognize the significant problems with the definition of performance for demand resources. As defined by PJM rules, performance, contrary to intuition, does not mean actually reducing load in response to a PJM request for demand resources. Performance means only that, on a net portfolio basis, the amount of capacity paid for in the capacity market (PLC) minus actual metered load is equal to the amount of demand side capacity sold in the capacity market (ICAP). If a demand resource location was already at a reduced load level when PJM called a PAI, the demand resource would be deemed to have performed if the PLC less the metered load level was equal to the ICAP sold in the capacity market. The standard reporting of demand side response is therefore misleading because it includes loads that were already lower for any reason as a response. That is exactly what happened during Elliott. In addition, PRD is not required to respond if the LMP is less than the PRD strike price. This flawed rule meant that PRD did not fully respond during Winter Storm Elliott because PRD offered at the maximum price of $1,849 per MWh.

Overview: Section 7, Net Revenue

Net Revenue

- Energy market net revenues are significantly affected by energy prices and fuel prices. Energy prices, gas prices and coal prices increased in the first nine months of 2025 compared to the first nine months of 2024. The net effects were that in the first nine months of 2025, average energy market theoretical net revenues increased by 30 percent for a new combustion turbine (CT), increased by 35 percent for a new combined cycle (CC), increased by 148 percent for a new coal plant (CP), increased by 46 percent for a new nuclear plant, increased by 279 percent for a new diesel (DS), increased by 52 percent for a new onshore wind installation, increased by 49 percent for a new offshore wind installation and increased by 42 percent for a new solar installation.
- The price of natural gas and coal increased in the first nine months of 2025. The marginal costs of a new CT were greater than the marginal cost of a new CP only in January, February and March 2025. The marginal costs of a new CC were greater than the marginal cost of a new CP only in January 2025.
- In the first nine months of 2025, spark spreads and dark spreads and the volatility of spark spreads and dark spreads increased in BGE, COMED and Western Hub compared to the first nine months of 2024. In the first nine months of 2025, spark spreads decreased while dark spreads and the volatility of both spark spreads and dark spreads increased in PSEG compared to the first nine months of 2024.
- Of the 16 PJM nuclear plants analyzed, all are expected to cover their avoidable costs from energy and capacity market revenues in 2025, 2026 and 2027, without any subsidies.

Section 7 Recommendations

- The MMU recommends that the net revenue calculation used by PJM to calculate the net Cost of New Entry (CONE) and net ACR be based on a forward looking calculation of expected energy and ancillary services net revenues using historical revenues that are scaled based on forward prices for energy and fuel. (Priority: Medium. First reported 2019. Status: Not adopted.)

Section 7 Conclusion

Wholesale electric power markets are affected by externally imposed reliability requirements. A regulatory authority external to the market makes a determination as to the acceptable level of reliability which is enforced through a requirement to maintain a target level of installed or unforced capacity. The requirement to maintain a target level of installed capacity can be enforced via a variety of mechanisms, including government construction of generation, full requirement contracts with developers to construct and operate generation, state utility commission mandates to construct capacity, or capacity markets of various types. Regardless of the enforcement mechanism, the exogenous requirement to construct capacity in excess of what is constructed in response to energy market signals alone has an impact on energy markets. The reliability requirement results in maintaining a level of capacity in excess of the level that would result from the operation of an energy market alone. The result of that additional capacity is to reduce the level and volatility of energy market prices and to reduce the duration of high energy market prices. This, in turn, reduces net revenue to generation owners which reduces the incentive to invest. The exact level of both aggregate and locational excess capacity is a function of the calculation methods used by RTOs and ISOs. A basic purpose of the capacity market is to allow all cleared capacity resources the opportunity to cover their net avoidable costs on an annual basis to ensure the economic sustainability of the reliable energy market.

PJM's introduction of a form of ELCC for defining available capacity has made the definition of reliability less clear. The ELCC derate factors are volatile and subject to changes for reasons that are not clear to generation owners or other market participants. There are significant issues with PJM's implementation of its approach to ELCC.

Overview: Section 8, Environmental and Renewables

Federal Environmental Regulation

- **MATS.** The U.S. Environmental Protection Agency's (EPA) Mercury and Air Toxics Standards rule (MATS) applies the Clean Air Act (CAA) maximum achievable control technology (MACT) requirement to new or modified sources of emissions of mercury and arsenic, acid gas, nickel, selenium and cyanide.[146] On April 24, 2024, the EPA finalized a strengthened and updated MATS rule reflecting recent developments in control technologies and the performance of coal fired plants.[147] On June 11, 2025, the EPA proposed to repeal the core changes of the 2024 amendments,[148] including the revised filterable particulate matter (fPM) emission standard, restoring the 0.030 lbs/MMBtu standard.[149]

- **Air Quality Standards (NO_X and SO_2 Emissions).** The CAA requires each state to attain and maintain compliance with fine particulate matter (PM) and ozone national ambient air quality standards (NAAQS). The CAA also requires that each state prohibit emissions that significantly interfere with the ability of another state to meet NAAQS.[150] (Transport Rule) On March 15, 2021, the EPA finalized decreases to allowable emissions under the Cross-State Air Pollution Rule (CSAPR) and the 2008 ozone NAAQS for 10 PJM states.[151] On February 28, 2022, the EPA issued a federal implementation plan for implementation of CSAPR (also known as the Good Neighbor Plan),[152] which applies when no state implementation plan has been approved. On June 27, 2024, the Supreme Court of the United States granted a stay of the federal implementation plan pending judicial review.[153] The effect of the stay is to eliminate the ozone season NO_X emissions budgets for electric generating units in the PJM states. Unless and until the stay is lifted, no federal implementation plan is effective in PJM states and the state emissions budgets are not effective. The EPA had previously rejected all proposed state implementation plans for PJM states. Under the new administration the future of the federal implementation plan is uncertain, and attempts to create state implementation plans are expected to resume.

- **NSR.** The CAA's NSR program is a preconstruction permitting program that requires certain stationary sources of air pollution to obtain permits prior to beginning construction. Parts C and D of Title I of the CAA provide for New Source Review (NSR) in order to prevent new projects and projects receiving major modifications from increasing emissions in areas currently meeting NAAQS or from inhibiting progress in areas that do not.[154] NSR requires permits before construction commences. NSR review applies a two part analysis to projects at facilities such as power plants, some of which involve multiple units and combinations of new and existing units.[155]

146 See *National Emission Standards for Hazardous Air Pollutants From Coal and Oil-Fired Electric Utility Steam Generating Units and Standards of Performance for Fossil Fuel Fired Electric Utility, Industrial-Commercial-Institutional, and Small Industrial-Commercial-Institutional Steam Generating Units*, EPA Docket No. EPA-HQ-OAR-2009-0234, 77 Fed. Reg. 9304 (Feb. 16, 2012).

153 Ohio v. EPA, Slip Op. No. 23A349. (S. Ct. June 27, 2024); Utah v. EPA, D.C. Cir. Case No. Case No. 23-1157, et al.
154 42 U.S.C § 7470 et seq.
155 40 CFR § 52.21.

- **RICE.** Stationary reciprocating internal combustion engines (RICE) are electrical generation facilities like diesel engines typically used for backup, emergency or supplemental power. RICE must be tested annually.[156] Environmental regulations allow stationary emergency RICE that do not meet the emissions limits and are participating in demand response programs to operate for up to 100 hours per calendar year when providing emergency demand response when there is a PJM declared NERC Energy Emergency Alert Level 2 or there are five percent voltage/frequency deviations.

  PJM does not prevent stationary emergency RICE that cannot meet its capacity market obligations as a result of EPA emissions standards from participating in PJM markets as DR. Some stationary emergency RICE that cannot meet its capacity market obligations as a result of emissions standards are now included in DR portfolios. Stationary emergency RICE should be prohibited from participation as DR either when registered individually or as part of a portfolio if it cannot meet its capacity market obligations as a result of emissions standards.

- **Greenhouse Gas Emissions.** On April 25, 2024, the EPA issued a rule (called "Carbon Emissions Rule" in this report) taking four separate actions under CAA § 111(a)(1) addressing greenhouse gas (GHG) emissions from fossil fuel-fired electric generating units (EGUs):[157] the rule repeals the Affordable Clean Energy (ACE) Rule; the rule finalizes emission guidelines for GHG emissions from existing coal fired and oil/gas fired steam generating EGUs; the rule revises the New Source Performance Standards (NSPS) for GHG emissions from new and reconstructed fossil fuel-fired stationary combustion turbine EGUs; the rule revises the NSPS for GHG emissions from fossil fuel-fired steam generating units that undertake a large modification, based upon the 8-year review required by the CAA. The rule deferred action on emission guidelines for GHG emissions from existing fossil fuel-fired stationary combustion turbines.

  The Carbon Emissions Rule reflects the application of the best system of emission reduction (BSER). The proposal includes emission guidelines for GHG emissions from existing fossil fuel-fired steam generating EGUs (including coal, oil or gas). For coal fired EGUs, compliance is required by January 1, 2030, with standards that vary based on whether the EGU commits to retire before 2032, 2035, 2040, or does not commit to retire before 2040.[158] The Carbon Emissions Rule proposes to repeal the Affordable Clean Energy Rule.[159]

- **Cooling Water Intakes.** An EPA rule implementing Section 316(b) of the Clean Water Act (CWA) requires that cooling water intake structures reflect the best technology available for minimizing adverse environmental impacts.[160]

- **Waters of the United States.** On August 29, 2023, the EPA issued a final rule defining adjacent wetlands consistent with the Supreme Court holding that an adjacent wetland is "... a relatively permanent body of water connected to traditional interstate navigable waters ... and ... that the wetland has a continuous surface connection with that water."[161] The rule became effective on September 8, 2023.[162]

- **Effluents.** Under the CWA, the EPA regulates (National Pollutant Discharge Elimination System (NPDES)) discharges from and intakes to power plants, including water cooling systems at steam electric power generating stations. Since 2015, the EPA has been strengthening certain discharge limits applicable to steam generating units, and some plant owners have already indicated an intent to close certain generating units as a result. In May 2024, the EPA finalized a rule strengthening regulation of effluent discharges.[163]

- **Coal Ash.** The EPA administers the Resource Conservation and Recovery Act (RCRA), which governs the disposal of solid and hazardous waste.[164]

162 See *id.*
163 See *Supplemental Effluent Limitations Guidelines and Standards for the Steam Electric Power Generating Point Source Category*, Final Rule, EPA Docket No. EPA-HQ-OW-2009-0819; FRL-8794-01- OW, 89 Fed. Reg. 40199 (May 9, 2024).
164 42 U.S.C. §§ 6901 *et seq.*

The EPA has adopted significant changes to the implementing regulations that will require closing noncompliant impoundments, and, as a result, the host power plant. The EPA is implementing a process for extensions to as late as October 17, 2028. The EPA is reviewing applications received from PJM plant owners for extensions of the deadline for compliance with the revised Coal Combustion Residuals Rule.

State Environmental Regulation

- **Regional Greenhouse Gas Initiative (RGGI).** The Regional Greenhouse Gas Initiative (RGGI) is a CO_2 emissions cap and trade agreement among Connecticut, Delaware, Maine, Maryland, Massachusetts, New Hampshire, New Jersey, New York, Rhode Island, and Vermont that applies to power generation facilities. The most recent RGGI auction, held on September 3, 2025, cleared at $22.25 per short ton, or $24.53 per metric tonne.
- **Illinois Climate and Equitable Jobs Act (CEJA).** On September 16, 2021, the Climate and Equitable Jobs Act (CEJA) became effective. CEJA created an expanded nuclear subsidy program. CEJA mandated that all fossil fuel plants close by 2045. CEJA established emissions caps for investor owned, gas-fired units with three years of operating history, effective October 1, 2021, on a rolling 12 month basis. More than 10,000 MW of capacity are currently affected. The CEJA operating hour limits have resulted in significant opportunity cost adders to cost-based energy market offers for affected units.
- **Carbon Price.** If the price of carbon were $50.00 per metric tonne, short run marginal costs would have increased by $24.45 per MWh or 62.1 percent for a new combustion turbine (CT) unit, $16.85 per MWh or 57.7 percent for a new combined cycle (CC) unit and $43.12 per MWh or 111.4 percent for a new coal plant (CP) for the first nine months of 2025.
- **Offshore Wind.** New Jersey and Maryland have taken significant steps to promote offshore wind. Both states enacted legislation for offshore wind renewable energy credits (ORECs) in 2010.[165] On January 20, 2025, the Trump Administration issued a Presidential Memorandum withdrawing "from disposition for wind energy leasing all areas within the Offshore Continental Shelf."[166] The withdrawal effectively puts on hold indefinitely the offshore wind projects in New Jersey and Maryland. On May 5, 2025, the Attorneys General of New Jersey and Maryland, along with the 16 other states, filed suit against the withdrawal of offshore leasing.[167]

State Renewable Portfolio Standards

- **RPS.** In PJM, ten of 14 jurisdictions have enacted legislation requiring that a defined percentage of retail suppliers' load be served by renewable resources, for which definitions vary. These are typically known as renewable portfolio standards, or RPS. As of September 30, 2025, Delaware, Illinois, Maryland, Michigan, New Jersey, North Carolina, Ohio, Pennsylvania, Virginia and Washington, DC have renewable portfolio standards. Indiana has a voluntary renewable portfolio standard. Kentucky, Tennessee and West Virginia do not have renewable portfolio standards.
- **RPS Cost.** The cost of complying with RPS, as reported by the states, is $14.6 billion over the ten year period from 2014 through 2023, an average annual RPS compliance cost of $1.5 billion. The compliance cost for 2023, the most recent year with almost complete data, was $2.9 billion.[168]

Emissions Controls in PJM Markets

- **Regulations.** Environmental regulations affect decisions about emission control investments in existing units, investment in new units and decisions to retire units. As a result of environmental regulations and agreements to limit emissions, many PJM units burning fossil fuels have installed emission control technology.

165 See Offshore Wind Economic Development Act of 2010, P.L. 2010, c. 57, as amended, N.J.S.A. 48:3-87 to -87.2.

166 *Temporary Withdrawal of all Areas on the Outer Continental Shelf from Offshore Wind Leasing and Review of the Federal Government's Leasing and Permitting Practices for Wind Projects*, Presidential Memorandum (January 20, 2025) <https://www.whitehouse.gov/presidential-actions/2025/01/temporary-withdrawal-of-all-areas-on-the-outer-continental-shelf-from-offshore-wind-leasing-and-review-of-the-federal-governments-leasing-and-permitting-practices-for-wind-projects/>.

167 *State of New York v. Trump*, Case No. 1:25-cv-11221 (Dist. of Mass. May 5, 2025).

168 The 2023 compliance cost value for PJM states does not include Delaware, Michigan or North Carolina. Based on past data these states generally account for approximately 2.0 percent of the total RPS compliance cost of PJM states.

- **Emissions Controls.** In PJM, as of September 30, 2025, 98.0 percent of coal steam MW had some type of flue-gas desulfurization (FGD) technology to reduce SO_2 emissions, 99.8 percent of coal steam MW had some type of particulate matter (PM) control, and 99.7 percent of coal steam MW had NO_X emission control technology. All coal steam units in PJM are compliant with the state and federal emissions limits established by MATS.

Renewable Generation

- **Renewable Generation.** Wind and solar generation was 6.5 percent of total generation in PJM for the first nine months of 2025. RPS Tier I generation was 7.6 percent of total generation in PJM and RPS Tier II generation was 1.9 percent of total generation in PJM for the first nine months of 2025. Only Tier I generation is defined to be renewable but Tier I includes some carbon emitting generation.

  PJM states with RPS rely heavily on imports and generation from behind the meter resources for RPS compliance. In the first nine months of 2025, Tier I generation from PJM generators met only 46.8 percent of the Tier I RPS requirements.

Section 8 Recommendations

- The MMU recommends that renewable energy credit markets based on state renewable portfolio standards be brought into PJM markets as they are an increasingly important component of the wholesale energy market. The MMU recommends that there be a single PJM operated forward market for RECs, for a single product based on a common set of state definitions of renewable technologies, with a single clearing price, trued up to real-time delivery. (Priority: High. First reported 2010. Status: Not adopted.)
- The MMU recommends that jurisdictions with a renewable portfolio standard make the price and quantity data on supply and demand more transparent. (Priority: Low. First reported 2018. Status: Not adopted.)
- The MMU recommends that the Commission reconsider its disclaimer of jurisdiction over RECs markets because, given market changes since that decision, it is clear that RECs materially affect jurisdictional rates. (Priority: Low. First reported 2018. Status: Not adopted.)
- The MMU recommends that PJM provide a full analysis of the impact of carbon pricing on PJM generating units and carbon pricing revenues to the PJM states in order to permit the states to consider a potential agreement on the development of a multistate framework for carbon pricing and the distribution of carbon revenues. (Priority: High. First reported 2018. Status: Not adopted.)
- The MMU recommends that load and generation located at separate nodes be treated as separate resources in order to ensure that load and generation face consistent incentives throughout the markets. (Priority: High. First reported 2019. Status: Not adopted.)
- The MMU recommends that stationary emergency RICE be prohibited from participation as DR either when registered individually or as part of a portfolio if it cannot meet the capacity market requirements to be DR as a result of emissions standards that impose environmental run hour limitations. (Priority: Medium. First reported 2019. Status: Not adopted.)

Section 8 Conclusion

Environmental requirements and renewable energy mandates at both the federal and state levels have a significant impact on the cost of energy and capacity in PJM markets.

Environmental requirements and initiatives at both the federal and state levels, and state renewable energy mandates and associated subsidies have resulted in the construction of substantial amounts of renewable capacity in the PJM footprint, especially wind and solar resources, and the retirement of emitting resources. Renewable energy credit (REC) markets created by state programs, federal subsidies, and federal tax credits have significant impacts on PJM wholesale markets. But state renewables programs in PJM are not coordinated with one another, are generally not consistent with the PJM market design or PJM prices, have widely differing objectives, including supporting some emitting resources, have widely differing implied prices of carbon and are not transparent on pricing and quantities. The effectiveness of state renewables programs would be enhanced if they were coordinated with one another and with PJM markets, and if they increased transparency. States could evaluate the impacts of a range of carbon prices if PJM would provide a full analysis of the impact of carbon pricing on PJM generating units and carbon pricing revenues to the PJM states in order to permit the states to consider a potential agreement on the development of a multistate framework for carbon pricing and the distribution of carbon revenues. A single carbon price across PJM, established by the states, would be the most efficient way to reduce carbon output, if that is the goal.

In the absence of a PJM market carbon price, a single PJM market for RECs would contribute significantly to market efficiency and to the procurement of renewable resources in a least cost manner. Ideally, there would be a single PJM operated forward market for RECs, for a single product based on a common set of state definitions of renewable technologies, with a single clearing price, trued up to real-time delivery. States would continue to have the option to create separate RECs for additional products that did not fit the product definition, e.g. waste coal, trash incinerators, or black liquor.

RECs are an important mechanism used by PJM states to implement environmental policy. RECs clearly affect prices in the PJM wholesale power market. Some resources are not economic except for the ability to purchase or sell RECs. RECs provide out of market payments to qualifying renewable resources, primarily wind and solar. The credits provide an incentive to make negative energy offers and more generally provide an incentive to enter the market, to remain in the market and to operate whenever possible. These subsidies affect the offer behavior and the operational behavior of these resources in PJM markets and in some cases the existence of these resources and thus the market prices and the mix of clearing resources.

RECs markets are, as an economic fact, integrated with PJM markets including energy and capacity markets, but are not formally recognized as part of PJM markets. It would be preferable to have a single, transparent market for RECs operated by the PJM RTO on behalf of the states that would meet the standards and requirements of all states in the PJM footprint. This would provide better information for market participants about supply and demand and prices and contribute to a more efficient and competitive market and to better price formation. This could also facilitate entry by qualifying renewable resources by reducing the risks associated with lack of transparent market data.

Existing REC markets are not consistently or adequately transparent. Data on REC prices, clearing quantities and markets are not publicly available for all PJM states. The economic logic of RPS programs and the associated REC and SREC prices are not always clear. The price of carbon implied by REC prices ranges from $10.24 per tonne in Ohio to $65.23 per tonne in Virginia. The price of carbon implied by SREC prices ranges from $69.05 per tonne in Pennsylvania to $832.21 per tonne in Washington, DC. The effective prices for carbon compare to the RGGI clearing price in September 2025 of $24.53 per tonne and to the social cost of carbon which is estimated in the range of $50 per tonne.[169] [170] The impact on the cost of generation from a new combined cycle unit of a $50 per tonne carbon price would be $16.85 per MWh.[171] The impact of an $800 per tonne carbon price would be $269.59 per MWh. This wide range of implied carbon prices is not consistent with an efficient, competitive, least cost approach to the reduction of carbon emissions.

In addition, even the explicit environmental goals of RPS programs are not clear. While RPS is frequently considered to target carbon emissions, Tier 1 resources include some carbon emitting generation and Tier 2 resources include additional carbon emitting generation.

PJM markets provide a flexible mechanism for incorporating the costs of environmental controls and meeting environmental requirements in a cost effective manner. Costs for environmental controls are part of offers for capacity resources in the PJM Capacity Market. The costs of emissions credits are included in energy offers. PJM markets also provide a flexible mechanism that incorporates renewable resources and the impacts of renewable energy credit markets, and ensures that renewable resources have access to a broad

169 "Technical Update of the Social Cost of Carbon for Regulatory Impact Analysis – Under Executive Order 12899," Interagency Working Group on the Social Cost of Greenhouse Gases, United States Government, (Aug. 2016), <https://19january2017snapshot.epa.gov/sites/production/files/2016-12/documents/sc_co2_tsd_august_2016.pdf>.

170 A recent update by the EPA estimates the social cost of carbon emissions for 2030 to be between $140 and $380 per metric ton (2020 dollars). See Table ES.1 in Report on the Social Cost of Greenhouse Gases, U.S. Environmental Protection Agency (November 2023) <https://www.epa.gov/environmental-economics/scghg>.

171 The cost impact calculation assumes a heat rate of 6.296 MMBtu per MWh and a carbon emissions rate of 52.91 kg per MMBtu. The $800 per tonne carbon price represents the approximate upper end of the carbon prices implied by the 2025 REC and SREC prices in the PJM jurisdictions with RPS. Additional cost impacts are provided in Table 8-9.

market. PJM markets provide efficient price signals that permit valuation of resources with very different characteristics when they provide the same product.

If the states chose this policy option, PJM markets could also provide a flexible mechanism to limit carbon output, for example by incorporating a consistent carbon price in unit offers which would be reflected in PJM's economic dispatch. If there is a social decision to limit carbon output, a consistent carbon price would be the most efficient way to implement that decision. The states in PJM could agree, if they decided it was in their interests, with the appropriate information, on a carbon price and on how to allocate the revenues from a carbon price that would make all states better off. A mechanism like RGGI leaves all decision making with the states. The carbon price would not be FERC jurisdictional or subject to PJM decisions. The MMU continues to recommend that PJM provide a full analysis of the impact of carbon pricing on PJM generating units and carbon pricing revenues to the PJM states in order to permit the states to consider a potential agreement on the development of a multistate framework for carbon pricing and the distribution of carbon revenues. The results of the analysis would include the impact on the dispatch of every unit, the impact on energy prices and the carbon pricing revenues that would flow to each state.

For example, states receiving high levels of revenue could shift revenue to states disproportionately hurt by a carbon price if they believed that all states would be better off as a result. A carbon price would also be an alternative to specific subsidies to individual nuclear power plants and to the current wide range of implied carbon prices embedded in RPS programs and instead provide a market signal to which any resource could respond. The imposition of specific and prescriptive environmental dispatch rules would, in contrast, pose a threat to economic dispatch and efficient markets and create very difficult market power monitoring and mitigation issues. The provision of subsidies to individual units creates a discriminatory regime that is not consistent with competition. The use of inconsistent implied carbon prices by state is also inconsistent with an efficient market and inconsistent with the least cost approach to meeting state environmental goals.

The annual average cost of complying with RPS over the ten year period from 2014 through 2023 for the ten jurisdictions that had RPS was $1.5 billion, or a total of $14.6 billion over ten years. The RPS compliance cost for 2023, the most recent year for which there is almost complete data, was $2.9 billion.[172] RPS costs are payments by customers to the sellers of qualifying resources. The revenues from carbon pricing flow to the states.

If all the PJM states participated in a regional carbon market, the estimated revenue returned to the states/customers from selling carbon allowances would be approximately $7.4 billion per year if the carbon price were $22.25 per short ton and emissions levels were five percent below 2024 emission levels. If all the PJM states participated in a regional carbon market, the estimated revenue returned to the states/customers from selling carbon allowances would be approximately $16.5 billion if the carbon price were $50 per short ton and emission levels were five percent below 2024 levels. If only the current RPS states participated in a regional carbon market, the estimated revenue returned to the states/customers from selling carbon allowances at $22.25 per short ton would be about $5.0 billion. The costs of a carbon price are the impact on energy market prices, net of the revenue returned to states/customers.

Overview: Section 9, Interchange Transactions

Interchange Transaction Activity

- **Aggregate Imports and Exports in the Real-Time Energy Market.** In the first nine months of 2025, PJM was a monthly net exporter of energy in the real-time energy market in all months.[173] In the first nine months of 2025, the real-time net interchange was -29,800.7 GWh. The real-time net interchange in the first nine months of 2024 was -27,542.0 GWh.
- **Aggregate Imports and Exports in the Day-Ahead Energy Market.** In the first nine months of 2025, PJM was a monthly net exporter of energy in the day-ahead energy market in all months. In the first nine months of 2025,

172 The 2023 compliance cost value for PJM states does not include Delaware, Michigan or North Carolina. Based on past data these states generally account for approximately 2.0 percent of the total RPS compliance cost of PJM states.
173 Calculated values shown in Section 9, "Interchange Transactions," are based on unrounded, underlying data and may differ from calculations based on the rounded values in the tables.

the total day-ahead net interchange was -26,230.6 GWh. The day-ahead net interchange in the first nine months of 2024 was -24,393.4 GWh.

- **Aggregate Imports and Exports in the Day-Ahead and the Real-Time Energy Market.** In the first nine months of 2025, gross imports in the day-ahead energy market were 62.0 percent of gross imports in the real-time energy market (75.3 percent in the first nine months of 2024). In the first nine months of 2025, gross exports in the day-ahead energy market were 80.4 percent of the gross exports in the real-time energy market (84.8 percent in the first nine months of 2024).
- **Interface Imports and Exports in the Real-Time Energy Market.** In the first nine months of 2025, there were net scheduled exports at 14 of PJM's 19 interfaces in the real-time energy market.
- **Interface Pricing Point Imports and Exports in the Real-Time Energy Market.** In the first nine months of 2025, there were net scheduled exports at five of PJM's seven interface pricing points eligible for real-time transactions in the real-time energy market.
- **Interface Imports and Exports in the Day-Ahead Energy Market.** In the first nine months of 2025, there were net scheduled exports at 15 of PJM's 19 interfaces in the day-ahead energy market.
- **Interface Pricing Point Imports and Exports in the Day-Ahead Energy Market.** In the first nine months of 2025, there were net scheduled exports at six of PJM's seven interface pricing points eligible for day-ahead transactions in the day-ahead energy market.
- Up To Congestion Interface Pricing Point Imports and Exports in the Day-Ahead Energy Market. In the first nine months of 2025, up to congestion transactions were net exports at three of PJM's seven interface pricing points eligible for day-ahead transactions in the day-ahead energy market.
- **Inadvertent Interchange.** In the first nine months of 2025, net scheduled interchange was -29,800.7 GWh and net actual interchange was -29,592.4 GWh, a difference of 208.4 GWh. In the first nine months of 2024, the difference was 196.4 GWh. This difference is inadvertent interchange.
- **Loop Flows.** In the first nine months of 2025, the Northern Indiana Public Service (NIPS) Interface had the largest loop flows of any interface with -799.7 GWh of net scheduled interchange and -8,409.3 GWh of net actual interchange, a difference of 7,609.6 GWh. In the first nine months of 2025, the SOUTH interface pricing point had the largest loop flows of any interface pricing point with 2,746.0 GWh of net scheduled interchange and 6,535.3 GWh of net actual interchange, a difference of 3,789.3 GWh.

Interactions with Bordering Areas

PJM Interface Pricing with Organized Markets

- **PJM and MISO Interface Prices.** In the first nine months of 2025, the direction of the hourly flow was consistent with the real-time hourly price differences between the PJM/MISO Interface and the MISO/PJM Interface in 52.4 percent of the hours.
- **PJM and New York ISO Interface Prices.** In the first nine months of 2025, the direction of the hourly flow was consistent with the real-time hourly price differences between the PJM/NYIS Interface and the NYISO/PJM proxy bus in 59.2 percent of the hours.
- **Neptune Underwater Transmission Line to Long Island, New York.** In the first nine months of 2025, the hourly flow (PJM to NYISO) was consistent with the real-time hourly price differences between the PJM Neptune Interface and the NYISO Neptune bus in 81.5 percent of the hours.
- **Linden Variable Frequency Transformer (VFT) Facility.** In the first nine months of 2025, the hourly flow (PJM to NYISO) was consistent with the real-time hourly price differences between the PJM Linden Interface and the NYISO Linden bus in 80.3 percent of the hours.
- **Hudson DC Line.** In the first nine months of 2025, the hourly flow (PJM to NYISO) was consistent with the real-time hourly price differences between the PJM Hudson Interface and the NYISO Hudson bus in 80.7 percent of the hours.

Interchange Transaction Issues

- **PJM Transmission Loading Relief Procedures (TLRs).** PJM issued two TLRs of level 3a or higher in the first nine months of 2025, and zero such TLRs in the first nine months of 2024.
- **Up To Congestion.** The average number of up to congestion bids submitted in the day-ahead energy market increased by 57.7 percent, from 36,083 bids per day in the first nine months of 2024 to 48,979 bids per day in the first nine months of 2025. The average cleared volume of up to congestion bids submitted in the day-ahead energy market decreased by 10.1 percent, from 237,417 MWh per day in the first nine months of 2024, to 264,091 MWh per day in the first nine months of 2025.

Section 9 Recommendations

- The MMU recommends that PJM implement rules to prevent sham scheduling. The MMU recommends that PJM apply after the fact market settlement adjustments to identified sham scheduling segments to ensure that market participants cannot benefit from sham scheduling. (Priority: High. First reported 2012. Status: Not adopted.)
- The MMU recommends that PJM implement a validation method for submitted transactions that would prohibit market participants from breaking transactions into smaller segments to defeat the interface pricing rule by concealing the true source or sink of the transaction. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM implement a validation method for submitted transactions that would require market participants to submit transactions on paths that reflect the expected actual power flow in order to reduce unscheduled loop flows. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that transactions sourcing in the Western Interconnection be priced at either the MISO interface pricing point or the SOUTH interface pricing point based on the locational price impact of flows between the DC tie line point of connection with the Eastern Interconnection and PJM. (Priority: High. First reported 2020. Status: Not adopted.)
- The MMU recommends that PJM eliminate the IMO interface pricing point, and assign the transactions that originate or sink in the IESO balancing authority to the MISO interface pricing point. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM review the mappings of external balancing authorities to individual interface pricing points to reflect changes to the impact of the external power source on PJM tie lines as a result of system topology changes. The MMU recommends that this review occur at least annually. (Priority: Low. First reported 2009. Status: Not adopted.)
- The MMU recommends that, in order to permit a complete analysis of loop flow, FERC and NERC ensure that the identified data are made available to market monitors as well as other industry entities determined appropriate by FERC. (Priority: Medium. First reported 2003. Status: Not adopted.)
- The MMU recommends that PJM explore an interchange optimization solution with its neighboring balancing authorities that would remove the need for market participants to schedule physical transactions across seams. Such a solution would include an optimized, but limited, joint dispatch approach that uses supply curves and treats seams between balancing authorities as constraints, similar to other constraints within an LMP market. (Priority: Medium. First reported 2014. Status: Not adopted.)
- The MMU recommends that PJM permit unlimited spot market imports as well as unlimited nonfirm point to point willing to pay congestion imports and exports at all PJM interfaces in order to improve the efficiency of the market. (Priority: Medium. First reported 2012. Status: Not adopted.)
- The MMU recommends that the emergency interchange cap be replaced with a market based solution. (Priority: Low. First reported 2015. Status: Not adopted.)
- The MMU recommends that the submission deadline for real-time dispatchable transactions be modified from 1800 on the day prior, to

three hours prior to the requested start time, and that the minimum duration be modified from one hour to 15 minutes. These changes would give PJM a more flexible product that could be used to meet load in the most economic manner. (Priority: Medium. First reported 2014. Status: Partially adopted, 2015.)

- The MMU recommends eliminating the mechanism that defines FFE and M2M payments. These mechanisms are not consistent with markets and are not needed for efficient interface pricing. The MMU recommends that PJM file with the Commission to eliminate the FFE calculation and M2M payment of the PJM and MISO joint operating agreement. (Priority: Medium. First reported 2024. Status: Not adopted.)
- The MMU recommends clear, explicit and detailed rules that define the conditions under which PJM will and will not recall energy from PJM capacity resources and prohibit new energy exports from PJM capacity resources. The MMU recommends that those rules define the conditions under which PJM will purchase emergency energy while at the same time not recalling energy exports from PJM capacity resources. The MMU recommends clear rules governing when PJM may recall capacity backed exports. (Priority: Medium. First reported 2010. Status: Partially adopted.)

Section 9 Conclusion

Transactions between PJM and multiple balancing authorities in the Eastern Interconnection are part of a single energy market. While some of these balancing authorities are termed market areas and some are termed nonmarket areas, all electricity transactions are part of a single energy market. Nonetheless, there are significant differences between market and nonmarket areas. Market areas, like PJM, include essential features of an energy market including locational marginal pricing, financial congestion offsets (FTRs and ARRs in PJM) and transparent, least cost, security constrained economic dispatch for all available generation. Nonmarket areas do not include these features. Pricing in the market areas is transparent and pricing in the nonmarket areas is not transparent.

The MMU's recommendations related to transactions with external balancing authorities all share the goal of improving the economic efficiency of interchange transactions. The standard of comparison is an LMP market. In an LMP market, redispatch based on LMP and competitive generator offers results in an efficient dispatch and efficient prices. The goal of designing interface transaction rules should be to match the outcomes that would exist in an LMP market across the interfaces.

It is not appropriate to have special pricing agreements between PJM and any external entity. The same market pricing should apply to all transactions. External entities wishing to receive the benefits of the PJM LMP market should join PJM.

In 2020, PJM terminated a number of interface pricing points, consistent with longstanding MMU recommendations. Following the termination of the Northwest pricing point on October 1, 2020, PJM failed to correctly map the pricing points to transactions that had been mapped to the Northwest pricing point to pricing points that are consistent with electrical impacts on the PJM system. The MMU recommends that transactions sourcing in the Western Interconnection be priced at either the MISO interface pricing point or the SOUTH interface pricing point based on the electrical impact of flows between the DC tie line point of connection with the Eastern Interconnection and PJM. The MMU continues to recommend the termination of the Ontario interface pricing point. The Ontario interface pricing point is noncontiguous to the PJM footprint that creates opportunities for market participants to engage in sham scheduling activities.

Overview: Section 10, Ancillary Services

Primary Reserve

Primary reserves consist of both synchronized and nonsynchronized reserves that can provide energy within 10 minutes and sustain that output for at least 30 minutes during a contingency event. PJM made several changes to the primary reserve market, effective October 1, 2022. These included a must offer requirement and correction of misspecified cost-based offers. By removing opportunities for physical and economic withholding, the changes resulted in clearing increased quantities of available synchronized reserves at competitive prices. Starting in May 2023, to compensate for poor unit specific resource performance, PJM unilaterally increased the synchronized reserve reliability requirement, which in turn increased the primary reserve reliability requirement.

Market Structure

- **Supply.** Primary reserve is provided by both synchronized reserve (generation or demand response currently synchronized to the grid and available within 10 minutes) and nonsynchronized reserve (generation currently offline but available to start and provide energy within 10 minutes).
- **Demand.** The primary reserve reliability requirement is equal to 150 percent of the synchronized reserve reliability requirement. The primary reserve requirement is equal to the primary reserve reliability requirement, with a shortage penalty price of $850 per MWh, plus the extended reserve requirement (190 MW), with a shortage penalty price of $300 per MWh. The synchronized reserve requirement is equal to the synchronized reserve reliability requirement plus the extended reserve requirement, with a default level of 190 MW. The synchronized reserve reliability requirement is normally equal to the most severe single contingency (MSSC). Starting in May 2023, PJM increased the size of the synchronized reserve reliability requirement in the RTO Reserve Zone by 30 percentage points to 130 percent of the most severe single contingency (MSSC), in effect increasing the primary reserve reliability requirement to 195 percent of the MSSC. In the first nine months of 2025, the real-time average primary reserve requirement was 3,401.4 MW in the RTO Reserve Zone and 2,584.7 MW in the Mid-Atlantic Dominion Reserve Subzone. In the first nine months of 2025, the day-ahead average primary reserve requirement was 3,384.4 MW in the RTO Reserve Zone and 2,559.0 MW in the Mid-Atlantic Dominion Reserve Subzone.
- **Market Concentration.** Both the Mid-Atlantic Dominion (MAD) Reserve Subzone Market and the RTO Reserve Zone Market for primary reserve were characterized by structural market power in the first nine months of 2025. The average HHI for real-time primary reserve in the RTO Reserve Zone was 980, which is classified as unconcentrated. The average HHI for day-ahead primary reserve in the RTO Zone was 915, which is classified as unconcentrated. The average HHI for real-time primary reserve in the MAD Reserve Subzone was 1563, which is classified as moderately concentrated. The average HHI for day-ahead primary reserve in the MAD Reserve Subzone was 1401, which is classified as moderately concentrated.

Synchronized Reserve Market

Synchronized reserves include all capacity synchronized to the grid and available to satisfy PJM's power balance requirements within 10 minutes. This includes online resources loaded below their full output, storage or condensing resources synchronized to the grid but consuming energy, and 10-minute demand response capability. As of October 1, 2022, all generation capacity resources must offer their entire synchronized reserve capability to the PJM market at all times. PJM jointly optimizes energy, synchronized reserve, primary reserve, and 30-minute reserve needs in both the day-ahead and real-time markets. Synchronized reserve prices are based on opportunity costs calculated by PJM in the market optimization and the anticipated cost of a performance penalty. All real-time cleared synchronized reserves are obligated to perform when PJM initiates a synchronized reserve event based on a loss of supply.

Market Structure

- **Supply.** In the first nine months of 2025, the real-time average supply of available synchronized reserve was 5,763.4 MW in the RTO Reserve Zone, of which 2,814.0 MW on average was located in the Mid-Atlantic Dominion Reserve Subzone. In the first nine months of 2025, the day-ahead average supply of available synchronized reserve was 6,664.6 MW in the RTO Reserve Zone, of which 3,392.5 MW on average was located in the Mid-Atlantic Dominion Reserve Subzone.
- **Demand.** The synchronized reserve requirement is equal to the synchronized reserve reliability requirement, with a shortage penalty price of $850 per MWh, plus the extended reserve requirement, with a shortage penalty price of $300 per MWh and a default value of 190 MW. The synchronized reserve reliability requirement is normally equal to the most severe single contingency (MSSC). Since May 19, 2023, PJM has inappropriately set the synchronized reserve reliability requirement to 130 percent of the MSSC for the RTO Reserve Zone. The real-time average synchronized reserve requirement in the first nine months of 2025 was 2,330.9 MW in the RTO Reserve Zone and 1,786.4 MW in the Mid-Atlantic Dominion Reserve Subzone. The day-ahead average synchronized reserve requirement in the first nine months of 2025 was 2,319.6 MW in the RTO Reserve Zone and 1,769.4 MW in the Mid-Atlantic Dominion Reserve Subzone.
- **Market Concentration.** The Mid-Atlantic Dominion (MAD) Reserve Subzone Market for synchronized reserve was characterized by structural market power in the first nine months of 2025. The average HHI for real-time synchronized reserve in the RTO Reserve Zone was 911, which is classified as unconcentrated. The average HHI for day-ahead synchronized reserve in the RTO Zone was 799, which is classified as unconcentrated. The average HHI for real-time synchronized reserve in the MAD Reserve Subzone was 1721, which is classified as moderately concentrated. The average HHI for day-ahead synchronized reserve in the MAD Reserve Subzone was 1341, which is classified as moderately concentrated.

Market Conduct

- **Offers.** There is a must offer requirement for synchronized reserve. All nonemergency generation capacity resources are required to offer their entire synchronized reserve capability. PJM calculates the available synchronized reserve for all conventional resources based on the energy offer ramp rate, energy dispatch point, and the lesser of the synchronized reserve maximum or economic maximum output. Hydro resources, energy storage resources, and demand response resources submit their available synchronized reserve MW. Wind, solar, and nuclear resources are by default considered incapable of providing synchronized reserve, but may offer with an exception approved by PJM. Synchronized reserve offers are capped at cost plus the expected value of performance penalties. PJM calculates opportunity costs based on LMP.

  Significant communications technology and modelling issues when calling resources during spinning events continue to result in slow response from a significant share of resources.

Market Performance

- **Price.** In the first nine months of 2025, for the Mid-Atlantic Dominion Reserve Subzone, the weighted average real-time price for synchronized reserve was $3.94 per MWh and the weighted average day-ahead price was $6.26 per MWh. In the first nine months of 2025, for the RTO Reserve Zone, the weighted average real-time price for synchronized reserve was $4.55 per MWh and the weighted average day-ahead price was $6.23 per MWh.

Nonsynchronized Reserve

Nonsynchronized reserve is comprised of nonemergency energy resources not currently synchronized to the grid that can provide energy within 10 minutes. Nonsynchronized reserve is available to meet the portions of the primary reserve requirement and the 30-minute reserve requirement not already satisfied by reserve cleared for the synchronized reserve requirement.

Market Structure

- **Supply.** In the first nine months of 2025, the real-time average supply of eligible and available nonsynchronized reserve was 1,006.5 MW in the RTO Reserve Zone, of which 614.1 MW on average was available in the Mid-Atlantic Dominion Reserve Subzone. In the first nine months of 2025, the real-time average supply of eligible and available nonsynchronized reserve was 1,039.6 MW in the RTO Reserve Zone, of which 476.9 MW on average was available in the Mid-Atlantic Dominion Reserve Subzone.
- **Demand.** Demand for nonsynchronized reserve is the primary reserve requirement less the amount of synchronized reserves cleared by PJM.[174] Although nonsynchronized reserve can be used to meet the 30-minute reserve requirement, any 30-minute reserve beyond the primary reserve requirement is usually provided by secondary reserve due to its lower cost and greater availability.

Market Conduct

- **Offers.** Generation owners do not submit supply offers for nonsynchronized reserve from non-hydroelectric units. Nonemergency generation resources that are available to provide energy and can start in 10 minutes or less are defined to be available for nonsynchronized reserves. For non-hydroelectric units, PJM calculates the MW available from a unit based on the unit's energy offer. Hydroelectric units set their own offered reserve amount. For all units, the offer price of nonsynchronized reserve is $0 per MWh.[175] Hybrid units and energy storage resources are not eligible to provide nonsynchronized reserves.

Market Performance

- **Price.** The nonsynchronized reserve price is determined by the marginal primary reserve resource. In the first nine months of 2025, the nonsynchronized reserve weighted average real-time price for all intervals in the RTO Reserve Zone was $1.87 per MWh and the weighted average day-ahead price was $2.42 per MWh. In the first nine months of 2025, the nonsynchronized reserve weighted average real-time price for all intervals in the MAD Reserve Subzone was $2.22 per MWh and the weighted average day-ahead price was $3.43 per MWh.

30-Minute Reserve Market

The supply of 30-minute reserves consists of resources, online or offline, which can respond within 30 minutes. This includes primary reserves and secondary reserves. There is no reserve subzone for 30-minute reserves.

Market Structure

- **Supply.** The supply of 30-minute reserve is provided by both primary reserve (synchronized and nonsynchronized resources that can provide energy within 10 minutes) and secondary reserve (synchronized and nonsynchronized resources that can provide energy within 30 minutes but that take more than 10 minutes). In the first nine months of 2025, the real-time average supply of available 30-minute reserve was 27,655.6 MW in the RTO Zone.
- **Demand.** The 30-minute reserve requirement is equal to the 30-minute reserve reliability requirement, with a shortage penalty price of $850 per MWh, plus the extended reserve requirement (190 MW), with a shortage penalty price of $300 per MWh. The 30-minute reserve reliability requirement is equal to the maximum of: the primary reserve reliability requirement; the largest active gas contingency; and 3,000 MW. Since PJM increased the synchronized reserve reliability requirement, the 30-minute reserve reliability requirement is frequently equal to the primary reserve reliability requirement. In the first nine months of 2025, the average 30-minute reserve requirement was 3,519.5 MW in the real-time market and 3,508.8 MW in the day-ahead market.
- **Market Concentration.** The RTO Reserve Zone Market for 30-minute reserves was characterized by moderate structural market power in the first nine months of 2025. In the first nine months of 2025, the average HHI for real-time 30-minute reserves was 869, which is classified as unconcentrated. In the first nine months of 2025, the average HHI for day-ahead 30-minute reserves was 857, which is classified as unconcentrated.

174 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations," § 4.1 Overview of the PJM Reserve Markets, Rev. 134 (Apr. 23, 2025).
175 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations," § 4.2.3 Reserve Market Resource Offer Structure, Rev. 134 (Apr. 23, 2025).

Secondary Reserve

Secondary reserves are reserves that take more than 10 minutes to convert to energy, but less than 30 minutes. This includes the unloaded capacity of online generation that can be achieved according to the resource ramp rates in 10 to 30 minutes, and offline resources with a start time of less than 30 minutes. Secondary reserves can only be used to satisfy the 30-minute reserve requirement.

Market Structure

- **Supply.** In the first nine months of 2025, in the RTO Reserve Zone, the real-time average supply of available secondary reserve was 21,163.8 MW and the day-ahead average supply of available secondary reserve was 12,402.1 MW. As with the 30-minute reserve service, there is no defined reserve subzone for secondary reserves.
- **Demand.** Demand for secondary reserve is the 30-minute reserve requirement less the amount of primary reserves cleared by PJM.[176]

Market Conduct

- **Offers.** Energy storage resources, hydroelectric resources, hybrid resources, and demand-side response resources submit their available secondary reserve MW. For all other resource types, PJM calculates the MW available from a resource based on the resource's energy offer. For all resources, the offer price of secondary reserve is $0 per MWh.[177] In both the day-ahead and real-time secondary reserves markets, PJM uses lost opportunity costs as the offers and not offers submitted by market participants. For online secondary reserves, PJM calculates an opportunity cost based on LMP.

Market Performance

- **Price.** The secondary reserve price is determined by the marginal 30-minute reserve resource. In the first nine months of 2025, the secondary reserve real-time price for all intervals was $0.01 per MWh. In the first nine months of 2025, the secondary reserve day-ahead price for all intervals was $0.00 per MWh.

176 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations," § 4.1 Overview of the PJM Reserve Markets, Rev. 134 (Apr. 23, 2025).
177 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations," § 4.2.3 Reserve Market Resource Offer Structure, Rev. 134 (Apr. 23, 2025).

Regulation Market

The PJM Regulation Market is a real-time market. Regulation is provided by generation resources and demand response resources that qualify to follow one of two regulation signals, RegA or RegD. PJM jointly optimizes regulation with synchronized reserve and energy to provide all three products at least cost. The PJM regulation market design includes three clearing price components: capability; performance; and opportunity cost. The RegA signal is designed for energy unlimited resources with physically constrained ramp rates. The RegD signal is designed for energy limited resources with fast ramp rates. In the regulation market RegD MW are converted to effective MW using a marginal rate of technical substitution (MRTS), called a marginal benefit factor (MBF). Correctly implemented, the MBF would be the marginal rate of technical substitution (MRTS) between RegA and RegD, holding the level of regulation service constant. The current market design is critically flawed as it has not properly implemented the MBF as an MRTS between RegA and RegD resource MW and the MBF has not been consistently applied in the optimization, clearing and settlement of the regulation market.

PJM filed significant changes to the regulation market design on April 16, 2024, that were accepted as filed by order of June 17, 2024.[178] PJM will implement the changes to the regulation market in two phases. Phase 1, implemented on October 1, 2025, is a single product, single signal market with one clearing price. Phase 2, to be implemented on October 1, 2026, will include separate regulation up and regulation down markets. The proposed Phase 1 changes will eliminate many of the significant issues identified by the MMU that have resulted from a two product, two signal market design including the incorrect and inconsistent use and application of the MBF/MRTS.

This report analyzes the current (as of the third quarter of 2025) regulation market design and results during the first nine months of 2025.

178 PJM, "Regulation Market Design Filing," Docket No. ER24-1772-000 (April 16, 2024).

Market Structure

- **Supply.** In the first nine months of 2025, the average hourly offered supply of regulation for nonramp hours was 788.7 performance adjusted MW (787.2 effective MW). This was an increase of 93.2 performance adjusted MW (an increase of 78.9 effective MW) from the first nine months of 2024, when the average hourly offered supply of regulation was 695.5 actual MW (708.3 effective MW). In the first nine months of 2025, the average hourly offered supply of regulation for ramp hours was 1,063.0 performance adjusted MW (1,119.1 effective MW). This was an increase of 68.6 performance adjusted MW (an increase of 72.1 effective MW) from the first nine months of 2024, when the average hourly offered supply of regulation was 994.4 performance adjusted MW (1,047.0 effective MW).
- **Demand.** The hourly regulation demand is 525.0 effective MW for nonramp hours and 800.0 effective MW for ramp hours.
- **Supply and Demand.** The nonramp regulation requirement of 525.0 effective MW was provided by a combination of cleared RegA and RegD resources equal to 486.9 hourly average performance adjusted actual MW in the first nine months of 2025. This is an increase of 8.3 performance adjusted actual MW from the first nine months of 2024, when the average hourly total regulation cleared performance adjusted actual MW for nonramp hours were 478.5 performance adjusted actual MW. The ramp regulation requirement of 800.0 effective MW was provided by a combination of cleared RegA and RegD resources equal to 690.8 hourly average performance adjusted actual MW in the first nine months of 2025. This is a decrease of 6.6 performance adjusted actual MW from the first nine months of 2024, where the average hourly regulation cleared MW for ramp hours were 697.5 performance adjusted actual MW.

  The ratio of the average hourly offered supply of regulation to average hourly regulation demand (performance adjusted cleared MW) for nonramp hours was 1.62 in the first nine months of 2025 (1.45 in the first nine months of 2024). The ratio of the average hourly offered supply of regulation to average hourly regulation demand (performance adjusted cleared MW) for ramp hours was 1.54 in the first nine months of 2025 (1.42 in the first nine months of 2024).
- **Market Concentration.** In the first nine months of 2025, the three pivotal supplier test was failed in 94.2 percent of hours. In the first nine months of 2025, the effective MW weighted average HHI of RegA resources was 2632 which is highly concentrated and the effective MW weighted average HHI of RegD resources was 2015 which is also highly concentrated. The effective MW weighted average HHI of all resources was 1315, which is moderately concentrated.

Market Conduct

- **Offers.** Daily regulation offer prices are submitted for each unit by the unit owner. Owners are required to submit a cost-based offer and may submit a price-based offer. Offers include both a capability offer and a performance offer. Owners must specify which signal type the unit will be following, RegA or RegD.[179] In the first nine months of 2025, there were 193 resources following the RegA signal and 60 resources following the RegD signal.

Market Performance

- **Price and Cost.** The weighted average clearing price for regulation was $42.42 per MW of regulation in the first nine months of 2025, an increase of $11.12 per MW, or 35.5 percent, from the weighted average clearing price of $31.30 per MW in the first nine months of 2024. The weighted average cost of regulation in the first nine months of 2025 was $52.35 per MW of regulation, an increase of 33.2 percent, from the weighted average cost of $39.31 per MW in the first nine months of 2024.
- **Prices.** RegD resources continue to be incorrectly compensated relative to RegA resources due to an inconsistent application of the marginal benefit factor in the optimization, assignment and settlement processes. If the regulation market were functioning efficiently and competitively, RegD and RegA resources would be paid the same price per effective MW.

179 See the *2024 Annual State of the Market Report for PJM*, Appendix F "Ancillary Services Markets."

- **Marginal Benefit Factor.** The marginal benefit factor (MBF) is intended to measure the operational substitutability of RegD resources for RegA resources. The marginal benefit factor is incorrectly defined and applied in the PJM market clearing. The current incorrect and inconsistent implementation of the MBF has resulted in the PJM Regulation Market over procuring RegD relative to RegA in most hours and in an inefficient market signal about the value of RegD in every hour.

Black Start Service

Black start service is required for the reliable restoration of the grid following a blackout. Black start service is the ability of a generating unit to start without an outside electrical supply, or is the demonstrated ability of a generating unit to automatically remain operating at reduced levels when disconnected from the grid (automatic load rejection or ALR).[180]

In the first nine months of 2025, total black start charges were $39.6 million, a decrease of $15.6 million (28.3 percent) from 2024. In the first nine months of 2025, total revenue requirement charges were $39.2 million, a decrease of $15.7 million (28.6 percent) from 2024. In the first nine months of 2025, total black start uplift charges were $0.4 million, a increase of $.01 million (30.4 percent) from 2024. Black start revenue requirements consist of fixed black start service costs, variable black start service costs, training costs, fuel storage costs, and an incentive payment. Black start uplift charges are paid to units scheduled in the day-ahead energy market or committed in real time to provide black start service under the ALR option or for black start testing. Black start zonal charges in the first nine months of 2025 ranged from $0 in the OVEC and REC Zones to $6.6 million in the AEP Zone.

CRF values are a key determinant of total payments to black start units. The CRF values in PJM tariff tables should have been changed for both black start and the capacity market when the tax laws changed effective January 1, 2018. As a result of the failure to reduce the CRF values, black start units have been and continue to be significantly overcompensated since the changes to the tax code. In March 2023, FERC issued an order establishing hearing and settlement judge procedures.[181] By order issued September 23, 2025, the Commission approved a settlement over the MMU's objection that continued to allow overcompensation.[182] On July 4, 2025, enactment of the One Big Beautiful Bill Act (OBBBA) changed the rules for bonus depreciation again, allowing 100 percent bonus depreciation for assets constructed between January 20, 2025 and December 31, 2028, and placed in service before January 1, 2031.[183] The CRF values for affected units should incorporate 100 percent bonus depreciation. It is essential that PJM not repeat its earlier mistake when it ignored the tax law changes in 2017.

180 OATT Schedule 1 § 1.3BB. There are no ALR units currently providing black start service.

Reactive

Reactive service, reactive supply and voltage control are provided by generation and other sources of reactive power (measured in MVAr). Reactive power helps maintain appropriate voltage levels on the transmission system and is essential to the flow of real power (measured in MW). The same equipment provides both MVAr and MW. Generation resources are required to meet defined reactive capability requirements as a condition to receive interconnection service in PJM.[184] RTOs and their customers are not required to separately compensate generation resources for such reactive capability.[185] In the first nine months of 2025, PJM customers paid $273.1 million for reactive capability based on archaic, nonmarket and unsupported assertions about cost allocation and a regulatory review process of filings by individual units that results in unsupported black box settlements. The current rules have permitted over recovery of reactive costs through reactive capability charges. All costs of generators should be incorporated in the market.

181 See 182 FERC ¶ 61,194.
182 See 193 FERC ¶ 61,059.
183 OBBA § 70301(b)(3).
184 OATT Attachment O.
185 See 182 FERC ¶ 61,033 at P 52 (2023); *see also Standardization of Generator Interconnection Agreements & Procedures*, Order No. 2003, 104 FERC ¶ 61,103 at P 546 (2003), *order on reh'g*, Order No. 2003-A, 106 FERC ¶ 61,220 at P 28, *order on reh'g*, Order No. 2003-B, 109 FERC ¶ 61,287 (2004), *order on reh'g*, Order No. 2003-C, 111 FERC ¶ 61,401 (2005), *aff'd sub nom. National Association of Regulatory Utility Commissioners v. FERC*, 475 F.3d 1277 (D.C. Cir. 2007); *California ISO*, 160 FERC ¶ 61,035 at P 19 (2017); 119 FERC ¶ 61,199 at P 28 (2007), *order on reh'g*, 121 FERC ¶ 61,196 (2007); *see also* 178 FERC ¶ 61,088, at PP 29–31 (2022); 179 FERC ¶ 61,103, at PP 20-21 (2022).

The nonmarket approach to reactive capability payments will be eliminated effective June 1, 2026, based on FERC's Order No. 904 and the order approving PJM's compliance filing.[186]

Reactive service charges based on opportunity costs are appropriately paid to units that operate in real time outside of their normal range at the direction of PJM for the purpose of providing real-time reactive power.

In the first nine months of 2025, total reactive charges were $273.7 million, a decrease of $12.1 million (4.24 percent) from 2024. In the first nine months of 2025, total reactive capability charges were $273.1 million, a decrease of $11.7 million (4.1 percent) from 2024. In the first nine months of 2025, total reactive service charges were $0.59 million, a decrease of $0.41 million (41.4 percent) from 2024.

Total zonal reactive service charges ranged from $0 in the REC and OVEC Zones, to $28.6 million in the AEP Zone in the first nine months of 2025.

Primary Frequency Response

On February 15, 2018, the Commission issued Order No. 842, which modified the pro forma large and small generator interconnection agreements and procedures to require all newly interconnecting non-nuclear generating facilities, both synchronous and nonsynchronous, to include equipment for primary frequency response capability as a condition to receive interconnection service.[187]

Primary frequency response begins within a few seconds and extends up to a minute. The purpose of primary frequency response is to arrest and stabilize the system until other measures (secondary and tertiary frequency response) become active. This includes a governor or equivalent controls capable of operating with a maximum five percent droop and a +/- 0.036 Hz deadband.[188] In addition to resource capability, resource owners must comply by setting control systems to autonomously adjust real power output in a direction to correct for frequency deviations.

The response of generators within PJM to NERC identified frequency events occurs two to three times per month. A frequency event is declared whenever the system frequency stays outside ±0.040 Hz deadband for at least one minute, and the minimum/maximum frequency reaches ±0.053 Hz. Exclusions to PJM monitoring include nuclear plants, offline units, units with no available headroom, units assigned to regulation, and units with a current outage ticket in eDART. Effective June 2024 through June 2025, the NERC BAL-003-2 requirement for balancing authorities (PJM is a balancing authority) uses a threshold value (L_{10}) equal to +/- 258.3 MW/0.1 Hz.[189]

The MMU has identified several issues with PJM's enforcement and evaluation of generation PFR performance.

Market Procurement of Real-Time Ancillary Services

PJM uses market mechanisms to varying degrees in the procurement of ancillary services including synchronized reserves, primary reserves and 30-minute reserves, and regulation. Ideally, all ancillary services would be procured taking full account of the interactions with the energy market. When a resource is used for an ancillary service instead of providing energy in real time, the cost of removing the resource, either fully or partially, from the energy market should be included in the offer for the ancillary service. The degree to which PJM markets account for these interactions depends on the timing of the product clearing, software limitations, and the accuracy of resource parameters and offers.

All reserve products are jointly cleared with energy in every real-time market solution. The synchronized reserve market clearing is more integrated with the energy market clearing than the other ancillary services because dispatched energy and synchronized reserve are outputs of the same optimization problem for each market interval. Given the joint clearing of energy and flexible synchronized reserves, the synchronized reserve market clearing price should

186 See *Compensation for Reactive Power within the Standard Power Factor Range*, Order No. 904, 189 FERC ¶ 61,034 (2024); PJM compliance filing, Docket No. ER24-1073 (January 28, 2025); 192 FERC ¶ 61,113 (2025).
187 Nuclear Regulatory Commission (NRC) regulated facilities are exempt from this provision. Behind the meter generation that is sized to load is also exempt.
188 OATT Attachment O § 4.7.2 (Primary Frequency Response).
189 See NERC. "2024 Frequency Bias Settings," June 11, 2024. <https://www.nerc.com/comm/OC/Documents/OY_2024_Frequency_Bias_Annual_Calculations_correction_06112024.pdf>.

always cover the opportunity cost of providing flexible synchronized reserves. Inflexible synchronized reserves, provided by resources that require hourly commitments due to run-time or staffing constraints, are not cleared with energy in the real-time market solution.[190] Instead, inflexible synchronized reserves are cleared hourly by the Ancillary Service Optimizer (ASO) or the day-ahead energy market. The ASO considers energy market price forecasts, availability of resources for flexible synchronized reserves, and regulation requirements to estimate the costs and benefits of using a resource for inflexible synchronized reserves. The ASO selected inflexible reserves are a fixed input to RT SCED, which clears the balance of the requirement with flexible synchronized reserves.

Nonsynchronized reserves and offline secondary reserves are cleared with every real-time energy market solution. The energy commitment decisions to keep the resources offline have already been made when the RT SCED clears the five-minute reserves markets. Therefore, offline reserves have no lost opportunity cost. They will not be called on for energy during the market interval for which they are assigned as offline resources.

Prices for the regulation and reserve markets are set by the pricing calculator (LPC), which uses the RT SCED solution as an input. The LPC includes fast start pricing logic and system marginal price caps, so the final prices can be inconsistent with the marginal cost of the resources that clear regulation and reserves.

Section 10 Recommendations

Reserve Markets

- The MMU recommends that to minimize lag and improve performance, PJM use an electronic synchronized reserve event notification process for all resources and that all resources be required to have the ability to receive and automatically respond to the notifications. (Priority: Medium. First reported 2023. Status: Partially adopted 2024.)
- The MMU recommends that PJM replace the Mid-Atlantic Dominion Reserve Subzone with a reserve zone structure consistent with the actual deliverability of reserves based on current transmission constraints. (Priority: High. First reported 2019. Status: Partially adopted 2022.)
- The MMU recommends that the components of the cost-based offers for providing regulation and synchronous condensing be defined in Schedule 2 of the Operating Agreement. (Priority: Low. First reported 2019. Status: Not adopted.)
- The MMU recommends that, for calculating the penalty for a synchronized reserve resource failing to meet its scheduled obligation during a spinning event, the unit repay all credits back to the last time that the unit successfully responded to an event 10 minutes or longer. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that, for calculating the penalty for a synchronized reserve resource failing to meet its scheduled obligation during a spinning event, the synchronized reserve shortfall penalty should include LOC payments as well as SRMCP and MW of shortfall. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that aggregation not be permitted to offset unit specific penalties for failure to respond to a synchronized reserve event. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that PJM immediately remove the 30 percent increase to the synchronized reserve reliability requirement. (Priority: High. First reported 2024. Status: Not adopted.)

Regulation Market

- The MMU recommends that the two signal regulation market design be replaced with a one signal regulation market design. (Priority: Medium. First reported 2023. Status: Not adopted.)[191]
- The MMU recommends that the ability to make dual offers (to make offers as both a RegA and a RegD resource in the same market hour) be removed

190 See PJM. "PJM Manual 11: Energy & Ancillary Services Market Operations," § 4.4.3 Reserve Market Clearing, Rev. 134 (Apr. 23, 2025).

191 PJM filed proposed changes to the regulation market with the FERC on April 16, 2024, (Regulation Market Design Filing," Docket No. ER24-1772-000). The Commission Order on June 17, 2024 accepted the PJM Proposal as filed. PJM will implement the changes to the regulation market in two phases. Phase 1, scheduled to be implemented on October 1, 2025, will result in a single signal, bidirectional market with one clearing price that eliminates the need for an MBF. Phase 1 will eliminate RegA and RegD dual offers. Phase 1 will reduce the regulation commitment period from a 60-minute commitment to a 30-minute commitment. In Phase 1 the lost opportunity cost calculation used in the regulation market will be based on the resource's dispatched energy offer schedule, not the lower of its price or cost offer schedule.

from the regulation market. (Priority: High. First reported 2019. Status: Not adopted.)[192]

- The MMU recommends that the regulation market be modified to incorporate a consistent application of the marginal benefit factor (MBF) throughout the optimization, assignment and settlement process. The MBF should be defined as the Marginal Rate of Technical Substitution (MRTS) between RegA and RegD. (Priority: High. First reported 2012. Status: Not adopted. FERC rejected.)[193]
- The MMU recommends that the current calculation of the performance score (based on precision, delay and correlation metrics) be replaced with the current calculation of the precision score. (Priority: Medium. First reported 2023. Status: Not adopted.).
- The MMU recommends that the regulation market commitment period be reduced from a 60-minute commitment to a 30-minute commitment. (Priority: Medium. First reported 2023. Status: Not adopted.).[194]
- The MMU recommends that the lost opportunity cost in the ancillary services markets be calculated using the schedule on which the unit was scheduled to run in the energy market. (Priority: High. First reported 2010. Status: Not adopted.[195] FERC rejected.)[196]
- The MMU recommends that the lost opportunity cost calculation used in the regulation market be based on the resource's dispatched energy offer schedule, not the lower of its price or cost offer schedule. (Priority: Medium. First reported 2010. Status: Not adopted. FERC rejected.)[197]
- The MMU recommends that the $12.00 margin adder be eliminated from the definition of the cost based regulation offer because it is a markup and not a cost. (Priority: Medium. First reported 2021. Status: Not adopted.)
- The MMU recommends that the ramp rate limited desired MW output be used in the regulation uplift calculation, to reflect the physical limits of the unit's ability to ramp and to eliminate overpayment for opportunity costs when the payment uses an unachievable MW. (Priority: Medium. First reported 2022. Status: Not adopted.)[198]
- The MMU recommends enhanced documentation of the implementation of the regulation market design. (Priority: Medium. First reported 2010. Status: Not adopted. FERC rejected.)[199]
- The MMU recommends that PJM be required to save data elements necessary for verifying the performance of the regulation market. (Priority: Medium. First reported 2010. Status: Not adopted.)
- The MMU recommends that all data necessary to perform the regulation market three pivotal supplier test be saved by PJM so that the test can be replicated. (Priority: Medium. First reported 2016. Status: Not adopted.)
- The MMU recommends that the total regulation (TReg) signal sent on a fleet wide basis be eliminated and replaced with individual regulation signals for each unit. (Priority: Low. First reported 2019. Status: Not adopted.)
- The MMU recommends that, to prevent gaming, there be a penalty enforced in the regulation market as a reduction in performance score and/or a forfeiture of revenues when resource owners elect to deassign assigned regulation resources within the hour. (Priority: Medium. First reported 2016. Status: Not adopted. FERC rejected.)[200]

Frequency Response, Reactive, and Black Start

- The MMU recommends that all resources, new and existing, have a requirement to include and maintain equipment for primary frequency response capability as a condition of interconnection service. The PJM markets already compensate resources for frequency response capability and any marginal costs. (Priority: Medium. First reported 2018. Status: Partially adopted.)
- The MMU recommends that all data necessary to perform the generator primary frequency response evaluation be saved by PJM so that the test

192 See *id.*
193 See 162 FERC ¶ 61,295 (2018), *reh'g denied*, 170 FERC ¶ 61,259 (2020).
194 See *id.*
195 This recommendation was adopted by PJM for the energy market. Lost opportunity costs in the energy market are calculated using the schedule on which the unit was scheduled to run. In the regulation market, this recommendation has not been adopted, as the LOC continues to be calculated based on the lower of price or cost in the energy market offer.
196 See 162 FERC ¶ 61,295 (2018), *reh'g denied*, 170 FERC ¶ 61,259 (2020).
197 See *id.*
198 In Phase 1 the ramp rate limited desired MW output will be used in the regulation uplift calculation. The MMU does not agree with how this change will be implemented and will be reviewing the market results in Phase 1.
199 See *id.*
200 See *id.*

can be replicated. (Priority: Medium. First reported 2023. Status: Not adopted.)

- The MMU recommends that PJM maintain a full list of all units subject to the Primary Frequency Response generator requirements. (Priority: Medium. First reported Q1, 2025. Status: Not adopted.)
- The MMU recommends that PJM develop the metric(s) necessary to objectively evaluate each unit's performance during primary frequency response events. (Priority: Medium. First reported Q2, 2025. Status: Not adopted.)
- The MMU recommends that PJM create the necessary tariff/manual language to properly enforce compliance with the NERC mandated Primary Frequency Response generator requirements. (Priority: Medium. First reported Q1, 2025. Status: Not adopted.)
- The MMU recommends that separate cost of service payments for reactive capability be eliminated and the cost of reactive capability be recovered in PJM markets. (Priority: Medium. First reported 2016. Status: Adopted 2024.)[201]
- The MMU recommends that payments for reactive capability, if continued, be based on the 0.95 power factor included in the voltage schedule in Interconnection Service Agreements. (Priority: Medium. First reported 2018. Status: Not adopted.)[202]
- The MMU recommends that, if payments for reactive are continued, fleet wide cost of service rates used to compensate resources for reactive capability be eliminated and replaced with compensation based on unit specific costs. (Priority: Low. First reported 2019. Status: Not adopted.)[203]
- The MMU recommends that, if payments for reactive are continued, Schedule 2 to OATT be revised to state explicitly that only generators that provide reactive capability to the transmission system that PJM operates and has responsibility for are eligible for reactive capability compensation. (Priority: Medium. First reported 2020. Status: Not adopted.)[204]
- The MMU recommends that new CRF rates for black start units, incorporating current tax code changes, be implemented immediately. The new CRF rates should apply to all black start units. Black start units should be required to commit to providing black start service for the life of the unit. CRF rates effective January 20, 2025, should reflect 100 percent bonus depreciation.[205] (Priority: High. First reported 2020. Status: Not adopted.)
- The MMU recommends that black start planning and coordination be on a regional basis recognizing cross zonal cranking paths and not on a narrowly or purely zonal basis and that the costs of black start service be shared on an equal per MWh basis across the region. (Priority: Medium. First reported 2023. Status: Not adopted.)
- The MMU recommends that the fuel assurance rules be modified to recognize actual fuel assured resources within and across zones. (Priority: High. First reported Q2, 2025. Status: Not adopted.)
- The MMU recommends that the Reliability Backstop for black start service be eliminated. There is no reason that PJM cannot acquire black start resources if the TOs can acquire black start resources. (Priority: High. First reported Q2, 2025. Status: Not adopted.)

Section 10 Conclusion

The October 1, 2022, changes to the reserve markets included a synchronized reserve must offer requirement applicable to all generation capacity resources. This resulted in an increase in available supply. Combined with the removal of the $7.50 per MWh margin and the invalid variable operations and maintenance cost, supply and demand logic predicts lower prices, which occurred in 2022, except during Winter Storm Elliott. This is evidence of market efficiency. With the elimination of tier 1 reserves, the total reserve market clearing price credits, while based on lower prices, are paid to a larger

201 On October 17, 2024, the Commission issued a final rule, Order No. 904, eliminating separate payments for reactive in all jurisdictional markets, including PJM. On January 28, 2025, PJM submitted a compliance filing to implement Order No. 904 ("Compliance Filing") that proposed a transition mechanism lasting through May 31, 2026. See Docket No. ER25-1073. This recommendation will be implemented effective June 1, 2026.
202 *Id.* FERC Order No. 904 eliminates payments for reactive capability. When Order 904 is in effect, which is planned for June 1, 2026, this recommendation will be withdrawn as no longer relevant.
203 *Id.*
204 *Id.*
205 OBBA § 70301(b)(3).

MW quantity. Prices have been higher since PJM increased the demand for reserves in May 2023.

The new reserve market design has been called into question by PJM based on a slow response during synchronized reserve events. In all cases, other than during Winter Storm Elliott, the ACE recovered within the required time frame. No reliability problems have occurred. While the total response met the needs of the system, PJM responded to the poor performance of individual units by unilaterally and inappropriately increasing reserve requirements. This increase shifts the burden of poor resource performance from the resources themselves to customers, clearing more reserves instead of directly dealing with the causes of poor performance. These increases in reserve requirements were the primary cause of higher reserve prices in 2023, 2024, and the first nine months of 2025, including 35 intervals of shortage pricing in May 2023 and several intervals of shortage pricing during spin events in 2024 and the first nine months of 2025, even while reserve markets cleared over 1,000 MW more than what was normally cleared in the months and years prior.

The data on synchronized reserve event recovery do not support the conclusion that there was or is a need to increase the demand for reserves. The focus should be on correcting issues related to the responses of individual units rather than increasing demand.

Significant communications technology and modelling issues when calling resources during spinning events result in slow response. While PJM now calculates reserve offer MW for the majority of resource types, a resource's cleared reserve MW are based on a resource's energy output at the end of a scheduling interval. If a unit is still moving when an event is called, such as near the beginning of a scheduling interval, it may or may not be able to achieve its scheduled output. Likewise, a unit that is decreasing output to create more headroom might not be able to immediately increase output when an event is called.

Although PJM now augments a resource's economic basepoint with its dispatched reserve MW during a spin event, PJM does not require resources to be able to receive this signal. Many resources are still dispatched using phone calls, either from markets operation centers waiting for the PJM ALL-CALL or from MOCs themselves manually calling plant personnel.

Even if a unit is on AGC and receiving the augmented basepoint, depending on where that unit finds itself on its ramp rate curve, it might have to spend time coming off AGC or decreasing output in order to start ramping using power augmentation. Having a synchronized reserve maximum that is less than the unit's economic maximum can address this case, but it is the responsibility of that unit to request the exception.

The immediate solution is to improve the deployment of reserves in synchronized reserve events by requiring the capability to use an electronic signal for all synchronized reserves and the actual use of the signal. The archaic telephone communications technology has been a source of slow response times, such as markets operation centers waiting for the PJM ALL-CALL or manually calling unit personnel to deploy reserves. Phone calls are not an effective or efficient method for deploying resources for immediate response. The MMU recommends that to minimize lag and improve performance, PJM use an electronic synchronized reserve event notification process for all resources and that all resources be required to have the ability to receive and automatically respond to the notifications. On December 17, 2024, PJM partially adopted this recommendation by implementing an electronic deployment of reserves via an augmented dispatch signal, but PJM does not require that resources be able to receive this signal nor that the receiving units be able to follow the signal for deploying reserves. Further improvements in communications technology and requirements are necessary and PJM should pursue them immediately.

Along with changes to the communications and deployment process, PJM and the MMU have worked with generators to identify circumstances where reserves were not accurately measured based on the energy and reserve offer parameters. More broadly, the MMU's proposal is to buy the correct amount of reserves. No increase in demand is required. There has been no change in the need/demand for reserves. PJM ignored the supply side. The issue is that resources have not provided the reserves that were offered and paid for. With improved communications technology, instead of buying more MW of poorly performing reserves, PJM will be able to accurately recognize the actual supply of reserves and to more efficiently deploy them in synchronized reserve events. PJM should immediately remove the 30 percent increase to the synchronized reserve reliability requirement in place from May 2023 through September 2025.

The design of the current PJM Regulation Market is significantly flawed.[206] The market design does not correctly incorporate the marginal rate of technical substitution (MRTS) in market clearing and settlement. The market design uses the marginal benefit factor (MBF) to incorrectly represent the MRTS and uses a mileage ratio instead of the MBF in settlement. The current market design allows regulation units that have the capability to provide both RegA and RegD MW to submit an offer for both signal types in the same market hour. However, the method of clearing the regulation market for an hour in which one or more units has a dual offer incorrectly accounts for the amount of RegD and the effective MW of the RegD that it clears. The result of the flaw is that the MBF in the clearing phase is incorrectly low compared to the MBF in the solution phase and the actual amount of effective MW procured is higher than the regulation requirement. This failure to correctly and consistently incorporate the MRTS into the regulation market design has resulted in both underpayment and overpayment of RegD resources and in the over procurement of RegD resources in all hours. Under the current design, slower response RegA resources (generating units) must provide additional regulation to offset the negative impact of RegD resources (largely batteries) that are charging in the middle of a regulation hour. The ability of some resources to submit offers for both RegA and RegD (dual offers) results in inefficient high prices. The market results continue to include the incorrect definition of opportunity cost. These issues are the basis for the MMU's conclusion that the regulation market design is flawed.

PJM filed significant changes to the regulation market design on April 16, 2024, that were accepted as filed by order of June 17, 2024.[207] PJM will implement the changes to the regulation market in two phases. Phase 1, implemented on October 1, 2025, is a single product, single signal market with one clearing price. Phase 2, to be implemented on October 1, 2026, will include separate regulation up and regulation down markets. The proposed Phase 1 changes will eliminate many of the significant issues identified by the MMU that have resulted from a two product, two signal market design including the incorrect and inconsistent use and application of the MBF/MRTS.

The benefits of markets can be realized under the current approach to ancillary service markets. Even in the presence of structurally noncompetitive markets, there can be transparent, market clearing prices based on competitive offers that account explicitly and accurately for opportunity cost. This is consistent with the market design goal of ensuring competitive outcomes that provide appropriate incentives without reliance on the exercise of market power and with explicit mechanisms to prevent the exercise of market power. However, there are significant issues with the PJM ancillary services markets.

The MMU concludes that the synchronized reserve market results were not competitive. The MMU concludes that the nonsynchronized reserve market results were not competitive. The MMU concludes that the secondary reserve market results were competitive. The MMU concludes that the regulation market results were not competitive, and the market design is significantly flawed.

Overview: Section 11, Congestion and Marginal Losses

Congestion Cost

- **Total Congestion.** Total congestion costs increased by $848.0 million or 61.2 percent, from $1,385.8 million in the first nine months of 2024 to $2,233.8 million in the first nine months of 2025.
- **Day-Ahead Congestion.** Day-ahead congestion costs increased by $985.1 million or 60.9 percent, from $1,618.5 million in the first nine months of 2024 to $2,603.6 million in the first nine months of 2025.
- **Balancing Congestion.** Negative balancing congestion costs increased by $137.1 million, from -$232.7 million in the first nine months of 2024 to -$369.8 million in the first nine months of 2025. Negative balancing

206 The current PJM regulation market design that incorporates two signals using two resource types was a result of FERC Order No. 755 and subsequent orders. Order No. 755, 137 FERC ¶ 61,064 at PP 197–200 (2011).
207 PJM, "Regulation Market Design Filing," Docket No. ER24-1772-000 (April 16, 2024).

explicit charges increased by $45.6 million, from -$148.0 million in the first nine months of 2024 to -$193.6 million in the first nine months of 2025.

- **Real-Time Congestion.** Real-time congestion costs increased by $1,143.6 million, from $1,659.3 million in the first nine months of 2024 to $2,802.9 million in the first nine months of 2025.
- **Monthly Congestion.** Monthly total congestion costs in the first nine months of 2025 ranged from $124.5 million in February to $608.9 million in July.
- **Geographic Differences in CLMP.** Differences in CLMP between southern and eastern control zones in PJM were primarily a result of binding constraints on the Pleasant View Line, Lenox – North Meshoppen Line, Pleasant View – Ashburn Line, the Goose Creek Transformer, and Ashburn – Goose Creek Line.
- **Congestion Frequency.** Congestion frequency continued to be significantly higher in the day-ahead energy market than in the real-time energy market in the first nine months of 2025. The number of congestion event hours in the day-ahead energy market was about five times the number of congestion event hours in the real-time energy market.

  Day-ahead congestion frequency decreased by 1.9 percent from 57,459 congestion event hours in the first nine months of 2024 to 56,377 congestion event hours in the first nine months of 2025.

  Real-time congestion frequency increased by 4.4 percent from 20,748 congestion event hours in the first nine months of 2024 to 21,659 congestion event hours in the first nine months of 2025.
- **Congested Facilities.** Day-ahead, congestion event hours decreased on transformers and lines and increased on interfaces and flowgates.

  The Pleasant View Transformer was the largest contributor to congestion costs in the first nine months of 2025. With $286.5 million in total congestion costs, it accounted for 12.8 percent of the total PJM congestion costs in the first nine months of 2025.
- **CT Price Setting Logic and Closed Loop Interface Related Congestion.** PJM's use of CT pricing logic officially ended with the implementation of fast start pricing on September 1, 2021. While CT pricing logic was officially discontinued, PJM continues to use a related logic to force inflexible units and demand response to be on the margin in both real time and day ahead. None of the PJM defined closed loop interfaces were binding in the first nine months of 2024 or 2025.
- **Zonal Congestion.** DOM had the highest zonal congestion costs among all control zones in the first nine months of 2025. DOM had $414.9 million in zonal congestion costs, comprised of $482.06 million in day-ahead congestion costs and -$67.1 million in balancing congestion costs.

Marginal Loss Cost

- **Total Marginal Loss Costs.** Total marginal loss costs increased by $400.4 million or 57.6 percent, from $695.2 million in the first nine months of 2024 to $1,095.5 million in the first nine months of 2025. The loss MWh in PJM increased by 745.4 GWh or 6.2 percent, from 12,066.6 GWh in the first nine months of 2024 to 12,812.0 GWh in the first nine months of 2025. The loss component of real-time LMP in the first nine months of 2025 was $0.04, compared to $0.03 in the first nine months of 2024.
- **Day-Ahead Marginal Loss Costs.** Day-ahead marginal loss costs increased by $404.2 million or 54.2 percent, from $745.3 million in the first nine months of 2024 to $1,149.5 million in the first nine months of 2025.
- **Balancing Marginal Loss Costs.** Negative balancing marginal loss costs increased by $3.8 million or 7.6 percent, from -$50.1 million in the first nine months of 2024 to -$53.9 million in the first nine months of 2025.
- **Total Marginal Loss Surplus.** The total marginal loss surplus increased by $146.7 million or 56.8 percent, from $258.5 million in the first nine months of 2024, to $405.2 million in the first nine months of 2025.
- **Monthly Total Marginal Loss Costs.** Monthly total marginal loss costs in the first nine months of 2025 ranged from $74.9 million in May to $222.8 million in January.

System Energy Cost

- **Total System Energy Costs.** Total system energy costs decreased by $253.4 million or 58.3 percent, from -$434.8 million in the first nine months of 2024 to -$688.2 million in the first nine months of 2025.
- **Day-Ahead System Energy Costs.** Day-ahead system energy costs decreased by $255.5 million or 48.9 percent, from -$522.9 million in the first nine months of 2024 to -$778.5 million in the first nine months of 2025.
- **Balancing System Energy Costs.** Balancing system energy costs increased by $17.9 million or 22.7 percent, from $78.7 million in the first nine months of 2024 to $96.5 million in the first nine months of 2025.
- **Monthly Total System Energy Costs.** Monthly total system energy costs in the first nine months of 2025 ranged from -$137.8 million in January to -$46.4 million in May.

Section 11 Conclusion

Congestion is defined as the total payments by load in excess of the total payments to generation, excluding marginal losses. The level and distribution of congestion reflects the underlying characteristics of the power system, including the nature and defined capability of transmission facilities, the offers and geographic distribution of generation facilities, the level and geographic distribution of incremental bids and offers and the geographic and temporal distribution of load.

Total congestion costs increased by $848.0 million or 61.2 percent, from $1,385.8 million in the first nine months of 2024 to $2,233.8 million in the first nine months of 2025.

Monthly total congestion costs ranged from $124.5 million in February to $608.9 million in July in the first nine months of 2025.

The current ARR/FTR design does not ensure that load receives the rights to all congestion revenues. The congestion offset provided by ARRs and self-scheduled FTRs in the first four months of the 2025/2026 planning period was 66.6 percent. The cumulative offset of congestion by ARRs for the 2011/2012 planning period through the first four months of the 2025/2026 planning period, using the rules effective for each planning period, was 68.7 percent. Load has received $5.4 billion less than load should have received from the 2011/2012 planning period through the first four months of the 2025/2026 planning period.

Overview: Section 12, Generation and Transmission Planning

Generation Interconnection Planning

Existing Generation Mix

- As of September 30, 2025, PJM had a total installed capacity of 200,952.5 MW, of which 38,366.4 MW (19.1 percent) are coal fired steam units, 57,064.2 MW (28.4 percent) are combined cycle units and 33,452.6 MW (16.6 percent) are nuclear units. This measure of installed capacity differs from capacity market installed capacity because it includes energy only units, excludes all external units, and uses nameplate values for solar and wind resources.
- Of the 200,952.5 MW of installed capacity, 72,221.3 MW (35.9 percent) are from units older than 40 years, of which 30,814.3 MW (42.7 percent) are coal fired steam units, 255.0 MW (0.4 percent) are combined cycle units and 25,550.6 MW (35.4 percent) are nuclear units.

Generation Retirements[208]

- As of September 30, 2025, there were 64,079.0 MW of generation that have been, or are planned to be, retired between 2011 and 2030, of which 46,526.8 MW (72.6 percent) are coal fired steam units.
- In the first nine months of 2025, 981.8 MW of generation retired. The largest generator that retired in the first nine months of 2025 was the 410.0 MW Indian River 4 coal fired steam unit located in the DPL Zone. Of the 981.8 MW of generation that retired in the first nine months of 2025, 410.0 MW (41.8 percent) were located in the DPL Zone.

208 See PJM. Planning. "Generator Deactivations," (Accessed on September 30, 2025) <https://www.pjm.com/planning/service-requests/gen-deactivations>.

- As of September 30, 2025, there were 8,351.9 MW of generation that have requested retirement after September 30, 2025, of which 2,620.0 MW (31.4 percent) are located in the AEP Zone. Of the generation requesting retirement in the AEP Zone, 2,620.0 MW (100.0 percent) are coal fired steam units.

Generation Queue

New Service Requests Serial Process[209]

- On November 29, 2022, the Commission issued an order accepting PJM's tariff revisions to improve the queue process.[210] The new queue process includes modifications to implement a cluster/cycle based processing method to replace the first in/first out serial processing method.[211] This change will allow projects to move forward based on a first ready/first out analysis, where readiness is demonstrated through site control and financial milestones and there is an option to exit the study process early based on system impacts. The transition to the new queue process began on July 10, 2023.
- There were 8,190 generation request projects submitted in the new service request serial process queue from 1997 until the implementation of the new cycle process on July 10, 2023. As a result of the transition to the new services cycle process, 312 projects were moved to transition cycle 1 (TC1). There were 1,347 projects eligible to resubmit for evaluation in transition cycle 2 (TC2). Of those 1,347 eligible projects, 550 projects resubmitted and are now being evaluated in TC2. Of the 1,347 eligible projects, 797 projects did not resubmit, and were withdrawn from the queue. There were 1,070 projects initially entered into the AH2 queue and beyond. Those 1,070 projects are now considered invalid and have been removed from the queue. As a result of the transition to the cycle process, the 8,190 projects in the serial process queue have been reduced to 5,461 projects. Projects that will be evaluated in TC1 and TC2, and those projects no longer eligible to be evaluated in the serial process have been removed from the new service requests serial process metrics. New service requests cycle process metrics are reported separately from the serial process metrics.
- As of September 30, 2025, a total of 43,634.4 MW, on an energy basis, were in generation request serial service queues in the status of active, under construction or suspended.[212] Based on historical completion rates, 23,288.8 MW (53.4 percent), on an energy basis, of new generation in the queue are expected to go into service. As projects move through the queue process, projects can be removed from the queue due to incomplete or invalid data, withdrawn by the market participant or placed in service.
- Of the 4,158.8 MW, on an energy basis, of combined cycle projects in the serial queue, 2,958.5 MW (71.1 percent) are expected to go in service based on historical completion rates as of September 30, 2025.
- Of the 3,426.1 MW, on an energy basis, of battery projects in the serial queue, only 931.2 MW (27.2 percent) are expected to go in service based on historical completion rates as of September 30, 2025.
- Of the 34,851.8 MW, on an energy basis, of renewable projects in the serial queue, 18,564.5 MW (53.3 percent) are expected to go in service based on historical completion rates as of September 30, 2025.
- Of the 3,949.1 MW, on a capacity basis that requested CIRs, of combined cycle projects requested in the generation serial queues in the status of active, under construction or suspended, 2,777.1 MW (70.3 percent) are expected to go into service based on historical completion rates. Based on historical completion rates and the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction,[213] the 3,949.1 MW of capacity requests currently under construction, suspended or active in the serial queue would be reduced to 2,055.1 MW of capacity (52.0 percent of the total requested capacity).[214]

209 See PJM. Planning. "Serial Service Request Status," (Accessed on September 30, 2025) <https://www.pjm.com/planning/service-requests/serial-service-request-status>.
210 See 181 FERC ¶ 61,162 (2022).
211 See "Interconnection Process Reform," presented at April 27, 2022 meeting of the Members Committee. <https://www.pjm.com/-/media/committees-groups/committees/mc/2022/20220427/20220427-item-01a-1-interconnection-process-reform-presentation.ashx>.
212 Unless otherwise noted, the queue totals in this report are the winter net MW energy for the interconnection requests ("MW Energy") as shown in the queue.
213 Unless otherwise noted, the ELCC derate factors in this section are based on the *ELCC Class Ratings for 2027/2028 Base Residual Auction*, PJM Interconnection L.L.C. (August 1, 2025) <https://www.pjm.com/-/media/DotCom/planning/res-adeq/elcc/2027-28-bra-elcc-class-ratings.pdf>.
214 Unless otherwise noted, the ELCC derate adjusted MW are calculated using the 2027/2028 Base Residual Auction ELCC factors. The adjusted MW are calculated using the four hour storage ELCC derate for battery resources, tracking solar for solar resources and onshore wind for wind resources.

- Of the 2,232.3 MW, on a capacity basis that requested CIRs, of battery projects requested in the generation serial queues in the status of active, under construction or suspended, 161.5 MW (7.2 percent) are expected to go into service based on historical completion rates. Based on historical completion rates and the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction, the 2,232.3 MW of capacity requests currently under construction, suspended or active in the serial queue would be reduced to 93.7 MW of capacity (4.2 percent of the total requested capacity).
- Of the 18,186.8 MW, on a capacity basis that requested CIRs, of renewable projects requested in the serial generation queues in the status of active, under construction or suspended, 9,797.0 MW (53.9 percent) are expected to go into service based on historical completion rates. Based on historical completion rates and the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction, the 18,186.8 MW of capacity requests currently under construction, suspended or active in the serial queue would be reduced to 965.8 MW of capacity (5.3 percent of the total requested capacity).
- As of September 30, 2025, 25,603.7 MW of capacity requests (requested CIRs) were in the generation serial queues in the status of active, under construction or suspended. Based on historical completion rates, 13,565.8 MW (53.0 percent) are expected to go into service. Based on historical completion rates and the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction, the 25,603.7 MW of capacity requests currently under construction, suspended or active in the serial queue would be reduced to 3,631.5 MW of capacity (14.2 percent of the total requested capacity).
- As of September 30, 2025, 5,461 projects, representing 609,132.6 MW, have entered the serial queue process since its inception. Of those, 1,267 projects, representing 93,774.7 MW (15.4 percent of the MW), went into service. Of the projects that entered the serial queue process, 3,734 projects, representing 471,723.5 MW (77.4 percent of the MW) withdrew prior to completion. Such projects may create barriers to entry for projects that would otherwise be completed, by taking up queue positions, increasing interconnection costs and creating uncertainty.
- In the first nine months of 2025, 2,117.1 MW from the serial queue went into service. Of the 2,117.1 MW that went in service, 1,883.2 MW (89.0 percent) were solar units, 150.0 MW (7.1 percent) were solar + storage units, 54.9 MW (2.6 percent) were wind units and 29.0 MW (1.3 percent) were coal fired steam units.
- The number of serial queue entries increased during the past several years, primarily renewable projects. Of the 2,809 projects that entered the serial queue from January 1, 2015, through July 10, 2023, 2,062 projects (73.4 percent) were renewable. Of the 690 projects that entered the serial queue in 2020, 545 projects (79.0 percent) were renewable. Renewable projects make up 85.9 percent of all projects in the serial queue and account for 79.9 percent of the nameplate MW currently active, suspended or under construction in the serial queue as of September 30, 2025.
- On September 30, 2025, 31,841.9 MW, on an energy basis, were in generation request serial queues that had reached the construction service agreement milestone or equivalent, in the status of active, suspended or under construction. Of the 31,841.9 MW, 12,683.3 MW (39.8 percent) had not begun construction, 9,873.5 MW (31.0 percent) had begun construction, but are now suspended, and 9,285.2 MW (29.2 percent) are currently under construction. Reaching the final milestone required prior to construction does not mean a project will immediately begin construction or even that it necessarily will ever begin construction.

New Service Requests Cycle Process[215]

Transition Cycle 1 (TC1)

- Transition cycle 1 (TC1) is comprised of 312 proposed generation projects. Those projects make up 40,650.2 MW. On September 30, 2025, all projects in TC1 were either in the status of active or were withdrawn from the cycle. Of the 40,650.2 MW in TC1, 17,873.8 MW (44.0 percent) were active and 22,776.3 MW (56.0 percent) were withdrawn.

215 See PJM. Planning. "Cycle Service Request Status," (Accessed on September 30, 2025) <https://www.pjm.com/planning/m/cycle-service-request-status>.

- On September 30, 2025, there were 17,873.8 MW, on an energy basis, of which 8,854.3 MW are on a capacity basis that requested CIRs, in TC1 in the status of active.
- Of the 8,854.3 MW, on a capacity basis that requested CIRs in TC1 in the status of active, 2,152.8 MW (24.3 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.
- Of the 5,082.0 MW, on a capacity basis that requested CIRs, of solar projects requested in TC1 in the status of active, 406.6 MW (8.0 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.
- Of the 1,565.3 MW, on a capacity basis that requested CIRs, of battery projects requested in TC1 in the status of active, 907.9 MW (58.0 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.
- Of the 6,720.0 MW, on a capacity basis that requested CIRs, of renewable projects requested in TC1 in the status of active, 897.9 MW (13.4 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.

Transition Cycle 2 (TC2) and Reliability Resource Initiative (RRI)

- On December 13, 2024, PJM submitted modifications to its Open Access Transmission Tariff to add provisions, through a one-time reliability based expansion of the projects in TC2.[216] On February 11, 2025, the Commission approved the RRI tariff modifications.[217] The proposed RRI Tariff revisions created a second TC2 application window that enabled RRI projects to join TC2 and be studied for interconnection during the transition period.
- PJM received 97 applications (28.6 GW) of RRI projects during the RRI application window. Of these projects, 48 involve uprates, in which existing resources are modified to increase the economic maximum generation capability, and 49 propose building new generation. PJM reviewed the submitted RRI projects using the Commission approved scoring criteria, and approved 51 projects (11,577.4 MW).[218] On September 30, 2025, all RRI projects were either in the status of active or withdrawn from the cycle. Of the 11,577.4 MW of approved RRI projects, 10,938.4 MW (94.5 percent) were active and 639.0 MW (5.5 percent) were withdrawn.
- Transition cycle 2 (TC2) is comprised of 647 proposed generation projects. TC2 includes 550 projects submitted during the TC2 window, and 97 projects submitted through the RRI window. Those projects make up 78,329.4 MW. On September 30, 2025, all projects in TC2 were either in the status of active or were withdrawn from the cycle. Of the 78,329.4 MW in TC2, 45,977.6 MW (58.7 percent) were active and 32,351.8 MW (41.3 percent) were withdrawn.
- On September 30, 2025, there were 45,977.6 MW, on an energy basis, of which 32,120.8 MW are on a capacity basis that requested CIRs, in TC2 in the status of active.
- Of the 32,120.8 MW, on a capacity basis that requested CIRs in TC2 in the status of active, 14,167.2 MW (44.1 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.
- Of the 10,051.8 MW, on a capacity basis that requested CIRs, of solar projects requested in TC2 in the status of active, 804.1 MW (8.0 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.
- Of the 7,400.0 MW, on a capacity basis that requested CIRs, of battery projects requested in TC2 in the status of active, 4,292.0 MW (58.0 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.
- Of the 13,167.0 MW, on a capacity basis that requested CIRs, of renewable projects requested in TC2 in the status of active, 1,146.4 MW (8.7 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.

216 See *PJM Interconnection LLC*. Docket No. ER25-712 (December 13, 2024).
217 190 FERC ¶ 61,084 (February 11, 2025).
218 The RRI proposal was to select the top 50 projects using the approved scoring criteria. The implemented scoring criteria resulted in a tie for the 50th project. This resulted in PJM selecting 51 projects as part of the RRI process.

Cycle Process Totals[219]

- On September 30, 2025, there were 959 proposed generation projects in the new services cycle process queues. Those projects make up 118,979.6 MW. On September 30, 2025, all projects in the cycle process queues were either in the status of active or were withdrawn. Of the 118,979.6 MW in the cycle process queues, 63,851.5 MW (53.7 percent) were active and 55,128.1 MW (46.3 percent) were withdrawn.
- On September 30, 2025, there were 63,851.5 MW, on an energy basis, of which 40,975.1 MW are on a capacity basis that requested CIRs, in cycle process queues in the status of active.
- Of the 40,975.1 MW, on a capacity basis that requested CIRs in the cycle process queues in the status of active, 16,320.0 MW (39.8 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.
- Of the 15,133.8 MW, on a capacity basis that requested CIRs, of solar projects requested in cycle process queues in the status of active, 1,210.7 MW (8.0 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.
- Of the 8,965.3 MW, on a capacity basis that requested CIRs, of battery projects requested in cycle process queues in the status of active or under construction, 5,199.9 MW (58.0 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.
- Of the 19,887.0 MW, on a capacity basis that requested CIRs, of renewable projects requested in cycle process queues in the status of active or under construction, 2,044.2 MW (10.3 percent) are expected to go into service after accounting for the ELCC derate factors using the class ratings for the 2027/2028 Base Residual Auction.

219 As of September 30, 2025, the cycle process totals include those projects included in TC1 and TC2.

Regional Transmission Expansion Plan (RTEP)

Market Efficiency Process

- There are significant issues with PJM's benefit/cost analysis that should be addressed prior to approval of additional projects. If done correctly and if FTRs/ARRs returned 100 percent of congestion to load, the benefit/cost analysis would include the total net change in production costs and would not include congestion. In addition, PJM's benefit/cost analysis includes only the decreases in costs to load and ignores the increases in costs to load associated with market efficiency projects.
- Through September 30, 2025, PJM has completed five market efficiency cycles under Order No. 1000.[220] PJM delayed the opening of the 2022/2023 Long-Term Window until the reliability violations for the 2022 Window 3 were addressed. In January 2024, PJM completed updating the 2022/2023 market efficiency base case to include the solution selected from the 2022 Window 3. No flowgates experienced historical congestion that required an open window. PJM will continue to analyze the congestion patterns as part of the 2024/25 Market Efficiency cycle. In February 2024, PJM completed the 2024/2025 market efficiency base case. In May 2024, PJM posted the 2024/2025 Market Efficiency planning assumptions. PJM posted an updated 2024/2025 base case in July 2024, and requested stakeholder feedback by August 31, 2024. As of June 5, 2025, PJM completed its production cost simulations for the 2025 study year using existing topology and production cost simulations using the RTEP topology. As of June 5, 2025, PJM completed its production cost simulation of the 2029 study year with RTEP topology. The long term market efficiency window opened on April 11, 2025, and closed on June 10, 2025. The next step in the annual RTEP project acceleration process (RTEP market efficiency process) is to identify the specific RTEP reliability projects that reduce congestion costs in the simulation results.[221] The chosen projects will be presented in the fourth quarter of 2025.

220 See *Transmission Planning and Cost Allocation by Transmission Owning and Operating Public Utilities*, Order No. 1000, FERC Stats. & Regs. ¶ 31,323 (2011) (Order No. 1000), *order on reh'g*, Order No. 1000-A, 139 FERC ¶ 61,132 (2012).
221 See PJM Operating Agreement, Section 1.5.7 (b) and (c).

PJM MISO Interregional Market Efficiency Process (IMEP)

- PJM and MISO developed a process to facilitate the construction of interregional projects in response to the Commission's concerns about interregional coordination along the PJM-MISO seam. This process, called the Interregional Market Efficiency Process (IMEP), operates on a two year study schedule and is designed to address forward looking congestion.
- The simultaneous use for joint projects of an incorrectly defined benefit/cost method by PJM and the correct method by MISO results in an over allocation of the costs associated with joint PJM/MISO projects to PJM participants and in some cases approval of projects that do not pass a correctly defined benefit/cost test.

PJM MISO Targeted Market Efficiency Process (TMEP)

- PJM and MISO developed the Targeted Market Efficiency Process (TMEP) to facilitate the resolution of historic congestion issues that could be addressed through small, quick implementation projects.

PJM MISO Interregional Transfer Capability Study (ITCS)

- PJM and MISO developed the Interregional Transfer Capability Study (ITCS) to help identify potential transmission projects that could incrementally improve the systems' ability to mitigate constraints, improve market efficiency, respond to extreme weather and increase interregional transfer capability.

Supplemental Transmission Projects

- Supplemental projects are defined to be "transmission expansions or enhancements that are not required for compliance with PJM criteria and are not state public policy projects according to the PJM Operating Agreement. These projects are used as inputs to RTEP models, but are not required for reliability, economic efficiency or operational performance criteria, as determined by PJM."[222] Supplemental projects are exempt from competition.
- The average number of supplemental projects in each expected in service year increased by 1,110.0 percent, from 20 for years 1998 through 2007 (pre Order No. 890) to 242 for years 2008 through 2025 (post Order 890).[223]

End of Life Transmission Projects

- An end of life transmission project is a project submitted for the purpose of replacing existing infrastructure that is at, or is approaching, the end of its useful life. End of life transmission projects should be included in the RTEP process and should be subject to a transparent, robust and clearly defined mechanism to require competition to build the project. Under the current approach, end of life projects are excluded from the RTEP process and exempt from competition.

Board Authorized Transmission Upgrades

- The Transmission Expansion Advisory Committee (TEAC) reviews proposals to improve transmission reliability in PJM and between PJM and neighboring regions. These proposals, which include reliability baseline, network, market efficiency and targeted market efficiency projects, as well as scope changes and project cancellations, but exclude supplemental and end of life projects, are periodically presented to the PJM Board of Managers for authorization.[224] In the first nine months of 2025, the PJM Board approved $7.9 billion in upgrades. As of September 30, 2025, the PJM Board has approved $58.0 billion in system enhancements since 1999.

Transmission Competition

- The MMU makes several recommendations related to the competitive transmission planning process. The recommendations include improved process transparency, incorporation of competition between transmission and generation alternatives, and the removal of barriers to competition from nonincumbent transmission. These recommendations would help ensure that the process is an open and transparent process that results in the most competitive solutions.

222 See PJM. "Transmission Construction Status," (Accessed on September 30, 2025) <https://www.pjm.com/planning/m/project-construction>.

223 See *Preventing Undue Discrimination and Preference in Transmission Service*, Order No. 890, 118 FERC ¶ 61,119, *order on reh'g*, Order No. 890-A, 121 FERC ¶ 61,297 (2007), *order on reh'g*, Order No. 890-B, 123 FERC ¶ 61,299 (2008), *order on reh'g*, Order No. 890-C, 126 FERC ¶ 61,228, *order on clarification*, Order No. 890-D, 129 FERC ¶ 61,126 (2009).

224 Supplemental Projects, including the end of life subset of supplemental projects, do not require PJM Board of Managers authorization.

- On May 24, 2018, the PJM Markets and Reliability Committee (MRC) approved a motion that required PJM, with input from the MMU, to develop a comparative framework to evaluate the quality and effectiveness of competitive transmission proposals with binding cost containment proposals compared to proposals from incumbent and nonincumbent transmission companies without cost containment provisions.

Qualifying Transmission Upgrades (QTU)

- A Qualifying Transmission Upgrade (QTU) is an upgrade to the transmission system, financed and built by market participants, that increases the Capacity Emergency Transfer Limit (CETL) into an LDA and can be offered into capacity auctions as capacity. Once a QTU is in service, the upgrade is eligible to continue to offer the approved incremental import capability into future RPM Auctions. As of September 30, 2025, no QTUs have cleared a Base Residual Auction or an Incremental Auction.

Transmission Facility Outages

- PJM maintains a list of reportable transmission facilities. When a reportable transmission facility needs to be taken out of service, PJM transmission owners are required to report planned transmission facility outages as early as possible. PJM processes the transmission facility outage requests according to rules in PJM's Manual 3 to decide if the outage is on time or late and whether or not they will allow the outage.[225]
- There were 11,918 transmission outage requests submitted in the first four months of the 2025/2026 planning period. Of the requested outages, 66.6 percent were planned for less than or equal to five days and 13.6 percent were planned for greater than 30 days. Of the requested outages, 31.0 percent were late according to the rules in PJM's Manual 3.

225 See "PJM Manual 03: Transmission Operations," Rev. 68 (May 21, 2025).

Section 12 Recommendations

Generation Retirements

- The MMU recommends that CIRs should end on the date of retirement in order to help ensure competitive markets and competitive access to the grid. The rules need to ensure that incumbents cannot exploit control of CIRs to block or postpone entry of competitors or to exercise market power by requiring high payments for CIRs.[226] (Priority: Medium. First reported 2013. Status: Partially adopted, 2012.)

Generation Queue

- Given the significance of data to market participants and regulators, the MMU recommends that all queue data and supplemental, network and baseline project data, including projected in service dates and estimated and final costs, be regularly updated with accurate and verifiable data. PJM does not update this data. (Priority: High. First reported 2023. Not adopted.)
- The MMU recommends that barriers to entry be addressed in a timely manner in order to help ensure that the capacity market will result in the entry of new capacity to meet the needs of PJM market participants. (Priority: Low. First reported 2012. Status: Not adopted.)
- The MMU recommends that PJM establish an expedited PJM managed queue process to identify commercially viable projects that could help eliminate or reduce the need for specific RMRs or that could address specific reliability needs and allow the identified projects to advance in the queue ahead of projects which have failed to make progress, subject to rules to prevent gaming. (Priority: High. First reported 2024. Status: Not adopted.)
- The MMU recommends improvements in queue management including that PJM establish a review process to ensure that projects are removed from the queue if they are not viable, as well as an expedited process to allow commercially viable projects to advance in the queue ahead of projects which have failed to make progress, subject to rules to prevent

226 See Comments of the Independent Market Monitor for PJM, Docket No. ER12-1177-000 (March 12, 2012) <http://www.monitoringanalytics.com/Filings/2012/IMM_Comments_ER12-1177-000_20120312.PDF>.

gaming.[227] (Priority: Medium. First reported 2013. Status: Partially adopted.)

- The MMU recommends continuing analysis of the study phase of PJM's transmission planning to reduce the need for postponements of study results, to decrease study completion times, and to improve the likelihood that a project at a given phase in the study process will successfully go into service.[228] (Priority: Medium. First reported 2014. Status: Partially adopted.)
- The MMU recommends outsourcing interconnection studies to an independent party to avoid potential conflicts of interest. Currently, these studies are performed by incumbent transmission owners under PJM's direction. This creates potential conflicts of interest, particularly when transmission owners are vertically integrated and the owner of transmission also owns generation. (Priority: Low. First reported 2013. Status: Not adopted.)

Market Efficiency Process

- The MMU recommends that the market efficiency process be eliminated because it is not consistent with a competitive market design. (Priority: Medium. First reported 2019. Status: Not adopted.)
- The MMU recommends that, if the market efficiency process is retained, PJM modify the rules governing benefit/cost analysis, the evaluation process for selecting among competing market efficiency projects and cost allocation for economic projects in order to ensure that all changes in production costs but not congestion costs, including increased costs to load and the risk of project cost increases, in all zones are included in order to ensure that the correct metrics are used for defining benefits. The MMU also recommends that, if the market efficiency process is retained, market efficiency projects that fail to meet PJM benefit/cost criteria in a Schedule 6 annual reevaluation, prior to construction commencing or prior to state approval, be canceled and removed from further consideration. (Priority: Medium. First reported 2018. Status: Not adopted.)

227 PJM Filing, FERC Docket No. ER22-2110-000 (June 14, 2022); 181 FERC ¶ 61,162 (2022).
228 Ibid.

Comparative Cost Framework

- The MMU recommends that PJM modify the project proposal templates to include data necessary to perform a detailed project lifetime financial analysis. The required data includes, but is not limited to: capital expenditure; capital structure; return on equity; cost of debt; tax assumptions; ongoing capital expenditures; ongoing maintenance; and expected life. (Priority: Medium. First reported 2020. Status: Not adopted.)

Transmission Competition

- The MMU recommends, to increase the role of competition, that the exemption of supplemental projects from the Order No. 1000 competitive process be terminated and that the basis for all such exemptions be reviewed and modified to ensure that the supplemental project designation is not used to exempt transmission projects from a transparent, robust and clearly defined mechanism to require competition to build such projects or to effectively replace the RTEP process. (Priority: Medium. First reported 2017. Status: Not adopted. Rejected by FERC.)[229]
- The MMU recommends, to increase the role of competition, that the exemption of end of life projects from the Order No. 1000 competitive process be terminated and that end of life transmission projects be included in the RTEP process and should be subject to a transparent, robust and clearly defined mechanism to require competition to build such projects. (Priority: Medium. First reported 2019. Status: Not adopted. Rejected by FERC.)[230]
- The MMU recommends that PJM enhance the transparency and queue management process for nonincumbent transmission investment. Issues related to data access and complete explanations of cost impacts should be addressed. The goal should be to remove barriers to competition from nonincumbent transmission providers. (Priority: Medium. First reported 2015. Status: Not adopted.)

229 The FERC accepted tariff provisions that exclude supplemental projects from competition in the RTEP. 162 FERC ¶ 61,129 (2018), *reh'g denied*, 164 FERC ¶ 61,217 (2018).
230 In recent decisions addressing competing proposals on end of life projects, the Commission accepted a transmission owner proposal excluding end of life projects from competition in the RTEP process, 172 FERC ¶ 61,136 (2020), *reh'g denied*, 173 FERC ¶ 61,225 (2020), *affirmed*, American Municipal Power, Inc., et al. v. FERC, Case No. 20-1449 (D.C. Cir. November 17, 2023), and rejected a proposal from PJM stakeholders that would have included end of life projects in competition in the RTEP process, 173 FERC ¶ 61,242 (2020).

- The MMU recommends that PJM incorporate the principle that the goal of transmission planning should be the incorporation of transmission investment decisions into market driven processes as much as possible. (Priority: Low. First reported 2001. Status: Not adopted.)
- The MMU recommends the creation of a mechanism to permit a direct comparison, or competition, between transmission and generation alternatives, including which alternative is less costly and who bears the risks associated with each alternative. (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM establish fair terms of access to rights of way and property, such as at substations, in order to remove any barriers to entry and require competition between incumbent transmission providers and nonincumbent transmission providers in the RTEP. (Priority: Medium. First reported 2014. Status: Not adopted.)
- The MMU recommends that rules be implemented to require competition to provide financing for transmission projects. This competition could reduce the cost of capital for transmission projects and significantly reduce total costs to customers. (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends that storage resources not be includable as transmission assets for any reason. (Priority: High. First reported 2020. Status: Not adopted.)

Cost Allocation

- The MMU recommends a comprehensive review of the ways in which the solution based dfax allocation method is implemented. The goal for such a process would be to ensure that the most rational and efficient approach to implementing the solution based dfax method is used in PJM. Such an approach should allocate costs consistent with benefits and appropriately calibrate the incentives for investment in new transmission capability. No replacement approach should be approved until all potential alternatives, including the status quo, are thoroughly reviewed. (Priority: Medium. First reported 2020. Status: Not adopted.)
- The MMU recommends changing the minimum distribution factor in the allocation from 0.01 to 0.00 and adding a threshold minimum usage impact on the transmission facilities.[231] (Priority: Medium. First reported 2015. Status: Not adopted.)

Transmission Line Ratings

- The MMU recommends that all PJM transmission owners use the same methods to define line ratings and that all PJM transmission owners implement dynamic line ratings (DLR), subject to NERC standards and guidelines, subject to review by NERC, PJM and the MMU, and approval by FERC. (Priority: Medium. First reported 2019. Status: Partially adopted.)
- The MMU recommends that all PJM transmission owners investigate the applicability and potential cost savings of Grid Enhancing Technology (GET) and that all PJM transmission owners implement cost effective GET, subject to NERC standards and guidelines, subject to review by NERC, PJM and the MMU, and approval by FERC. (Priority: Medium. First reported 2024. Status: Not adopted.)
- The MMU recommends that the implementation of Grid Enhancing Technology (GET) be opened to competition from third parties, subject to NERC standards and guidelines, subject to review by NERC, PJM and the MMU, and approval by FERC. (Priority: Medium. First reported 2024. Status: Not adopted.)

Transmission Facility Outages

- The MMU recommends that PJM reevaluate all transmission outage tickets as on time or late as if they were new requests when an outage is rescheduled, create options for late requests based on the reasons, and apply the modified rules for late submissions to any such outages. The MMU recommends that PJM create options for treatment of late outages. The current rules apply more stringent rules, based on controlling actions, to late outages without distinguishing among reasons for late outages. (Priority: Low. First reported 2014. Status: Not adopted.)

231 See *2015 State of the Market Report for PJM*, Volume 2, Section 12: Generation and Transmission Planning, at 463, Cost Allocation Issues.

- The MMU recommends that PJM draft a definition of the economic and physical congestion analysis required for transmission outage requests and associated triggers, including both the extent of overloaded facilities and the level of economic congestion, to include in PJM manuals after appropriate review with appropriate rules for on time and late outage requests. (Priority: Medium. First reported 2015. Status: Not adopted.)
- The MMU recommends that PJM create options for late requests based on the reasons, and modify the rules to reduce or eliminate the approval of late outage requests submitted or rescheduled after the FTR auction bidding opening date, based on those options. (Priority: Low. First reported 2015. Status: Not adopted.)
- The MMU recommends that PJM not permit transmission owners to divide long duration outages into smaller segments to avoid complying with the requirements for long duration outages. (Priority: Low. First reported 2015. Status: Not adopted.)

Section 12 Conclusion

The goal of the PJM market design should be to enhance competition and to ensure that competition is the core element of all PJM markets. Transmission investments have not been fully incorporated into competitive markets. The construction of new transmission facilities has significant impacts on the energy and capacity markets. When generating units retire or load increases, there is no market mechanism in place that would require or even permit direct competition between transmission and generation to meet loads in the affected area. In addition, despite FERC Order No. 1000, there is not yet a transparent, robust and clearly defined mechanism to require competition to build transmission projects, to ensure that competitors provide a total project cost cap, or to obtain least cost financing through the capital markets.

The MMU recognizes that the Commission has issued orders that are inconsistent with the recommendations of the MMU and that PJM cannot unilaterally modify those directives. It remains the recommendation of the MMU that the PJM rules for competitive transmission development through the RTEP should build upon FERC Order No. 1000 to create real competition between incumbent transmission providers and nonincumbent transmission providers. The ability of transmission owners to block competition for supplemental projects and end of life projects and the reasons for that policy should be reevaluated. PJM should enhance the transparency and queue management process for nonincumbent transmission investment. Issues related to data access and complete explanations of cost impacts should be addressed. The goal should be to remove barriers to competition from nonincumbent transmission.

Order No. 1000 removed the right of first refusal (ROFR) for transmission projects for incumbent transmission owners except for the case of supplemental projects. This created an incentive for incumbent transmission owners to designate projects as supplemental projects to avoid the Order No. 1000 competitive provisions. Two PJM states, Indiana and Michigan, have passed laws that provide ROFR to incumbent utilities/transmission owners.[232] [233]

Given the significant impact of transmission line ratings on all aspects of wholesale power markets, ensuring and improving the accuracy and transparency of line ratings is essential. Line ratings should incorporate ambient temperature conditions, wind speed and other relevant operating conditions. PJM real-time prices are calculated every five minutes for thousands of nodes. PJM prices are extremely sensitive to transmission line ratings. For consistency with the dynamic nature of wholesale power markets, line ratings should be updated in real time to reflect real time conditions and to help ensure that real-time prices are based on actual current line ratings. New technologies that permit dynamic line ratings (DLR) should be implemented. All PJM Transmission Owners should be required to immediately adopt current dynamic line rating (DLR) methods for all transmission facilities, subject to NERC standards and guidelines, subject to review by NERC, PJM and the MMU, and approval by FERC.

Given the slow pace of adoption by Transmission Owners of Grid Enhancing Technologies (GETs), PJM and the Commission should introduce rules that would allow third parties to propose adding GETs to the transmission system,

232 See IN Code § 8-1-38-9, effective 7/1/2023. Applies to transmission facilities approved for construction through an RTO planning process. Incumbent Transmission Owner must exercise within 90 days.
233 See MCL §460.593, effective 12/17/2021. Applies to regionally cost shared transmission lines included in a plan adopted by a recognized planning authority. Must be exercised by the incumbent (s) within 90 days after plan is adopted/approved.

subject to NERC standards and guidelines, subject to review by NERC, PJM and the MMU, and approval by FERC. The third parties would be compensated in the same way that TOs would be compensated for comparable investments.

Another element of opening competition would be to consider transmission owners' ownership of property and rights of way at or around transmission substations. In many cases, the land acquired included property intended to support future expansion of the grid. Incumbents have included the costs of the property in their rate base, paid for by customers. PJM now has the responsibility for planning the development of the grid under its RTEP process. Property bought to facilitate future expansion should be a part of the RTEP process and be made available to all providers on equal terms.

It would be antithetical to competition to permit transmission owners to own black start units under the backstop rules, to own batteries (storage as a transmission asset) or to permit transmission owners to build new generation, all under the antiquated cost of service regulation rules that were displaced by more efficient competitive markets. Such an approach would undermine competitive markets and require market projects built with investors' capital at risk to compete with subsidized resources.

The process for determining the reasonableness or purpose of supplemental transmission projects that are asserted to be not needed for reliability, economic efficiency or operational performance as defined under the RTEP process needs additional oversight and transparency. If there is a need for a supplemental project, that need should be clearly defined and there should be a transparent, robust and clearly defined mechanism to require competition to build the project. If there is no defined need for a supplemental project for reliability, economic efficiency or operational performance then the project should not be included in rates.

Managing the generation queues is a complex process. The PJM queue evaluation process will be significantly improved, based on the proposal submitted by PJM on June 14, 2022, and approved by FERC on November 29, 2022.[234] [235] The new rules include significant modifications to the interconnection process designed to address some of the key underlying issues and significantly improve the efficiency of the process. These modifications include process efficiency enhancements, recognition of project clusters affecting the same transmission facilities, incentives to reduce the entry of speculative projects in the queue, and incentives to remove projects that are not expected to reach commercial operation. The new process should help to reduce backlog and to remove projects that are not viable earlier to help improve the overall efficiency of the queue process.

While the changes in the queue process will clearly improve the process, the MMU's recommendations related to the queue process will remain until the new process is fully in place and it can be evaluated. The impact of the modifications to the queue process will need to be evaluated to determine if they successfully remove projects from the queue if they are not viable, and allow commercially viable projects to advance in the queue ahead of projects which have failed to make progress. The behavior of project developers also creates issues with queue management. When developers put multiple projects in the queue to maintain their own optionality while planning to build only one they also affect all the projects that follow them in the queue. Project developers may also enter speculative projects in the queue and then put the project in suspended status while they address financing. The impacts of such behavior and the incentives for such behavior are addressed in the new process which includes nonrefundable fees, credit requirements, enhanced site control, elimination of the ability to suspend a project and milestone requirements. The impact of these aspects of the revised interconnection process should continue to be evaluated to ensure that they are having the desired effect on project developer behavior. Initial results from the transition cycles have shown that developers are withdrawing their projects at the specified decision points, which is helping to remove speculative projects from the queue process sooner. Whether the new cycle process will result in enough new dispatchable and renewable generation to meet system needs cannot be determined until after a full cycle has been completed, projects go in service and completion rates can be evaluated. The PJM queue evaluation process should continue to be improved to help ensure that barriers to competition for new generation investments are not created. Issues that need to be addressed

234 See *PJM*, Docket No. ER22-2110 (June 14, 2022).
235 See 181 FERC ¶ 61,162 (2022).

include the ownership rights to CIRs and whether transmission owners should perform interconnection studies.

The roles and efficiency of PJM, TOs and developers in the queue process all need to be examined and enhanced in order to help ensure that the queue process can function effectively and efficiently as the gateway to competition in the energy and capacity markets and not as a barrier to competition.

The Commission should require PJM, for example, to enhance the transparency and queue management process for nonincumbent transmission investment. Issues related to data access and complete explanations of cost impacts should be addressed. The goal should be to remove barriers to competition from nonincumbent transmission.

On January 31, 2025, PJM submitted revisions to the PJM Tariff to expedite the transfer of CIRs from deactivating generating resources to new replacement resources.[236] The Market Monitor filed opposing comments.[237] The Commission rejected the filing, finding (i) "that the lack of a maximum time limit for Commercial Operation Date extensions, which introduces the opportunity to delay commercial operation for an indefinite period of time, would result in a generator replacement process that does not promote the efficient interconnection of new resources;" and (ii) "because the unrestricted opportunity for a Replacement Generation Resource Project Developer to significantly delay commercial operation may result in CIRs and associated transmission capacity dedicated to accommodate the Replacement Generation Resource's operation going unused."[238] PJM has filed a new proposal for rule transferring CIRs to replacement resources which attempts to correct the deficiencies identified by FERC but continues to be flawed. [239]

The suggestion that generation owners should be permitted to avoid the queue process and directly transfer the generation CIRs to an affiliate or directly sell the CIRs to an unaffiliated entity should be rejected.[240] [241] This proposed approach is about creating a process to maximize the value of existing CIRs to incumbent generators and not about facilitating the efficient replacement of retiring resources. In effect, this approach, if adopted by the large number of retiring units, would create a chaotic, bilateral private queue process that would create market power and facilitate the exercise of market power in the sale of CIRs by incumbent generators. In effect the proposed approach would replace a significant part of the recently redesigned PJM queue process. The proposed continuation of retention of CIRs by incumbent generators creates the potential for delays of up to a year and the proponents have proposed the option to request further delays. This approach would inappropriately delegate the authority from PJM to the incumbent generator to choose the new resource based on highest offer for CIRs rather than based on PJM defined system reliability needs. There would be no requirement to even be a capacity resource and there would be no requirement to offer the capacity into the capacity market. After the entire process, the contribution to PJM reliability could be zero. PJM's recently proposed expedited process for addressing reliability needs (RRI) is preferable and should be considered as the preferred alternative to the proposed approach from the Planning Committee stakeholder process.

The MMU recommends that PJM establish an expedited PJM managed queue process to identify commercially viable projects that could help eliminate or reduce the need for specific RMRs or that could address specific reliability needs and allow the identified projects to advance in the queue ahead of projects which have failed to make progress, subject to rules to prevent gaming. Rules should be developed to permit PJM to advance projects in the queue if they would resolve immediate reliability issues that result, for example, from unit retirements. The rules should be consistent with the flexibility included in the new queue process but add the option for PJM to expedite the interconnection and commercial operation of projects in the queue that

236 See PJM Interconnection, L.L.C., Docket No. ER25-1128 (January 31, 2025).

238 192 FERC ¶ 61,137 at PP 38–39 (2025).
239 *See PJM Interconnection, L.L.C.*, Docket No. ER26-403-000 (October 31, 2025).

240 See PJM. "*Enhancing Capacity Interconnection Rights (CIR) Transfer Efficiency: Problem / Opportunity Statement*," <https://www.pjm.com/-/media/committees-groups/subcommittees/ips/2023/20230731/20230731-item-08b---enhancing-capacity-interconnection-rights---cir---transfer-efficiency-problem-statement.ashx>.
241 On April 30, 2024, the CIR Transfer Efficiency issue was transferred from the Interconnection Process Subcommittee (IPS) to the Planning Committee (PC).

would address identified reliability issues, consistent with the standing of the projects in the queue.

The PJM queue process should continue to define available and needed CIRs for all capacity queue projects. CIRs from retiring units should be made available to the next resource in the queue that can use them, on the retirement date of the retiring resource. Generation owners do not have property rights in CIRs. The value of CIRs is a result of the entire transmission system which has been paid for by customers and other generators. The value of CIRs is a result of the existence of a network and is not a result solely or even primarily of the investment that may or may not have been required in order to get CIRs. The cost of CIRs is part of project costs included in generation owners' investment decisions like any other project cost and subject to the same risk and reward structure. Open access to the transmission system by new resources should not be limited by claims to own the access rights by retiring units. In addition, the proposal to bypass the PJM interconnection process with a private, bilateral process ignores the fact that if the new resource is a renewable resource or a storage resource, the new resource does not have a capacity market must offer requirement. The PJM interconnection process could be bypassed, CIRs transferred and then the resource does not offer into the capacity market. In that case, scarce CIRs will be withheld by a generator who does not provide capacity and customers have to pay for an additional capacity resource instead.

The fundamental purpose of the queue process is to provide open access to the grid for supply resources. More specifically, the fundamental purpose of the queue process for capacity resources is to provide open access to the grid and to ensure that the energy from capacity resources is deliverable so that capacity resources can meet their must offer obligations in the energy market and provide reliable energy supply during all conditions. In order to ensure that open access, all capacity resources should be required to have a must offer obligation in the capacity market. If they do not, such resources are effectively withholding access to the grid from capacity resources that would take on a must offer obligation in the capacity market. The result creates market power for the resources with no must offer obligation, noncompetitively limits access to the grid, increases capacity market prices above the competitive level, and creates uncertainty and unpredictable volatility in the capacity market.

The addition of a planned transmission project changes the parameters of the capacity auction for the area, changes the amount of capacity needed in the area, changes the capacity market supply and demand fundamentals in the area and may effectively forestall the ability of generation to compete. But there is no mechanism to permit a direct comparison, let alone competition, between transmission and generation alternatives. There is no mechanism to evaluate whether the generation or transmission alternative is less costly, whether there is more risk associated with the generation or transmission alternatives, or who bears the risks associated with each alternative. Creating such a mechanism should be an explicit goal of PJM market design.

The current market efficiency process does exactly the opposite by permitting transmission projects to be approved without competition from generation. The broader issue is that the market efficiency project approach explicitly allows transmission projects to compete against future generation projects, but without allowing the generation projects to compete. Projecting speculative transmission related benefits for 15 years based on the existing generation fleet and existing patterns of congestion eliminates the potential for new generation to respond to market signals. The market efficiency process allows assets built under the cost of service regulatory paradigm to displace generation assets built under the competitive market paradigm. In addition, there are significant issues with PJM's current benefit/cost analysis which cause it to consistently overstate the potential benefits of market efficiency projects. The market efficiency process is misnamed. The MMU recommends that the market efficiency process be eliminated.

In addition, the use of an incorrectly defined cost-benefit method by PJM and the correct method by MISO results in an over allocation of the costs associated with joint PJM/MISO transmission projects to PJM participants and in some cases approval of projects that do not pass a correctly defined benefit/cost test.

If it is retained, there are significant issues with PJM's benefit/cost analysis that should be addressed prior to approval of additional projects. The current benefit/cost analysis explicitly and incorrectly ignores the increased costs to load in zones that results from an RTEP project when calculating the energy market benefits. All increases and decreases in costs should be included in all zones and LDAs. The definition of benefits should also be reevaluated.

The benefit/cost analysis should also account for the fact that the transmission project costs are not subject to cost caps and may exceed the estimated costs by a wide margin. When actual costs exceed estimated costs, the benefit/cost analysis is effectively meaningless and low estimated costs may result in inappropriately favoring transmission projects over market generation projects. The risk of cost increases for transmission projects should be incorporated in the benefit/cost analysis.

Recent proposals to use storage as a transmission asset (SATA) raises a number of additional concerns about PJM's benefit/cost analysis. Storage is a market asset and should not be owned by transmission owners. PJM should not be evaluating SATA at all without a decision from FERC that SATA is allowable in PJM. At present it is not allowed.

A significant flaw in PJM's benefit/cost analysis is that projected benefits are based on load forecasts which are currently dominated by projected large data center loads that are not verified by PJM and cannot be verified by PJM. That creates a bias towards finding transmission projects beneficial despite the fact that data center loads are imposing transmission costs on other customers as a result.

There are currently no market incentives for transmission owners to plan, submit and complete transmission outages in a timely and efficient manner. Requiring transmission owners to pay does not create an effective incentive when those payments are passed through to transmission customers. The process for the submission of planned transmission outages needs to be carefully reviewed and redesigned to limit the ability of transmission owners to submit transmission outages that are late for FTR auction bid submission dates and are late for the day-ahead energy market and that have large and unnecessary impacts on the PJM energy market. The submission of late transmission outages can inappropriately affect market outcomes when market participants do not have the ability to modify market bids and offers. The PJM process for evaluating the congestion impact of transmission outages needs to be clearly defined and upgraded to provide for management of transmission outages to minimize market impacts. The MMU continues to recommend that PJM draft a clear and expanded definition of the congestion analysis required for transmission outage requests that is incorporated in the PJM Market Rules. PJM Manual 38 currently defines congestion resulting from a transmission outage as an overload on transmission facilities rather than using the general economic definition of congestion resulting from out of merit generation to control constraints. PJM does not currently evaluate the economic impact of congestion when reviewing proposed transmission outages.[242]

The treatment by PJM and Dominion Virginia Power of the outage for the Lanexa – Dunnsville Line illustrates some of the issues with the current process. The outage was submitted and delayed more than once. PJM's analysis of expected congestion did not highlight the magnitude of the issue. Dominion Virginia Power did not stage the outage so as to minimize market disruption and congestion until after there were significant disruptions and congestion.

As an example of the complexities of defining the benefits of transmission investments, the reduction in congestion is frequently and incorrectly cited as a metric of benefits. Congestion is frequently misunderstood. Congestion is not static. Congestion exhibits dynamic intertemporal variability and dynamic locational variability. More importantly, congestion is not the correct metric for evaluating the potential benefits of enhancing the transmission grid. The correct metric is the total net change in production costs.

There is not a secular trend towards increasing congestion in PJM. Congestion is volatile on a monthly basis. Congestion is also volatile on an hourly and daily basis. For example, higher congestion can result from changes in seasonal and daily/hourly fuel costs.

242 PJM, "Manual 38: Operations Planning," Rev. 19 (January 23, 2025) at 19-20.

The level and distribution of congestion at a point in time is a function of the location and size of generating units, the relative costs of the fuels burned and the associated marginal costs of generating units, the location and size of load and the locational capability of the transmission grid. Each of these factors changes over time.

The geographic distribution of congestion is dynamic. The nature and location of congestion in the PJM system has changed significantly over the last 10 years and continues to change. The nature and location of congestion in PJM can also change from one day to the next as a result of changes in relative fuel costs. As a result, building transmission to address a specific pattern of congestion does not make sense, unless the technology can be easily moved to new locations as conditions change. The transmission system is only one of many reasons that congestion exists. The dynamic nature of congestion and the multiple, interactive causes of congestion make it virtually impossible to identify the standalone impacts of an individual transmission investment on future congestion. It is possible, for example, that congestion occurring during a period of a few days in the winter as a result of very high fuel prices, significantly increases the reported level of congestion for the entire year. This has occurred in PJM. It would be a mistake to consider that level of congestion to be a signal to build transmission.

At a more fundamental level, congestion is not the correct metric for evaluating the potential benefits of enhancing the transmission grid. When there are binding transmission constraints and locational price differences, load pays more for energy than generation is paid to produce that energy. The difference is congestion. Congestion is neither good nor bad, but is a direct measure of the extent to which there are multiple marginal generating units with different offers dispatched to serve load as a result of transmission constraints. Congestion occurs when available, least-cost energy cannot be delivered to all load because transmission facilities are not adequate to deliver that energy to one or more areas, and higher cost units in the constrained area(s) must be dispatched to meet the load. The result is that the price of energy in the constrained area(s) is higher than in the unconstrained area. Load in the constrained area pays the higher price for all energy including energy from low cost generation and energy from high cost generation, while only high cost generators are paid the high price at their bus and low cost generators are paid only the low price at their bus.

If FTRs worked perfectly and were assigned directly to load, FTRs would return all congestion to the load that paid the congestion. Congestion is not a cost, it is an accounting result of a market based on locational energy prices in which all load in a constrained area pays the higher single market clearing locational price, resulting in excess payments by load that are not paid to generation, which should be returned to load.

Counterintuitively, congestion actually increases when the transmission capacity between areas with lower cost generation and areas with higher cost generation increases but does not fully eliminate the need for some higher cost local generation. The smaller the amount of higher cost local generation needed to meet load, the more of the local load is met via low cost generation delivered over the transmission system and therefore the higher is the difference between what load pays and generation receives, congestion.

For all these reasons, if done correctly and if FTRs/ARRs returned 100 percent of congestion to load, the benefit/cost analysis for transmission projects would include the total net change in production costs and would not include congestion. The change in production costs correctly measures the changes in cost to load that result from a project.

The PJM Regional Transmission Expansion Plan (RTEP) successfully addresses the need for transmission investment to reliably meet load. Together with the requirement that new generation pay interconnection costs, the RTEP process has resulted in the appropriate level of new transmission investment in PJM. There is no evidence that the PJM planning process is not adequate to meet the requirements of the PJM markets. Additional transmission investment is not a panacea. Transmission investment is expensive and long lived and it is essential that transmission investments be carefully planned for clearly identified needs in order to ensure that power markets can continue to provide reliable service at a competitive price.

PJM must make out of market payments to units that want to retire (deactivate) but that PJM requires to remain in service, for limited operation, for a defined period because the unit is needed for reliability.[243] This provision has been known as Reliability Must Run (RMR) service but RMR is not defined in the PJM tariff. The correct term is Part V reliability service. The need to retain uneconomic units in service reflects a flawed market design and/or planning process problems. If a unit is needed for reliability, the market should reflect a locational value consistent with that need which would result in the unit remaining in service or being replaced by a competitor unit. The planning process should evaluate the impact of the loss of units at risk and determine in advance whether transmission upgrades are required in order to limit the duration of Part V service for individual units. It is essential that the deactivation provisions of the tariff be evaluated and modified. It is also essential that PJM look forward and attempt to plan for foreseeable unit retirements, whether for economic or regulatory reasons. PJM should consider an expedited queue process for projects that could replace the retiring capacity including the immediate transfer of the retiring unit's CIRs to units in the queue in order to permit generation to compete as an alternative to the current transmission only approach.

An area in northern Virginia in the Dominion Transmission Zone, known as Data Center Alley, has experienced significant load growth from data centers. Dominion has presented 44 supplemental project requests to serve the increase in load through the summer of 2025. As part of the supplemental planning process, PJM performs a do no harm analysis. PJM identified the need for additional baseline reinforcements to support the load growth. These baseline reinforcements were addressed in the 2022 RTEP Window 3, when the PJM board approved $1.4 billion of necessary baseline upgrades specific to the Data Center Alley reinforcements.[244] These regional transmission costs were allocated according to Schedule 12 of PJM's Open Access Transmission Tariff (OATT), where costs are shared across all zones by a combination of load ratio share and distribution factor impacts. The transmission owners include these project costs in their base case, and all retail customers in the PJM footprint pay for those upgrade costs through increased energy bills. The cost allocation of the $1.4 billion in baseline upgrades are assigned to all retail customers and not solely to the customers requesting interconnection.

The high level of customer requests in Data Center Alley resulted in the need for significant baseline reliability upgrades. These costs were allocated per Schedule 12 of the PJM OATT. Not all customer requests result in reliability upgrades. Transmission upgrades for customer requests that are submitted through the supplemental planning process are allocated 100 percent to the zone where they are interconnecting. The transmission owner of that zone then includes those project costs in their rate base, and all retail customers in that zone pay those costs.

The Virginia case illustrates the imposition of transmission costs by data centers on other PJM customers. These additional transmission costs are in addition to the significant capacity market costs imposed on other customers by the actual and forecast addition of large data centers.

The main focus of PJM's planning requirements has been to ensure adequate transmission to allow for generation to reliably serve load. Historically, PJM has had enough excess generation to serve the forecasted load in the RTEP process. In recent years, due in part to the significant increase in load resulting from large load data center interconnection requests and an increase in thermal unit deactivations, meeting forecasted loads and reserves with existing generation has become an issue. In order to solve the RTEP study cases, PJM must make assumptions about the existing and future generation to include in the RTEP model based on the need to serve load. The RTEP analysis first includes all existing generation that is expected to remain in service for the year being studied. When the forecasted load exceeds the expected in service generation, the RTEP analysis includes future generation. Planned generators with a signed interconnection service agreement (ISA) or generation interconnection agreement (GIA), or that cleared a BRA, are included. When the PJM load in the RTEP analysis exceeds the sum of existing generation and generation with an executed final agreement, the RTEP analysis simply adds speculative new generation that is in its Phase 3 system impact study status to meet the load. If needed, additional generation (pre-GIA stage or with a suspended status)

243 OATT Part V §114.
244 See "*Transmission Expansion Advisory Committee (TEAC) Recommendations to the PJM Board*," December 2023. <https://www.pjm.com/-/media/committees-groups/committees/teac/2023/20231205/20231205-pjm-teac-board-whitepaper-december-2023.ashx>.

may be modeled (assumed) consistent with the procedures noted in Manual 14B.[245] [246] The RTEP analysis is not adequately coordinated with PJM markets analysis including the energy and capacity markets.

Overview: Section 13, FTRs and ARRs

Auction Revenue Rights

Market Structure

- **ARR Ownership.** In the 2025/2026 planning period ARRs were allocated to 1,560 individual participants, held by 130 parent companies, up from 1,523 individual parents, held by 126 parent companies in the 2024/2025 planning period. ARR ownership for the 2025/2026 planning period was unconcentrated with an HHI of 600, down from 610 for the 2024/2025 planning period.

Market Behavior

- **Self Scheduled FTRs.** For the 2025/2026 planning period, 25.9 percent of eligible ARRs were self scheduled as FTRs, up from 25.3 percent for the 2024/2025 planning period.

Market Performance

- **ARRs as an Offset to Congestion.** ARRs have not served as an effective mechanism to return all congestion revenues to load. For the first four months of the 2025/2026 planning period, ARRs and self scheduled FTRs offset only 66.6 percent of total congestion. Congestion payments by load in some zones were more than offset and congestion payments in some zones were less than offset. Load has been underpaid congestion revenues by $5.4 billion from the 2011/2012 planning period through the first four months of the 2025/2026 planning period. The cumulative offset for that period was only 68.7 percent of total congestion. If ARR holders had self scheduled all of their allocated FTRs as ARRs for the first four months of the 2025/2026 planning period, the ARR target allocations would have increased the offset from 66.6 percent to 98.7 percent of total congestion.

- **ARR Payments.** For the first four months of the 2025/2026 planning period, the ARR target allocations, which are based on the nodal price differences from the Annual FTR Auction, were $1,859.0 million, while PJM collected $2,088.2 million from the combined Long Term, Annual and Monthly Balance of Planning Period FTR Auctions. For the 2024/2025 planning period, the ARR target allocations were $1,448.1 million while PJM collected $1,664.9 million from the combined Annual and the first four Monthly Balance of Planning Period FTR Auctions.

- **ARR.** For the first four months of the 2025/2026 planning period there was enough total day-ahead congestion to pay FTR target allocations. However, as a result of the monthly settlement logic for FTRs and ARRs, $22.6 million of FTR auction revenue over ARR target allocations was transferred from ARR holders (load) to FTR holders. In the 2024/2025 all $196.2 million of FTR auction revenue over ARR target allocations was transferred from ARR holders to FTR holders. Although PJM refers to this as a surplus, there is no such thing as surplus FTR auction revenue based on market logic. FTR Auction revenue results from the market prices paid by willing FTR buyers, should be paid to ARR holders, and should not be returned to FTR buyers for any reason.

- **Residual ARRs.** Residual ARRs are only available on contract paths prorated in Stage 1 of the annual ARR allocation, are only effective for single, whole months and cannot be self scheduled. Residual ARR clearing prices are based on monthly FTR auction clearing prices. Residual ARRs with negative target allocations are not allocated to participants. Instead they are removed and the model is rerun.

  In the first four months of the 2025/2026 planning period, as a result of transmission capability being returned to service from outages included in the annual model, PJM allocated a total of 16,614.7 MW of residual ARRs, up 8,616.5 MW (a 107.7 percent increase) from 7,998.2 MW, with a total target allocation of $50.5 million, up $45.0 million (an 819.9 percent increase) from $5.5 million in the same period of the 2024/2025 planning period.

245 See "Review of 2025 RTEP Assumptions," presented at the January 7, 2025 meeting of the Transmission Expansion Advisory Committee. <https://www.pjm.com/-/media/DotCom/committees-groups/committees/teac/2025/20250107/20250107-item-11---2025-rtep-assumption.pdf>.
246 See "PJM Manual 14B: PJM Region Transmission Planning Process," Rev. 57 (September 25, 2024).

- **ARR Deficiency.** In July 2025 there was not enough FTR auction revenue collected from the monthly FTR auction to pay the high target allocations from Residual ARRs. As a result, July ARR funding was deficient for the first time since ARRs were introduced. Deficient ARRs will be funded at the end of the planning period from surplus FTR revenues, if there is an FTR surplus, or through an uplift charge to FTR holders if there is not an FTR surplus.
- **ARR Reassignment for Retail Load Switching.** There were 16,509 MW of ARRs associated with $385.7 thousand of revenue that were reassigned for the first four months of the 2025/2026 planning period. There were 11,996 MW of ARRs associated with $184.3 thousand of revenue that were reassigned in the same period of the 2024/2025 planning period.

Financial Transmission Rights

Market Design

- **Monthly Balance of Planning Period FTR Auctions.** The design of the Monthly Balance of Planning Period FTR Auctions includes auctions for each remaining month in the planning period.

Market Structure

- **Patterns of Ownership.**[247] For the Monthly Balance of Planning Period Auctions, financial entities purchased 96.4 of all prevailing and counter flow FTRs, including 95.3 percent of prevailing flow and 97.7 percent of counter flow FTRs for the first four months of the 2025/2026 planning period. Financial entities owned 88.7 percent of all prevailing and counter flow FTRs, including 82.5 percent of all prevailing flow FTRs and 95.7 percent of all counter flow FTRs during the first four months of the 2025/2026 planning period. Self scheduled FTRs account for 4.3 percent of all FTR held.
- **Market Concentration.** In the Monthly Balance of Planning Period Auctions for the first four months of the 2025/2026 planning period, ownership of cleared prevailing flow bids was unconcentrated in all periods. Ownership of cleared counter flow bids was unconcentrated in 47.6 percent of periods and moderately concentrated in 52.4 percent of periods.

Market Behavior

- **Sell Offers.** In a given auction, market participants can sell FTRs acquired in preceding auctions or preceding rounds of auctions. In the 2025/2028 Long Term FTR Auction, total participant FTR sell offers were 1,557,455 MW. In the 2025/2026 Annual FTR Auction, total participant FTR sell offers were 1,695,004 MW. In the Monthly Balance of Planning Period FTR Auctions for the first four months of the 2025/2026 planning period, total participant FTR sell offers were 31,730,557 MW.
- **Buy Bids.** In the 2025/2028 Long Term FTR auction, total FTR buy bids were 6,729,000 MW, up 72.0 percent from 5,729,618 MW the previous long term auction. There were 6,658,483 MW of buy and self scheduled bids in the 2025/2026 Annual FTR Auction, up 39.6 percent from 4,770.381 MW the previous planning period. The total FTR buy bids from the Monthly Balance of Planning Period FTR Auctions for the first four months of the 2025/2026 planning period were 48,912,396 MW.
- **FTR Forfeitures.** Total FTR forfeitures were $1,312.2 thousand for the first four months of the 2025/2026 planning period, up 38.0 percent from $951.0 thousand from the same period of the2024/2025 planning period.
- **Credit.** There were no collateral defaults and two payment defaults in the first nine months of 2025.

Market Performance

- **Quantity.** In the 2025/2028 Long Term FTR Auction 923,869 MW (13.7 percent) of buy bids cleared and 168,852 MW (10.8 percent) of sell offers cleared. In the 2025/2026 Annual FTR Auction 1,324,299 MW (19.9 percent) of buy and self scheduled bids cleared, up 28.8 percent from the 2024/2025 Annual FTR Auction, and 183,410 MW (10.8 percent) of sell offers cleared, up 47.6 percent from the 2024/2025 Annual Auction. In the first four months of the 2025/2026 planning period, Monthly Balance of Planning Period FTR Auctions 8,010,114 MW (16.4 percent) of FTR buy

247 Beginning in the *2025 Quarterly State of the Market Report for PJM: January through March*, the MMU categorizes all participants owning FTRs in PJM as either physical or financial at an account level. In prior reports, participants were categorized as either physical or financial at an organization level.

bids cleared, up 54.9 percent from the the same period of the 2024/2025 planning period and 5,089,192 MW (16.0 percent) of FTR sell offers cleared, up 36.5 percent from the same period of the 2024/2025 planning period.

- **Price.** The weighted average buy bid FTR price in the 2025/2028 Long Term FTR Auction was $0.09 per MW, up from $0.07 from the 2024/2027 Long Term FTR Auction. The weighted average buy bid FTR price in the Annual FTR Auction for the 2025/2026 planning period was $0.50 per MW, up from $0.30 per MW in the 2024/2025 planning period. The weighted average buy bid cleared FTR price in the Monthly Balance of Planning Period FTR Auctions for all periods in the first four months of the 2025/2026 planning period was $0.36 per MWh, down from $0.42 in the 2024/2025 planning period.
- **Revenue.** The 2025/2028 Long Term FTR Auction generated $162.3 million of net revenue for all FTRs, up 58.2 percent from $102.6 million from the 2024/2027 Long Term FTR Auction. The 2025/2026 Annual FTR Auction generated $1,895.3 million in net revenue, up 28.5 percent from $1,475.3 million for the 2024/2025 Annual FTR Auction. The Monthly Balance of Planning Period FTR Auctions resulted in net revenue of $39.9 million in the first four months of the 2025/2026 planning period, down 20.4 percent from $50.1 million in the same period of the 2024/2025 planning period.
- **"Revenue Adequacy."** For the first four months of the 2025/2026 planning period there was enough total day-ahead congestion revenue to pay FTR target allocations. However, as a result of the monthly settlement logic for FTRs and ARRs, $22.6 million of FTR auction revenue was transferred from ARR holders (load) to FTR holders, and FTRs were paid 100.0 percent of the target allocations for the first four months of the 2025/2026 planning period. Based on market logic, there is no such thing as surplus FTR auction revenue and there is no such thing as revenue inadequacy. FTR Auction revenue results from the market prices paid by willing FTR buyers, should be paid to ARR holders, and should not be returned to FTR buyers for any reason.
- **Profitability.** FTR profitability is the difference between the revenue received directly from holding an FTR plus any revenue from the sale of an FTR, and the cost of buying the FTR. In the first four months of the 2025/2026 planning period, profits for all participants were $445.8 million, up from $351.8 million in profits in the same time period in the 2024/2025 planning period. In the first four months of the 2025/2026 planning period, physical entities received $93.0 million in profits on FTRs purchased directly (not self scheduled), up from $36.4 million profits in the same time period in the 2024/2025 planning period. Financial entities received $352.8 million in profits, up from $315.4 million profits in the same time period in the 2024/2025 planning period.

Section 13 Recommendations

Market Design

- The MMU recommends that the current ARR/FTR design be replaced with defined congestion revenue rights (CRRs). A CRR is the right to actual congestion revenue that is paid by physical load at a specific bus, zone or aggregate. (Priority: High. First reported 2015. Status: Not adopted.)

ARR

- The MMU recommends that the ARR/FTR design be modified to ensure that the rights to all congestion revenues are assigned to load. (Priority: High. First reported 2015. Status: Not adopted.)
- The MMU recommends that all historical generation to load paths be eliminated as a basis for assigning ARRs. The MMU recommends that the current design be replaced with a design in which the rights to actual congestion paid are assigned directly to the load that paid that congestion by node. (Priority: High. First reported 2015. Status: Partially adopted.)
- The MMU recommends that, under the current FTR design, the rights to all congestion revenue be allocated as ARRs prior to sale as FTRs. Reductions in allocated revenue as a contingency for outages and increased system capability should be reserved for ARRs rather than sold in the Long Term FTR Auction. (Priority: High. First reported 2017. Status: Not adopted.)

- The MMU recommends that IARRs be eliminated from PJM's tariff, but that if IARRs are not eliminated, IARRs should be subject to the same proration rules that apply to all other ARR rights. (Priority: Low. First reported 2018. Status: Not adopted.)

FTR

- The MMU recommends that FTR funding be based on total congestion, including both day-ahead and balancing congestion. (Priority: High. First reported 2017. Status: Not adopted.)
- The MMU recommends that bilateral transactions be eliminated and that all FTR transactions occur in the PJM market. (Priority: High. First reported 2022. Status: Not adopted.)[248]
- The MMU recommends a requirement that the details of all bilateral FTR transactions be reported to PJM. (Priority: High. First reported 2020. Status: Not adopted.)
- The MMU recommends that PJM continue to evaluate the bilateral indemnification rules and any asymmetries they may create. (Priority: Low. First reported 2018. Status: Not adopted.)
- The MMU recommends that PJM reduce FTR sales on paths with persistent overallocation of FTRs, including a clear definition of persistent overallocation and how the reduction will be applied. (Priority: High. First reported 2013. Status: Partially adopted, 2014/2015 planning period.)
- The MMU recommends that PJM eliminate generation to generation paths and all other paths that do not represent the delivery of power to load. (Priority: High. First reported 2018. Status: Not adopted.)
- The MMU recommends that the Long Term FTR product be eliminated. If the Long Term FTR product is not eliminated, the Long Term FTR Market should be modified so that the supply of prevailing flow FTRs in the Long Term FTR Market is based solely on counter flow offers in the Long Term FTR Market. (Priority: High. First reported 2017. Status: Not adopted.)
- The MMU recommends that PJM improve transmission outage modeling in the FTR auction models, including the use of probabilistic outage modeling. (Priority: Low. First reported 2013. Status: Not adopted.)

"Surplus"

- The MMU recommends that all FTR auction revenue be distributed to ARR holders monthly, regardless of FTR funding levels. (Priority: High. First reported 2015. Status: Not adopted.)
- The MMU recommends that, under the current FTR design, all congestion revenue in excess of FTR target allocations be distributed to ARR holders on a monthly basis. (Priority: High. First reported 2018. Status: Not adopted.)
- The MMU recommends that FTR auction revenues not be used by PJM to buy counter flow FTRs for the purpose of improving FTR payout ratios.[249] (Priority: High. First reported 2015. Status: Not adopted.)

FTR Subsidies

- The MMU recommends that PJM eliminate portfolio netting to eliminate cross subsidies among FTR market participants. (Priority: High. First reported 2012. Status: Not adopted. Rejected by FERC.)
- The MMU recommends that PJM eliminate subsidies to counter flow FTRs by applying the payout ratio to counter flow FTRs in the same way the payout ratio is applied to prevailing flow FTRs. (Priority: High. First reported 2012. Status: Not adopted.)
- The MMU recommends that PJM eliminate geographic cross subsidies. (Priority: High. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM examine the mechanism by which self scheduled FTRs are allocated when load switching among LSEs occurs throughout the planning period. (Priority: Low. First reported 2011. Status: Not adopted.)

248 If adopted, this recommendation would replace the next two recommendations.

249 See "PJM Manual 6: Financial Transmission Rights," Rev. 34 (May 21, 2025).

FTR Liquidation

- The MMU recommends that the FTR portfolio of a defaulted member be canceled rather than liquidated or allowed to settle as a default cost to the membership. (Priority: High. First reported 2018. Status: Not adopted.)

Credit

- The MMU recommends that PJM's minimum credit requirements be reviewed and updated to appropriately reflect the risk created for the markets and other market participants. The PJM minimum credit requirements (minimum tangible net worth and minimum tangible assets) were set as fixed dollars amounts in 2011 in FERC order 741 based on the specific market participation (FTRs or other). (Priority: Medium. New recommendation. Status: Not adopted.)

Section 13 Conclusion

Solutions

The annual ARR allocation should be designed to ensure that the rights to all congestion revenues are assigned to load, without requiring contract path or point to point physical or financial transmission rights that are inconsistent with the network based delivery of power and the actual way congestion is generated in PJM's security constrained LMP market. When there are binding transmission constraints and locational price differences, load pays more for energy than generation is paid to produce that energy. The difference is congestion. As a result, congestion belongs to load and should be returned to load.

The current contract path based design should be replaced with a design in which the rights to actual congestion paid are assigned directly to the load that paid that congestion by node. The assigned right should be to the actual difference between load payments, both day-ahead and balancing, and revenues paid to the generation used to serve that load. The load can retain the right to the congestion revenues or sell the rights through auctions. The correct assignment of congestion revenues to load is fully consistent with retaining FTR auctions for the voluntary sale by load of their congestion revenue rights at terms defined by load, recognizing that load has property rights to congestion.

Issues

If the original PJM FTR approach had been designed to return congestion revenues to load without the use of generation to load contract paths, and if the distortions subsequently introduced into the FTR design had not been added, many of the subsequent issues with the FTR design and complex redesigns would have been avoided. PJM would not have had to repeatedly intervene in the functioning of the FTR system in an effort to meet the artificial and incorrectly defined goal of revenue adequacy.

PJM has persistently and subjectively intervened in the FTR market in order to affect the payments to FTR holders. These interventions are not appropriate. For example, in the 2014/2015, 2015/2016 and 2016/2017 planning periods, PJM significantly reduced the allocation of ARR capacity, and FTRs, in order to guarantee full FTR funding. PJM reduced system capability in the FTR auction model by including more outages, reducing line limits and including additional constraints. PJM's modeling changes resulted in significant reductions in Stage 1B and Stage 2 ARR allocations, a corresponding reduction in the available quantity of FTRs, a reduction in congestion revenues assigned to ARRs, and an associated surplus of congestion revenue relative to FTR target allocations. This also resulted in a significant redistribution of ARRs among ARR holders based on differences in allocations between Stage 1A and Stage 1B ARRs. Starting in the 2017/2018 planning period, with the allocation of balancing congestion and M2M payments to load rather than FTRs, PJM increased system capability allocated to Stage 1B and Stage 2 ARRs, but continued to conservatively select outages to manage FTR funding levels.

PJM has intervened aggressively in the FTR market since its inception in order to meet various subjective objectives including so called revenue adequacy. PJM should not intervene in the FTR market to subjectively manage FTR funding. PJM should fix the FTR/ARR design and then should let the market work to return congestion to load and to let FTR values reflect actual congestion.

Load should never be required to subsidize payments to FTR holders, regardless of the reason.[250] The FERC order of September 15, 2016, introduced a subsidy to FTR holders at the expense of ARR holders.[251] The order requires PJM to ignore balancing congestion when calculating total congestion dollars available to fund FTRs. As a result, balancing congestion and M2M payments are assigned to load, rather than to FTR holders, as of the 2017/2018 planning period. When combined with the direct assignment of both surplus day-ahead congestion and surplus FTR auction revenues to FTR holders, the Commission's order shifted substantial revenue from load to the holders of FTRs and further reduced the offset to congestion payments by load. This approach ignores the fact that load pays both day-ahead and balancing congestion, and that actual congestion is the sum of day-ahead and balancing congestion. Eliminating balancing congestion from the FTR revenue calculation requires load to pay twice for congestion. Load pays total congestion and pays negative balancing congestion again. The fundamental reasons that there has been a significant and persistent difference between day-ahead and balancing congestion include inadequate transmission modeling in the FTR auction and the role of UTCs in taking advantage of these modeling differences and creating negative balancing congestion. There is no reason to impose these costs on load.

These changes were made in order to increase the payout to holders of FTRs who are not loads. Increasing the payout to FTR holders at the expense of the load is not a supportable market objective. PJM should implement an FTR design that calculates and assigns congestion rights to load rather than continuing to modify the current, fundamentally flawed, design.

Load was made significantly worse off as a result of the changes made to the FTR/ARR process by PJM based on the FERC order of September 15, 2016. ARR revenues were significantly reduced for the 2017/2018 FTR Auction, the first auction under the new rules. ARRs and self scheduled FTRs offset only 49.5 percent of total congestion costs for the 2017/2018 planning period rather than the 58.0 percent offset that would have occurred under the prior rules, a difference of $101.4 million.

250 Such subsidies have been suggested repeatedly. See FERC Dockets Nos. EL13-47-000 and EL12-19-000.
251 See 156 FERC ¶ 61,180 (2016), *reh'g denied*, 158 FERC ¶ 61,093 (2017).

A subsequent rule change was implemented that modified the allocation of what is termed surplus auction revenue to load. Beginning with the 2018/2019 planning period, surplus day-ahead congestion and surplus FTR auction revenue are assigned to FTR holders only up total target allocations, and then distributed to ARR holders.[252] ARR holders will only be allocated this surplus after FTRs are paid 100 percent of their target allocations. While this rule change increased the level of congestion revenues returned to load under some conditions, the rules do not recognize ARR holders' rights to all congestion revenue, and only improves congestion payouts to load when there is a surplus. There was no surplus for the 2020/2021 or 2021/2022 planning years. With this rule in effect for the 2021/2022 planning period, ARRs and self scheduled FTRs offset 31.6 percent of total congestion. There was surplus for the 2022/2023 and the 2023/2024 planning periods. However, FTR auction surplus revenues were taken from load and given to FTR holders because day-ahead congestion revenues were less than target allocations in the 2023/2024 planning period. For the 2024/2025 planning period, there was not enough congestion revenue to fund FTR target allocations and all FTR auction surplus revenues were taken from load and given to FTR holders. Based on market logic, there is no such thing as surplus FTR auction revenue. FTR Auction revenue results from the market prices paid by willing FTR buyers, should be paid to ARR holders, and should not be returned to FTR buyers for any reason. ARRs and self scheduled FTRs offset only 66.6 percent of total congestion paid by load in the first four months of the 2025/2026 planning period. Load has been underpaid congestion revenues by $5.4 billion from the 2011/2012 planning period through the first four months of the 2025/2026 planning period. The cumulative offset for that period was only 68.7 percent of total congestion.

The complex process related to what is termed the overallocation of Stage 1A ARRs is entirely an artificial result of reliance on the contract path model in the assignment of FTRs. For example, there is a reason that transmission is not actually built to address the Stage 1A overallocation issue. The Stage 1A overallocation issue is a fiction based on the use of outdated and irrelevant

252 163 FERC ¶ 61,165 (2018).

generation to load contract paths to assign Stage 1A rights that have nothing to do with actual power flows.

PJM proposed, and on March 11, 2022, FERC accepted, an increase to Stage 1A ARR allocations from 50 percent of Network Service Base Load (NSBL) to 60 percent of Network Service Peak Load (NSPL).[253] NSBL is a network service customer's contribution to the lowest daily zonal peak load in the prior twelve month period, and NSPL is a network service customer's contribution to the highest daily zonal peak load in the prior twelve month period. PJM's new ARR allocation rules have increased Stage 1A rights at the cost of Stage 1B and Stage 2 ARR allocations. More importantly, PJM's new ARR allocation rules have exacerbated the current misalignment between congestion property rights and the congestion paid by load.

Proposed Design

To address the issues with the current contract path based ARR/FTR market design, the MMU recommends that the current design be replaced with a design in which the rights to actual congestion paid are assigned directly to the load that paid that congestion by node. The assigned right would be the actual difference between load payments, both day-ahead and balancing, and revenues paid to the generation used to serve that load. The load could retain the right to the congestion or sell the right through auctions. The correct assignment of congestion revenues to load is fully consistent with retaining FTR auctions for the voluntary sale by load of their congestion revenue rights at terms defined by load.

With a network assignment of actual congestion, there would be no cross subsidies among rights holders and no over or under allocation of rights relative to actual network market solutions. There would be no revenue shortfalls as congestion payments equal congestion collected. The risk of default would be isolated to the buyer and seller of the right, and any default would not be socialized to other rights holders. In the case of a defaulting buyer, the rights to the congestion revenues would revert to the load. There would be no risk of a network right flipping in value from positive to negative, because congestion is always the positive difference between what load pays for energy and what generation is paid for energy as a result of transmission constraints.

The MMU proposal requires the calculation of constraint specific congestion and the calculation of that specific constraint's congestion related charges to each physical load bus downstream of that constraint. Under the MMU proposal, the constraint specific congestion calculated by hour, from both the day-ahead and balancing market would be paid directly to the physical load as a credit against the associated load serving entity's (LSE) energy bill. This right to the congestion is defined as the congestion revenue right (CRR) that belongs to the physical load at a defined bus, zone or aggregate. The LSE could choose to sell all or a portion of the CRR through auctions.

A CRR is the right to actual, realized network related congestion that is paid by physical load at a specific bus, zone or aggregate. Under the MMU proposal a bus, zone or aggregate specific CRR could be sold as a defined share of the actual congestion. For example, an LSE could sell 50 percent of its congestion revenue right for the planning period to a third party. The third party buyer would then be entitled to 50 percent of the congestion that is credited to that specific bus, zone or aggregate for the planning period. The remaining 50 percent of the congestion credit for the specified bus, zone or aggregate would be paid to the LSE along with the auction clearing price for the 50 percent of the CRR that was sold to the third party. Depending on actual congestion and the price paid for a CRR, an LSE selling its congestion revenue rights could be better or worse off than if it retained its rights.

Under the MMU proposal, the LSE would be able to set reservation prices in the auction for the sale of portions or all of its CRR. Third parties would have an opportunity to bid for the offered portions of the CRR, and the market for the congestion revenue associated with the specified bus, zone or aggregate would clear at a price. If the reservation price of an identified portion of the offered CRR was not met at the clearing price, that portion of the offered CRR would remain with the load. Auctions could be annual and/or monthly and/or more frequent.

253 See 178 FERC ¶ 61,170.

Under the MMU proposal, point to point rights (FTRs) could exist as a separate, self-funded hedging product based on simultaneously feasible prevailing and counter flows in a PJM managed network based auction. The only supply and the only source of revenues in the point to point market for prevailing flow FTRs would be counter flow offers and direct payments for specific rights.

Recommendations

In order to perform its role in PJM market design, the MMU evaluates existing and proposed PJM Market Rules and the design of the PJM Markets.[1] The MMU initiates and proposes changes to the design of the markets and the PJM Market Rules in stakeholder and regulatory proceedings.[2] In support of this function, the MMU engages in discussions with stakeholders, State Commissions, PJM management, and the PJM Board; participates in PJM stakeholder meetings and working groups regarding market design matters; publishes proposals, reports and studies on market design issues; and makes filings with the Commission on market design issues.[3] The MMU also recommends changes to the PJM Market Rules to the staff of the Commission's Office of Energy Market Regulation, State Commissions, and the PJM Board.[4] The MMU may provide in its annual, quarterly and other reports "recommendations regarding any matter within its purview."[5]

Recommendation Priority

Priority rankings are relative. The creation of rankings recognizes that there are limited resources available to address market issues and that problems must be ranked in order to determine the order in which to address them. It does not mean that all the problems should not be addressed. Priority rankings are dynamic and as new issues are identified, priority rankings will change. The rankings reflect a number of factors including the significance of the issue for efficient markets, the difficulty of completion and the degree to which items are already in progress. A low ranking does not necessarily mean that an issue is not important, but could mean that the issue would be easy to resolve.

There are three priority rankings: High, Medium and Low. High priority indicates that the recommendation requires action because it addresses a market design issue that creates significant market inefficiencies and/or long lasting negative market effects. Medium priority indicates that the recommendation addresses a market design issue that creates intermediate market inefficiencies and/or near term negative market effects. Low priority indicates that the recommendation addresses a market design issue that creates smaller market inefficiencies and/or more limited market effects or that it could be easily resolved.

Recommendation Status

The MMU also tracks PJM's progress in addressing these recommendations. The MMU recognizes that part of the process of addressing recommendations may include discussions in the stakeholder process, FERC decisions and court decisions and those elements are included in the tracking. The MMU recognizes that PJM does not have the unilateral authority to implement changes to the tariff but PJM has a significant role in the issues PJM focuses on, in proposed changes to the PJM manuals, and in the recommendations PJM makes to the stakeholders and to FERC. Each recommendation includes a status. The status categories are:

- **Adopted:** PJM has implemented the recommendation made by the MMU.
- **Partially adopted:** PJM has implemented part of the recommendation made by the MMU.
- **Not adopted:** PJM does not plan to implement the recommendation made by the MMU, or has not yet implemented any part of the recommendation made by the MMU. Where the subject of the recommendation is pending stakeholder, FERC, or court action, that status is noted.
- **Withdrawn:** The MMU no longer makes the recommendation because it has become irrelevant or because it has been replaced by another recommendation.

New Recommendations

Consistent with its core function to "[e]valuate existing and proposed market rules, tariff provisions and market design elements and recommend proposed rule and tariff changes," the MMU recommends specific enhancements to existing market rules and implementation of new rules that are required for competitive results in PJM markets and for continued improvements in the functioning of PJM markets.[6]

In this *2025 Quarterly State of the Market Report for PJM: January through September*, the MMU includes three new recommendations.

New Recommendations from Section 6, Demand Response

- The MMU recommends that DER aggregations that clear in a capacity auction not be permitted to change status from homogeneous demand response to any other status for any additional auctions for the same delivery year, or for the delivery year. (Priority: High. New recommendation. Status: Not adopted.)
- The MMU recommends that PRD be required to respond during a PAI, regardless of whether the real-time LMP at the applicable location meet or exceeds the PRD strike price, to be consistent with all CP resources. (Priority: Medium. New recommendation. Status: Not adopted.)

New Recommendation from Section 13, Financial Transmission Rights and Auction Revenue Rights

- The MMU recommends that PJM's minimum credit requirements be reviewed and updated to appropriately reflect the risk created for the markets and other market participants. The PJM minimum credit requirements (minimum tangible net worth and minimum tangible assets) were set as fixed dollars amounts in 2011 in FERC order 741 based on the specific market participation (FTRs or other). (Priority: Medium. New recommendation. Status: Not adopted.)

6 18 CFR § 35.28(g)(3)(ii)(A); see also OATT Attachment M § IV.D.

Complete List of Current MMU Recommendations

The recommendations are explained in each section of the report.

Section 3, Energy Market

Market Power

- The MMU recommends that the market rules explicitly require that offers in the energy market be competitive, where competitive is defined to be the short run marginal cost of the units. The short run marginal cost should reflect opportunity cost when appropriate. The MMU recommends that the level of incremental costs includable in cost-based offers per the PJM Operating Agreement not exceed the short run marginal cost of the unit. (Priority: Medium. First reported 2009. Status: Not adopted.)

Fuel Cost Policies

- The MMU recommends that PJM require that all fuel cost policies be algorithmic, verifiable, and systematic, and accurately reflect short run marginal costs. (Priority: Medium. First reported 2016. Status: Not adopted.)
- The MMU recommends that the temporary cost method be removed and that all units that submit nonzero cost-based offers be required to have an approved fuel cost policy. (Priority: Low. First reported 2020. Status: Not adopted.)
- The MMU recommends that the penalty exemption provision be removed and that all units that submit nonzero cost-based offers be required to follow their approved fuel cost policy. (Priority: Medium. First reported 2020. Status: Not adopted.)

Cost-Based Offers

- The MMU recommends removal of all use of FERC System of Accounts in the Cost Development Guidelines. (Priority: Medium. First reported 2016. Status: Not adopted.)

- The MMU recommends the removal of all use of cyclic starting and peaking factors from the Cost Development Guidelines. (Priority: Medium. First reported 2016. Status: Not adopted.)
- The MMU recommends the removal of all maintenance costs from the Cost Development Guidelines. (Priority: Medium. First reported 2019. Status: Not adopted.)
- The MMU recommends, given that maintenance costs are currently allowed in cost-based offers, that market participants be permitted to include only variable maintenance costs, linked to verifiable operational events and that can be supported by clear and unambiguous documentation of the operational data (e.g. run hours, MWh, MMBtu) that support the maintenance cycle of the equipment being serviced/replaced. (Priority: Medium. First reported 2020. Status: Partially adopted 2023.)
- The MMU recommends explicitly accounting for soak costs and changing the definition of the start heat input for combined cycles to include only the amount of fuel used from first fire to the first breaker close in the Cost Development Guidelines. (Priority: Medium. First reported 2016. Status: Partially adopted.)
- The MMU recommends that soak costs, soak time and the MWh produced during soaking be modeled separately. This will ensure that the time required for units to reach a dispatchable level is known and used in the unit commitment process instead of only being communicated verbally between dispatchers and generators. Separating soak costs from start costs and modeling the MWh produced during soaking allows for a better representation of the costs because it eliminates the need to simply assume the price paid for those MWh. (Priority: Medium. First reported 2022. Status: Not adopted.)
- The MMU recommends the removal of nuclear fuel and nonfuel operations and maintenance costs that are not short run marginal costs from the Cost Development Guidelines. (Priority: Medium. First reported 2016. Status: Not adopted.)
- The MMU recommends revising the pumped hydro fuel cost calculation to include day-ahead and real-time power purchases. (Priority: Low. First reported 2016. Status: Not adopted.)

Market Power: TPS Test and Offer Capping

- The MMU recommends that the rules governing the application of the TPS test be clarified and documented. The TPS test application in the day-ahead energy market is not documented. (Priority: High. First reported 2015. Status: Partially adopted.)[7]
- The MMU recommends that PJM modify the process of applying the TPS test in the day-ahead energy market to ensure that all local markets created by binding constraints are tested for market power and to ensure that market sellers with market power are appropriately mitigated to their competitive offers. (Priority: High. First reported 2022. Status: Not adopted.)
- The MMU recommends, in order to ensure effective market power mitigation when the TPS test is failed, that offer capping be applied to units that fail the TPS test in the real-time market that were not offer capped at the time of commitment in the day-ahead market or at a prior time in the real-time market. (Priority: High. First reported 2020. Status: Not adopted.)
- The MMU recommends, in order to ensure effective market power mitigation and to ensure that capacity resources meet their obligations to be flexible, that capacity resources be required to use flexible parameters in all offers at all times. (Priority: High. First reported 2021. Status: Not adopted.)
- The MMU recommends, in order to ensure effective market power mitigation, PJM always use cost-based offers for units that fail the TPS test, and always use flexible parameters for all cost-based and all price-based offers during high load conditions such as cold and hot weather alerts and emergency conditions. (Priority: High. First reported 2015. Status: Not adopted.)

7 The real-time market formula for determining the lowest cost schedule is documented. The day-ahead market formula for determining the lowest cost schedule is not documented.

- The MMU recommends that PJM require every market participant to make available at least one cost schedule based on the same hourly fuel type(s) and parameters at least as flexible as their offered price schedule. (Priority: Medium. First reported 2015. Status: Not adopted.)
- The MMU recommends, in order to ensure effective market power mitigation when the TPS test is failed, that markup be consistently positive or negative across the full MWh range of price and cost-based offers. (Priority: High. First reported 2015. Status: Not adopted.)
- The MMU recommends, in order to ensure effective market power mitigation, that PJM commit all resources that fail the TPS test on their cost-based offers, that the Market Seller designate the cost-based offer if there is more than one, and that PJM implement this solution as soon as possible. (Priority: High. First reported Q3 2024. Status: Not adopted.)
- The MMU recommends that PJM retain the $1,000 per MWh offer cap in the PJM energy market except when cost-based offers exceed $1,000 per MWh, and retain other existing rules that limit incentives to exercise market power. (Priority: High. First reported 1999. Status: Partially adopted, 1999, 2017.)
- The MMU recommends the elimination of FMU and AU adders. FMU and AU adders no longer serve the purpose for which they were created and interfere with the efficient operation of PJM markets. (Priority: Medium. First reported 2012. Status: Partially adopted, 2014.)[8]

Offer Behavior

- The MMU recommends that resources not be allowed to violate the ICAP must offer requirement. The MMU recommends that PJM enforce the ICAP must offer requirement by assigning a forced outage to any unit that is derated in the energy market below its committed ICAP without an outage that reflects the derate. (Priority: Medium. First reported 2020. Status: Not adopted.)
- The MMU recommends that storage resources be subject to an enforceable ICAP must offer rule in the day-ahead and real-time energy markets that reflects the limitations of these resources. (Priority: Medium. First reported 2020. Status: Not adopted.)
- The MMU recommends that capacity resources not be allowed to offer any portion of their capacity market obligation as maximum emergency energy. (Priority: Medium. First reported 2012. Status: Not adopted.)
- The MMU recommends that PJM integrate all the outage reporting tools in order to enforce the ICAP must offer requirement, ensure that outages are reported correctly and eliminate reporting inconsistencies. Generators currently submit availability in three different tools that are not integrated, Markets Gateway, eDART and eGADS. (Priority: Medium. First reported 2022. Status: Not adopted.)
- The MMU recommends that gas generators be required to check with pipelines throughout the operating day to confirm that nominations are accepted beyond the NAESB deadlines, that gas generators be required to inform PJM about whether they have gas, and that gas generators be required to place their units on forced outage until the time that pipelines allow nominations to consume gas at a unit. (Priority: Medium. First reported 2022. Status: Not adopted.)

Capacity Resources

- The MMU recommends that capacity resources be held to the OEM operating parameters of the capacity market CONE reference resource for performance assessment and energy uplift payments and that this standard be applied to all technologies on a uniform basis. (Priority: Medium. First reported 2015. Status: Not adopted.)
- The MMU recommends that the parameters which determine nonperformance charges and the amounts of uplift payments should reflect the flexibility goals of the capacity market design. The operational parameters used by generation owners to indicate to PJM operators what a unit is capable of during the operating day should not determine capacity resource performance assessment or uplift payments. (Priority: Medium. First reported 2015. Status: Partially adopted.)[9]

8 The applicability of the FMU and AU adders is limited by the rule implemented in 2014 requiring that net revenues must fall below avoidable costs, but the possibility of FMU and AU adders is still part of the PJM Market Rules.

9 Flexible parameter standards are in place for combined cycle and combustion turbine resources when operating on a parameter limited schedule, but not for other schedules or generating technologies.

- The MMU recommends that PJM clearly define the business rules that apply to the unit specific parameter adjustment process, including PJM's implementation of the tariff rules in the PJM manuals to ensure market sellers know the requirements for their resources. (Priority: Low. First reported 2018. Status: Not adopted.)
- The MMU recommends that PJM update the tariff to clarify that all generation resources are subject to unit specific parameter limits on their cost-based offers using the same standard and process as capacity resources. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that resources not be paid the daily capacity payment when unable to operate to their unit specific parameter limits. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that PJM not approve temporary exceptions that are based on pipeline tariff terms that are not enforced at the time, or are based on inferior transportation service procured by the generator. (Priority: Medium. First reported 2019. Status: Not adopted.)
- The MMU recommends that PJM require generators that violate their approved turn down ratio (by either using the fixed gen option or increasing their economic minimum) to use the temporary parameter exception process that requires market sellers to demonstrate that the request is based on a physical and actual constraint. (Priority: Medium. First reported 2021. Status: Not adopted.)
- The MMU recommends: that gas generators be required to confirm, regularly during the operating day, that they can obtain gas if requested to operate at their economic maximum level; that gas generators provide that information to PJM during the operating day; and that gas generators be required to be on forced outage if they cannot obtain gas during the operating day to meet their must offer requirement as a result of pipeline restrictions, and they do not have backup fuel. As part of this, the MMU recommends that PJM collect data on each individual generator's fuel supply arrangements at least annually or when such arrangements change, and analyze the associated locational and regional risks to reliability. (Priority: Medium. First reported 2022. Status: Not adopted.)

Accurate System Modeling

- The MMU recommends that PJM explicitly state its policy on the use of transmission penalty factors including: the level of the penalty factors; the triggers for the use of the penalty factors; the appropriate line ratings to trigger the use of penalty factors; the allowed duration of the violation and when the transmission penalty factors will be used to set the shadow price. The MMU recommends that PJM end the practice of manual and automated discretionary reductions in the control limits on transmission constraint line ratings used in the market clearing software (SCED) and included in LMP. (Priority: Medium. First reported 2015. Status: Partially adopted 2020.)[10]
- The MMU recommends that PJM routinely review all transmission facility ratings and any changes to those ratings to ensure that the normal, emergency and load dump ratings used in modeling the transmission system are accurate and reflect standard ratings practice. (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM not use closed loop interface or surrogate constraints to artificially override nodal prices based on fundamental LMP logic in order to: accommodate rather than resolve the inadequacies of the demand side resource capacity product; address the inability of the power flow model to incorporate the need for reactive power; accommodate rather than resolve the flaws in PJM's approach to scarcity pricing; or for any other reason. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM update the outage impact studies, the reliability analyses used in RPM for capacity deliverability, and the reliability analyses used in RTEP for transmission upgrades to be consistent with the more conservative emergency operations (post contingency load dump limit exceedance analysis) in the energy market that were implemented in June 2013.[11] (Priority: Low. First reported 2013. Status: Not adopted.)

10 PJM created a more transparent process for transmission constraint penalty factors and added it to the tariff in 2020. Policies on reductions in control limits and the duration of violations remain discretionary and undocumented in the PJM Market Rules.
11 This recommendation was the result of load shed events in September, 2013. For detailed discussion, please see *2013 Annual State of the Market Report for PJM*, Volume 2: Section 3 at 114 – 116.

- The MMU recommends that PJM include in the tariff or appropriate manual an explanation of the initial creation of hubs, the process for modifying hub definitions and a description of how hub definitions have changed.[12] [13] (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends that all buses with a net withdrawal be treated as load for purposes of calculating load and load-weighted LMP, even if the MW are settled to the generator. The MMU recommends that during hours when a load bus shows a net injection, the energy injection be treated as generation, not negative load, for purposes of calculating generation and load-weighted LMP, even if the injection MW are settled to the load serving entity. (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM identify and collect data on available behind the meter generation resources, including nodal location information and relevant operating parameters. (Priority: Low. First reported 2013. Status: Partially adopted.)
- The MMU recommends that PJM document how LMPs are calculated when demand response is marginal. (Priority: Low. First reported 2014. Status: Not adopted.)
- The MMU recommends that PJM not allow nuclear generators which do not respond to prices or which only respond to manual instructions from the operator to set the LMPs in the real-time market. (Priority: Low. First reported 2016. Status: Not adopted.)
- The MMU recommends that PJM increase the coordination of outage and operational restrictions data submitted by market participants via eDART/eGADs and offer data submitted via Markets Gateway. (Priority: Low. First reported 2017. Status: Not adopted.)
- The MMU recommends that PJM model generators' operating transitions, including soak time for units with a steam turbine, configuration transitions for combined cycles, and peak operating modes. (Priority: Medium. First reported 2019. Status: Not adopted.)

12 According to minutes from the first meeting of the Energy Market Committee (EMC) on January 28, 1998, the EMC unanimously agreed to be responsible for approving additions, deletions and changes to the hub definitions to be published and modeled by PJM. Since the EMC has become the Market Implementation Committee (MIC), the MIC now appears to be responsible for such changes.

13 There is currently no PJM documentation in the tariff or manuals explaining how hubs are created and how their definitions are changed. The general definition of a hub can be found in the PJM.com Glossary <http://www.pjm.com/Glossary.aspx>.

- The MMU recommends that PJM clarify, modify and document its process for dispatching reserves and energy when SCED indicates that supply is less than total demand including forecasted load and reserve requirements. The modifications should define: a SCED process to economically convert reserves to energy; a process for the recall of energy from capacity resources; and the minimum level of synchronized reserves that would trigger load shedding. (Priority: Medium. First reported 2020. Status: Not adopted.)
- The MMU recommends that PJM stop capping the system marginal price in RT SCED and LPC and instead limit the sum of violated reserve constraint shadow prices that are included in the determination of LMP in LPC to $1,700 per MWh. While PJM no longer caps prices in RT SCED, PJM continues to apply a cap to the system marginal price in the pricing run (LPC) under fast start pricing. (Priority: Medium. First reported 2021. Status: Not adopted.)
- The MMU recommends that PJM adjust the ORDCs during spin events to reduce the reserve requirement for synchronized and primary reserves by the amount of the reserves deployed. (Priority: Medium. First reported 2021. Status: Not adopted.)

Transparency

- The MMU recommends that PJM clearly document the calculation of shortage prices and implementation of reserve price caps in the PJM manuals, including defining all the components of reserve prices, and all the constraints whose shadow prices are included in reserve prices. (Priority: High. First reported 2021. Status: Not adopted.)
- The MMU recommends that PJM allow generators to report fuel type on an hourly basis in their offer schedules and to designate schedule availability on an hourly basis. (Priority: Medium. First reported 2015. Status: Partially adopted.)[14]
- The MMU recommends that PJM define clear criteria for operator approval of RT SCED cases, including shortage cases, that are used to send dispatch

14 Fuel type is reported by offer schedule, but it can be inaccurate on an hourly basis.

signals to resources, and for pricing, to minimize discretion. (Priority: High. First reported 2018. Status: Partially adopted.)[15]

Virtual Bids and Offers

- The MMU recommends eliminating up to congestion (UTC) bidding at pricing nodes that aggregate only small sections of transmission zones with few physical assets. (Priority: Medium. First reported 2020. Status: Not adopted.)
- The MMU recommends eliminating INC, DEC, and UTC bidding at pricing nodes that allow market participants to profit from modeling issues. (Priority: Medium. First reported 2020. Status: Not adopted.)

Section 4, Energy Uplift

- The MMU recommends that uplift be paid only based on operating parameters that reflect the flexibility of the benchmark new entrant unit (CONE unit) in the PJM Capacity Market. (Priority: High. First reported 2018. Status: Not adopted.)
- The MMU recommends that PJM not pay uplift to units not following dispatch, including uplift related to fast start pricing, and require refunds where it has made such payments. This includes units whose offers are flagged for fixed generation in Markets Gateway because such units are not dispatchable. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that PJM pay uplift based on the offer at the lower of the actual unit output or the dispatch signal MW. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends eliminating intraday segments from the calculation of uplift payments and returning to calculating the need for uplift based on the entire 24 hour operating day. (Priority: High. First reported 2018. Status: Not adopted.)
- The MMU recommends the elimination of day-ahead uplift to ensure that units receive an energy uplift payment based on their real-time output and not their day-ahead scheduled output. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that units not be paid lost opportunity cost uplift credits when PJM directs a unit to reduce output based on a transmission constraint or other reliability issue. There is no lost opportunity because the unit is required to reduce for the reliability of the unit and the system. (Priority: High. First reported 2021. Status: Not adopted.)
- The MMU recommends reincorporating the use of net regulation revenues as an offset in the calculation of balancing generator credits. (Priority: Medium. First reported 2009. Status: Not adopted.)
- The MMU recommends that self scheduled units not be paid energy uplift credits for their startup cost when the units are scheduled by PJM to start before the self scheduled hours. (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends three modifications to the energy lost opportunity cost calculations:
  - The MMU recommends calculating LOC based on 24 hour daily periods for combustion turbines and diesels scheduled in the day-ahead energy market, but not committed in real time. (Priority: Medium. First reported 2014. Status: Not adopted.)
  - The MMU recommends that units scheduled in the day-ahead energy market and not committed in real time should be compensated for LOC based on their real-time desired and achievable output, not their scheduled day-ahead output. (Priority: Medium. First reported 2015. Status: Not adopted.)
  - The MMU recommends that only flexible fast start units (startup plus notification times of 10 minutes or less) and units with short minimum run times (one hour or less) be eligible by default for the LOC compensation to units scheduled in the day-ahead energy market and not committed in real time. Other units should be eligible for LOC compensation only if PJM explicitly cancels their day-ahead commitment. (Priority: Medium. First reported 2015. Status: Not adopted.)

15 The PJM Market Rules clarify that shortage case approval will be based on RT SCED, but does not address RT SCED case choice or load bias.

- The MMU recommends that up to congestion (UTC) transactions be required to pay energy uplift charges for both the injection and the withdrawal sides of the UTC. (Priority: High. First reported 2011. Status: Partially adopted.)
- The MMU recommends allocating the energy uplift credits paid to units scheduled by PJM as must run in the day-ahead energy market for reasons other than voltage/reactive or black start services as a reliability charge to real-time load, real-time exports and real-time wheels. (Priority: Medium. First reported 2014. Status: Not adopted. Stakeholder process.)
- The MMU recommends that the total cost of providing reactive support be categorized and allocated as reactive services. Reactive services credits should be calculated consistent with the balancing generator credit calculation. (Priority: Medium. First reported 2012. Status: Not adopted. Stakeholder process.)
- The MMU recommends including real-time exports and real-time wheels in the allocation of the cost of providing reactive support to the 500 kV system or above, in addition to real-time load. (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends modifications to the calculation of lost opportunity costs credits paid to wind units. The lost opportunity costs credits paid to wind units should be based on the lesser of the desired output, the estimated output based on actual wind conditions and the capacity interconnection rights (CIRs). The MMU recommends that PJM require wind units to request CIRs based on the maximum output used in the ELCC calculation for wind units. (Priority: Low. First reported 2012. Status: Partially adopted.)
- The MMU recommends that PJM clearly identify and classify all reasons for incurring uplift in the day-ahead and the real-time energy markets and the associated uplift charges in order to make all market participants aware of the reasons for these costs and to help ensure a long term solution to the issue of how to allocate the costs of uplift. (Priority: Medium. First reported 2011. Status: Partially adopted.)
- The MMU recommends that PJM revise the current uplift confidentiality rules in order to allow the disclosure of complete information about the level of uplift by unit and the detailed reasons for the level of uplift credits by unit in the PJM region. (Priority: High. First reported 2013. Status: Partially adopted.)[16]

Section 5, Capacity Market

Definition of Capacity

- The MMU recommends elimination of the key remaining components of the CP model because they interfere with competitive outcomes in the capacity market and create unnecessary complexity and risk. (Priority: High. First reported 2022. Status: Not adopted.)
- The MMU recommends the enforcement of a consistent definition of capacity resources. The MMU recommends that the tariff requirement to be a physical resource be enforced and enhanced. The requirement to be a physical resource should apply at the time of auctions and should also constitute a commitment to be physical in the relevant delivery year. The requirement to be a physical resource should be applied to all resource types, including planned generation, demand resources, and imports.[17] [18] (Priority: High. First reported 2013. Status: Not adopted.)
- The MMU recommends that DR providers be required to have a signed contract with specific customers for specific facilities for specific levels of DR at least six months prior to any capacity auction in which the DR is offered. (Priority: High. First reported 2016. Status: Not adopted.)
- The MMU recommends that Energy Efficiency Resources (EE) not be included in the capacity market construct because PJM's load forecasts have accounted for EE since the 2016 load forecast for the 2019/2020 delivery year. EE is not a capacity resource as defined in the tariff, and

16 On September 7, 2018, PJM made a compliance filing for FERC Order No. 844 to publish unit specific uplift credits. The compliance filing was accepted by FERC on June 21, 2019. 166 FERC ¶ 61,210 (2019). PJM began posting unit specific uplift reports on May 1, 2019. 167 FERC ¶ 61,280 (2019).

17 See also Comments of the Independent Market Monitor for PJM, Docket No. ER14-503-000 (December 20, 2013).

18 See "Analysis of Replacement Capacity for RPM Commitments: June 1, 2007 to June 1, 2019," <http://www.monitoringanalytics.com/reports/Reports/2019/IMM_Analysis_of_Replacement_Capacity_for_RPM_Commitments_June_1_2007_to_June_1_2019_20190913.pdf> (September 13, 2019).

there is no reason to continue to pay large subsidies to EE providers.[19] (Priority: Medium. First reported 2016. Status: Adopted 2024.)[20]

- The MMU recommends that PJM require all market participants to meet their deliverability requirements under the same rules. PJM should end the practice of giving away winter CIRs to intermittent resources that appear to exist because other resources paid for the supporting network upgrades. (Priority: High. First reported 2017. Status: Not adopted.)[21]
- The MMU recommends that the must offer rule in the capacity market apply to all capacity resources. There is no reason to exempt intermittent and capacity storage resources, including hydro, and demand resources from the must offer requirement. The same rules should apply to all capacity resources in order to ensure open access to the transmission system and prevent the exercise of market power through withholding. (Priority: High. First reported 2021. Status: Partially adopted.)
- The MMU recommends that PJM require all market sellers of proposed generation capacity resources, including thermal and intermittent, to submit a binding notice of intent to offer at least six months prior to the base residual auction. This is consistent with the overall MMU recommendation that all capacity resources have a must offer obligation in the capacity market auctions. (Priority: High. First reported 2023. Status: Partially adopted.)
- The MMU recommends that PJM's application of the ELCC approach be replaced with an ELCC approach that is based on the actual hourly availability of all individual generators for accreditation and for payment. The MMU recommends short term modifications to PJM's approach to include hourly data that would permit unit specific ELCC ratings, to weight summer and winter risk in a more balanced manner, to eliminate PAI risks, and to pay for actual hourly performance rather than based on inflexible class capacity accreditation ratings derived from a small number of nonrepresentative hours of poor performance from PV1 and WSE. (Priority: High. First reported 2023. Status: Not adopted.)

19 "PJM Manual 19: Load Forecasting and Analysis," § 3.2 Development of the Forecast, Rev. 37 (Dec. 18, 2024).
20 See 189 FERC ¶ 61,095 (2024).
21 This recommendation was first made in the 2020/2021 BRA report in 2017. See the "Analysis of the 2020/2021 RPM Base Residual Auction," <http://www.monitoringanalytics.com/reports/Reports/2017/IMM_Analysis_of_the_20202021_RPM_BRA_20171117.pdf> (November 11, 2017).

Market Design and Parameters

- The MMU recommends that PJM establish a load queue for large new data center loads to ensure that such loads are not added until there is adequate generation capacity to serve them. The MMU recommends that an expedited queue option that would permit both the load and the generation to be added without delays be available to large data centers if they bring their own new generation with locational and temporal characteristics reasonably matched to their load profile. (Priority: High. First reported Q2, 2025. Status: Not adopted.)
- The MMU recommends that PJM reevaluate the shape of the VRR curve. The shape of the VRR curve directly results in load paying substantially more for capacity than load would pay with a vertical demand curve. More specifically, the MMU recommended that the VRR curve be rotated half way towards the vertical demand curve at the reliability requirement in the 2022 Quadrennial Review. (Priority: High. First reported 2021. Status: Partially adopted.)
- The MMU recommends that the maximum price on the VRR curve be defined as 1.5 times Net CONE, capped at Gross CONE. (Priority: Medium. First reported 2019. Status: Not adopted.)
- The MMU recommends that the reference resource be a CT rather than a CC. The MMU recommends that the ELCC value used to convert the gross CONE in ICAP terms for a CT to the gross CONE in UCAP terms be the ELCC based on winter ratings. (Priority: High. First reported 2024. Status: Adopted 2025.)
- The MMU recommends that the test for determining modeled Locational Deliverability Areas (LDAs) in RPM be redefined. A detailed reliability analysis of all at risk units should be included in the redefined model including transmission constraints inside LDAs. The market design should clear and pay units that are needed for reliability per PJM's transmission reliability analysis in order to forestall RMRs. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM clear the capacity market based on nodal capacity resource locations and the characteristics of the transmission

system inside and outside LDAs consistent with the actual electrical facts of the grid. Absent a fully nodal capacity market clearing process, the MMU recommends that PJM use a non-nested model with all LDAs modeled including VRR curves for all LDAs. Each LDA requirement should be met with the capacity resources located within the LDA and exchanges from neighboring LDAs up to the transmission limit. LDAs should be allowed to price separate if that is the result of the LDA supply curves and the transmission constraints between LDAs. (Priority: Medium. First reported 2017. Status: Not adopted.)

- The MMU recommends that the net revenue offset calculation used by PJM to calculate the net Cost of New Entry (CONE) and net ACR be based on a forward looking calculation of expected energy and ancillary services net revenues using historical net revenues that are scaled based on forward prices for energy and fuel. (Priority: High. First reported 2014. Status: Not adopted.)[22]
- The MMU recommends that PJM reduce the number of incremental auctions to a single incremental auction held three months prior to the start of the delivery year and reevaluate the triggers for holding conditional incremental auctions. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM not sell back any capacity in any IA procured in a BRA. If PJM continues to sell back capacity, the MMU recommends that PJM offer to sell back capacity in incremental auctions only at the BRA clearing price for the relevant delivery year. (Priority: Medium. First reported 2017. Status: Not adopted.)
- The MMU recommends that PJM not buy any capacity in any IA if PJM has already procured excess reserves. (Priority: Medium. First reported 2023. Status: Not adopted.)
- The MMU recommends changing the RPM solution method to explicitly incorporate the cost of uplift (make whole) payments in the objective function. (Priority: Medium. First reported 2014. Status: Not adopted.)
- The MMU recommends that the Fixed Resource Requirement (FRR) rules, including obligations and performance requirements, be revised and updated to ensure that the rules reflect current market realities and that FRR entities do not unfairly take advantage of those customers paying for capacity in the PJM Capacity Market. (Priority: Medium. First reported 2019. Status: Not adopted.)
- The MMU recommends that the value of CTRs be defined by the total MW cleared in the capacity market, the internal MW cleared and the imported MW cleared, and not redefined later prior to the delivery year. (Priority: Medium. First reported 2021. Status: Not adopted.)
- The MMU recommends that the market clearing results be used in settlements rather than the reallocation process currently used, or that the process of modifying the obligations to pay for capacity be reviewed. (Priority: Medium. First reported 2021. Status: Not adopted.)[23]
- The MMU recommends that PJM improve the clarity and transparency of its CETL calculations. The MMU also recommends that CETL for capacity imports into PJM be based on the ability to import capacity only where PJM capacity exists and where that capacity has a must offer requirement in the PJM Capacity Market. (Priority: Medium. First reported 2021. Status: Partially adopted 2022.)

Offer Caps, Offer Floors, and Must Offer

- The MMU recommends using the lower of the cost or price-based energy market offer to calculate energy costs in the calculation of the historical net revenues which are an offset to gross ACR in the calculation of unit specific capacity resource offer caps based on net ACR. (Priority: Medium. First reported 2021. Status: Not adopted.)
- The MMU recommends that modifications to existing resources, including relatively small proposed increases in the capability of a Generation Capacity Resource be treated as an existing resource and subject to the corresponding market power mitigation rules and no longer be treated as

22 This recommendation was first made during the Quadrennial Review in 2014, including the PJM Capacity Senior Task Force (CSTF), the MRC and the MC. <https://www.pjm.com/committees-and-groups/closed-groups/cstf>.

23 This recommendation was first made in the 2023/2024 BRA report in 2022. See "Analysis of the 2023/2024 RPM Base Residual Auction Revised," <http://www.monitoringanalytics.com/reports/Reports/2022/IMM_Analysis_of_the_20232024_RPM_Base_Residual_Auction_20221028.pdf> (October 28, 2022).

planned and exempt from offer capping. (Priority: Medium. First reported 2012. Status: Not adopted.)[24]

- The MMU recommends that the RPM market power mitigation rules be modified to apply offer caps in all cases when the three pivotal supplier test is failed and the sell offer is greater than the offer cap. This will ensure that market power does not result in an increase in uplift (make whole) payments for seasonal products. (Priority: Medium. First reported 2017. Status: Not adopted.)
- The MMU recommends that any combined seasonal resources be required to be in the same LDA and at the same location, in order for the energy market and capacity market to remain synchronized and reliability metrics correctly calculated. (Priority: Medium. First reported 2021. Status: Not adopted.)
- The MMU recommends that the definition of avoidable costs in the tariff be corrected to be consistent with the economic definition. Avoidable costs are costs that are neither short run marginal costs, like fuel or consumables, nor fixed costs like depreciation and rate of return. Avoidable costs are the marginal costs of capacity and therefore the competitive offer level for capacity resources and therefore the market seller offer cap. Avoidable costs are the marginal costs of capacity for both new resources and existing resources. (Priority: Medium. First reported 2017. Status: Not adopted.)[25]
- The MMU recommends that major maintenance costs be included in the definition of avoidable costs and removed from energy offers because such costs are avoidable costs and not short run marginal costs. (Priority: High. First reported 2019. Status: Not adopted.)
- The MMU recommends that capacity market sellers be required to explicitly request and support the use of minimum MW quantities (inflexible sell offer segments) and that the requests only be permitted for defined physical reasons. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that, as part of the MOPR unit specific standard of review, all projects be required to use the same basic modeling assumptions. That is the only way to ensure that projects compete on the basis of actual costs rather than on the basis of modeling assumptions.[26] (Priority: High. First reported 2013. Status: Not adopted.)

Performance Incentive Requirements of RPM

- The MMU recommends that any unit not capable of supplying energy equal to its day-ahead must offer requirement (ICAP) be required to reflect an appropriate outage and associated performance penalty. (Priority: Medium. First reported 2009. Status: Not adopted.)
- The MMU recommends that retroactive replacement transactions associated with a failure to perform during a PAI not be allowed and that, more generally, retroactive replacement capacity transactions not be permitted. (Priority: Medium. First reported 2016. Status: Not adopted.)
- The MMU recommends that there be an explicit requirement that capacity resource offers in the day-ahead energy market be competitive, where competitive is defined to be the short run marginal cost of the units, including flexible operating parameters. (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends that Capacity Performance resources be required to perform without excuses. Resources that do not perform should not be paid regardless of the reason for nonperformance. (Priority: High. First reported 2019. Status: Not adopted.)
- The MMU recommends that PJM require actual seasonal tests as part of the Summer/Winter Capability Testing rules, that the number of tests

24 This recommendation was first made in the 2014/2015 BRA report in 2012. See "Analysis of the 2014/2015 RPM Base Residual Auction," <http://www.monitoringanalytics.com/reports/Reports/2012/Analysis_of_2014_2015_RPM_Base_Residual_Auction_20120409.pdf> (April 9, 2012).

25 This recommendation was first made in the 2023/2024 BRA report in 2022. See "Analysis of the 2023/2024 RPM Base Residual Auction Revised," <http://www.monitoringanalytics.com/reports/Reports/2022/IMM_Analysis_of_the_20232024_RPM_Base_Residual_Auction_20221028.pdf> (October 28, 2022).

26 See 143 FERC ¶ 61,090 (2013) ("We encourage PJM and its stakeholders to consider, for example, whether the unit-specific review process would be more effective if PJM requires the use of common modeling assumptions for establishing unit-specific offer floors while, at the same time, allowing sellers to provide support for objective, individual cost advantages. Moreover, we encourage PJM and its stakeholders to consider these modifications to the unit-specific review process together with possible enhancements to the calculation of Net CONE."); see also, Comments of the Independent Market Monitor for PJM, Docket No. ER13-535-001 (March 25, 2013); Complaint of the Independent Market Monitor for PJM v. Unnamed Participant, Docket No. EL12-63-000 (May 1, 2012); Motion for Clarification of the Independent Market Monitor for PJM, Docket No. ER11-2875-000, et al. (February 17, 2012); Protest of the Independent Market Monitor for PJM, Docket No. ER11-2875-002 (June 2, 2011); Comments of the Independent Market Monitor for PJM, Docket Nos. EL11-20 and ER11-2875 (March 4, 2011).

be limited, and that the ambient conditions under which the tests are performed be defined to reflect seasonal extreme conditions. (Priority: Medium. First reported 2022. Status: Not adopted.)

- The MMU recommends that PJM select the time and day that a unit undergoes Net Capability Verification Testing, not the unit owner, and that this information not be communicated in advance to the unit owner. (Priority: Medium. First reported 2022. Status: Not adopted.)

Capacity Imports and Exports

- The MMU recommends that all capacity imports be required to be deliverable to PJM load in an identified LDA, zonal or subzonal, or defined combinations of specific zones, e.g. MAAC, prior to the relevant delivery year to ensure that they are full substitutes for internal, physical capacity resources. Pseudo ties alone are not adequate to ensure deliverability to PJM load. (Priority: High. First reported 2016. Status: Not adopted.)
- The MMU recommends that all costs incurred as a result of a pseudo tied unit be borne by the unit itself and included as appropriate in unit offers in the capacity market. (Priority: High. First reported 2016. Status: Not adopted.)

Deactivations/Retirements

- The MMU recommends that the notification requirement for deactivations be extended from the current one quarter prior (See Table 5-29) to 12 months prior to an auction in which the unit will not be offered due to deactivation; and no less than 12 months prior to the date of deactivation (Priority: Low. First reported 2012. Status: Partially adopted.)
- The MMU recommends that the same reliability standard be used in capacity auctions as is used by PJM transmission planning. One result of the current design is that a unit may fail to clear in a BRA, decide to retire as a result, but then be found to be needed for reliability by PJM planning and paid under Part V of the OATT (RMR) to remain in service while transmission upgrades are made. (Priority: High. First reported 2023. Status: Not adopted.)
- The MMU recommends elimination of both the cost of service recovery rate option and the deactivation avoidable cost rate option for providing Part V reliability service (RMR), and their replacement with clear language that provides for the recovery of 100 percent of the actual incremental costs required to operate to provide the service plus a defined incentive. (Priority: High. First reported 2017. Status: Not adopted.)
- The MMU recommends that units recover all and only the incremental costs, including incremental investment costs without a cap, required to provide Part V reliability service (RMR service) that the unit owner would not have incurred if the unit owner had deactivated its unit as it proposed, plus a defined incentive payment. Customers should bear no responsibility for paying previously incurred (sunk) costs, including a return on or of prior investments. (Priority: High. First reported 2010. Status: Not adopted.)
- The MMU recommends that if units that are paid under Part V of the OATT (RMR) are included in the calculation of CETO and/or reliability in the relevant LDA, the capacity of the RMR resources should also be included in capacity market supply at zero cost, but without all the obligations of a capacity resource, in order to ensure that the capacity market price signal reflects the appropriate supply and demand conditions. (Priority: High. First reported 2023. Status: Partially adopted.)
- The MMU recommends that units that are paid under Part V of the OATT (RMR) not be included in the calculation of CETO or reliability in the relevant LDA, in order to ensure that the capacity market price signal reflects the appropriate supply and demand conditions, until a decision is made to build transmission as a replacement, and then should be included. (Priority: High. First reported 2023. Status: Not adopted.)
- The MMU recommends that all CIRs be returned to the pool of available interconnection capability on the retirement date of generation resources in order to facilitate timely and competitive entry into the PJM markets, open access to the transmission system and maintain the priority order defined by the queue process. (Priority: High. First reported 2023. Status: Not adopted.)

Section 6, Demand Response

- The MMU recommends that PJM report the response of emergency demand response resources to dispatch by PJM as the actual change in load rather than simply the difference between the amount of capacity purchased by the customer and the actual metered load. The current approach significantly overstates the expected response to PJM dispatch. (Priority: High. First reported 2023. Status: Not adopted.)
- The MMU recommends that emergency demand response resources offering as supply in the capacity market be required to offer a guaranteed load drop (GLD) below their PLC to ensure that demand resources provide an identifiable MW resource to PJM when called. (Priority: High. First reported 2023. Status: Not adopted.)
- The MMU recommends, as an alternative to including emergency demand response resources as supply in the capacity market, that demand resources have the option to be on the demand side of the markets, that customers be able to avoid capacity and energy charges by not using capacity and energy at their discretion, that customer payments be determined only by metered load, and that PJM forecasts immediately incorporate the impacts of demand side behavior. (Priority: High. First reported 2014. Status: Not adopted.)
- The MMU recommends that the option to specify a minimum dispatch price (strike price) for emergency demand response resources be eliminated and that participating resources receive the hourly real-time LMP less any generation component of their retail rate.[27] (Priority: Medium. First reported 2010. Status: Not adopted.)
- The MMU recommends that the maximum offer for emergency demand response resources and price response demand resources be the same as the maximum offer for generation resources and that the same cost verification rules applied to generation resources apply to demand resources. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that the emergency demand response resources be treated as economic resources, responding to economic price signals like other capacity resources. The MMU recommends that emergency demand response resources not be treated as emergency resources. The MMU recommends that emergency demand response resources be available for every hour of the year. (Priority: High. First reported 2012. Status: Partially adopted.)
- The MMU recommends that the Emergency Program Energy Only option be eliminated because the opportunity to receive the appropriate energy market prices is already provided in the economic program. (Priority: Low. First reported 2010. Status: Not adopted.)
- The MMU recommends that, if emergency demand response resources remain in the capacity market, a daily energy market must offer requirement apply to emergency demand response resources, comparable to the rule applicable to generation capacity resources.[28] (Priority: High. First reported 2013. Status: Not adopted.)
- The MMU recommends that emergency demand response resources be required to provide their nodal location, comparable to generation resources. (Priority: High. First reported 2011. Status: Not adopted.)
- The MMU recommends that PJM require nodal dispatch of emergency demand response resources with no advance notice required or, if nodal location is not required, subzonal dispatch of demand resources with no advance notice required. The MMU recommends that, if PJM continues to use subzones for any purpose, PJM clearly define the role of subzones in the dispatch of demand response. (Priority: High. First reported 2015. Status: Not adopted.)
- The MMU recommends that PJM not remove any defined subzones and maintain a public record of all created and removed subzones. (Priority: Low. First reported 2016. Status: Not adopted.)
- The MMU recommends that PJM eliminate the measurement of compliance across zones within a compliance aggregation area (CAA). The multiple zone approach is less locational than the zonal and subzonal approach and creates larger mismatches between the locational need for

27 See "Complaint and Motion to Consolidate of the Independent Market Monitor for PJM," Docket No. EL14-20-000 (January 28, 2014), "Comments of the Independent Market Monitor for PJM," Docket No. ER15-852-000 (February 13, 2015).

28 See "Complaint and Motion to Consolidate of the Independent Market Monitor for PJM," Docket No. EL14-20-000 (January 27, 2014) at 1.

the resources and the actual response. (Priority: High. First reported 2015. Status: Not adopted.)

- The MMU recommends that measurement and verification methods for all demand resources be modified to reflect compliance more accurately. (Priority: Medium. First reported 2009. Status: Not adopted.)
- The MMU recommends that compliance rules be revised to include submittal of all necessary hourly load data, and that negative values be included when calculating event compliance across hours and registrations. (Priority: Medium. First reported 2012. Status: Not adopted.)
- The MMU recommends that PJM adopt the ISO-NE five-minute metering requirements in order to ensure that operators have the necessary information for reliability and that market payments to demand resources be calculated based on interval meter data at the site of the demand reductions.[29] (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends demand response event compliance be calculated on a five minute basis for all emergency demand response resources and that the penalty structure reflect five minute compliance. (Priority: Medium. First reported 2013. Status: Partially adopted.)
- The MMU recommends that demand response testing be initiated by PJM with advance notice to CSPs identical to the actual lead time required in an emergency in order to accurately represent the conditions of an emergency event. (Priority: Low. First reported 2012. Status: Partially adopted.)
- The MMU recommends that shutdown cost be defined as the cost to curtail load for a given period that does not vary with the measured reduction or, for behind the meter generators, be the start cost defined in Manual 15 for generators. (Priority: Low. First reported 2012. Status: Not adopted.)
- The MMU recommends that the Net Benefits Test be eliminated and that economic demand response resources be paid LMP less any generation component of the applicable retail rate. (Priority: Low. First reported 2015. Status: Not adopted.)
- The MMU recommends that the tariff rules for emergency demand response resources clarify that a resource and its CSP, if any, must notify PJM of material changes affecting the capability of the resource to perform as registered and must terminate or modify registrations that are no longer capable of responding to PJM dispatch directives at defined levels because load has been reduced or eliminated, as in the case of bankrupt and/or out of service facilities. (Priority: Medium. First reported 2015. Status: Not adopted.)
- The MMU recommends that there be only one demand response product in the capacity market, with an obligation to respond when called for any hour of the delivery year. (Priority: High. First reported 2011. Status: Partially adopted.[30])
- The MMU recommends that all demand resources register as Pre-Emergency and that the Emergency Program be eliminated. (Priority: High. First reported 2020. Status: Not adopted.)
- The MMU recommends that the lead times for emergency demand response resources be shortened to 30 minutes with a one hour minimum dispatch for all resources. (Priority: Medium. First reported 2013. Status: Partially adopted.)
- The MMU recommends setting the baseline for measuring capacity compliance under winter compliance at the customers' PLC, similar to GLD, to avoid double counting. (Priority: High. First reported 2010. Status: Partially adopted.)
- The MMU recommends the Relative Root Mean Squared Test be required for all demand resources with a CBL. (Priority: Low. First reported 2017. Status: Partially adopted.)
- The MMU recommends that 30 minute pre-emergency and emergency demand response be considered to be 30 minute reserves. (Priority: Medium. First reported 2018. Status: Not adopted.)

29 See ISO-NE Tariff, Section III, Market Rule 1, Appendix E1 and Appendix E2, "Demand Response," <http://www.iso-ne.com/regulatory/tariff/sect_3/mr1_append-e.pdf>. (Accessed October 17, 2017) ISO-NE requires that DR have an interval meter with five-minute data reported to the ISO and each behind the meter generator is required to have a separate interval meter. After June 1, 2017, demand response resources in ISO-NE must also be registered at a single node.

30 PJM's Capacity Performance design requires resources to respond when called for any hour of the delivery year, but demand resources still have a limited mandatory compliance window.

- The MMU recommends that energy efficiency resources (EE) not be included in the capacity market mechanism and that PJM should ensure that the impact of EE measures on the load forecast is incorporated immediately. (Priority: Medium. First reported 2018. Status: Adopted 2024.)[31] [32]
- The MMU recommends that demand reductions based entirely on behind the meter generation be capped at the lower of economic maximum or actual generation output. (Priority: High. First reported 2019. Status: Not adopted.)
- The MMU recommends that DER aggregations that clear in a capacity auction not be permitted to change status from homogeneous demand response to any other status for any additional auctions for the same delivery year, or for the delivery year. (Priority: High. New recommendation. Status: Not adopted.)
- The MMU recommends that EDCs not be allowed to participate in markets as DER aggregators in addition to their EDC role. (Priority: High. First reported 2021. Status: Not adopted.)
- The MMU recommends that PJM include a 5.0 MW maximum size cap on DER aggregations. (Priority: Medium. First reported 2021. Status: Not adopted.)
- The MMU recommends that PJM use a nodal approach for DER participation in PJM markets that excludes multinodal aggregation. (Priority: Medium. First reported 2022. Status: Partially adopted.)
- The MMU recommends that the Commission require PJM to include in OATT Attachment M the explicit statement that the Market Monitor's role includes the right to collect information from EDCs and DERA related to actions taken on the distribution system related to DERs. (Priority: Medium. First reported 2023. Status: Not adopted.)
- The MMU recommends that net metering resources be prohibited from participating in wholesale ancillary services markets if they are compensated for the service at the retail level. (Priority: Medium. First reported Q2, 2025. Status: Not adopted.)
- The MMU recommends that PJM revise the requirements for reporting expected real time energy load reductions by CSPs to PJM to improve the accuracy and usefulness to PJM's system operators. (Priority: Medium. First reported 2023. Status: Not adopted.)
- The MMU recommends that PJM define when operators can and should call on demand resources, given that a call on demand resources no longer triggers a PAI. The MMU recommends that PJM revise the performance requirements for demand resources to include an event specific measurement for dispatch occurring outside of Performance Assessment Events and penalties for nonperformance. (Priority: Medium. First reported 2023. Status: Not adopted.)
- The MMU recommends that PRD be required to respond during a PAI, regardless of whether the real-time LMP at the applicable location meet or exceeds the PRD strike price, to be consistent with all CP resources. (Priority: Medium. New recommendation. Status: Not adopted.)

Section 7, Net Revenue

- The MMU recommends that the net revenue calculation used by PJM to calculate the net Cost of New Entry (CONE) and net ACR be based on a forward looking calculation of expected energy and ancillary services net revenues using historical revenues that are scaled based on forward prices for energy and fuel. (Priority: Medium. First reported 2019. Status: Not adopted.)

Section 8, Environmental and Renewables

- The MMU recommends that renewable energy credit markets based on state renewable portfolio standards be brought into PJM markets as they are an increasingly important component of the wholesale energy market. The MMU recommends that there be a single PJM operated forward market for RECs, for a single product based on a common set of state definitions of renewable technologies, with a single clearing price, trued up to real-time delivery. (Priority: High. First reported 2010. Status: Not adopted.)

31 See 189 FERC ¶ 61,095.
32 Originally incorporated with auctions conducted in 2016 for the 2016/2017 Delivery Year and forward. The mechanics of the EE addback mechanism were modified beginning with the 2023/2024 Delivery Year.

- The MMU recommends that jurisdictions with a renewable portfolio standard make the price and quantity data on supply and demand more transparent. (Priority: Low. First reported 2018. Status: Not adopted.)
- The MMU recommends that the Commission reconsider its disclaimer of jurisdiction over RECs markets because, given market changes since that decision, it is clear that RECs materially affect jurisdictional rates. (Priority: Low. First reported 2018. Status: Not adopted.)
- The MMU recommends that PJM provide a full analysis of the impact of carbon pricing on PJM generating units and carbon pricing revenues to the PJM states in order to permit the states to consider a potential agreement on the development of a multistate framework for carbon pricing and the distribution of carbon revenues. (Priority: High. First reported 2018. Status: Not adopted.)
- The MMU recommends that load and generation located at separate nodes be treated as separate resources in order to ensure that load and generation face consistent incentives throughout the markets. (Priority: High. First reported 2019. Status: Not adopted.)
- The MMU recommends that stationary emergency RICE be prohibited from participation as DR either when registered individually or as part of a portfolio if it cannot meet the capacity market requirements to be DR as a result of emissions standards that impose environmental run hour limitations. (Priority: Medium. First reported 2019. Status: Not adopted.)

Section 9, Interchange Transactions

- The MMU recommends that PJM implement rules to prevent sham scheduling. The MMU recommends that PJM apply after the fact market settlement adjustments to identified sham scheduling segments to ensure that market participants cannot benefit from sham scheduling. (Priority: High. First reported 2012. Status: Not adopted.)
- The MMU recommends that PJM implement a validation method for submitted transactions that would prohibit market participants from breaking transactions into smaller segments to defeat the interface pricing rule by concealing the true source or sink of the transaction. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM implement a validation method for submitted transactions that would require market participants to submit transactions on paths that reflect the expected actual power flow in order to reduce unscheduled loop flows. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that transactions sourcing in the Western Interconnection be priced at either the MISO interface pricing point or the SOUTH interface pricing point based on the locational price impact of flows between the DC tie line point of connection with the Eastern Interconnection and PJM. (Priority: High. First reported 2020. Status: Not adopted.)
- The MMU recommends that PJM eliminate the IMO interface pricing point, and assign the transactions that originate or sink in the IESO balancing authority to the MISO interface pricing point. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM review the mappings of external balancing authorities to individual interface pricing points to reflect changes to the impact of the external power source on PJM tie lines as a result of system topology changes. The MMU recommends that this review occur at least annually. (Priority: Low. First reported 2009. Status: Not adopted.)
- The MMU recommends that, in order to permit a complete analysis of loop flow, FERC and NERC ensure that the identified data are made available to market monitors as well as other industry entities determined appropriate by FERC. (Priority: Medium. First reported 2003. Status: Not adopted.)
- The MMU recommends that PJM explore an interchange optimization solution with its neighboring balancing authorities that would remove the need for market participants to schedule physical transactions across seams. Such a solution would include an optimized, but limited, joint dispatch approach that uses supply curves and treats seams between

balancing authorities as constraints, similar to other constraints within an LMP market. (Priority: Medium. First reported 2014. Status: Not adopted.)

- The MMU recommends that PJM permit unlimited spot market imports as well as unlimited nonfirm point to point willing to pay congestion imports and exports at all PJM interfaces in order to improve the efficiency of the market. (Priority: Medium. First reported 2012. Status: Not adopted.)
- The MMU recommends that the emergency interchange cap be replaced with a market based solution. (Priority: Low. First reported 2015. Status: Not adopted.)
- The MMU recommends that the submission deadline for real-time dispatchable transactions be modified from 1800 on the day prior, to three hours prior to the requested start time, and that the minimum duration be modified from one hour to 15 minutes. These changes would give PJM a more flexible product that could be used to meet load in the most economic manner. (Priority: Medium. First reported 2014. Status: Partially adopted, 2015.)
- The MMU recommends eliminating the mechanism that defines FFE and M2M payments. These mechanisms are not consistent with markets and are not needed for efficient interface pricing. The MMU recommends that PJM file with the Commission to eliminate the FFE calculation and M2M payment of the PJM and MISO joint operating agreement. (Priority: Medium. First reported 2024. Status: Not adopted.)
- The MMU recommends clear, explicit and detailed rules that define the conditions under which PJM will and will not recall energy from PJM capacity resources and prohibit new energy exports from PJM capacity resources. The MMU recommends that those rules define the conditions under which PJM will purchase emergency energy while at the same time not recalling energy exports from PJM capacity resources. The MMU recommends clear rules governing when PJM may recall capacity backed exports. (Priority: Medium. First reported 2010. Status: Partially adopted.)

Section 10, Ancillary Services

Reserve Markets

- The MMU recommends that to minimize lag and improve performance, PJM use an electronic synchronized reserve event notification process for all resources and that all resources be required to have the ability to receive and automatically respond to the notifications. (Priority: Medium. First reported 2023. Status: Partially adopted 2024.)
- The MMU recommends that PJM replace the Mid-Atlantic Dominion Reserve Subzone with a reserve zone structure consistent with the actual deliverability of reserves based on current transmission constraints. (Priority: High. First reported 2019. Status: Partially adopted 2022.)
- The MMU recommends that the components of the cost-based offers for providing regulation and synchronous condensing be defined in Schedule 2 of the Operating Agreement. (Priority: Low. First reported 2019. Status: Not adopted.)
- The MMU recommends that, for calculating the penalty for a synchronized reserve resource failing to meet its scheduled obligation during a spinning event, the unit repay all credits back to the last time that the unit successfully responded to an event 10 minutes or longer. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that, for calculating the penalty for a synchronized reserve resource failing to meet its scheduled obligation during a spinning event, the synchronized reserve shortfall penalty should include LOC payments as well as SRMCP and MW of shortfall. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that aggregation not be permitted to offset unit specific penalties for failure to respond to a synchronized reserve event. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that PJM immediately remove the 30 percent increase to the synchronized reserve reliability requirement. (Priority: High. First reported 2024. Status: Not adopted.)

Regulation Market

- The MMU recommends that the two signal regulation market design be replaced with a one signal regulation market design. (Priority: Medium. First reported 2023. Status: Not adopted.)[33]
- The MMU recommends that the ability to make dual offers (to make offers as both a RegA and a RegD resource in the same market hour) be removed from the regulation market. (Priority: High. First reported 2019. Status: Not adopted.)[34]
- The MMU recommends that the regulation market be modified to incorporate a consistent application of the marginal benefit factor (MBF) throughout the optimization, assignment and settlement process. The MBF should be defined as the Marginal Rate of Technical Substitution (MRTS) between RegA and RegD. (Priority: High. First reported 2012. Status: Not adopted. FERC rejected.)[35]
- The MMU recommends that the current calculation of the performance score (based on precision, delay and correlation metrics) be replaced with the current calculation of the precision score. (Priority: Medium. First reported 2023. Status: Not adopted.).
- The MMU recommends that the regulation market commitment period be reduced from a 60-minute commitment to a 30-minute commitment. (Priority: Medium. First reported 2023. Status: Not adopted.).[36]
- The MMU recommends that the lost opportunity cost in the ancillary services markets be calculated using the schedule on which the unit was scheduled to run in the energy market. (Priority: High. First reported 2010. Status: Not adopted.[37] FERC rejected.)[38]

33 PJM filed proposed changes to the regulation market with the FERC on April 16, 2024, (Regulation Market Design Filing," Docket No. ER24-1772-000). The Commission Order on June 17, 2024 accepted the PJM Proposal as filed. PJM will implement the changes to the regulation market in two phases. Phase 1, scheduled to be implemented on October 1, 2025, will result in a single signal, bidirectional market with one clearing price that eliminates the need for an MBF. Phase 1 will eliminate RegA and RegD dual offers. Phase 1 will reduce the regulation commitment period from a 60-minute commitment to a 30-minute commitment. In Phase 1 the lost opportunity cost calculation used in the regulation market will be based on the resource's dispatched energy offer schedule, not the lower of its price or cost offer schedule.
34 See *id.*
35 See 162 FERC ¶ 61,295 (2018), *reh'g denied*, 170 FERC ¶ 61,259 (2020).
36 See *id.*
37 This recommendation was adopted by PJM for the energy market. Lost opportunity costs in the energy market are calculated using the schedule on which the unit was scheduled to run. In the regulation market, this recommendation has not been adopted, as the LOC continues to be calculated based on the lower of price or cost in the energy market offer.
38 See 162 FERC ¶ 61,295 (2018), *reh'g denied*, 170 FERC ¶ 61,259 (2020).

- The MMU recommends that the lost opportunity cost calculation used in the regulation market be based on the resource's dispatched energy offer schedule, not the lower of its price or cost offer schedule. (Priority: Medium. First reported 2010. Status: Not adopted. FERC rejected.)[39]
- The MMU recommends that the $12.00 margin adder be eliminated from the definition of the cost based regulation offer because it is a markup and not a cost. (Priority: Medium. First reported 2021. Status: Not adopted.)
- The MMU recommends that the ramp rate limited desired MW output be used in the regulation uplift calculation, to reflect the physical limits of the unit's ability to ramp and to eliminate overpayment for opportunity costs when the payment uses an unachievable MW. (Priority: Medium. First reported 2022. Status: Not adopted.)[40]
- The MMU recommends enhanced documentation of the implementation of the regulation market design. (Priority: Medium. First reported 2010. Status: Not adopted. FERC rejected.)[41]
- The MMU recommends that PJM be required to save data elements necessary for verifying the performance of the regulation market. (Priority: Medium. First reported 2010. Status: Not adopted.)
- The MMU recommends that all data necessary to perform the regulation market three pivotal supplier test be saved by PJM so that the test can be replicated. (Priority: Medium. First reported 2016. Status: Not adopted.)
- The MMU recommends that the total regulation (TReg) signal sent on a fleet wide basis be eliminated and replaced with individual regulation signals for each unit. (Priority: Low. First reported 2019. Status: Not adopted.)
- The MMU recommends that, to prevent gaming, there be a penalty enforced in the regulation market as a reduction in performance score and/or a forfeiture of revenues when resource owners elect to deassign assigned regulation resources within the hour. (Priority: Medium. First reported 2016. Status: Not adopted. FERC rejected.)[42]

39 See *id.*
40 In Phase 1 the ramp rate limited desired MW output will be used in the regulation uplift calculation. The MMU does not agree with how this change will be implemented and will be reviewing the market results in Phase 1.
41 See *id.*
42 See *id.*

Frequency Response, Reactive, and Black Start

- The MMU recommends that all resources, new and existing, have a requirement to include and maintain equipment for primary frequency response capability as a condition of interconnection service. The PJM markets already compensate resources for frequency response capability and any marginal costs. (Priority: Medium. First reported 2018. Status: Partially adopted.)
- The MMU recommends that all data necessary to perform the generator primary frequency response evaluation be saved by PJM so that the test can be replicated. (Priority: Medium. First reported 2023. Status: Not adopted.)
- The MMU recommends that PJM maintain a full list of all units subject to the Primary Frequency Response generator requirements. (Priority: Medium. First reported Q1, 2025. Status: Not adopted.)
- The MMU recommends that PJM develop the metric(s) necessary to objectively evaluate each unit's performance during primary frequency response events. (Priority: Medium. First reported Q2, 2025. Status: Not adopted.)
- The MMU recommends that PJM create the necessary tariff/manual language to properly enforce compliance with the NERC mandated Primary Frequency Response generator requirements. (Priority: Medium. First reported Q1, 2025. Status: Not adopted.)
- The MMU recommends that separate cost of service payments for reactive capability be eliminated and the cost of reactive capability be recovered in PJM markets. (Priority: Medium. First reported 2016. Status: Adopted 2024.)[43]
- The MMU recommends that payments for reactive capability, if continued, be based on the 0.95 power factor included in the voltage schedule in Interconnection Service Agreements. (Priority: Medium. First reported 2018. Status: Not adopted.)[44]
- The MMU recommends that, if payments for reactive are continued, fleet wide cost of service rates used to compensate resources for reactive capability be eliminated and replaced with compensation based on unit specific costs. (Priority: Low. First reported 2019. Status: Not adopted.)[45]
- The MMU recommends that, if payments for reactive are continued, Schedule 2 to OATT be revised to state explicitly that only generators that provide reactive capability to the transmission system that PJM operates and has responsibility for are eligible for reactive capability compensation. (Priority: Medium. First reported 2020. Status: Not adopted.)[46]
- The MMU recommends that new CRF rates for black start units, incorporating current tax code changes, be implemented immediately. The new CRF rates should apply to all black start units. Black start units should be required to commit to providing black start service for the life of the unit. CRF rates effective January 20, 2025, should reflect 100 percent bonus depreciation.[47] (Priority: High. First reported 2020. Status: Not adopted.)
- The MMU recommends that black start planning and coordination be on a regional basis recognizing cross zonal cranking paths and not on a narrowly or purely zonal basis and that the costs of black start service be shared on an equal per MWh basis across the region. (Priority: Medium. First reported 2023. Status: Not adopted.)
- The MMU recommends that the fuel assurance rules be modified to recognize actual fuel assured resources within and across zones. (Priority: High. First reported Q2, 2025. Status: Not adopted.)
- The MMU recommends that the Reliability Backstop for black start service be eliminated. There is no reason that PJM cannot acquire black start resources if the TOs can acquire black start resources. (Priority: High. First reported Q2, 2025. Status: Not adopted.)

43 On October 17, 2024, the Commission issued a final rule, Order No. 904, eliminating separate payments for reactive in all jurisdictional markets, including PJM. On January 28, 2025, PJM submitted a compliance filing to implement Order No. 904 ("Compliance Filing") that proposed a transition mechanism lasting through May 31, 2026. See Docket No. ER25-1073. This recommendation will be implemented effective June 1, 2026.

44 *Id.* FERC Order No. 904 eliminates payments for reactive capability. When Order 904 is in effect, which is planned for June 1, 2026, this recommendation will be withdrawn as no longer relevant.

45 *Id.*

46 *Id.*

47 OBBA § 70301(b)(3).

Section 11, Congestion and Marginal Losses

There are no recommendations in this section.

Section 12, Planning

Generation Retirements

- The MMU recommends that CIRs should end on the date of retirement in order to help ensure competitive markets and competitive access to the grid. The rules need to ensure that incumbents cannot exploit control of CIRs to block or postpone entry of competitors or to exercise market power by requiring high payments for CIRs.[48] (Priority: Medium. First reported 2013. Status: Partially adopted, 2012.)

Generation Queue

- Given the significance of data to market participants and regulators, the MMU recommends that all queue data and supplemental, network and baseline project data, including projected in service dates and estimated and final costs, be regularly updated with accurate and verifiable data. PJM does not update this data. (Priority: High. First reported 2023. Not adopted.)
- The MMU recommends that barriers to entry be addressed in a timely manner in order to help ensure that the capacity market will result in the entry of new capacity to meet the needs of PJM market participants. (Priority: Low. First reported 2012. Status: Not adopted.)
- The MMU recommends that PJM establish an expedited PJM managed queue process to identify commercially viable projects that could help eliminate or reduce the need for specific RMRs or that could address specific reliability needs and allow the identified projects to advance in the queue ahead of projects which have failed to make progress, subject to rules to prevent gaming. (Priority: High. First reported 2024. Status: Not adopted.)
- The MMU recommends improvements in queue management including that PJM establish a review process to ensure that projects are removed from the queue if they are not viable, as well as an expedited process to allow commercially viable projects to advance in the queue ahead of projects which have failed to make progress, subject to rules to prevent gaming.[49] (Priority: Medium. First reported 2013. Status: Partially adopted.)
- The MMU recommends continuing analysis of the study phase of PJM's transmission planning to reduce the need for postponements of study results, to decrease study completion times, and to improve the likelihood that a project at a given phase in the study process will successfully go into service.[50] (Priority: Medium. First reported 2014. Status: Partially adopted.)
- The MMU recommends outsourcing interconnection studies to an independent party to avoid potential conflicts of interest. Currently, these studies are performed by incumbent transmission owners under PJM's direction. This creates potential conflicts of interest, particularly when transmission owners are vertically integrated and the owner of transmission also owns generation. (Priority: Low. First reported 2013. Status: Not adopted.)

Market Efficiency Process

- The MMU recommends that the market efficiency process be eliminated because it is not consistent with a competitive market design. (Priority: Medium. First reported 2019. Status: Not adopted.)
- The MMU recommends that, if the market efficiency process is retained, PJM modify the rules governing benefit/cost analysis, the evaluation process for selecting among competing market efficiency projects and cost allocation for economic projects in order to ensure that all changes in production costs but not congestion costs, including increased costs to load and the risk of project cost increases, in all zones are included in order to ensure that the correct metrics are used for defining benefits. The MMU

48 See Comments of the Independent Market Monitor for PJM, Docket No. ER12-1177-000 (March 12, 2012) <http://www.monitoringanalytics.com/Filings/2012/IMM_Comments_ER12-1177-000_20120312.PDF>.

49 PJM Filing, FERC Docket No. ER22-2110-000 (June 14, 2022); 181 FERC ¶ 61,162 (2022).

50 Ibid.

also recommends that, if the market efficiency process is retained, market efficiency projects that fail to meet PJM benefit/cost criteria in a Schedule 6 annual reevaluation, prior to construction commencing or prior to state approval, be canceled and removed from further consideration. (Priority: Medium. First reported 2018. Status: Not adopted.)

Comparative Cost Framework

- The MMU recommends that PJM modify the project proposal templates to include data necessary to perform a detailed project lifetime financial analysis. The required data includes, but is not limited to: capital expenditure; capital structure; return on equity; cost of debt; tax assumptions; ongoing capital expenditures; ongoing maintenance; and expected life. (Priority: Medium. First reported 2020. Status: Not adopted.)

Transmission Competition

- The MMU recommends, to increase the role of competition, that the exemption of supplemental projects from the Order No. 1000 competitive process be terminated and that the basis for all such exemptions be reviewed and modified to ensure that the supplemental project designation is not used to exempt transmission projects from a transparent, robust and clearly defined mechanism to require competition to build such projects or to effectively replace the RTEP process. (Priority: Medium. First reported 2017. Status: Not adopted. Rejected by FERC.)[51]
- The MMU recommends, to increase the role of competition, that the exemption of end of life projects from the Order No. 1000 competitive process be terminated and that end of life transmission projects be included in the RTEP process and should be subject to a transparent, robust and clearly defined mechanism to require competition to build such projects. (Priority: Medium. First reported 2019. Status: Not adopted. Rejected by FERC.)[52]
- The MMU recommends that PJM enhance the transparency and queue management process for nonincumbent transmission investment. Issues related to data access and complete explanations of cost impacts should be addressed. The goal should be to remove barriers to competition from nonincumbent transmission providers. (Priority: Medium. First reported 2015. Status: Not adopted.)
- The MMU recommends that PJM incorporate the principle that the goal of transmission planning should be the incorporation of transmission investment decisions into market driven processes as much as possible. (Priority: Low. First reported 2001. Status: Not adopted.)
- The MMU recommends the creation of a mechanism to permit a direct comparison, or competition, between transmission and generation alternatives, including which alternative is less costly and who bears the risks associated with each alternative. (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM establish fair terms of access to rights of way and property, such as at substations, in order to remove any barriers to entry and require competition between incumbent transmission providers and nonincumbent transmission providers in the RTEP. (Priority: Medium. First reported 2014. Status: Not adopted.)
- The MMU recommends that rules be implemented to require competition to provide financing for transmission projects. This competition could reduce the cost of capital for transmission projects and significantly reduce total costs to customers. (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends that storage resources not be includable as transmission assets for any reason. (Priority: High. First reported 2020. Status: Not adopted.)

Cost Allocation

- The MMU recommends a comprehensive review of the ways in which the solution based dfax allocation method is implemented. The goal for such a process would be to ensure that the most rational and efficient approach

51 The FERC accepted tariff provisions that exclude supplemental projects from competition in the RTEP. 162 FERC ¶ 61,129 (2018), *reh'g denied*, 164 FERC ¶ 61,217 (2018).

52 In recent decisions addressing competing proposals on end of life projects, the Commission accepted a transmission owner proposal excluding end of life projects from competition in the RTEP process, 172 FERC ¶ 61,136 (2020), *reh'g denied*, 173 FERC ¶ 61,225 (2020), *affirmed*, American Municipal Power, Inc., et al. v. FERC, Case No. 20-1449 (D.C. Cir. November 17, 2023), and rejected a proposal from PJM stakeholders that would have included end of life projects in competition in the RTEP process, 173 FERC ¶ 61,242 (2020).

to implementing the solution based dfax method is used in PJM. Such an approach should allocate costs consistent with benefits and appropriately calibrate the incentives for investment in new transmission capability. No replacement approach should be approved until all potential alternatives, including the status quo, are thoroughly reviewed. (Priority: Medium. First reported 2020. Status: Not adopted.)

- The MMU recommends changing the minimum distribution factor in the allocation from 0.01 to 0.00 and adding a threshold minimum usage impact on the transmission facilities.[53] (Priority: Medium. First reported 2015. Status: Not adopted.)

Transmission Line Ratings

- The MMU recommends that all PJM transmission owners use the same methods to define line ratings and that all PJM transmission owners implement dynamic line ratings (DLR), subject to NERC standards and guidelines, subject to review by NERC, PJM and the MMU, and approval by FERC. (Priority: Medium. First reported 2019. Status: Partially adopted.)
- The MMU recommends that all PJM transmission owners investigate the applicability and potential cost savings of Grid Enhancing Technology (GET) and that all PJM transmission owners implement cost effective GET, subject to NERC standards and guidelines, subject to review by NERC, PJM and the MMU, and approval by FERC. (Priority: Medium. First reported 2024. Status: Not adopted.)
- The MMU recommends that the implementation of Grid Enhancing Technology (GET) be opened to competition from third parties, subject to NERC standards and guidelines, subject to review by NERC, PJM and the MMU, and approval by FERC. (Priority: Medium. First reported 2024. Status: Not adopted.)

Transmission Facility Outages

- The MMU recommends that PJM reevaluate all transmission outage tickets as on time or late as if they were new requests when an outage is rescheduled, create options for late requests based on the reasons, and apply the modified rules for late submissions to any such outages. The MMU recommends that PJM create options for treatment of late outages. The current rules apply more stringent rules, based on controlling actions, to late outages without distinguishing among reasons for late outages. (Priority: Low. First reported 2014. Status: Not adopted.)
- The MMU recommends that PJM draft a definition of the economic and physical congestion analysis required for transmission outage requests and associated triggers, including both the extent of overloaded facilities and the level of economic congestion, to include in PJM manuals after appropriate review with appropriate rules for on time and late outage requests. (Priority: Medium. First reported 2015. Status: Not adopted.)
- The MMU recommends that PJM create options for late requests based on the reasons, and modify the rules to reduce or eliminate the approval of late outage requests submitted or rescheduled after the FTR auction bidding opening date, based on those options. (Priority: Low. First reported 2015. Status: Not adopted.)
- The MMU recommends that PJM not permit transmission owners to divide long duration outages into smaller segments to avoid complying with the requirements for long duration outages. (Priority: Low. First reported 2015. Status: Not adopted.)

Section 13, FTRs and ARRs

Market Design

- The MMU recommends that the current ARR/FTR design be replaced with defined congestion revenue rights (CRRs). A CRR is the right to actual congestion revenue that is paid by physical load at a specific bus, zone or aggregate. (Priority: High. First reported 2015. Status: Not adopted.)

ARR

- The MMU recommends that the ARR/FTR design be modified to ensure that the rights to all congestion revenues are assigned to load. (Priority: High. First reported 2015. Status: Not adopted.)

53 See *2015 State of the Market Report for PJM*, Volume II, Section 12: Generation and Transmission Planning, at 463, Cost Allocation Issues.

- The MMU recommends that all historical generation to load paths be eliminated as a basis for assigning ARRs. The MMU recommends that the current design be replaced with a design in which the rights to actual congestion paid are assigned directly to the load that paid that congestion by node. (Priority: High. First reported 2015. Status: Partially adopted.)
- The MMU recommends that, under the current FTR design, the rights to all congestion revenue be allocated as ARRs prior to sale as FTRs. Reductions in allocated revenue as a contingency for outages and increased system capability should be reserved for ARRs rather than sold in the Long Term FTR Auction. (Priority: High. First reported 2017. Status: Not adopted.)
- The MMU recommends that IARRs be eliminated from PJM's tariff, but that if IARRs are not eliminated, IARRs should be subject to the same proration rules that apply to all other ARR rights. (Priority: Low. First reported 2018. Status: Not adopted.)

FTR

- The MMU recommends that FTR funding be based on total congestion, including both day-ahead and balancing congestion. (Priority: High. First reported 2017. Status: Not adopted.)
- The MMU recommends that bilateral transactions be eliminated and that all FTR transactions occur in the PJM market. (Priority: High. First reported 2022. Status: Not adopted.)[54]
- The MMU recommends a requirement that the details of all bilateral FTR transactions be reported to PJM. (Priority: High. First reported 2020. Status: Not adopted.)
- The MMU recommends that PJM continue to evaluate the bilateral indemnification rules and any asymmetries they may create. (Priority: Low. First reported 2018. Status: Not adopted.)
- The MMU recommends that PJM reduce FTR sales on paths with persistent overallocation of FTRs, including a clear definition of persistent overallocation and how the reduction will be applied. (Priority: High. First reported 2013. Status: Partially adopted, 2014/2015 planning period.)

54 If adopted, this recommendation would replace the next two recommendations.

- The MMU recommends that PJM eliminate generation to generation paths and all other paths that do not represent the delivery of power to load. (Priority: High. First reported 2018. Status: Not adopted.)
- The MMU recommends that the Long Term FTR product be eliminated. If the Long Term FTR product is not eliminated, the Long Term FTR Market should be modified so that the supply of prevailing flow FTRs in the Long Term FTR Market is based solely on counter flow offers in the Long Term FTR Market. (Priority: High. First reported 2017. Status: Not adopted.)
- The MMU recommends that PJM improve transmission outage modeling in the FTR auction models, including the use of probabilistic outage modeling. (Priority: Low. First reported 2013. Status: Not adopted.)

"Surplus"

- The MMU recommends that all FTR auction revenue be distributed to ARR holders monthly, regardless of FTR funding levels. (Priority: High. First reported 2015. Status: Not adopted.)
- The MMU recommends that, under the current FTR design, all congestion revenue in excess of FTR target allocations be distributed to ARR holders on a monthly basis. (Priority: High. First reported 2018. Status: Not adopted.)
- The MMU recommends that FTR auction revenues not be used by PJM to buy counter flow FTRs for the purpose of improving FTR payout ratios.[55] (Priority: High. First reported 2015. Status: Not adopted.)

FTR Subsidies

- The MMU recommends that PJM eliminate portfolio netting to eliminate cross subsidies among FTR market participants. (Priority: High. First reported 2012. Status: Not adopted. Rejected by FERC.)
- The MMU recommends that PJM eliminate subsidies to counter flow FTRs by applying the payout ratio to counter flow FTRs in the same way the payout ratio is applied to prevailing flow FTRs. (Priority: High. First reported 2012. Status: Not adopted.)

55 See "PJM Manual 6: Financial Transmission Rights," Rev. 34 (May 21, 2025).

- The MMU recommends that PJM eliminate geographic cross subsidies. (Priority: High. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM examine the mechanism by which self scheduled FTRs are allocated when load switching among LSEs occurs throughout the planning period. (Priority: Low. First reported 2011. Status: Not adopted.)

FTR Liquidation

- The MMU recommends that the FTR portfolio of a defaulted member be canceled rather than liquidated or allowed to settle as a default cost to the membership. (Priority: High. First reported 2018. Status: Not adopted.)

Credit

- The MMU recommends that PJM's minimum credit requirements be reviewed and updated to appropriately reflect the risk created for the markets and other market participants. The PJM minimum credit requirements (minimum tangible net worth and minimum tangible assets) were set as fixed dollars amounts in 2011 in FERC order 741 based on the specific market participation (FTRs or other). (Priority: Medium. New recommendation. Status: Not adopted.)

Energy Market

The PJM energy market comprises all types of energy transactions, including the sale or purchase of energy in PJM's Day-Ahead and Real-Time Energy Markets, bilateral and forward markets and self supply. Energy transactions analyzed in this report include those in the PJM Day-Ahead and Real-Time Energy Markets. These markets provide key benchmarks against which market participants may measure results of transactions in other markets.

The Market Monitoring Unit (MMU) analyzed measures of market structure, participant conduct and market performance, including market size, concentration, pivotal suppliers, offer behavior, markup, and price. The MMU concludes that the PJM energy market results were competitive in the first nine months of 2025.

Table 3-1 The energy market results were competitive

Market Element	Evaluation	Market Design
Market Structure: Aggregate Market	Partially Competitive	
Market Structure: Local Market	Not Competitive	
Participant Behavior	Competitive	
Market Performance	**Competitive**	**Effective**

- The aggregate market structure was evaluated as partially competitive because the aggregate market power test based on pivotal suppliers indicates that the aggregate day-ahead market structure was not competitive on 94.1 percent of the days in the first nine months of 2025. The hourly HHI (Herfindahl-Hirschman Index) results indicate that the PJM aggregate energy market in the first nine months of 2025 was, on average, unconcentrated by FERC HHI standards. The average HHI was 686 with a minimum of 511 and a maximum of 988. The baseload segment of the supply curve was unconcentrated. The intermediate segment of the supply curve was unconcentrated on average. The peaking segment of the supply curve was highly concentrated. The fact that the average HHI is in the unconcentrated range does not mean that the aggregate market was competitive in all hours. As demonstrated for the day-ahead market, it is possible to have pivotal suppliers in the aggregate market even when the HHI level is not in the highly concentrated range. It is possible to have an exercise of market power even when the HHI level is not in the highly concentrated range. The number of pivotal suppliers in the energy market is a more precise measure of structural market power than the HHI. The HHI is not a definitive measure of structural market power.
- The local market structure was evaluated as not competitive due to the highly concentrated ownership of supply in local markets created by transmission constraints and local reliability issues. The results of the three pivotal supplier (TPS) test, used to test local market structure, indicate the existence of market power in local markets created by transmission constraints. The local market performance is competitive as a result of the application of the TPS test. Transmission constraints create the potential for the exercise of local market power. The goal of PJM's application of the three pivotal supplier test is to identify local market power and offer cap to competitive offers, correcting for structural issues created by local transmission constraints. There are, however, identified issues with the definition of cost-based offers and the application of market power mitigation to resources whose owners fail the TPS test that need to be addressed because unit owners can exercise market power even when they fail the TPS test.
- Participant behavior was evaluated as competitive because the analysis of markup shows that marginal units generally make offers at, or close to, their marginal costs in both the day-ahead and real-time energy markets, although the behavior of some participants both routinely and during periods of high demand represents economic withholding. The ownership of marginal units is concentrated. The markups of pivotal suppliers in the aggregate market and of many pivotal suppliers in local markets remain unmitigated due to the lack of aggregate market power mitigation and the flawed implementation of offer caps for resources that fail the TPS test. The markups of those participants affected LMP.
- Market performance was evaluated as competitive because market results in the energy market reflect the outcome of a competitive market, as PJM prices are set, on average, by marginal units operating at, or close to, their

marginal costs in both day-ahead and real-time energy markets, although high markups for some marginal units did affect prices.

- Market design was evaluated as effective because the analysis shows that the PJM energy market resulted in competitive market outcomes. In general, PJM's energy market design provides incentives for competitive behavior and results in competitive outcomes. In local markets, where market power is an issue, the market design identifies market power and causes the market to provide competitive market outcomes in most cases although issues with the implementation of market power mitigation and development of cost-based offers remain. The role of UTCs in the day-ahead energy market continues to cause concerns. Market design implementation issues, including inaccuracies in modeling of the transmission system and of generator capabilities as well as inefficiencies in price formation, undermine market efficiency in the energy market. The implementation of fast start pricing on September 1, 2021, undermined market efficiency by setting inefficient prices that are inconsistent with the dispatch signals.
- PJM markets are designed to promote competitive outcomes derived from the interaction of supply and demand in each of the PJM markets. Market design itself is the primary means of achieving and promoting competitive outcomes in PJM markets. One of the MMU's core functions is to identify actual or potential market design flaws.[1] The approach to market power mitigation in PJM has focused on market designs that promote competition (a structural basis for competitive outcomes) and on mitigating market power in instances where the market structure is not competitive and thus where market design alone cannot mitigate market power. FERC relies on effective market power mitigation when it approves market sellers to participate in the PJM market at market based rates.[2] In the PJM energy market, market power mitigation occurs primarily in the case of local market power. When a transmission constraint creates the potential for local market power, PJM applies a structural test to determine if the local market is competitive, applies a behavioral test to determine if generator offers exceed competitive levels and applies a market performance test to determine if such generator offers would affect the market price.[3] There are, however, identified issues with the application of market power mitigation to resources whose owners fail the TPS test that can result in the exercise of local market power even when market power mitigation rules are applied. These issues need to be addressed, but, so far, PJM and FERC have failed to address them.[4] [5] [6] Some units with market power have positive markups and some have inflexible parameters, which means that the cost-based offer was not used and that the process for offer capping units that fail the TPS test does not consistently result in competitive market outcomes in the presence of market power. There are issues related to the definition of gas costs includable in energy offers that need to be addressed. There are issues related to the level of maintenance expense includable in energy offers that need to be addressed. There are currently no market power mitigation rules in place that limit the ability to exercise market power when aggregate market conditions are tight and there are pivotal suppliers in the aggregate market. Aggregate market power needs to be addressed. Market design must reflect appropriate incentives for competitive behavior, the application of local market power mitigation needs to be fixed, the definition of a competitive offer needs to be fixed, and aggregate market power mitigation rules need to be developed. The importance of these issues is amplified by the rules permitting cost-based offers in excess of $1,000 per MWh.

Overview

Supply and Demand

Market Structure

- **Supply.** In the first nine months of 2025, 2,756 MW of new resources were added in the energy market, and 982 MW of resources were retired.
- The real-time hourly on peak average offered supply in the first nine months of 2025 increased by 1.4 percent, from the first nine months of 2024, from 140,934 MWh to 142,851 MWh.
- The day-ahead hourly average offered supply in the first nine months of 2025 decreased by 1.5 percent, from the first nine months of 2024, from 153,603 MWh to 151,275 MWh.
- The real-time hourly average cleared generation in the first nine months of 2025 increased by 3.3 percent from the first nine months of 2024, from 96,954 MWh to 100,136 MWh.
- The day-ahead hourly average cleared supply in the first nine months of 2025, including INCs and UTCs, increased by 1.9 percent from the first nine months of 2024 from 112,192 MWh to 114,328 MWh.
- **Demand.** The real-time hourly peak load without exports in the first nine months of 2025 was 156,256 MWh (158,789 MWh with net exports) in the HE 1800 (EPT) on June 23, 2025, higher than the PJM peak load in the first nine months of 2024, which was 144,245 MWh (149,398 MWh with net exports) in the HE 1800 (EPT) on June 21, 2024.
- The real-time hourly average load in the first nine months of 2025 increased by 3.0 percent from the first nine months of 2024, from 90,917 MWh to 93,683 MWh.
- The day-ahead hourly average cleared demand in the first nine months of 2025, including DECs and UTCs, increased by 1.4 percent from the first nine months of 2024, from 106,355 MWh to 107,864 MWh.

Market Behavior

- **Virtual Offers and Bids.** Any market participant in the PJM Day-Ahead Energy Market can use increment offers, decrement bids, up to congestion transactions, import transactions and export transactions as financial instruments that do not require physical generation or load. The hourly average submitted increment offer MW increased by 4.6 percent and the cleared increment MW increased by 8.4 percent in the first nine months of 2025 compared to the first nine months of 2024. The hourly average submitted decrement bid MW increased by 17.7 percent and the cleared decrement MW decreased by 2.6 percent in the first nine months of 2025 compared to the first nine months of 2024. The hourly average submitted up to congestion bid MW decreased by 2.1 percent and the cleared up to congestion bid MW decreased by 8.2 percent in the first nine months of 2025 compared to the first nine months of 2024.

Market Performance

- **Generation Fuel Mix.** In the first nine months of 2025, generation from coal units increased 16.1 percent, generation from natural gas units decreased 1.6 percent, generation from oil units increased 25.8 percent, generation from wind units increased 1.8 percent, and generation from solar units increased 46.4 percent compared to the first nine months of 2024.
- **Fuel Diversity.** The fuel diversity of energy generation in the first nine months of 2025, measured by the fuel diversity index for energy (FDI_e), increased 2.5 percent compared to the first nine months of 2024.
- **Marginal Resources.** In the PJM Real-Time Energy Market in the first nine months of 2025, coal units were 7.6 percent, natural gas units were 77.9 percent and wind units were 10.3 percent of marginal resources. In the first nine months of 2024, coal units were 11.0 percent, natural gas units were 74.8 and wind units were 11.9 percent of marginal resources.
- **Prices.** The real-time load-weighted average LMP in the first nine months of 2025 increased $16.20 per MWh, or 47.2 percent from the first nine months of 2024, from $34.31 per MWh to $50.51 per MWh.

- The day-ahead load-weighted average LMP for the first nine months of 2025 increased $16.03 or 47.4 percent from the first nine months of 2024, from $33.85 per MWh to $49.88 per MWh.
- **Fast Start Pricing.** The real-time load-weighted average PLMP was $50.51 per MWh for the first nine months of 2025, which is 9.0 percent, $4.17 per MWh, higher than the real-time load-weighted average DLMP of $46.34 per MWh.
- **Components of Real-Time LMP.** In the PJM Real-Time Energy Market in the first nine months of 2025, 7.2 percent of the real-time load-weighted LMP was the result of coal costs, 43.4 percent was the result of gas costs, 4.3 percent was the result of the cost of emission allowances, and 10.5 percent was the result of transmission constraint violation penalty factors.
- **Components of Day-Ahead LMP.** In the PJM Day-Ahead Energy Market in the six months between April and September of 2025, 7.2 percent of the day-ahead load-weighted LMP was the result of coal costs, 12.2 percent was the result of gas costs, 33.2 percent was the result of the decrement bids, and 18.5 percent was the result of increment offers.
- **Changes in Real-Time LMP.** Of the $16.20 per MWh increase in the real-time load-weighted average LMP, $9.85 per MWh (60.8 percent) was the fuel and consumables cost components of LMP, -$0.16 per MWh (-1.0 percent) was the emissions cost components of LMP, $0.85 per MWh (5.2 percent) was the sum of the markup, maintenance, and ten percent adder components of LMP, $2.07 per MWh (12.8 percent) was the transmission constraint penalty factor component of LMP, and $1.14 per MWh (7.0 percent) was the scarcity component of LMP. The pre-emergency demand response called on by PJM during the hot weather days in June and July increased the LMP by $0.89 per MWh, 5.5 percent of the increase in LMP. The LMP increase would have been higher if PJM had not imposed a $3,700.00 per MWh administrative cap. The administrative cap reduced the LMP by $0.11 per MWh, a 0.7 percent decrease.
- **Price Convergence.** Hourly and daily price differences between the day-ahead and real-time energy markets fluctuate continuously and substantially from positive to negative. The average difference between day-ahead and real-time average prices was $0.38 per MWh in the first nine months of 2025, and $0.41 per MWh in the first nine months of 2024. The difference between day-ahead and real-time average prices, by itself, is not a measure of the competitiveness or effectiveness of the day-ahead energy market.

Scarcity

- **Shortage Intervals.** There were 130 intervals with five minute shortage pricing on 22 days in the first nine months of 2025. Of the 130 intervals, 79 occurred during the June 2025 heatwave, for which PJM issued several emergency warnings and actions. Seven of the 130 intervals of shortage overlapped with synchronized reserve events.
- **SCED Shortage Intervals.** In the first nine months of 2025, there were 4,082 five minute intervals, or 5.2 percent of all five minute intervals, for which at least one RT SCED solution showed a shortage of reserves. In the first nine months of 2025, there were 1,368 five minute intervals, or 1.7 percent of all five minute intervals, for which more than one RT SCED solution showed a shortage of reserves. In the first nine months of 2025, PJM triggered shortage pricing for 130 five minute intervals, or 0.2 percent of all five minute intervals.

Competitive Assessment

Market Structure

- **Aggregate Pivotal Suppliers.** The PJM energy market, at times, requires generation from pivotal suppliers to meet load, resulting in aggregate market power even when the HHI level indicates that the aggregate market is unconcentrated. Three suppliers were jointly pivotal in the day-ahead market on 257 days, 94.1 percent of the days, in the first nine months of 2025 and 138 days, 50.4 percent of the days, in the first nine months of 2024.
- **Local Market Power.** In the first nine months of 2025, in the real-time market, the 500 kV system, 13 zones, and the PJM/MISO interface experienced congestion resulting from one or more constraints binding

for 75 or more hours. For seven out of the top 10 congested facilities (by real-time binding hours) in the first nine months of 2025, the average number of suppliers providing constraint relief was three or fewer. There was a high level of concentration within the local markets for providing relief to the most congested facilities in the PJM Real-Time Energy Market. The local market structure was not competitive.

Market Behavior

- **Offer Capping for Local Market Power.** PJM offer caps units when the local market structure is noncompetitive. Offer capping is an effective means of addressing local market power when the rules are designed and implemented properly. Offer capping levels have historically been low in PJM. In the day-ahead energy market, for units committed to provide energy for local constraint relief, offer-capped unit hours decreased from 2.0 percent in the first nine months of 2024 to 1.9 percent in the first nine months of 2025. In the real-time energy market, for units committed to provide energy for local constraint relief, offer-capped unit hours decreased from 1.5 percent in the first nine months of 2024 to 1.4 percent in the first nine months of 2025. While overall offer capping levels have been low, there are a significant number of units with persistent structural local market power that would have had a significant impact on prices in the absence of local market power mitigation.

  The analysis of the application of the TPS test to local markets demonstrates that it is working to identify pivotal owners when the market structure is noncompetitive and to ensure that owners are not subject to offer capping when the market structure is competitive. There are, however, identified issues with the application of market power mitigation to resources whose owners fail the TPS test that can result in the exercise of local market power. These issues need to be addressed.

- **Offer Capping for Reliability.** PJM also offer caps units that are committed for reliability reasons, including for reactive support. In the day-ahead energy market, for units committed for reliability reasons, offer-capped unit hours decreased from 0.18 percent in the first nine months of 2024 to 0.10 percent in the first nine months of 2025. In the real-time energy market, for units committed for reliability reasons, offer-capped unit hours decreased from 0.23 percent in the first nine months of 2024 to 0.12 percent in the first nine months of 2025. The low offer cap percentages for reliability commitments, relative to offer capping for transmission constraints, do not mean that units committed for reliability reasons do not have market power. All units manually committed for reliability have market power and all are treated consistent with that fact.

- **Parameter Mitigation.** PJM applies operating parameter limits (PLS) to units that fail the TPS test and to all units during hot and cold weather alerts. In the first nine months of 2025, 29.3 percent of unit hours for units that failed the TPS test in the day-ahead market were committed on price-based schedules that were less flexible than their cost-based schedules. On days when cold weather alerts and hot weather alerts were declared, 31.2 percent of unit hours in the day-ahead energy market were committed on price-based schedules that were less flexible than their price PLS schedules.

- **Frequently Mitigated Units (FMU) and Associated Units (AU).** In the first nine months of 2025, no units qualified for an FMU adder. In 2024, 2023 and 2022, no units qualified for an FMU adder. In 2021, one unit qualified for an FMU adder.

- **Markup Index.** The markup index is a summary measure of participant offer behavior for individual marginal units. While the average markup index in the real-time market was -$0.07 when using unadjusted cost-based offers in the first nine months of 2025, some marginal units did have substantial markups. The highest markup for any marginal unit in the real-time market in the first nine months of 2025 was more than $900 per MWh and the highest markup in the first nine months of 2024 was more than $900 per MWh, using unadjusted cost-based offers.

- While the average markup index in the day-ahead market was $0.23 per MWh in the six months between April and September of 2025, some marginal units did have substantial markups. The highest markup for any marginal unit in the day-ahead market in the six months between April and September of 2025 was more than $550 per MWh.

- **Markup.** The markup frequency distributions show that a significant proportion of units make price-based offers less than the cost-based offers permitted under the PJM market rules. This behavior means that competitive price-based offers reveal actual unit marginal costs and that PJM market rules permit the inclusion of costs in cost-based offers that are not short run marginal costs.

  The markup frequency distributions also show that a significant proportion of units were offered with high markups, consistent with the exercise of market power.

Market Performance

- **Markup.** The markup conduct of individual owners and units has an identifiable impact on market prices. Markup is a key indicator of the competitiveness of the energy market.

  In the PJM Real-Time Energy Market in the first nine months of 2025, the unadjusted markup component (net of positive and negative markup components) of LMP was -$0.09 per MWh or -0.2 percent of the PJM load-weighted average LMP. July had the highest unadjusted peak markup component, $2.74 per MWh, or 3.5 percent of the real-time peak hour load-weighted average LMP for July.

  In the PJM Day-Ahead Energy Market in the six months between April and September of 2025, the unadjusted markup component (net of positive and negative markup components) of LMP was $2.64 per MWh or 12.2 percent of the PJM load-weighted average LMP. July had the highest unadjusted peak markup component, $7.59 per MWh, or 8.59 percent of the day-ahead peak hour load-weighted average LMP for July.

  Participant behavior was evaluated as competitive because the analysis of markup shows that marginal units generally make offers at, or close to, their marginal costs in both the day-ahead and real-time energy markets, although the behavior of some participants represents economic withholding.

- **Markup and Local Market Power.** Comparison of the markup behavior of marginal units with TPS test results shows that for 3.0 percent of all real-time marginal unit intervals in the first nine months of 2025, the marginal unit had both local market power as determined by the TPS test and a positive markup. The fact that units with market power had a positive markup means that the cost-based offer was not used, that a higher price-based offer was used, and that the process for offer capping units that fail the TPS test does not consistently result in competitive market outcomes in the presence of market power.

- **Markup and Aggregate Market Power.** In the first nine months of 2025, pivotal suppliers in the aggregate market, committed in the day-ahead market and identified as one of three day-ahead aggregate pivotal suppliers, set real-time market prices with markups over $100 per MWh on 117 days, compared to 76 days in the first nine months of 2024.[7] Some of the marginal units had local market power, but were not offer capped due to issues with the method that PJM uses to select offer schedules for units that fail the TPS test. Some of the marginal units had aggregate market power, for which there is no offer capping, and some had both local and aggregate market power.

Recommendations

Market Power

- The MMU recommends that the market rules explicitly require that offers in the energy market be competitive, where competitive is defined to be the short run marginal cost of the units. The short run marginal cost should reflect opportunity cost when appropriate. The MMU recommends that the level of incremental costs includable in cost-based offers per the PJM Operating Agreement not exceed the short run marginal cost of the unit. (Priority: Medium. First reported 2009. Status: Not adopted.)

Fuel Cost Policies

- The MMU recommends that PJM require that all fuel cost policies be algorithmic, verifiable, and systematic, and accurately reflect short

7 The number of days reported in the 2025 Quarterly State of the Market Report for PJM: January through March and the 2025 Quarterly State of the Market Report for PJM: January through June were understated, and have been correctly calculated in this 2025 Quarterly State of the Market Report for PJM: January through September.

run marginal costs. (Priority: Medium. First reported 2016. Status: Not adopted.)

- The MMU recommends that the temporary cost method be removed and that all units that submit nonzero cost-based offers be required to have an approved fuel cost policy. (Priority: Low. First reported 2020. Status: Not adopted.)
- The MMU recommends that the penalty exemption provision be removed and that all units that submit nonzero cost-based offers be required to follow their approved fuel cost policy. (Priority: Medium. First reported 2020. Status: Not adopted.)

Cost-Based Offers

- The MMU recommends removal of all use of FERC System of Accounts in the Cost Development Guidelines. (Priority: Medium. First reported 2016. Status: Not adopted.)
- The MMU recommends the removal of all use of cyclic starting and peaking factors from the Cost Development Guidelines. (Priority: Medium. First reported 2016. Status: Not adopted.)
- The MMU recommends the removal of all maintenance costs from the Cost Development Guidelines. (Priority: Medium. First reported 2019. Status: Not adopted.)
- The MMU recommends, given that maintenance costs are currently allowed in cost-based offers, that market participants be permitted to include only variable maintenance costs, linked to verifiable operational events and that can be supported by clear and unambiguous documentation of the operational data (e.g. run hours, MWh, MMBtu) that support the maintenance cycle of the equipment being serviced/replaced. (Priority: Medium. First reported 2020. Status: Partially adopted 2023.)
- The MMU recommends explicitly accounting for soak costs and changing the definition of the start heat input for combined cycles to include only the amount of fuel used from first fire to the first breaker close in the Cost Development Guidelines. (Priority: Medium. First reported 2016. Status: Partially adopted.)
- The MMU recommends that soak costs, soak time and the MWh produced during soaking be modeled separately. This will ensure that the time required for units to reach a dispatchable level is known and used in the unit commitment process instead of only being communicated verbally between dispatchers and generators. Separating soak costs from start costs and modeling the MWh produced during soaking allows for a better representation of the costs because it eliminates the need to simply assume the price paid for those MWh. (Priority: Medium. First reported 2022. Status: Not adopted.)
- The MMU recommends the removal of nuclear fuel and nonfuel operations and maintenance costs that are not short run marginal costs from the Cost Development Guidelines. (Priority: Medium. First reported 2016. Status: Not adopted.)
- The MMU recommends revising the pumped hydro fuel cost calculation to include day-ahead and real-time power purchases. (Priority: Low. First reported 2016. Status: Not adopted.)

Market Power: TPS Test and Offer Capping

- The MMU recommends that the rules governing the application of the TPS test be clarified and documented. The TPS test application in the day-ahead energy market is not documented. (Priority: High. First reported 2015. Status: Partially adopted.)[8]
- The MMU recommends that PJM modify the process of applying the TPS test in the day-ahead energy market to ensure that all local markets created by binding constraints are tested for market power and to ensure that market sellers with market power are appropriately mitigated to their competitive offers. (Priority: High. First reported 2022. Status: Not adopted.)
- The MMU recommends, in order to ensure effective market power mitigation when the TPS test is failed, that offer capping be applied to units that fail the TPS test in the real-time market that were not offer capped at the time of commitment in the day-ahead market or at a prior

8 The real-time market formula for determining the lowest cost schedule is documented. The day-ahead market formula for determining the lowest cost schedule is not documented.

time in the real-time market. (Priority: High. First reported 2020. Status: Not adopted.)

- The MMU recommends, in order to ensure effective market power mitigation and to ensure that capacity resources meet their obligations to be flexible, that capacity resources be required to use flexible parameters in all offers at all times. (Priority: High. First reported 2021. Status: Not adopted.)
- The MMU recommends, in order to ensure effective market power mitigation, PJM always use cost-based offers for units that fail the TPS test, and always use flexible parameters for all cost-based and all price-based offers during high load conditions such as cold and hot weather alerts and emergency conditions. (Priority: High. First reported 2015. Status: Not adopted.)
- The MMU recommends that PJM require every market participant to make available at least one cost schedule based on the same hourly fuel type(s) and parameters at least as flexible as their offered price schedule. (Priority: Medium. First reported 2015. Status: Not adopted.)
- The MMU recommends, in order to ensure effective market power mitigation when the TPS test is failed, that markup be consistently positive or negative across the full MWh range of price and cost-based offers. (Priority: High. First reported 2015. Status: Not adopted.)
- The MMU recommends, in order to ensure effective market power mitigation, that PJM commit all resources that fail the TPS test on their cost-based offers, that the Market Seller designate the cost-based offer if there is more than one, and that PJM implement this solution as soon as possible. (Priority: High. First reported Q3 2024. Status: Not adopted.)
- The MMU recommends that PJM retain the $1,000 per MWh offer cap in the PJM energy market except when cost-based offers exceed $1,000 per MWh, and retain other existing rules that limit incentives to exercise market power. (Priority: High. First reported 1999. Status: Partially adopted, 1999, 2017.)
- The MMU recommends the elimination of FMU and AU adders. FMU and AU adders no longer serve the purpose for which they were created and interfere with the efficient operation of PJM markets. (Priority: Medium. First reported 2012. Status: Partially adopted, 2014.)[9]

Offer Behavior

- The MMU recommends that resources not be allowed to violate the ICAP must offer requirement. The MMU recommends that PJM enforce the ICAP must offer requirement by assigning a forced outage to any unit that is derated in the energy market below its committed ICAP without an outage that reflects the derate. (Priority: Medium. First reported 2020. Status: Not adopted.)
- The MMU recommends that storage resources be subject to an enforceable ICAP must offer rule in the day-ahead and real-time energy markets that reflects the limitations of these resources. (Priority: Medium. First reported 2020. Status: Not adopted.)
- The MMU recommends that capacity resources not be allowed to offer any portion of their capacity market obligation as maximum emergency energy. (Priority: Medium. First reported 2012. Status: Not adopted.)
- The MMU recommends that PJM integrate all the outage reporting tools in order to enforce the ICAP must offer requirement, ensure that outages are reported correctly and eliminate reporting inconsistencies. Generators currently submit availability in three different tools that are not integrated, Markets Gateway, eDART and eGADS. (Priority: Medium. First reported 2022. Status: Not adopted.)
- The MMU recommends that gas generators be required to check with pipelines throughout the operating day to confirm that nominations are accepted beyond the NAESB deadlines, that gas generators be required to inform PJM about whether they have gas, and that gas generators be required to place their units on forced outage until the time that pipelines allow nominations to consume gas at a unit. (Priority: Medium. First reported 2022. Status: Not adopted.)

9 The applicability of the FMU and AU adders is limited by the rule implemented in 2014 requiring that net revenues must fall below avoidable costs, but the possibility of FMU and AU adders is still part of the PJM Market Rules.

Capacity Resources

- The MMU recommends that capacity resources be held to the OEM operating parameters of the capacity market CONE reference resource for performance assessment and energy uplift payments and that this standard be applied to all technologies on a uniform basis. (Priority: Medium. First reported 2015. Status: Not adopted.)
- The MMU recommends that the parameters which determine nonperformance charges and the amounts of uplift payments should reflect the flexibility goals of the capacity market design. The operational parameters used by generation owners to indicate to PJM operators what a unit is capable of during the operating day should not determine capacity resource performance assessment or uplift payments. (Priority: Medium. First reported 2015. Status: Partially adopted.)[10]
- The MMU recommends that PJM clearly define the business rules that apply to the unit specific parameter adjustment process, including PJM's implementation of the tariff rules in the PJM manuals to ensure market sellers know the requirements for their resources. (Priority: Low. First reported 2018. Status: Not adopted.)
- The MMU recommends that PJM update the tariff to clarify that all generation resources are subject to unit specific parameter limits on their cost-based offers using the same standard and process as capacity resources. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that resources not be paid the daily capacity payment when unable to operate to their unit specific parameter limits. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that PJM not approve temporary exceptions that are based on pipeline tariff terms that are not enforced at the time, or are based on inferior transportation service procured by the generator. (Priority: Medium. First reported 2019. Status: Not adopted.)
- The MMU recommends that PJM require generators that violate their approved turn down ratio (by either using the fixed gen option or increasing their economic minimum) to use the temporary parameter exception process that requires market sellers to demonstrate that the request is based on a physical and actual constraint. (Priority: Medium. First reported 2021. Status: Not adopted.)
- The MMU recommends: that gas generators be required to confirm, regularly during the operating day, that they can obtain gas if requested to operate at their economic maximum level; that gas generators provide that information to PJM during the operating day; and that gas generators be required to be on forced outage if they cannot obtain gas during the operating day to meet their must offer requirement as a result of pipeline restrictions, and they do not have backup fuel. As part of this, the MMU recommends that PJM collect data on each individual generator's fuel supply arrangements at least annually or when such arrangements change, and analyze the associated locational and regional risks to reliability. (Priority: Medium. First reported 2022. Status: Not adopted.)

Accurate System Modeling

- The MMU recommends that PJM explicitly state its policy on the use of transmission penalty factors including: the level of the penalty factors; the triggers for the use of the penalty factors; the appropriate line ratings to trigger the use of penalty factors; the allowed duration of the violation and when the transmission penalty factors will be used to set the shadow price. The MMU recommends that PJM end the practice of manual and automated discretionary reductions in the control limits on transmission constraint line ratings used in the market clearing software (SCED) and included in LMP. (Priority: Medium. First reported 2015. Status: Partially adopted 2020.)[11]
- The MMU recommends that PJM routinely review all transmission facility ratings and any changes to those ratings to ensure that the normal, emergency and load dump ratings used in modeling the transmission system are accurate and reflect standard ratings practice. (Priority: Low. First reported 2013. Status: Not adopted.)

10 Flexible parameter standards are in place for combined cycle and combustion turbine resources when operating on a parameter limited schedule, but not for other schedules or generating technologies.

11 PJM created a more transparent process for transmission constraint penalty factors and added it to the tariff in 2020. Policies on reductions in control limits and the duration of violations remain discretionary and undocumented in the PJM Market Rules.

- The MMU recommends that PJM not use closed loop interface or surrogate constraints to artificially override nodal prices based on fundamental LMP logic in order to: accommodate rather than resolve the inadequacies of the demand side resource capacity product; address the inability of the power flow model to incorporate the need for reactive power; accommodate rather than resolve the flaws in PJM's approach to scarcity pricing; or for any other reason. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM update the outage impact studies, the reliability analyses used in RPM for capacity deliverability, and the reliability analyses used in RTEP for transmission upgrades to be consistent with the more conservative emergency operations (post contingency load dump limit exceedance analysis) in the energy market that were implemented in June 2013.[12] (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM include in the tariff or appropriate manual an explanation of the initial creation of hubs, the process for modifying hub definitions and a description of how hub definitions have changed.[13] [14] (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends that all buses with a net withdrawal be treated as load for purposes of calculating load and load-weighted LMP, even if the MW are settled to the generator. The MMU recommends that during hours when a load bus shows a net injection, the energy injection be treated as generation, not negative load, for purposes of calculating generation and load-weighted LMP, even if the injection MW are settled to the load serving entity. (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM identify and collect data on available behind the meter generation resources, including nodal location information and relevant operating parameters. (Priority: Low. First reported 2013. Status: Partially adopted.)
- The MMU recommends that PJM document how LMPs are calculated when demand response is marginal. (Priority: Low. First reported 2014. Status: Not adopted.)
- The MMU recommends that PJM not allow nuclear generators which do not respond to prices or which only respond to manual instructions from the operator to set the LMPs in the real-time market. (Priority: Low. First reported 2016. Status: Not adopted.)
- The MMU recommends that PJM increase the coordination of outage and operational restrictions data submitted by market participants via eDART/eGADs and offer data submitted via Markets Gateway. (Priority: Low. First reported 2017. Status: Not adopted.)
- The MMU recommends that PJM model generators' operating transitions, including soak time for units with a steam turbine, configuration transitions for combined cycles, and peak operating modes. (Priority: Medium. First reported 2019. Status: Not adopted.)
- The MMU recommends that PJM clarify, modify and document its process for dispatching reserves and energy when SCED indicates that supply is less than total demand including forecasted load and reserve requirements. The modifications should define: a SCED process to economically convert reserves to energy; a process for the recall of energy from capacity resources; and the minimum level of synchronized reserves that would trigger load shedding. (Priority: Medium. First reported 2020. Status: Not adopted.)
- The MMU recommends that PJM stop capping the system marginal price in RT SCED and LPC and instead limit the sum of violated reserve constraint shadow prices that are included in the determination of LMP in LPC to $1,700 per MWh. While PJM no longer caps prices in RT SCED, PJM continues to apply a cap to the system marginal price in the pricing run (LPC) under fast start pricing. (Priority: Medium. First reported 2021. Status: Not adopted.)

12 This recommendation was the result of load shed events in September, 2013. For detailed discussion, please see *2013 Annual State of the Market Report for PJM*, Volume 2: Section 3 at 114 – 116.

13 According to minutes from the first meeting of the Energy Market Committee (EMC) on January 28, 1998, the EMC unanimously agreed to be responsible for approving additions, deletions and changes to the hub definitions to be published and modeled by PJM. Since the EMC has become the Market Implementation Committee (MIC), the MIC now appears to be responsible for such changes.

14 There is currently no PJM documentation in the tariff or manuals explaining how hubs are created and how their definitions are changed. The general definition of a hub can be found in the PJM.com Glossary <http://www.pjm.com/Glossary.aspx>.

- The MMU recommends that PJM adjust the ORDCs during spin events to reduce the reserve requirement for synchronized and primary reserves by the amount of the reserves deployed. (Priority: Medium. First reported 2021. Status: Not adopted.)

Transparency

- The MMU recommends that PJM clearly document the calculation of shortage prices and implementation of reserve price caps in the PJM manuals, including defining all the components of reserve prices, and all the constraints whose shadow prices are included in reserve prices. (Priority: High. First reported 2021. Status: Not adopted.)
- The MMU recommends that PJM allow generators to report fuel type on an hourly basis in their offer schedules and to designate schedule availability on an hourly basis. (Priority: Medium. First reported 2015. Status: Partially adopted.)[15]
- The MMU recommends that PJM define clear criteria for operator approval of RT SCED cases, including shortage cases, that are used to send dispatch signals to resources, and for pricing, to minimize discretion. (Priority: High. First reported 2018. Status: Partially adopted.)[16]

Virtual Bids and Offers

- The MMU recommends eliminating up to congestion (UTC) bidding at pricing nodes that aggregate only small sections of transmission zones with few physical assets. (Priority: Medium. First reported 2020. Status: Not adopted.)
- The MMU recommends eliminating INC, DEC, and UTC bidding at pricing nodes that allow market participants to profit from modeling issues. (Priority: Medium. First reported 2020. Status: Not adopted.)

15 Fuel type is reported by offer schedule, but it can be inaccurate on an hourly basis.
16 The PJM Market Rules clarify that shortage case approval will be based on RT SCED, but does not address RT SCED case choice or load bias.

Conclusion

The MMU analyzed key elements of PJM energy market structure, participant conduct and market performance in the first nine months of 2025, including aggregate supply and demand, concentration ratios, aggregate pivotal supplier results, local three pivotal supplier test results, offer capping, markup, marginal units, participation in demand response programs, virtual bids and offers, loads and prices.

Prices are a key outcome of markets. Prices vary across hours, days and years for multiple reasons. Price is an indicator of the level of competition in a market. In a competitive market, prices are directly related to input prices, the marginal cost to serve load. In the first nine months of 2025, LMP increased by $16.20 per MWh compared to the first nine months of 2024. The fuel cost components of LMP (the sum of gas, coal, oil, landfill gas, and consumables) increased $9.85 per MWh, 60.8 percent of the increase in LMP. The emissions cost components of LMP, including opportunity costs for emissions limited resources, decreased by $0.16 per MWh, -1.0 percent of the increase in LMP. The transmission constraint penalty factor component increased by $2.07 per MWh, 12.8 percent of the increase in LMP, primarily as a result of PJM actions to reduce the line limits applied in SCED (control limits) below the actual line limits. The pre-emergency demand response called on by PJM during the hot weather days in June and July increased the LMP by $0.89 per MWh, 5.5 percent of the increase in LMP. The LMP increase would have been higher if PJM had not imposed a $3,700.00 per MWh administrative cap. The administrative cap reduced the LMP by $0.11 per MWh, a 0.7 percent decrease.

The pattern of prices within days and across months and years illustrates how prices are directly related to supply and demand conditions and illustrates the potential significance of the impact of the price elasticity of demand on prices. Energy market results in the first nine months of 2025 generally reflected supply-demand fundamentals, although the behavior of some participants both routinely and during high demand periods represents economic withholding. Economic withholding occurs when generator offers are greater than competitive levels. In the first nine months of 2025, the sum of the markup, ten percent adder, and maintenance cost (not short run marginal cost) components increased by $0.85 per MWh or 5.2 percent of the increase in LMP. In addition, PJM actions in the form of transmission constraint penalty factors, significantly increased prices.

The potential for prolonged and excessively high administrative pricing in the energy market due to reserve penalty factors and transmission constraint penalty factors remains an issue that needs to be addressed.[17] There also continue to be significant issues with PJM's scarcity pricing rules, including the absence of a clear trigger based on accurately estimated reserve levels. For example, PJM approved 21.9 percent of solved shortage cases in June 2025, but only 3.2 percent for the first nine months of 2025. Six of the other eight months had a higher percent of shortage cases solved, but fewer approved. The pattern of shortage case approvals indicates that PJM considers factors that are not documented in the tariff when deciding whether to approve shortage cases. The application of shortage pricing should not involve operator discretion. As directed by FERC Order No. 825, PJM should approve shortage cases based on market software results alone.[18]

With or without a capacity market, energy market design must permit scarcity pricing when such pricing is consistent with market conditions and constrained by reasonable rules to ensure that market power is not exercised and to ensure no scarcity pricing when such pricing is not consistent with market conditions. Scarcity pricing for revenue adequacy, as in PJM's 2019 ORDC proposal that would have created administrative scarcity pricing, is not consistent with a competitive market design. Scarcity pricing for price signals that reflect market conditions during periods of scarcity is consistent with a competitive market design. Scarcity pricing is part of an appropriate incentive structure facing both load and generation owners in a working wholesale electric power market design. Scarcity pricing must be designed to ensure that market prices reflect actual market conditions, that scarcity pricing occurs with transparent triggers based on measured reserve levels and transparent prices, that scarcity pricing only occurs when scarcity exists, that scarcity pricing not be excessive or punitive, and that there are strong incentives for competitive behavior and strong disincentives to exercise market power. Such administrative scarcity pricing is a key link between energy and capacity markets.

PJM defined inputs to the dispatch tools, particularly RT SCED, have substantial effects on energy market outcomes. Transmission line ratings in SCED, transmission constraint penalty factors, load forecast bias, hydro resource schedules, fast start pricing, and the treatment of demand resources change the dispatch of the system, affect prices, and can create significant price increases, particularly through transmission constraint penalty factors. PJM operator interventions to reduce the control limits on transmission constraint line ratings in RT SCED unnecessarily trigger transmission constraint penalty factors and significantly increase prices. In the first nine months of 2025, the control limit used in RT SCED for 85 percent of violated transmission constraint intervals was less than 100 percent of the actual line limit, with an average reduction of 5.1 percent. If the control limits had not been artificially reduced for PJM transmission constraints and everything else remained unchanged, the transmission constraint penalty factor's contribution to the load weighted average LMP in the first nine months of 2025 would have decreased by 99.4 percent from $5.31 to $0.03 per MWh. PJM should evaluate its interventions in the market, including the unnecessary imposition of transmission constraint penalty factors, reconsider whether the interventions are appropriate, and provide greater transparency to enhance market efficiency.

Fast start pricing, implemented on September 1, 2021, has disconnected pricing from dispatch instructions and despite the stated goal of reducing overall uplift, created a greater reliance on uplift rather than price as an incentive to follow PJM's instructions. The objective of efficient short run price signals is to minimize system production costs, not to minimize uplift. Repricing the market to reflect commitment costs using fast start pricing prioritizes minimizing uplift over minimizing production costs.[19] The tradeoff exists because when commitment costs are included in prices, the price signal no longer equals the short run marginal cost and therefore no longer provides the correct signal for efficient behavior for market participants making decisions on the margin, whether resources, load, interchange transactions, or virtual traders. Units that start in one hour are not actually fast start units, and their commitment

17 177 FERC ¶ 61,209 (2021).
18 155 FERC ¶ 61,276 at P 161 (2016) ("shortage pricing is required only when a shortage of energy or operating reserves is indicated by the RTO's/ISO's software").
19 See 173 FERC ¶ 61,244 (2020).

costs are not marginal in a five minute market. The differences between the actual LMP and the fast start LMP distort the incentive for market participants to behave competitively and to follow PJM's dispatch instructions. PJM is paying uplift in an attempt to counter the distorted incentives inherent in fast start pricing. PJM is also using the pricing run to implement administrative pricing rules that are not related to fast start pricing. Specifically, PJM uses lower transmission constraint penalty factors in the day-ahead pricing run than in the dispatch run and implements system marginal price capping in the pricing run. Every difference between the dispatch run and the pricing run introduces another inefficiency in the market. In the four years since fast start pricing was introduced, the market has not responded with new entry of fast start units despite consistently higher LMPs when a fast start unit sets price.

The energy market requires more flexible operation of the dispatchable fleet as wind and solar resource penetration grows. Since 2018, PJM has argued that the way to incent investment in flexible units is to increase reserve requirements and to increase the administrative prices defined in the ORDCs. In fact, PJM's ORDCs would benefit inflexible units. Providing windfall gains to all generation through higher LMPs during more frequent reserve shortages is not an effective incentive for flexibility.

The question of how to provide market incentives for investment in flexibility, and for operating to the full capability of that flexibility should be addressed directly. Are units inflexible because they are old and inefficient, because owners have not invested in increased flexibility or because they serve as a mechanism for the exercise of market power? Are units inflexible because the PJM software does not model combined cycle transitions?

A direct solution would include improved modelling of generator capabilities, so that PJM can send more targeted dispatch signals that generators are consistently capable of following. A direct solution would include targeted reforms to PJM software, like multi-interval dispatch and combined cycle modelling would directly address PJM energy market performance. A direct solution would include stronger standards in the PJM Market Rules for performance of resources to their actual physical parameters. These reforms would be more efficient and effective than simply raising prices across the board.

The relationship between supply and demand is referred to as the supply-demand fundamentals, or economic fundamentals, or market structure. The market structure of the PJM aggregate energy market is partially competitive because aggregate market power does exist for a significant number of hours. The HHI is not a definitive measure of structural market power. The number of pivotal suppliers in the energy market is a more precise measure of structural market power than the HHI. It is possible to have pivotal suppliers in the aggregate market even when the HHI level is not in the highly concentrated range. Even a low HHI may be consistent with the exercise of market power with a low price elasticity of demand. The current market power mitigation rules for the PJM energy market rely on the assumption that the ownership structure of the aggregate market ensures competitive outcomes at all times. This assumption requires that the total demand for energy can be met without the supply from any individual supplier or the supply from a small group of suppliers. This assumption is not correct. There are pivotal suppliers in the aggregate energy market with increasing frequency. High markups for some units demonstrate the potential to exercise market power both routinely and during high demand conditions. The existing market power mitigation measures do not address aggregate market power. The MMU is developing an aggregate market power test and will propose market power mitigation rules to address aggregate market power.

The three pivotal supplier test is applied by PJM on an ongoing basis for local energy markets in order to determine whether offer capping is required for transmission constraints.[20] However, there are issues with the application of market power mitigation in the day-ahead energy market and the real-time energy market when market sellers fail the TPS test. The Commission recognized some of these issues in its order issued on June 17, 2021, but failed to address them in its November 30, 2023 order.[21] [22] Many of these issues can be resolved by simple rule changes. PJM filed and, on October 25, 2024, FERC accepted a proposal that would require that sellers that fail the TPS test will be

20 The MMU reviews PJM's application of the TPS test and brings issues to the attention of PJM.
21 See 175 FERC ¶ 61,231 (2021).
22 185 FERC ¶ 61,158 (2023).

offer capped at their cost-based offers and that operating parameters will be mitigated.[23] That order has no current effect because FERC approved the PJM filing that linked, for no logical reason, implementing the improved rules to PJM's adoption of an improved combined cycle model with no defined date. The flawed rules remain in place. There is no reason to delay implementation of the FERC approved rules until PJM addresses combined cycle modelling. The changes would decrease the solution time for the day-ahead market and enhance market efficiency. The approved approach should be implemented as soon as possible to help ensure effective market power mitigation.

The enforcement of market power mitigation rules is undermined if the definition of a competitive offer is not correct. A competitive offer is equal to short run marginal costs. The significance of competition metrics like markup is also undermined if the definition of a competitive offer is not correct. The definition of a competitive offer, under the PJM Market Rules, is not currently correct. The definition, that all costs that are related to electric production are short run marginal costs, is not clear or correct. All costs and investments for power generation are related to electric production. Under this definition, some unit owners include costs in cost-based energy offers that are not short run marginal costs in offers, especially maintenance costs. This issue can be resolved by simple rule changes to incorporate a clear and accurate definition of short run marginal costs. This rule also had unintended consequences for market seller offer caps in the capacity market. Maintenance costs includable in energy offers cannot be included in capacity market offer caps based on avoidable costs. As a result, capacity market offer caps based on net avoidable costs were lower than they would have been if maintenance costs had been correctly included in avoidable costs rather than incorrectly defined to be part of short marginal costs of producing energy and includable in energy offers.

A competitive power market will result in higher prices when fuel costs increase and lower prices when fuel costs decrease. A competitive market will not result in higher prices when markups increase based on market power, or when PJM selects a price-based offer including a markup rather than a cost-based offer in the presence of local market power, or when PJM artificially triggers transmission constraint penalty factors. The overall energy market results support the conclusion that energy prices in PJM are set, generally, by marginal units operating at, or close to, their marginal costs, although this was not always the case in the first nine months of 2025 or prior years. Given the structure of the energy market which can permit the exercise of aggregate and local market power, some participants' offer behavior is a source of concern in the energy market and provides a reason to use correctly defined short run marginal cost as the sole basis for cost-based offers and a reason for implementing an aggregate market power test and correcting the offer capping process for resources with local market power. In addition, PJM's extensive administrative interventions in the energy market should be reduced. The MMU concludes that the PJM energy market results were competitive in the first nine months of 2025.

Supply and Demand

Market Structure

Supply

Supply includes physical generation, imports and virtual transactions.

In the first nine months of 2025, 2,756 MW of new resources were added in the energy market, and 982 MW of resources were retired.

Figure 3-1 shows real-time and day-ahead hourly supply curves for the first nine months of 2024 and 2025.[24] The real-time supply curve includes hourly on peak average offers. The real-time supply curve only includes available MW from units that are online or have a notification plus start time that is no more than one hour. The day-ahead supply curve shows all available hourly on peak average offers.

The real-time hourly on peak average offered supply in the first nine months of 2025 increased by 1.4 percent, from the first nine months of 2024, from 140,934 MWh to 142,851 MWh. The day-ahead hourly average offered supply in the first nine months of 2025 decreased by 1.5 percent, from the first nine months of 2024, from 153,603 MWh to 151,275 MWh.

24 Real-time supply includes real-time generation offers and import MWh.

Figure 3-1 Real-time and day-ahead hourly supply curves: January through September, 2024 and 2025

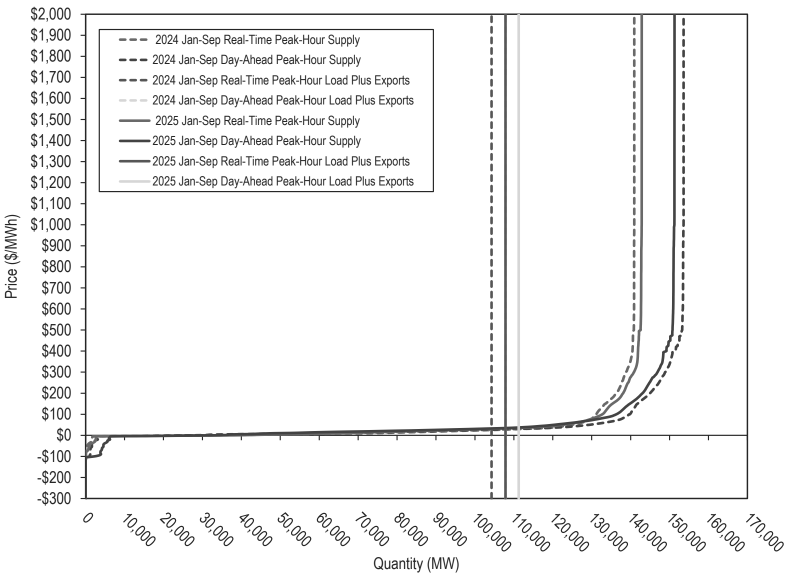

Figure 3-2 shows the typical dispatch range.

Figure 3-2 Typical dispatch range of supply curves

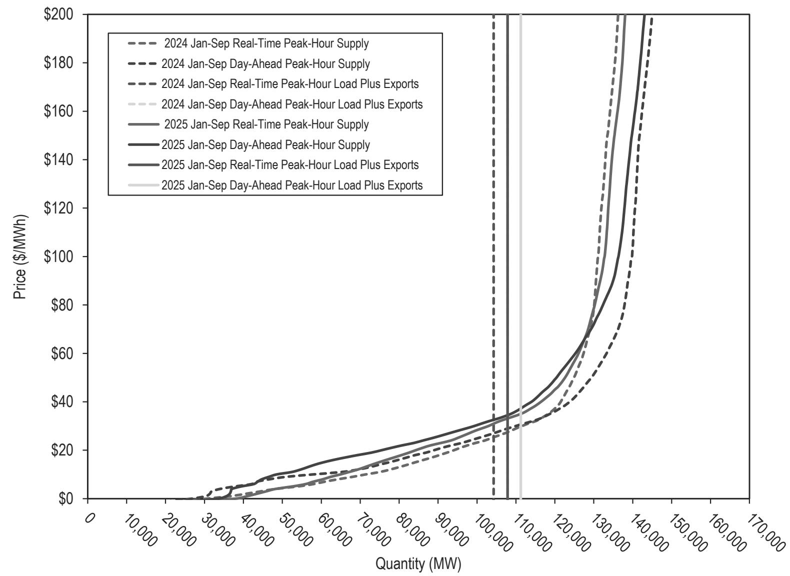

Table 3-2 shows the price elasticity of the real-time supply curve for the peak hours for the first nine months of 2024 and 2025 by load level.[25]

The supply curve in the first nine months of 2025 was most elastic in the 95 to 115 GW range at 0.428, which was more elastic than the supply curve in the 95 to 115 GW range in the first nine months of 2024, with an elasticity of 0.378.

The price elasticity of the supply curve measures the responsiveness of the quantity supplied (GW) to a change in price:

$$\text{Elasticity of Supply} = \frac{\text{Percent change in quantity supplied}}{\text{Percent change in price}}$$

25 The price elasticity results have been corrected from previous reports.

The supply curve is defined to be elastic when elasticity is greater than 1.0. The quantity supplied is more sensitive to changes in price the higher the elasticity. Although the aggregate supply curve may appear flat as a result of the wide range in prices and quantities, the supply curve is inelastic throughout.

Table 3-2 Price elasticity of the supply curve

	GW				
Jan-Sep	Min - 75	75 - 95	95 - 115	115 - 135	135 - Max
2020	0.138	0.643	0.686	0.039	0.004
2021	0.089	0.657	0.502	0.050	0.007
2022	0.046	0.556	0.384	0.102	0.012
2023	0.096	0.361	0.428	0.020	0.005
2024	0.108	0.316	0.378	0.032	0.008
2025	0.061	0.428	0.387	0.053	0.009

Real-Time Supply

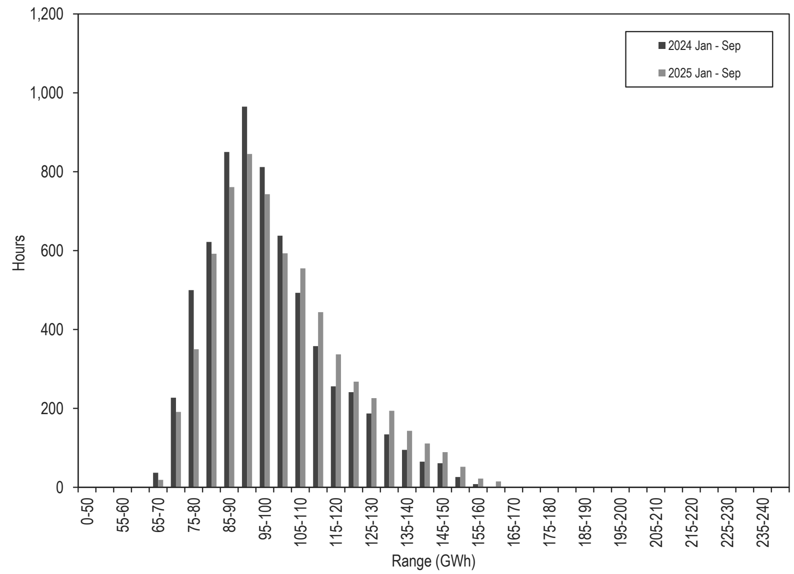
In the PJM Real-Time Energy Market, there are three types of supply offers:[26]

- **Self Scheduled Generation Offer.** Offer to supply a fixed block of MW, as a price taker, from a unit that may also have a dispatchable component above the fixed MW.
- **Dispatchable Generation Offer.** Offer to supply a schedule of MW and corresponding offer prices from a unit.
- **Import.** An import is an external energy transaction scheduled to PJM from another balancing authority. A real-time import must have a valid OASIS reservation when offered, must have available ramp room to support the import, must be accompanied by a NERC Tag, and must pass the neighboring balancing authority checkout process.

PJM Real-Time Supply Duration

Figure 3-3 shows the hourly distribution of the real-time generation plus imports for the first nine months of 2024 and 2025.

Figure 3-3 Distribution of real-time generation plus imports: January through September, 2024 and 2025[27]



PJM Real-Time Average Cleared Supply

Table 3-3 shows the real-time hourly average cleared supply and its standard deviation for the first nine months of 2001 through 2025.

The real-time hourly average cleared generation in the first nine months of 2025 increased by 3.3 percent from the first nine months of 2024, from 96,954 MWh to 100,136 MWh.

26 Generation data are the net MWh injections and withdrawals MWh at every generation bus in PJM.

27 Each range on the horizontal axis excludes the start value and includes the end value.

The real-time hourly average cleared supply including imports in the first nine months of 2025 increased by 3.5 percent from the first nine months of 2024, from 98,593 MWh to 102,018 MWh.

The real-time hour average cleared generation in the first nine months of 2025 was the highest since the start of PJM markets for the first nine months of a year at 100,136 MWh.

Table 3-3 Real-time hourly average generation and generation plus imports: January through September, 2001 through 2025

	PJM Real-Time Supply (MWh)				Year-to-Year Change			
	Generation		Generation Plus Imports		Generation		Generation Plus Imports	
Jan-Sep	Generation	Standard Deviation	Supply	Standard Deviation	Generation	Standard Deviation	Supply	Standard Deviation
2001	30,304	5,216	33,299	5,571	NA	NA	NA	NA

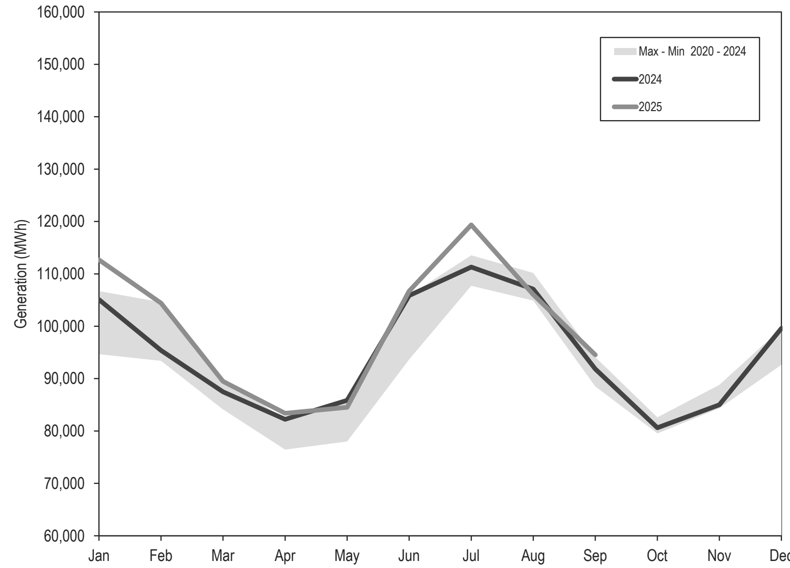
2019	95,531	17,206	96,659	17,378	(0.0%)	(1.7%)	(1.0%)	(2.1%)
2020	92,226	17,790	92,983	17,883	(3.5%)	3.4%	(3.8%)	2.9%
2021	95,792	18,039	96,519	18,173	3.9%	1.4%	3.8%	1.6%
2022	96,397	16,816	98,064	17,031	0.6%	(6.8%)	1.6%	(6.3%)
2023	93,886	15,544	95,437	15,561	(2.6%)	(7.6%)	(2.7%)	(8.6%)
2024	96,954	16,635	98,593	16,917	3.3%	7.0%	3.3%	8.7%
2025	100,136	18,290	102,018	18,551	3.3%	10.0%	3.5%	9.7%

PJM Real-Time Monthly Average Cleared Supply

Figure 3-4 compares the real-time monthly average generation in 2024 and the first nine months of 2025 with the historic five year range. The real-time monthly average generation in January, April, June, and September 2025 was higher than the maximum monthly average generation for the past five years.

Figure 3-4 Real-time monthly average generation: 2024 through September 2025



Day-Ahead Supply

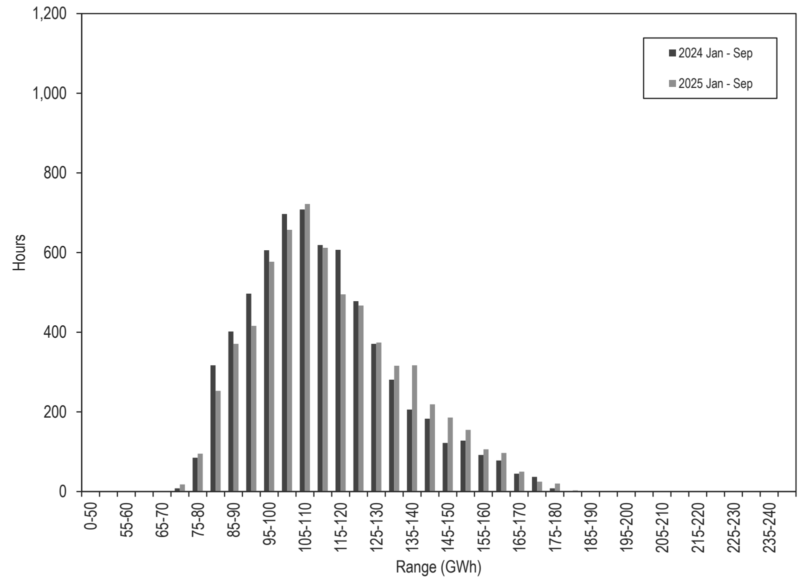
In the PJM Day-Ahead Energy Market, there are five types of financially binding supply offers:

- **Self Scheduled Generation Offer.** Offer to supply a fixed block of MW, as a price taker, from a unit that may also have a dispatchable component above the minimum.
- **Dispatchable Generation Offer.** Offer to supply a schedule of MW and corresponding offer prices from a unit.
- **Increment Offer (INC).** Financial offer to supply MW and corresponding offer prices. INCs can be submitted by any market participant.
- **Up to Congestion Transaction (UTC).** Conditional transaction that permits a market participant to specify a maximum price spread for a specific amount of MW between the transaction source and sink. An up to congestion transaction is a matched pair of an injection and a withdrawal.
- **Import.** An import is an external energy transaction for a specific MW amount scheduled to PJM from another balancing authority. An import must have a valid willing to pay congestion (WPC) OASIS reservation when offered. An import energy transaction that clears the day-ahead energy market is financially binding. There is no link between transactions submitted in the PJM Day-Ahead Energy Market and the PJM Real-Time Energy Market, so an import energy transaction approved in the day-ahead energy market will not physically flow in real-time unless it is also submitted through the real-time energy market scheduling process.

PJM Day-Ahead Supply Duration

Figure 3-5 shows the distribution of the day-ahead hourly cleared supply, including increment offers, up to congestion transactions, and imports for the first nine months of 2024 and 2025.

Figure 3-5 Distribution of day-ahead cleared supply plus imports: January through September, 2024 and 2025[28]



PJM Day-Ahead Average Cleared Supply

Table 3-4 presents day-ahead hourly cleared supply summary statistics for each year for the first nine months of 2001 through 2025.

The day-ahead hourly average cleared supply in the first nine months of 2025, including INCs and UTCs, increased by 1.9 percent from the first nine months of 2024 from 112,192 MWh to 114,328 MWh.

28 Each range on the horizontal axis excludes the start value and includes the end value.

The day-ahead hourly average cleared supply in the first nine months of 2025, including INCs, UTCs and imports, increased by 1.9 percent from the first nine months of 2024, from 112,477 MWh to 114,585 MWh.

Table 3-4 Day-ahead hourly average cleared supply and cleared supply plus imports: January through September, 2001 through 2025

	PJM Day-Ahead Supply (MWh)				Year-to-Year Change			
	Supply		Supply Plus Imports		Supply		Supply Plus Imports	
Jan-Sep	Supply	Standard Deviation	Supply	Standard Deviation	Supply	Standard Deviation	Supply	Standard Deviation

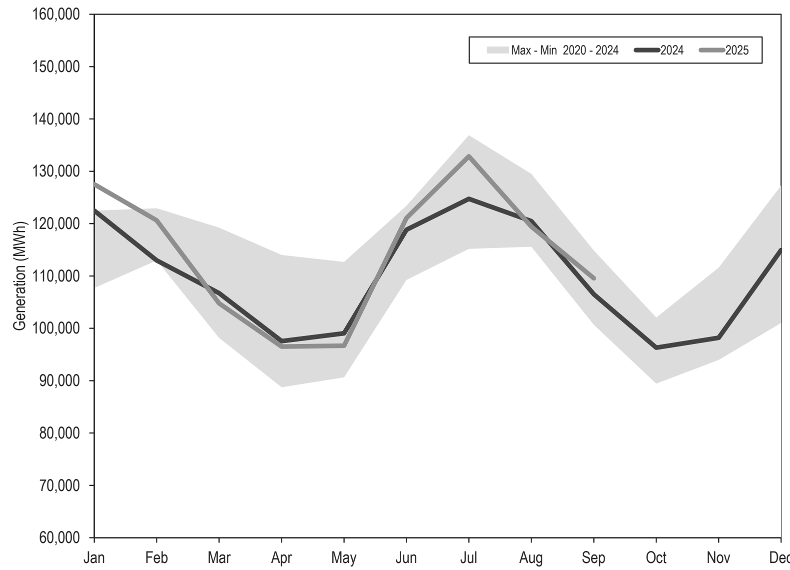
PJM Day-Ahead Monthly Average Cleared Supply

Figure 3-6 compares the day-ahead monthly average cleared supply including increment offers and up to congestion transactions in 2024 and the first nine months of 2025 with the historic five year range. The monthly average day-ahead cleared supply from January of 2025 was higher than the maximum of the past five years.

Figure 3-6 Day-ahead monthly average cleared supply: 2024 through September 2025



Real-Time and Day-Ahead Supply

Table 3-5 presents summary statistics for day-ahead and real-time cleared supply in the first nine months of 2024 and 2025. The last two columns of Table 3-5 are the day-ahead cleared supply minus the real-time cleared supply. The first column is the total physical day-ahead generation less the total physical real-time generation and the second column is the total day-ahead cleared supply less the total real-time cleared supply. The total real-time cleared supply includes real-time generation and real-time imports. The total day-ahead cleared supply includes physical day-ahead generation, INCs, UTCs, and day-ahead imports.

The total physical day-ahead average generation less the total physical real-time average generation in the first nine months of 2025 decreased 346 MWh from the first nine months of 2024, from -653 MWh to -999 MWh. The total day-ahead average supply less the total real-time average supply in the first nine months of 2025 decreased 1,316 MWh from the first nine months of 2024, from 13,883 MWh to 12,567 MWh.

Table 3-5 Day-ahead and real-time hourly cleared supply (MWh): January through September, 2024 and 2025

		Day Ahead					Real Time		Day Ahead Less Real Time	
	Jan-Sep	Generation	INC Offers	Up to Congestion	Imports	Total Supply	Generation	Total Supply	Generation	Supply
Average	2024	96,301	4,886	11,005	285	112,477	96,954	98,593	(653)	13,883
	2025	99,137	5,297	9,894	257	114,585	100,136	102,018	(999)	12,567

Figure 3-7 shows the average cleared volumes of day-ahead and real-time supply by hour of the day for the first nine months of 2025. The day-ahead cleared supply consists of cleared MW of physical generation, imports, increment offers and up to congestion transactions. The real-time cleared supply consists of cleared MW of physical generation and imports.

Figure 3-7 Day-ahead and real-time cleared supply (Average volumes by hour of the day): January through September, 2025

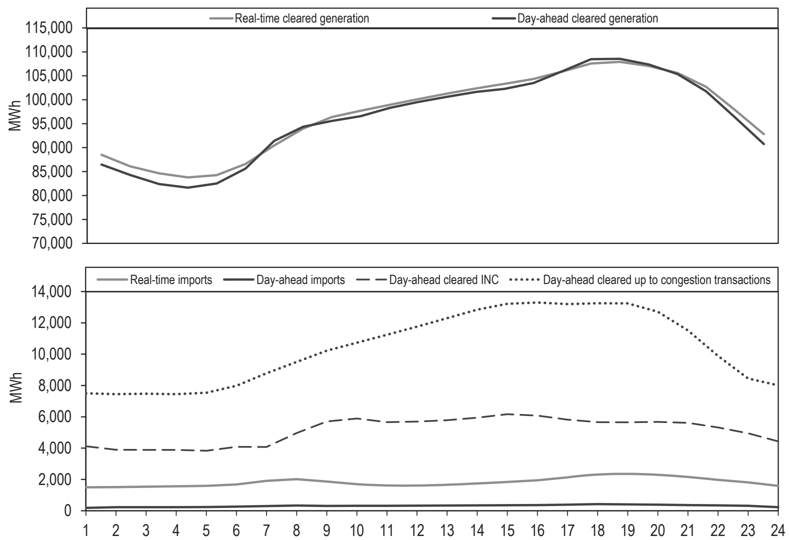

Figure 3-8 shows the difference between day-ahead and real-time daily average cleared supply in 2024 and the first nine months of 2025. The blue line is the total physical day-ahead generation less the total physical real-time generation, and the green line is the total day-ahead cleared supply less the total real-time cleared supply. The total real-time cleared supply includes real-time generation and real-time imports. The total day-ahead cleared supply includes physical day-ahead generation, INCs, UTCs, and day-ahead imports.

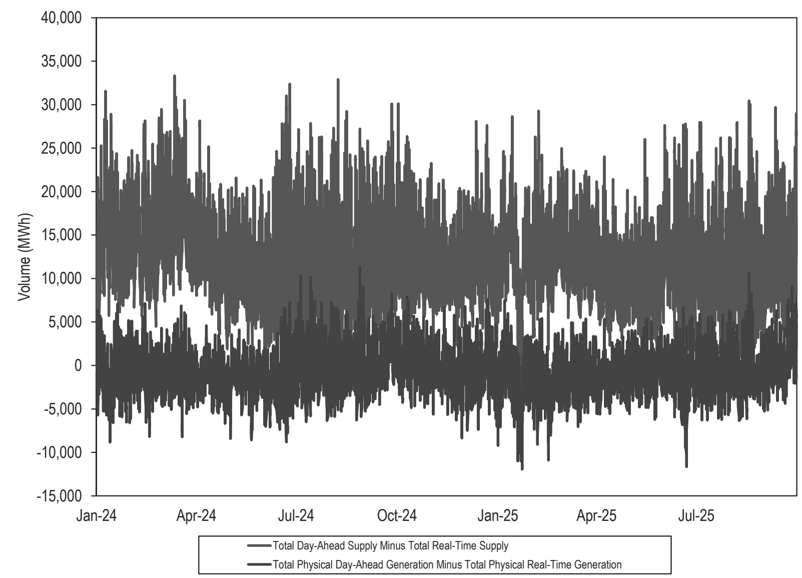
Figure 3-8 Difference between day-ahead and real-time daily average cleared supply: 2024 through September 2025



Demand

In the real-time energy market, demand includes physical load and exports. In the day-ahead energy market, demand includes physical load, exports, and virtual transactions.

Peak Demand

In the real-time energy market, demand refers to physical accounting load and exports, and in the day-ahead energy market, demand also includes virtual demand transactions.[29]

29 PJM reports peak load including accounting load plus an addback equal to PJM's estimated load drop from demand side resources. This will generally result in PJM reporting peak load values greater than accounting load values. PJM's load drop estimate is based on PJM Manual 19: Load Forecasting and Analysis," Attachment A: Load Drop Estimate Guidelines.

Table 3-6 shows the seasonal peak load, net exports, real-time generation and the LMP for the peak load hour from 2004 through September 2025.

The winter peak load in 2025 was 140,043 MWh in the HE 0900 (EPT) on January 22, 2025, higher than the winter peak load in 2024, which was 130,293 MWh in the HE 0900 (EPT) on January 17, 2024. This was the highest winter peak load since the start of the PJM market.

The summer peak load in the first nine months of 2025 was 156,256 MWh in the HE 1800 (EPT) on June 23, 2025, higher than the summer peak load in 2024, which was 144,245 MWh in the HE 1800 (EPT) on June 21, 2024. This was the highest summer peak load since the start of the PJM market.

Table 3-6 Actual PJM peak load by season: 2004 through September 2025[30 31]

Summer Peak Load Hour						Winter Peak Load Hour					
Date	Hour Ending	RT Load (MWh)	Net Export (MWh)	RT Generation (MWh)	LMP ($/MWh)	Date	Hour Ending	RT Load (MWh)	Net Export (MWh)	RT Generation (MWh)	LMP ($/MWh)
Tuesday, August 03, 2004	17	77,950	435	78,666	$90.55	Monday, December 20, 2004	19	96,838	1,796	98,797	$129.90

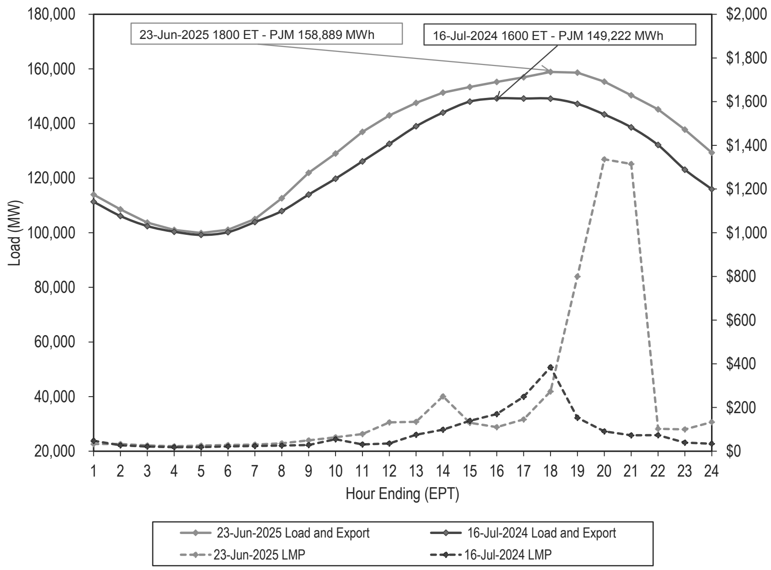
30 Peak loads shown are accounting load, without losses. See the *MMU Technical Reference for the PJM Markets*, at "Load Definitions," for detailed definitions of load. <http://www.monitoringanalytics.com/reports/Technical_References/references.shtml>.
31 Peak loads shown have been corrected to reflect the accounting load value excluding PJM loss adjustment. The values presented in this table do not include settlement adjustments made prior to January 1, 2017.

Figure 3-9 compares prices and load plus net exports on the peak load days for the first nine months of 2024 and 2025. The real-time average LMP for July 16, 2024, peak load hour was $33.90 per MWh, and for June 23, 2025, peak load hour it was $273.39 per MWh.

Figure 3-9 Peak load and net export day comparison



Real-Time Demand

In the PJM Real-Time Energy Market, there are two types of demand:[32]

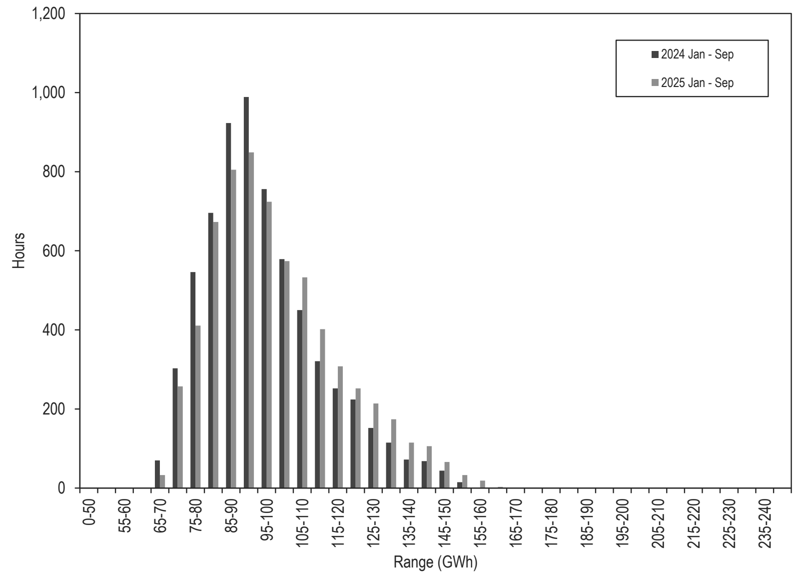
- **Load.** The actual MWh level of energy used by load within PJM.
- **Export.** An export is an external energy transaction scheduled from PJM to another balancing authority. A real-time export must have a valid OASIS reservation when offered, must have available ramp room to support the export, must be accompanied by a NERC Tag, and must pass the neighboring balancing authority's checkout process.

32 Load data are the net MWh injections and withdrawals MWh at every load bus in PJM.

PJM Real-Time Demand Duration

Figure 3-10 shows the distribution of the real-time hourly load plus exports for the first nine months of 2024 and 2025.[33]

Figure 3-10 Distribution of real-time load plus exports: January through September, 2024 and 2025[34]



33 All real-time load data in Section 3, "Energy Market," "Market Performance: Load and LMP," are based on PJM accounting load. See the *Technical Reference for PJM Markets*, "Load Definitions," for detailed definitions of accounting load. <http://www.monitoringanalytics.com/reports/Technical_References/references.shtml>.

34 Each range on the horizontal axis excludes the start value and includes the end value.

PJM Real-Time Average Demand

Table 3-7 presents real-time hourly demand summary statistics for the first nine months of 2001 through 2025.[35]

The real-time hourly average load in the first nine months of 2025 increased by 3.0 percent from the first nine months of 2024, from 90,917 MWh to 93,683 MWh.

The real-time hourly average demand including exports in the first nine months of 2025 increased by 3.5 percent from the first nine months of 2024, from 96,746 MWh to 100,114 MWh.

The real-time hourly average load in the first nine months of 2025 was the highest since the start of the PJM market for the first nine months of a year at 93,683 MWh.

Table 3-7 Real-time hourly average load and load plus exports: January through September, 2001 through 2025

	PJM Real-Time Demand (MWh)				Year to Year Change			
	Load		Load Plus Exports		Load		Load Plus Exports	
Jan-Sep	Load	Standard Deviation	Demand	Standard Deviation	Load	Standard Deviation	Demand	Standard Deviation
2001	31,060	6,156	32,900	5,861	NA	NA	NA	NA

2013	89,123	16,384	93,647	16,254	0.5%	(6.0%)	(0.1%)	(6.2%)
2014	90,567	16,662	96,015	16,518	1.6%	1.7%	2.5%	1.6%
2015	91,857	17,211	96,102	17,300	1.4%	3.3%	0.1%	4.7%
2016	90,599	18,183	95,340	18,571	(1.4%)	5.6%	(0.8%)	7.3%
2017	87,243	16,008	91,954	15,794	(3.7%)	(12.0%)	(3.6%)	(15.0%)
2018	91,905	17,064	95,795	17,245	5.3%	6.6%	4.2%	9.2%
2019	89,834	16,794	94,918	16,924	(2.3%)	(1.6%)	(0.9%)	(1.9%)
2020	85,886	17,201	91,356	17,464	(4.4%)	2.4%	(3.8%)	3.2%
2021	89,515	16,875	94,746	17,748	4.2%	(1.9%)	3.7%	1.6%
2022	90,514	16,367	96,196	16,581	1.1%	(3.0%)	1.5%	(6.6%)
2023	87,269	14,833	93,709	15,199	(3.6%)	(9.4%)	(2.6%)	(8.3%)
2024	90,917	16,529	96,746	16,478	4.2%	11.4%	3.2%	8.4%
2025	93,683	17,631	100,114	18,080	3.0%	6.7%	3.5%	9.7%

35 Accounting load is used because accounting load is the load customers pay for in PJM settlements. The use of accounting load with losses before June 1, and without losses after June 1, 2007, is consistent with PJM's calculation of LMP. Before June 1, 2007, transmission losses were included in accounting load. After June 1, 2007, transmission losses were excluded from accounting load and losses were addressed through the incorporation of marginal loss pricing in LMP.

PJM Real-Time Monthly Average Demand

Figure 3-11 compares the real-time monthly average load plus exports of 2024 and the first nine months of 2025 with the historic five year range. The real-time monthly average load plus exports in January, February, April, June and September 2025 was higher than the maximum monthly average load plus exports for the past five years.

Figure 3-11 Real-time monthly average hourly load plus exports: 2024 through September 2025

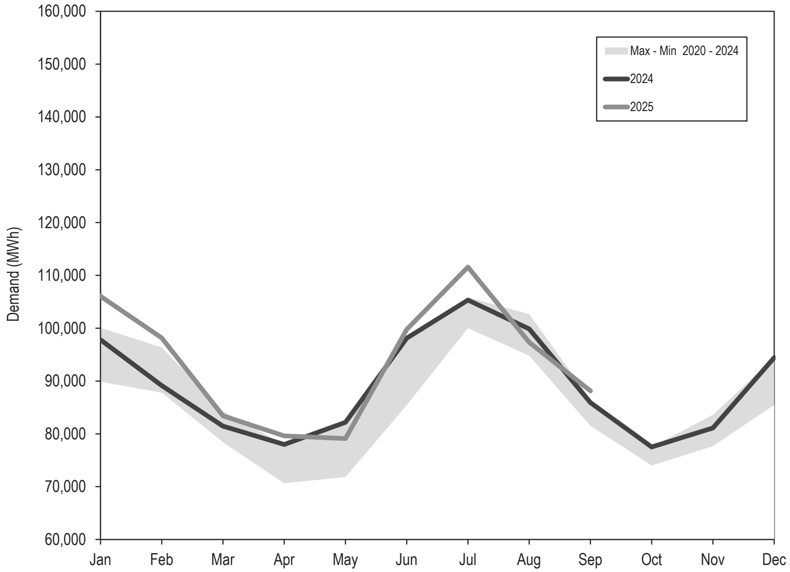

Figure 3-12 compares the real-time daily average load in 2024 and the first nine months of 2025, with the historic five year range. The daily average load in the first nine months of 2025 was higher than the historic five year range in January, February and June.

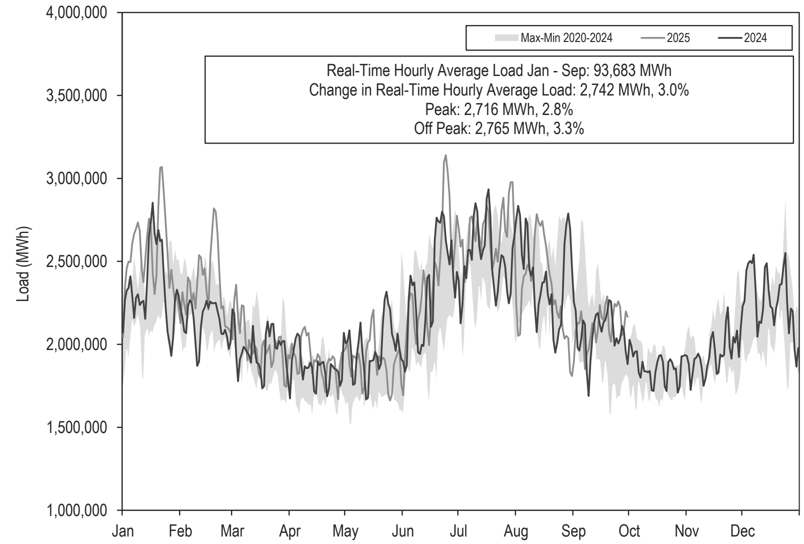
Figure 3-12 Real-time daily load: 2024 through September 2025



The real-time load is significantly affected by weather conditions. Table 3-8 compares the monthly heating and cooling degree days in 2024 and the first nine months of 2025.[36]

36 A heating degree day is defined as the number of degrees that a day's average temperature is below 65 degrees F (the temperature below which buildings need to be heated). A cooling degree day is the number of degrees that a day's average temperature is above 65 degrees F (the temperature when people will start to use air conditioning to cool buildings). Reference: <https://www.eia.gov/energyexplained/units-and-calculators/degree-days.php>. This calculation was modified starting in 2024 Q3 from the method used in prior State of the Market Reports which was the PJM calculation method based on 60 degrees for heating degree days and 65 degrees for cooling degree days.
Heating and cooling degree days are calculated by weighting the temperature at each weather station in the individual transmission zones using weights provided by PJM in Manual 19. Then the temperature is weighted by the real-time zonal accounting load for each transmission zone. After calculating an average hourly temperature across PJM, the heating and cooling degree formulas are used to calculate the daily heating and cooling degree days, which are summed for monthly reporting. The weather stations that provided the basis for the analysis are ABE, ACY, AVP, BWI, CAK, CLE, CMH, CRW, CVG, DAY, DCA, ERI, EWR, FWA, IAD, ILG, IPT, LEX, ORD, ORF, PHL, PIT, RIC, ROA, TOL and WAL.

Heating degree days increased 19.0 percent compared to the first nine months of 2024. Cooling degree days decreased 12.8 percent compared to the first nine months of 2024.

Table 3-8 Heating and cooling degree days: 2024 through September 2025

	2024		2025		Percent Change	
	Heating Degree Days	Cooling Degree Days	Heating Degree Days	Cooling Degree Days	Heating Degree Days	Cooling Degree Days

Day-Ahead Demand

In the PJM Day-Ahead Energy Market, there are five types of financially binding demand bids:

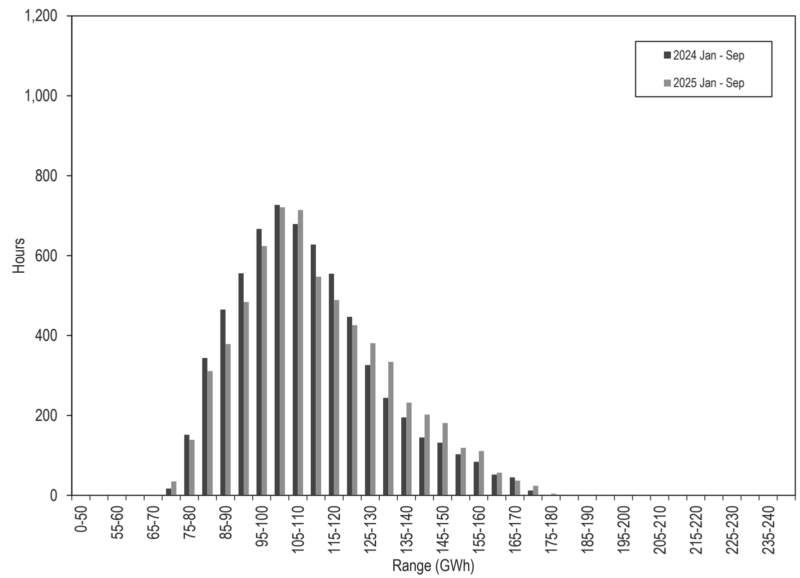
- **Fixed-Demand Bid.** Bid to purchase a defined MWh level of energy, regardless of LMP.
- **Price-Sensitive Bid.** Bid to purchase a defined MWh level of energy only up to a specified LMP, above which the load bid is zero.
- **Decrement Bid (DEC).** Financial bid to purchase a defined MWh level of energy up to a specified LMP, above which the bid is zero.
- **Up to Congestion Transaction (UTC).** A conditional transaction that permits a market participant to specify a maximum price spread between the transaction source and sink. An up to congestion transaction is evaluated as a matched pair of an injection and a withdrawal.
- **Export.** An external energy transaction scheduled from PJM to another balancing authority. An export must have a valid willing to pay congestion (WPC) OASIS reservation when offered. There is no link between transactions submitted in the PJM Day-Ahead Energy Market and the PJM Real-Time Energy Market, so an export energy transaction approved in the day-ahead energy market will not physically flow in real-time unless it is also submitted through the real-time energy market scheduling process.

PJM day-ahead demand is the sum of the five types of cleared demand bids.

PJM Day-Ahead Demand Duration

Figure 3-13 shows the hourly distribution of the day-ahead cleared demand including DECs, UTCs and exports for the first nine months of 2024 and 2025.

Figure 3-13 Distribution of day-ahead cleared demand plus exports: January through September, 2024 and 2025[37]



37 Each range on the horizontal axis excludes the start value and includes the end value.

PJM Day-Ahead Average Demand

Table 3-9 shows day-ahead hourly average cleared demand including DECs, UTCs and exports for the first nine months of 2001 through 2025.

The day-ahead hourly average cleared demand in the first nine months of 2025, including DECs and UTCs, increased by 1.4 percent from the first nine months of 2024, from 106,355 MWh to 107,864 MWh.

The day-ahead hourly average cleared demand in the first nine months of 2025, including DECs, UTCs and exports, increased by 1.9 percent from the first nine months of 2024, from 110,189 MWh to 112,308 MWh.

Table 3-9 Day-ahead hourly average cleared demand and demand plus exports: January through September, 2001 through 2025

	PJM Day-Ahead Demand (MWh)				Year to Year Change			
	Demand		Demand Plus Exports		Demand		Demand Plus Exports

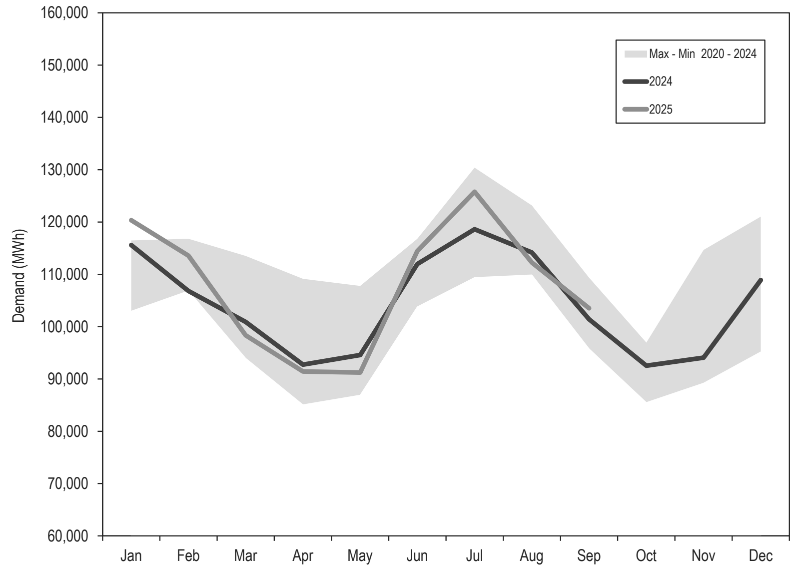
PJM Day-Ahead Monthly Average Demand

Figure 3-14 compares the day-ahead monthly average cleared demand including DECs and UTCs for 2024 and the first nine months of 2025, with the historic five year range. In January 2025, the day-ahead monthly average cleared demand was higher than the maximum of the past five years.

Figure 3-14 Day-ahead monthly average cleared demand: 2024 through September 2025



Real-Time and Day-Ahead Demand

Table 3-10 presents summary statistics for day-ahead and real-time cleared demand for the first nine months of 2024 and 2025. The last two columns of Table 3-10 are day-ahead cleared demand minus real-time cleared demand. The first column is the total physical day-ahead load (fixed demand plus cleared price-sensitive demand) less the physical real-time load. The second column is the total cleared day-ahead demand less the total cleared real-time demand.

The total physical day-ahead average load less the total physical real-time average load in the first nine months of 2025 decreased 288 MWh from the first nine months of 2024, from -1,014 MWh to -1,302 MWh. The total day-ahead average demand less the total real-time average demand in the first nine months of 2025 decreased 1,249 MWh from the first nine months of 2024, from 13,443 MWh to 12,194 MWh.

Table 3-10 Day-ahead and real-time demand (MWh): January through September, 2024 and 2025

		Day Ahead						Real Time		Day Ahead Less Real Time	
Jan-Sep	Year	Fixed Demand	Price Sensitive	DEC Bids	Up to Congestion	Exports	Total Demand	Load	Total Demand	Load	Demand
Average	2024	89,529	375	5,446	11,005	3,835	110,189	90,917	96,746	(1,014)	13,443

Figure 3-15 shows the average cleared volumes of day-ahead and real-time demand for the first nine months of 2025. The day-ahead demand includes day-ahead load, decrement bids, up to congestion transactions, and day-ahead exports. The real-time demand includes real-time load and real-time exports.

Figure 3-15 Day-ahead and real-time demand (Average hourly volumes): January through September, 2025

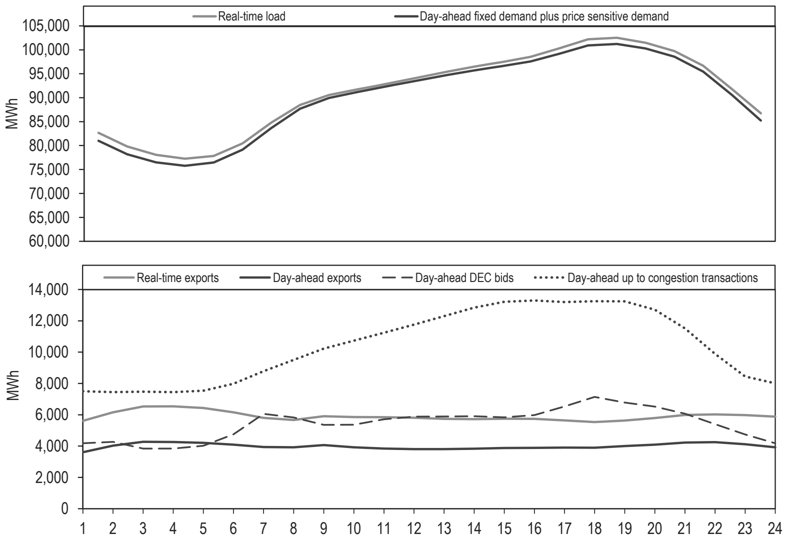

Figure 3-16 shows the difference between the physical day-ahead load and the physical real-time load, and the difference between the day-ahead demand including DECs, UTCs, and exports, and the real-time demand including exports, for 2024 and the first nine months of 2025.

Figure 3-16 Day-ahead minus real-time daily demand: 2024 through September 2025

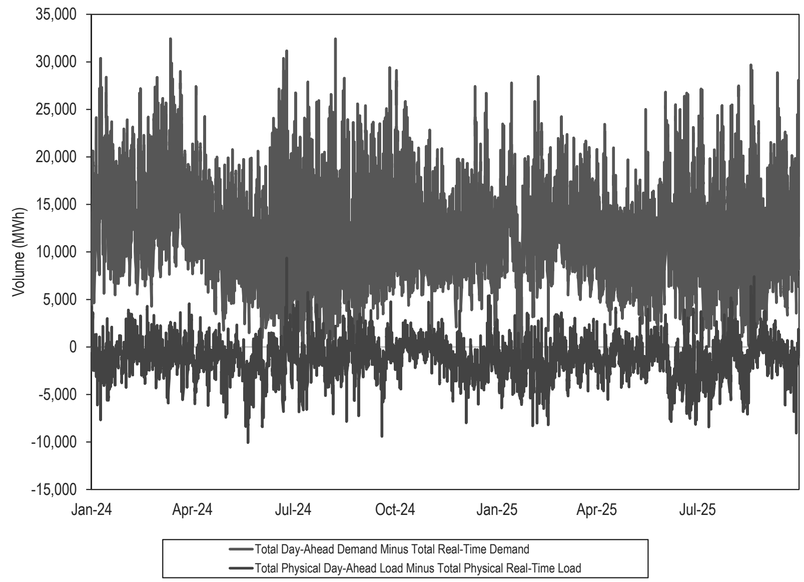

Figure 3-17 shows the difference between the day-ahead and real-time hourly average load by hour of the day. DECs, UTCs and exports are not included. The largest difference generally occurs during off peak hours, especially at hours beginning 1 and 2. The smallest difference generally occurs during peak hours, especially at hours beginning 9 and 10.

Figure 3-17 Difference between day-ahead and real-time hourly average physical load by hour of the day (Average hourly volumes): January through September, 2021 through 2025

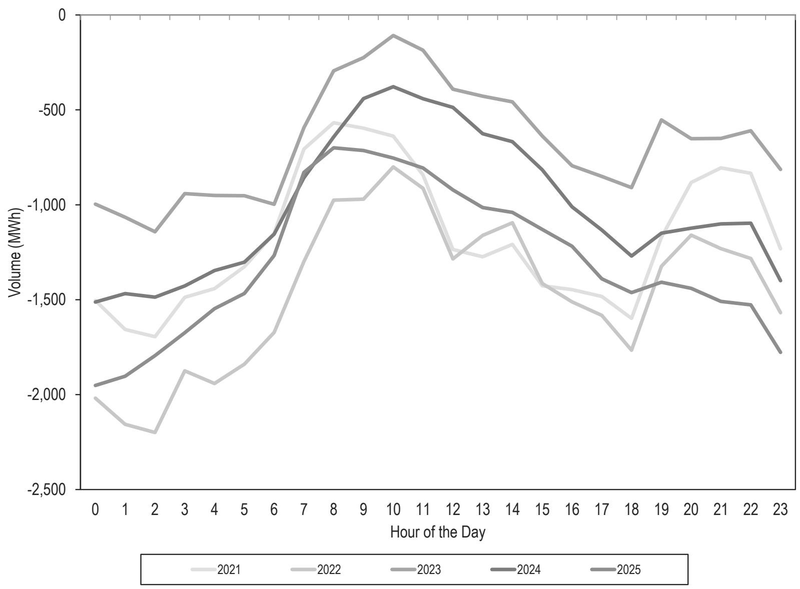

Figure 3-18 shows the difference between the day-ahead and real-time on peak and off peak hourly average physical load by month. DECs, UTCs and exports are not included.

Figure 3-18 Difference between day-ahead and real-time on peak and off peak hourly average physical load by month: 2021 through September 2025

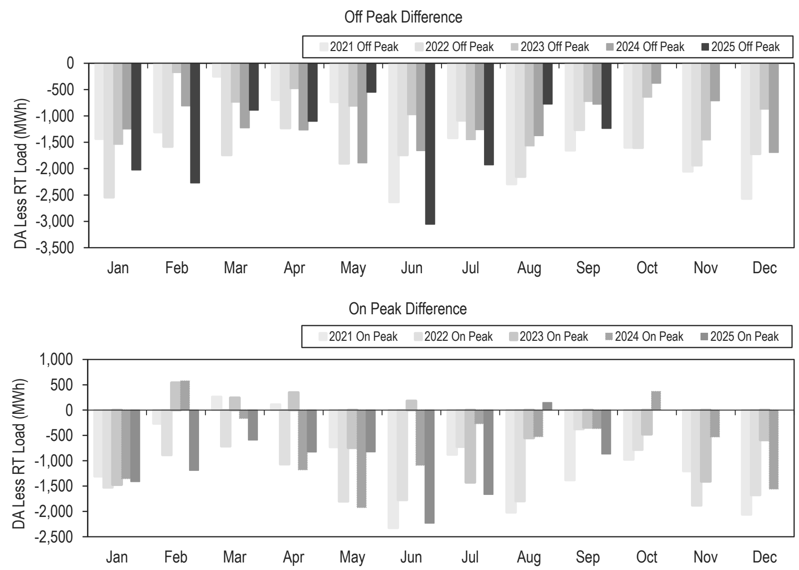

Table 3-11 shows the difference between the day-ahead and real-time on peak and off peak physical load by zone. DECs, UTCs and exports are not included. Some zones showed larger difference than other zones, such as DOM, BGE and APS. Some zones did not show a big difference between on peak and off peak, such as DOM and AEP. Some zones showed a significant difference between on peak and off peak, such as AECO and JCPL.

Market Behavior

Generator Offers

Generators indicate their availability for commitment and dispatch in the day-ahead market through their offers. Commitment availability status is economic, must run, or unavailable. Dispatch availability is defined by the difference between the economic minimum and maximum output levels. PJM will clear units that select must run status in the offer in the day-ahead market up to their economic minimum MW regardless of economics. Units may set their economic minimum MW equal to their economic maximum MW, also called block loading, or they may raise the economic minimum MW to a point between the actual economic minimum and the economic maximum. Must run units may commit at economic minimum and permit the balance to be dispatchable or block load the full output of the unit. If units select economic commitment status, the day-ahead market will determine whether to commit them based on their offers.

The Must Run column in Table 3-13 is the submitted offer MW of units offering with must run commitment status. The Eco Min column in Table 3-13 is the economic minimum MW of units offering with economic commitment status. The dispatchable range in Table 3-13 is the percent of MW offered by price range, between the economic minimum MW and economic maximum MW for all available units. Some units, like wind and solar, offer a dispatchable range in the day-ahead market although their availability in real time is determined by the presence of sun and wind rather than economics.

Units may designate all or a portion of their capacity as emergency MW.[38] Table 3-13 shows that 0.1 percent of offered MW are emergency MW. In some cases, higher shares of emergency MW result from offer behavior that does not accurately represent the availability of the emergency MW in real time.

In the day-ahead market for the first nine months of 2025, 22.4 percent of MW were offered as must run, 33.0 percent of MW were offered as the economic minimum MW for dispatchable units, 44.4 percent of MW were offered as dispatchable, and 0.1 percent of MW were offered as emergency maximum MW.

Table 3-13 Dispatchable status of day-ahead energy offers: January through September, 2025

38 "PJM Manual 11: Energy & Ancillary Services Market Operations," Rev. 136. (Oct. 1, 2025). § 2.3.3.2 (Generator Schedules) "Designation of all or part of a unit's capacity as Maximum Emergency (ME) constitutes withholding in the Day-ahead Market, if The capacity is not designated as ME in the bid for the Real-time Market, or; There is no physical reason to designate the unit as ME."

Hourly Offers and Intraday Offer Updates

All participants may make specific hourly offers. Hourly offers mean that participants can specify different MW and price pairs for each hour of the day. Hourly offers can be submitted in the day-ahead market and offers may be updated in the real-time market. Participants must opt in on a monthly basis to make intraday offer updates in real time. Participants that have opted in can make updates only based on the process defined in their fuel cost policies. Units typically use hourly offers to reflect the two gas days in a power day. A gas day is from 10:00 AM EPT to 10:00 AM EPT the next day. Therefore, gas fired units may face two different gas prices. Typically, gas units have one offer from 00:00 EPT until 10:00 EPT and a different offer from 10:00 EPT until 24:00 EPT. Units typically use intraday updates to reflect changes in gas costs that occur in real time.

Table 3-14 shows the daily average number of units that make hourly offers in the day-ahead market, that opted in to intraday offer updates and that make intraday offer updates. In the first nine months of 2025, an average of 373 units per day made hourly offers, an increase of seven units from the first nine months of 2024. In the first nine months of 2025, 612 units opted in for intraday offer updates, an increase of 26 units from the first nine months of 2024. In the first nine months of 2025, an average of 163 units made intraday offer updates each day, an increase of 15 units from the first nine months of 2024.

Table 3-14 Daily average number of units making hourly offers, opted in for intraday offers and making intraday offer updates: January through September, 2024 and 2025

	Fuel Type	2024 (Jan-Sep)	2025 (Jan-Sep)	Difference
Hourly Offers	Natural Gas	321	322	1
	Other Fuels	45	51	6
	Total	366	373	7
Opt In	Natural Gas	434	435	1

	Total	586	612	26
Intraday Offer Updates	Natural Gas	144	160	16
	Other Fuels	4	3	(1)
	Total	148	163	15
Total Units with nonzero offers		834	851	17

ICAP Must Offer Requirement

Generation capacity resources are required to offer their full ICAP MW into the day-ahead and real-time energy market, or report an outage for the difference.[39] The full installed capacity (ICAP) is the ICAP of the resources that cleared in the capacity market. This is known as the ICAP must offer requirement. The categorical exemption for intermittent resources, capacity storage resources, and hybrid resources from the capacity market must offer requirement was eliminated in February 2025.[40] Only demand resources are exempt from the capacity market must offer requirement.

The MMU recommends that all capacity resources have a must offer obligation. The MMU also recommends that performance penalties not be applied to solar and wind resources when they are not capable of performing based on ambient conditions. For example, solar resources should be subject to performance penalties if they fail to perform when the sun is shining but should not be subject to performance penalties in the middle of the night. This would be a rational application of the PAI penalties that recognizes the physical capabilities of resources and is therefore not discriminatory, in contrast to PJM's current treatment of such resources.

The current enforcement of the ICAP must offer requirement is inadequate.[41] The problem is a complex combination of generator behavior, and inadequate and inconsistent reporting tools that are not synchronized. Compliance is subject to mistakes and susceptible to manipulation.

Resources are required to submit their available capacity in three different systems. Resources are required to make offers in the energy market via Markets Gateway. Resources are required to report outages in the Dispatch Application Reporting Tool (eDART) in advance or in real time. Resources are required to report outages in the Generator Availability Data System (eGADS)

39 OA Schedule 1 § 1.10.1A(d).
40 FERC approved extending the RPM must offer requirement to intermittent resources, capacity storage resources, and hybrid resources but not to demand resources on February 20, 2025. 190 FERC ¶ 61,117.
41 PJM compares the data submitted in eDART to the data submitted in Markets Gateway using the eDART Gen Checkout. Generators are supposed to acknowledge their Gen Checkout reports. Manual 10 and the eDART User Guide do not specify what acknowledging the Gen Checkout report means, any requirements to acknowledge the Gen Checkout report or any consequences for not doing so. Gen Checkout is also only triggered if generators fail by more than defined thresholds.

after the fact. The three applications are not linked and there is no formal process to ensure consistency.

For example, ambient ratings are an issue. When the weather is hotter than test conditions, the capacity of some units is reduced below the ICAP levels. While this fact may be reported by unit owners in eDART and reflected in lower offered MW in the energy market, the derates are not reported as outages in eGADS and are therefore not included as outages for purposes of defining capacity using EFORd.

The MMU recommends that PJM enforce the ICAP must offer requirement by assigning a forced outage to any unit that is derated in the energy market below its committed ICAP without an outage that reflects the derate.

The MMU recommended that intermittent resources be subject to an enforceable ICAP must offer rule that reflects the limitations of these resources. In 2023, the MMU and PJM proposed to require intermittent resources to offer their median forecast on an hourly basis in the day-ahead and real-time energy market. This proposal was implemented on November 15, 2023.[42]

The MMU recommends that storage resources also be subject to an enforceable ICAP must offer requirement that reflects the limitations of these resources.

Table 3-15 shows average hourly MW, for each month, that violated the ICAP must offer requirement in the first nine months of 2025. On average for all hours, 1,905 MW did not meet the ICAP must offer requirement, but for 10 percent of the hours, 3,098 MW did not meet the must offer requirement. These MW levels are larger than the reserve shortages that trigger scarcity pricing and larger than most supply contingencies that lead to synchronized reserve events.

42 *See* "Renewable Dispatch Markets Manual Changes," PJM presentation to the Markets and Reliability Committee. (November 15, 2023) <https://www.pjm.com/-/media/committees-groups/committees/mrc/2023/20231115/20231115-consent-agenda-f---1-manual-11-revisions---renewable-dispatch---presentation.ashx>.

Table 3-15 Average hourly estimated capacity (MW) failing the ICAP must offer requirement: January through September, 2025

Month	90th Percentile	Average	10th Percentile
Jan-25	2,872	1,833	956
Feb-25	2,859	2,140	1,488
Mar-25	3,418	2,690	1,996
Apr-25	3,540	2,682	1,801
May-25	3,691	2,880	2,237
Jun-25	1,870	1,358	864
Jul-25	2,390	1,820	1,426
Aug-25	1,242	923	578
Sep-25	1,121	815	533
2025	3,098	1,905	798

The outage data reported in eGADS do not exactly match the energy market data submitted in Markets Gateway. For example, economic maximum MW levels submitted in Markets Gateway that reflect expected ambient conditions (including ambient derates) can be inconsistent with the maximum capability submitted in eGADS. Another example is the start and end times of planned outages in the shoulder months. In many situations units are derated in Markets Gateway to reflect an upcoming planned outage for which the unit must ramp down over an extended period but in eGADS the outage start time is not reported until the unit is completely unavailable. These differences can result in units not meeting their ICAP must offer requirement.

The MMU recommends that PJM integrate all the outage reporting tools in order to enforce the ICAP must offer requirement, ensure that outages are reported correctly and eliminate reporting inconsistencies. Generators currently submit availability in three different tools that are not integrated, Markets Gateway, eDART and eGADS.

Emergency Maximum MW

Generation resources are offered with economic maximum MW and emergency maximum MW. The economic maximum MW is the output level the resource can achieve following economic dispatch. The emergency maximum MW is the output level the resource can achieve when emergency conditions are declared by PJM. The MW difference between the two ratings equals emergency maximum MW. The PJM market rules allow generators to include emergency maximum MW as part of ICAP offered in the capacity market.[43]

Generation resources have to meet one of four conditions to offer any MW as emergency in the energy market: environmental limits imposed by a federal, state or other governmental agency that significantly limit availability; fuel limits beyond the control of the generation owner; temporary emergency conditions that significantly limit availability; or temporary MW additions not ordinarily available.[44]

The MMU recommends that capacity resources not be allowed to offer any portion of their capacity market obligation as maximum emergency energy.[45] Capacity resources should offer their full output in the energy market and be subject to economic dispatch. The result will be incentives for correct reporting of ICAP, more efficient energy market pricing, and a reduction in the need for manual overrides by PJM dispatchers during emergency conditions. Resources that do have capacity that can only be achieved with extraordinary measures could offer such capacity in the energy market but should not take on a capacity market obligation.

Table 3-16 shows average hourly maximum emergency MW, for each month. The levels of maximum emergency MW change hourly, daily and seasonally. For example, in July 2025, 10 percent of hours had maximum emergency MW greater than or equal to 701 MW while 10 percent of hours had maximum emergency MW less than 227 MW. The hourly average, in the first nine months of 2025, was 344 MW offered as maximum emergency, 38.6 percent lower than in the first nine months of 2024.

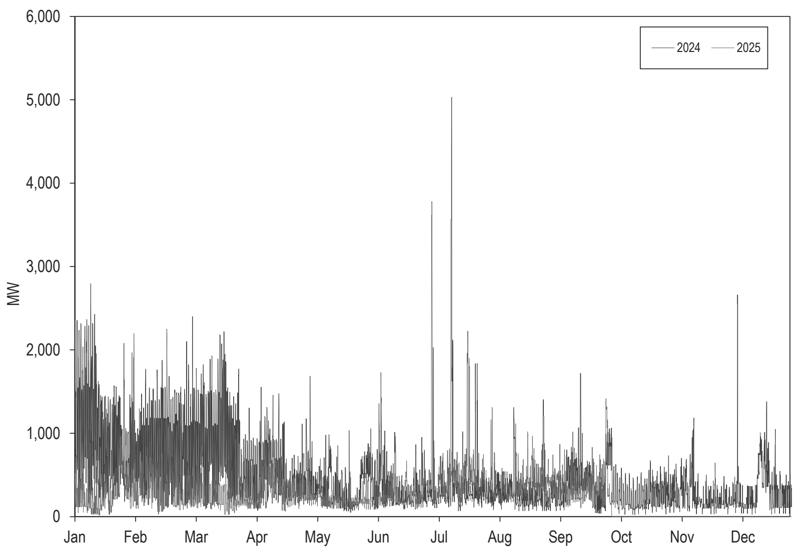
Table 3-16 Maximum emergency MW by month: January through September, 2025

Month	90th Percentile	Average	10th Percentile
Jan-25	680	338	97
Feb-25	728	399	120
Mar-25	430	254	97
Apr-25	601	350	165
May-25	307	214	130
Jun-25	464	280	154
Jul-25	701	506	227
Aug-25	551	384	258
Sep-25	592	377	189
2025	589	344	140

Figure 3-19 shows maximum emergency MW by hour in 2024 and the first nine months of 2025. The continued reduction of the use of emergency maximum that started in 2024 is mainly a result of improved compliance with the maximum emergency rules. The increases in maximum emergency MW are typically from short term situations at generators, such as testing of equipment which can be suspended in the event of a system emergency or operational restrictions such as limited run hours due to environmental permits.

43 See 151 FERC ¶ 61,208 at P 476 (2015).
44 OA Schedule 1 § 1.10.1A(d).
45 This recommendation was accepted by PJM and filed with FERC in 2014 as part of the capacity performance updates to the RPM. See PJM Filing, Attachment A (Redlines of OA Schedule 1 § 1.10.1A(d), EL15-29-000 (December 12, 2014). FERC rejected the proposed change. See 151 FERC ¶ 61,208 at P 476 (2015).

Figure 3-19 Maximum Emergency MW by hour: 2024 and January through September, 2025



Parameter Limited Schedules

Cost-Based Offers

All resources in PJM are required to submit at least one cost-based offer. Cost-based offers, submitted by capacity resources for a defined set of technologies, are parameter limited based on unit specific parameter limits. Nuclear, wind, solar and hydro units are not subject to parameter limits.

Price-Based Offers

All capacity resources that choose to make price-based offers are required to make available at least one price-based parameter limited offer (referred to as price-based PLS). The prices in a price-based PLS offer are at the discretion of the seller but the parameters are the same parameters used in the cost-based offers. For capacity resources, the price-based parameter limited schedule is used by PJM for committing generation resources when hot weather alerts and cold weather alerts are declared.

Offer Schedule Selection

PJM's current process for selecting unit offers (schedules) does not prevent the exercise of market power through the use of markups or through the use of inflexible parameters. The goal of having parameter limited offers is to prevent the use of inflexible operating parameters to exercise market power. Instead of ensuring that parameter limits apply, PJM chooses the lower of the price-based schedule and the price-based parameter limited schedule during hot and cold weather alerts. The goal of having cost-based offers is to prevent the use of markups to exercise market power. Instead of ensuring the least cost solution, PJM frequently chooses the higher price-based schedule that includes no parameter limits rather than the cost-based schedule that includes parameter limits when a resource fails the TPS test. The result is that PJM does not select the lowest cost schedule and allows market power to be exercised. The Commission recognized this flaw in the implementation of market power mitigation in its order to show cause, issued June 17, 2021, but did not take corrective action in its November 30, 2023 order.[46] [47]

PJM raised the schedule selection issues in the stakeholder process to address computational time in the day-ahead market. PJM's original proposal would have weakened market power mitigation. FERC rejected PJM's proposal because PJM's proposal would create the ability for market sellers to exercise market power.[48] PJM filed and, on October 25, 2024, FERC accepted a revised proposal that would require that sellers that fail the TPS test be offer capped at their cost-based offers and that operating parameters be mitigated.[49] FERC accepted PJM's proposal that has no specific plans to implement the improved rules and instead links implementation to PJM's long delayed improvements to its combined cycle modelling. PJM's revised proposal also continues to use the flawed formula, which was the basis for the first proposal rejected

46 See 175 FERC ¶ 61,231 (2021).
47 See 185 FERC ¶ 61,158 (2023).
48 See 187 FERC 61,051 at P 25 (2024).
49 See 189 FERC ¶ 61,060 (2024).

by FERC, to select among cost-based offers. This will result in the illogical selection of cost-based offers in some circumstances, for example if a dual fuel unit submits offers for both oil and gas on a day when the economics change between the two fuels midday. PJM should modify its implementation to address that issue. The result would allow market sellers to select the correct cost-based fuel schedule. There is no reason to delay implementation until PJM addresses combined cycle modelling. The changes would decrease the solution time for the day-ahead market and enhance market efficiency. The new approach should be implemented as soon as possible.

The MMU analyzed the extent of parameter mitigation in the day-ahead energy market when units are committed after failing the TPS test for transmission constraints in the first nine months of 2025. The analysis includes units with technologies that are subject to parameter limits and offer both price-based and cost-based schedules.[50] Table 3-17 shows the number and percentage of day-ahead unit run hours that failed the TPS test but were committed on price schedules. Table 3-17 shows that 29.3 percent of unit hours for units that failed the day-ahead TPS test were committed on price-based schedules that were less flexible than their cost-based schedules. For effective market power mitigation there would be zero units that fail the TPS test committed with parameters less flexible than their cost-based schedules.

Table 3-17 Parameter mitigation for units failing the day-ahead TPS test: January through September, 2025

Day-ahead Commitment For Units That Failed TPS Test	Day-ahead Unit Hours	Percent Day-ahead Unit Hours
Committed on price schedule less flexible than cost	20,721	29.3%
Committed on price schedule as flexible as cost	3,953	5.6%
Committed on cost (cost capped)	43,515	61.6%
Committed on price PLS	2,447	3.5%
Total committed on schedule as flexible as cost	49,915	70.7%
Total failed TPS test commitments	70,636	100.0%

The MMU analyzed the extent of parameter mitigation in the day-ahead energy market for units in zones with a cold weather alert, a hot weather alert, or a maximum generation emergency declaration in the first nine months of 2025. PJM declared cold weather alerts on 13 days and hot weather alerts on 18 days in the first nine months of 2025. The analysis includes units with technologies that are subject to parameter limits, with a capacity commitment, in the zones where the cold or hot weather alerts were declared. Table 3-18 shows that 31.2 percent of unit hours during weather alerts in the day-ahead energy market were committed on price-based schedules that were less flexible than their price PLS schedules. Effective market power mitigation would result in zero units committed during cold and hot weather alerts with parameters less flexible than their price PLS schedules.

Table 3-18 Parameter mitigation during weather alerts: January through September, 2025

Day-ahead Commitment During Hot And Cold Weather Alerts	Day-ahead Unit Hours	Percent Day-ahead Unit Hours
Committed on price schedule less flexible than PLS	51,165	31.2%
Committed on price schedule as flexible as PLS	10,808	6.6%
Committed on cost (cost capped)	8,135	5.0%
Committed on price PLS	93,923	57.3%
Total committed on schedule as flexible as PLS	112,866	68.8%
Total weather alert commitments	164,031	100.0%

Currently, there are no rules in the PJM tariff or manuals that limit the markup attributes of price-based PLS offers. The intent of the price-based PLS offer is to prevent the exercise of market power during high demand conditions by preventing units from offering inflexible operating parameters in order to extract higher market revenues or higher uplift payments. However, a generator can include a higher markup in the price-based PLS offer than in the price-based non-PLS schedule. The result is that the offer is higher and market prices are higher as a result of the exercise of market power using the PLS offer. This defeats the purpose of requiring price-based PLS offers.

The best solution to the use of inflexible parameters is to require the use of flexible parameters in all offers at all times for capacity resources. Capacity resources are paid to be flexible but that payment will not result in flexible offers in the energy market, the only place it matters, unless there are explicit requirements that energy offers from capacity resources incorporate that flexibility.

50 Nuclear, wind, solar and hydro units are not subject to parameter limits.

The MMU recommends, in order to ensure effective market power mitigation and to ensure that capacity resources meet their obligations to be flexible, that capacity resources be required to use flexible parameters in all offers at all times.

If flexible parameters are not required at all times, the use of flexible parameters should be required whenever a unit fails the TPS test and whenever the system is facing weather alerts or emergency conditions. PJM should always use cost-based offers for units that fail the TPS test, and always use flexible parameters in all price-based offers during weather alerts and emergencies. This approach would allow PJM to effectively mitigate inflexible operating parameters consistent with PJM's asserted processing time constraints. PJM's revised schedule selection proposal adopts this approach, but PJM has failed to propose an implementation date and the flawed rules remain in place as a result.

The MMU recommends that in order to ensure effective market power mitigation, PJM always use cost-based offers for units that fail the TPS test, and always use flexible parameters for all cost-based and all price-based offers during cold and hot weather alerts and emergency conditions.[51] [52]

Parameter Limits

The unit specific parameter limits for capacity resources are based on default minimum operating parameter limits posted by PJM by technology type, and any adjustments based on a unit specific review process. These default parameters were based on analysis by the MMU.

The PJM tariff specifies that all generation capacity resources, regardless of the current commitment status, are subject to parameter limits on their cost-based offers. The MMU recommends that PJM update the tariff to clarify that all generation resources are subject to unit specific parameter limits on their cost-based offers using the same standard and process as capacity resources.

Unit Specific Adjustment Process

Market participants can request an adjustment to the default values of parameter limits for capacity resources by submitting supporting documentation which is reviewed by PJM and the MMU. The default minimum operating parameter limits or approved adjusted values are used by capacity resources for their parameter limited schedules.

PJM has the authority to approve adjusted parameters with input from the MMU. PJM has inappropriately applied different review standards to coal units than to CTs and CCs despite the objections of the MMU. PJM has approved parameter limits for boiler based steam units based on historical performance and existing equipment while holding CTs and CCs to higher standards based on OEM documentation and a best practices equipment configuration.

The PJM process for the review of unit specific parameter limit adjustments is generally described in Manual 11: Energy and Ancillary Services Market Operations. The standards used by PJM to review the requests are currently not described in the tariff or PJM manuals. The MMU recommends that PJM clearly define the business rules that apply to the unit specific parameter adjustment process, including PJM's implementation of the tariff rules in the PJM manuals to ensure market sellers know the requirements for their resources.

Only certain technology types are subject to limits on operating parameters in their parameter limited schedules.[53] Solar units, wind units, run of river hydro units, and nuclear units are currently not subject to parameter limits. The MMU analyzed, for the units that are subject to parameter limits, the proportion of units that use the default limits published by PJM and the proportion of units that have unit specific adjustments for some of the parameters. Table 3-19 shows, for the delivery year beginning June 1, 2025, the number of units with approved unit specific parameter limits, and the number of units that used the default parameter limits published by PJM.

53 For the default parameter limits by technology type, see PJM. "Unit-Specific Minimum Operating Parameters for Capacity Performance and Base Capacity Resources," which can be accessed at <https://www.pjm.com/~/media/committees-groups/committees/elc/postings/20150612-june-2015-capacity-performance-parameter-limitations-informational-posting.ashx>.

Table 3-19 Adjusted unit specific parameter limit statistics: 2025/2026 Delivery Year

Technology Classification	Units Using Default Parameter Limits	Units with One or More Adjusted Parameter Limits	Percent of Units with One or More Adjusted Parameter Limits
Aero CT	117	37	24.0%
Frame CT	149	106	41.6%
Combined Cycle	94	28	23.0%
Reciprocating Internal Combustion Engines	56	3	5.1%
Solid Fuel NUG	32	6	15.8%
Oil and Gas Steam	10	22	68.8%
Subcritical and Supercritical Coal Steam	7	64	90.1%
Total	465	266	36.4%

Parameter Limited Schedule Exceptions

There are three different types of exceptions to the parameter limited schedule default values: temporary exceptions, period exceptions, and persistent exceptions, each differentiated by the length of time it applies. Market sellers must submit requests for exceptions to PJM and the MMU for approval, along with data and documentation. Valid exceptions must be based on physical operational or contractual limits.[54]

There are no defined consequences for real-time exceptions for units that change their parameters but do not meet the requirements in the tariff. Units that override their turn down ratio (economic maximum divided by economic minimum) either use PJM's fixed gen flag or simply increase their hourly economic minimum.[55] The turn down ratio has a defined parameter limit, but the limit can be evaded by the use of the fixed gen flag. These resources override their output limit parameters with no consequence.

The MMU has proposed that such a unit should not be paid a portion of its capacity market revenues, the daily value for each day, if it fails to include its defined parameter values in its offer (by either using the fixed gen option or increasing their economic minimum). The MMU recommends that PJM require generators to request temporary parameter exceptions for the use of the fixed gen flag. The request process requires generators to demonstrate that the request is based on a physical and actual constraint.

Consistent with the no excuses approach of the capacity performance paradigm and consistent with long term incentives for flexibility, resources that operate with a denied temporary parameter limit exception should not be paid the corresponding portion of the daily capacity value of the resource for days when it is not fully available consistent with its parameter limited schedule. If flexibility is valued as a generator attribute, the market design should not provide incentives to be inflexible. An effective market design should reward flexible operation, and ensure that capacity resources are paid for their capacity only when they meet their required level of flexibility. Without clearly defined consequences, market sellers will continue to submit inflexible parameters. The MMU recommends that resources not be paid the daily capacity payment when unable to operate to their unit specific parameter limits.[56]

Generator Flexibility Incentives in the Capacity Market

In its June 9, 2015, order on capacity performance, the Commission determined that capacity performance resources should be able to submit operating parameters to the market based not just on the resource physical constraints, but also based on other constraints, such as contractual limits.[57] The order primarily addressed limits imposed by natural gas pipelines. The Commission directed PJM to revise its tariff to establish a process through which capacity performance resources that operate outside the defined unit specific parameter limits can justify such operation and therefore remain eligible for make whole payments.[58]

A primary goal of the capacity performance market design is to assign performance risk to generation owners and to ensure that capacity prices reflect underlying supply and demand conditions, including the cost of mitigating the performance risk. The June 9th Order's determination on parameters is not consistent with that goal. By permitting generation owners

58 *Id.* at P 440.

to establish unit parameters based on nonphysical limits, the June 9th Order weakened the incentives for units to be flexible and weakened the assignment of performance risk to generation owners. Contractual limits and the option to choose from a range of gas pipeline tariff provisions, unlike generating unit operational limits, are a function of the interests and incentives of the generators making the choices. If a generation owner expects to be compensated through uplift payments for running for 24 hours regardless of whether the energy is economic or needed, that generation owner has no incentive to pay more to purchase the flexible gas service that would permit the unit to be flexible in response to dispatch.

The approach to parameters defined in the June 9th Order will increase energy market uplift payments substantially. While some uplift is necessary and efficient in an LMP market, this uplift is not. Electric customers are not in a position to determine the terms of the contracts that resources enter into. Customers rely on the market rules to create incentives that protect them by assigning operational risk to generators, who are in the best position to efficiently manage those risks.

The MMU recommends that capacity performance resources be held to the OEM operating parameters of the capacity market reference resource used for the Cost of New Entry (CONE) calculation for performance assessment and energy uplift payments and that this standard be applied to all technologies on a uniform basis. This solution creates the incentives for flexibility and preserves, to the extent possible, the incentives to follow PJM's dispatch instructions during high demand conditions.

Parameter Impacts of Gas Pipeline Conditions

During extreme cold weather conditions, and more recently, also during hot weather conditions, a number of gas fired generators request temporary exceptions to parameter limits for their parameter limited schedules due to restrictions imposed by natural gas pipelines. The parameters affected include notification time, minimum run time (MRT) and turn down ratio (TDR, the ratio of economic maximum MW to economic minimum MW). When pipelines issue critical notices and enforce ratable take requirements, generators may, depending on the nature of the transportation service purchased, be forced to nominate an equal amount of gas for each hour in a 24 hour period, with penalties for deviating from the nominated quantity. This leads to requests for 24 hour minimum run times and turn down ratios close to 1.0, to avoid deviations from the hourly nominated quantity. The frequency of 24 hour minimum run time requests increased after Winter Storm Elliott in December 2022. Table 3-20 shows the number of units, and the installed capacity MW that submitted parameter exception requests for a 24 hour minimum run time due to gas pipeline restrictions. In the first nine months of 2025, there were 93 units in PJM with a total installed capacity of 11,137 MW that requested a 24 hour minimum run time on their parameter limited schedules based on pipeline restrictions.

Table 3-20 Units with 24 hour minimum run times due to gas pipeline restrictions: January 2018 through September 2025

Year	Number of Units With 24 Hour Minimum Run Time Exceptions	Installed Capacity (MW) With 24 Hour Minimun Run Time Exceptions
2018	25	3,627
2019	37	5,616
2020	13	3,873
2021	61	7,514
2022	81	10,019
2023	75	9,824
2024	79	10,476
2025	93	11,137

The increase in units requesting 24 hour minimum run times is a result of pipelines enforcing the pipeline tariff ratable take provisions. Pipelines have the authority to require ratable takes under their tariffs at any time although pipelines do not enforce ratable takes on a routine basis. Some generators have also requested extremely long notification times based on pipeline nomination deadlines. (See Table 3-66.) When pipelines enforce these deadlines, generators cannot obtain gas to flow for a given market hour once the deadline has passed for that hour and therefore they cannot start according to their normal notification plus start times (normally less than 30 minutes). For example, at 1700 EPT, the next nomination cycle is intraday 3 (ID3). The ID3 deadline is 2000 EPT for gas to flow starting at 2300 EPT.

When these nomination deadlines are enforced, at 1700 EPT, a gas unit can only start at 2300 EPT (or in 6 hours). This effectively increases the time to start (notification time plus start time) from 30 minutes to 6 hours. The long notification times make the units unavailable for commitment in ITSCED and the units can only be committed manually in real time. Generators may request temporary exceptions based on pipeline restrictions in order to provide PJM with offers that accurately reflect their capabilities. Units operating inflexibly due to pipeline restrictions are eligible for uplift. Temporary exceptions should be limited to the duration of restrictions imposed by pipelines.

In the first nine months of 2025, PJM paid $147.7 million in day ahead uplift to gas fired units with a 24 hour minimum run time, primarily during the 2025 Polar Vortex. PJM paid an additional $30.9 million in balancing uplift for real-time commitments of units with a 24 hour minimum run time in the first nine months of 2025, with $15.0 million paid to units during the 2025 Polar Vortex.

After observing the misuse of and the failure to use temporary exceptions during Winter Storm Elliott, on September 8, 2023, PJM and the MMU posted guidelines for the correct use of temporary exceptions for pipeline related restrictions. The guidelines detail exactly how units should use temporary exceptions to reflect pipeline restrictions in units' minimum run time, notification time and turn down ratio parameters.[59] During Winter Storm Elliott (December 22-24, 2022), 71 units on average (totaling 8,791 MW) requested temporary exceptions due to pipeline restrictions. During Winter Storm Gerri (January 16-18, 2024), 96 units on average (totaling 13,462 MW) requested temporary exceptions due to pipeline restrictions. During the 2025 Polar Vortex (January 18-23, 2025) 115 units on average (totaling 17,635 MW) requested exceptions due to pipeline restrictions.

The MMU recognizes that pipeline restrictions must be reflected in units' operating parameters in order for PJM to properly schedule and manage the system but it is important to prevent abuse through the submission of inflexible parameters not based on actual constraints. The MMU recommends that PJM only approve temporary exceptions that are based on pipeline tariff terms and/or pipeline notices when actually enforced by the pipelines.

Virtual Offers and Bids

Market participants may make virtual offers and bids in the PJM Day-Ahead Energy Market, and such offers and bids may be marginal.

Any market participant in the PJM Day-Ahead Energy Market may use increment offers, decrement bids, up to congestion transactions, import transactions and export transactions as financial instruments that do not require physical generation or load. Because virtual positions do not require physical generation or load, participants must buy or sell out of their virtual positions at real-time energy market prices. On February 20, 2018, FERC issued an order limiting the eligible bidding points for up to congestion transactions to hubs, interfaces and residual aggregate metered load nodes, and limiting the eligible bidding points for INCs and DECs to the same nodes plus active generation and load nodes.[60] Up to congestion transactions may be submitted between any two aggregates on a list of 46 aggregates eligible for up to congestion transaction bidding.[61] Import and export transactions may be submitted at any interface pricing point, where an import is equivalent to a virtual offer that is injected into PJM and an export is equivalent to a virtual bid that is withdrawn from PJM.

Figure 3-20 shows an example of the PJM day-ahead daily aggregate supply curve of increment offers, the system aggregate supply curve of imports, the system aggregate supply curve without increment offers and imports, the system aggregate supply curve with increment offers, and the system aggregate supply curve with increment offers and imports for an example day in 2025.

59 *See* "Temporary Operating Parameter Limit (PLS) Exceptions due to Pipeline Restrictions" PJM and MMU memorandum to PJM Market Participants (September 8, 2023) <https://www.monitoringanalytics.com/reports/Market_Messages/Messages/IMM_Temporary_Operating_Parameter_Limit_(PLS)_Exceptions_due_to_Pipeline_Restrictions_20230908.pdf>.

60 See 162 FERC ¶ 61,139 (2018), *reh'g denied*, 164 FERC ¶ 61,170 (2018).

61 Prior to November 1, 2012, market participants were required to specify an interface pricing point as the source for imports, an interface pricing point as the sink for exports or an interface pricing point as both the source and sink for transactions wheeling through PJM. For the list of eligible sources and sinks for up to congestion transactions, see www.pjm.com "*OASIS-Source-Sink-Link.xls*,"<http://www.pjm.com/~/media/etools/oasis/references/oasis-source-sink-link.ashx>.

Figure 3-20 Day-ahead aggregate supply curves: 2025 example day

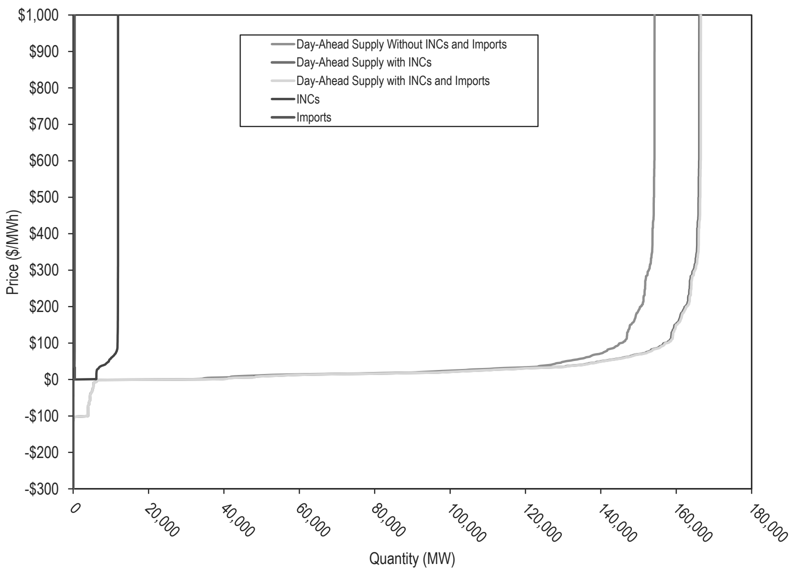

Table 3-21 shows the hourly average number of cleared and submitted increment offers and decrement bids by month in 2024 and the first nine months of 2025.[62] The hourly average submitted increment offer MW increased by 4.6 percent and cleared increment MW increased by 8.4 percent in the first nine months of 2025 compared to the first nine months of 2024. The hourly average submitted decrement bid MW increased by 17.7 percent and cleared decrement MW increased by 2.6 percent in the first nine months of 2025 compared to the first nine months of 2024.

Table 3-21 Average hourly number of cleared and submitted INCs and DECs by month: January 2024 through September 2025

		Increment Offers				Decrement Bids

Table 3-22 shows the average hourly number of up to congestion transactions and the average hourly MW by month in 2024 and the first nine months of 2025. The hourly average submitted up to congestion bid MW decreased by 1.4 percent and cleared up to congestion bid MW decreased by 10.1 percent in the first nine months of 2025 compared to the first nine months of 2024.

62 Table 3-21 uses cleared day-ahead market data while final settlements data is used elsewhere in this report.

Table 3-22 Average hourly cleared and submitted up to congestion bids by month: January 2024 through September 2025

Table 3-23 shows the average hourly number of day-ahead import and export transactions and the average hourly MW in 2024 and the first nine months of 2025.[63] In the first nine months of 2025, the average hourly submitted import transaction MW decreased by 10.9 percent and the average hourly cleared import transaction MW decreased by 11.4 percent compared to the first nine months of 2024. In the first nine months of 2025, the average hourly submitted export transaction MW increased by 16.4 percent and the average hourly cleared export transaction MW increased by 15.9 percent compared to the first nine months of 2024.

Figure 3-21 shows the monthly volume of bid and cleared INC, DEC and up to congestion bids by month from 2005 through September 2025. Cleared volumes were greater in 2023 than any year since 2020, when uplift charges for up to congestion transactions took effect on November 1, 2020. The monthly MW volume of UTC bids in April 2023 was at its highest level since 2017, but decreased significantly beginning May 2023 and has remained stable beginning August 2023 through September 2025.

63 Table 3-23 uses cleared day-ahead market data, while final settlements data is used elsewhere in this report.

Figure 3-21 Monthly bid and cleared INCs, DECs and UTCs (GWh): January 2005 through September 2025

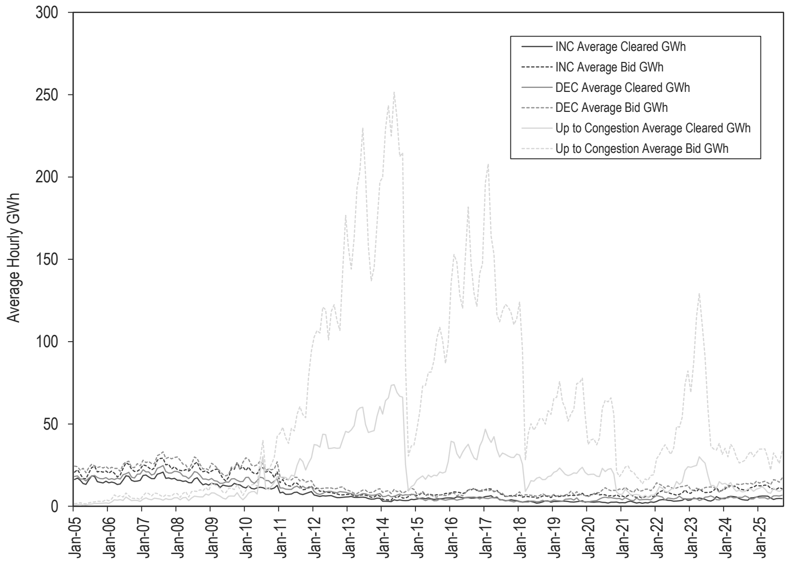

Figure 3-22 shows the daily volume of bid and cleared INC, DEC and up to congestion bids from January 2024 through September 2025.

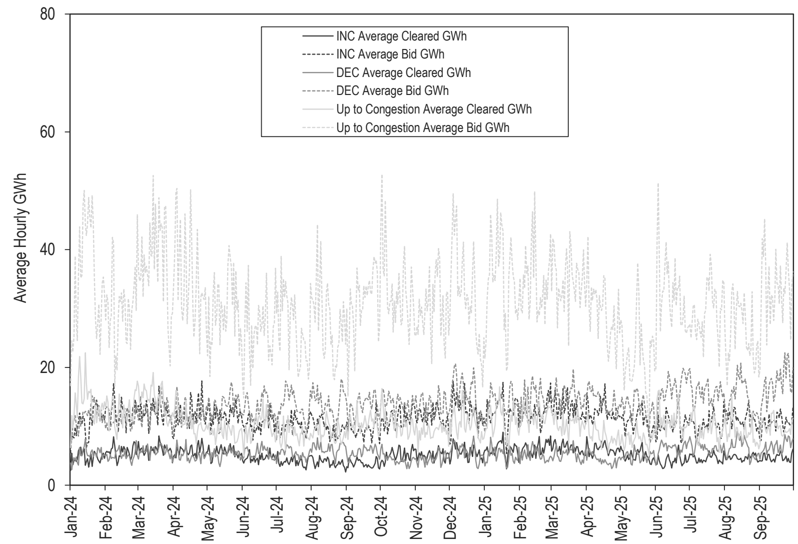
Figure 3-22 Daily bid and cleared INCs, DECs, and UTCs (GWh): January 2024 through September 2025



In order to evaluate the ownership of virtual bids, the MMU categorizes all participants making virtual bids in PJM as either physical or financial at an account level.[64] Physical entities are defined as individual accounts in PJM's settlement systems that take physical positions in PJM markets and typically include utilities and customers. Financial entities are defined as individual accounts in PJM's settlement systems that take financial positions in PJM markets and typically include banks and trading firms. International market participants that primarily take financial positions in PJM markets are generally considered to be financial entities even if they are utilities in their own countries. Financial entities' share of cleared MWh of INCs and DECs in the first nine months of 2025 increased to 97.2 percent from 95.3 percent in the nine months of 2024.

64 The MMU modified the method for categorizing participants as physical and financial participants. See the explanation in the *2025 Quarterly State of the Market Report for PJM: January through March*, Section 13: Financial Transmission Rights at Market Structure (May 8, 2025).

Table 3-24 shows, in the first nine months of 2024 and 2025, the total increment offers and decrement bids and cleared MW by organization type.

Table 3-24 INC and DEC bids and cleared MWh by organization type (MWh): January through September, 2024 and 2025

	2024 (Jan-Sep)				2025 (Jan-Sep)

Table 3-25 shows the total up to congestion bid and cleared MWh by organization type in the first nine months of 2024 and 2025. Up to congestion bids submitted by financial entities decreased in the first nine months of 2025 compared to the first nine months of 2024 from 200.3 million MWh to 196.2 million MWh, while up to congestion bids submitted by physical entities increased from 2.6 million MWh to 3.1 million MWh. Financial entities submitted 97.5 percent of all up to congestion bids, down from 97.8 percent, and cleared 95.2 percent of all up to congestion bids, down from 96.4 percent. In the first nine months of 2025, almost all up to congestion trading activity was by financial participants.

Table 3-27 shows the top 10 locations by total cleared INC and DEC MWh in the first nine months of 2024 and 2025. The top 10 locations included four hubs, four interface pricing points, and two residual metered load aggregates. For generator pnodes not included in the top 10 by the sum of INCs and DECs, DAVISBES25 KV DB10 cleared the most INC volume of 486,147 MWh and REMNTNCT18 KV GT1 with the most DEC volume of 348,822 MWh in the first nine months of 2025.

Table 3-28 shows up to congestion transactions for the top 10 source and sink pairs and associated source, sink and overall profits on each path in the first nine months of 2024 and 2025. Total profits for up to congestion transactions in the first nine months of 2025 were $50.7 million, a 50.4 million increase compared to profits of $0.2 million in the first nine months of 2024.[65] The UTCs from DOMINION HUB to DOM_RESID_AGG constituted 10.7 percent of all UTC cleared volume in the first nine months of 2025, yielding a profit of $19.3 million.

65 The source and sink aggregates in these tables refer to the name and location of a bus and do not include information about the behavior of any individual market participant.
66 The columns "Source Revenue" and "Sink Revenue" are totals before uplift charges are subtracted. The column "UTC Profit" includes uplift charges, in addition to the source and sink revenue, and so is less than the sum of the revenue from each side of the transaction.

Table 3-29 shows the average daily number of distinct source-sink pairs that were offered and cleared each month from January 2024 through September 2025. The average number of submitted source-sink pairs per day increased from 1,212 source-sink pairs submitted in the first nine months of 2024 to 1,507 in the first nine months of 2025. The average number of cleared source-sink pairs per day increased from 907 in the first nine months of 2024 to 1,204 per day in the first nine months of 2025.

Table 3-30 and Figure 3-23 show total cleared up to congestion transactions and the share of the top 10 up to congestion paths by transaction type (import, export, wheel, or internal) in the first nine months of 2024 and 2025. Total cleared up to congestion transactions decreased by 10.4 percent from 72.3 million MWh in the first nine months of 2024 to 64.8 million MWh in the first nine months of 2025. Internal up to congestion transactions in the first nine months of 2025 were 85.0 percent of all up to congestion transactions, an increase from 83.5 percent in the first nine months of 2024.

Table 3-30 Cleared up to congestion transactions and share of top 10 paths by type (MW): January through September, 2024 and 2025

	2024 (Jan-Sep)				
	Cleared Up to Congestion Bids				
	Import	Export	Wheel	Internal	Total
Top ten total (MW)	2,429,265	3,664,188	1,504,309	24,622,166	32,219,929
PJM total (MW)	4,617,138	5,670,164	1,624,775	60,448,950	72,361,028
Top ten total as percent of PJM total	52.6%	64.6%	92.6%	40.7%	44.5%
PJM total as percent of all up to congestion transactions	6.4%	7.8%	2.2%	83.5%	100.0%
	2025 (Jan-Sep)				
	Cleared Up to Congestion Bids				
	Import	Export	Wheel	Internal	Total
Top ten total (MW)	2,714,664	1,563,471	886,913	16,459,605	21,624,653
PJM total (MW)	4,952,707	3,753,697	1,006,894	55,101,521	64,814,819
Top ten total as percent of PJM total	54.8%	41.7%	88.1%	29.9%	33.4%
PJM total as percent of all up to congestion transactions	7.6%	5.8%	1.6%	85.0%	100.0%

Figure 3-23 shows the total volume of import, export, wheel, and internal up to congestion transactions by month from January 2005 through June 2025. An initial increase and continued increase in internal up to congestion transactions by month followed the November 1, 2012, rule change permitting such transactions, until September 8, 2014. The reduction in up to congestion transactions (UTC) that followed a FERC order setting September 8, 2014, as the effective date for any uplift charges subsequently assigned to UTCs, was reversed.[67] There was an increase in up to congestion volume as a result of the expiration of the 15 month refund period for the proceeding related to uplift charges for UTC transactions. In 2018, total UTC activity and the percent of marginal up to congestion transactions again decreased significantly as the result of a FERC order issued on February 20, 2018, and implemented on February 22, 2018.[68] The order limited UTC trading to hubs, residual metered load, and interfaces. UTC activity increased following that reduction.

UTC activity decreased again beginning November 1, 2020, after a FERC order requiring UTCs to pay day-ahead and balancing operating reserve charges equivalent to a DEC at the UTC sink point became effective on that date.[69] In 2022 and the first six months of 2023, the volume of cleared UTCs increased significantly, primarily internal transactions. The volume of cleared UTCs decreased consistently from July 2023 through September 2025.

Figure 3-23 Monthly cleared up to congestion transactions by type (GWh): January 2005 through September 2025

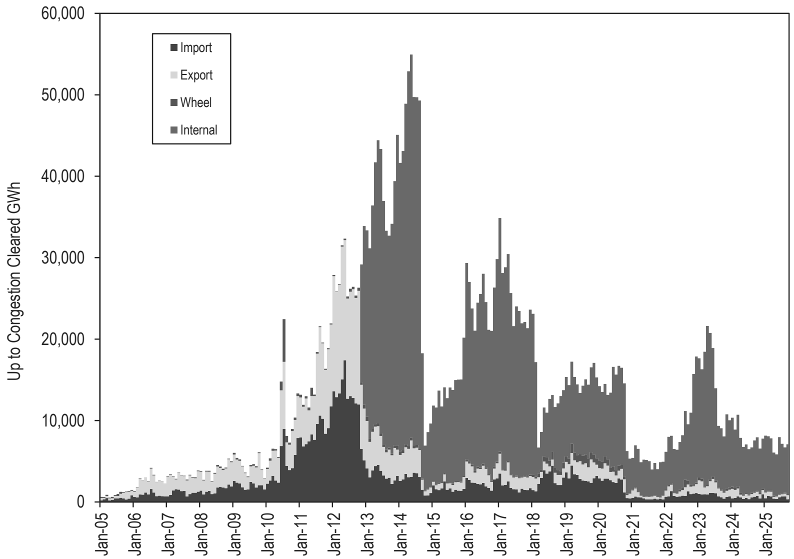

Figure 3-24 shows the daily cleared up to congestion GWh by transaction type from January 1, 2024, through September 30, 2025. In the first nine months of 2025, the total cleared GWh of import, export, and internal up to congestion transactions remained relatively unchanged compared to 2024.

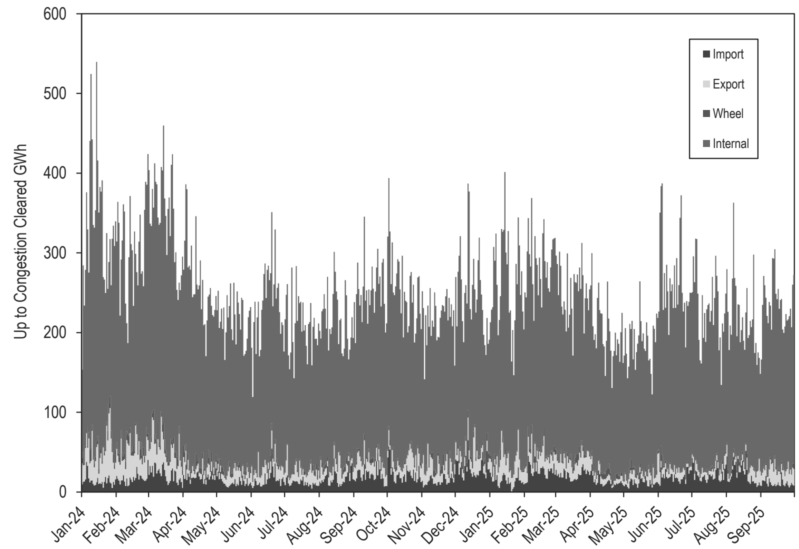
Figure 3-24 Daily cleared up to congestion transaction by type (GWh): January 2024 through September 2025



One of the goals of the February 2018 FERC order accepting PJM's proposal limiting UTC bidding to hubs, interfaces and residual aggregate metered load nodes, and limiting INC and DEC bidding to the same nodes plus active generation nodes, was to limit the opportunities for traders to profit from opportunities for false arbitrage in which price spreads between the day-ahead and real-time energy markets result from differences in the models used to operate each market that cannot be corrected through virtual bidding.[70]

A key assumption underlying the February 2018 order was that the limited set of nodes available for virtual trading is sufficiently protected from false arbitrage trades because price spreads resulting from modeling differences between the day-ahead and real-time markets are mitigated by the averaging

70 PJM Interconnection, LLC, "Proposed Revisions To Reduce Bidding Points for Virtual Transactions," Docket No. ER18-88, October 17, 2017 at 9–10: "Discrepancies between the models can occur for various reasons despite PJM's best attempts to minimize them…Because individual nodes are more highly impacted by modeling discrepancies than aggregated locations due to averaging, they are often locations where Virtual Transactions can profit. Profits collected by Virtual Transactions in these cases lead to additional costs for PJM members without any benefits."

of prices over a large number of buses at aggregate nodes.[71] This assumption is not correct, given the large share of INC, DEC, and UTC profits still attributable to modeling or operational differences between day-ahead and real-time models since the February 2018 order.

The assumption that modeling differences are averaged out over the multiple individual nodes included in aggregate nodes does not hold for multiple aggregate nodes in the current list of available up to congestion bidding nodes. The MMU recommends eliminating up to congestion (UTC) bidding at pricing nodes that aggregate only small sections of transmission zones with few physical assets. For example, the MMU recommends eliminating UTC bidding at the following pricing points: DPLEASTON_RESID_AGG, PENNPOWER_RESID_AGG, UGI_RESID_AGG, SMECO_RESID_AGG, AEPKY_RESID_AGG, and VINELAND_RESID_AGG.

Prices at larger aggregate nodes can also be affected by transmission constraints, especially when the line ratings on constraints are violated and transmission penalty factors are applied in the real-time energy market. This occurs both when line ratings are actually violated and when PJM operators reduce the line ratings in SCED. Even when the same constraints are modeled in day ahead and real time, constraint violations in real time may result from differences in the day-ahead and real-time operational environments such as intra hourly ramping limitations, changes to constraint limits, and unit commitments and decommitments. Price spreads due to modeling or operational differences can be significant, even when averaged over an aggregate node, and may persist for days or weeks. Virtual traders can often identify and profit from price spreads resulting from systematic modeling and operational differences between day-ahead and real-time affecting specific generators or aggregate nodes. The MMU recommends eliminating INC, DEC, and UTC bidding at pricing nodes that allow market participants to profit from modeling issues.

71 See 162 FERC ¶ 61,139 at PP 35–36 ("We accept PJM's proposal to limit eligible bidding points for UTCs to hubs, residual metered load, and interfaces. First, we agree with the IMM's statement that PJM's proposal to limit the UTC bid locations to interfaces, zones, and hubs will minimize false arbitrage opportunities for UTCs currently being pursued through penny bids, as the effect of modeling differences between the day-ahead and real-time markets are minimized at these aggregates.").

Market Performance

PJM locational marginal prices (LMPs) are a direct measure of market performance. The market performs optimally when the market structure provides incentives for market participants to behave competitively. In a competitive market, prices equal the short run marginal cost of the marginal unit of output and reflect the most efficient and least cost allocation of resources to meet demand.

LMP

The behavior of individual market entities within a market structure is reflected in market prices. PJM locational marginal prices (LMPs) are a direct measure of market performance. Price level is a good, general indicator of market performance, although overall price results must be interpreted carefully because of the multiple factors that affect them. Among other things, overall average prices reflect changes in supply and demand, generation fuel mix, the cost of fuel, emission related expenses, markup and local price differences caused by congestion. PJM also may administratively set prices with shortage pricing, the creation of closed loop interfaces related to demand side resources, surrogate constraints for reactive power and generator stability, or influence prices through manual interventions such as load biasing, changing constraint limits and transmission constraint penalty factors, and committing reserves beyond the requirement, or change price formation through fast start pricing.

The real-time average LMP in the first nine months of 2025 increased $14.57 per MWh, or 46.2 percent, from the first nine months of 2024, from $31.50 per MWh to $46.05 per MWh. The real-time load-weighted average LMP in the first nine months of 2025 increased $16.20 per MWh, or 47.2 percent from the first nine months of 2024, from $34.31 per MWh to $50.51 per MWh.

The costs of fuel, emissions, and consumables, fundamental components of the real-time load-weighted average LMP, increased $9.85 per MWh from $19.75 per MWh in the first nine months of 2024 to $29.59 per MWh in the first nine months of 2025, or 60.8 percent of the increase in real-time load-weighted average LMP.

The day-ahead average LMP for the first nine months of 2025 increased $14.60 per MWh, or 47.0 percent from the first nine months of 2024, from $31.09 per MWh to $45.69 per MWh. The day-ahead load-weighted average LMP for the first nine months of 2025 increased $16.03 or 47.4 percent from the first nine months of 2024, from $33.85 per MWh to $49.88 per MWh.

Occasionally, in a constrained market, the LMPs at some pricing nodes can exceed the offer price of the highest cleared generator in the supply curve.[72] In the nodal pricing system, the LMP at a pricing node is the total cost of meeting incremental demand at that node. When there are binding transmission constraints, satisfying the marginal increase in demand at a node may require increasing the output of some generators while simultaneously decreasing the output of other generators, to ensure that the transmission constraints are not violated. The total cost of redispatching multiple generators can at times exceed the cost of marginally increasing the output of the most expensive generator offered. Thus, the LMPs at some pricing nodes exceed $1,000 per MWh, the cap on the generators' offer price in the PJM market.[73]

LMP may, at times, be set by administratively defined transmission constraint penalty factors, which equal a default level of $30,000 per MWh in the day-ahead market dispatch run and $2,000 per MWh in the real-time market and in the day-ahead market pricing run. When a transmission constraint is binding and there are no generation alternatives to resolve the constraint, the transmission limits may be violated in the market dispatch solution. When this occurs, the shadow price of the constraint is set by transmission constraint penalty factors. The shadow price directly affects the LMP. Transmission constraint penalty factors are administratively determined and can be thought of as a form of locational scarcity pricing. However, PJM operator interventions to reduce the control limits on transmission constraint line ratings used in the market clearing unnecessarily trigger transmission constraint penalty factors and significantly increase prices. A competitive market does not require that prices increase when PJM artificially triggers transmission constraint penalty factors.

72 See O'Neill R. P, Mead D. and Malvadkar P. "On Market Clearing Prices Higher than the Highest Bid and Other Almost Paranormal Phenomena." *The Electricity Journal* 2005; 18(2) at 19–27.

73 The offer cap in PJM was temporarily increased to $1,800 per MWh prior to the winter of 2014/2015. A new cap of $2,000 per MWh, only for offers with costs exceeding $1,000 per MWh, went into effect on December 14, 2015. See 153 FERC ¶ 61,289 (2015).

Fast Start Pricing: DLMP and PLMP

PJM implemented fast start pricing in both the day-ahead and real-time markets on September 1, 2021. Fast start pricing is based on an incorrect LMP calculation called the pricing run. The pricing run LMP (PLMP) is the official settlement LMP in PJM, replacing the dispatch run LMP (DLMP). Unless otherwise specified, the LMP tables and figures show the PLMP for September 1, 2021, and after.

The pricing run calculates LMP using the same optimal power flow algorithm as the dispatch run while simultaneously ignoring (relaxing) the economic minimum and maximum output MW constraints for all eligible fast start units. Fast start units must have notification time plus start time less than or equal to one hour; minimum run time less than or equal to one hour; and can set price only when online and running for PJM, not self scheduled.

The goal of fast start pricing is to allow inflexible resources to set prices based on the sum of their commitment costs per MWh and their marginal costs. The price signal no longer equals the short run marginal cost and therefore no longer provides the correct signal for efficient behavior for market participants making decisions on the margin, whether resources, load, interchange transactions, or virtual traders. Units that start in one hour are not actually fast start units, and their commitment costs are not marginal in a five minute market. The differences between the actual LMP and the fast start LMP distort the incentive for market participants to behave competitively and to follow PJM's dispatch instructions. PJM is paying new forms of uplift in an attempt to counter the distorted incentives inherent in fast start pricing.

PJM has also introduced other differences between the dispatch run and pricing run that are not related to fast start pricing. For example, in the day-ahead market, PJM uses a default $30,000 per MWh transmission constraint penalty factor in the dispatch run and a $2,000 per MWh transmission constraint penalty factor in the pricing run. Starting on October 1, 2022, PJM uses capping of the system marginal price only in the pricing run, which affected real-time market prices during Winter Storm Elliott in December 2022. On June 24, PJM capped the energy LMP in the pricing run at $3,700 per MWh for two five minute intervals in the hour beginning at 1800 and one five minute interval in the hour beginning at 1900. This system marginal price (SMP) capping process has not been reviewed by FERC or included in the PJM Operating Agreement.

DLMP and PLMP

Table 3-31 shows the day-ahead and real-time monthly load-weighted average PLMP and DLMP in 2024 and the first nine months of 2025.

The real-time load-weighted average PLMP was $50.51 per MWh for the first nine months of 2025, which is 9.0 percent, $4.17 per MWh, higher than the real-time load-weighted average DLMP of $46.34 per MWh.

The day-ahead load-weighted average PLMP was $49.88 per MWh for the first nine months of 2025, which is 0.1 percent, $0.07 per MWh, higher than the day-ahead load-weighted average DLMP of $49.81 per MWh.

Table 3-31 Day-ahead and real-time load-weighted average DLMP and PLMP: 2024 through September 2025

		Day-Ahead Load-Weighted Average				Real-Time Load-Weighted Average			
Year	Month	DLMP	PLMP	Difference	Percent Difference	DLMP	PLMP	Difference	Percent Difference

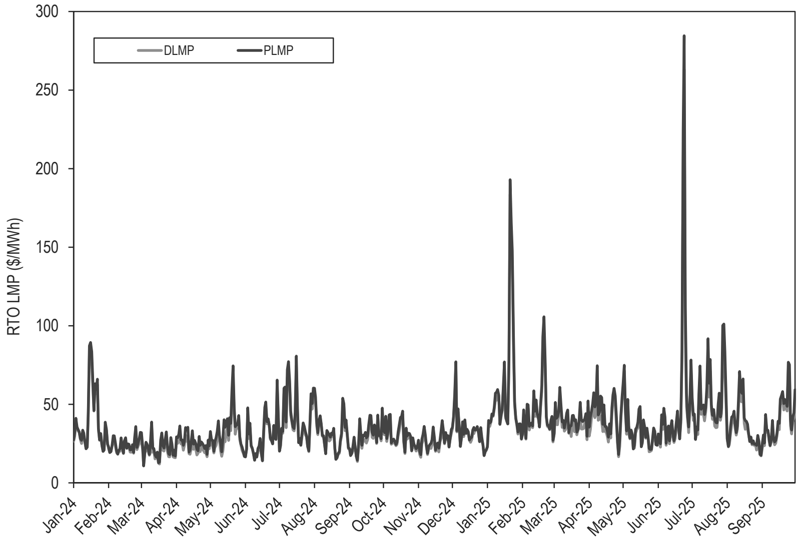
Figure 3-25 shows the real-time daily average DLMP and PLMP in 2024 through September 2025.

Figure 3-25 Real-time daily average DLMP and PLMP: 2024 through September 2025



Fast start pricing created a larger difference between DLMP and PLMP in real time than in day ahead. Figure 3-26 shows the hourly difference between DLMP and PLMP in day-ahead and real-time for the first nine months of 2025.

The large differences between DA DLMP and PLMP on January 20, 2025, were caused by the higher transmission constraint penalty factors in the day-ahead dispatch run. In the dispatch run, the penalty factor was set at $30,000, while in the pricing run the penalty factor was set at $2,000.

The large differences between RT DLMP and PLMP on June 24, 2025, occurred when the energy component of the pricing run LMP was administratively set at $3,500 per MWh.

Figure 3-26 Hourly difference between DLMP and PLMP for day-ahead and real-time: January through September, 2025

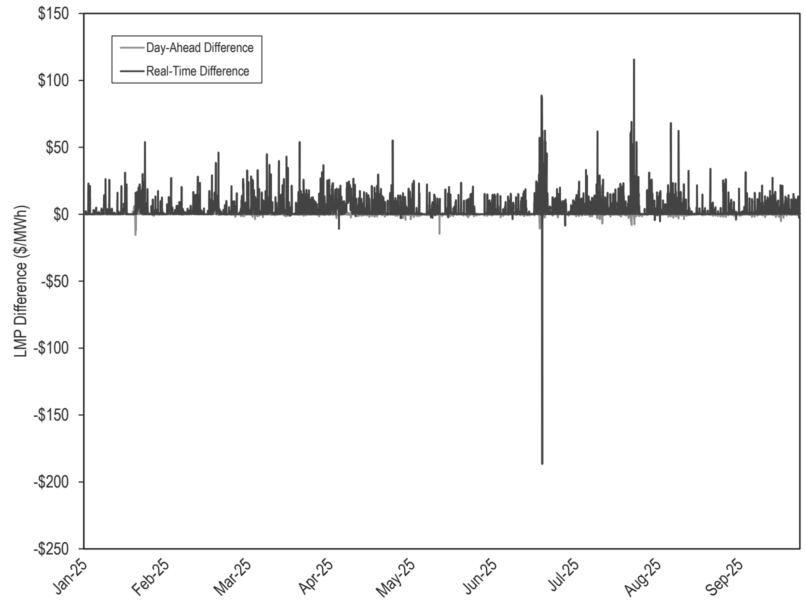


Figure 3-27 shows the hourly average load and LMP difference by hour of the day for the first nine months of 2025. The PLMP minus DLMP difference is largest at the times of the morning and evening peak loads.

Figure 3-27 Hourly average load and LMP difference: January through September, 2025

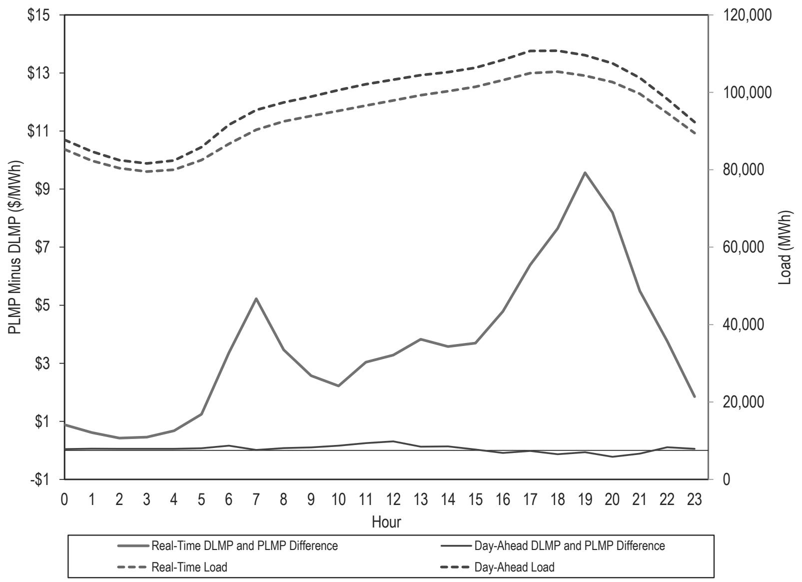

Table 3-32 shows the percent of total marginal units that are fast start units by unit type in 2024 and the first nine months of 2025. While wind units are defined as fast start units, a wind unit on the margin does not result in a higher PLMP than DLMP when the unit has no commitment costs.

Table 3-32 Fast start units as a percent of real-time marginal units: 2024 through September 2025

		Dispatch Run				Pricing Run			
Year	Month	CT	Diesel	Wind	All Fast Start Units	CT	Diesel	Wind	All Fast Start Units
2024	Jan	0.7%	0.6%	0.0%	1.3%	3.5%	1.1%	0.0%	4.7%
2024	Feb	0.4%	0.1%	0.1%	0.5%	2.2%	0.1%	0.1%	2.4%

2025	Sep	1.2%	0.4%	0.0%	1.6%	5.7%	1.2%	0.0%	6.9%
2025	Jan - Sep	1.4%	1.0%	0.1%	2.6%	5.9%	1.8%	0.1%	7.9%

Table 3-33 shows the difference between day-ahead and real-time zonal average DLMP and PLMP for the first nine months of 2025.

Fast start pricing affects some zones more than others. The average increase in real-time prices in BGE was $4.53 per MWh, 8.9 percent, while the average increase in real-time prices in PECO was $2.83 per MWh, 7.8 percent.

Table 3-33 Day-ahead and real-time zonal average DLMP and PLMP (Dollars per MWh): January through September, 2025

	2025 (Jan-Sep)							
	Day-Ahead				Real-Time			
Zone	Average DLMP	Average PLMP	Difference	Percent Difference	Average DLMP	Average PLMP	Difference	Percent Difference
ACEC	$40.68	$40.75	$0.07	0.2%	$37.41	$40.34	$2.93	7.8%

Real-Time Average LMP

Real-time average LMP is the hourly average LMP for the PJM Real-Time Energy Market.[74]

PJM Real-Time Average LMP

Table 3-36 shows the real-time average LMP for the first nine months of 1998 through 2025.[75] The real-time average LMP in the first nine months of 2025 increased $14.57 per MWh, or 46.2 percent, from the first nine months of 2024, from $31.50 per MWh to $46.05 per MWh.

Table 3-36 Real-time average LMP (Dollars per MWh): January through September, 1998 through 2025

	Real-Time LMP			Year to Year Change			
Jan-Sep	Average	Median	Standard Deviation	Average	Average Percent	Median	Standard Deviation
1998	$23.18	$16.86	$36.00	NA	NA	NA	NA

2006	$51.79	$43.50	$34.93	($2.90)	(5.3%)	(2.3%)	3.7%
2007	$57.34	$49.40	$35.52	$5.55	10.7%	13.6%	1.7%
2008	$71.94	$61.33	$41.64	$14.59	25.4%	24.2%	17.2%
2009	$37.42	$33.00	$17.92	($34.51)	(48.0%)	(46.2%)	(57.0%)
2010	$46.13	$37.89	$26.99	$8.70	23.3%	14.8%	50.6%
2011	$45.79	$37.05	$32.25	($0.33)	(0.7%)	(2.2%)	19.5%
2012	$32.45	$28.78	$21.94	($13.34)	(29.1%)	(22.3%)	(32.0%)
2013	$37.30	$32.44	$22.84	$4.85	15.0%	12.7%	4.1%
2014	$52.72	$36.06	$74.17	$15.42	41.3%	11.2%	224.8%
2015	$35.96	$27.88	$30.75	($16.76)	(31.8%)	(22.7%)	(58.5%)
2016	$27.43	$23.61	$15.73	($8.53)	(23.7%)	(15.3%)	(48.8%)
2017	$28.79	$25.28	$16.81	$1.36	5.0%	7.1%	6.9%
2018	$36.52	$27.26	$33.22	$7.73	26.8%	7.8%	97.6%
2019	$26.30	$23.39	$17.69	($10.22)	(28.0%)	(14.2%)	(46.8%)
2020	$19.95	$17.87	$10.48	($6.34)	(24.1%)	(23.6%)	(40.7%)
2021	$33.49	$26.82	$24.08	$13.54	67.9%	50.1%	129.8%
2022	$72.57	$59.66	$59.73	$39.08	116.7%	122.4%	148.0%
2023	$29.29	$25.56	$18.21	($43.28)	(59.6%)	(57.2%)	(69.5%)
2024	$31.50	$24.73	$26.35	$2.21	7.6%	(3.2%)	44.7%
2025	$46.07	$34.73	$53.62	$14.57	46.2%	40.5%	103.5%

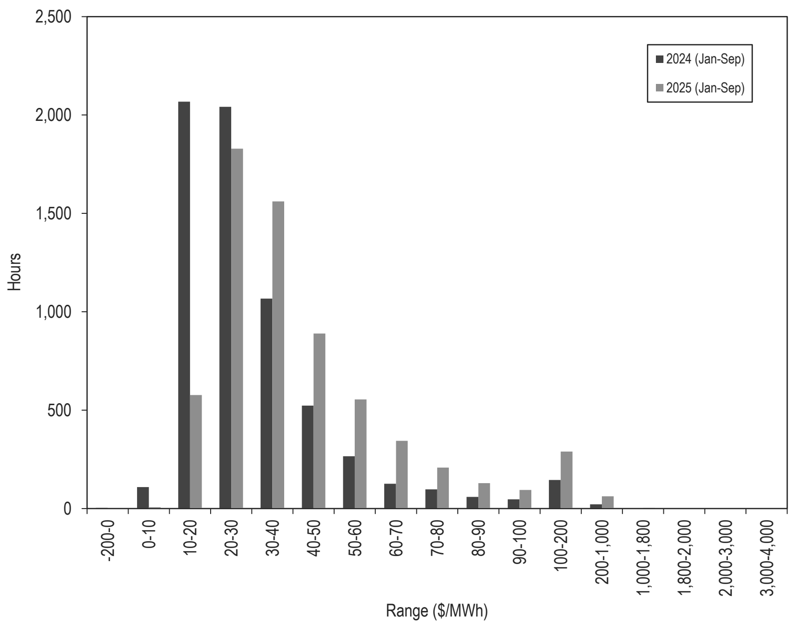
74 See the *Technical Reference for PJM Markets*, at "Calculating Locational Marginal Price," p 16-18 for detailed definition of Real-Time LMP. <http://www.monitoringanalytics.com/reports/Technical_References/references.shtml>.

75 The system average LMP is the average of the hourly LMP without any weighting. The only exception is that market-clearing prices (MCPs) are included for January to April 1998. MCP was the single market-clearing price calculated by PJM prior to implementation of LMP.

PJM Real-Time Average LMP Duration

Figure 3-28 shows the hourly distribution of the real-time average LMP in the first nine months of 2024 and 2025. In the first nine months of 2024, the most common price range was $10 to $20 per MWh. In the first nine months of 2025, the most common price range was $20 to $30 per MWh.

Figure 3-28 Distribution of real-time LMP: January through September, 2024 and 2025



Real-Time Load-Weighted Average LMP

Higher demand generally results in higher prices, all else constant. As a result, load-weighted, average prices are generally higher than average prices. Load-weighted average LMP reflects the average real-time LMP paid for actual MWh consumed during a year. Load-weighted average LMP is the average of PJM hourly LMP, with each hourly LMP weighted by the PJM total hourly load.

PJM Real-Time Load-Weighted Average LMP

Table 3-37 shows the real-time load-weighted average LMP for the first nine months of 1998 through 2025. The real-time load-weighted average LMP in the first nine months of 2025 increased $16.20 per MWh, or 47.2 percent from the first nine months of 2024, from $34.31 per MWh to $50.51 per MWh.

Table 3-37 Real-time load-weighted average LMP (Dollars per MWh): January through September, 1998 through 2025

	Real-Time Load-Weighted Average LMP			Year to Year Change

	Load-Weighted Average LMP	Inflation Adjusted Load-Weighted Average LMP
	Jan-Sep	Jan-Sep
1998	$26.06	$25.86
1999	$38.65	$37.55
2000	$28.49	$26.82
2001	$40.96	$37.39
2002	$31.95	$28.72
2003	$43.57	$38.33
2004	$46.44	$39.85
2005	$60.44	$50.09
2006	$56.39	$45.16
2007	$61.83	$48.36
2008	$77.27	$57.70
2009	$39.57	$29.93
2010	$49.91	$37.04
2011	$49.48	$35.59
2012	$35.02	$24.68
2013	$39.75	$27.58
2014	$58.60	$40.11
2015	$38.94	$26.60
2016	$29.32	$19.77
2017	$30.36	$20.05
2018	$39.43	$25.45
2019	$27.60	$17.49
2020	$21.22	$13.27
2021	$35.68	$21.39
2022	$77.84	$43.04
2023	$30.87	$16.41
2024	$34.31	$17.71
2025	$50.51	$25.40

Real-Time Dispatch and Pricing

On November 1, 2021, PJM implemented a new real-time dispatch process that aligned the timing of dispatch and pricing in the real-time energy market. The PJM Real-Time Energy Market is based on applications that produce the generator dispatch for energy and reserves, and five minute locational marginal prices (LMPs). These applications include the real-time security constrained economic dispatch (RT SCED), the locational pricing calculator (LPC), and the ancillary services optimizer (ASO).[77] The final real-time LMPs and ancillary service clearing prices are determined for every five minute interval by LPC.

77 See PJM. "Manual 11: Energy & Ancillary Services Market Operations," Rev. 133 (Dec. 17, 2024).

Real-Time SCED and LPC

The LPC uses data from an approved RT SCED solution that was used to dispatch the resources in the system. RT SCED solves to meet load and reserve requirements forecast for a future point in time, called the target time. Prior to 2021, on average, PJM operators approved more than one RT SCED solution per five minute target time to send dispatch signals to resources. From January 2021 through September 2025, on average, PJM operators approved one RT SCED solution per five minute target time to send dispatch signals to resources. PJM uses a subset of these approved RT SCED solutions in LPC to calculate real-time LMPs every five minutes. Prior to October 15, 2020, LPC used the latest available approved RT SCED solution to calculate prices, regardless of the target dispatch time of the RT SCED solution, but LPC assigned the prices to a five minute interval that did not contain the target time of the RT SCED case it used. On November 1, 2021, PJM implemented changes to RT SCED that solved the energy dispatch case using a five-minute dispatch period, and ramped resources for five minutes to meet the load and reserve requirements at the end of each five minute period. The approved RT SCED solution that dispatched units for each five minute period was also used to calculate prices for the same five minute interval, aligning the prices with the dispatch signals.

Table 3-40 shows the number of RT SCED case solutions, the number of solutions that were approved, and the number and percent of approved solutions used in LPC. The RT SCED execution frequency is once every five minutes. PJM operators have the ability to execute additional RT SCED cases. Each execution of RT SCED produces five solutions, using five different levels of load bias. Since prices are calculated every five minutes while five SCED solutions are produced every five minutes, there is, by definition, a larger number of SCED solutions than there are five minute intervals in any given period.

Table 3-40 shows that in the first nine months of 2025, 97.8 percent of approved RT SCED solutions that were used to send dispatch signals to generators were used in calculating real-time energy market prices, compared to 97.2 percent in all of 2024.

Table 3-40 RT SCED cases solved, approved and used in pricing: January 2024 through September 2025

	2024				2025			
Month	Number of RT SCED Solutions	Number of Approved RT SCED Solutions	Number of Approved RT SCED Solutions Used in LPC	RT SCED Solutions Used in LPC as Percent of Approved RT SCED Solutions	Number of RT SCED Solutions	Number of Approved RT SCED Solutions	Number of Approved RT SCED Solutions Used in LPC	RT SCED Solutions Used in LPC as Percent of Approved RT SCED Solutions

Recalculation of Five Minute Real-Time Prices

PJM's five minute interval LMPs are obtained from solved LPC cases. PJM recalculates five minute interval real-time LMPs as it believes necessary to correct errors. To do so, PJM reruns LPC cases with modified inputs. The PJM OATT allows for posting of recalculated real-time prices no later than 1700 (EPT) of the tenth calendar day following the operating day. The OATT also requires PJM to notify market participants of the underlying error no later than 1700 (EPT) of the second business day following the operating day.[78] Table 3-41 shows the number of five minute intervals in each month and number of five minute intervals in each month for which PJM recalculated real-time prices in 2024 and the first nine months of 2025. In the first nine months of 2025, PJM recalculated LMPs for 1,926 five minute intervals or 2.45 percent of the total 78,612 five minute intervals.

78 OA Attachment K Section 1 § 1.10.8(e).

Day-Ahead Average LMP

Day-ahead average LMP is the hourly average LMP for the PJM Day-Ahead Energy Market.[79]

PJM Day-Ahead Average LMP

Table 3-42 shows the day-ahead average LMP for the first nine months of 2001 through 2025. The day-ahead average LMP for the first nine months of 2025 increased $14.60 per MWh, or 47.0 percent from the first nine months of 2024, from $31.09 per MWh to $45.69 per MWh.

Table 3-42 Day-ahead average LMP (Dollars per MWh): January through September, 2001 to 2025

	Day-Ahead LMP			Year to Year Change			
Jan-Sep	Average	Median	Standard Deviation	Average	Average Percent	Median	Standard Deviation
2001	$36.07	$30.02	$34.25	NA	NA	NA	NA
2002	$28.29	$22.54	$19.09	($7.78)	(21.6%)	(24.9%)	(44.3%)
2003	$41.20	$38.24	$22.02	$12.91	45.6%	69.7%	15.4%
2004	$42.64	$42.07	$17.47	$1.44	3.5%	10.0%	(20.7%)
2005	$54.48	$46.67	$28.83	$11.85	27.8%	10.9%	65.1%

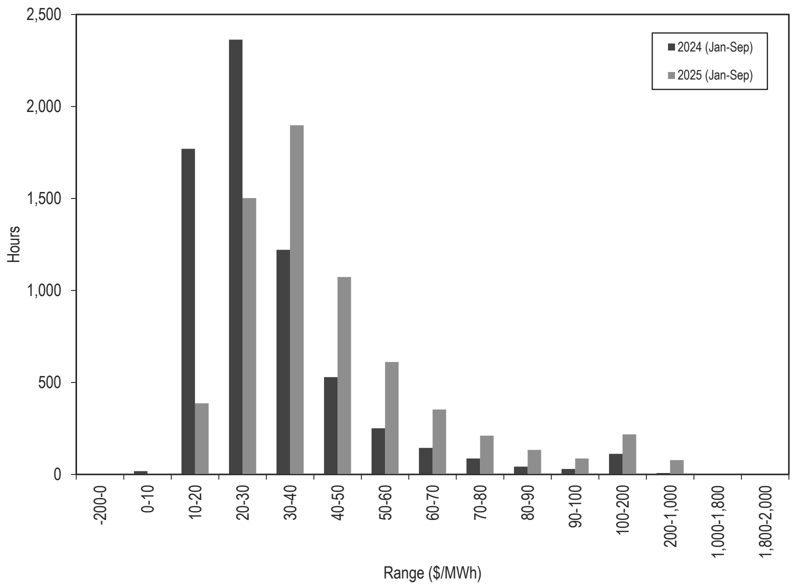
2023	$30.10	$27.83	$15.28	($42.26)	(58.4%)	(56.2%)	(54.8%)
2024	$31.09	$25.71	$21.00	$0.99	3.3%	(7.6%)	37.5%
2025	$45.69	$36.75	$35.12	$14.60	47.0%	42.9%	67.2%

79 See the *MMU Technical Reference for the PJM Markets*, at "Calculating Locational Marginal Price," for a detailed definition of day-ahead LMP. <http://www.monitoringanalytics.com/reports/Technical_References/references.shtml>.

PJM Day-Ahead Average LMP Duration

Figure 3-32 shows the hourly distribution of the day-ahead average LMP for the first nine months of 2024 and 2025.

Figure 3-32 Distribution of day-ahead LMP: January through September, 2024 and 2025



Day-Ahead Load-Weighted Average LMP

Day-ahead load-weighted LMP reflects the average LMP paid for day-ahead MWh. Day-ahead load-weighted LMP is the average of PJM day-ahead hourly LMP, each hourly LMP weighted by the PJM total cleared day-ahead, hourly load, including day-ahead fixed load, price-sensitive load, decrement bids and up to congestion.

PJM Day-Ahead Load-Weighted Average LMP

Table 3-43 shows the day-ahead load-weighted average LMP for the first nine months of 2001 through 2025. The day-ahead load-weighted average LMP for the first nine months of 2025 increased $16.03 or 47.4 percent from the first nine months of 2024, from $33.85 per MWh to $49.88 per MWh.

Table 3-43 Day-ahead load-weighted average LMP (Dollars per MWh): January through September, 2001 to 2025

	Day-Ahead Load-Weighted Average LMP			Year to Year Change			
Jan-Sep	Average	Median	Standard Deviation	Average	Average Percent	Median	Standard Deviation
2001	$39.88	$32.68	$42.01	NA	NA	NA	NA
2002	$32.29	$25.22	$22.81	($7.59)	(19.0%)	(22.8%)	(45.7%)
2003	$44.11	$41.51	$22.34	$11.82	36.6%	64.6%	(2.1%)
2004	$44.59	$44.47	$17.40	$0.49	1.1%	7.1%	(22.1%)
2005	$59.51	$51.33	$31.13	$14.92	33.5%	15.4%	78.9%

2025	$49.88	$25.09

Price Convergence

The introduction of the PJM Day-Ahead Energy Market with virtuals as part of the design created the possibility that competition, exercised through the use of virtual offers and bids, could tend to cause prices in the day-ahead and real-time energy markets to converge more than would be the case without virtuals. Convergence is not the goal of virtual trading, but it is a possible outcome.

80 To obtain the inflation adjusted monthly load-weighted average LMP, the PJM system-wide load-weighted average LMP is deflated using US Consumer Price Index for all items, Urban Consumers (base period: January 1998), published by *Bureau of Labor Statistics*. <http://download.bls.gov/pub/time.series/cu/cu.data.1.AllItems> (Accessed October24, 2025).

In practice, virtuals can receive a positive profit whenever there is a difference in prices at any location in any hour between the day-ahead and real-time energy markets that is greater than uplift and administrative charges.

Virtual trading can only result in price convergence at a given location and market hour if the factors affecting prices at that location and hour, such as modeled contingencies, transmission constraint limits and sources of flows, are the same in both the day-ahead and real-time models.

Where arbitrage incentives are created by systematic modeling differences, such as differences between the day-ahead and real-time modeled transmission contingencies and marginal loss calculations, virtual bids and offers cannot result in more efficient market outcomes. Such offers may result in positive profits for the virtual but cannot change the underlying reason for the price difference. The virtual transactions will continue to profit from the activity for that reason regardless of the volume of those transactions and without improving the efficiency of the energy market. This is termed false arbitrage.

The degree of convergence, by itself, is not a measure of the competitiveness or effectiveness of the day-ahead energy market. Price convergence does not necessarily mean a zero or even a very small difference in prices between day-ahead and real-time energy markets. There may be factors, from uplift charges to differences in risk that result in a competitive, market-based differential. In addition, convergence in the sense that day-ahead and real-time prices are equal at individual buses or aggregates on a day to day basis is not a realistic expectation as a result of uncertainty, lags in response time and modeling differences.

INCs, DECs and UTCs allow participants to benefit from price differences between the day-ahead and real-time energy market. In theory, virtual transactions receive positive profits, after uplift and administrative charges, when they contribute to price convergence, but with false arbitrage, profits result with little or no price convergence. The seller of an INC must buy energy in the real-time energy market to fulfill the financial obligation to provide energy. If the day-ahead price for energy is higher than the real-time price for energy, after uplift and administrative charges, the INC is profitable. The buyer of a DEC must sell energy in the real-time energy market to fulfill the financial obligation to buy energy. If the day-ahead price for energy is lower than the real-time price for energy, after uplift and administrative charges, the DEC is profitable.

The profit of a UTC transaction is the net of the separate revenues of the component INC and DEC, after uplift and administrative charges. A UTC can be profitable if the profits on one side of the UTC transaction exceed the losses on the other side.

Virtual transactions, including UTCs since November 1, 2020, are required to pay uplift charges. Cleared INCs and DECs pay deviation charges based on the daily RTO and applicable regional operating reserve charge rates. DECs pay day-ahead operating reserve charges in addition to deviation charges. Cleared UTCs are treated, for uplift purposes, like DECs at the UTC sink point, and pay the regional and RTO deviation rates in addition to the day-ahead rate. Uplift charges for deviations may not apply if the virtual transaction is partially or fully offset by a corresponding real-time physical transaction at the same location.

In the day-ahead market, load bids are submitted by market buyers at aggregate pnodes, and PJM uses historic bus level load data to distribute the aggregate bids among the bus level pnodes that comprise the aggregate pnode. Effective December 14, 2023, PJM modified the method used to assign load bids to nodes from a single snapshot at 8:00 AM the week prior to the hourly demand data from one week prior to the Operating Day for each hour.[81]

Profitability of Virtual Transactions

The profit of a virtual transaction equals its net day-ahead and real-time energy market revenues minus uplift and administrative charges.

Table 3-45 shows, for cleared UTCs, the number of UTCs, the number of profitable UTCs, and the number of UTCs profitable at their source point, at their sink point, and at both source and sink points in the first nine months of 2024 and 2025. In the first nine months of 2025, 40.5 percent of all cleared

81 PJM Interconnection, L.L.C., Tariff Revisions to Improve the Determination of Day-Ahead Zonal Load Factors, Docket No. ER23-1529 (March 31, 2023).

UTC transactions were profitable. Of cleared UTC transactions, 62.7 percent were profitable on the source side and 35.1 percent were profitable on the sink side, but only 8.0 percent were profitable on both the source and sink side.

Table 3-45 Cleared UTCs with positive profits at source and sink points: January through September, 2024 and 2025[82]

(Jan-Sep)	Number of Cleared UTCs	Number of Profitable UTCs	Profitable at Source	Profitable at Sink	Profitable at Source and Sink	Share Profitable Overall	Share Profitable Source	Share Profitable Sink	Shar Sour
2024	4,486,499	1,780,160	2,732,000	1,674,097	345,697	39.7%	60.9%	37.3%	
2025	4,857,966	1,965,649	3,047,662	1,707,480	388,714	40.5%	62.7%	35.1%	

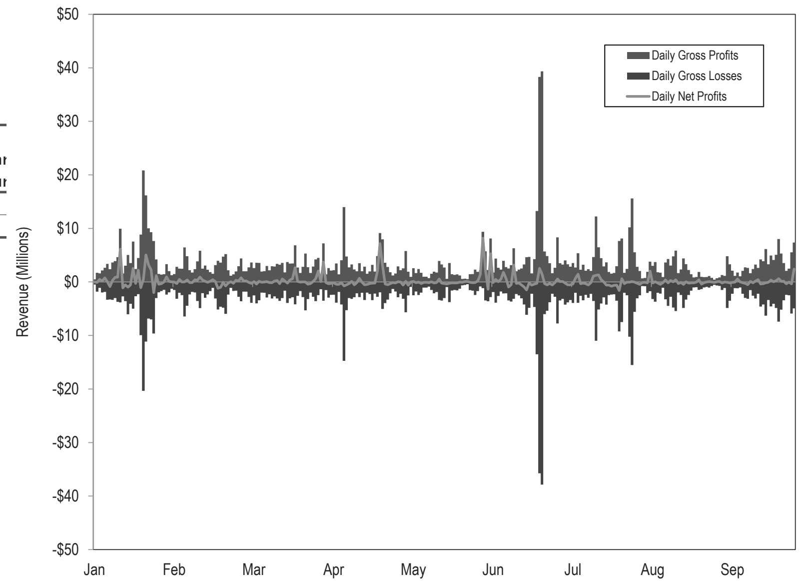
Table 3-46 shows the number of cleared INC and DEC transactions and the number of profitable transactions in the first nine months of 2024 and 2025. Of cleared INC and DEC transactions in the first nine months of 2025, 51.7 percent of INCs were profitable and 30.9 percent of DECs were profitable.

Table 3-46 Cleared INC and DEC transactions with positive profits: January through September, 2024 and 2025

(Jan-Sep)	Cleared INC	Profitable INC	Profitable INC Share	Cleared DEC	Profitable DEC	Profitable DEC Share
2024	2,794,484	1,422,401	50.9%	2,505,187	794,620	31.7%
2025	3,480,378	1,798,995	51.7%	3,253,797	1,006,376	30.9%

Figure 3-36 shows the positive, negative, and net daily profits for UTCs in the first nine months of 2025.

Figure 3-36 Positive, negative, and net daily UTC profits: January through September, 2025



82 Calculations exclude PJM administrative charges.

Figure 3-37 shows the cumulative UTC daily total net profits for each year from 2013 through September 2025.[83] Administrative charges are included for all dates, and uplift charges are included starting from November 1, 2020, when uplift was first charged to UTCs.

Figure 3-37 Cumulative daily UTC profits: January 2013 through September 2025

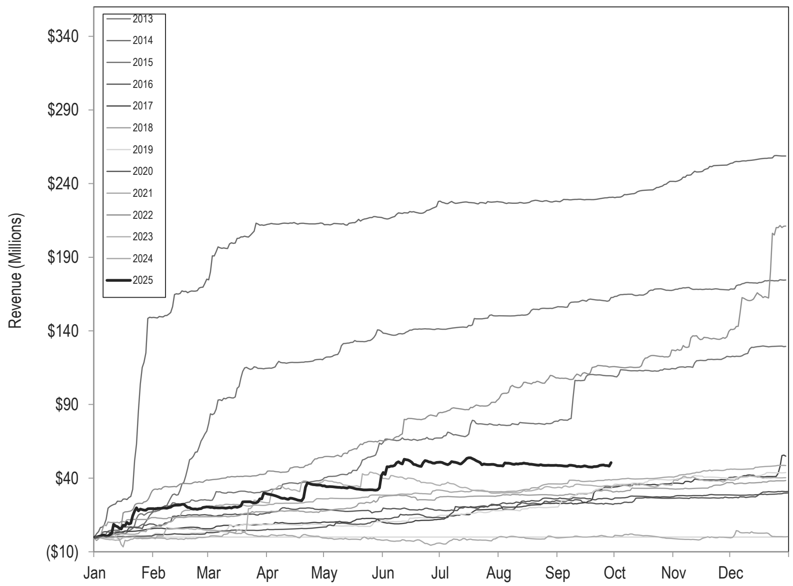


Table 3-47 shows UTC monthly total net profits for January 2013 through September 2025. Administrative charges are included for all months and uplift charges are included starting from November 1, 2020, when uplift was first charged to UTCs. UTC profits were $211 million in 2022, higher than any year since 2014, with the largest monthly total in December 2022 at $75 million. In 2023, the most profitable UTC transactions were concentrated in the Dominion Zone and on dates with high real-time congestion in the Dominion Zone, which occurred primarily in January through May, 2023. The year 2024 was the least profitable year ever for UTC transactions, with very large profitable days occurring with less frequency than prior years. DOMINION HUB to DOM_RESID_AGG UTC remains the path with the highest cleared volume in the first nine months of 2025, June 2025 was the most profitable summer month for UTCs since August 2022.

83 UTCs paid uplift only after October 31, 2020.

Table 3-47 UTC profits by month: January 2013 through September 2025

	January	February	March	April	May	June	July	August	September	October	November	December	Total
2013	$17,048,654	$8,304,767	$5,629,392	$7,560,773	$25,219,947	$3,484,372	$8,781,526	$2,327,168	$31,160,618	$4,393,583	$8,730,701	$6,793,990	$129,435,490
2014	$148,973,434	$23,235,621	$39,448,716	$1,581,786	$3,851,636	$7,353,460	$3,179,356	$287,824	$2,727,763	$10,889,817	$11,042,443	$6,191,101	$258,762,955
2015	$16,132,319	$53,830,098	$44,309,656	$6,392,939	$19,793,475	$824,817	$8,879,275	$5,507,608	$6,957,012	$4,852,454	$392,876	$6,620,581	$174,493,110

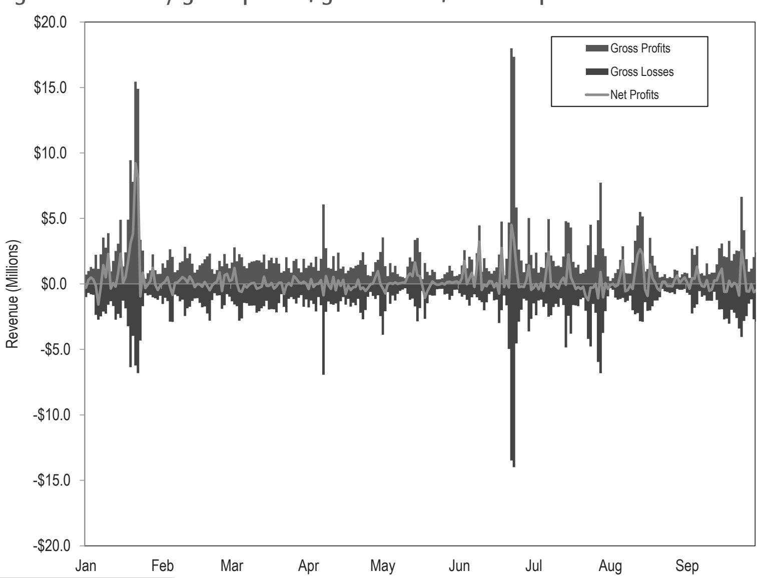
2025	$19,307,539	$965,550	$9,446,437	$5,569,957	($1,921,483)	$17,309,458	($1,634,565)	($406,499)	$1,936,052				$50,572,446

Figure 3-38 shows the positive, negative, and net daily profits for INCs and DECs in the first nine months of 2025. Differences in the modeling of transmission constraints between day ahead and real time, including the use of different constraint limits or a constraint being modeled in one market but not the other, remain a principal source of false arbitrage profits and a major reason for the overall profitability of virtual transactions.

Figure 3-38 Daily gross profits, gross losses, and net profits of all INC and DEC transactions: January through September, 2025[84]



84 Calculations exclude PJM administrative charges.

Figure 3-39 shows the positive, negative, and net daily profits for INCs in the first nine months of 2025.

Figure 3-39 Daily gross profits, gross losses, and net profits for INC transactions: January through September, 2025[85]

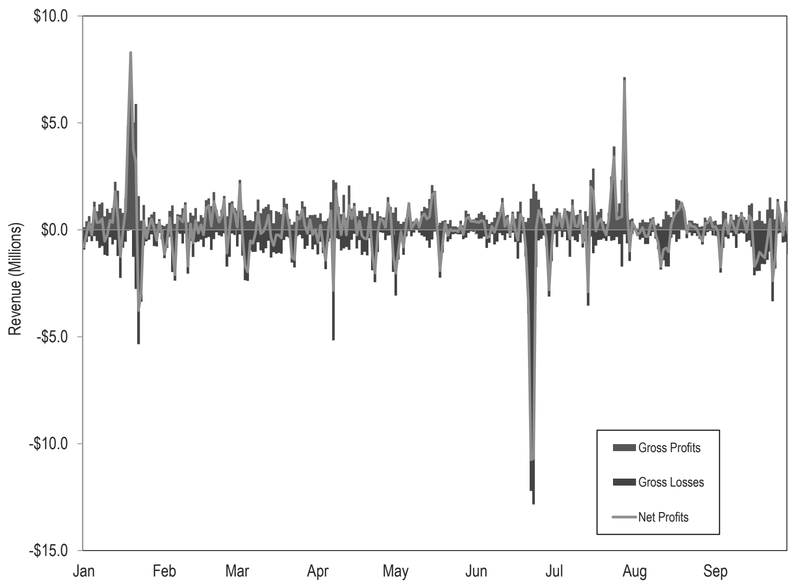


Figure 3-40 shows the positive, negative, and net daily profits for DECs in the first nine months of 2025.

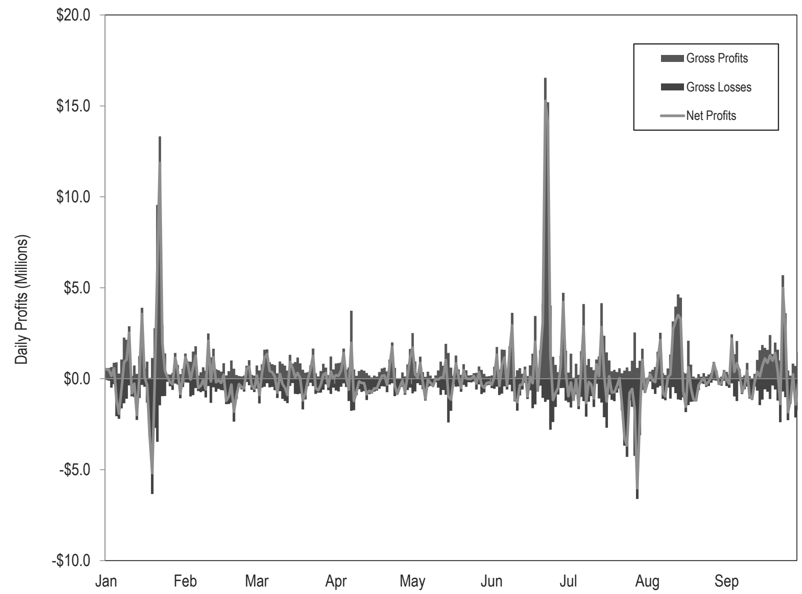
Figure 3-40 Daily gross profits, gross losses, and net profits for DEC transactions: January through September, 2025



85 Calculations exclude PJM administrative charges.

Figure 3-41 shows the cumulative INC and DEC daily profits in the first nine months of 2025. Virtual trading can be profitable without contributing to price convergence because the addition of virtual supply or demand in the day-ahead market does not and cannot correct for factors not included in the day-ahead model, such as the use of different transmission constraint limits in day ahead versus real time.

Figure 3-41 Cumulative daily INC and DEC profit: January through September, 2025

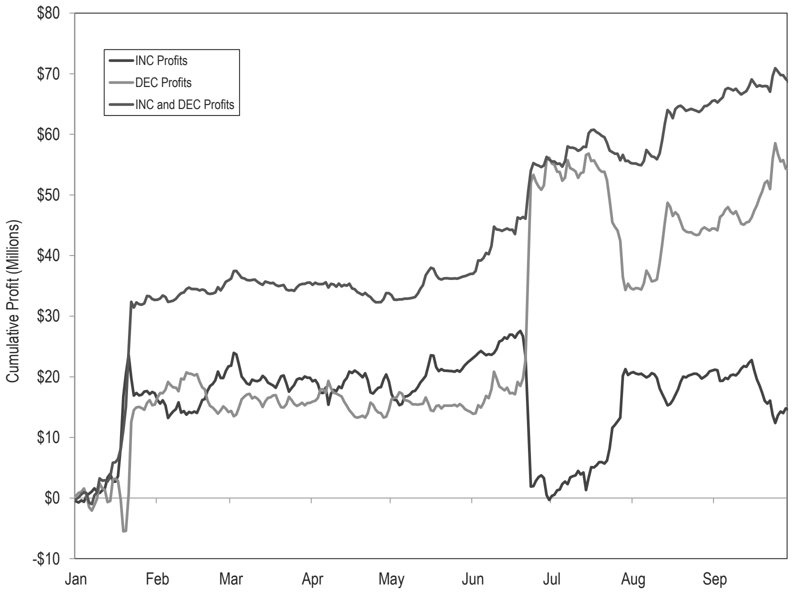


Table 3-48 shows INC and DEC profits by month in the first nine months of 2025.

Table 3-48 INC and DEC profits by month: January through September, 2025

Month	January	February	March	April	May	June	July	August	September	Total
INCs	$17,506,715	$3,444,425	($1,114,741)	$550,610	$1,968,221	($21,882,359)	$19,815,130	$611,357	($6,283,299)	$14,616,059
DECs	$15,315,025	($575,819)	$944,652	($2,254,255)	$990,626	$41,395,416	($20,450,397)	$8,744,220	$9,946,108	$54,055,576
INCs and DECs	$32,821,739	$2,868,606	($170,089)	($1,703,644)	$2,958,846	$19,513,057	($635,267)	$9,355,577	$3,662,809	$68,671,635

All virtual transactions are subject to uplift charges. Each cleared MWh of a virtual transaction pays uplift at the daily operating reserve charge rates, but UTCs pay uplift only at the transaction sink. Cleared increment offers pay the regional and RTO deviation rates, and cleared decrement bids pay the day-ahead rate in addition. Cleared up to congestion transactions pay the same rate as a decrement bid but only at the transaction's sink point, the day-ahead rate and RTO and regional deviation rates.

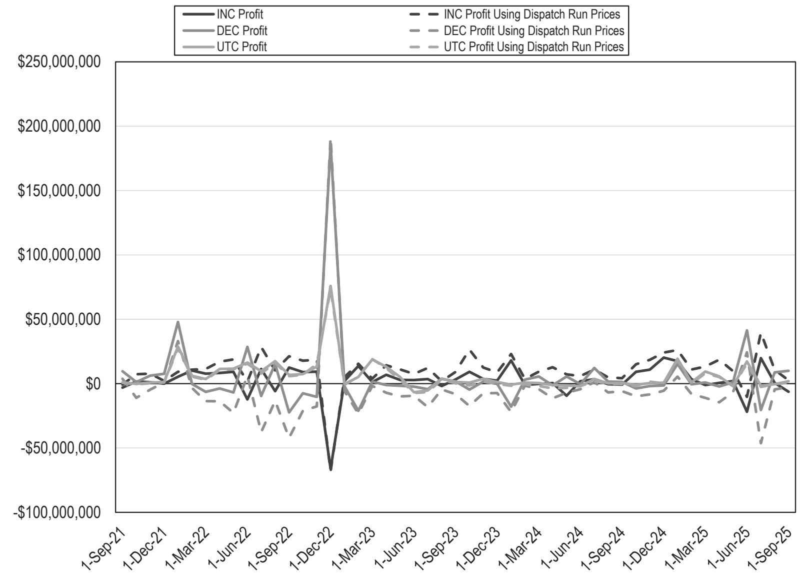
In the first nine months of 2025, INCs paid a total of $19.6 million, DECs paid a total of $24.1 million, and UTCs paid a total of $46.3 million in uplift. This compares to total INC profits of $14.6 million, total DEC profits of $54.1 million, and total UTC profits of $50.7 million.

Effect of Fast Start Pricing on Virtuals

The implementation of fast start pricing on September 1, 2021, has resulted in changes to the settlement of virtual transactions. Prior to fast start pricing, virtual products were cleared and settled based on a single set of prices. The dispatch and pricing run prices were the same. With fast start pricing, all virtual products are cleared using day-ahead dispatch run prices, but pay and receive the day-ahead and real-time pricing run prices. The use of fast start pricing has a direct effect on virtual settlements through the use of prices different from those used to dispatch virtuals. This means that a DEC may clear in the day-ahead market, based on the dispatch run, even though its offer is lower than the final, pricing run price. This means that an INC may clear even though its offer is higher than the day-ahead market price. The use of fast start pricing also results in divergence between day-ahead and real-time prices, which can be targeted by virtual traders. The fact that fast start pricing increases prices more in the real-time market, all else held equal, increases the profitability of DECs and decreases the profitability of INCs.

Figure 3-42 shows the total monthly profits received by INCs, DECs, and UTCs, compared to the profits they would have received if dispatch run prices had been used in settlement for each month since the initial implementation of fast start pricing in September 2021. Since its implementation, fast start pricing has consistently increased profits for DECs and decreased profits for INCs but has not significantly affected profits for UTCs. Fast start pricing creates a difference between day-ahead and real-time prices. Virtual traders can benefit from this difference without contributing to price convergence.

Figure 3-42 Monthly profits for virtuals using pricing run versus dispatch run prices: September 1, 2021 through September 30, 2025



From the implementation of fast start pricing on September 1, 2021, through September 30, 2025, the cumulative difference in profit between the pricing run and the dispatch run for INCs was -$387.0 million, the cumulative difference in profit for DECs was $499.5 million, and the cumulative difference in profit for UTCs was $44.8 million. Fast start pricing led to a net increase of $157.3 million in cumulative profits for virtual transactions since September 1, 2021.

There are incentives to use virtual transactions to profit from price differences between the day-ahead and real-time energy markets, but there is no reason to believe that such activity will result in price convergence and no data to support that claim. As a general matter, virtual offers and bids are based on expectations about both day-ahead and real-time energy market conditions and reflect the uncertainty about conditions in both markets, about modeling differences and the fact that these conditions change hourly and daily. PJM markets do not provide a mechanism that could result in immediate convergence after a change in system conditions as there is at least a one day lag after any change in system conditions before offers could reflect such changes. PJM markets do not provide a mechanism that could ever result in convergence in the presence of modeling differences.

Substantial virtual trading activity does not guarantee that market power cannot be exercised in the day-ahead energy market. Hourly and daily price differences between the day-ahead and real-time energy markets fluctuate continuously and substantially from positive to negative. There may be substantial, persistent differences between day-ahead and real-time prices even on a monthly basis.

Day-ahead and Real-time Prices

Table 3-49 shows the difference between the day-ahead and the real-time average LMP in the first nine months of 2024 and 2025.

Table 3-49 Day-ahead and real-time average LMP (Dollars per MWh): January through September, 2024 and 2025[86]

	2024 (Jan-Sep)				2025 (Jan-Sep)			
	Day-Ahead	Real-Time	Difference	Percent of Real Time	Day-Ahead	Real-Time	Difference	Percent of Real Time
Average	$31.09	$31.50	$0.41	1.3%	$45.69	$46.07	$0.38	0.8%

Figure 3-45 is a map of the real-time load-weighted average LMP in the first nine months of 2025. In the legend, green represents the real-time load-weighted average LMP in the first nine months of 2025 and each increment to the right represents five percent of the pricing nodes above the real-time load-weighted average LMP in the first nine months of 2025 and each increment to the left represents 25 percent of the pricing nodes below the real-time load-weighted average LMP in the first nine months of 2025.

Figure 3-45 Real-time load-weighted average LMP: January through September, 2025

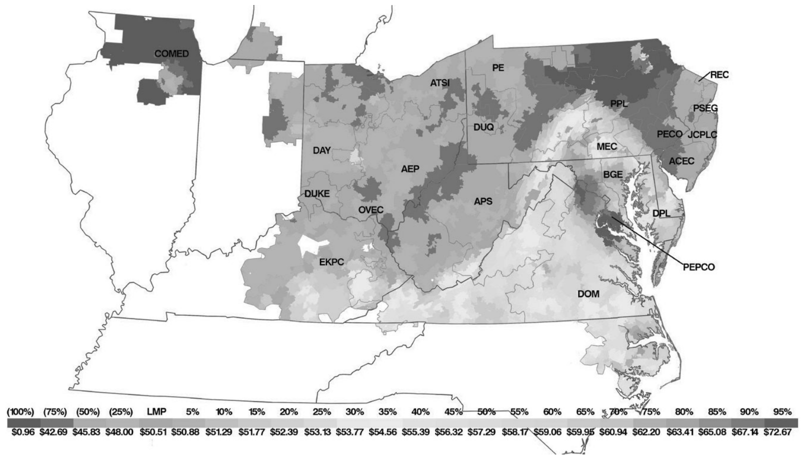

Figure 3-46 includes maps of the real-time load-weighted average LMP in the first nine months of 2022 through 2025. In the legend, green represents the average price in the first nine months of 2022 through 2025 and each block to the right represents five percent of the pricing nodes above the average price in the first nine months of 2022 through 2025 and each block to the left represents 25 percent of the pricing nodes below the average price in the first nine months of 2022 through 2025.

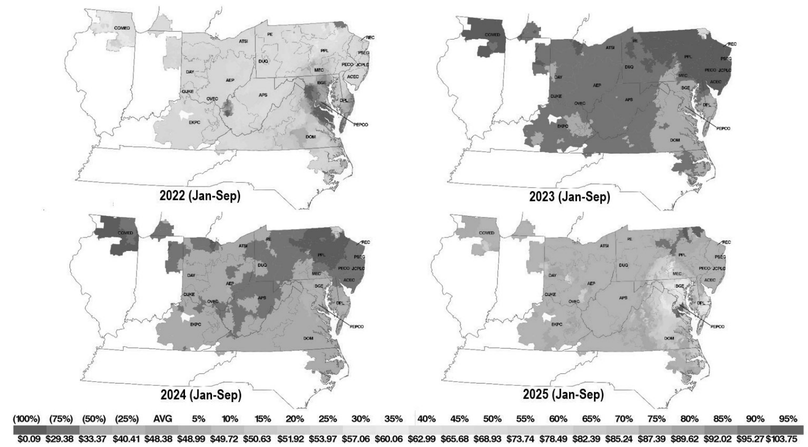
Figure 3-46 Real-time load-weighted average LMP map: January through September, 2022 through 2025



Transmission Constraint Penalty Factors (TCPF)

LMPs are generally set by the offer prices of marginal resources. When a transmission constraint is binding, the flow on the constraint is equal to its limit and the shadow price of the constraint is a function of offer prices of marginal resources. LMP may, at times, be set by transmission constraint penalty factors. When a transmission constraint is limiting and there are no generation alternatives to resolve the constraint, system operators may allow the transmission limit to be violated. When this occurs, the shadow price of the constraint is set by transmission constraint penalty factors. The shadow price directly affects the LMP. Transmission constraint penalty factors are administratively determined and can be thought of as a form of locational scarcity pricing, but only when properly applied. The TCPFs are applied incorrectly about 94 percent of the time. In addition, it is not clear that the line ratings are correctly defined, by duration of the flow and ambient conditions, by the transmission owners who have sole control over the line ratings with no meaningful oversight.

PJM operators routinely reduce the control limits on transmission constraint line ratings used in the market clearing software (SCED) by setting the control limits to 95 percent of the actual line ratings.[87] The result is that transmission constraint penalty factors set price much more frequently than needed or appropriate. PJM reduces the control limits both to control for actual flows and for flows that would only result from a contingency (N-1).

Since the implementation of fast start pricing on September 1, 2021, PJM set the default level of the transmission constraint penalty factor in the pricing run of the day-ahead market at $2,000 per MWh. The default level of the transmission constraint penalty factor in the dispatch run of the day-ahead market was left unchanged at $30,000 per MWh.

Table 3-54 shows the frequency and average shadow price of transmission constraints in the PJM real-time market. In the first nine months of 2025, there were 158,826 transmission constraint five minute intervals in the real-time market with a nonzero shadow price. For 18,497, or 11.6 percent, of these transmission constraint intervals, the control limit was violated, meaning that the flow exceeded the facility limit used in SCED.[88] The data on violations includes both violations that result from reductions in the SCED control limit by PJM and violations that are based on the actual line ratings. Of the 18,497 constraint intervals, PJM used actual line limits for 2,773 or 1.7 percent of the constraint intervals. For the remaining 15,724 or 9.9 percent of the constraint intervals, PJM used reduced line limits. In those cases, the actual line limit was not violated. In all cases where violations resulted from reductions by PJM from actual line ratings the shadow prices and resulting LMPs were set by the violation penalty factors. In the first nine months of 2025, the average shadow price of transmission constraints ($1,995.20)) when the line limit used in SCED was violated with a reduced line limit was 6.4 times higher than when the transmission constraint was binding but not violated ($310.95) at its limit used in SCED.

87 Actual transmission line limits are set by the transmission owner. PJM chooses the control limits. At present the actual line rating methods are not reviewed by FERC, or PJM, or the MMU.

88 The line limit of a facility associated with a transmission constraint is not necessarily the rated line limit. In PJM, the dispatcher has the discretion to lower the rated line limit.

Market to Market Transmission Constraints are categorized separately because of the unique rules governing the congestion management of these constraints by PJM and MISO. In the real-time market, PJM and MISO initiate a joint congestion management process commonly referred as "market to market" if they recognize substantial flows originating from the other RTO on their constraints. The identified constraints are then modeled in the dispatch optimizations of the both RTOs. After every approved solution, the shadow prices are exchanged between the RTOs.

Table 3-54 Frequency and average shadow price of transmission constraints in the real-time market: January through September, 2024 and 2025

	Frequency (Constraint Intervals)		Average Shadow Price	
Description	2024 (Jan - Sep)	2025 (Jan - Sep)	2024 (Jan - Sep)	2025 (Jan - Sep)
Violated Transmission Constraints (Actual)	441	2,773	$677.59	$943.53
Violated Transmission Constraints (Reduced)	9,320	15,724	$1,979.52	$1,995.20
Binding Transmission Constraints	99,671	104,982	$215.40	$310.95
Market to Market Transmission Constraints	40,642	35,347	$264.81	$426.85
All Transmission Constraints	150,074	158,826	$339.69	$514.53

Table 3-55 shows the frequency and average shadow price of transmission constraints in the PJM day-ahead market. In the first nine months of 2025, there were 56,386 transmission constraint hours in the day-ahead market with a nonzero shadow price. For 145, or less than one percent, of these transmission constraint hours, the line limit was violated, meaning that the flow exceeded the facility limit used in the day-ahead pricing run solution.

Table 3-55 Frequency and average shadow price of transmission constraints in the day-ahead market: January through September, 2024 and 2025

	Frequency (Constraint Intervals)		Average Shadow Price	
Description	2024 (Jan - Sep)	2025 (Jan - Sep)	2024 (Jan - Sep)	2025 (Jan - Sep)
Violated Transmission Constraints (Actual)	31	145	$2,000.00	$2,000.00
Market to Market Transmission Constraints	52,558	48,900	$64.81	$103.01
Binding Transmission Constraints	4,880	7,341	$105.35	$145.23
All Transmission Constraints	57,469	56,386	$69.29	$113.39

Table 3-56 shows the frequency of violated transmission constraints by voltage level in the real-time market. In the first nine months of 2025, 76.4 percent of the violated transmission constraint intervals had a voltage level at or below 230 kV.

Table 3-56 Frequency of PJM violated transmission constraints in the real-time market by voltage: January through September, 2024 and 2025

	2024 (Jan - Sep)		2025 (Jan - Sep)	
Voltage	Frequency (Constraint Intervals)	Percent	Frequency (Constraint Intervals)	Percent
1 kV	56	0.6%	269	1.5%
69 kV	702	7.2%	1,069	5.8%
115 kV	1,928	19.8%	5,794	31.3%
138 kV	2,772	28.4%	3,422	18.5%
161 kV	16	0.2%	-	0.0%
230 kV	2,536	26.0%	3,585	19.4%
345 kV	618	6.3%	486	2.6%
500 kV	911	9.3%	3,825	20.7%
765 kV	222	2.3%	47	0.3%
Total	9,761	100.0%	18,497	100.0%

Transmission constraint penalty factors should be applied without discretion, but not without additional rules that prevent unintended consequences. PJM adopted the MMU's recommendation to remove the constraint relaxation logic and allow transmission penalty factors to set prices in the day-ahead and real-time markets for all internal transmission constraints.[89] But the potential for prolonged and excessively high administrative pricing in the energy market due to transmission constraint penalty factors remains an issue that needs to be addressed. There can be situations in which the application of transmission penalty factors in real time for significant periods creates manipulation opportunities for virtuals and creates inefficient wealth transfers when market participants do not have the ability to react to the high prices either on the supply or demand side.[90] This could be the result of a lengthy planned transmission outage, for example.[91] It can also result from PJM reducing the control limit on the line rating in RT SCED below 100 percent of the actual line limit and triggering the transmission constraint penalty factor, while operating the system below the actual line limit for a prolonged period. PJM should not reduce the control limit on the transmission line ratings in SCED to trigger the inclusion of transmission constraint penalty factors in price. In addition, PJM has no information about the accuracy of the line ratings that are determined by each transmission owner. It is not clear whether the line ratings that trigger the transmission constraint penalty factors are defined for the actual expected period of the power flow on the line. Line ratings vary significantly by duration of power flows, and by ambient conditions.

PJM also revised the tariff to list the conditions under which transmission constraint penalty factors would be changed from their default value of $2,000 per MWh. The new rules went into effect on February 1, 2019. The Commission approved the PJM and MISO joint filing to remove the constraint relaxation logic for market to market constraints on March 6, 2020. PJM and MISO implemented the changes to their dispatch software in the second half of 2020. On March 21, 2023, FERC approved new rules proposed by PJM to allow for reducing the transmission constraint penalty factors below the default $2,000 per MWh for constraints that are violated due to a transmission outage caused by the construction of upgrades to relieve congestion, for which limited generation resources are available to provide relief.[92]

PJM routinely, based on discretion, reduces the control limits on the transmission constraint line ratings modeled in SCED to below 100 percent, generally to 95 percent of the actual limit, administratively triggering the use of transmission constraint penalty factors.[93] The control limits set the limit of the constraint modeled in SCED. For example, in SCED, a transmission facility with a 100 MW line rating set at a 90 percent control limit would be modeled as a constraint with a limit of 90 MW. Table 3-57 shows the frequency of changes to the control limits for transmission constraints for binding and violated transmission constraints in the PJM real-time market. In the first nine months of 2025, there were 15,724, or 85 percent, of 18,497 violated transmission constraint intervals in the real-time market with a control limit less than 100 percent. In the first nine months of 2025, among the constraints

89 PJM applied a procedure that PJM termed constraint relaxation logic, under which a revised SCED dispatch solution was obtained with an artificially increased limit for the violated transmission facility. The logic typically resulted in reducing the shadow prices to be slightly below the defined constraint violation penalty factor.
90 See Comments of the Independent Market Monitor for PJM, Docket No. EL22-26-000 et al. (February 1, 2022); 178 FERC ¶ 61,104 (2022).
91 See *id.*
92 See 182 FERC ¶ 61,183 (March 21, 2023). The Commission approved PJM's proposed tariff revisions to allow PJM to lower transmission constraint penalty factors generally for any situation similar to the high prices caused by Lanexa-Dunnsville-Northern Neck line outage in the Northern Neck peninsula in Virginia.
93 Actual transmission line limits are set by the transmission owner. PJM chooses the control limits. At present the actual line rating methods are not reviewed by FERC, or PJM, or the MMU.

with a reduced control limit, the constraint limit was reduced on average by 5.1 percent. In the first nine months of 2025, there were 101,632, or 97 percent, of 104,982 binding transmission constraint intervals in the real-time market with a control limit less than 100 percent. By arbitrarily lowering transmission facility limits, PJM is not using the full transmission system capacity available to serve the load to achieve the least cost dispatch solution. The cost to serve the load and the load payments would be lower had PJM not reduced the transmission line ratings.

Table 3-57 Frequency of reduction in control limit of line ratings (constraint intervals) in the real-time market: January through September, 2024 and 2025

	Frequency (Constraint Intervals)		Constraints with Reduced Control Percent (Constraint Intervals)		Average Reduction (Percent)	
Description	2024 (Jan - Sep)	2025 (Jan - Sep)	2024 (Jan - Sep)	2025 (Jan - Sep)	2024 (Jan - Sep)	2025 (Jan - Sep)
Violated Transmission Constraints (Actual)	441	2,773	-	-	0.0%	0.0%
Violated Transmission Constraints (Reduced)	9,320	15,724	9,320	15,724	5.0%	5.1%
Binding Transmission Constraints	99,671	104,982	98,944	101,632	5.3%	5.8%
Market to Market Transmission Constraints	40,642	35,347	14,026	13,056	5.9%	7.2%
All Transmission Constraints	150,074	158,826	122,290	130,412	5.3%	5.9%

Table 3-58 shows the reasons provided by the PJM operators for changing the control limit on the line rating for violated transmission constraints. In the first nine months of 2025, of the 15,724 violated transmission constraint intervals with reduced control limits, no reason was provided for 12,698 cases, or 80.8 percent of all the cases. In 1,952 cases, or 12.4 percent, the control limits were reduced because the relief calculated by the SCED optimization was less than the operator's desired relief for the transmission constraint. In 13 cases, or 0.1 percent, the control limits were reduced because PJM designates the constraint as a thermal surrogate. Thermal surrogate constraints are constraints that PJM activates and for which PJM generally reduces the line rating to enable specific resources called on to control a constraint to set price.

The MMU recommends that PJM end the practice of manual and automated discretionary reductions in the control limits on transmission constraint line ratings used in the market clearing software (SCED) and included in LMP. This practice has significant market effects by limiting economic power flows and increasing prices above the level that would exist if 100 percent of the actual line rating were used in clearing the market and setting energy market prices.

Table 3-58 PJM's reasons for reduction in control limits of line ratings (constraint intervals) in the real-time market: January through September, 2024 and 2025

	Constraint Intervals		Average Reduction (Percent)	
Reason	2024 (Jan - Sep)	2025 (Jan - Sep)	2024 (Jan - Sep)	2025 (Jan - Sep)
No reason provided	8,013	12,698	4.5%	4.4%
Prepositioning of generation resources to support an operational requirement	38	313	8.7%	8.7%
Inadequate relief calculated by the SCED optimization	897	1,952	6.7%	7.6%
Transmission owner identified the flow on their constraint to be greater than PJM's calculated flow on the same constraint.	47	195	8.2%	7.6%
Modeled constraint is a thermal surrogate	101	13	21.2%	52.2%
Power flow on the constraint is volatile due to various system conditions	224	553	7.3%	7.3%
All violated constraints	9,320	15,724	5.0%	5.1%

Table 3-59 shows the impact on LMP of PJM dispatchers reducing the control limit of line ratings of transmission constraints and causing artificial line limit violations.[94] The transmission constraint penalty factor contribution to the load-weighted average LMP in the first nine months of 2025 was $5.31 per MWh or $3.25 billion of the total $30.9 billion cost of real-time load. This impact includes reductions to the line limits of violated constraints on high load summer days, June 23 and 24, 2025. If 100 percent of the line limits had been used for the PJM transmission constraints and everything else remained unchanged, fewer constraints would have been violated and the transmission penalty factor's contribution to the load-weighted average LMP would have decreased to $0.03 per MWh, a 99.4 percent reduction.

Table 3-59 Real-time LMP effect of reduced control limits on transmission constraint line ratings (Dollars per MWh): January through September, 2024 and 2025

	Contribution to LMP	
Line Limit Scenario for Violated Constraints	2024 (Jan - Sep)	2025 (Jan - Sep)
Line Limits Reduced by PJM (Actual)	$3.23	$5.31
Hypothetical Use of Full Line Limits	$0.02	$0.03
Change in Contribution to LMP	($3.21)	($5.27)
Percent Change in Contribution to LMP	(99.4%)	(99.4%)

Table 3-60 shows the frequency of changes to the magnitude of transmission penalty factors for binding and violated transmission constraints in the PJM Real-Time Energy Market. In the first nine months of 2025, there were 16,739, or 90 percent, violated transmission constraint intervals, which includes 1,032 violated transmission constraint intervals with actual line limits and 15,707 violated transmission constraint intervals with reduced line limits, in the real-time market with a transmission penalty factor equal to the default $2,000 per MWh.

94 The MMU calculates the impact on system prices based on analysis using sensitivity factors. The transmission penalty factor contribution with actual line limits is not based on a counterfactual redispatch of the system. See Technical Reference for PJM Markets, "Calculation and Use of Generator Sensitivity/Unit Participation Factors," <http://www.monitoringanalytics.com/reports/Technical_References/references.shtml>.

Table 3-60 Frequency of changes to the magnitude of transmission penalty factor (constraint intervals) in the real-time market: January through September, 2024 and 2025

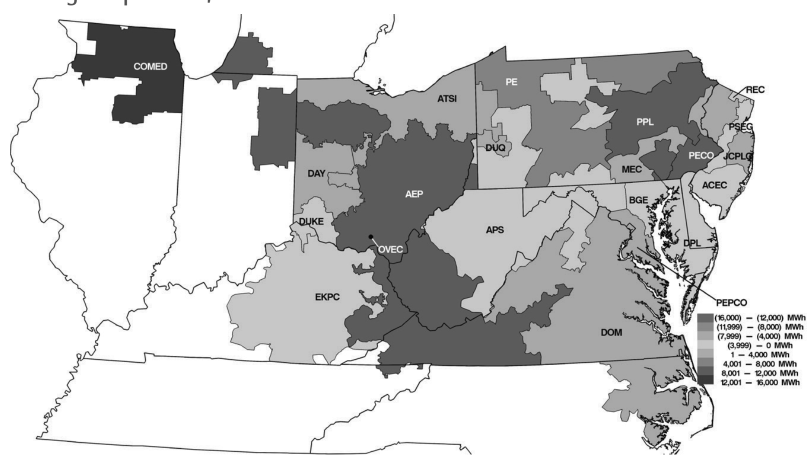
	2024 (Jan - Sep)			2025 (Jan - Sep)		
Description	$2,000 per MWh (Default)	Above $2,000 per MWh	Below $2,000 per MWh	$2,000 per MWh (Default)	Above $2,000 per MWh	Below $2,000 per MWh
Violated Transmission Constraints (Actual)	96	-	345	1,032	-	1,741
Violated Transmission Constraints (Reduced)	9,215	-	105	15,707	-	17
Binding Transmission Constraints	99,470	-	201	102,497	-	2,485
Market to Market Transmission Constraints	5,811	17	34,814	8,703	19	26,625
All Transmission Constraints	114,592	17	35,465	127,939	19	30,868

Prior to September 1, 2022, transmission constraint penalty factors frequently set prices when PJM modeled a stability surrogate constraint to limit the dispatch of a generator that would experience voltage instability at its full output due to a transmission outage. Since September 1, 2022, PJM uses a generator output limit constraint to manage generator voltage instability issues. In the first nine months of 2025, there were 11,264 constraint intervals during which PJM reduced the output of generators to manage instability. Changes to the surrogate constraint limit that exceed the unit's ability to reduce output cause constraint violations. Constraint violations also occur when the unit follows the regulation signal or increases its minimum operating parameters above the surrogate constraint limit. Prices set at the $2,000 per MWh penalty factor are not useful signals to the market under these conditions and create false arbitrage opportunities for virtuals.

Net Generation by Zone

Figure 3-47 shows the difference between the PJM real-time generation and real-time load by zone for the first nine months of 2025. Figure 3-47 is color coded using a scale on which red shades represent zones that have less generation than load and green shades represent zones that have more generation than load, with darker shades meaning greater amounts of net generation or load. Table 3-61 shows the difference between the real-time generation and real-time load by zone for the first nine months of 2024 and 2025.

Figure 3-47 Map of real-time generation less real-time load by zone: January through September, 2025[95]



95 Real-time zonal generation data for the map and corresponding table is based on the zonal designation for every bus listed in the most current PJM LMP bus model, which can be found at <http://www.pjm.com/markets-and-operations/energy/lmp-model-info.aspx>.

Net Generation and Load

PJM sums all negative (injections) and positive (withdrawals) at each designated load bus when calculating net load (accounting load). PJM sums all of the negative (withdrawals) and positive (injections) at each generation bus when calculating net generation. Netting withdrawals and injections by bus type (generation or load) affects the measurement of total load and total generation. Energy withdrawn at a generation bus to provide, for example, auxiliary/parasitic power or station power, power to synchronous condenser motors, power to onsite customers, or power to run pumped storage pumps, is actually load, not negative generation. Energy injected at load buses by behind the meter generation is actually generation, not negative load.

The zonal load-weighted LMP is calculated by weighting the zone's load bus LMPs by the zone's load bus accounting load. The definition of injections and withdrawals of energy as generation or load affects PJM's calculation of zonal load-weighted LMP.

The MMU recommends that during intervals when a generation bus shows a net withdrawal, the energy withdrawal be treated as load, not negative generation, for purposes of calculating load and load-weighted LMP. The MMU also recommends that during intervals when a load bus shows a net injection, the energy injection be treated as generation, not negative load, for purposes of calculating generation and load-weighted LMP.

Fuel Prices, LMP, and Dispatch

Energy Production by Fuel Source

Table 3-62 shows PJM generation by fuel source in GWh for the first nine months of 2024 and 2025.

In the first nine months of 2025, generation from coal units increased 16.1 percent, generation from natural gas units decreased 1.6 percent, generation from oil units increased 25.8 percent, generation from wind units increased 1.8 percent, and generation from solar units increased 46.4 percent compared to the first nine months of 2024.

Table 3-62 Generation (By fuel source (GWh)): January through September, 2024 and 2025[96 97]

	2024 (Jan-Sep)		2025 (Jan-Sep)		Change in
	GWh	Percent	GWh	Percent	Output
Coal	95,995.4	14.8%	111,408.4	16.7%	16.1%

Fuel Diversity

Figure 3-48 shows the fuel diversity index (FDI_e) for PJM energy generation.[98] The FDI_e is defined as $\mathbf{1-\sum_{i=1}^{N} s_i^2}$, where s_i is the share of fuel type i. The minimum possible value for the FDI_e is zero, corresponding to all generation from a single fuel type. The maximum possible value for the FDI_e results when each fuel type has an equal share of total generation. For a generation fleet composed of 10 fuel types, the maximum achievable index is 0.9. The fuel type categories used in the calculation of the FDI_e are the 10 primary fuel sources in Table 3-62 with nonzero generation values. As fuel diversity has increased, seasonality in the FDI_e has decreased and the FDI_e has exhibited less volatility. Since 2012, the monthly FDI_e has been less volatile as a result of the decline in the share of coal from 51.3 percent prior to 2012 to 27.9 percent from 2012 through September 2025. A significant drop in the FDI_e occurred in the fall of 2004 as a result of the expansion of the PJM market footprint into ComEd, AEP, and Dayton Power & Light Zones and the increased shares of coal and nuclear that resulted.[99] The increasing trend that began in 2008 is a result of decreasing coal generation, increasing gas generation and increasing renewable generation. Coal generation as a share of total generation was 55.0 percent for the first nine months of 2008 and 16.8 percent for the first nine months of 2025. Gas generation as a share of total generation was 7.7 percent for the first nine months of 2008 and 42.8 percent for the first nine months of 2025. Wind and solar generation as a share of total generation was 0.4 percent for the first nine months of 2008 and 6.5 percent for the first nine months of 2025.

The FDI_e increased 2.5 percent in the first nine months of 2025 compared to the first nine months of 2024. Increased coal generation in the first nine months of 2025 and less generation from gas fired generators led to the increase in the FDI_e.

The FDI_e was also used to measure the impact on fuel diversity of potential retirements in 2025 through 2030. A total of 34,733 MW of capacity are at risk of retirement, consisting of 4,684 MW currently planning to retire, 16,786 MW expected to retire for regulatory reasons and 13,264 MW expected to be uneconomic.[100] This capacity consists primarily of coal steam plants and CTs. The units expected to retire by the end of 2025 generated 34,394.2 GWh in the first nine months of 2025. The dashed line (green) in Figure 3-48 shows a counterfactual result for FDI_e assuming the 34,394.2 GWh of generation from uneconomic units and expected 2025 retirements were replaced by gas, wind and solar generation.[101] The FDI_e for the first nine months of 2025 under this counterfactual assumption would have been 1.6 percent lower than the actual FDI_e. The units expected to retire by the end of 2030 generated 65,235.4 GWh in the first nine months of 2025. Replacing this generation with gas, wind and solar generation results in a counterfactual FDI_e that is 1.2 percent lower than the actual FDI_e.[102] The dashed line (blue) in Figure 3-48 shows a counterfactual

98 The MMU developed the FDI to provide an objective metric of fuel diversity. The FDI metric is similar to the HHI used to measure market concentration. The FDI is calculated separately for energy output and for installed capacity.

99 See the *2019 Annual State of the Market Report for PJM*, Appendix A, "PJM Geography" for an explanation of the expansion of the PJM footprint. The integration of the ComEd Control Area occurred in May 2004 and the integration of the AEP and Dayton Zones occurred in October 2004.

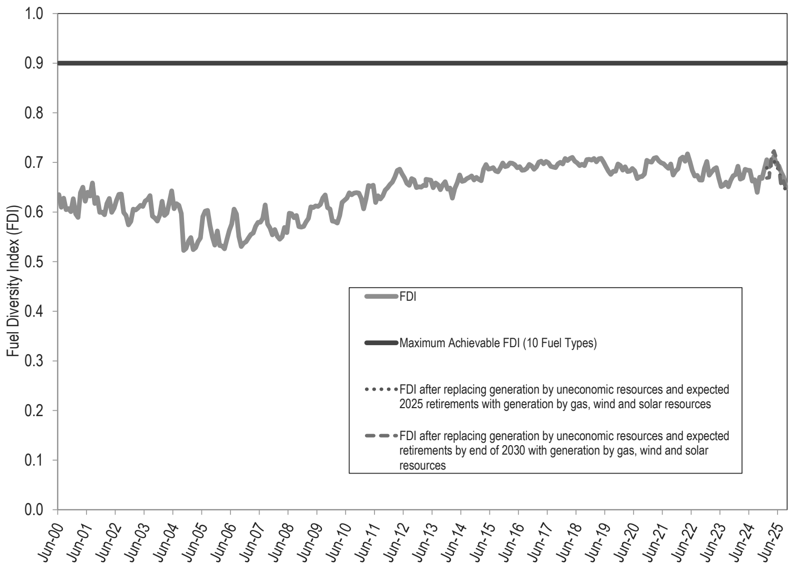
100 See Units At Risk of Retirement in the *2024 Annual State of the Market Report for PJM*, Volume 2, Section 7: Net Revenue.

101 It is assumed that 8,962.7 GWh of the replacement energy will be from new wind and solar units. This value represents the increase over 2025 levels in renewable generation that is required by RPS in 2026. The split between solar (78.9 percent) and wind (21.1 percent) is based on queue data and 2025 capacity factors in Table 8-33 and Table 8-37.

102 It is assumed that 33,840.5 GWh of the replacement energy will be from new wind and solar units. This value represents the increase over 2025 levels in renewable generation that is required by RPS in 2030. The split between solar (78.9 percent) and wind (21.1 percent) is based on queue data and 2025 capacity factors in Table 8-33 and Table 8-37.

result for FDI_e assuming that this generation is replaced with gas, wind and solar generation.

Figure 3-48 Fuel diversity index for monthly generation: June 2000 through September 2025



Natural Gas Supply Issues

Both pipeline transportation and commodity natural gas are needed to deliver natural gas to power plants. Generators have a number of options which vary by pipeline and market area. A generator could purchase a delivered service in which the seller bundles the transportation and commodity, on a term contract or a spot basis. A generator could purchase pipeline transportation and commodity natural gas separately with a term supply contract or through daily purchases in the spot market. Generators could purchase storage service. Storage services can be bundled with pipeline transportation, or storage and transportation purchased separately to move gas to or from a storage facility. The storage service will determine the total storage capacity and the injection and withdrawal rights. Storage offers the owner the ability to have on demand supplies, or the ability to redirect unused supplies to storage. Predetermined allocation (PDA) nominations can be used to direct the pipeline as to how to treat an excess or a deficiency of gas at a delivery point. Combinations of these options are also available.

Pipelines build transportation capacity and sell firm capacity to customers. Most of the transportation capacity is sold at tariff rates but in some cases negotiated rates are agreed to. A majority of firm capacity is contracted with gas utilities, gas marketers, industrial customers and generators. The purchasers of firm transportation capacity have the right to resell their capacity. Any such release must be done on the pipeline's electronic bulletin board. Bidders must be approved by the pipeline. When firm capacity on the pipelines is not being used, the pipeline tariffs provide for interruptible service.

In order to be able to actually use the purchased pipeline transportation service, pipelines may enforce nomination deadlines to require generation owners to nominate the flow of gas by defined deadlines. Some pipelines may also impose site specific restrictions that limit the ability of generators to nominate and schedule gas beyond the nomination deadlines. Table 3-66 shows the approved nomination deadlines and corresponding start time of gas flow.[103] Pipelines provide that firm service requests may replace, or bump, interruptible nominations on the pipeline under defined conditions.

Table 3-66 Approved nomination deadlines

	Nomination Cycle	Nom Deadline (EPT)	Time of Flow (EPT)	Bumping	Hours left in gas day for supply to flow
Day Before Flow	Timely	1400	1000		24
Day Before Flow	Evening	1900	1000	Yes	24
Day of Flow	Intraday 1	1100	1500	Yes	19
Day of Flow	Intraday 2	1530	1900	Yes	15
Day of Flow	Intraday 3	2000	2300	No	11

In 2024 and 2025, some interstate gas pipelines that provide service in the PJM service territory issued notices limiting the flexibility of firm and nonfirm transportation services. These notices include alerts, constraints, warnings of

103 Nomination deadlines approved in FERC Order No. 809, implemented April 1, 2016.

operational flow orders (OFO) and actual OFOs. These notices generally permit the pipelines to enforce nomination deadlines and to restrict the provision of gas to 24 hour ratable takes, meaning that nominations must be the same for each hour in the gas day. Pipelines may also enforce strict balancing constraints which limit the ability of gas users to deviate from the 24 hour ratable take and which may limit the ability of users to have access to unused gas. The pipelines providing service in the PJM service territory that issued notices were: ANR Pipeline, Columbia Gas Transmission, Cove Point, East Tennessee Natural Gas, Eastern Gas Transmission & Storage, Eastern Shore, Equitrans Transmission, Horizon Pipeline, Natural Gas Pipeline, Northern Border Pipeline, Texas Eastern, Tennessee Gas Pipeline and Transcontinental Gas Pipeline.

Pipeline operators use restrictive and inflexible rules to manage the balance of supply and demand during constrained operating conditions determined by the pipeline. The independent operations of geographically overlapping pipelines during extreme conditions highlight the shortcomings of a gas pipeline network that relies on individual pipelines to manage the balancing of total supply and demand across a broad geographical area that includes multiple pipelines. The independent operational restrictions imposed by pipelines and the impact on electric generators during extreme conditions demonstrate the potential benefits to creating a separate gas ISO/RTO structure to coordinate the supply of gas across pipelines and with the electric RTOs and to facilitate the interoperability of the pipelines in an explicit network.

The increase in natural gas fired capacity in PJM, and the expected further increase, has highlighted issues with the dependence of PJM system reliability on the fuel transportation arrangements entered into by generators. The risks to the fuel supply for gas generators, including the risk of interruptible supply on cold days and the ability to get gas on short notice during times of critical pipeline operations, create risks for the bulk power system.

In general, the availability status of gas generators in the PJM energy market does not accurately reflect their ability to procure and nominate gas on the pipelines based on the rules defined by the pipelines. If the result of the pipeline rules is that some gas generators cannot reliably procure gas during the operating day in order to respond to PJM directions to generate, the result could be an inflated estimate of reserves on the PJM system, if the generator does not have back up fuel. Gas units should be required to be on forced outage if they cannot obtain gas during the operating day to meet their must offer requirement.

PJM requires real-time situational awareness of the availability of all generators, including gas-fired generators, during the operating day, in order to operate the system effectively including knowledge of the level of available reserves. The MMU recommends: that gas generators be required to confirm, regularly during the operating day, that they can obtain gas if requested to operate at their economic maximum level; that gas generators provide that information to PJM during the operating day; and that gas generators be required to be on forced outage if they cannot obtain gas during the operating day to meet their must offer requirement as a result of pipeline restrictions, and they do not have backup fuel. As part of this, the MMU recommends that PJM collect data on each individual generator's fuel supply arrangements at least annually or when such arrangements change, and analyze the associated locational and regional risks to reliability.

Notification time is the period between PJM's notification and the beginning of the start sequence for a generating resource. Combustion turbines normally have notification times between six and 30 minutes. When pipelines require generators to nominate gas per the NAESB deadlines, generators must nominate gas well in advance and cannot start in six or 30 minutes. Instead, generators need significantly more time to nominate gas. This increase in the time needed should be requested and reflected in the units' notification time.

For example, the last nomination cycle available per NAESB is intraday 3 (ID3), see Table 3-66. The ID3 deadline is 20:00 EPT for gas that starts flowing at 23:00 (in three hours). The previous cycle, intraday 2 (ID2) deadline is at 15:30 EPT for gas that starts flowing at 19:00. A generator that has not nominated gas by ID2 cannot start until 23:00. Therefore, at 19:00, the unit has an implied time to start of four hours. Four hours is equal to 23:00 (the earliest the unit can start) minus 19:00. Table 3-67 shows the notification time gas fired generators should be requesting and submitting when pipelines require nominating per the NAESB cycle deadlines.

Table 3-67 Generator notification times when pipeline NAESB cycle deadlines are imposed

Hour	HE1	HE2	HE3	HE4	HE5	HE6	HE7	HE8	HE9	HE10	HE11	HE12
Notification Time	15	14	13	12	11	10	9	8	7	6	9	8
Time On (If Called)	15:00	15:00	15:00	15:00	15:00	15:00	15:00	15:00	15:00	15:00	19:00	19:00

The MMU proposed enhancements for situational awareness and transparency to improve the scheduling problem that PJM and gas fired units face, addressing how to reflect pipeline constraints in generator operating parameters, including how generators should submit notification times, and minimum run times and request temporary parameter exceptions.[104] The resultant guidelines were posted by the MMU and PJM on September 8, 2023.[105]

Types of Marginal Resources

LMPs result from the operation of a market based on security-constrained, least-cost dispatch in which marginal resources determine system LMPs, based on their offers. Marginal resource designation is not limited to physical resources in the day-ahead energy market. INC offers, DEC bids and up to congestion transactions are dispatchable injections and withdrawals in the day-ahead energy market that can set price via their offers and bids.

Table 3-68 shows the type of fuel used and technology by marginal resources in the real-time energy market. There can be more than one marginal resource in any given interval as a result of transmission constraints. In the first nine months of 2025, coal units were 7.6 percent and natural gas units were 77.9 percent of marginal resources. In the first nine months of 2025, natural gas combined cycle units were 63.8 percent of marginal resources. In the first nine months of 2024, coal units were 11.0 percent and natural gas units were 74.8 percent of the total marginal resources. In the first nine months of 2024, natural gas combined cycle units were 61.5 percent of the total marginal resources. In the first nine months of 2025, 68.7 percent of the wind marginal units had negative offer prices, 30.2 percent had zero offer prices and 1.1 percent of the wind marginal units had positive offer prices. In the first nine months of 2024, 49.2 percent of the wind marginal units had negative offer prices, 40.7 percent had zero offer prices and 10.0 percent had positive offer prices.

The proportion of marginal nuclear units decreased from 0.35 percent in the first nine months of 2024 to 0.11 percent in the first nine months of 2025. Most nuclear units are offered as fixed generation in the PJM market. A small number of nuclear units have been offered with a dispatchable range since 2015. The dispatchable nuclear units do not always respond to dispatch instructions.

PJM implemented fast start pricing on September 1, 2021. The marginal resources shown in Table 3-68 are from the pricing run, which may not be the same as marginal resources from the dispatch run.

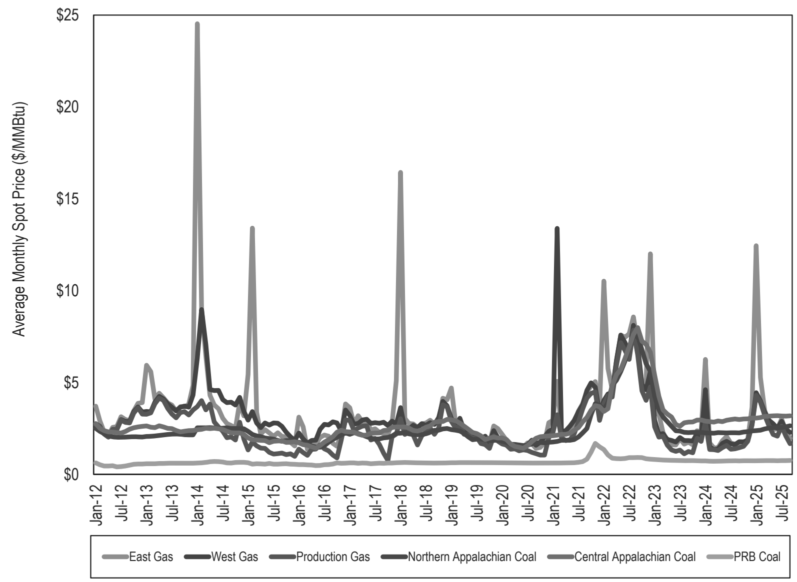
Fuel Price Trends and LMP

In a competitive market, changes in LMP follow changes in the marginal costs of marginal units, the units setting LMP. In general, fuel costs make up between 80 percent and 90 percent of short run marginal cost depending on generating technology, unit efficiency, unit age and other factors. The impact of fuel cost on marginal cost and on LMP depends on the fuel burned by marginal units and changes in fuel costs. Changes in emission allowance costs also contribute to changes in the marginal cost of marginal units.

Figure 3-50 shows fuel prices in PJM for 2012 through September 2025. Natural gas prices and coal prices increased and oil prices decreased in the first nine months of 2025 compared to the first nine months of 2024. In the first nine months of 2025, the price of eastern natural gas was 83.4 percent higher and the price of western natural gas was 59.2 percent higher than in the first nine months of 2025. The price of Northern Appalachian coal was 11.4 percent higher; the price of Central Appalachian coal was 7.8 percent higher; and the price of Powder River Basin coal was 2.5 percent higher.[107] The price of ULSD NY Harbor Barge (ultra low sulfur diesel) was 6.4 percent lower in the first nine months of 2025 than in the first nine months of 2024.

Figure 3-50 Spot average fuel price comparison: 2012 through September 2025 ($/MMBtu)



107 Eastern natural gas consists of the average of Texas M3, Transco Zone 6 non-NY, Transco Zone 6 NY and Transco Zone 5 daily indices. Western natural gas prices are the average of Columbia Appalachia and Chicago Citygate daily indices. Production gas prices are the average of Dominion South Point, Tennessee Zone 4, and Transco Leidy Line receipts daily indices. Coal prices are the average of daily fuel prices for Central Appalachian coal, Northern Appalachian coal, and Powder River Basin coal. All fuel prices are from Platts.

Components of LMP

Components of Real-Time Load-Weighted LMP

LMPs result from the operation of a market based on security-constrained, economic (least cost) dispatch (SCED) in which marginal units determine system LMPs, based on their offers and up to fourteen minute ahead forecasts of system conditions. Those offers can be decomposed into components including fuel costs, emission costs, variable operation and maintenance (VOM) costs, markup, FMU adder and the 10 percent cost adder. As a result, it is possible to decompose LMP by the components of unit offers.

Cost offers of marginal units are separated into their component parts. The fuel related component is based on unit specific heat rates and spot fuel prices. Emission costs are calculated using spot prices for NO_x, SO_2 and CO_2 emission credits, emission rates for NO_x, emission rates for SO_2 and emission rates for CO_2. The CO_2 emission costs are applicable to PJM units in the PJM states that participate in RGGI: Delaware, Maryland, and New Jersey.[108] The FMU adder is the calculated contribution of the FMU and AU adders to LMP that results when units with FMU or AU adders are marginal.

Since the implementation of scarcity pricing on October 1, 2012, PJM jointly optimizes the commitment and dispatch of energy and reserves. When generators providing energy have to be dispatched down from their economic operating level to meet reserve requirements, the joint optimization of energy and reserves takes into account the opportunity cost of the reduced generation and the associated incremental cost to maintain reserves. If a unit incurring such opportunity costs is a marginal resource in the energy market, this opportunity cost will contribute to LMP. The component, ancillary service redispatch cost, shows the contribution of this cost to the PJM's load-weighted LMP. In addition, in periods when the pricing run solution does not meet the reserve requirements, PJM invokes shortage pricing, based on the operating reserve demand curve. During shortage conditions, the LMPs of marginal generators reflect the cost of not meeting the reserve requirements, the scarcity component, which is defined by the operating reserve demand curve.[109]

Starting on September 1, 2021, the components shown in Table 3-70 and Table 3-72 are from the pricing run, which includes the impact of amortized start cost and amortized no load cost of the fast start marginal units. The components of LMP are shown in Table 3-70, including markup using unadjusted cost-based offers.[110] Table 3-70 shows that in the first nine months of 2025, 7.2 percent of the load-weighted LMP was the result of coal costs, 43.4 percent was the result of gas costs and 4.1 percent was the result of the cost of carbon emission allowances. The fuel-related components of LMP reflect the degree to which the cost of the identified fuel affects LMP and does not reflect the other components of the offers of units burning that fuel. Using unadjusted cost-based offers, negative markup was -7.4 percent of the load-weighted LMP. Using unadjusted cost-based offers, positive markup was 7.2 percent of the load-weighted LMP. LMP may, at times, be set by transmission constraint penalty factors. In the first nine months of 2025, 10.5 percent of the load-weighted LMP was the result of transmission penalty factors. More than 99 percent of this impact occurred as a result of PJM's reduction to line ratings in SCED. The percent contribution of transmission penalty factors has increased substantially since PJM allowed penalty factors to affect LMPs starting February 1, 2019. The component NA is the unexplained portion of load-weighted LMP. For several intervals, PJM failed to provide all the data needed to accurately calculate generator sensitivity factors. As a result, the LMP for those intervals cannot be decomposed into component costs. The NA component is the cumulative effect of excluding those five minute intervals. The percent column is the difference (in percentage points) in the proportion of LMP represented by each component in the first nine months of 2024 and 2025.

108 New Jersey withdrew from RGGI, effective January 1, 2012, and rejoined RGGI effective January 1, 2020. Virginia joined RGGI effective January 1, 2021, and left RGGI on December 31, 2023. Litigation over Virginia's participation is pending. See Virginia Court of Appeals (Case No. 1494-23-4).

109 Scarcity component includes ancillary service redispatch cost component during periods of scarcity.

110 These components are explained in the *Technical Reference for PJM Markets*, at p 27 "Calculation and Use of Generator Sensitivity/Unit Participation Factors," <http://www. monitoringanalytics.com/reports/Technical_References/references.shtml>.

Table 3-70 Components of real-time (Unadjusted) load-weighted average LMP: January through September, 2024 and 2025

	2024 (Jan - Sep)		2025 (Jan - Sep)		
Element	Contribution to LMP	Percent	Contribution to LMP	Percent	Change in Percent

Components of Change in LMP

Table 3-71 shows the components of the increase in real-time load-weighted average LMP from the first nine months of 2024 to the first nine months of 2025. In the first nine months of 2025, the real-time load-weighted average LMP increased by $16.20 per MWh, 47.2 percent. Fuel and consumables cost components of LMP (the sum of gas, coal, oil, landfill gas, variable operations) increased the LMP by $9.85 per MWh, 60.8 percent of increase in LMP. The emissions cost components of LMP (the sum of NO_X, CO_2, opportunity cost adder, SO_2, and renewable energy credits) decreased the LMP by $0.16 per MWh, -1.0 percent of the increase in LMP. The sum of the positive and negative markups, ten percent adder, and maintenance cost components, all of which reflect market power, increased the LMP $0.85 per MWh, 5.2 percent of the increase in LMP. The scarcity component increased the LMP by $1.14 per MWh, 7.0 percent of the increase in the LMP. The transmission constraint penalty factor increased the LMP by $2.07 per MWh, 12.8 percent, primarily as a result of PJM's reduction of line ratings in SCED. The ancillary service redispatch cost, the opportunity cost of reduced marginal generation to meet reserve requirements, decreased the LMP by $0.21 per MWh, -1.3 percent. The pre-emergency demand response called on by PJM during the hot weather days in June increased the LMP by $0.89 per MWh, 5.5 percent of the increase in LMP. The LMP increase would have been higher if PJM had not imposed a $3,700.00 per MWh administrative cap. The administrative cap reduced the LMP by $0.11 per MWh, a 0.7 percent decrease.

Table 3-71 Components of Change in real-time load-weighted average LMP: January through September, 2024 and 2025

Component	2024 (Jan - Sep)	2025 (Jan - Sep)	Change in LMP	Percent of Total Change
Fuel and Consumables	$19.75	$29.59	$9.85	60.8%
Emission Related	$3.34	$3.18	($0.16)	(1.0%)
Market Power Related	$5.57	$6.42	$0.85	5.2%
Scarcity	$0.18	$1.32	$1.14	7.0%
Transmission Constraint Penalty Factor	$3.23	$5.31	$2.07	12.8%
Ancillary Service Redispatch Cost	$1.41	$1.21	($0.21)	(1.3%)
Pre-emergency Demand Response	$0.00	$0.89	$0.89	5.5%
PJM Administrative Cap	$0.00	($0.11)	($0.11)	(0.7%)
All Other	$0.82	$2.71	$1.89	11.6%
Total Change	$34.31	$50.51	$16.20	100.0%

In order to understand the markup behavior of market participants, real-time and day-ahead LMPs are decomposed using two different approaches. In the first approach (Table 3-70) markup is the difference between the price offer and the cost-based offer (unadjusted markup). In the second approach (Table 3-72), the 10 percent markup is removed from the cost-based offers of coal, gas, and oil units (adjusted markup).

Table 3-72 Components of real-time (Adjusted) load-weighted average LMP: January through September, 2024 and 2025

	2024 (Jan - Sep)		2025 (Jan - Sep)		
Element	Contribution to LMP	Percent	Contribution to LMP	Percent	Change in Percent
Gas	$13.00	37.9%	$21.94	43.4%	5.6%
Positive Markup	$4.90	14.3%	$5.43	10.7%	(3.5%)
Transmission Constraint Penalty Factor	$3.23	9.4%	$5.31	10.5%	1.1%
Coal	$4.17	12.1%	$3.62	7.2%	(5.0%)

Decrease Generation Differential	($0.05)	(0.1%)	($0.25)	(0.5%)	(0.3%)
Negative Markup	($2.62)	(7.6%)	($2.48)	(4.9%)	2.7%
Total	$34.31	100.0%	$50.51	100.0%	0.0%

The components of LMP for the dispatch run and the pricing run are shown in Table 3-73, including markup using unadjusted cost-based offers for in the first nine months of 2025. The variable maintenance cost component is the component with the largest change in the share of total LMP from the dispatch run to the pricing run is, constituting 4.5 percent of the dispatch run LMP and 6.8 percent of the pricing run LMP.

Table 3-73 Comparison of components of real-time (Unadjusted) load-weighted average LMP in the dispatch run and pricing run: January through September, 2025

	Dispatch		Pricing		
Element	Contribution to LMP	Percent	Contribution to LMP	Percent	Change in Percent

Total	$46.34	100.0%	$50.51	100.0%	0.0%

The components of the total cost to real-time load ($M) are shown in Table 3-74, including markup using unadjusted cost-based offers. The components of the total cost to real-time load are shown in Table 3-75, including markup using adjusted cost-based offers. In the first nine months of 2025, the cost of real-time load increased by $10,488.1 million or 51.1 percent. Of the $30,996.6 million in the total cost of real-time load in the first nine months of 2025, $13,463.2 million is due to the cost of gas, $3,255.9 million is due to the transmission penalty factor, $2,234.5 million is due to the positive markup, $2,218.7 million is due to the cost of coal, $2,122.1 million is due to the variable maintenance and $1,876.2 million is due to the ten percent adder.

Table 3-74 Components of the cost of real-time (Unadjusted) load: January through September, 2024 and 2025

	Contribution to Real Time Cost of Load ($Million)

Table 3-76 shows the components of the increase in the cost of real-time load from the first nine months of 2024 to the first nine months of 2025. In the first nine months of 2025, the cost of real-time load increased $10,488.1 million. Fuel and consumables cost components of LMP (the sum of gas, coal, oil, landfill gas, variable operations) increased the cost of real-time load by $6,357.3 million, 60.6 percent of the increase in the cost of real-time load. The emissions cost components (the sum of NO_X, CO_2, opportunity cost adder, SO_2, and renewable energy credits) decreased the real-time cost of load by $47.9 million, -0.5 percent of the increase in the cost of real-time load. The sum of the positive and negative markups, ten percent adder, and maintenance cost components, all of which reflect market power, increased the cost of real-time load by $609.8 million, 5.8 percent of the increase in the cost of real time load. The scarcity component increased the cost of real-time load by $703.5 million, 6.7 percent of the increase in the cost of real-time load. The transmission constraint penalty factor increased the cost of real-time load by $1,324.2 million, 12.6 percent. The ancillary service redispatch cost, the opportunity cost of reduced marginal generation to meet reserve requirements, decreased the cost of real-time load by $106.0, 1.0 percent of the cost of real time load. The emergency demand response called on by PJM during the hot weather days in June and July increased the cost of real time load by $545.0 million, 5.2 percent of the increase in the cost of real time load. The cost of real time load would have been higher if PJM had not imposed a $3,700.00 per MWh administrative cap on SMP. The administrative cap reduced the cost of real time load by $68.0 million, a 0.6 percent decrease.

Table 3-76 Components of Change in the cost of real-time load: January through September, 2024 and 2025

	($ Million)			
Component	2024 (Jan - Sep)	2025 (Jan - Sep)	Change	Percent of Total Change
Fuel and Consumables	$11,803.5	$18,160.8	$6,357.3	60.6%
Emission Related	$1,999.0	$1,951.1	($47.9)	(0.5%)
Market Power Related	$3,330.6	$3,940.4	$609.8	5.8%
Scarcity	$105.9	$809.5	$703.5	6.7%
Transmission Constraint Penalty Factor	$1,931.7	$3,255.9	$1,324.2	12.6%
Ancillary Service Redispatch Cost	$845.7	$739.7	($106.0)	(1.0%)
Pre-emergency Demand Response	$0.0	$545.0	$545.0	5.2%
PJM Administrative Cap	$0.0	($68.0)	($68.0)	(0.6%)
All Other	$492.0	$1,662.1	$1,170.1	11.2%
Total Change	$20,508.5	$30,996.6	$10,488.1	100.0%

Components of Day-Ahead Load-Weighted LMP

LMPs result from the operation of a market based on security-constrained, least-cost dispatch in which marginal resources determine system LMPs, based on their offers. For physical units, those offers can be decomposed into their components including fuel costs, emission costs, variable operation and maintenance costs, markup, and the 10 percent cost offer adder. INC offers, DEC bids and up to congestion transactions are dispatchable injections and withdrawals in the day-ahead energy market with an offer price that cannot be decomposed. Using identified marginal resource offers and the components of unit offers, it is possible to decompose PJM system LMP using the components of unit offers and sensitivity factors.

Table 3-77 shows the components of the PJM day-ahead annual load-weighted average LMP. In the first nine months of 2025, 12.2 percent of the load-weighted LMP was the result of gas costs, 7.2 percent of the load-weighted LMP was the result of coal costs, 18.3 percent was the result of INCs, 33.2 percent was the result of DECs, 4.0 percent was the result of UTCs, and 7.1 percent was the result of positive markup.[111]

Table 3-77 Components of day-ahead (Unadjusted) load-weighted average LMP (Dollars per MWh): April through September, 2025

	2025 (Apr - Sep)	
Element	Contribution to LMP	Percent
DEC	$15.92	33.2%
INC	$8.79	18.3%
Gas	$5.86	12.2%
NA	$5.07	10.6%
Coal	$3.46	7.2%
Positive Markup	$3.39	7.1%
Up to Congestion	$1.92	4.0%
Variable Maintenance	$1.20	2.5%
Ten Percent Adder	$1.12	2.3%
Variable Operations	$0.88	1.8%
Ancillary Service Redispatch Cost	$0.79	1.6%
CO_2 Cost	$0.69	1.4%
Oil	$0.32	0.7%
Increase Generation Differential	$0.13	0.3%
Opportunity Cost Adder	$0.07	0.1%
NO_x Cost	$0.05	0.1%
Other	$0.01	0.0%
SO_2 Cost	$0.00	0.0%
Landfill Gas	$0.00	0.0%
Decrease Generation Differential	($0.00)	(0.0%)
Scarcity	($0.01)	(0.0%)
Transmission Constraint Penalty Factor	($0.02)	(0.0%)
Negative Markup	($0.76)	(1.6%)
Renewable Energy Credits	($0.88)	(1.8%)
Total	$48.00	100.0%

111 MMU identified an error in the marginal resource identification algorithm within the day ahead clearing optimization. The calculation of generator sensitivity factors requires accurate identification of marginal resources. The error was fixed by the PJM software vendor in March 2025. MMU was unable to calculate the component breakdown for 2024 and the first quarter of 2025 due to the inaccurate identification of marginal resources.

Table 3-78 shows the components of the PJM day-ahead annual load-weighted average LMP including the adjusted markup calculated by excluding the 10 percent adder from the coal, gas and oil units.[112]

Table 3-78 Components of day-ahead (Adjusted) load-weighted average LMP (Dollars per MWh): April through September, 2025

	2025 (Apr - Sep)	
Element	Contribution to LMP	Percent
DEC	$15.92	33.2%
INC	$8.79	18.3%
Gas	$5.86	12.2%
NA	$5.07	10.6%
Positive Markup	$4.07	8.5%
Coal	$3.46	7.2%
Up to Congestion	$1.92	4.0%
Variable Maintenance	$1.20	2.5%
Variable Operations	$0.88	1.8%

112 Id.

Shortage

PJM's real-time energy market experienced five-minute shortage pricing for one or more reserve products for 130 unique five-minute intervals across 22 days in the first nine months of 2025. PJM implemented fast start pricing on September 1, 2021, creating the possibility that the pricing run and the dispatch run could classify different intervals as short. In the first nine months of 2025, there were 130 unique five-minute intervals with real-time shortage pricing in the pricing run for one or more reserve products, and 111 unique intervals with real-time shortage pricing in the dispatch run for one or more reserve products.

Emergency Procedures

PJM issues advisories usually several days in advance to notify members of possible emergency actions that could be taken during the operating day. PJM declares alerts at least a day prior to the operating day to notify members of possible emergency actions that could be taken during the operating day. In real time, on the operating day, PJM issues warnings notifying members of system conditions that could result in emergency actions during the operating day.

Some emergency actions serve as triggers for performance assessment intervals (PAIs) when declared for the RTO or the active subzone. Some emergency actions trigger PAIs unconditionally while others only trigger PAIs when there is a primary reserve shortage for that area.[113] [114] The declaration of such emergency actions for smaller areas, such as for specific control zones, does not trigger a PAI. When communicating emergency procedures, PJM will also post NERC energy emergency alert (EEA) levels.[115] Table 3-79 provides a

113 See PJM. "PJM Manual 18: PJM Capacity Market," § 8.4A Non-Performance Assessment, Rev. 61 (Jul. 23, 2025).
114 OATT, Part I (Common Service Provisions) § 1.
115 NERC Attachment 1-EOP-011-4. "Energy Emergency Alerts," February 15, 2024. <https://www.nerc.com/pa/Stand/Reliability%20 Standards/EOP-011-4.pdf>.

description of PJM declared emergency procedures, in alphabetical order, including whether they are a trigger for PAIs and the NERC EEA level triggered with the procedure, if any.[116] [117] [118] [119]

Table 3-79 Description of emergency procedures

Emergency Procedure	Priority Level	Triggers NERC Energy Emergency Alert	Triggers Performance Assessment Interval	Purpose
Cold Weather Advisory	Advisory			To notify personnel and facilities that PJM may issue a Cold Weather Alert.
Cold Weather Alert	Alert			To prepare personnel and facilities for extreme cold weather conditions, generally when forecast weather conditions approach minimum or temperatures fall below ten degrees Fahrenheit.
Conservative Operations	Alert			To notify personnel and facilities that PJM may operate more conservatively. This can be due to natural phenomena, weather events, security events, and other conditions. Conservative operations may result in the use of larger contingencies and stricter transfer limits.
Emergency Energy Bids Requested	Informational			To request bids for emergency energy after declaring a Maximum Emergency Generation Action.
Emergency Mandatory Load Management Reduction Action	Action	EEA2		To request load reductions from customers registered in the PJM Demand Response program that need 30, 60, or 120 minute lead time to provide additional load relief, generally declared simultaneously with NERC Energy Emergency Alert Level 2 (EEA2)
Geomagnetic Disturbance Action	Action			To inform members that PJM will operate the grid with more conservative transfer limits developed for such disturbances. Transmission owners must coordinate with PJM before acting upon their own disturbance procedures.
Geomagnetic Disturbance Warning	Warning			To warn members than the National Oceanic and Atmospheric Administration predict a possible geomagnetic storm of severity K7 or greater, which can induce currents in the system and equipment.
High System Voltage Action	Action			To prepare the system for possible high voltages and to coordinate with transmission owners and generation owners for managing those high voltages.
Hot Weather Alert	Alert			To prepare personnel and facilities for extreme hot and/or humid weather conditions, generally when forecast temperatures exceed 90 degrees with high humidity.
Load Shed Directive	Action		Yes	To shed load in a local area, reserve subzone, or the entire RTO. A load shed directive for the reserve subzone or the entire RTO triggers a Performance Assessment Interval.
Low Voltage Alert	Alert			To alert transmission owners and generation owners that a period of low voltage and high load are expected.
Maintenance Outage Recall	Informational			To request that generation owners make units available by canceling any maintenance outages within at least 72 hours of posting. After that time, maintenance outages are converted into forced outages.
Maximum Emergency Action	Action		Yes with PR shortage	To provide real time notice to increase generation above the maximum economic level. It is implemented whenever generation is needed that is greater than the maximum economic level.
Maximum Emergency Generation Alert	Alert	EEA1		To provide an early alert at least one day prior to the operating day that system conditions may require the use of the PJM emergency procedures and resources must be able to increase generation above the maximum economic level of their offers.
Non-Market Post Contingency Local Load Relief Warning	Warning			To warn transmission owners of the possibility of load shed in their area for non-market facilities.
Post Contingency Local Load Relief Warning	Warning			To warn transmission owners of the possibility of load shed in their area.
Pre-Emergency Mandatory Load Management Reduction Action	Action			To request load reductions from customers registered in the PJM Demand Response program that need 30, 60, or 120 minute lead time before declaring emergency load management reductions
Transmission Loading Relief (TLR)	Informational			To maintain transmission operating security limits. This can involve curtailing external transactions and charging outside customers for the cost of congestion.
Unit Startup Notification Alert	Alert			To direct generation owners to prepare units so that long lead time units can come online within 48 hours. This notice is given days in advance of the predicted need.
Voltage Reduction Action	Action	EEA2 or EEA3 depending on circumstance	Yes	To reduce load to provide sufficient reserve capacity to maintain tie flow schedules and preserve limited energy sources. It is implemented when load relief is needed to maintain tie schedules.

116 See PJM. "PJM Manual 13: Emergency Operations," § 3.3 Cold Weather Advisory / Alert, Rev. 94 (Dec. 18, 2024).
117 See PJM. "PJM Manual 13: Emergency Operations," § 3.4 Hot Weather Alert, Rev. 94 (Dec. 18, 2024).
118 See PJM. "PJM Manual 13: Emergency Operations,"§ 2.3.1 Advanced Notice Emergency Procedures: Alerts, Rev. 94 (Dec. 18, 2024).
119 See PJM. "PJM Manual 13: Emergency Operations," § 2.3.2 Real-Time Emergency Procedures (Warnings and Actions), Rev. 94 (Dec. 18, 2024).

Not all emergency procedures defined in Table 3-79 are included in Table 3-80, Table 3-81, Figure 3-51, Figure 3-52, Figure 3-54 and Figure 3-55, even if they occurred in the first nine months of 2025. Synchronized reserve events are covered in more detail in Section 10. Information about frequent events is treated separately. Post Contingency Local Load Relief Warnings (PCLLRWs) and Non-Market Post Contingency Local Load Relief Warnings (NMPCLLRWs) are shown in Figure 3-56 and Figure 3-57. Transmission loading relief informational postings (TLRs) are discussed in other sections of this report. Local load relief warnings provide to transmission owners advanced warning of possible local load shed in an area in order to relieve a local constraint and are separate from manual load dump warnings. Transmission loading relief is a NERC procedure for curtailing interchange transactions to avoid violating operational limits of the system.[120] [121]

Table 3-80 shows the dates affected by emergency alerts, warnings, actions, and informational postings in the first nine months of 2025. Events in Table 3-80 can span multiple days, but only the first day is shown. Advisories, alerts, warnings, and informational postings do not necessarily take effect immediately. For example, for cold weather alerts, the dates affected are when PJM expects the cold weather requiring the alert to occur. For maintenance outage recalls, the dates affected are from the date PJM initiates the recall until the date the units are expected to be available. Figure 3-51 shows the timeline of the advisories, alerts, warnings, actions, and the maintenance outage recall during the January 2025 polar vortex. Figure 3-52 shows the timeline of the alerts, actions, and the maintenance outage recall during the June 2025 hot weather event. Figure 3-53 shows the timeline of the alerts, actions, and the maintenance outage recall during the July 2025 heatwave.

Power Balance Constraint Violation

The purpose of the real-time energy market is to dispatch sufficient supply to meet demand. In the RT SCED optimization, the power balance constraint enforces the requirement that total dispatched generation (supply) equals the sum total of forecasted load, losses and net interchange (demand). The power balance constraint is violated when supply is less than demand. In some cases, the power balance constraint is violated while the reserve requirements are satisfied.

The current process for meeting energy and reserve requirements in real time, and pricing the system conditions when RT SCED forecasts that energy supply is less than the demand for energy and reserves, is opaque and not defined in the PJM governing documents. It is unclear whether and how PJM converts reserves to energy before violating the power balance constraint. It is unclear whether and when PJM uses its authority under the tariff to curtail exports from PJM capacity resources to meet the power balance constraint. It is unclear why PJM does not include demand side capacity resources in the definition of reserves. It is unclear whether PJM would maintain a minimum level of synchronized reserves even if that would result in a controlled load shed. The current RT SCED does not have a mechanism to convert inflexible reserves procured by the ASO to energy to satisfy the power balance constraint.[127] SCED solutions from October 1, 2019, February 16, 2020, and April 21, 2020, indicate that the defined logic met transmission constraint limits and reserve requirements but violated the power balance constraint, and did not reflect this constraint violation in prices. The definitions and implementation of reserves, combined with operator discretion to bias load, make it difficult to define when there is an actual power balance constraint violation. Effective August 8, 2024, PJM updated SCED and LPC to convert reserves to energy before violating the power balance constraint.

During Winter Storm Elliott, on December 23, and December 24, 2022, PJM created what PJM termed virtual generation in real time to satisfy the power balance constraint. PJM did not convert any inflexible reserves to energy. In summary, the power balance constraint was violated solely as a result of load bias added by PJM and that violation was corrected by PJM adding generation that does not actually exist to the supply (virtual generation). To the extent that there was not an actual violation of the power balance constraint, it was appropriate that PJM did not take actions to address the nonexistent violation.

The MMU recommends that PJM clarify, modify and document its process for dispatching reserves and energy when SCED indicates that supply is less than total demand including forecasted load and reserve requirements. The modifications should include: the exact definition of the power balance constraint including the role of PJM load bias; a SCED process to economically convert reserves to energy; a process for the recall of energy from capacity resources to address any actual or potential power balance issue; a process to call on demand side capacity resources, and the minimum level of synchronized reserves that would trigger load shedding. Table 3-82 shows the number of five minute intervals for which the RT SCED solutions did not balance demand and supply. Prior to August 8, 2024, PJM reran the RT SCED with artificially increased supply to satisfy the power balance constraint. In the first nine months of 2025, there were six five-minute intervals that used an RT SCED solution with an apparently violated power balance constraint.

On June 24, 2025, PJM apparently violated the power balance constraint for two five minute intervals in the hour beginning at 1800 in the pricing run. In those two five minute intervals, PJM also capped the energy LMP at $3,700 per MWh. However, PJM positively biased the load forecast in the two intervals where the power balance constraint was violated.

Table 3-82 Number of five minute intervals using RT SCED solutions with apparently violated power balance constraint by year

Year	Number of five minute intervals	Average Energy Component of LMP in SCED ($/MWh)	Average Energy Component of LMP in Pricing Run ($/MWh)
2013	-	$0.00	$0.00
2014	655	$36.29	$36.29
2015	71	($0.76)	($0.76)
2016	42	$93.06	$93.06
2017	31	$279.86	$279.86
2018	16	$268.21	$268.21
2019	36	$845.48	$845.48
2020	5	$351.56	$351.56
2021	10	$976.06	$976.06
2022	121	$2,347.33	$2,066.21
2023	23	$357.34	$361.14
2024	6	$907.95	$907.95
2025 (Jan - Sep)	6	$3,542.96	$3,123.31

Shortage and Shortage Pricing

In electricity markets, shortage means that demand, including reserve requirements, is nearing the limits of the currently available capacity of the system. Shortage pricing is a mechanism for signaling scarcity conditions through higher energy prices. Under the PJM rules that were in place through September 30, 2012, shortage pricing resulted from the exercise of aggregate market power by individual generation owners for specific units when the system was close to its available capacity. That was not an efficient way to

127 Inflexible reserves are those reserves that clear in the hour ahead Ancillary Service Optimizer (ASO) but cannot be dispatched in the real time dispatch tool, RT SCED.

manage shortage pricing and made it difficult to distinguish between market power and shortage pricing. Shortage pricing is an administrative pricing mechanism that sets a defined higher price when the system operates with real-time reserves that are lower than the target level.

In the first nine months of 2025, there were 130 five-minute intervals with real-time shortage pricing for one or more reserve products that occurred on 22 days in PJM.

In Order No. 825, the Commission required each RTO/ISO to trigger shortage pricing for any dispatch and pricing interval in which a shortage of energy or operating reserves is indicated by the RTO/ISO's software.[128] Prior to May 11, 2017, if the dispatch tools (Intermediate-Term SCED and Real-Time SCED) reflected a shortage of reserves (primary or synchronized) for a time period shorter than a defined threshold (30 minutes), it was considered a transient shortage, a shortage event was not declared, and shortage pricing was not implemented. As of May 11, 2017, the rule requires PJM to trigger shortage pricing for any five minute interval for which the Real-Time SCED (Security Constrained Economic Dispatch) indicates a shortage of synchronized reserves or primary reserves. In January 2019, PJM updated its business rules in Manual 11 to describe PJM's implementation of the five minute shortage pricing process. PJM Manual 11 states that shortage pricing is triggered when an approved RT SCED case that was used in the Locational Pricing Calculator (LPC) indicates a shortage of reserves. The implementation is not fully algorithmic or well defined because RT SCED can indicate a shortage that PJM does not use in pricing and because the load bias added to SCED may artificially create or suppress shortages. On June 22, 2020, PJM reduced the frequency of automatic RT SCED executions to every five minutes in order to match the frequency of pricing in the LPC, which reduced the frequency of unpriced shortage solutions.

Prior to September 1, 2021, the reserves calculated in the LPC solution, and the reserves calculated in the reference RT SCED case used by the LPC solution were the same. With the implementation of fast start pricing on September 1, 2021, shortage pricing is now triggered by the pricing run in LPC.[129] This can lead to differences between the dispatched reserves in RT SCED and the reserves calculated in the pricing run in LPC. In the pricing run in LPC, shortage pricing could be triggered even when there is no actual shortage in dispatched reserves as determined by the reference RT SCED solution. This occurred for 19 intervals in the first nine months of 2025.

Voltage reduction actions and manual load dump actions are also triggers for shortage pricing, reflecting the fact that when operators need to take these emergency actions to maintain reliability, the system is short reserves and prices should reflect that condition, even if the power balance constraint is met and there is no defined shortage of reserves.[130]

Operating Reserve Demand Curves

Shortage pricing in the PJM Energy Market can occur in either the day-ahead or the real-time market for any of five reserve requirements: RTO Synchronized Reserves, Subzone Synchronized Reserves, RTO Primary Reserves, Subzone Primary Reserves, and 30-Minute Reserves. Each requirement is modelled in the market clearing engines as a demand curve priced at $850 per MWh up to the minimum reserve requirement (MRR) and at $300 per MWh for additional reserves of at least 190 MW.[131] [132] During reserve shortages, the prices on the demand curve are added to LMP. This is called shortage pricing. Mathematically, when a reserve constraint is not satisfied, the area under the demand curve for the unmet MW of the reserve requirement is added to the market clearing cost-minimization objective function as a penalty for violating a reserve constraint, which causes the administrative price on the ORDC to determine the marginal cost of the reserve shortage. This is why the values on the ORDC are sometimes called penalty factors. Because an additional MW of energy on the margin would require another MW of reserves shortage, the administrative marginal cost of reserves defined by the ORDC is added to LMP.

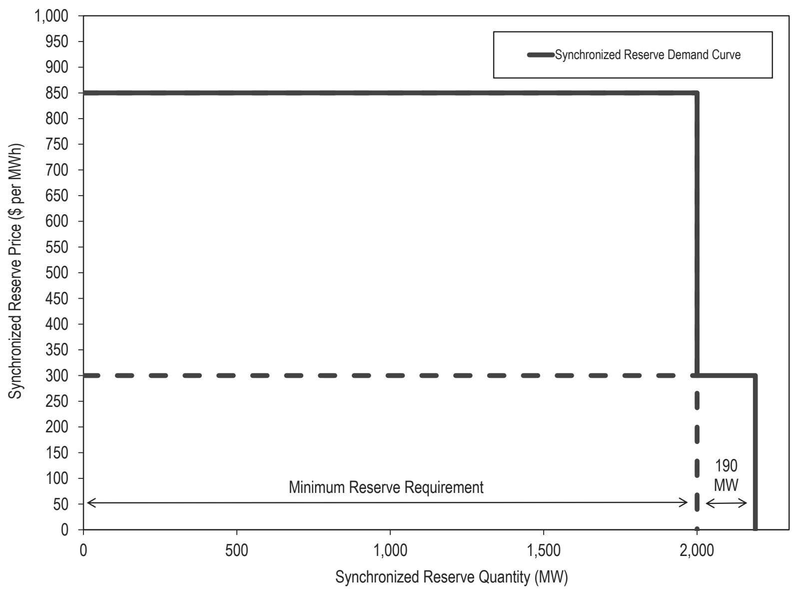
Shortage Pricing and Energy Price Formation

The current operating reserve demand curves (ORDC) in PJM define an administrative price for estimated reserves (synchronized, primary, and 30-minute reserves) up to the extended reserve requirement quantities, which for each reserve service is the sum of that service's minimum reserve requirement (MRR) and an extended requirement of at least 190 MW. The price is $850 per MWh for reserve quantities less than the MRR. The price is $300 per MWh for reserve quantities between the MRR and the sum of the MRR and the extended requirement. The example demand curve shown in Figure 3-58 drops to a zero price for quantities above the extended reserve requirement.

Figure 3-58 Example real-time extended synchronized reserve demand curve showing the permanent second step



Historically, the minimum reserve requirement for each operating interval has equaled the size of the largest single source of supply on the PJM system during that operating interval, known as the most severe single contingency. Beginning May 12, 2023, PJM unilaterally increased the minimum reserve requirement based on what appeared to be low response rates from reserves but not based on any evidence about reliability issues. The changes to the reserve requirements are discussed in more detail in Section 10: Ancillary Service Markets.

Nesting

The reserve requirements are nested such that the reserves with shorter allowed response times and stricter synchronization requirements count toward the requirements for reserves with longer allowed response times and less strict synchronization requirements, and such that the reserves in the subzone count toward the total RTO requirement. For example, synchronized reserves count toward the primary reserve requirement, and Mid-Atlantic Dominion reserves count toward the PJM RTO reserve requirement. This nesting means that the effect of reserve constraints on prices can be additive.

The effect of the reserve constraints on pricing depends on the constraint shadow price. The market uses constraints to ensure that reliability requirements are met while production costs are minimized. A binding constraint means that the market incurred some additional production cost to satisfy the constraint. A violated constraint has no associated production cost, so the market assigns an administrative cost based on the ORDC. The shadow price of a constraint is the change in the total production cost (the objective function of the market dispatch software) if that constraint limit were increased at the margin. A reserve constraint violation (a shortage) means that the constraint cannot be satisfied at a marginal cost less than the value on the ORDC. For the RTO synchronized reserve constraint, the shadow price during a shortage is defined to equal the ORDC value. For the MAD synchronized reserve constraint, when reserves from both the RTO and MAD can be used, the shadow price equals the sum of the ORDC value for each constraint when both are violated. The same occurs for the primary and secondary reserve constraints. The total shadow price of reserve violations can reach five times the highest ORDC value of

$850 per MWh, which is $4,250 per MWh. This value exceeds the PJM $1,700 per MWh price caps on reserve prices and the $3,700 per MWh price cap applied to the energy component of LMP, also called the system marginal price.

Energy and Reserve Price Caps

Table 3-83 shows six example scenarios, under the current ORDCs, with combinations of energy offers, reserve shortage penalty factors and transmission constraint penalty factors that can add up to produce high LMPs at sample pnodes in the MAD Reserve Subzone and outside the MAD Reserve Subzone.

Scenario A shows a simple shortage in the RTO Reserve Zone. In scenario B, there is a reserve shortage for both primary and synchronized reserves in both MAD and RTO Reserve Zones that results in a $1,700 per MWh reserve shortage penalty in the RTO Zone LMP and a $3,400 per MWh reserve shortage penalty in the MAD Zone LMP. The marginal resource for energy is in the RTO Zone. The RTO to MAD reserve transfer constraint is binding, so the higher MAD reserve penalty does not affect the rest of RTO LMP.

In scenario C, there is a reserve shortage for both primary and synchronized reserves in both MAD and RTO Reserve Zones and a violated transmission constraint that affects the marginal congestion costs in the system marginal price. In scenario C, the sum of the marginal unit cost, reserve and transmission constraint penalty factors equals $5,450 per MWh, which exceeds $3,700 per MWh, so SMP capping is triggered whether the marginal unit for energy can provide reserves for the MAD Zone or only the RTO Zone.

In scenario D, with a $1,000 per MWh offer price for the marginal unit for energy, violation of four reserve penalty factors does not trigger SMP capping, because the marginal unit for energy cannot serve the MAD reserve requirement. Scenario E and F show that LMPs can exceed $3,700 per MWh if there is a violated transmission constraint that is not exacerbated by an increase in load at the load weighted reference pricing node, which determines the SMP.[133]

In Scenario F, the energy component of LMP is at its highest level, $2,000 per MWh and there is a reserve shortage for primary and synchronized reserves in both MAD and RTO Reserve Zones and a shortage of 30 minute reserves, resulting in a capped $1,700 per MWh scarcity adder, and a violated transmission constraint with a $2,000 per MWh penalty factor that results in a $5,700 per MWh LMP. The LMPs in Scenario F are not the highest possible LMPs in the PJM energy market under the current rules. If there are multiple violated transmission constraints, the congestion costs contributing to the LMP at a pnode can exceed $2,000 per MWh resulting in LMPs higher than $5,700 per MWh.

Scenarios G and H are similar to conditions during the highest priced hours of Winter Storm Elliott on December 23 and 24, 2022. In G, the marginal unit offer price is $500 per MWh. The synchronized and primary reserve requirements are violated for the RTO and MAD zones. Transmission constraints affect both the system marginal price and other locations. The SMP in G is capped at $3,700 per MWh. In H, the marginal unit offer price is lower, at $40 per MWh, and the 30 minute reserve constraint is also violated. With the offer caps, the SMP is also at $3,700 per MWh.

The extent to which each transmission penalty factor for a constraint affects the LMP at a pnode is directly proportional to the pnode's distribution factor (dfax) with respect to that constraint. In addition, the LMP at a pnode includes a loss component calculated as the product of the marginal loss factor and the uncapped system marginal price.

133 The impact of the transmission constraint penalty factor at a pnode depends on its distribution factor (dfax) with respect to the constraint. The scenarios here assume a single violated transmission constraint with dfax of 1.0. If there are multiple violated transmission constraints, the total impact at a pnode is the sum of the product of transmission constraint penalty factors and distribution factors.

Table 3-83 Real-time additive penalty factors under reserve shortage and transmission constraint violations: Status Quo

Scenario	Marginal Unit Offer Price	Synchronized Reserve Penalty Factor		Primary Reserve Penalty Factor		30 Minute Reserve Penalty Factor	Transmission Constraint Penalty Factor in SMP	System Marginal Price		Transmission Constraint Penalty Factor in CLMP	Total LMP	
		RTO	MAD	RTO	MAD	RTO		RTO Marginal	MAD Marginal		RTO Marginal	MAD Marginal
A	$50	$850	$0	$0	$0	$0	$0	$900	$900	$0	$900	$900
B	$50	$850	$850	$850	$850	$0	$0	$1,750	$3,450	$0	$1,750	$3,450
C	$50	$850	$850	$850	$850	$0	$2,000	$3,700	$3,700	$0	$3,700	$3,700
D	$1,000	$850	$850	$850	$850	$0	$0	$2,700	$3,700	$0	$2,700	$3,700
E	$1,000	$850	$850	$850	$850	$850	$2,000	$3,700	$3,700	$2,000	$5,700	$5,700
F	$2,000	$850	$850	$850	$850	$850	$2,000	$3,700	$3,700	$2,000	$5,700	$5,700
G	$500	$850	$850	$850	$850	$0	$2,000	$3,700	$3,700	$2,000	$5,700	$5,700

Shortage Pricing During Synchronized Reserve Events

Synchronized reserves are deployed when PJM declares a synchronized reserve event, also known as a spinning event. PJM's method of communication prior to December 2024 failed to result in reliably timely responses, defined to be within 10 minutes. For units that could receive an electronic signal, PJM's instruction to units supplying reserves was to ignore the dispatch signals sent by RT SCED and to instead ramp their units up until the spin event ends. A significant number of resources did not have the capability to receive the electronic signals that PJM offered. The ALL-CALL system only calls a limited number of contacts at the same time. Although PJM's stated goal was an immediate response, in practice it took minutes for a generator's designated contact to respond to the ALL-CALL, who could then take minutes more to call personnel at the plant. If a unit was following automatic generation control when an event was declared, then additional minutes could also be lost switching to manual control. The end result of these communications issues was that resources started responding only after minutes into an event, even when everything went well.[134] In December 2024, PJM added an automated communication method that would add the reserve deployment instruction to the dispatch signal, which will allow generators following automatic generation control to automatically follow the signal. The new method did not affect any synchronized reserve events in 2024. The new method applied to all 19 events in the first nine months of 2025, of which only four exceeded ten minutes. The new method did not resolve the communications issues for all resources. Significant communications issues remain unresolved.

Although PJM signals resources to increase their output, the approved SCED cases are solved with the reserve requirement intact, which dispatches the system to meet the load and reserve requirements 8 to 10 minutes into the future. Currently, RT SCED has the ability to back down units during events to create available reserves, which counteracts PJM's recovery effort. This results in a discrepancy between the RT SCED solutions and the operational need during a spinning event. While PJM recovers from a disturbance during a spinning event, PJM should adjust the operating reserve demand curve (ORDC) for synchronized reserves to ensure that RT SCED does not have a competing objective of immediately replacing reserves that have been paid for and are being used as intended. Without such an adjustment, the prices will be artificially inflated, potentially triggering shortage pricing, during the times when reserves are used for their intended purpose. For example, nine shortage pricing intervals were artificially triggered during the spin events on February 5, February 11, June 22, August 14, September 4, and September 25, 2025. The MMU recommends that PJM adjust the ORDCs during spin events to reduce the reserve requirements by the amount of the reserves deployed.

134 See the *2024 State of the Market Report for PJM*, Volume 2: Section 10: Ancillary Service Markets for a more detailed discussion of these issues.

Reserve Shortages in the First Nine Months of 2025

Reserve Shortage in Real-Time SCED

The MMU analyzed the RT SCED solutions to determine how many of the five minute target time RT SCED solutions indicated a shortage of any of the reserve products in the RTO Reserve Zone and the MAD Reserve Subzone (synchronized reserve and primary reserve in both areas and 30-minute reserve in the RTO), when multiple solutions indicated shortage of reserves, and how many of these resulted in shortage prices in LPC. Reserves are considered short if the quantity (MW) of reserves dispatched by RT SCED for a five minute interval is less than the extended reserve requirement. To trigger shortage pricing, PJM operators must approve an LPC case in which the MW of reserves in the pricing run of the LPC are short of the extended reserve requirement.

Until June 2, 2021, PJM generally solved one RT SCED case with three solutions per case, for each five minute target time.[135] [136] On June 3, 2021, PJM updated RT SCED to solve two additional scenarios, or a total of five solutions per case. In 2021, the frequency with which RT SCED solutions were approved increased to one solution per five minute interval. This approval frequency increased the proportion of approved SCED solutions that are reflected in LMPs. However, the process of selecting the SCED solution to approve, among the solutions available to PJM operators, is subjective and is not based on clearly defined criteria. The criteria are especially important when only some of the SCED solutions reflect shortage pricing.

The MMU analyzed the target times for which one or more RT SCED case solutions indicated a shortage of one or more reserve products. Table 3-84 shows, in 2024 and the first nine months of 2025, the total number of target times, the number of target times for which at least one RT SCED solution showed a shortage of reserves, the number of target times for which multiple RT SCED solutions showed a shortage of reserves, and the number of five-minute pricing intervals for which the LPC solution showed a shortage of reserves. Each execution of RT SCED produces five solutions, using five different levels of load bias. Table 3-84 shows that, in 2024, 6,811 target times, or 6.5 percent of all five-minute target times, had at least one RT SCED solution showing a shortage of reserves, and 1,905 target times, or 1.8 percent of all five-minute target times, had more than one RT SCED solution showing a shortage of reserves. In the first nine months of 2025, there were 4,082 target times, or 5.2 percent of all five-minute target times, that had at least one RT SCED solution showing a shortage of reserves, and 1,368 target times, or 1.7 percent of all five-minute target times, that had multiple RT SCED solutions showing a shortage of reserves.

135 A case is executed when it begins to solve. Most but not all cases are solved. RT SCED cases take about one to two minutes to solve.
136 PJM updated the RT SCED execution frequency to solve one case for each five minute target time beginning June 22, 2020. PJM dispatchers may solve additional cases at their discretion.

Table 3-84 Real-time monthly five minute SCED target times and pricing intervals with shortage: January 2024 through September 2025

Year	Month	Number of Five Minute Intervals	Number of Target Times With At Least One SCED Solution Short of Reserves	Percent Target Times With At Least One SCED Solution Short of Reserves	Number of Target Times With Multiple SCED Solutions Short of Reserves	Percent Target Times With Multiple SCED Solutions Short of Reserves	Number of Five Minute Intervals With Shortage Prices in LPC	Percent RT SCED Target Times With Reserve Shortage With Shortage Prices in LPC
2024	Jan	8,928	398	4.5%	119	1.3%	10	2.5%

2025	Jul	8,928	384	4.3%	124	1.4%	16	4.2%
2025	Aug	8,928	365	4.1%	109	1.2%	7	1.9%
2025	Sep	8,640	468	5.4%	160	1.9%	9	1.9%
2025	Total	78,612	4,082	5.2%	1,368	1.7%	130	3.2%

As shown in Table 3-84, in 2024, there were 1,905 unique five-minute target times for which multiple RT SCED solutions showed a shortage of reserves for one or more reserve services, while there were 39 unique five-minute intervals with real-time shortage pricing for one or more reserve products. In the first nine months of 2025, there were 1,368 unique five-minute target times for which multiple RT SCED solutions showed a shortage of reserves for one or more reserve services, while there were 130 unique five minute intervals with real-time shortage pricing for one or more reserve products. Clear criteria for approval of shortage cases are needed.

The PJM Real-Time Energy Market produces an efficient outcome only when prices are allowed to reflect the fundamental supply and demand conditions in the market in real time. While it is appropriate for operators to ensure that cases use data that reflect the actual state of the system, it is essential that operator discretion not extend beyond what is necessary and that operator discretion not prevent shortage pricing when there are shortage conditions or implement shortage pricing when there are no shortage conditions. This is a critical issue now that PJM settles all real-time energy transactions on a five minute basis using the prices calculated by LPC. The MMU recommends that PJM define clear criteria for operator approval of RT SCED cases, including shortage cases that are used to send dispatch signals to resources, and for pricing, to minimize discretion. A rule based approach is essential for defining how LMPs are determined so that all market participants can be confident that energy market pricing is efficient.

Shortage Pricing Intervals in LPC

Beginning October 1, 2022, shortage pricing can occur in both the PJM Day-Ahead and Real-Time Energy Markets for Synchronized Reserves, Primary Reserves, and 30-Minute Reserves.

In May 2023, PJM increased reserve requirements in response to poor reserve performance by the units selected to provide reserves. PJM unilaterally increased the synchronized reserve reliability requirement by 30 percentage points to 130 percent of the most severe single contingency (MSSC), which consequently increased the primary reserve reliability requirement by 45 percentage points to 195 percent of the MSSC. While the intervals listed in this section were short of their target requirements, many of these intervals still cleared above the average values of the requirements from before the increase.

The average primary reserve requirement from January 2023 through April 2023 was 2,511.4 MW and the average synchronized reserve requirement was 1,741.7 MW. Many of the intervals with shortage pricing were not short in the sense of failing to clear a sufficient amount of reserves for recovering from a contingency event. They were short because of PJM's unilateral increase to the synchronized reserve reliability requirement. Table 3-85 shows the count of intervals with shortage pricing for synchronized reserve (SR), primary reserve (PR), and 30-minute reserve (TMR). As seen in Table 3-85, the majority of intervals with shortage pricing cleared reserves in excess of the original reserve requirements absent PJM's adder.

Table 3-85 Number of shortage pricing intervals which satisfied the unmodified reserve service requirement: January through September, 2025

	Intervals with Shortage Pricing			Intervals where RT SCED Satisfied Original Requirement			Percentage of Intervals where RT SCED Satisfied Original Requirement			Intervals where RT SCED Did Not Satisfy Original Requirement		
Location	SR	PR	TMR	SR	PR	TMR	SR	PR	TMR	SR	PR	TMR
RTO	17	111	22	17	79	16	100.0%	71.2%	72.7%	0	32	6
MAD	6	6	0	4	2	0	66.7%	33.3%	NA	2	4	0

There were 130 unique real-time five minute intervals with shortage pricing for one or more reserve products in the first nine months of 2025, compared to 29 intervals in the first nine months of 2024. In the first nine months of 2025, there were 130 five minute intervals with shortage pricing in the pricing run for one or more reserve products, and there were 111 intervals with shortage in the dispatch run for one or more reserve products. The following tables show intervals with shortage pricing in the pricing run for each reserve service for the RTO Reserve Zone and the MAD Reserve Subzone. PJM implemented fast start pricing on September 1, 2021. Fast start pricing can result in differences in reserve shortages between the dispatch run and the pricing run.

In 2024, there were no hours with shortage pricing in the day-ahead reserve markets. In the first nine months of 2025, there were four unique day-ahead hours with shortage pricing for one or more reserve products. For February 25, in the day-ahead market, there was one hour with shortage pricing for primary reserves in the MAD Reserve Subzone. For July 29, in the day-ahead market, there were three hours with shortage pricing for primary reserves in the RTO Reserve Zone.

Table 3-86 shows the extended synchronized reserve requirement, the total synchronized reserves, the synchronized reserve shortage, and the synchronized reserve clearing prices for the RTO Reserve Zone during the 20 intervals with shortage pricing in the pricing run due to synchronized reserve shortage in the first nine months of 2025. Table 3-86 shows that the 20 intervals were short of synchronized reserves in both the pricing run and the dispatch run. Seven intervals were also short of synchronized reserves in MAD in the pricing and dispatch run. Thirteen intervals were also short of primary reserves in the RTO in the pricing and dispatch runs. Nine intervals were also short of primary reserves in MAD in the pricing and dispatch runs. Seven intervals were also short of 30-minute reserves in the RTO in the pricing and dispatch runs. Six intervals overlapped with spinning events on February 5, February 11, June 22, 2025, and September 4, 2025.

Table 3-87 shows the extended synchronized reserve requirement, the total synchronized reserves, the synchronized reserve shortage, and the synchronized reserve clearing prices for the MAD Reserve Zone during the three intervals with shortage pricing in the pricing run due to synchronized reserve shortage in the first nine months of 2025. Table 3-87 shows that the three intervals were short of synchronized reserves in both the pricing run and the dispatch run. One interval was also short of primary reserves in the RTO in the pricing and dispatch run. Three intervals were also short of 30-minute reserves in the pricing and dispatch run. Five intervals occurred during synchronized reserve events and were also short of synchronized reserve in the RTO in the pricing and dispatch run.

Table 3-88 shows a summary of the extended primary reserve requirement, the total primary reserves, the primary reserve shortage, and the primary reserve clearing prices for the RTO Reserve Zone during the 125 intervals with shortage pricing in the pricing run due to primary reserve shortage in the first nine months of 2025. Of the 125 intervals that were short of primary reserves, 106 were short in both the pricing run and the dispatch run. Eight intervals were also short of primary reserve in the MAD Reserve Subzone in the pricing run and dispatch run. Thirteen intervals were also short of synchronized reserve in the RTO Reserve Zone in the dispatch run and pricing run. Five intervals were also short of synchronized reserve in the MAD Reserve Subzone in the dispatch run and pricing run. Twenty-three intervals were also short of 30-minute reserves in the RTO Reserve Zone in the dispatch run and pricing run. The one interval on February 11, two intervals on June 22, two intervals on August 14, one interval on September 4, and one interval on September 25 overlapped with synchronized reserve events.

Table 3-89 shows the extended primary reserve requirement, the total primary reserves, the primary reserve shortage, and the primary reserve clearing prices for the MAD Reserve Subzone during the nine intervals with shortage pricing in the pricing run due to primary reserve shortage in the first nine months of 2025. Table 3-88 shows that all nine intervals were short of primary reserves in both the pricing run and the dispatch run. All nine intervals were also short of primary reserves in the RTO Reserve Zone in the pricing run and the dispatch run. All nine intervals were also short of synchronized reserve in the RTO Reserve Zone in the pricing run and the dispatch run. Four of the intervals were also short of synchronized reserve in the MAD Reserve Subzone in the pricing run and the dispatch run. The intervals on June 22 and September 4 overlapped with synchronized reserve events.

Table 3-90 shows the extended 30-minute reserve requirement, the total 30-minute reserves, the 30-minute reserve shortage, and the 30-minute reserve clearing prices for the RTO Reserve Zone during the 23 intervals with shortage pricing in the pricing run due to primary reserve shortage in the first nine months of 2025. Table 3-88 shows that all 23 intervals were short of 30-minute reserves in both the pricing run and the dispatch run. All 23 intervals were also short of primary reserves in the RTO Reserve Zone in the pricing run and the dispatch run. Three intervals were also short of primary reserve in the MAD Reserve Subzone in the pricing run and the dispatch run. Six intervals were also short of synchronized reserve in the RTO Reserve Zone in the pricing run and the dispatch run. Three of the intervals were also short of synchronized reserve in the MAD Reserve Subzone in the pricing run and the dispatch run. The interval on June 22 occurred during a synchronized reserve event.

PJM enforces an RTO wide reserve requirement and a reserve requirement for the MAD region. The MAD Reserve Subzone is inside the RTO Reserve Zone. Resources located in the MAD Reserve Subzone can simultaneously satisfy the synchronized reserve requirement of the RTO Reserve Zone and the synchronized reserve requirement of the MAD Reserve Subzone. Resources located outside the MAD Reserve Subzone can satisfy the synchronized reserve requirement of the RTO Reserve Zone, and subject to transfer limits defined by transmission constraints, satisfy the reserve requirement of the MAD Subzone. The synchronized reserve clearing price of the RTO Reserve Zone is set by the shadow price of the binding reserve requirement constraint of the RTO Reserve Zone.[137] The synchronized reserve clearing price of the MAD Reserve Subzone is set by the sum of the shadow prices of the binding reserve requirement constraint of the RTO Reserve Zone and the shadow price of the binding reserve requirement constraint of the MAD Reserve Subzone.

The process of calculating reserve constraint shadow prices and implementing reserve price caps in PJM is not transparent. The MMU recommends that PJM clearly document the calculation of shortage prices and implementation of reserve price caps in the PJM manuals, including definitions of all the components of reserve prices, and all the constraints whose shadow prices are included in reserve prices.

The PJM tariff caps the MCP for primary reserves at one and a half times the nonsynchronized reserve penalty factor for each zone or subzone, and caps the MCP for synchronized reserves at the sum of the penalty factor for synchronized reserve and the penalty factor for nonsynchronized reserve, but the PJM tariff does not explicitly specify a cap on the system marginal price.[138] The system marginal penalty of $3,700 per MWh that is actually applied by PJM should be included in the PJM tariff and Operating Agreement.

137 If the reserve requirement cannot be met by the resources located within the reserve zone, the shadow price of the reserve requirement is set by the applicable operating reserve demand curve.
138 OA Schedule 1, Section 3.2.3A(d) and Section 3.2.3A.001(c).

System Marginal Price Cap

Prior to PJM's implementation of the modified reserve markets on October 1, 2022, in the PJM real-time market, the SMP was capped at $3,750 per MWh. This cap was the sum of the Energy Offer Cap ($2,000 per MWh under defined conditions), the Synchronous Reserve Penalty Factor from the first step on the demand curve ($850 per MWh), the Primary Reserve Penalty Factor from the first step on the demand curve ($850 per MWh) and a threshold ($50 per MWh). The Operating Agreement stated that only two of the four reserve penalty factors may be applied.

In that prior implementation, if the SMP would otherwise exceed $3,750 per MWh, PJM solved the SCED optimization by progressively relaxing reserve requirement constraints until the SMP fell below the cap. For instance, if the original SMP was above $3,750, PJM would solve the SCED optimization by disabling the subzone (MAD) primary reserve requirement constraint. If the SMP from the relaxed SCED optimization was still above $3,750, PJM would solve the SCED optimization by disabling subzone (MAD) primary and synchronized reserve requirement constraints. If the relaxed SCED optimization was still above $3,750, PJM would solve the SCED optimization by disabling subzone (MAD) primary and synchronized reserve requirement constraints and the RTO primary reserve constraint.

Starting with PJM's implementation of the new Reserve Price Formation rules on October 1, 2022, in the PJM real-time market, the SMP has an administrative maximum price of $3,700 per MWh. Unlike the prior implementation, PJM's new cap does not include a $50 per MWh threshold and is not enforced by progressively relaxing reserve requirement constraints. PJM's new cap is an ex post administrative override of the SMP calculated in the pricing run (LPC). The SMP is not capped in the dispatch run (SCED). The congestion component of the LMP and the loss component of the LMP are not subject to this maximum price. The LMP at a pricing node could still exceed $3,700 per MWh. Unlike other administrative caps, such as the cap on the shadow price of a transmission constraint enforced through transmission penalty factor within the optimization, the SMP cap is not enforced within the optimization. When the SMP cap is enforced, the resulting LMPs are not consistent and do not accurately reflect the marginal cost of serving energy and reserves.

Table 3-91 shows the number of five minute intervals in the real-time market where the SMP was capped for each year since 2018. In the first nine months of 2025, there were four five minute intervals in the real-time market in which the SMP was capped.

Table 3-91 Number of five minute intervals with capped SMP: 2018 through September 2025

Year	Number of Five Minute Intervals with capped SMP
2018	0
2019	1
2020	1
2021	2
2022	51
2023	1
2024	0
2025 (Jan - Sep)	4

The MMU recommends that PJM stop capping the system marginal price and instead limit the sum of violated reserve constraint shadow prices used in LPC to $1,700 per MWh.

Accuracy of Reserve Measurement

The definition of a shortage of synchronized and primary reserves is based on the measured and estimated levels of load, generation, interchange, demand response, and reserves from the real-time SCED software. The definition of such shortage also includes discretionary operator inputs to the ASO (Ancillary Service Optimizer) or RT SCED software, such as operator load bias. For shortage pricing to be accurate, there must be accurate measurement of real-time reserves. That does not appear to be the case at present in PJM, but there does not appear to be any reason that PJM cannot accurately measure reserves. Without accurate measurement of reserves on a minute by minute basis, system operators cannot know with certainty that there is a shortage condition and a reliable trigger for five minute shortage pricing does not exist. The benefits of five minute shortage pricing are based on the assumption that a shortage can be precisely and transparently defined.[139] PJM cannot accurately measure or price reserves due to the inaccuracy of its generator models. PJM's commitment and dispatch models rely on generator data to properly commit and dispatch generators. Generator data includes offers and parameters. When the models do not properly account for the different generator characteristics, both PJM dispatchers and generators have to make simplifications and assumptions using the tools available. Most of these actions taken by generators and by PJM dispatchers are not transparent. PJM manuals do not provide clarity regarding what actions generators can take when the PJM models and tools do not reflect their operational characteristics and PJM manuals do not provide sufficient clarity regarding the actions PJM dispatchers can take when generators do not follow dispatch.

In the energy and reserve markets, the actions that both generators and PJM dispatchers take have a direct impact on the amount of supply available for energy and reserves and the prices for energy and reserves. These flaws in PJM's models do not allow PJM to accurately calculate the amount of reserves available. PJM does not accurately model discontinuities in generator ramp rates, such as duct burners on combined cycle plants. PJM's generator models do not account for the complexities that may result in generators underperforming their submitted ramp rates. PJM should address these

139 See Comments of the Independent Market Monitor for PJM, Docket No. RM15-24-000 (December 1, 2015) at 9.

complexities through generator modeling improvements. PJM also fails to accurately model unit starts. The market software does not account for the energy output a resource produces prior to reaching its economic minimum output level, during its soak time.

Generators can deselect themselves from providing reserves by communicating to PJM that their resources will not follow the dispatch signal (e.g. offer fixed gen or operate as nondispatchable). These actions allow generators to withhold reserves and result in a violation of the reserve must offer requirement when the resources operate below their economic maximum.

Competitive Assessment

Market Structure

Market Concentration

The Herfindahl-Hirschman Index (HHI) concentration ratio is the sum of the squares of the market shares of all firms in a market. Hourly PJM energy market HHIs are based on the shares of the real-time energy output of generators, adjusted for scheduled imports. Hourly HHIs for the baseload, intermediate and peaking segments of generation supply are based on hourly energy market shares, unadjusted for imports.

The HHI is not a definitive measure of structural market power. It is possible to have pivotal suppliers even when the HHI level is not in the highly concentrated range. It is possible to have an exercise of market power even when the HHI level is not in the highly concentrated range. The number of pivotal suppliers in the energy market is a more precise measure of both local and aggregate structural market power than the HHI.

The HHI may not accurately capture market power issues in situations where, for example, there is moderate concentration in all on line resources but there is a high level of concentration in resources needed to meet increases in load. A pivotal supplier test is required to accurately measure the ability of incremental resources to exercise market power.

FERC's Merger Policy Statement defines levels of concentration by HHI level. The market is unconcentrated if the market HHI is below 1000, the HHI if there were 10 firms with equal market shares. The market is moderately concentrated if the market HHI is from 1000 to 1800. The market is highly concentrated if the market HHI is greater than 1800, the HHI if there were between five and six firms with equal market shares.[140]

When transmission constraints exist, local markets are created in which ownership is typically significantly more concentrated than the overall energy market. PJM offer capping rules that limit the exercise of local market power were generally effective in preventing the exercise of market power in the first nine months of 2025, although there are issues with the application of market power mitigation for resources whose owners fail the TPS test that permit local market power to be exercised even when PJM's flawed market power mitigation rules are applied. These issues include the lack of a method for consistently determining the cheaper of the cost and price schedules and the lack of rules requiring that cost-based offers equal short run marginal costs.

PJM HHI Results

Hourly HHIs indicate that by FERC standards, the PJM energy market in the first nine months of 2025 was unconcentrated on average (Table 3-92).[141] The fact that the average HHI and the maximum hourly HHI are in the unconcentrated range does not mean that the aggregate market was competitive in all hours. It is possible to have pivotal suppliers in the aggregate market even when the HHI level does not indicate a highly concentrated market structure. Given the low responsiveness of consumers to prices (inelastic demand), it is possible to have high markup even when HHI is low. It is possible to have an exercise of market power even when the HHI level does not indicate a highly concentrated market structure.

140 See *Inquiry Concerning the Commission's Merger Policy under the Federal Power Act: Policy Statement*, 77 FERC ¶ 61,263 *mimeo* at 80 (1996).
141 The HHI calculations use actual real time settled generation data for each unit in PJM. Each unit's output is assigned to the owner that is responsible for offering the unit in the energy market.

Table 3-92 Real-time hourly aggregate energy market HHI: January through September, 2024 and 2025

HHI Statistic	Hourly Market HHI (Jan-Sep 2024)	Hourly Market HHI (Jan-Sep 2025)
Average	699	686
Minimum	553	511
Maximum	983	988
Highest market share (One hour)	26%	24%
Average of the highest hourly market share	18%	17%
# Hours	6,575	6,551
# Hours HHI > 1800	0	0
% Hours HHI > 1800	0%	0%

Table 3-93 includes HHI values by supply curve segment, including base, intermediate and peaking plants in the first nine months of 2024 and 2025. On average, ownership in the baseload segment was unconcentrated, in the intermediate segment was moderately concentrated, and in the peaking segment was highly concentrated.[142]

Table 3-93 Real-time hourly energy market HHI by generation segment: January through September, 2024 and 2025

	Jan-Sep 2024			Jan-Sep 2025		
	Minimum	Average	Maximum	Minimum	Average	Maximum
Base	573	727	1015	645	800	1101
Intermediate	438	1586	5992	424	912	2746
Peak	829	6293	10000	839	6616	10000

Figure 3-59 shows the total installed capacity (ICAP) MW of units in the baseload, intermediate and peaking segments by fuel source in the first nine months of 2025.[143]

Figure 3-59 Real-time ICAP distribution by fuel and segment: January through September, 2025[144]

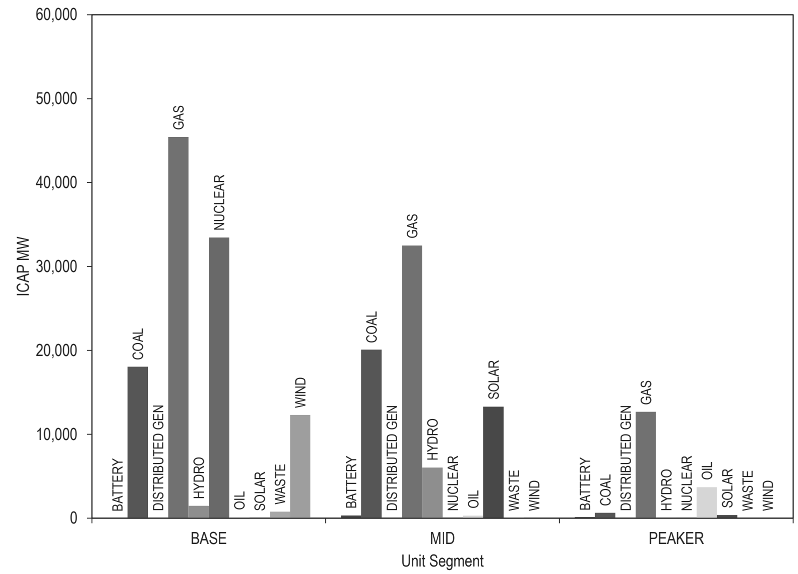

Figure 3-60 shows the ICAP of coal fired and gas fired units in PJM that are classified as baseload, intermediate and peaking from the first nine months of 2014 through 2025. Figure 3-60 shows that the total ICAP of coal fired units in PJM classified as baseload generally decreased from the first nine months of 2014 through 2025, while the total ICAP of gas fired units in PJM classified as baseload generally increased. In 2019, the ICAP of gas fired units classified as baseload exceeded the ICAP of coal fired units classified as baseload for the first time.

142 A unit is classified as base load if it runs for 50 percent of hours or more, as intermediate if it runs for less than 50 percent but greater than or equal to 10 percent of hours, and as peak if it runs for less than 10 percent of hours.
143 The installed capacity (ICAP) used for wind and solar units here is their nameplate capacity in MW. In PJM's Capacity Market, the ICAP value of wind and solar units is derated from the nameplate capacity to reflect their intermittent output characteristics.
144 The units classified as Distributed Gen are buses within Electric Distribution Companies (EDCs) that are modeled as generation buses to accurately reflect net energy injections from distribution level load buses. The modeling change was the outcome of the Net Energy Metering Task Force stakeholder group in July, 2012. See PJM. "Net Energy Metering Senior Task Force (NEMSTF) 1st Read - Final Report and Proposed Manual Revisions," (June 28, 2012).

Figure 3-60 Real-time annual gas and coal unit segment classification: January through September, 2014 through 2025

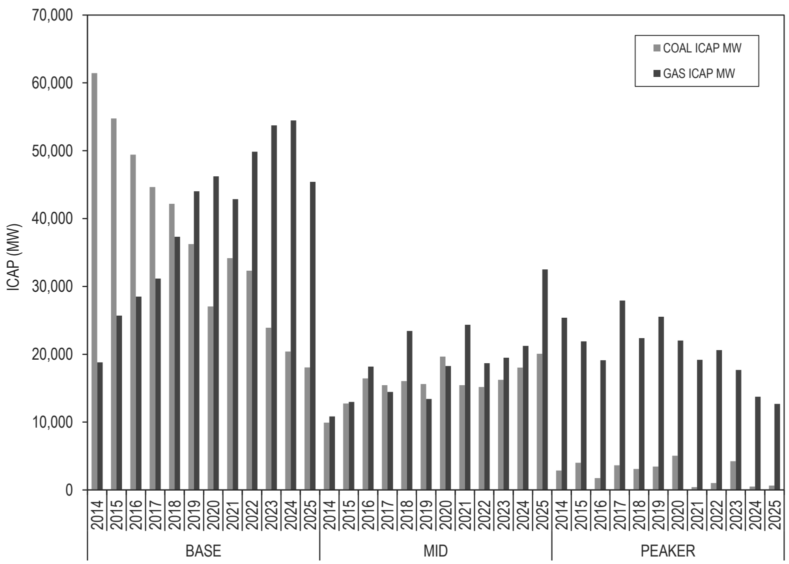

Figure 3-61 Real-time hourly aggregate energy market HHI: January through September, 2025

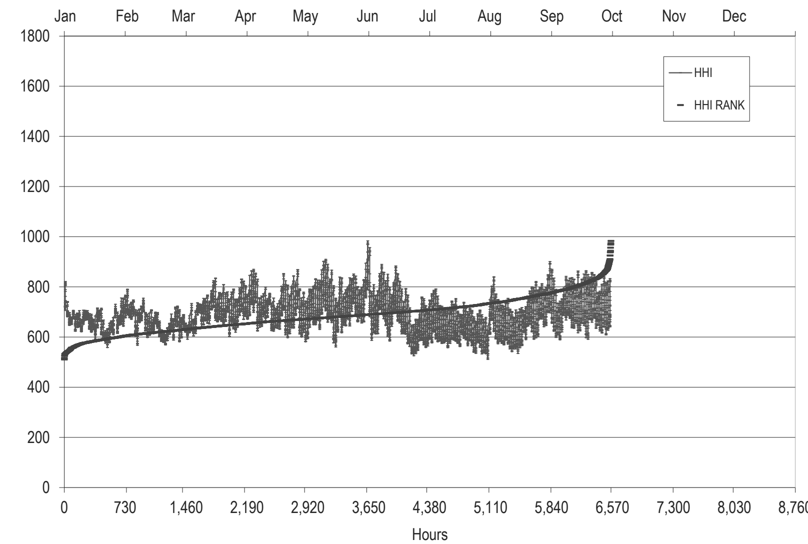

Figure 3-61 presents the hourly HHI values in chronological order and an HHI duration curve for the first nine months of 2025.

Market Based Rates

Participation by generators in the PJM market using offers that exceed costs requires market based rate authority approved by FERC.[145] FERC reviews the market based rate authority of PJM market sellers of generation on a triennial schedule to ensure that market sellers do not have market power or that market power is appropriately mitigated. The entire PJM region is included in the Northeast Region for purposes of the triennial review schedule. Triennial filings by utilities with market based rates authorizations must include a market power analysis or a statement that market power has been adequately mitigated under the PJM market rules. Based on Order No. 861, sellers may, in lieu of filing a market power analysis, rely on a rebuttable presumption

145 See *Market-Based Rates for Wholesale Sales of Electric Energy, Capacity and Ancillary Services by Public Utilities*, Order No. 697, FERC Stats. & Regs. ¶ 31,252 (2007), *clarified*, 121 FERC ¶ 61,260 (2007), *order on reh'g*, Order No. 697-A, 123 FERC ¶ 61,055, *clarified*, 124 FERC ¶ 61,055, *order on reh'g*, Order No. 697-B, 125 FERC ¶ 61,326 (2008), *order on reh'g*, Order No. 697-C, 127 FERC ¶ 61,284 (2009), *order on reh'g*, Order No. 697-D, 130 FERC ¶ 61,206 (2010), *aff'd sub nom.* Mont. Consumer Counsel v. FERC, 659 F.3d 910 (9th Cir. 2011).

that market monitoring and market power mitigation are sufficient to ensure competitive market outcomes.[146]

The rules specify a separate filing schedule for transmission owning utilities and nontransmission owning utilities. The rules define a study period for market power analyses including four complete seasons. A study runs from December of one year through November of the following year (i.e., the period includes one complete winter season rather than splitting winter as a calendar year approach would). The study period is not relevant for companies that choose the rebuttable presumption option.

The most recent triennial review filings for nontransmission owning utilities in PJM were filed in June 2023. The applicable study period for the June 2023 filings, ran from December 1, 2020, to November 30, 2021. Triennial review filings for transmission owners in PJM were filed in December 2022. The applicable study period for the December 2022 filings ran from December 1, 2020, to November 30, 2021.

The MMU has recommended since 2015 that changes to the offer capping process for the energy market are needed to ensure effective market power mitigation of units that fail the TPS test. With these results and the supporting evidence, the MMU challenged the rebuttable presumption of sufficient market power mitigation for the June 2020, December 2022, and June 2023 triennial review filings by generating unit owners in PJM. The MMU explained the issues with PJM's offer schedule selection process that allow generators to avoid energy market power mitigation as well as the then overstated capacity market seller offer cap. The MMU recommended that generators not be allowed to rely on PJM's implementation of market power mitigation rules to ensure competitive market outcomes until improvements are made to the offer capping processes in the energy and capacity markets so that suppliers cannot exercise market power.[147] In 2021, FERC issued orders requiring review of the adequacy of the market power mitigation rules and their implementation in the capacity and energy markets.[148] [149] FERC addressed the capacity market Market Seller Offer Cap later in 2021.[150] [151] FERC did not address the energy market power mitigation issues.

Merger Reviews

FERC reviews proposed dispositions, consolidations, acquisitions, and changes in control of jurisdictional generating units and transmission facilities under section 203 of the Federal Power Act to determine whether such transactions are "consistent with the public interest."[152] [153]

FERC applies tests set forth in the 1996 Merger Policy Statement, written prior to the introduction of competitive markets in PJM.[154] [155] The 1996 Merger Policy Statement provides for review of jurisdictional transactions based on "(1) the effect on competition; (2) the effect on rates; and (3) the effect on regulation." FERC adopted the 1992 Department of Justice Guidelines and the Federal Trade Commission Horizontal Merger Guideline (1992 Guidelines) to evaluate the effect on competition. FERC continues to use the 1992 Guidelines even after the Department of Justice modified its guidelines in 2010.[156] Following the 1992 Guidelines, FERC applies a five step framework, which includes: defining the market; analyzing market concentration; analyzing mitigative effects of new entry; assessing efficiency gains; and assessing viability of the parties without a merger. FERC also evaluates the results of a Competitive Analysis Screen measuring HHI changes for markets defined by transmission zones. This approach does not take into account the effect of a transaction on actual PJM LMPs or capacity market prices.

The MMU reviews proposed mergers and acquisitions based on analysis of the impact of the merger or acquisition on market power given actual PJM market

conditions under the current competitive market design. The analysis includes use of the three pivotal supplier test results in the real-time energy market. The MMU's review ensures that mergers are evaluated based on their impact on local market power in the PJM energy market using actual observed market conditions, actual binding constraints and actual congestion results. This is in contrast to the typical merger filing that uses predefined local markets based on historical conditions that no longer exist rather than the actual local markets based on current and potential market conditions. The MMU files comments with FERC including such analyses.[157] The MMU has proposed that FERC adopt this approach when evaluating mergers in PJM.[158] Subsequent to the MMU's arguments about local markets, FERC has required further analysis of local markets from applicants at the transmission zone level.[159] FERC has considered the MMU's analysis in reviewing mergers but continues to apply an analysis that does not accurately account for locational market power in an LMP market.[160]

Neither the MMU's analysis nor the FERC defined analysis is an adequate replacement for effective market power mitigation, because system conditions are dynamic and any owner can become pivotal at any time. FERC routinely approves mergers and acquisitions and grants Market Based Rates authority to PJM market sellers despite known issues in the market power mitigation process that allow market sellers to exercise their market power. For this reason, the MMU recommends that FERC approve mergers and acquisitions conditioned on behavioral commitments by the market sellers that prevent the exercise of market power.

The MMU has also reached agreements to mitigate market power in cases where market power concerns have been identified.[161] [162] Such mitigation is designed to mitigate behavior over the long term, in addition to or instead of structural mitigation in the form of asset divestiture requirements.

The MMU also reviews transactions that involve ownership changes of PJM generation resources that are submitted to the Commission pursuant to section 203 of the Federal Power Act. Table 3-94 shows ownership changes in the PJM market that involved entire resources that were completed in the first nine months of 2025, as reported to the Commission. Table 3-95 shows transactions that involved transfers of partial unit ownership that were completed in the first nine months of 2025, as reported to the Commission.[163]

Aggregate Market Pivotal Supplier Results

Notwithstanding the HHI level, a supplier may have the ability to raise energy market prices. If reliably meeting the PJM system load requires energy from a single supplier, that supplier is singly pivotal and has monopoly market power in the aggregate energy market. If reliably meeting the PJM system load requires energy from a small number of suppliers, those suppliers are jointly pivotal and have oligopoly market power in the aggregate energy market. The number of pivotal suppliers in the energy market is a more precise measure of structural market power than the HHI. The HHI is not a definitive measure of structural market power. The identification of jointly pivotal suppliers as a source of market power does not require an assumption that the suppliers collude. There are multiple mechanisms that would permit the exercise of market power when there are limited suppliers providing relief to a constraint. FERC Order No. 697 also recognizes this explicitly in the discussion of HHI and pivotal suppliers.[164] FERC's definition of highly concentrated markets, based on an HHI greater than 1800, includes between five and six owners with equal market shares.

The current market power mitigation rules for the PJM energy market rely on the assumption that the aggregate market includes sufficient competing sellers to ensure competitive market outcomes. With sufficient competition, any attempt to economically or physically withhold generation would not result in higher market prices, because another supplier would replace the generation at a similar price. This assumption requires that the total demand for energy can be met without the supply from any individual supplier or without the supply from a small group of suppliers. This assumption is not generally correct, as demonstrated by these results. There are pivotal suppliers in the aggregate energy market.

The existing market power mitigation measures do not address aggregate market power.[165] Aggregate market power should be mitigated in the PJM Day-Ahead and Real-Time Markets when the three pivotal supplier test for the aggregate market is failed.

Day-Ahead Aggregate Energy Market Pivotal Suppliers

To assess the number of pivotal suppliers in the aggregate day-ahead energy market, the MMU determined, for each supplier, the MW available for economic commitment that were already running or were available to start between the close of the day-ahead energy market and the peak load hour of the operating day. The available supply is defined as MW offered at a price less than 150 percent of the applicable LMP because supply available at higher prices is not competing to meet the demand for energy. Generating units, import transactions, economic demand response, and INCs, are included for each supplier.[166] Demand is the total MW required by PJM to meet physical load, cleared load bids, export transactions, and DECs, which is the total cleared supply for the peak hour of the day. A supplier is pivotal if PJM would require some portion of the supplier's available economic capacity in the peak hour of the operating day in order to meet demand. Suppliers are jointly pivotal if PJM would require some portion of the joint suppliers' available economic capacity in the peak hour of the operating day in order to meet demand.

Figure 3-62 shows the number of days in the first nine months of 2025 with one pivotal supplier, two jointly pivotal suppliers, and three jointly pivotal suppliers in the day-ahead aggregate energy market by daily peak load level. It shows that market power, measured by the average number of suppliers that are pivotal, increases with daily peak load. The average number of suppliers that were one of three pivotal suppliers (yellow line) was 65.1 on the 26 days with a peak load less than 90 GW (gray bar) and was 135.9 suppliers on the 30 days with a peak load between 120 and 130 GW. The number of pivotal suppliers generally increases with load. There were eight days with load greater than 150 GW. On two of those days, four suppliers were singly pivotal. On three of those days, five suppliers were singly pivotal. All suppliers that failed the three pivotal supplier screen failed the two pivotal supplier screen on all eight of those days.

164 Order No. 697, FERC Stats. & Regs. ¶ 31,252 at PP 104–117.

165 One supplier, Exelon Generating Company, LLC, is partially mitigated for aggregate market power through a settlement agreement with the MMU filed December 30, 2021 and approved by the Maryland Public Service Commission as a condition of its merger. *In the Matter of the Merger of Exelon Corporation and Constellation Energy Group, Inc.*, Order No. 90084, Maryland PSC Case No. 9271 (February 22, 2022). Order No. 90084 replaces the original 10 year settlement in this case included as a condition in Order No. 84698, issued February 17, 2012, which approved the merger between Exelon and Constellation Energy Group.

166 Generation, imports, demand response, and virtual transactions are assigned to parent companies based on the ultimate parent company owner of their PJM account.

Figure 3-62 Average number of pivotal suppliers in the day-ahead energy market by load level: January through September, 2025

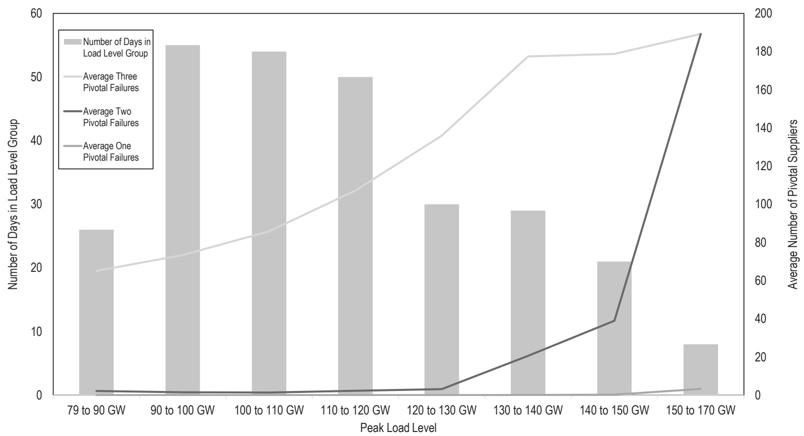

Table 3-96 provides the frequency with which each of the top 10 pivotal suppliers was singly or jointly pivotal for the day-ahead aggregate energy market in the first nine months of 2025. All of the top 10 suppliers were one of three pivotal suppliers on at least 168 days in the first nine months of 2025 (61.5 percent of the days). One supplier was singly pivotal on 13 days.

Table 3-96 Day-ahead market pivotal supplier frequency: January through September, 2025

Pivotal Supplier Rank	Days Singly Pivotal	Percent of Days	Days Jointly Pivotal with One Other Supplier	Percent of Days	Days Jointly Pivotal with Two Other Suppliers	Percent of Days
1	13	4.8%	145	53.1%	254	93.0%
2	6	2.2%	161	59.0%	257	94.1%

10	0	0.0%	27	9.9%	168	61.5%

Market Behavior

Local Market Power

In the PJM energy market, market power mitigation rules currently apply only for local market power. Local market power exists when transmission constraints or reliability issues create local markets that are structurally noncompetitive.[167] If the owners of the units required to solve the constraint or reliability issue are pivotal or jointly pivotal, they have the ability to set the price. Absent market power mitigation, unit owners that submit noncompetitive offers, or offers with inflexible operating parameters, could exercise market power. This could result in LMPs being set at higher than competitive levels, or could result in noncompetitive uplift payments.

The three pivotal supplier (TPS) test is the test for local market power in the energy market.[168] If the TPS test is failed, market power mitigation is applied by offer capping the resources of the owners who have been identified as having local market power. Offer capping is designed to set offers at competitive levels. Competitive offers are defined to be cost-based energy offers. In the PJM energy market, units are required to submit cost-based energy offers, defined by fuel cost policies, and have the option to submit market-based offers, also called price-based offers. Units are committed and dispatched on price-based offers, if offered, as the default offer. When a unit that submits both cost-based and price-based offers is mitigated to its cost-based offer by PJM, it is considered offer capped. A unit that submits only cost-based offers, or that requests PJM to dispatch it on its cost-based offer, is not considered offer capped.

Local market power mitigation is implemented in both the day-ahead and real-time energy markets. However, the implementation of the TPS test and offer capping differ in the day-ahead and real-time energy markets.

167 OA Schedule 1, Section 6.4.1.
168 See the MMU Technical Reference for PJM Markets, at "Three Pivotal Supplier Test" for a more detailed explanation of the three pivotal supplier test. <http://www.monitoringanalytics.com/reports/Technical_References/references.shtml>.

TPS Test Statistics for Local Market Power

The TPS test in the energy market defines whether three suppliers are jointly pivotal in a defined local market. The TPS test is applied when the system solution indicates that a transmission constraint is binding or requires the commitment of additional resources. The TPS test result for a constraint for a specific interval indicates whether a supplier failed or passed the test for that constraint for that interval. A failed test indicates that the resource owner has structural market power.

A metric to describe the number of local markets created by transmission constraints and the applicability of the TPS test is the number of hours that each transmission constraint was binding in the real-time energy market over a period, by zone.

In the first nine months of 2025, in the day-ahead energy market, the 500 kV system, 19 of 21 zones, and PJM/MISO experienced congestion resulting from one or more constraints binding for 75 or more hours, or resulting from a binding interface constraint (Table 3-97).[169] Table 3-97 shows that the 500 kV system, 13 of 20 zones and PJM/MISO experienced congestion resulting from one or more constraints binding for 75 or more hours or resulting from a binding interface constraint in the first nine months in every year from 2016 through 2025. DUKE and one zone did not experience congestion resulting from one or more constraints binding for 75 or more hours or resulting from any binding interface constraint in the first nine months in any year from 2016 through 2025.

Table 3-97 Day-ahead congestion hours resulting from one or more constraints binding for 75 or more hours: January through September, 2016 through 2025

TVA	223	0	0	206	75	0	0	0	0	0

In the first nine months of 2025, in the real-time energy market, the 500 kV system, 13 zones, and PJM/MISO experienced congestion resulting from one or more constraints binding for 75 or more hours, or resulting from a binding interface constraint (Table 3-98).[170] Table 3-98 shows that the 500 kV system, six zones, and PJM/MISO experienced congestion resulting from one or more

169 A constraint is mapped to the 500 kV system if its voltage is 500 kV and it is located in one of the zones including AECO, BGE, DPL, JCPLC, MEC, PECO, PENELEC, PEPCO, PPL and PSEG. All PJM/MISO reciprocally coordinated flowgates (RCF) are mapped to MISO regardless of the location of the flowgates. All PJM/NYISO RCF are mapped to NYISO as location regardless of the location of the flowgates.

170 A constraint is mapped to the 500 kV system if its voltage is 500 kV and it is located in one of the zones including AECO, BGE, DPL, JCPLC, MEC, PECO, PENELEC, PEPCO, PPL and PSEG. All PJM/MISO reciprocally coordinated flowgates (RCF) are mapped to MISO regardless of the location of the flowgates. All PJM/NYISO RCF are mapped to NYISO as location regardless of the location of the flowgates.

constraints binding for 75 or more hours or resulting from a binding interface constraint in every year from 2016 through 2025. Three zones (DUQ, OVEC and REC), and DUKE did not experience congestion resulting from one or more constraints binding for 75 or more hours or resulting from any binding interface constraint in the first nine months in any year from 2016 through 2025.[171]

171 In this report, the MMU used the dispatch run marginal resource and sensitivity factor data, rather than the pricing run data, in the analysis of constraints since 2021 because the PJM pricing run sensitivity factor data for day-ahead LMP was not correct for a small number of hours. The PJM pricing run LMPs are the final settlement LMPs.

In the PJM Day-Ahead Energy Market, the TPS test is performed in PROBE, as part of the unit commitment process. Table 3-99 shows the average constraint relief required on the constraint, the average effective supply available to relieve the constraint, the average number of owners with available relief in the defined market and the average number of owners passing and failing the TPS test for the interface constraints in the PJM Day-Ahead Energy Market.

Table 3-99 Day-ahead three pivotal supplier test details for internal interface constraints: January through September, 2025

Constraint	Period	Number of Tests	Average Constraint Relief (MW)	Average Effective Supply (MW)	Average Number Owners	Average Number Owners Passing	Average Number Owners Failing
AEP - DOM	Peak	29	501	378	24	3	20

Table 3-100 shows the average constraint relief required on the constraint, the average effective supply available to relieve the constraint, the average number of owners with available relief in the defined market, whether the TPS test was applied, and the average number of owners passing and failing the TPS test for the 10 constraints that were binding for the most hours in the day-ahead energy market. In the day-ahead energy market, the TPS test evaluates each constraint that was binding for each hour during the operating day after the initial unit commitment run. The set of constraints that are binding in the unit commitment run, for which the TPS test is applied, is not necessarily the same as the set of constraints that bind in the final day-ahead energy market solution. This is because PJM's day-ahead market is solved in three stages, and the initial set of constraints is from the Resource Scheduling and Commitment (RSC) (unit commitment) stage while the final set of binding constraints is from the Scheduling Pricing and Dispatch (SPD) (unit dispatch) stage.[172] The PJM approach fails to apply the TPS test to market sellers that provide relief to constraints in the final dispatch solution, and therefore fails to mitigate such sellers for market power.

The MMU recommends that PJM modify the process for applying the TPS test in the day-ahead energy market to ensure that all local markets created by binding constraints are tested for market power and to ensure that market sellers with market power are appropriately mitigated to their competitive offers.

172 *See* PJM. "Manual 11: Energy & Ancillary Services Market Operations," Section 5.2.6, Rev. 136 (Oct. 1, 2025).

The local market structure in the real-time energy market associated with each of the frequently binding constraints was analyzed using the three pivotal supplier results for the first nine months of 2025.[173] While the real-time constraint hours include constraints that were binding in the five minute real-time dispatch solution (RT SCED), IT SCED, the software that performs the TPS test, may contain different binding constraints because IT SCED looks ahead to target times that are in the near future to solve for constraints that could be binding, using the load forecast for those times.[174] IT SCED solves for target times that occur at 15 minute time increments, unlike RT SCED that solves for every five minute time increment. The TPS statistics shown in this section present the data from the IT SCED TPS solution. Some IT SCED TPS solutions are used to commit units, while others are not. PJM operators have discretion in choosing which units to commit and which IT SCED results to use as the basis for the commitment and therefore which units are tested for market power using the TPS test. The results of the TPS test are shown for tests that could have resulted in offer capping and tests that did result in offer capping.

Table 3-101 shows the average constraint relief required on the constraint, the average effective supply available to relieve the constraint, the average number of owners with available relief in the defined market and the average number of owners passing and failing for the interface constraints in the PJM Real-Time Energy Market. Table 3-102 shows the average constraint relief required on the constraint, the average effective supply available to relieve the constraint, the average number of owners with available relief in the defined market and the average number of owners passing and failing for the 10 constraints that were binding for the most hours in the PJM Real-Time Energy Market. Table 3-101 and Table 3-102 include analysis of all the tests for every target time where IT SCED determined that constraint relief was needed for each of the constraints shown. The same target time can be evaluated by multiple IT SCED cases at different look ahead times. Each 15 minute target time is solved by 12 different IT SCED cases at different look

173 See the *MMU Technical Reference for PJM Markets*, p. 38 "Three Pivotal Supplier Test" for a more detailed explanation of the three pivotal supplier test. <http://www.monitoringanalytics.com/reports/Technical_References/references.shtml>.

174 Prior to September 1, 2021, the real-time binding constraints were identical in the dispatch (RT SCED) and pricing (LPC) solutions. Beginning September 1, 2021, with implementation of fast start pricing, the set of binding constraints can differ between RT SCED and LPC pricing solutions. The set of constraints reported here are based on the binding constraints in RT SCED. This is because PJM commits and mitigates units based on a dispatch solution in IT SCED without fast start pricing.

ahead times. The set of binding constraints for a target time may be different in 12 look ahead IT SCED solutions.

	Off Peak	3,330	57	109	3	0	3

The three pivotal supplier test is applied every time the IT SCED solution indicates that incremental relief is needed to relieve a transmission constraint. While every system solution that requires incremental relief to transmission constraints will result in a test, not all tested providers of effective supply are eligible for offer capping. Steam unit offers that are offer capped in the day-ahead energy market continue to be offer capped in the real-time energy market regardless of their inclusion in the TPS test in real time or the outcome of the TPS test in real time. Steam unit offers that are not offer capped in the day-ahead energy market continue to not be offer capped in the real-time energy market regardless of their inclusion in the TPS test in real time or the outcome of the TPS test in real time.[175] Offline units that are committed to provide relief for a transmission constraint, whose owners fail the TPS test, are committed on the cheaper of their cost or price-based offers. Beginning November 1, 2017, with the introduction of hourly offers and intraday offer updates, online units whose commitment is extended beyond the day-ahead or real-time commitment, and whose owners fail the TPS test, are also switched to the cost-based offer if it is cheaper than the price-based offer.

Units committed in the day-ahead market often fail the TPS test in the real-time market when they are redispatched to provide relief to transmission constraints, even though they did not fail the TPS test in the day-ahead market. Day-ahead committed units are not evaluated for offer capping in real-time unless they update their cost-based offer. These units are able to set prices with a positive markup in the real-time market. Units that cleared the day-ahead market on their price based schedule were evaluated to identify the units whose offers were mitigated in real-time and the units that cleared on price offers in real-time despite failing the real-time TPS test. Table 3-103 shows that, in the first nine months of 2025, 4.6 percent of unit hours that cleared the day-ahead market on their price based offer were switched to cost in real-time. Table 3-103 shows that 7.8 percent of unit hours that cleared the day-ahead market on their price based offer cleared on their price based offer in real-time despite failing the real-time TPS test.

175 If a steam unit were to lower its cost-based offer in real time, it would become eligible for offer capping based on the online TPS test.

Table 3-103 Day-ahead units committed on price-based offers that cleared real-time: January through September, 2024 and 2025

	Day Ahead Price Based Unit Hours That Cleared Real-Time			Percent Day Ahead Price Based Unit Hours That Cleared Real-Time	
Year (Jan-Sep)	On Cost	On Price	On Price and Failed TPS Test	On Cost	On Price and Failed TPS Test
2024	89,947	2,294,967	199,788	3.9%	8.7%
2025	106,325	2,431,227	191,273	4.6%	7.8%

The MMU recommends, in order to ensure effective market power mitigation when the TPS test is failed, that offer capping be applied to units that fail the TPS test in the real-time market that were not offer capped at the time of commitment in the day-ahead market or at a prior time in the real-time market.

Table 3-104 and Table 3-105 provide, for the identified constraints, information on total tests applied, the subset of three pivotal supplier tests that could have resulted in offer capping and the portion of those tests that did result in offer capping in the real-time energy market. Tests where there was at least one offline unit or an online unit eligible for offer capping are considered tests that could have resulted in offer capping. PJM operators also manually commit units for reliability reasons other than providing relief to a binding constraint. Manual commitments are offer capped along with resources that fail the TPS test.

Offer Capping for Local Market Power

In the PJM energy market, offer capping occurs as a result of structurally noncompetitive local markets and noncompetitive offers in the day-ahead and real-time energy markets. PJM also uses offer capping for units that are committed for reliability reasons, like voltage support and N-2 contingencies, for providing black start and for providing reactive service as well as for conservative operations. There are no explicit rules governing market structure or the exercise of market power in the aggregate energy market.

There are some issues with the application of mitigation in the day-ahead energy market and the real-time energy market when market sellers fail the TPS test. There are also issues with the absence of a TPS test under some conditions. There is no tariff or manual language that defines in detail the application of the TPS test and offer capping in the day-ahead energy market and the real-time energy market. There is no tariff or manual language that defines the PJM process for evaluating units for multi-day commitments in the day-ahead energy market.

In both the day-ahead and real-time energy markets, generators with market power have the ability to evade mitigation by using varying markups in their price-based offers, offering different operating parameters in their price-based and cost-based offers, and using different fuels in their price-based and cost-based offers. These issues can be resolved by simple rule changes.

When an owner fails the TPS test, the units offered by the owner that are committed to provide relief are committed on the cheaper of cost-based or price-based offers. In the day-ahead energy market, PJM commits a unit on the schedule that results in the lower overall system production cost. The day-ahead energy market selects which schedule to use for a resource that failed the TPS test based on its objective of clearing resources to meet the total demand at the lowest bid production cost for the system over the 24 hour period.

In the real-time energy market, PJM uses a dispatch cost formula to compare price-based offers and cost-based offers to select the cheaper offer.[176]

$$\text{Total Dispatch Cost} = \text{Startup Cost} + \sum_{\text{Min Run}} \text{Hourly Dispatch Cost}$$

where the hourly dispatch cost is calculated for each hour using the offers applicable for that hour as:

$$\text{Hourly Dispatch Cost} = (\text{Incremental Energy Offer@EcoMin} \times \text{EcoMin MW}) + \text{NoLoad Cost}$$

The hourly dispatch cost is calculated only at the economic minimum level and not at higher output levels. Given the ability to submit offer curves with different markups at different output levels in the price-based offer, unit owners with market power can evade mitigation by using a low markup at low output levels and a high markup at higher output levels. This strategy is called crossing curves, or markup switching. Figure 3-63 shows an example of offers from a unit that has a negative markup at the economic minimum MW level and a positive markup at the economic maximum MW level. The result would be that a unit that failed the TPS test would be committed on its price-based offer that has a lower dispatch cost, even though the price-based offer is higher than cost-based offer at higher output levels and includes positive markups, inconsistent with the explicit goal of local market power mitigation.

176 See OA Schedule 1 § 6.4.1(g).

Figure 3-63 Offers with varying markups at different MW output levels

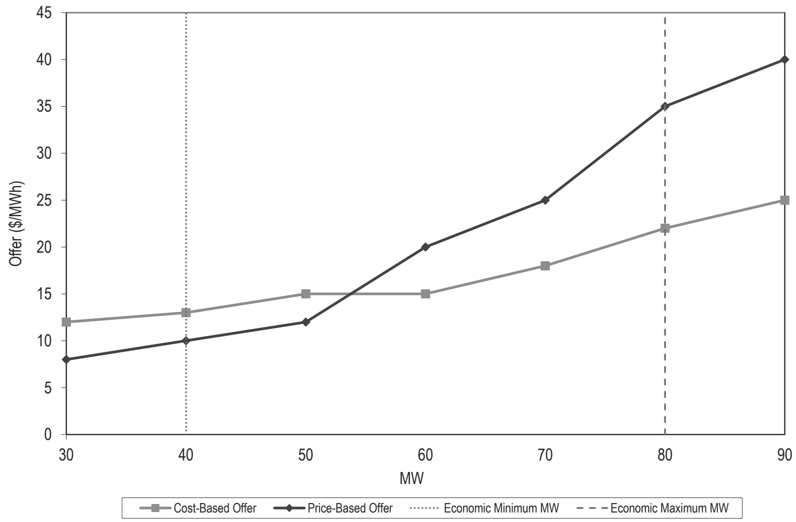

Table 3-106 shows the number and percent of unit schedule hours, by month, when unit offers included crossing curves (markup switch) in the PJM Day-Ahead and Real-Time Energy Markets in the first nine months of 2025. The analysis only includes units that offer both price-based and cost-based offers. Units in PJM are only required to submit cost-based offers, but they may elect to offer price-based offers.

Table 3-106 Units offered with crossing curves (markup switch): January through September, 2025

	Day-Ahead			Real-Time		
2025	Number of Schedule Hours with Crossing Curves	Total Number of Cost Schedule Hours Offered by Price Based Units	Percent of Schedule Hours with Crossing Curves	Number of Schedule Hours with Crossing Curves	Total Number of Cost Schedule Hours Offered by Price Based Units	Percent of Schedule Hours with Crossing Curves
Jan	81,057	889,896	9.1%	70,170	825,887	8.5%

Total	780,470	7,858,997	9.9%	635,126	7,023,915	9.0%

Table 3-107 shows the percent of unit schedule hours offered with crossing curves (markup switch), their average markup, their MW output weighted markup, and their average marginal unit LMP and markup contribution, when units failed the three pivotal supplier test in the PJM Day-Ahead Market and were marginal in the Real-Time Energy Market in the first nine months of 2025. The analysis only includes units that offer both price-based and cost-based offers.

Table 3-107 Marginal units offered with crossing curves (markup switch) and local market power: January through September, 2022 through 2025

Unit hours with Crossing Curves Committed on Price Offer and Eligible for Offer-Capping DA and Marginal in Real-Time							
Year (Jan-Sep)	Percent of Unit hours with Crossing Curves	Average Markup Day-Ahead	Average Markup Real-Time	Load-Weighted Average Markup Day-Ahead	Load-Weighted Average Markup Real-Time	Average Marginal Unit LMP Contribution	Average Marginal Unit Markup Contribution
2022	12.7%	$14.40	$8.26	$17.21	$12.60	$3.45	$0.47
2023	12.1%	$10.24	$3.23	$11.71	$5.25	$1.37	$0.17
2024	12.3%	$9.27	$3.34	$10.61	$5.54	$1.32	$0.14
2025	18.2%	$11.46	$9.17	$14.46	$13.66	$1.68	$0.27

Table 3-108 shows the percent of unit schedule hours offered with crossing curves (markup switch), their average markup, their MW output weighted markup, and their average marginal unit LMP and markup contribution, when units failed the three pivotal supplier test in the PJM Day-Ahead Market, were marginal in the Real-Time Energy Market and had a negative markup in the PJM Day-Ahead Market in the first nine months of 2025. The analysis only includes units that offer both price-based and cost-based offers.

Table 3-108 Marginal units offered with crossing curves (markup switch), local market power and negative markup day-ahead: January through September, 2022 through 2025

Unit hours with Crossing Curves Committed on Price Offer with Negative Markup and Eligible for Offer-Capping DA and Marginal with Positive Markup in Real-Time							
Year (Jan-Sep)	Percent of Unit hours with Crossing Curves	Average Markup Day-Ahead	Average Markup Real-Time	Load-Weighted Average Markup Day-Ahead	Load-Weighted Average Markup Real-Time	Average Marginal Unit LMP Contribution	Average Marginal Unit Markup Contribution
2022	2.0%	($8.20)	$20.83	($7.89)	$25.20	$3.73	$0.77
2023	2.7%	($3.16)	$10.54	($2.90)	$12.19	$1.22	$0.24
2024	2.6%	($3.48)	$11.37	($3.03)	$13.04	$1.47	$0.42
2025	3.7%	($3.98)	$23.24	($2.74)	$30.97	$1.69	$0.38

Offering a different economic minimum MW level, different minimum run times, or different start up and notification times in the cost-based and price-based offers can also be used to evade mitigation. For example, a unit may have a price-based offer with a positive markup, but have a shorter minimum run time (MRT) in the price-based offer resulting in a lower dispatch cost for the price-based offer but setting prices at a level that includes a positive markup. Table 3-109 shows the number and percent of unit schedule hours when units offered lower minimum run times in price-based offers than in cost-based offers while having a positive markup in the price-based offer.

Table 3-109 Units offered with lower minimum run time on price compared to cost and with positive markup: January through September, 2025

	Day-Ahead			Real-Time		
2025	Number of Schedule Hours with Lower Min Run Time in Price Compared to Cost	Total Number of Cost Schedule Hours Offered by Price Based Units	Percent of Schedule Hours with Lower Min Run Time in Price Compared to Cost	Number of Schedule Hours with Lower Min Run Time in Price Compared to Cost	Total Number of Cost Schedule Hours Offered by Price Based Units	Percent of Schedule Hours with Lower Min Run Time in Price Compared to Cost
Jan	2,733	889,896	0.3%	2,424	825,887	0.3%
Feb	2,634	807,696	0.3%	2,769	743,801	0.4%
Mar	10,697	891,245	1.2%	2,411	771,283	0.3%
Apr	5,914	866,880	0.7%	2,342	689,439	0.3%

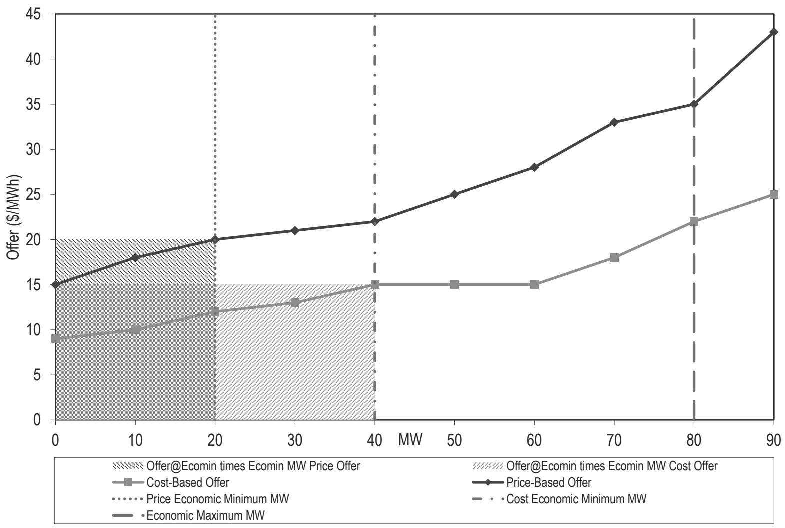
Sep	2,256	866,904	0.3%	2,256	768,015	0.3%
Total	35,233	7,858,997	0.4%	20,722	7,023,915	0.3%

A unit may offer a lower economic minimum MW level on the price-based offer than the cost-based offer. Such a unit may appear to be cheaper to commit on the price-based offer even with a positive markup. A unit with a positive markup can have lower dispatch cost with the price-based offer with a lower economic minimum level compared to the cost-based offer. Figure 3-64 shows an example of offers from a unit that has a positive markup and a price-based offer with a lower economic minimum MW than the cost-based offer. Keeping the startup cost, Minimum Run Time and no load cost constant between the price-based offer and cost-based offer, the dispatch cost for this unit is lower on the price-based offer than on the cost-based offer solely as a result of the lower economic minimum MW. However, the price-based offer includes a positive markup and could result in setting the market price at a noncompetitive level even after the resource owner fails the TPS test.

Figure 3-64 Offers with a positive markup but different economic minimum MW



The behavior in which units offered lower economic minimum MW in price-based offers than in cost-based offers while having a positive markup in the price-based offer is limited to a number of units that does not permit data to be provided under the PJM confidentiality rules in both the day-ahead and real-time energy markets.

In the case of dual fuel units, if the price-based offer uses a cheaper fuel and the cost-based offer uses a more expensive fuel, the price-based offer will appear to be cheaper even when it includes a markup. Figure 3-65 shows an example of offers by a dual fuel unit, where the active cost-based offer uses a more expensive fuel and the price-based offer uses a cheaper fuel and includes a markup. Table 3-110 shows the number and percent of dual fuel unit hours where the price-based offer does not have a comparable cost-based offer with a matching fuel, and the cost-based offer exceeds the price-based offer. The analysis includes only those units that offered multiple offers (cost or price) with different fuels in the first nine months of 2025.

Figure 3-65 Dual fuel unit offers

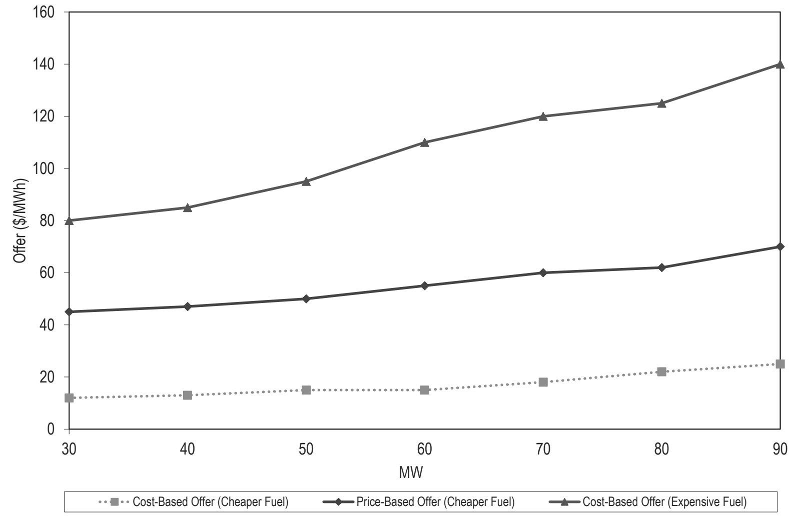


Table 3-110 Dual fuel unit offers with cost-based offers exceeding price-based offers (negative markup) but different fuel: January through September, 2025

	Day-Ahead			Real-Time

These issues can be solved by simple rule changes.[177] The MMU recommends, in order to ensure effective market power mitigation when the TPS test is failed, that markup be consistently positive or negative across the full MWh range of price and cost-based offers. This means that the cost-based and price-based offer curves never cross.[178]

PJM filed and, on October 25, 2024, FERC accepted a revised proposal that would require that sellers that fail the TPS test will be offer capped at their cost-based offers and that operating parameters will be mitigated. However, PJM has no plans to implement the improved rules, so the flawed rules remain in place. PJM's proposal also uses the flawed formula rejected by FERC to select among cost-based offers. This will result in the illogical selection of cost-based offers in some circumstances, particularly if a dual fuel unit submits offers for both oil and gas on a day when the economics change between the two fuels midday. PJM should modify its implementation to address that issue. The result would allow market sellers to select the correct cost-based fuel schedule. There is no reason to delay implementation until PJM addresses combined cycle modelling. The changes would decrease the solution time for the day-ahead market and enhance market efficiency. The new approach should be implemented as soon as possible to help ensure effective market power mitigation.

The issues with offer capping will continue to allow the exercise of market power to affect prices until PJM implements the new approach. Currently, there is no implementation date. The simplified schedule selection process would shorten the time required to reach the day-ahead market solution, which is a market efficiency gain regardless of whether PJM implements combined cycle modelling. The MMU recommends that PJM commit all resources that fail the TPS test on their cost-based offers and that PJM implement that solution as soon as possible.[179]

Levels of offer capping have historically been low in PJM, as shown in Table 3-112. But offer capping remains a critical element of PJM market rules because it is designed to prevent the exercise of local market power. While overall offer capping levels have been low, there are a significant number of units with persistent structural local market power that would have a significant impact on prices in the absence of local market power mitigation. Until November 1, 2017, only uncommitted resources, started to relieve a transmission constraint, were subject to offer capping. Beginning November

177 The MMU proposed these offer rule changes as part of a broader reform to address generator offer flexibility and associated impact on market power mitigation rules in the Generator Offer Flexibility Senior Task Force (GOFSTF) and subsequently in the MMU's protest in the hourly offers proceeding in Docket No. ER16-372-000, filed December 14, 2015.

178 See related recommendations about mitigation of operating parameters and financial offer parameters.

179 See "Schedule Selection: IMM Package," MMU Presentation to the Market Implementation Committee (September 6, 2023), <https://www.monitoringanalytics.com/reports/Presentations/2023/IMM_MIC_Schedule_Selection_IMM_Package_20230906.pdf>.

1, 2017, under certain circumstances, online resources that are committed beyond their original commitment (day-ahead or real-time) can be offer capped if the owner fails the TPS test, and the latest available cost-based offer is determined to be lower than the price-based offer.[180] Units running in real time as part of their original commitment on the price-based offer on economics, and that can provide incremental relief to a constraint, cannot be switched to their cost-based offer by PJM.

The offer capping percentages shown in Table 3-111 include units that are committed to provide constraint relief whose owners failed the TPS test in the energy market, but excluding units that were committed for reliability reasons, providing black start or providing reactive support. Offer capped unit run hours and offer capped generation (in MWh) are shown as a percentage of the total run hours and the total generation (MWh) from all the units in the PJM energy market.[181] Beginning November 1, 2017, with the introduction of hourly offers, certain online units, whose owners fail the TPS test in the real-time energy market for providing constraint relief, can be offer capped and dispatched on their cost-based offer subsequent to a real-time hourly offer update.

Table 3-111 Offer capping statistics – energy only: January through September, 2018 to 2025

	Real-Time		Day-Ahead	
Year (Jan - Sep)	Unit Hours Capped	MWh Capped	Unit Hours Capped	MWh Capped
2018	1.1%	0.5%	0.1%	0.2%
2019	1.6%	1.1%	1.2%	0.8%
2020	1.0%	1.2%	1.6%	1.4%
2021	1.3%	1.0%	1.4%	0.8%
2022	1.4%	1.1%	1.4%	1.0%
2023	1.3%	1.0%	1.6%	0.7%
2024	1.5%	1.0%	2.0%	1.0%
2025	1.4%	1.1%	1.9%	1.0%

Table 3-112 shows the offer capping percentages including both units committed to provide constraint relief and units committed for reliability reasons, black start or reactive support. Reliability reasons include reactive support or local voltage support. PJM creates closed loop interfaces to, in some cases, model reactive constraints. The closed loop interface creates demand for the output of the resource needed to provide reactive power. The resulting higher LMPs in the closed loop interfaces increased economic dispatch, which contributed to the reduction in units offer capped for reactive support over time in Table 3-113. In instances where units are committed and offer capped for the modeled closed loop interface constraints, they are considered offer capped for providing constraint relief, and not for reliability. They are included in the offer capping percentages in Table 3-111. Prior to closed loop interfaces, these units were considered as committed for reactive support, and were included in the offer capping statistics for reliability in Table 3-113.

Table 3-112 Offer capping statistics for energy and reliability: January through September, 2018 to 2025

	Real-Time		Day-Ahead	
Year (Jan - Sep)	Unit Hours Capped	MWh Capped	Unit Hours Capped	MWh Capped
2018	1.2%	0.8%	0.2%	0.4%
2019	1.6%	1.1%	1.2%	0.8%
2020	1.0%	1.2%	1.6%	1.4%
2021	1.3%	1.0%	1.4%	0.8%
2022	1.5%	1.4%	1.5%	1.1%
2023	1.4%	1.2%	1.8%	1.0%
2024	1.7%	1.4%	2.2%	1.4%
2025	1.5%	1.3%	2.1%	1.2%

Table 3-113 shows the offer capping percentages only for units committed for reliability reasons, black start or reactive support. The low offer capping percentages do not mean that units manually committed for reliability reasons do not have market power. All units manually committed for reliability have market power, and all are treated consistent with that fact.[182]

180 See OA Schedule 1 § 6.4.1.
181 Prior to the *2018 Quarterly State of the Market Report for PJM: January through June*, these tables presented the offer cap percentages based on total bid unit hours and total load MWh. Beginning with the quarterly report for January through June, 2018, the statistics have been updated with percentages based on run hours and total generation MWh from units modeled in the energy market.
182 OA Schedule 1, Section 6.4.1.

Table 3-113 Offer capping statistics for reliability: January through September, 2018 to 2025

	Real-Time		Day-Ahead	
Year (Jan - Sep)	Unit Hours Capped	MWh Capped	Unit Hours Capped	MWh Capped
2018	0.14%	0.29%	0.12%	0.23%
2019	0.01%	0.02%	0.01%	0.01%
2020	0.00%	0.01%	0.00%	0.00%
2021	0.02%	0.04%	0.02%	0.02%
2022	0.15%	0.27%	0.06%	0.12%
2023	0.13%	0.23%	0.17%	0.27%
2024	0.18%	0.38%	0.23%	0.42%
2025	0.10%	0.23%	0.12%	0.24%

Table 3-114 presents data on the frequency with which units were offer capped in the first nine months of 2024 and 2025 as a result of failing the TPS test to provide energy for constraint relief in the real-time energy market, or for reliability reasons.

Table 3-114 Real-time offer capped unit statistics: January through September, 2024 and 2025

		Offer-Capped Hours					
Run Hours Offer-Capped, Percent Greater Than Or Equal To:	Jan - Sep	Hours ≥ 500	Hours ≥ 400 and < 500	Hours ≥ 300 and < 400	Hours ≥ 200 and < 300	Hours ≥ 100 and < 200	Hours ≥ 1 and < 100

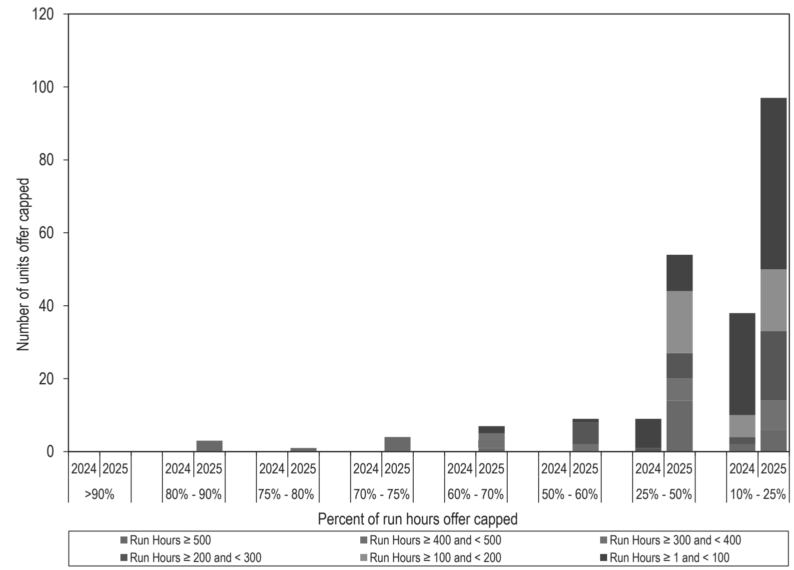
Figure 3-66 shows the frequency with which units were offer capped in the first nine months of 2024 and 2025 for failing the TPS test to provide energy for constraint relief in the real-time energy market or for reliability reasons.

Figure 3-66 Real-time offer capped unit statistics: January through September, 2024 and 2025



In response to FERC's request for Common Metrics for 2019 through 2022, which were published in FERC's 2023 Common Metrics Staff report, PJM filed a report stating that between 2019 and 2022 the percent of unit hours in the day-ahead energy market with active market power mitigation was between 78.8 and 100 percent, while the actual results were between 1.4 and 1.6 percent.[183] [184] PJM also reported that between 2019 and 2022, the percent of unit intervals in the real-time energy market with active market power mitigation was between 43.3 and 53.3 percent, while the actual results were

183 See Common Performance Metrics, Docket No. AD19-16-000, PJM Compliance Filing, PJM Metrics Spreadsheet 2023 (April 17, 2023).
184 See 2023 Common Metrics: Performance Metrics for ISOs, RTOs, and Regions Outside ISOs and RTOs for the Reporting Period 2019 to 2022, FERC Staff Report (January 31, 2024), <https://elibrary.ferc.gov/eLibrary/filelist?accession_num=20240131-4000>.

between 1.0 and 1.7 percent. PJM's reported results were incorrect because PJM provided hours of mitigation instead of unit hours or unit intervals mitigated. In the day-ahead market, a mitigated unit hour is one unit mitigated for one hour. The denominator is all cleared units cleared for all hours. In the real-time market, a mitigated unit interval is one unit mitigated for one interval. The denominator is all cleared units for all intervals. For example, if there were 10 units running in a given hour in the day-ahead market, if one unit was mitigated for that hour, then the percent of unit hours mitigated would be 10 percent, but PJM defined the percent mitigated as 100 percent of the hour. The PJM filed report dramatically overstated the frequency of market power mitigation in the PJM energy market. The MMU has correctly reported this metric in the State of the Market Reports for 2002 and subsequent years. The MMU also reports the MWh subject to market power mitigation, which reflects the relative size of the units subject to market power mitigation.

Markup Index

Markup is a summary measure of the degree to which a participant's offer behavior or conduct for individual units is competitive. When a seller makes a competitive offer, markup is zero. When a seller exercises market power in its offer, markup is positive. The degree of markup increases with the degree of market power. The markup index for each marginal unit is calculated as (Price – Cost)/Price.[185] The markup index is normalized and can vary from -1.00 when the offer price is less than the cost-based offer price, to 1.00 when the offer price is higher than the cost-based offer price. The markup index does not measure the impact of unit markup on total LMP. The dollar markup for a unit is the difference between price and cost.

Real-Time Markup Index

Table 3-115 shows the average markup index of marginal units in the real-time energy market, by offer price category using unadjusted cost-based offers. Table 3-116 shows the average markup index of marginal units in the real-time energy market, by offer price category using adjusted cost-based offers. The unadjusted markup is the difference between the price-based offer and the cost-based offer including the 10 percent adder in the cost-based offer at the dispatch point on the offer curves. The adjusted markup is the difference between the price-based offer and the cost-based offer excluding the 10 percent adder from the cost-based offer. The adjusted markup is calculated for coal, gas and oil units because these units have consistently had price-based offers less than cost-based offers.[186] The markup is negative if the cost-based offer of the marginal unit is greater than its price-based offer at its operating point.

All generating units are allowed to add an additional 10 percent to their cost-based offer. The 10 percent adder was included prior to the implementation of PJM markets in 1999, based on the uncertainty of calculating the hourly operating costs of CTs under changing ambient conditions. The owners of coal units, facing competition, typically exclude the additional 10 percent from their actual offers. The owners of many gas fired and oil fired units have also begun to exclude the 10 percent adder. The introduction of hourly offers and intraday offer updates in November 2017 allows gas and oil generators to directly incorporate the impact of ambient temperature changes in fuel consumption in offers.

PJM implemented Fast Start Pricing on September 1, 2021. For all the fast start marginal units beginning on September 1, 2021, the markup includes markup in the incremental offer, markup in the amortized start up offer, and markup in the amortized no load offer.

Even the adjusted markup overestimates the negative markup because units facing increased competitive pressure have excluded both the 10 percent and components of operating and maintenance costs that are not short run marginal costs. The PJM Market rules permit the 10 percent adder and maintenance costs, which are not short run marginal costs, under the definition of cost-based offers. Actual market behavior reflects the fact that neither is part of a competitive offer and neither is a short run marginal cost.[187]

185 In order to normalize the index results (i.e., bound the results between +1.00 and -1.00) for comparison across both low and high cost units, the index is calculated as (Price – Cost)/Price when price is greater than cost, and (Price – Cost)/Cost when price is less than cost.

186 The MMU will calculate adjusted markup for gas units also in future reports because gas units also more consistently have price-based offers less than cost-based offers.

187 See PJM. "Manual 15: Cost Development Guidelines," Rev. 47 (Oct. 1, 2025).

In the first nine months of 2025, the average dollar markup of units with offer prices less than $10 was negative (-$5.20 per MWh) when using unadjusted cost-based offers. The average dollar markup of units with offer prices between $10 and $15 was negative (-$2.32 per MWh) when using unadjusted cost-based offers. Negative markup means the unit is offering to run at a price less than its cost-based offer, revealing a short run marginal cost that is less than the maximum allowable cost-based offer under the PJM Market Rules.

Some marginal units did have substantial markups. Among the units that were marginal in the first nine months of 2025, 2.9 percent had offer prices above $150 per MWh. Among the units that were marginal in the first nine months of 2024, 1.4 percent had offer prices greater than $150 per MWh. Using the unadjusted cost-based offers, the highest markup for any marginal unit in the first nine months of 2025 was more than $900, and the highest markup in the first nine months of 2024 was more than $900.

Table 3-115 Real-time average marginal unit markup index (By offer price category unadjusted): January through September, 2024 and 2025

	2024 (Jan - Sep)			2025 (Jan - Sep)		
Offer Price Category	Average Markup Index	Average Dollar Markup	Frequency	Average Markup Index	Average Dollar Markup	Frequency

Table 3-118 shows the percentage of marginal units that had markups, calculated using adjusted cost-based offers, below, above and equal to zero for coal, gas and oil fuel types. In the first nine months of 2025, using unadjusted cost-based offers for coal units, 47.89 percent of marginal coal units had negative markups. The share of marginal coal units with negative markups at the dispatch point on their offer curve decreased from 60.08 percent in the first nine months of 2024 to 47.89 percent in the first nine months of 2025 when using unadjusted cost based offers.

Table 3-117 Percent of marginal units with markup below, above and equal to zero (By fuel type with unadjusted offers): January through September, 2024 and 2025

	2024 (Jan - Sep)			2025 (Jan - Sep)		
Type/Fuel	Negative	Zero	Positive	Negative	Zero	Positive
Coal	60.08%	27.04%	12.88%	47.89%	32.05%	20.06%
Gas	63.26%	16.78%	19.95%	65.47%	18.42%	16.11%
Oil	10.26%	88.05%	1.69%	16.44%	80.80%	2.76%

In the first nine months of 2025, using adjusted cost-based offers for coal units, 33.82 percent of marginal coal units had negative markups.

188 Other fuel types were excluded based on data confidentiality rules.

Table 3-118 Percent of marginal units with markup below, above and equal to zero (By fuel type with adjusted offers): January through September, 2024 and 2025

	2024 (Jan - Sep)			2025 (Jan - Sep)		
Type/Fuel	Negative	Zero	Positive	Negative	Zero	Positive
Coal	49.81%	9.42%	40.77%	33.82%	8.79%	57.40%
Gas	45.03%	10.93%	44.04%	33.17%	11.11%	55.72%
Oil	9.85%	87.50%	2.64%	15.51%	79.59%	4.90%

Figure 3-67 shows the frequency distribution of hourly markups for all gas units offered in the first nine months of 2024 and the first nine months of 2025 using unadjusted cost-based offers. The highest markup within the economic operating range of the unit's offer curve was used in the frequency distributions.[189] Of the gas units offered in the PJM market in the first nine months of 2025, 18.2 percent of gas unit hours had a maximum markup that was negative and 23.6 percent of gas fired unit hours had a maximum markup above $100 per MWh. The share of offered gas units with maximum markup that was negative decreased in the first nine months of 2025 compared to the first nine months of 2024, while the share of marginal gas units with negative markups at the dispatch point increased.

Figure 3-67 Frequency distribution of highest markup of gas units offered using unadjusted cost offers: January through September, 2024 and 2025

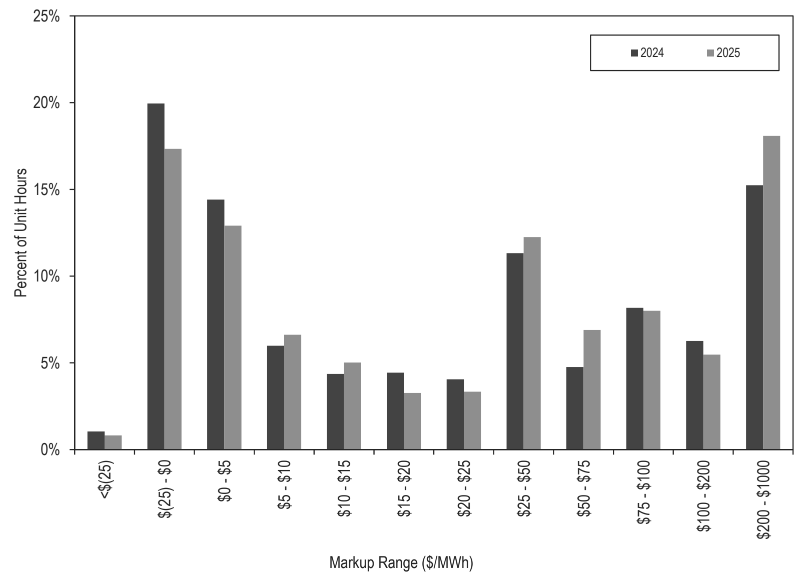

Figure 3-68 shows the frequency distribution of hourly markups for all coal units offered in the first nine months of 2024 and the first nine months of 2025 using unadjusted cost-based offers. Of the coal units offered in the PJM market in the first nine months of 2025, 36.3 percent of coal unit hours had a maximum markup that was negative or equal to zero, increasing from 34.0 percent in the first nine months of 2024. The share of offered coal units with maximum markup that was negative increased in the first nine months of 2025, while the share of marginal coal units with negative markups at the dispatch point decreased in the first nine months of 2025 compared to the first nine months of 2024.

189 The categories in the frequency distribution were chosen so as to maintain data confidentiality.

Figure 3-68 Frequency distribution of highest markup of coal units offered using unadjusted cost offers: January through September, 2024 and 2025

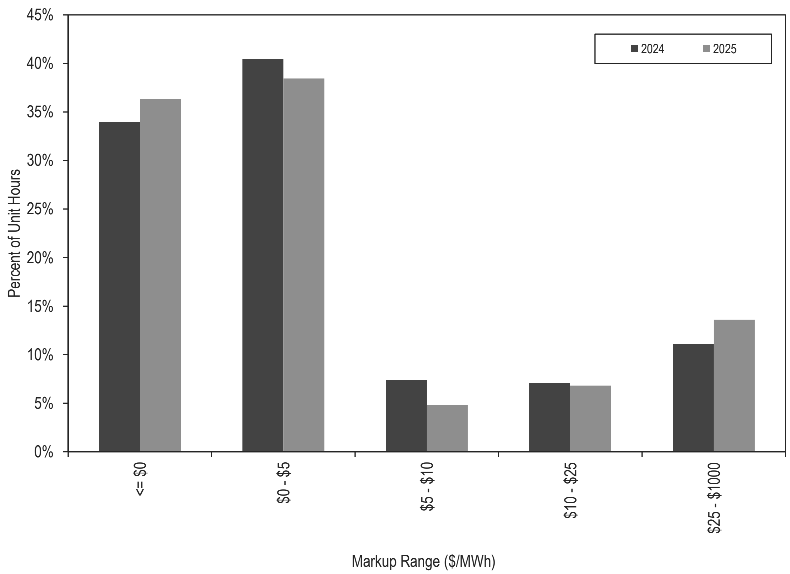

Figure 3-69 Frequency distribution of highest markup of oil units offered using unadjusted cost offers: January through September, 2024 and 2025

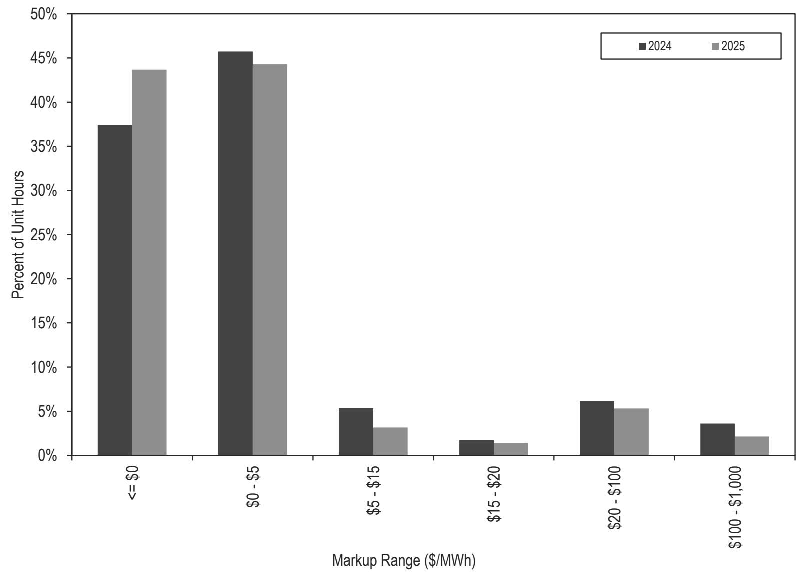

Figure 3-69 shows the frequency distribution of hourly markups for all offered oil units in the first nine months of 2024 and the first nine months of 2025 using unadjusted cost-based offers. Of the oil units offered in the PJM market in the first nine months of 2025, 43.7 percent of oil unit hours had a maximum markup that was negative or equal to zero. More than 2.1 percent of oil fired unit hours had a maximum markup above $100 per MWh.

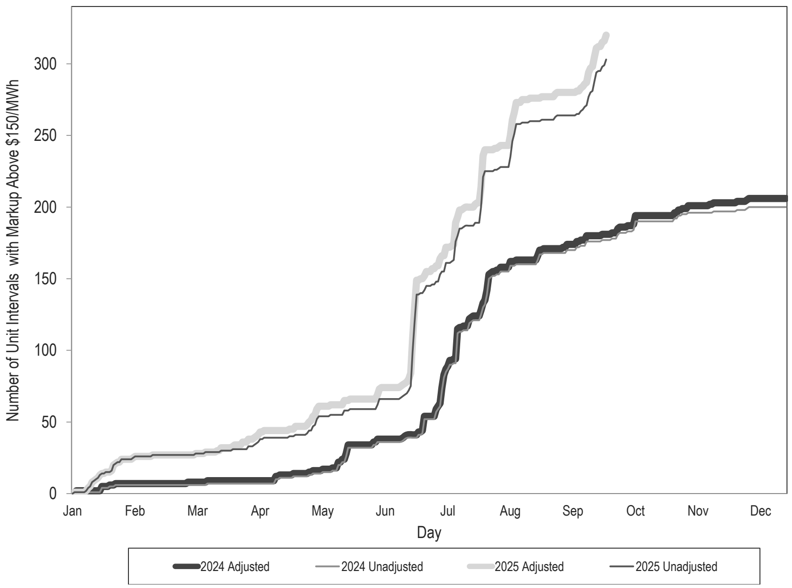
The markup frequency distributions show that a significant proportion of units make price-based offers less than the cost-based offers permitted under the PJM market rules. This behavior means that competitive price-based offers reveal actual unit marginal costs and that PJM market rules permit the inclusion of costs in cost-based offers that are not short run marginal costs.

The markup behavior shown in the markup frequency distributions also shows that a substantial number of units were offered with high markups, consistent with the exercise of market power.

Figure 3-70 shows the number of marginal unit intervals in the first nine months of 2025 and 2024 with markup above $150 per MWh.

Figure 3-70 Cumulative number of unit intervals with markups above $150 per MWh: January 2024 through September 2025



Day-Ahead Markup Index

Table 3-119 shows the average markup index of marginal generating units in the day-ahead energy market, by offer price category using unadjusted cost-based offers.[190]

In the six months between April and September of 2025, the average dollar markup of units with offer prices less than $10 was positive ($6.63 per MWh) when using unadjusted cost-based offers. The average dollar markup of units with offer prices between $10 and $15 was positive ($6.38 per MWh) when using unadjusted cost-based offers. Negative markup means the unit is offering to run at a price less than its cost-based offer, revealing a short run marginal cost that is less than the maximum allowable cost-based offer under the PJM Market Rules.

Some marginal units did have substantial markups. Among the units that were marginal in the six months between April and September of 2025, 1.3 percent had offer prices above $150 per MWh. Using the unadjusted cost-based offers, the highest markup for any marginal unit in the six months between April and September of 2025 was more than $550 per MWh.

Table 3-119 Average day-ahead marginal unit markup index (By offer price category, unadjusted): April through September, 2025

	2025 (Apr - Sep)		
Offer Price Category	Average Markup Index	Average Dollar Markup	Frequency
< $10	2.15	$6.63	7.1%
$10 to $15	0.66	$6.38	9.1%
$15 to $20	0.11	$0.97	13.6%
$20 to $25	0.05	$0.41	15.0%
$25 to $50	0.09	$2.27	43.9%
$50 to $75	0.24	$14.74	7.2%
$75 to $100	0.23	$19.61	2.0%
$100 to $125	0.29	$31.22	0.6%
$125 to $150	0.32	$45.19	0.1%
>= $150	0.27	$76.94	1.3%
All Offers	0.23	$4.96	100.0%

190 MMU identified an error in the marginal resource identification algorithm within the day ahead clearing optimization. The calculation of generator sensitivity factors and markup index require accurate identification of marginal resources. The error was fixed by the PJM software vendor in March 2025. MMU was unable to calculate markup index for 2024 and the first quarter of 2025 due to the inaccurate identification of marginal resources.

Table 3-120 shows the average markup index of marginal generating units in the day-ahead energy market, by offer price category using adjusted cost-based offers.

Table 3-120 Average day-ahead marginal unit markup index (By offer price category, adjusted): April through September, 2025

	2025 (Apr - Sep)		
Offer Price Category	Average Markup Index	Average Dollar Markup	Frequency
< $10	2.18	$6.85	7.1%
$10 to $15	0.73	$7.32	9.1%
$15 to $20	0.18	$2.51	13.6%
$20 to $25	0.11	$2.21	15.0%
$25 to $50	0.16	$4.82	43.9%
$50 to $75	0.29	$17.71	7.2%
$75 to $100	0.27	$22.89	2.0%
$100 to $125	0.32	$35.06	0.6%
$125 to $150	0.34	$47.62	0.1%
>= $150	0.30	$87.37	1.3%
All Offers	0.29	$7.10	100.0%

No Load and Start Cost Markup

Generator energy offers in PJM are comprised of three parts, an incremental energy offer curve, no load cost and start cost. In cost-based offers, all three parts are capped at the level allowed by Schedule 2 of the Operating Agreement, the Cost Development Guidelines (Manual 15) and fuel cost policies approved by PJM. In price-based offers, the incremental energy offer curve is capped at $1,000 per MWh (unless the verified cost-based offer exceeds $1,000 per MWh, but cannot exceed $2,000 per MWh). Generators are allowed to choose whether to use price-based or cost-based no load cost and start costs twice a year. If price-based is selected, the no load and start costs do not have a cap, but the offers cannot be changed for six months (April through September and October through March). If cost-based is selected, the cap is the same as the cap of the no load and start costs in the cost-based offers, and the offers can be updated daily or hourly based on changes in costs. Table 3-121 shows the caps on the three parts of cost-based and price-based offers.

Table 3-121 Cost-based and price-based offer caps

Offer Type	No Load and Start Cost Option	Incremental Offer Curve Cap	No Load Cost Cap	Start Cost Cap
Cost-Based	Cost-Based	Based on OA Schedule 2, Cost Development Guidelines (Manual 15) and Fuel Cost Policies		
Price-Based	Cost-Based	$1,000/MWh or based on OA Schedule 2, Cost Development Guidelines (Manual 15) and Fuel Cost Policies if verified cost-based offer exceeds $1,000/MWh but no more than $2,000/MWh.	Based on OA Schedule 2, Cost Development Guidelines (Manual 15) and Fuel Cost Policies	Based on OA Schedule 2, Cost Development Guidelines (Manual 15) and Fuel Cost Policies
	Price-Based		No cap but can only be changed twice a year.	No cap but can only be changed twice a year.

Table 3-122 shows the number of units that chose the cost-based option and the price-based option. In the first nine months of 2025, 90 percent of all generators that submitted no load or start costs chose to have cost-based no load and start costs in their price-based offers, the same as in the first nine months of 2024.

Table 3-122 Number of units selecting cost-based and price-based no load and start costs: January through September, 2024 and 2025

No Load and Start Cost Option	2024 (Jan-Sep) Number of units	Percent	2025 (Jan-Sep) Number of units	Percent
Cost-Based	480	90%	468	90%
Price-Based	51	10%	50	10%
Total	531	100%	518	100%

Generators can have positive or negative markups in their no load and start costs under the price-based option. Generators cannot have positive markups in no load and start costs when they select the cost-based option. Table 3-123 shows the average markup in the no load and start costs in the first nine months of 2024 and 2025. Generators that selected the cost-based start and no load option offered on average with a negative markup on the no load cost and a negative markup on the start costs. The price-based offers were lower than the cost-based offers. In the first nine months of 2025, generators that selected the price-based start and no load option offered on average with a positive markup on the no load cost and with very large positive markups on the start costs.

Table 3-123 No load and start cost markup: January through September, 2024 and 2025

Period	No Load and Start Cost Option	No Load Cost	Cold Start Cost	Intermediate Start Cost	Hot Start Cost
2024 (Jan-Sep)	Cost-Based	(8%)	(6%)	(6%)	(7%)
	Price-Based	10%	197%	183%	186%
2025 (Jan-Sep)	Cost-Based	(14%)	(5%)	(5%)	(7%)
	Price-Based	23%	139%	123%	122%

Energy Market Cost-Based Offers

The application of market power mitigation rules in the day-ahead energy market and the real-time energy market helps ensure competitive market outcomes even in the presence of structural market power.

Cost-based offers in PJM affect all aspects of the PJM energy market. Cost-based offers affect prices when units are committed and dispatched on their cost-based offers. In the first nine months of 2025, 9.8 percent of the marginal units set prices based on cost-based offers, 2.3 percentage points higher than in the first nine months of 2024.

The efficacy of market power mitigation rules depends on the definition of a competitive offer. A competitive offer is equal to short run marginal costs. The enforcement of market power mitigation rules is undermined if the definition of a competitive offer is not correct. The significance of competition metrics like markup is also undermined if the definition of a competitive offer is not correct. The definition of a competitive offer in the PJM market rules is not correct. Some unit owners include costs that are not short run marginal costs in offers, including maintenance costs. The market rules allow these overstated cost-based offers. This issue can be resolved by simple changes to the PJM market rules to incorporate a clear and accurate definition of short run marginal costs.

The efficacy of market power mitigation rules also depends on the accuracy of cost-based offers. Some unit owners use fuel cost policies that are not algorithmic, verifiable, and systematic. These inadequate fuel cost policies permit overstated fuel costs in cost-based offers.

When market power mitigation is not effective due to inaccurate cost-based offers that exceed short run marginal costs, market power causes increases in market prices above the competitive level.

Short Run Marginal Costs

Short run marginal costs are the only costs relevant to competitive offers in the energy market. Specifically, the competitive energy offer level is the short run marginal cost of production. The current PJM market rules distinguish costs includable in cost-based energy offers from costs includable in cost-based capacity market offers based on whether costs are "directly related to energy production." The rules do not provide a clear standard. Energy production is the sole purpose of a power plant. Therefore, all costs, including the sunk costs, are directly related to energy production. This current ambiguous criterion is incorrect and allows for multiple interpretations, which could lead to tariff violations. The incorrect rules lead to higher energy market prices and higher uplift.

There are three types of costs identified in PJM rules as of April 15, 2019: variable costs, avoidable costs, and fixed costs. The criterion for whether a generator may include a cost in an energy market cost-based offer, a variable cost, is that the cost is "directly related to electric production."[191]

Variable costs, as defined in the PJM rules, are comprised of short run marginal costs and avoidable costs that are directly related to electric production. Short run marginal costs are the cost of inputs consumed or converted to produce energy, and the costs associated with byproducts that result from consuming or converting materials to produce energy, net of any revenues from the sale of those byproducts. The categories of short run marginal costs are fuel costs, emission allowance costs, operating costs, and energy market opportunity costs.[192]

Avoidable costs are annual costs that would be avoided if energy were not produced over an annual period. The PJM rules divide avoidable costs into those that are directly related to electric production and those not directly related to electric production. The distinction is ambiguous at best. PJM includes overhaul and maintenance costs, replacement of obsolete equipment, and overtime staffing costs in costs related to electric production. PJM includes taxes, preventative maintenance to auxiliary equipment, improvement of working equipment, maintenance expenses triggered by a time milestone (e.g. annual, weekly) and pipeline reservation charges in costs not related to electric production.

191 See 167 FERC ¶ 61,030 (2019).
192 See OA Schedule 2 § 1.1(a).

Fixed costs are costs associated with an investment in a facility including the return on and of capital.

The MMU recommends that PJM require that the level of costs includable in cost-based offers in the energy market not exceed the unit's short run marginal cost.

Fuel Cost Policies

Fuel cost policies (FCP) document the process by which market sellers calculate the fuel cost component of their cost-based offers. Short run marginal fuel costs include commodity costs, transportation costs, fees, and taxes for the purchase of fuel.

Fuel Cost Policy Review

Table 3-124 shows the status of all fuel cost policies (FCP). As of September 30, 2025, 715 units (92 percent) had an FCP passed by the MMU and 65 units (eight percent) had an FCP failed by the MMU. The units with fuel cost policies failed by the MMU represented 15,740 MW. All units' FCPs were approved by PJM. As of September 30, 2025, 612 units did not have FCPs. Units without FCPs cannot submit nonzero cost based offers, unless they use the temporary cost method.[193]

Table 3-124 FCP Status for PJM generating units: September 30, 2025

	MMU Status				Units without
PJM Status	Pass	Submitted	Fail	Total	FCPs
Approved	715	0	65	780	
Rejected	0	0	0	0	
Under Review	0	0	0	0	
Customer Input Required	0	0	0	0	
Submitted	0	0	0	0	
Total	715	0	65	780	612

The MMU performed a detailed review of every FCP. PJM approved the FCPs that the MMU passed. PJM approved every FCP failed by the MMU.

The standards for the MMU's market power evaluation are that FCPs be algorithmic, verifiable and systematic, accurately reflecting the short run

193 See OA Schedule 2 § 2.1.

marginal cost of producing energy. In its filings with FERC, PJM agreed with the MMU that FCPs should be verifiable and systematic.[194] Verifiable means that the FCP requires a market seller to provide a fuel price that can be calculated by the MMU after the fact with the same data available to the market seller at the time the decision was made, and documentation for that data from a public or a private source. Systematic means that the FCP must document a clearly defined quantitative method or methods for calculating fuel costs, including objective triggers for each method.[195] PJM and FERC did not agree that fuel cost policies should be algorithmic, although PJM's standard effectively requires algorithmic fuel cost policies by describing the requirements.[196] Algorithmic means that the FCP must use a set of defined, logical steps, analogous to a recipe, to calculate the fuel costs. These steps may be as simple as a single number from a contract, a simple average of broker quotes, a simple average of bilateral offers, or the weighted average index price posted on the Intercontinental Exchange trading platform ('ICE').[197]

FCPs are not verifiable and systematic if they are not algorithmic. The natural gas FCPs failed by the MMU and approved by PJM are not verifiable and systematic.

Not all FCPs approved by PJM met the standard of the PJM tariff. The tariff standards that some fuel cost policies did not meet are: accuracy (reflect applicable costs accurately); and fuel contracts (reflect the market seller's applicable commodity and/or transportation contracts where it holds such contracts).[198]

The MMU failed FCPs not related to natural gas submitted by some market sellers because they do not accurately describe the short run marginal cost of fuel. Some policies include contractual terms (in dollars per MWh or in dollars per MMBtu) that do not reflect the actual cost of fuel. The MMU determined that the terms used in these policies do not reflect the cost of fuel based on the information provided by the market sellers and information gathered by the MMU for similar units.

The MMU failed the remaining FCPs because they do not accurately reflect the cost of natural gas. The main issues identified by the MMU in the natural gas policies were the use of available market information that results in inaccurate and overstated expected costs. Overstated costs permit the exercise of market power.

Some of the failed fuel cost polices include the use of available market information that results in inaccurate expected costs because the information does not represent a cleared market price. Some market sellers include the use of offers to sell natural gas on ICE as the sole basis for the cost of natural gas. An offer to sell is not a market clearing price and is not an accurate indication of the expected fuel cost. The price of uncleared offers on the exchange generally exceeds the price of cleared transactions, often by a wide margin. Use of sell offers alone is equivalent to using the supply curve alone to determine the market price of a good without considering the demand curve. It is clearly incorrect.

The FCPs that failed the MMU's evaluation also fail to meet the standards defined in the PJM tariff. PJM should not have approved noncompliant fuel cost policies. The MMU recommends that PJM require that all fuel cost policies be algorithmic, verifiable, and systematic.

Units are required to have an approved fuel cost policy before they can submit nonzero cost-based offers or request from PJM the use of a temporary cost method. The temporary cost offer method allows units to submit nonzero cost-based offers without an approved fuel cost policy if they follow the temporary cost offer method. The use of the method results in cost-based offers that do not follow the fuel cost policy rules. The approach significantly weakens market power mitigation by allowing market sellers to make offers without an approved fuel cost policy, allowing the use of an inaccurate and unsupported fuel cost calculation in place of an accurate fuel cost policy.

194 Answer of PJM Interconnection, L.L.C. to Protests and Comments, Docket No. ER16-372-002 (October 7, 2016) at P 11 ("October 7th Filing").
195 Protest of the Independent Market Monitor for PJM, Docket No. ER16-372-002 (September 16, 2016) at P 8 ("September 16th Filing").
196 October 7th Filing at P12; 158 FERC ¶ 61,133 at P 57 (2017).
197 September 16th Filing at P 8.
198 See PJM Operating Agreement Schedule 2 § 2.3 (a).

The MMU recommends that the temporary cost method be removed and that all units that submit nonzero cost-based offers be required to have an approved fuel cost policy.

Cost-Based Offer Penalties

Market sellers are assessed penalties when they submit cost-based offers that do not comply with Schedule 2 of the PJM Operating Agreement and PJM Manual 15.[199] Penalties are assessed when both PJM and the MMU are in agreement.

In the first nine months of 2025, 28 penalty cases were identified, 27 have been assessed cost-based offer penalties and one remains pending. These cases were for 28 units owned by 11 different companies. Table 3-125 shows the penalties by the year in which participants were notified.

Table 3-125 Cost-based offer penalty cases by year notified: May 2017 through September 2025

Year notified	Cases	Assessed penalties	Self Identified	MMU and PJM Disagreement	Pending cases	Number of units impacted	Number of companies impacted
2017	57	56	0	1	0	55	16
2018	187	161	0	26	0	138	35
2019	57	57	0	0	0	57	19
2020	142	137	24	5	0	124	25
2021	129	124	42	5	0	124	21
2022	116	116	51	0	0	110	20
2023	65	65	13	0	0	61	18
2024	77	77	39	0	0	67	21
2025	28	27	2	0	1	28	11
Total	858	820	171	37	1	516	81

Since 2017, of the 858 penalty cases, 820 resulted in assessed cost-based offer penalties, 37 resulted in disagreement between the MMU and PJM and one remains pending. A total of 171 were self identified by market sellers. The 820 cases were from 516 units owned by 81 different companies. The total penalties were $6.0 million, charged to units that totaled 165,275 available MW. The average penalty was $1.60 per available MW. This means that a 100 MW unit would have paid a penalty of $3,840.[200] There is no link between the increased costs to the market that result from a penalized fuel cost policy and the amount of the penalty. The increased costs to the market can exceed the penalty payment and the reverse can also be true. Table 3-126 shows the total cost-based offer penalties since 2017 by year.

Table 3-126 Cost-based offer penalties by year: May 2017 through September 2025

Year	Number of units	Number of companies	Penalties	Average Available Capacity Charged (MW)	Average Penalty ($/MW)
2017	92	21	$556,826	16,930	$1.56
2018	127	35	$1,242,102	25,743	$2.28
2019	73	24	$378,245	15,073	$1.14
2020	140	28	$407,283	21,908	$0.85
2021	125	27	$753,463	24,808	$1.31
2022	123	22	$1,613,621	24,385	$2.76
2023	61	16	$333,948	10,383	$1.33
2024	79	22	$549,736	21,900	$1.05
2025	27	10	$181,937	4,145	$1.84
Total	847	78	$6,017,161	165,275	$1.60

The incorrect cost-based offers resulted from incorrect application of fuel cost policies, lack of approved fuel cost policies, fuel cost policy violations, miscalculation of no load costs, inclusion of prohibited maintenance costs, use of incorrect incremental heat rates, use of incorrect start cost, and use of incorrect emission costs.

Penalties do not apply when PJM determines that an unforeseen event hindered the market seller's ability to submit a compliant cost-based offer. This allows market sellers to not follow their fuel cost policy, submit cost-based offers that are not verifiable or systematic and not face any penalties for doing so. This practice is inappropriate and should stop.

The MMU recommends that the penalty exemption provision be removed and that all units that submit nonzero cost-based offers be required to follow their approved fuel cost policy.

199 See OA Schedule 2 § 6.

200 Cost-based offer penalties are assessed by hour. Therefore, a $1 per available MW penalty results in a total of $24 for a 1 MW unit if the violation is for the entire day.

Cost Development Guidelines

The Cost Development Guidelines contained in PJM Manual 15 do not clearly or accurately describe the short run marginal cost of generation. The MMU recommends that PJM Manual 15 be replaced or updated with a straightforward description of the components of cost-based offers based on short run marginal costs and the correct calculation of cost-based offers for thermal resources. In 2022, PJM made updates recommended by the MMU to Manual 15 to add straightforward descriptions for some of the most essential cost offer calculations.[201]

Variable Operating and Maintenance Costs

PJM Manual 15 and the PJM Operating Agreement Schedule 2 include rules related to VOM costs. On October 29, 2018, PJM filed tariff revisions changing the rules related to VOM costs.[202] The changes proposed by PJM attempted but failed to clarify the rules. The proposed rules defined all costs directly related to electricity production as includable in cost-based offers. This also included the long term maintenance costs of combined cycles and combustion turbines, which had been explicitly excluded in PJM Manual 15.

On April 15, 2019, FERC accepted PJM's filing, subject to revisions requested by FERC.[203] On October 28, 2019, FERC issued a final order accepting PJM's compliance filing.[204] Regardless of the changes, the rules remain unclear and are now inconsistent with economic theory and effective market power mitigation and competitive market results.

Maintenance costs are not short run marginal costs. Generators perform maintenance during outages. Generators do not perform maintenance in the short run, while operating the generating unit. Generators do not perform maintenance in real time to increase the output of a unit. Some maintenance costs are correlated with the historic operation of a generator. Correlation between operating hours or starts and maintenance expenditures over a long run, multiyear time frame does not indicate the necessity of any specific maintenance expenditure to produce power in the short run.

201 See PJM Manual 15: Cost Development Guidelines, Revision 47 (Oct. 1, 2025).
202 See PJM Interconnection Maintenance Adder Revisions to the Amended and Restated Operating Agreement, L.L.C., Docket No. EL19-8-000.

204 168 FERC ¶ 61,134 (2019).

A generating unit does not consume a defined amount of maintenance parts and labor in order to start. A generating unit does not consume a defined amount of maintenance parts and labor in order to produce an additional MWh. Maintenance events do not occur in the short run. The company cannot optimize its maintenance costs in the short run.

PJM allows for the calculation of VOM costs in dollars per MWh, dollars per MMBtu, dollars per run hour, dollars per equivalent operating hour (EOH) and dollars per start. The MMU converted all VOM costs into dollars per MWh using the units' heat rates, the average economic maximum and average minimum run time of the units in 2024.

Table 3-127 shows the average VOM by unit type. The VOM equals the sum of variable operating cost, major maintenance adder and minor maintenance adder as submitted by market participants.

Table 3-127 Effective VOM costs in dollars per MWh in 2024

Unit Type	VOM ($/MWh)
Combined Cycles	$3.00
Combustion Turbines and RICE	$22.62
Gas/Oil Steam Turbines	$12.19
Coal	$6.01

The level of costs accepted by PJM for inclusion in VOM depends on PJM's interpretation of the maintenance activities or expenses directly related to electricity production and the level of detailed support provided by market sellers to PJM.

PJM's VOM review is not adequate to determine whether all costs included in VOM are compliant. PJM's VOM review focuses only on the expenses submitted for the last year of up to 20 years of data. For example, a market seller can provide data from ten years ago without any supporting documentation as long as the data from the current year has documentation. PJM's review is dependent on the level of detail provided by the market seller. As a result of questions raised by the MMU, PJM now requires more details from market sellers, which has led to the appropriate exclusion of expenses that were previously included.[205]

The flaws in PJM's review process for VOM are compounded by the ambiguity in the criteria used to determine if costs are includable. PJM's definition of allowable costs for cost-based offers, "costs resulting from electric production," is so broad as to be meaningless. Most costs incurred at a generating station result from electric production in one way or another. The generator itself would not exist but for the need for electric production. PJM's broad definition cannot identify which costs associated with electric production are includable in cost-based offers. The definition is not verifiable or systematic and permits wide discretion by PJM and generators.

On February 17, 2023, PJM filed tariff revisions changing the rules related to VOM costs. The changes included separating maintenance expenses into major and minor maintenance, allowing the use of default adders for minor maintenance and operating costs and eliminating the annual review requirement for units that choose to use default adders. The proposal, that included the tariff changes, also included Manual 15 changes that introduced additional documentation requirements. Regarding maintenance expenses, market participants will be required to provide all supporting documentation for all expenses submitted, regardless of year. Regarding operating expenses, market participants will be required to provide the amount of consumables used during operation and the cost per unit of each consumable. On April 18, 2023, FERC accepted PJM's filing. Table 3-128 shows the default adders for operating cost and minor maintenance.

Table 3-128 Default operating cost and minor maintenance adder: 2024

Unit Type	Operating Cost ($/MWh)	Minor Maintenance Cost ($/MWh)
Combined Cycle	0.46	1.13
Combustion Turbine	0.86	4.14
Reciprocating Engine	1.87	4.64
Steam Turbine	3.31	1.97

205 See "Maintenance Adder & Operating Cost Submission Process," 55-57 PJM presentation to the Tech Change Forum. (April 21, 2020) <https://pjm.com/-/media/committees-groups/forums/tech-change/2020/20200421-special/20200421-item-01-maintenance-adder-and-operating-cost-submission-process.ashx>

The MMU recommended that market participants be required to document the amount and cost of consumables used when operating in order to verify that the total operating cost is consistent with the total quantity used and the unit characteristics. The revisions to Manual 15 based on the February 17, 2023, filing included this requirement.

The MMU recommends, given that maintenance costs are currently allowed in cost-based offers, that market participants be permitted to include only variable maintenance costs, linked to verifiable operational events and that can be supported by clear and unambiguous documentation of operational data (e.g. run hours, MWh, MMBtu) that support the maintenance cycle of the equipment being serviced/replaced. The revisions to Manual 15 based on the February 17, 2023, filing partially included this requirement. Even though Manual 15 requires maintenance expenses to be the result of operating hours, starts or a combination of the two, the expenses are not tied to a maintenance cycle. Therefore, it is not possible to distinguish between maintenance that resulted from operating the resource versus maintenance from normal wear and tear.

The MMU understands that companies have different document retention policies but in order to be allowed to include maintenance costs, such costs must be verified, and they cannot be verified without documentation. Supporting documentation includes internal financial records, maintenance project documents, invoices, and contracts. Market participants should be required to provide the operational data (e.g. run hours, MWh, MMBtu) that supports the maintenance cycle of the equipment being serviced/replaced. For example, if equipment is serviced every 5,000 run hours, the market participant must include at least 5,000 run hours of historical operation in its maintenance cost history.

FERC System of Accounts

PJM Manual 15 relies on the FERC System of Accounts, which predates markets and does not define costs consistent with market economics. Market sellers should not rely solely on the FERC System of Accounts for the calculation of their variable operating and maintenance costs. The FERC System of Accounts does not differentiate between short run marginal costs and avoidable costs. The FERC System of Accounts does not differentiate between costs directly related to energy production and costs not directly related to energy production. Reliance on the FERC System of Accounts for the calculation of variable operating and maintenance costs is likely to lead to incorrect, overstated costs.

The MMU recommends removal of all references to and reliance on the FERC System of Accounts in PJM Manual 15.

Cyclic Starting and Peaking Factors

The use of cyclic starting and peaking factors for calculating VOM costs for combined cycles and combustion turbines is designed to allocate a greater proportion of long term maintenance costs to starts and the tail block of the incremental offer curve. The use of such factors is not appropriate given that long term maintenance costs are not short run marginal costs and should not be included in cost offers. PJM Manual 15 allows for a peaking cyclic factor of three, which means that a unit with a $300 per hour (EOH) VOM cost can add $180 per MWh to a 5 MW peak segment.[206]

The MMU recommends the removal of all cyclic starting and peaking factors from PJM Manual 15.

Labor Costs

PJM Manual 15 allows for the inclusion of plant staffing costs in energy market cost offers. This is inappropriate given that labor costs are not short run marginal costs.

The MMU recommends the removal of all labor costs from the PJM Manual 15. On December 2, 2022, PJM filed tariff changes removing labor costs from cost-based offers. The changes were approved by the Commission on January 10, 2023 and became effective on June 1, 2023.[207]

Combined Cycle Start Heat Input Definition

PJM Manual 15 defines the start heat input of combined cycles as the amount of fuel used from the firing of the first combustion turbine to the close of the steam turbine breaker plus any fuel used by other combustion turbines in the combined cycle from firing to the point at which the HRSG steam pressure matches the steam turbine steam pressure. This definition is inappropriate given that after each combustion turbine is synchronized, some of the fuel is used to produce energy for which the unit is compensated in the energy market. To account for this, PJM Manual 15 requires reducing the station service MWh used during the start sequence by the output in MWh produced by each combustion turbine after synchronization and before the HRSG steam pressure matches the steam turbine steam pressure. The formula and the language in this definition are not appropriate and are unclear.

The MMU recommended changing the definition of the start heat input for combined cycles to include only the amount of fuel used from firing each combustion turbine in the combined cycle to the breaker close of each combustion turbine. This change will make the treatment of combined cycles consistent with steam turbines. Exceptions to this definition should be granted when the amount of fuel used from synchronization to steam turbine breaker close is greater than the no load heat plus the output during this period times the incremental heat rate.

In 2022, the MMU and PJM proposed changing the start cost definition of units with a steam process to include the costs from the beginning of the start sequence to dispatchable.[208] The new definition included what is commonly consider soak costs in the start cost. The new definition was combined with the elimination of make whole payments to units with a steam process for MW produced before the unit becomes dispatchable. The proposal was approved by the Commission on January 10, 2023 and became effective on June 1, 2023.[209]

Even though the MMU developed and supported the new definition, it is important to recognize that this approach should be temporary until PJM implements an approach that reflects soak time, soak costs and soak energy output. The main shortcoming of the new definition is that PJM models do not properly value the energy produced during the soak process (soak energy output). Instead, the proposal simply assumes that such MWh are valued at PJM's station service rate. The ideal solution is to model start costs and soak

206 The peak adder is equal to $300 times three divided by 5 MW.
207 *See* Federal Energy Regulatory Commission, Docket No. ER23-557-000 (January 10, 2023) at 1.
208 *See* "Start Cost Alternate Proposal," MMU presentation to the Cost Development Subcommittee. (December 2, 2021) <20211202-item-06-start-cost-alternate-proposal.ashx>.
209 *See* Federal Energy Regulatory Commission, Docket No. ER23-557-000 (January 10, 2023) at 1.

costs separately since there are revenues associated with the MWh produced during soaking, while during the start process there are no MWh being injected into the grid.

The MMU recommends that soak costs, soak time and the MWh produced during soaking be modeled separately. This will ensure that the time required for units to reach a dispatchable level is known and used in the unit commitment process instead of only being communicated verbally between dispatchers and generators. Separating soak costs from start costs and modeling the MWh produced during soaking allows for a better representation of the costs because it eliminates the need to simply assume the price paid for those MWh.

Nuclear Costs

The fuel costs for nuclear plants are fixed in the short run and amortized over the period between refueling outages. The short run marginal cost of fuel for nuclear plants is zero. Operations and maintenance costs for nuclear power plants consist primarily of labor and maintenance costs incurred during outages, which are also fixed in the short run.

The MMU recommends the removal of nuclear fuel and nonfuel operations and maintenance costs that are not short run marginal costs from the PJM Manual 15.

Pumped Hydro Costs

The calculation of pumped hydro costs for energy storage in Section 7.3 of PJM Manual 15 is inaccurate. The mathematical formulation does not take into account the purchase of power for pumping in the day-ahead market.

The MMU recommends revising the pumped hydro fuel cost calculation to include day-ahead and real-time power purchases.

Gas Pipeline Penalties

Section 2.2.2 of PJM Manual 15 states that gas pipeline penalties are not includable in cost-based offers. Penalties can be incurred by units for many reasons, for example, withdrawing gas not nominated and deviating from an imposed threshold during an operational flow order. Any unit with cost-based offers that include gas pipeline penalties will be subject to penalties per Schedule 2 of the PJM Operating Agreement.

Many Market Sellers rely on independent third party quotes to estimate or determine the gas spot price. The quotes received from these third parties should not be based on incurring gas pipeline penalties. It is recommended that Market Sellers confirm with their third parties that gas is available to them without the need to incur gas pipeline penalties. If that is not possible, the units should be unavailable until the third party can confirm that gas is available without incurring penalties.

Frequently Mitigated Units (FMU) and Associated Units (AU)

The rules for determining the qualification of a unit as an FMU or AU became effective November 1, 2014. The number of units that were eligible for an FMU or AU adder declined from an average of 70 units during the first 11 months of 2014, to zero units eligible for an FMU or AU adder for the period between December 2014 and August 2019.[210] One unit qualified for an FMU adder for the months of September and October, 2019. In 2020, five units qualified for an FMU adder in at least one month. In 2021, one unit qualified for an FMU adder in January. In 2022, 2023, and 2024, no units qualified for an FMU adder. In the first nine months of 2025, no units qualified for an FMU adder.

Table 3-129 shows, by month, the number of FMUs and AUs from January 2021 through September 2025. For example, in January 2021, there were zero units that qualified as an FMU or AU in Tier 1, one unit qualified as an FMU or AU in Tier 2, and zero units qualified as an FMU or AU in Tier 3.

210 For a definition of FMUs and AUs, and for historical FMU/AU results, see the *2018 Annual State of the Market Report for PJM*, Volume 2, Section 3, Energy Market, at Frequently Mitigated Units (FMU) and Associated Units (AU).

Table 3-129 Number of frequently mitigated units and associated units (By month): January 2021 through September 2025

	2021				2022				2023				2024				2025

September	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
October	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0				
November	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0				
December	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0				

The MMU recommends the elimination of FMU and AU adders. FMU and AU adders no longer serve the purpose for which they were created and interfere with the efficient operation of PJM markets.

Market Performance

Ownership of Marginal Resources

Table 3-130 shows the contribution to real-time, load-weighted LMP by individual marginal resource owners.[211] The contribution of each marginal resource to price at each load bus is calculated for each five-minute interval of the first nine months of 2025, and summed by the parent company that offers the marginal resource into the real-time energy market. In the first nine months of 2025, the offers of one company resulted in 16.3 percent of the real-time load-weighted PJM system LMP and the offers of the top four companies resulted in 40.8 percent of the real-time load-weighted average PJM system LMP. In the first nine months of 2025, the offers of one company resulted in 15.0 percent of the peak hour real-time load-weighted PJM system LMP.

211 See the *MMU Technical Reference for PJM Markets*, at "Calculation and Use of Generator Sensitivity/Unit Participation Factors."

Table 3-130 Marginal unit contribution to real-time load-weighted LMP (By parent company): January through September, 2024 and 2025

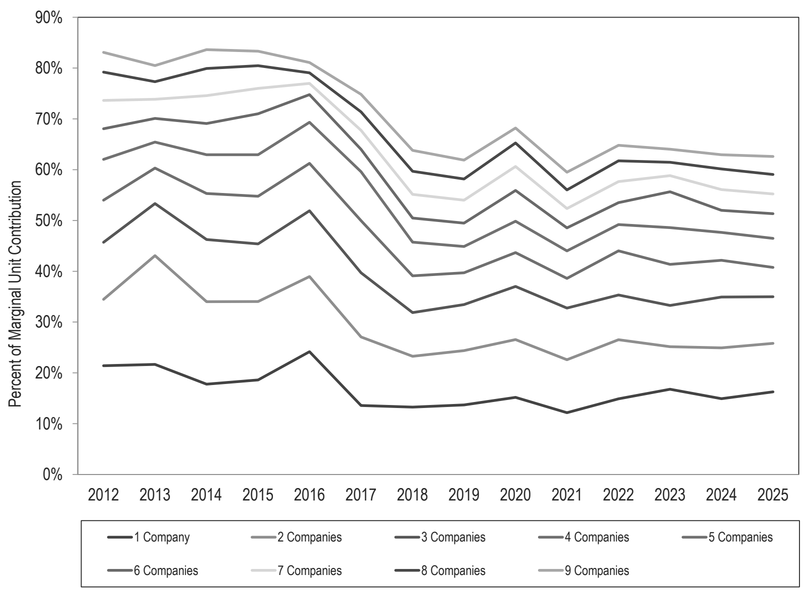
Figure 3-71 shows the marginal unit contribution to the real-time load-weighted PJM system LMP summed by parent companies for the first nine months of every year since 2012.

Figure 3-71 Marginal unit contribution to real-time load-weighted LMP (By parent company): January through September, 2012 through 2025



Markup

The markup index is a measure of the competitiveness of participant behavior for individual units. The markup in dollars is a measure of the impact of participant behavior on the generator bus market price when a unit is marginal. As an example, if unit A has a $90 cost and a $100 price, while unit B has a $9 cost and a $10 price, both would show a markup index of 10 percent, but the price impact of unit A's markup at the generator bus would be $10 while the price impact of unit B's markup at the generator bus would be $1. Depending on each unit's location on the transmission system, those bus level impacts could also have different impacts on total system price. Markup can also affect prices when units with markups are not marginal by altering the economic dispatch order of supply.

The MMU calculates an explicit measure of the impact of marginal unit incremental energy offer markups on LMP using the mathematical relationships among LMPs in the market solution.[212] The markup impact calculation sums, over all marginal units, the product of the dollar markup of the unit and the marginal impact of the unit's offer on the system load-weighted LMP. The markup impact includes the impact of the identified markup behavior of all marginal units. Positive and negative markup impacts may offset one another. The markup analysis is a direct measure of market performance. It does not take into account whether or not marginal units have either locational or aggregate structural market power.

The markup calculation is not based on a counterfactual redispatch of the system to determine the marginal units and their marginal costs that would have occurred if all units had made all offers at short run marginal cost. A full redispatch analysis is practically impossible and a limited redispatch analysis would not be dispositive. Nonetheless, such a hypothetical counterfactual analysis would reveal the extent to which the actual system dispatch is less than competitive if it showed a difference between dispatch based on short run marginal cost and actual dispatch. It is possible that the unit specific markup, based on a redispatch analysis, would be lower than the markup component of price if the reference point were an inframarginal unit with a lower price and a higher cost than the actual marginal unit. If the actual marginal unit has short run marginal costs that would cause it to be inframarginal, a new unit would be marginal. If the offer of that new unit were greater than the cost of the original marginal unit, the markup impact would be lower than the MMU measure. If the newly marginal unit is on a price-based schedule, the analysis would have to capture the markup impact of that unit as well.

Real-Time Markup

Markup Component of Real-Time Price by Fuel, Unit Type

The markup component of price is the difference between the system price, when the system price is determined by the active offers of the marginal units, whether price or cost-based, and the system price, based on the cost-based offers of those marginal units.

PJM implemented fast start pricing on September 1, 2021. Under the fast start pricing rules, the LMPs are calculated in the pricing run, where the offer price of a marginal fast start unit includes amortized commitment costs. For all the fast start marginal units starting from September 1, 2021, the markup includes markup in the incremental offer, markup in the amortized start up offer and markup in the amortized no load offer.

Table 3-131 shows the impact (markup component of LMP) of the marginal unit markup behavior by fuel type and unit type on the real-time load-weighted average system LMP using unadjusted and adjusted offers. The adjusted markup component of LMP increased from $2.28 per MWh in the first nine months of 2024 to $2.95 per MWh in the first nine months of 2025. The adjusted markup contribution of coal units in the first nine months of 2025 was $0.64 per MWh, an increase of $0.40 per MWh from the first nine months of 2024. The adjusted markup component of gas fired units in the first nine months of 2025 was $2.93 per MWh, an increase of $0.43 per MWh from the first nine months of 2024. The markup component of wind units was

212 The MMU calculates the impact on system prices of marginal unit price-cost markup, based on analysis using sensitivity factors. The calculation shows the markup component of LMP based on a comparison between the price-based incremental energy offer and the cost-based incremental energy offer of each actual marginal unit on the system. This is the same method used to calculate the fuel cost adjusted LMP and the components of LMP. *See* Calculation and Use of Generator Sensitivity/Unit Participation Factors, 2010 State of the Market Report for PJM: Technical Reference for PJM Markets.

$0.01 per MWh. If a price-based offer is negative, but less negative than a cost-based offer, the markup is positive. In the first nine months of 2025, among the wind units that were marginal, 68.7 percent had negative offer prices.

Table 3-131 Markup component of real-time load-weighted average LMP by primary fuel type and unit type: January through September, 2024 and 2025[213]

		2024 (Jan - Sep)		2025 (Jan - Sep)

Markup Component of Real-Time Price

Table 3-132 shows the markup component, calculated using unadjusted offers, of average prices and of average monthly on peak and off peak prices. Table 3-133 shows the markup component, calculated using adjusted offers, of average prices and of average monthly on peak and off peak prices. In the first nine months of 2025, when using unadjusted cost-based offers, -$0.09 per MWh of the PJM real-time load-weighted average LMP was attributable to markup. Using adjusted cost-based offers, $2.94 per MWh of the PJM real-time load-weighted average LMP was attributable to markup. In the first nine months of 2025, the peak markup component was highest in July, $2.74 per MWh using unadjusted cost-based offers and $6.66 per MWh using adjusted cost-based offers. This corresponds to 3.5 percent and 8.6 percent of the real-time peak load weighted average LMP in July.

213 The unit type RICE refers to Reciprocating Internal Combustion Engines.

Table 3-132 Monthly markup components of real-time load-weighted LMP (Unadjusted): January 2024 through September 2025

Hourly Markup Component of Real-Time Prices

Figure 3-72 shows the markup contribution to the hourly load-weighted LMP using unadjusted cost offers in the first nine months of 2025 and 2024. Figure 3-73 shows the markup contribution to the hourly load-weighted LMP using adjusted cost-based offers in the first nine months of 2025 and 2024.

Figure 3-72 Markup contribution to real-time hourly load-weighted LMP (Unadjusted): January 2024 through September 2025

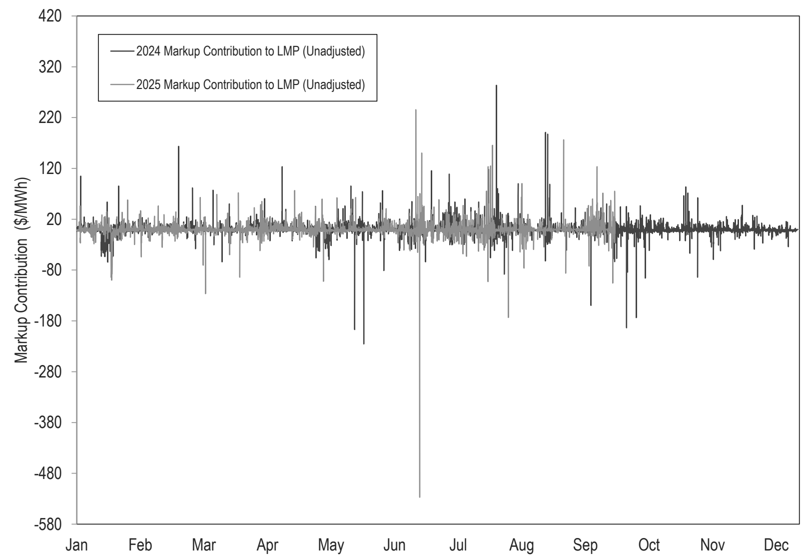

Figure 3-73 Markup contribution to real-time hourly load-weighted LMP (Adjusted): January 2024 through September 2025

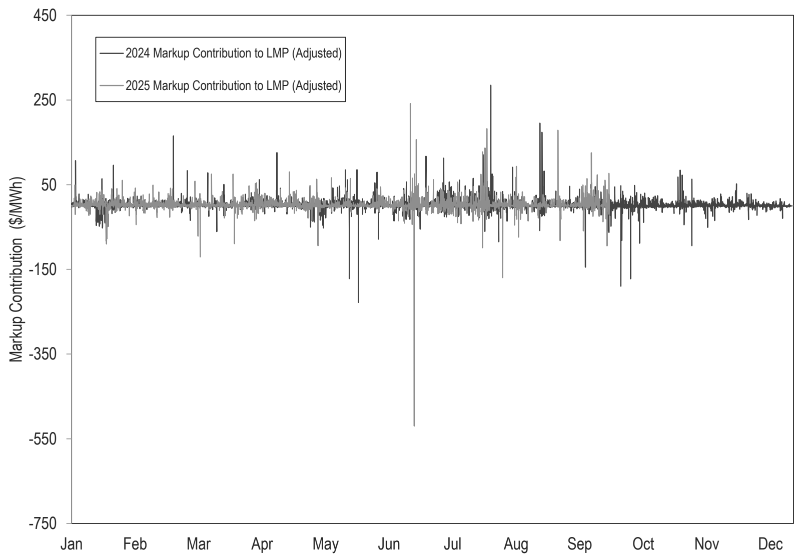

Markup Component of Real-Time Zonal Prices

The unit markup component of average real-time price using unadjusted offers is shown for each zone in the first nine months of 2024 and 2025 in Table 3-134 and for adjusted offers in Table 3-135.[214] The smallest zonal all hours average markup component using unadjusted offers in the first nine months of 2025, was in the DPL Zone, -$2.09 per MWh, while the highest was in the BGE Zone, $0.72 per MWh. The smallest zonal on peak average markup component using unadjusted offers in the first nine months of 2025, was in the DPL Zone, -$2.88 per MWh, while the highest was in the PE Zone, $1.23 per MWh.

>= $150	$37.36	0.8%	$19.23	2.0%

Markup by Company

Table 3-138 shows the markup contribution based on the unadjusted cost-based offers and adjusted cost-based offers to real-time load-weighted average LMP by individual marginal resource owners. The markup contribution of each marginal resource to price at each load bus is calculated for each five-minute interval, and summed by the parent company that offers the marginal resource into the real-time energy market. In the first nine months of 2025, when using unadjusted cost-based offers, the markup of one company accounted for 0.8 percent of the load-weighted average LMP, the markup of the top five companies accounted for 2.8 percent of the load-weighted average LMP and the markup of all companies accounted for -0.3 percent of the load-weighted average LMP. The share of top five companies' markup contribution to the load-weighted average LMP decreased and the dollar values of their markup decreased in the first nine months of 2025. The markup contribution to the load-weighted average LMP decreased and share of the markup contribution to the load-weighted average LMP decreased in the first nine months of 2025. The markup contribution of a unit to the real-time load-weighted average LMP can be positive or negative.

Table 3-138 Markup component of real-time load-weighted average LMP by Company: January through September, 2024 and 2025

	2024 (Jan - Sep)				2025 (Jan - Sep)

Day-Ahead Markup[215]

Markup Component of Day-Ahead Price by Fuel, Unit Type

The markup component of the PJM day-ahead load-weighted average LMP by primary fuel and unit type is shown in Table 3-139. INC, DEC and up to congestion transactions (UTC) have zero markups. The adjusted markup of coal, gas and oil units is calculated as the difference between the price-based offer and the cost-based offer excluding the 10 percent adder.

Table 3-139 shows the markup component of LMP for marginal generating resources. The adjusted markup component of LMP for coal fired units was $0.28 per MWh in the six months between April and September of 2025. The adjusted markup component of LMP for gas fired CC units was $1.38 per MWh in the six months between April and September of 2025.

215 MMU identified an error in the marginal resource identification algorithm within the day ahead clearing optimization. The calculation of generator sensitivity factors and markup index require accurate identification of marginal resources. The error was fixed by the PJM software vendor in March 2025. MMU was unable to calculate markup index for 2024 and the first quarter of 2025 due to the inaccurate identification of marginal resources.

Table 3-139 Markup component of day-ahead load-weighted average LMP by primary fuel type and technology type: April through September, 2025

		2025 (Apr - Sep)	
Fuel	Technology	Markup Component of LMP (Unadjusted)	Markup Component of LMP (Adjusted)
Coal	Steam	($0.12)	$0.28
Gas	CC	$0.53	$0.96
Gas	CT	$0.32	$0.48
Gas	RICE	($0.00)	$0.00
Gas	Steam	($0.16)	($0.07)
Oil	CC	$0.00	$0.00
Oil	CT	($0.01)	($0.01)
Oil	RICE	$0.00	$0.00
Oil	Steam	($0.05)	($0.04)
Other	Solar	$1.42	$1.42
Other	Steam	$0.01	$0.01
Wind	Wind	$0.71	$0.71
Total		$2.64	$3.76

Markup Component of Day-Ahead Price

The markup component of price is the difference between the system price, when the system price is determined by the active offers of the marginal units, whether price or cost-based, and the system price, based on the cost-based offers of those marginal units. Only hours when generating units were marginal on either priced-based offers or on cost-based offers were included in the markup calculation.

Table 3-140 shows the markup component of average prices and of average monthly on peak and off peak prices using unadjusted cost-based offers. Table 3-141 shows the markup component of average prices and of average monthly on peak and off peak prices using adjusted cost-based offers. In the six months between April and September of 2025, when using unadjusted cost-based offers, $2.64 per MWh of the PJM day-ahead load-weighted average LMP was attributable to markup. Using adjusted cost-based offers, $3.76 per MWh of the PJM real-time load-weighted average LMP was attributable to markup. In the six months between April and September of 2025, the peak markup component was highest in July, $7.59 per MWh using unadjusted cost-based offers and $9.07 per MWh using adjusted cost-based offers. This corresponds to 8.6 percent and 10.2 percent of the day-ahead peak load weighted average LMP in July.

Table 3-140 Monthly markup components of day-ahead (Unadjusted) load-weighted LMP: April 2025 through September 2025

	2025		
	Markup Component (All Hours)	Peak Markup Component	Off Peak Markup Component
Apr	$2.45	$3.01	$1.82
May	($0.44)	($1.07)	$0.19
Jun	$2.64	$4.06	$1.07
Jul	$4.10	$7.59	$0.19
Aug	$4.16	$5.53	$2.77
Sep	$1.71	$3.93	($0.66)
Total	$2.64	$4.16	$0.91

Table 3-141 Monthly markup components of day-ahead (Adjusted) load-weighted LMP: April 2025 through September 2025

	2025		
	Markup Component (All Hours)	Peak Markup Component	Off Peak Markup Component
Apr	$3.30	$4.04	$2.48
May	$0.81	$0.10	$1.52

Sep	$2.20	$4.03	$0.25
Total	$3.76	$5.14	$2.09

Markup Component of Day-Ahead Zonal Prices

Table 3-142 shows the markup component of annual average day-ahead price using unadjusted cost-based offers for each zone and for adjusted offers in Table 3-143.

The smallest zonal all hours average markup component using unadjusted cost-based offers for the six months between April and September of 2025 was in OVEC, $2.16 per MWh, while the highest was in PEPCO, $6.75 per MWh. The smallest zonal on peak average markup using unadjusted cost-based offers was in OVEC, $3.22 per MWh, while the highest was in PEPCO, $12.26 per MWh.

Market Structure, Participant Behavior, and Market Performance

The goal of regulation through competition is to achieve competitive market outcomes even in the presence of market power. Market structure in the PJM energy market is not competitive in local markets created by transmission constraints. At times, market structure is not competitive in the aggregate energy market. Market sellers pursuing their financial interests may choose behavior that benefits from structural market power in the absence of an effective market power mitigation program. The overall competitive assessment evaluates the extent to which participant behavior results in competitive or above competitive pricing. The competitive assessment brings together the structural measures of market power, HHI and pivotal suppliers, with participant behavior, specifically markup, and pricing outcomes.

HHI and Markup

In theory, the HHI provides insight into the relationship between market structure, behavior, and performance. In the case where participants compete by producing output at constant, but potentially different, marginal costs, the HHI is directly proportional to the expected average price cost markup in the market:[216]

$$\frac{HHI}{\varepsilon} = \frac{P - MC}{P}$$

where ε is the absolute value of the price elasticity of demand, P is the market price, and MC is the average marginal cost of production. This is called the Lerner Index. The left side of the equation quantifies market structure, and the right side of the equation measures market performance. The assumed participant behavior is profit maximization. As HHI decreases, implying a more competitive market, prices converge to marginal cost, the competitive market outcome. But even a low HHI may result in substantial markup with a low price elasticity of demand. If HHI is very high, meaning competition is lacking, prices can reach the monopoly level. Price elasticity of demand (ε) determines the degree to which suppliers with market power can impose higher prices on customers. The Lerner Index is a measure of market power that connects market structure (HHI and demand elasticity) to market performance (markup).

The PJM energy market HHIs and application of the FERC concentration categories understate the degree of market power because, in the absence of aggregate market power mitigation, even the unconcentrated HHI level implies substantial markups due to the low short run price elasticity of

216 *See* Tirole, Jean. *The Theory of Industrial Organization*, MIT (1988), Chapter 5: Short-Run Price Competition.

demand. For example, research estimates find short run electricity demand elasticity ranging from -0.2 to -0.4.[217] Using the Lerner Index, the elasticity of -0.2 implies, for example, an average markup ranging from 25 to 50 percent at the low end of the moderately concentrated threshold HHI of 1000:[218]

$$\frac{HHI}{\varepsilon} = \frac{0.1}{0.2} = \frac{P - MC}{P} = 0.5$$

With knowledge of HHI, elasticity, and marginal cost, one can solve for the price level theoretically indicated by the Lerner Index, based on profit maximizing behavior including the exercise of market power. With marginal costs of $50.61 per MWh and an average HHI of 686 in the first nine months of 2025, average PJM prices would theoretically range from $61 to $77 per MWh, an implied markup of 17.2 to 34.3 percent, using the elasticity range of -0.2 to -0.4. Given the elasticity estimates, the theoretical prices exceed marginal costs because the exercise of market power is profit maximizing. In the PJM market, market power mitigation limits the exercise of market power, so prices cannot reach the higher theoretical level. Actual prices, averaging $50.51 per MWh with markups at -0.2 percent, are lower than the theoretical range, supporting the MMU's competitive assessment of the market. However, markup is not zero. In some market intervals, markup and prices reach levels that reflect the exercise of market power.

Market Power Mitigation and Markup

Fully effective market power mitigation would not allow a seller that fails the structural market power test (the TPS test) to set prices with a positive markup. With the flaws in PJM's implementation of the TPS test, resources can and do set prices with a positive markup while failing the TPS test.

Table 3-146 categorizes day-ahead and real-time marginal unit intervals by markup level and TPS test status. In the first nine months of 2025, 3.0 percent of real-time marginal unit intervals and 3.3 percent of day-ahead marginal unit hours included a positive markup even though the resource failed the TPS test for local market power. Unmitigated local market power affects PJM market prices. Zero markup with a TPS test failure indicates the mitigation of a marginal unit.

Table 3-146 Percent of real-time marginal unit intervals with markup and local market power: January through September, 2025

	Day-ahead Market			Real-time Market		
Markup Category	Not Failing TPS Test	Failing TPS Test	Percent in Category	Not Failing TPS Test	Failing TPS Test	Percent in Category
Negative Markup	40.1%	3.1%	43.3%	52.7%	6.2%	58.9%
Zero Markup	21.6%	5.8%	27.4%	17.7%	7.3%	25.0%
$0 to $5	11.6%	1.1%	12.6%	7.4%	1.4%	8.9%
$5 to $10	4.3%	0.7%	5.0%	2.6%	0.4%	3.0%
$10 to $15	2.1%	0.6%	2.7%	1.2%	0.3%	1.5%
$15 to $20	1.1%	0.3%	1.3%	0.4%	0.3%	0.7%
$20 to $25	0.7%	0.1%	0.8%	0.2%	0.1%	0.3%
$25 to $50	3.3%	0.3%	3.6%	0.7%	0.4%	1.0%
$50 to $75	1.4%	0.1%	1.5%	0.2%	0.1%	0.3%
$75 to $100	1.1%	0.1%	1.2%	0.1%	0.0%	0.2%
Above $100	0.5%	0.0%	0.6%	0.1%	0.1%	0.2%
Total Positive Markup	26.1%	3.3%	29.3%	13.0%	3.0%	16.1%
Total	87.9%	12.1%	100.0%	83.5%	16.5%	100.0%

The markup of marginal units was zero or negative in 83.9 percent of real-time marginal unit intervals and 70.7 percent of day-ahead marginal unit intervals in the first nine months of 2025. Zero and negative markup are the expected results in a competitive market. Pivotal suppliers in the aggregate market also set prices with high markups in the first nine months of 2025. The 26.1 percent of day-ahead marginal units and 13.0 percent of real-time marginal units setting price with a markup without failing the TPS test could represent units with aggregate market power or units that maintain markup in their offer for times when they have local market power. Allowing positive markups to affect prices in the presence of market power permits the exercise of market power and has a negative impact on the competitiveness of the PJM energy market. This problem can and should be addressed.

Wolak (1997), "Estimating the Customer-Level Demand for Electricity Under Real-Time Market Prices," <https://web.stanford.edu/group/fwolak/cgi-bin/sites/default/files/files/Estimating%20the%20Customer-Level%20Demand%20for%20Electricity%20Under%20Real-Time%20Market%20Prices_Aug%201997_Patrick,%20Wolak.pdf>, last accessed August 3, 2018 and Fan, Shu and Rob Hyndman (2010), "The price elasticity of electricity demand in South Australia," <https://robjhyndman.com/papers/Elasticity2010.pdf>.

218 The HHI used in the equation is based on market shares. For the FERC HHI thresholds and standard HHI reporting, market shares are multiplied by 100 prior to squaring the market shares.

Energy Uplift (Operating Reserves)

In a well designed wholesale power market, energy uplift is paid as credits to market participants under specified conditions in order to ensure that competitive energy and ancillary service market outcomes do not require efficient resources operating at the direction of PJM, to operate at a loss.[1] Referred to in PJM as operating reserve credits, lost opportunity cost credits, dispatch differential lost opportunity credits, reactive services credits, synchronous condensing credits or black start services credits, these uplift payments are intended to be one of the incentives to generation owners to offer their energy to the PJM energy market for dispatch based on short run marginal costs and to operate their units as directed by PJM. These uplift credits are paid by PJM market participants as operating reserve charges, reactive services charges, synchronous condensing charges or black start services charges. Fast start pricing, implemented on September 1, 2021, required a new uplift credit to pay the lost opportunity costs of units that are backed down in real time to accommodate the less flexible fast start units for which fast start pricing assumes flexibility. The result of fast start pricing is to create a greater reliance on uplift rather than price signals as an incentive to follow PJM's instructions.

Uplift is an inherent part of the PJM market design. Part of uplift is the result of the nonconvexity of power production costs. Uplift payments cannot be eliminated, but uplift payments should be limited to the efficient level. In wholesale power market design, a choice must be made between efficient prices and prices that fully compensate costs. Economists recognize that no single price achieves both goals in markets with nonconvex production costs, like the costs of producing electric power.[2] [3] In wholesale power markets like PJM, efficient prices equal the short run marginal cost of production by location. The dispatch of generators based on these efficient price signals minimizes the total market cost of production. For generators with nonconvex costs, marginal cost prices may not cover the total cost of starting the generator and running at the efficient output level. Uplift payments cover the difference. The PJM market design concept incorporates efficient prices with minimal uplift payments.

But PJM's practice does not minimize uplift payments. In some cases, PJM pays uplift that is not consistent with the rules. In some cases, the rules permit the payment of uplift that is not consistent with the goal of PJM market design. Regulation revenues should be included as an offset to the daily uplift calculation for generators that receive regulation revenues, but are not currently included. The need for uplift should be calculated on a daily basis, as incorporated in the initial PJM market design, rather than on an hourly segment basis. The goal of uplift should be to ensure that units are not required to run at a loss on a daily basis. The goal should not be to lock in profits in some hourly segments and require uplift in other hourly segments. In the case where PJM makes multiday commitments, the uplift calculation should cover the entire multiday period rather than allowing a generator to be paid uplift on day one and earn significant profits on day three. There are identified improvements to PJM's application of the rules, and to the market design and uplift rules that could reduce uplift payments to the efficient level.

PJM's day-ahead generator credits and balancing generator credits are calculated by operating day and by hourly segments. Segments for day-ahead generator credits equal the hours in which the unit cleared in the day-ahead market. Segments for balancing generator credits are defined as the greater of the day-ahead schedule and the unit's minimum run time. Intervals in excess of the minimum run time or in excess of the hours cleared in the day-ahead market become new segments. The net revenues in those new segments are not counted as contributing to covering costs in the initial segment. The reverse is also true. Uplift is paid even when total net revenues cover or more than cover costs when the entire day is included.

In PJM, all energy payments to demand response resources are uplift payments. The energy payments to these resources are not part of the supply and demand balance, they are not paid by LMP revenues and therefore the

1 Losses occur when gross energy and ancillary services market revenues are less than short run marginal costs, including all elements of the energy offer, which are startup, no load and incremental offers, and the unit is following PJM instructions including both commitment and dispatch instructions. There is no corresponding assurance required when units are self scheduled or not following PJM dispatch instructions.

2 *See* Stoft, *Power System Economics: Designing Markets for Electricity*, New York: Wiley (2002) at 272; Mas-Colell, Whinston, and Green, *Microeconomic Theory*, New York: Oxford University Press (1995) at 570; and Quinzii, *Increasing Returns and Efficiency*, New York: Oxford University Press (1992).

3 The production of output is convex if the production function has constant or decreasing returns to scale, which result in constant or rising average costs with increases in output. Production is nonconvex with increasing returns to scale, which is the case when generating units have start or no load costs that are large relative to marginal costs. *See* Mas-Colell, Whinston, and Green at 132.

energy payments to demand response resources have to be paid as out of market uplift. The energy payments to economic DR are funded by real-time load and real-time exports. The energy payments to emergency DR are funded by participants with net energy purchases in the real-time energy market. The current payment structure for DR is an inefficient element of the PJM market design.[4]

Polar Vortex 2025 resulted in a significant increase in uplift payments as a result of the fact that PJM chose to prepare for the weather related risks of Polar Vortex 2025 in very different ways than for Winter Storm Elliott. Rather than rely on PAI incentives to provide assurance that generators would be ready for cold weather, PJM took direct steps to ensure a reliable outcome. The results of Polar Vortex 2025 vindicated PJM's strategy. PJM took conservative measures to ensure reliability by scheduling resources well in advance of the day-ahead energy market. PJM took additional advance actions to ensure transmission reliability. These commitments were not made to meet reserve requirements. Higher reserve requirements would not have addressed the Polar Vortex 2025 issues or cold weather reliability issues more generally.

The uplift associated with Polar Vortex 2025 was an expected outcome of conservative operations. This uplift is part of the way that PJM markets work and was the result of PJM's successful conservative operations approach to dealing with the cold weather risks of Polar Vortex 2025. PJM's commitment approach during Polar Vortex 2025 was significantly different than in 2024, for example. PJM committed only 1.4 percent of units on schedules less flexible than PLS during Polar Vortex 2025 compared to 17.2 percent during weather alert days in 2024. Nonetheless, improvements are needed to make the advance commitment process more predictable and transparent and to help ensure that these uplift charges are incurred only when needed for reliability.

4 Demand response payments are addressed in Section 6: Demand Response.

Overview

Energy Uplift Credits

- **Energy uplift credits.** Total energy uplift credits increased by $442.1 million, or 202.3 percent, in the first nine months of 2025 compared to the first nine months of 2024, from $218.5 million to $660.6 million.
- **Types of energy uplift credits.** In the first nine months of 2025, total energy uplift credits included $181.5 million in day-ahead generator credits, $447.7 million in balancing generator credits, $28.9 million in lost opportunity cost credits. Dispatch differential lost opportunity credits, which are a subset of balancing operating reserves, were implemented as part of fast start pricing on September 1, 2021, and were $2.0 million in the first nine months of 2025.
- **Types of units.** In the first nine months of 2025, steam coal units received 9.1 percent of day-ahead generator credits, and combustion turbines received 53.5 percent of balancing generator credits and 64.8 percent of lost opportunity cost credits. Combined cycle units and combustion turbines received 36.3 percent of dispatch differential lost opportunity credits, and hydro units received 47.5 percent of dispatch differential lost opportunity credits
- **Concentration of energy uplift credits.** In the first nine months of 2025, the top 10 units receiving energy uplift credits received 37.5 percent of all credits and the top 10 organizations received 70.3 percent of all credits.
- **Lost opportunity cost credits.** Lost opportunity cost credits increased by $3.2 million, or 12.3 percent, in the first nine months of 2025, compared to the first nine months of 2024, from $25.7 million to $28.9 million.

  Some combustion turbines and diesels are scheduled day-ahead but not requested in real time, and receive day-ahead lost opportunity cost credits as a result. This was the source of 65.2 percent of the $29.0 million of lost opportunity costs.
- **Following dispatch.** Some units are incorrectly paid uplift despite not meeting uplift eligibility requirements, including not following dispatch, not having the correct commitment status, or not operating with PLS

offer parameters. Since 2018, the MMU has made cumulative resettlement requests for the most extreme overpaid units of $17.9 million, of which PJM has resettled only $3.9 million, or 22.0 percent.

Energy Uplift Charges

- **Energy Uplift Charges.** In the first nine months of 2025, total energy uplift charges increased by $443.1 million, or 203.8 percent, compared to the first nine months of 2024, from $217.4 million to $660.6 million.
- **Types of Energy Uplift Charges.** In the first nine months of 2025, total uplift charges included $181.4 million in day-ahead operating reserve charges, $478.1 million in balancing generator charges, $0.6 million in reactive charges, and $0.4 million in black start services.

Recommendations

- The MMU recommends that uplift be paid only based on operating parameters that reflect the flexibility of the benchmark new entrant unit (CONE unit) in the PJM Capacity Market. (Priority: High. First reported 2018. Status: Not adopted.)
- The MMU recommends that PJM not pay uplift to units not following dispatch, including uplift related to fast start pricing, and require refunds where it has made such payments. This includes units whose offers are flagged for fixed generation in Markets Gateway because such units are not dispatchable. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that PJM pay uplift based on the offer at the lower of the actual unit output or the dispatch signal MW. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends eliminating intraday segments from the calculation of uplift payments and returning to calculating the need for uplift based on the entire 24 hour operating day. (Priority: High. First reported 2018. Status: Not adopted.)
- The MMU recommends the elimination of day-ahead uplift to ensure that units receive an energy uplift payment based on their real-time output and not their day-ahead scheduled output. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that units not be paid lost opportunity cost uplift credits when PJM directs a unit to reduce output based on a transmission constraint or other reliability issue. There is no lost opportunity because the unit is required to reduce for the reliability of the unit and the system. (Priority: High. First reported 2021. Status: Not adopted.)
- The MMU recommends reincorporating the use of net regulation revenues as an offset in the calculation of balancing generator credits. (Priority: Medium. First reported 2009. Status: Not adopted.)
- The MMU recommends that self scheduled units not be paid energy uplift credits for their startup cost when the units are scheduled by PJM to start before the self scheduled hours. (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends three modifications to the energy lost opportunity cost calculations:
  - The MMU recommends calculating LOC based on 24 hour daily periods for combustion turbines and diesels scheduled in the day-ahead energy market, but not committed in real time. (Priority: Medium. First reported 2014. Status: Not adopted.)
  - The MMU recommends that units scheduled in the day-ahead energy market and not committed in real time should be compensated for LOC based on their real-time desired and achievable output, not their scheduled day-ahead output. (Priority: Medium. First reported 2015. Status: Not adopted.)
  - The MMU recommends that only flexible fast start units (startup plus notification times of 10 minutes or less) and units with short minimum run times (one hour or less) be eligible by default for the LOC compensation to units scheduled in the day-ahead energy market and not committed in real time. Other units should be eligible for LOC compensation only if PJM explicitly cancels their day-ahead commitment. (Priority: Medium. First reported 2015. Status: Not adopted.)

- The MMU recommends that up to congestion (UTC) transactions be required to pay energy uplift charges for both the injection and the withdrawal sides of the UTC. (Priority: High. First reported 2011. Status: Partially adopted.)
- The MMU recommends allocating the energy uplift credits paid to units scheduled by PJM as must run in the day-ahead energy market for reasons other than voltage/reactive or black start services as a reliability charge to real-time load, real-time exports and real-time wheels. (Priority: Medium. First reported 2014. Status: Not adopted. Stakeholder process.)
- The MMU recommends that the total cost of providing reactive support be categorized and allocated as reactive services. Reactive services credits should be calculated consistent with the balancing generator credit calculation. (Priority: Medium. First reported 2012. Status: Not adopted. Stakeholder process.)
- The MMU recommends including real-time exports and real-time wheels in the allocation of the cost of providing reactive support to the 500 kV system or above, in addition to real-time load. (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends modifications to the calculation of lost opportunity costs credits paid to wind units. The lost opportunity costs credits paid to wind units should be based on the lesser of the desired output, the estimated output based on actual wind conditions and the capacity interconnection rights (CIRs). The MMU recommends that PJM require wind units to request CIRs based on the maximum output used in the ELCC calculation for wind units. (Priority: Low. First reported 2012. Status: Partially adopted.)
- The MMU recommends that PJM clearly identify and classify all reasons for incurring uplift in the day-ahead and the real-time energy markets and the associated uplift charges in order to make all market participants aware of the reasons for these costs and to help ensure a long term solution to the issue of how to allocate the costs of uplift. (Priority: Medium. First reported 2011. Status: Partially adopted.)
- The MMU recommends that PJM revise the current uplift confidentiality rules in order to allow the disclosure of complete information about the level of uplift by unit and the detailed reasons for the level of uplift credits by unit in the PJM region. (Priority: High. First reported 2013. Status: Partially adopted.)[5]

Conclusion

Competitive market outcomes result from energy offers equal to short run marginal costs that incorporate flexible operating parameters. When PJM permits a unit to include inflexible operating parameters in its offer and pays uplift based on those inflexible parameters, there is an incentive for the unit to remain inflexible. The rules regarding operating parameters should be implemented in a way that creates incentives for flexible operations rather than inflexible operations. The standard for paying uplift should be the maximum achievable flexibility, based on OEM standards for the benchmark new entrant unit (CONE unit) in the PJM Capacity Market demand (VRR) curve. Applying a weaker standard effectively subsidizes inflexible units by paying them based on inflexible parameters that result from lack of investment and that could be made more flexible. The result inflates uplift costs, suppresses energy prices, and is an incentive to inflexibility.

It is not appropriate to accept that inflexible units should be paid uplift based on inflexible offers. The question of why units make inflexible offers should be addressed directly. Are units inflexible because they are old and inefficient, because owners have not invested in increased flexibility or because they serve as a mechanism for the exercise of market power? The question of why the inflexible unit was built, whether it was built under cost of service regulation and whether it is efficient to retain the unit should be answered directly. The question of how to provide market incentives for investment in flexible units and for investment in increased flexibility of existing units should be addressed directly. The question of whether inflexible units should be paid uplift at all should be addressed directly. Marginal cost pricing without paying uplift to inflexible units would create incentives for market participants to

5 On September 7, 2018, PJM made a compliance filing for FERC Order No. 844 to publish unit specific uplift credits. The compliance filing was accepted by FERC on June 21, 2019. 166 FERC ¶ 61,210 (2019). PJM began posting unit specific uplift reports on May 1, 2019. 167 FERC ¶ 61,280 (2019).

provide flexible solutions including replacing inefficient units with flexible, efficient units.

Implementing combined cycle modeling, to permit the energy market model optimization to take advantage of the versatility and flexibility of combined cycle technology in commitment and dispatch, would provide significant flexibility without requiring a distortion of the market rules. Such modeling should not be used as an excuse to eliminate market power mitigation or an excuse to permit inflexible offers to be paid uplift. There are defined steps that could and should be taken immediately to improve the modeling of combined cycle plants that do not require investment in combined cycle modeling software, including modeling soak time, and accurately accounting for transition times to power augmentation offer segments.

The reduction of uplift payments should not be a goal to be achieved at the expense of the fundamental logic of the LMP system. For example, the use of closed loop interfaces to reduce uplift should be eliminated because it is not consistent with LMP fundamentals and constitutes a form of subjective price setting. The same is true of fast start pricing. The same is true of PJM's proposals to modify the ORDC in order to increase energy prices and reduce uplift.

Accurate short run price signals, equal to the short run marginal cost of generating power, provide market incentives for cost minimizing production to all economically dispatched resources and provide market incentives to load based on the marginal cost of additional consumption. The objective of efficient short run price signals is to minimize system production costs, not to minimize uplift. Repricing the market to reflect commitment costs creates a tradeoff between minimizing production costs and reduction of uplift. The tradeoff exists because when commitment costs are included in prices, the price signal no longer equals the short run marginal cost and therefore no longer provides the correct signal for efficient behavior for market participants making decisions on the margin, whether resources, load, interchange transactions, or virtual traders. This tradeoff now exists based on PJM's recently implemented fast start pricing approach.[6] Fast start pricing affects uplift calculations by introducing a new category of uplift in the balancing market, and changing the calculation of uplift in the day-ahead market.

When units routinely receive substantial revenues through energy uplift payments, these payments are not fully transparent to the market, in part because of the current confidentiality rules. As a result, other market participants, including generation and transmission developers, do not have the opportunity to compete to displace them. As a result, substantial energy uplift payments to a concentrated group of units and organizations have persisted. FERC Order No. 844 authorized the publication of unit specific uplift payments for credits incurred after July 1, 2019.[7] However, Order No. 844 failed to require the publication of unit specific uplift credits for the largest units receiving significant uplift payments, inflexible steam units committed for reliability by PJM in the day-ahead market.

Uplift payments could be significantly reduced by reversing many of the changes that have been made to the original basic uplift rules. The goal of uplift is to ensure that competitive energy and ancillary service market outcomes do not require efficient resources operating for the PJM system, at the direction of PJM, to operate at a loss. In the original PJM design, uplift was calculated on a daily basis, including all costs and net revenues. But that rule was changed to use only segments of the day. The result is to overstate uplift payments because units may be paid uplift for a day in which their net revenues exceed their costs. In the original PJM design, all net revenues from energy and ancillary services were an offset to uplift payments. That rule was changed to eliminate net revenue from the regulation market. The result is to overstate uplift payments, for no logical reason.

Uplift payments could also be significantly reduced to a more efficient level by eliminating all day-ahead operating reserve credits. It is illogical and unnecessary to pay units day-ahead operating reserve credits because units

6 Fast start pricing was approved by FERC and implemented on September 1, 2021. See 173 FERC ¶ 61,244 (2020).

7 On June 21, 2019, FERC accepted PJM's Order No. 844 compliance filing. 166 FERC ¶ 61,210 (2019). The filing stated that PJM would begin posting unit specific uplift reports on May 1, 2019. On April 8, 2019, PJM filed for an extension on the implementation date of the zonal uplift reports and unit specific uplift reports to July 1, 2019. On June 28, 2019, FERC accepted PJM's request for extension of effective dates. 167 FERC ¶ 61,280 (2019).

do not incur any costs to run and any revenue shortfalls are addressed by balancing generator credits.

PJM needs to pay substantially more attention to the details of uplift payments including accurately tracking whether units are following dispatch, identifying the actual need for units to be dispatched out of merit and determining whether better definitions of constraints would be a more market based approach. PJM pays uplift to units even when they do not operate as requested by PJM, i.e. when units do not follow dispatch. PJM uses dispatcher logs as a primary screen to determine if units are eligible for uplift regardless of how they actually operate or if they followed the PJM dispatch signal. The reliance on dispatcher logs for this purpose is impractical, inefficient, and incorrect. PJM needs to define and implement systematic and verifiable rules for determining when units are following dispatch as a primary screen for eligibility for uplift payments. PJM should not pay uplift to units that do not follow dispatch. PJM continues to pay uplift to units that do not follow dispatch. PJM and the MMU are actively working together to revise the definition of following dispatch to address these issues.

The MMU notifies PJM and generators of instances in which, based on the PJM dispatch signal and the real-time output of the unit, it is clear that the unit did not operate as requested by PJM. The MMU sends requests for resettlements to PJM to make the units with the most extreme overpayments ineligible for uplift credits. Since 2018, the MMU has requested that PJM require the return of $17.9 million of incorrect uplift credits of which PJM has agreed and resettled only $3.9 million over the last two years, or 22.0 percent. In addition, PJM has refused to accept the return of incorrectly paid uplift credits by generators when the MMU has identified such cases and generators offer to repay the credits.

While energy uplift charges are an appropriate part of the cost of energy, market efficiency would be improved by ensuring that the level and variability of these charges are as low as possible consistent with the reliable operation of the system and consistent with pricing at short run marginal cost. The goal should be to minimize the total incurred energy uplift charges and to increase the transactions over which those charges are spread in order to reduce the impact of energy uplift charges on markets. The result would be to reduce the level of per MWh charges, to reduce the uncertainty associated with uplift charges and to reduce the impact of energy uplift charges on decisions about how and when to participate in PJM markets. The result would also be to increase incentives for flexible operation and to decrease incentives for the continued operation of inflexible and uneconomic resources. PJM does not need a new flexibility product. PJM needs to provide incentives to existing and new entrant resources to unlock the significant flexibility potential that already exists, to end incentives for inflexibility and to stop creating new incentives for inflexibility.

Polar Vortex 2025 resulted in 51.3 percent of uplift credits in the first nine months of 2025. This level of uplift was consistent with the efficient operation of a reliable market. In anticipation of the cold weather and to avoid a repetition of the poor performance during Winter Storm Elliott, PJM made out of market commitments to mitigate generation performance risks associated with cold temperatures and natural gas commodity illiquidity over the weekend and intraday. PJM took conservative measures to ensure reliability by scheduling resources well in advance of the day-ahead energy market. As there is no multiday market, out of market actions taken before the market starts generally result in uplift. While the results of the Polar Vortex 2025 vindicated PJM's strategy, the rules governing PJM's actions should be more transparent and clearly documented. The results of Polar Vortex 2025 are preferred to Winter Storm Elliott and increased uplift is the expected result. Nonetheless, the uplift rules need significant improvement. In addition, the process of conservative operations and advanced commitments needs to be improved, formalized, and made as market based as possible in order to minimize uplift.

Energy Uplift Credits

The level of energy uplift credits paid to specific units depends on the level of the resource's energy offer, the LMP, the resource's operating parameters and the decisions of PJM operators. Energy uplift credits result in part from decisions by PJM operators, who follow reliability requirements and market rules, to start resources or to keep resources operating even when LMP is less than the offer price including incremental, no load and startup costs. Energy uplift payments also result from units' operational parameters that require PJM to schedule or commit resources when they are not economic. Energy uplift payments currently also result, incorrectly, from decisions by units to maintain an output level not consistent with PJM dispatch instructions. The resulting costs not covered by energy revenues are collected as energy uplift credits.

The day-ahead operating reserves category includes multiple credit types that are paid to resources cleared uneconomically in the day-ahead market. These resources include generators, imports, and load response.

The balancing operating reserves category includes multiple credit types based on the service provided by the resources. These credit types, paid to compensate for uneconomic generation in the balancing market, include generator credits, lost opportunity cost credits, dispatch differential lost opportunity cost credits, local constraint control credits, load response credits, import credits, and canceled resource credits. The largest credit type in the balancing operating reserves category is balancing generator credits. The reactive services category includes multiple credit types. Black start services credits exist to compensate resources for black start services in the day-ahead and balancing markets, as well as testing. Starting with this report, black start credits and local constraint credits are not broken out individually and are included in the category of balancing generator credits, matching PJM's Market Settlements Reporting System.

Table 4-1 shows the uplift totals for each credit category during the first nine months of 2024 and 2025.[8] In the first nine months of 2025, energy uplift credits increased by $442.1 million or 202.3 percent compared to the first nine months of 2024. PJM commitment and dispatch decisions associated with the 2025 Polar Vortex caused significant increases in day-ahead generator credits, balancing generator credits, and lost opportunity cost credits.

The dispatch differential lost opportunity cost is a credit that exists only as a result of fast start pricing. This credit is paid to flexible resources that are artificially dispatched down, to an output level below the level that is economic at fast start prices, in order to accommodate inflexible fast start resources. Fast start pricing was introduced on September 1, 2021.

Table 4-1 Energy uplift credits by category: January through September, 2024 and 2025[9]

Category	Type	(Jan - Sep) 2024 Credits (Millions)	(Jan - Sep) 2025 Credits (Millions)	Change	Percent Change	2024 Share	2025 Share
Day-Ahead	Generators	$93.8	$181.5	$87.7	93.5%	42.9%	27.5%

8 Billing data can be modified by PJM Settlements at any time to reflect changes in the evaluation of energy uplift. The billing data reflected in this report were current on October 10, 2025.
9 Year to year change is rounded to $0.01 million.

Categories of Credits and Charges

Energy uplift charges include day-ahead and balancing operating reserves, reactive services, synchronous condensing and black start services categories. Uplift credits paid to individual participants are paid for by charges to the groups of PJM market participants. The groups of participants charged varies depending on the type of uplift credit. For this reason, operating reserve charges do not always have the same value as operating reserve credits, since not all categories of uplift credits are paid for by the same PJM participants. For example, in the case of local constraint credits, credits are paid to generators in the form of balancing operating reserve credits but charges are allocated as local constraint charges. The same applies in the case of units scheduled day ahead for reactive support, for which the credits are paid in the form of day-ahead operating reserve credits but charges are allocated as reactive services charges. Table 4-2 and Table 4-3 show the categories of credits and charges and their relationships.

For example, in Table 4-2, day-ahead operating reserve credits for generators are paid for by day-ahead operating reserve charges. Those charges are paid for by market participants in proportion to their day-ahead load, day-ahead exports, and virtual transactions (DECs and UTCs). The charges are aggregated over the entire RTO region. Balancing generator reserve credits are paid for by two different types of charges: balancing operating reserve charges for reliability and balancing operating reserve charges for deviations. Charges for reliability are paid for by PJM members in proportion to their real-time load and real-time export transactions. Reliability charges are aggregated regionally over the entire RTO region, within the Western region, or within the Eastern region. Balancing operating reserve charges for deviations are paid for by PJM members in proportion to their deviations, which includes virtuals (INCs and DECs), UTCs, load, and interchange. The deviation charges are aggregated regionally over the entire RTO region, within the Western region, and within the Eastern region. Lost opportunity cost credits are paid for by balancing operating reserve charges for deviations. The charges for deviations are paid for by PJM members in proportion to their deviations, which includes virtuals (INCs and DECs), UTCs, load, and interchange. The deviation charges are aggregated regionally over the entire RTO region.

Starting with the *2024 Annual State of the Market Report for PJM*, black start credits and local constraint credits are not broken out individually and are included in the category of balancing generator credits. Similarly, cancellation charges, lost opportunity charges, and dispatch differential lost opportunity cost charges are not broken out individually and are included in the category of balancing generator charges.

Table 4-3 shows the relationship between credits and charges for resources providing reactive, synchronous condensing, and black start services. For example, the five sub-categories of reactive services credits (day-ahead operating reserves, generator, LOC, condensing, and synchronous condensing LOC) are paid by two different charge categories: reactive service charges and local constraint reactive services. The reactive service charges are paid by PJM members in proportion to their zonal real-time load, while the local constraint reactive service charges are paid for by transmission owners.

Table 4-2 Day-ahead and balancing operating reserve credits and charges

	Credit Category	Charges Category	Charge Responsibility	Geographic Charge Aggregation
DAY-AHEAD	Day-Ahead Operating Reserve Transaction	Day-Ahead Operating Reserves for Transactions	Day-Ahead Load, Day-Ahead Exports, DECs & UTCs	RTO Region
	Day-Ahead Operating Reserve Generator	Day-Ahead Operating Reserve for Generators		
	Day-Ahead Operating Reserves for Load Response	Day-Ahead Operating Reserve for Load Response

Types of Units

Table 4-4 shows the distribution of total energy uplift credits by unit type in the first nine months of 2025 and the first nine months of 2024. A combination of factors led to overall increased uplift payments, including unit specific issues and market issues of high fuel costs and PJM conservative operations during Polar Vortex 2025.

The longstanding rule which inexplicably exempted CTs from the otherwise generally applicable rules governing the payment of uplift credits was terminated effective November 1, 2022. Prior to November 1, CTs were paid uplift regardless of their output and regardless of whether they followed dispatch and as a result, CTs had no incentive to follow PJM dispatch signals.

Uplift credits paid to combustion turbines increased by $163.9 million or 168.7 percent during the first nine months of 2025 compared to the first nine months of 2024. In the first nine months of 2025, CTs received 64.8 percent of lost opportunity cost credits. Lost opportunity cost credits increased by $28.9 million or 12.3 percent compared to the first nine months of 2024.

Uplift credits paid to steam coal units increased by $3.8 million or 8.6 percent in the first nine months of 2025 compared to the first nine months of 2024. In the first nine months of 2025, day-ahead uplift credits in the PEPCO Zone made up 82.3 percent of total day-ahead uplift credits, and accounted for 135.3 percent of the increase in day-ahead uplift during the first nine months of 2025, primarily as a result of unit specific issues for the Chalk Point 3 and 4 units. In the first nine months of 2025, steam coal units in the BGE Zone received 91.5 percent of day-ahead uplift credits paid to steam coal units, primarily as a result of unit specific issues for the Brandon Shores 1 and 2 units.

Uplift credits paid to non-coal (gas or oil fired) steam units increased by $121.0 million or 190.6 percent in the first nine months of 2025 compared to the first nine months of 2024. In the first nine months of 2025, gas or oil fired steam units received $184.6 million, 27.9 percent of total credits, compared to $63.5 million, 29.1 percent of total credits, during the first nine months of 2024. In the first nine months of 2025, the day-ahead uplift paid to gas or oil fired steam units was 201.1 percent higher than during the first nine months of 2024, and accounted for 122.1 percent of the total increase in day-ahead operating reserves. The increase in day-ahead generator credits paid to gas or oil fired steam units in the PEPCO Zone accounted for 122.1 percent of the overall increase in day-ahead generator credits in the first nine months of 2025. In the PEPCO Zone, gas fired steam units Chalk Point 3 and 4 received $152.2 million in uplift in the first nine months of 2025.[10] During the 2025 Polar Vortex, non-coal steam units received $132.4 million, or 71.8 percent of all credits received by non-coal steam units during the first nine months of 2025. Non-coal steam units received 39.0 percent of total uplift credits during the 2025 Polar Vortex.

Uplift credits paid to combined cycle units increased by $146.9 million or 1,471.2 percent in the first nine months of 2025 compared to the first nine months of 2024. This increase occurred primarily in January 2025 as a result of the commitments made in advance of the day-ahead energy market during the 2025 Polar Vortex. The 2025 Polar Vortex accounted for 89.3 percent of the uplift credits paid to combined cycle units, and accounted for 51.3 percent of total uplift credits during the first nine months of 2025.

In the first nine months of 2025, uplift credits to wind units were $6.0 million, up by 346.1 percent compared to the first nine months of 2024.

Table 4-4 Total energy uplift credits by unit type: January through September, 2024 and 2025[11 12]

Unit Type	(Jan - Sep) 2024 Credits (Millions)	(Jan - Sep) 2025 Credits (Millions)	Change	Percent Change	(Jan - Sep) 2024 Share	(Jan - Sep) 2025 Share
Combined Cycle	$10.0	$156.9	$146.9	1,471.2%	4.6%	23.7%
Combustion Turbine	$97.2	$261.1	$163.9	168.7%	44.5%	39.5%
Diesel	$1.4	$2.7	$1.2	87.0%	0.7%	0.4%
Hydro	$0.9	$0.9	$0.0	1.2%	0.4%	0.1%
Nuclear	$0.0	$0.0	($0.0)	(100.0%)	0.0%	0.0%
Solar	$0.2	$0.8	$0.6	226.9%	0.1%	0.1%
Steam - Coal	$43.9	$47.6	$3.8	8.6%	20.1%	7.2%
Steam - Other	$63.5	$184.6	$121.0	190.6%	29.1%	27.9%
Wind	$1.4	$6.0	$4.7	346.1%	0.6%	0.9%
Total	$218.5	$660.6	$442.1	202.3%	100.0%	100.0%

10 See Table 4-14.
11 Table 4-4 does not include balancing imports credits and load response credits in the total amounts.
12 Solar units should be ineligible for all uplift payments because they do not follow PJM's dispatch instructions. The MMU notified PJM of the discrepancy.

Table 4-5 shows the distribution of energy uplift credits by category and by unit type in the first nine months of 2025. The largest share of day-ahead credits, 97.5 percent, went to steam units. Steam units tend to be longer lead time units that are committed before the operating day. If a steam unit is needed for reliability and it is uneconomic, it will be committed in the day-ahead energy market and receive day-ahead uplift credits. The PJM market rules permit combustion turbines (CT), unlike other unit types, to be committed and decommitted in the real-time market. As a result of the rules and the characteristics of CT offers, CTs received 53.5 percent of balancing credits and 64.8 percent of lost opportunity cost credits. Combustion turbines committed in the real-time market may be paid balancing credits due to inflexible operating parameters, volatile real-time LMPs, and intraday segment settlements. Combustion turbines committed in the day-ahead market but not committed in real time receive lost opportunity credits to cover the profits they would have made had they operated in real time.

Table 4-5 Energy uplift credits by unit type: January through September, 2025

Unit Type	Day-Ahead Generator	Balancing Generator	Canceled Resources	Lost Opportunity Cost	Reactive Services	Synchronous Condensing	Dispatch Differential Lost Opportunity Cost
Combined Cycle	1.3%	34.0%	0.0%	7.5%	1.0%	0.0%	18.2%
Combustion Turbine	1.2%	53.5%	0.0%	64.8%	22.9%	0.0%	18.1%
Diesel	0.0%	0.4%	0.0%	1.6%	74.3%	0.0%	0.3%
Hydro	0.0%	0.0%	0.0%	0.0%	0.0%	0.0%	47.5%
Nuclear	0.0%	0.0%	0.0%	0.0%	0.0%	0.0%	0.0%
Solar	0.0%	0.0%	0.0%	2.8%	0.0%	0.0%	0.6%
Steam - Coal	9.1%	6.8%	0.0%	2.2%	1.9%	0.0%	9.8%

Total (Millions)	$181.5	$447.7	$0.0	$28.9	$0.5	$0.0	$2.0

Day-Ahead Unit Commitment for Reliability

PJM can schedule units as must run in the day-ahead energy market that would otherwise not have been committed in the day-ahead market, when needed in real time to address reliability issues. Such reliability issues include thermal constraints, reactive transfer interface constraints, and reactive service.[13] Units committed for reliability by PJM are eligible for day-ahead operating reserve credits and may set LMP if raised above economic minimum and follow the dispatch signal. Participants can submit units as self scheduled (must run), meaning that the unit must be committed, but a unit submitted as self scheduled by a participant is not eligible for day-ahead operating reserve credits.[14]

Pool scheduled units are units that are committed in the day-ahead market based on economics. Units committed for reliability by PJM are units that are committed to satisfy reliability needs, regardless of whether the offers are economic. Self scheduled units are self committed by the generation owner and are not eligible for uplift. Pool scheduled units and units committed for reliability are made whole in the day-ahead energy market if their total cost-based offer (including no load and startup costs) is greater than the revenues from the day-ahead energy market. Such units are paid day-ahead uplift.

It is illogical and unnecessary to pay units day-ahead operating reserves because units do not incur any costs to run in the day-ahead market and any revenue shortfalls are addressed by balancing operating reserve payments.

Balancing Uplift (Operating Reserve) Credits/ Balancing Generator Credits

Balancing operating reserve (BOR) credits are paid to resources that operate as requested by PJM that do not recover all of their operating costs from market revenues. Balancing operating reserves include multiple credit types that are paid to units in the balancing market, such as generator credits, lost opportunity cost credits, dispatch differential lost opportunity cost credits, local constraints control credits, load response credits, import credits, and canceled resource credits. Balancing generator credits are the largest category of balancing operating reserves. Balancing generator credits are calculated by hourly segments as the difference between a resource's revenues (day-ahead market, balancing market, reserve markets, reactive service credits, and day-ahead operating reserve credits but excluding regulation revenues) and its real-time

13 See OA Schedule 1 § 3.2.3(b).

14 See OA Schedule 1 § 3.2.3(a).

offer (startup, no load, and incremental energy offer). Segments for balancing generator credits are defined as the greater of the day-ahead schedule and the unit's minimum run time. Intervals in excess of the minimum run time are treated as new segments. Table 4-5 shows that combustion turbines (CTs) received 53.5 percent of balancing generator credits in the first nine months of 2025, or $239.7 million. Combined cycles (CCs) received 34.0 percent of balancing generator credits in the first nine months of 2025, or $152.0 million. During the 2025 Polar Vortex, the balancing generator credits to CCs exceeded CTs due to conservative operations commitments.

Uplift is higher than necessary because settlement rules do not include all revenues and costs for the entire day. Uplift is also higher than necessary because settlement rules do not disqualify units from receiving uplift when they do not follow PJM's dispatch instructions. PJM apparently considers units that start when requested and turn off when requested to be operating as requested by PJM regardless of how well the units follow the dispatch signal.[15] Units should be disqualified from receiving uplift when the units do not follow dispatch instructions, block load or self schedule.

PJM's position on the payment of uplift is illogical and PJM's definition of units not operating as requested is illogical. The logical definition of operating as requested includes both start and shutdown when requested and that units follow their dispatch signal. Both should be required in order to receive uplift. Paying uplift to units not following dispatch does not provide an incentive for flexibility. The MMU recommends that PJM develop and implement an accurate metric to define when a unit is following dispatch, instead of relying on PJM dispatchers' manual determinations, to evaluate eligibility for receiving balancing generator credits and for assessing generator deviations. As part of the metric, the MMU recommends that PJM designate units whose offers are flagged for fixed generation in Markets Gateway as not eligible for uplift. Units that are flagged for fixed generation are not dispatchable. Following dispatch is an eligibility requirement for uplift compensation.

15 *See* "Operating Reserve Make Whole Credit Education," slide 13, PJM presentation to the Market Implementation Committee. (April 13, 2022) <https://pjm.com/-/media/committees-groups/committees/mic/2022/20220413/item-11a---operating-reserve-make-whole-credits-education.ashx>.

Table 4-1 shows that balancing generator credits increased by 364.3 percent in the first nine months of 2025 compared to the first nine months of 2024.

CTs that operate on a day-ahead schedule tend to receive lower balancing generator credits because it is more likely that the day-ahead LMPs will support (prices above offer) committing the units. The day-ahead model optimizes the system for all 24 hours, unlike in real time when PJM uses ITSCED to optimize CT commitments with an approximately two hour look ahead. In addition, uplift rules continue to define all day-ahead scheduled hours as one segment for the uplift calculation (in which profits and losses during all hours offset each other). The shorter segments in real-time are defined by the minimum run time and allow for fewer offsets, resulting in greater amounts of uplift. Losses during the minimum run time segment are not offset by profits made in other segments on that day.

There are multiple reasons why the commitment of CTs is different in the day-ahead and real-time markets, including differences in the hourly pattern of load, and differences in interchange transactions. Modeling differences between the day-ahead and real-time markets also affect CT commitment, including: the modeling of different transmission constraints in the day-ahead and real-time market models; the exclusion of soak time for generators in the day-ahead market model; and the different optimization time periods used in the day-ahead and real-time markets.

Lost Opportunity Cost Credits

Balancing operating reserve lost opportunity cost (LOC) credits are intended to provide an incentive for units to follow PJM's dispatch instructions when PJM's dispatch instructions deviate from a unit's desired or scheduled output. LOC credits are paid under two scenarios.[16] The first scenario occurs if a unit of any type generating in real time with an offer price lower than the real-time LMP at the unit's bus is manually reduced or suspended by PJM due to a transmission constraint or other reliability issue. In this scenario the unit will receive a credit for LOC based on its desired output. Such units are not actually forgoing an option to increase output because the reliability of the system and in some cases the generator depend on reducing output. This LOC is referred to

16 Desired output is defined as the MW on the generator's offer curve consistent with the LMP at the generator's bus.

as real-time LOC. The second scenario occurs if a combustion turbine or diesel engine clears the day-ahead energy market, but is not committed in real time. In this scenario the unit will receive a credit which covers any lost profit in the day-ahead financial position of the unit plus the balancing energy market position. This LOC is referred to as day-ahead LOC.

Table 4-6 shows monthly day-ahead and real-time LOC credits in 2024 and the first nine months of 2025. In the first nine months of 2025, LOC credits increased by $3.2 million or 12.3 percent compared to the first nine months of 2024. The overall change was an increase, which included a $3.6 million decrease in day-ahead LOC which was offset by a $6.7 million increase in real-time LOC.

In the first nine months of 2025, wind units received $6.0 million of uplift, up by $4.7 million compared to the first nine months of 2024. Wind units that are capacity resources are now required to procure Capacity Interconnection Rights (CIRs) equal to the maximum facility output included in the calculation of their ELCC value. Wind units that are capacity resources are paid uplift when PJM requests that the units reduce output below the maximum facility output but above the CIR level. Units do not have a right to inject power at levels greater than the CIR level that they pay for and therefore should not be paid uplift when system conditions do not permit output at a level greater than the CIR. The real-time lost opportunity costs credits paid to wind units should use the lowest of the desired output, the estimated output based on actual wind conditions, or the capacity interconnection rights (CIRs) as the definition of the foregone opportunity.

Table 4-6 Monthly lost opportunity cost credits (Millions): 2024 and January through September, 2025[17 18]

	2024			2025		
	Day-Ahead Lost Opportunity Cost	Real-Time Lost Opportunity Cost	Total	Day-Ahead Lost Opportunity Cost	Real-Time Lost Opportunity Cost	Total

Energy Uplift Charges

Energy Uplift Charges

Table 4-7 shows that energy uplift charges for the first nine months of 2025 were $660.6 million, or 1.8 percent of total PJM billing.

Table 4-7 Total energy uplift charges: 2001 through September 2025

	Total Energy Uplift Charges (Millions)	Change (Millions)	Percent Change	Energy Uplift as a Percent of Total PJM Billing
2001	$284.0	$67.0	30.9%	8.5%
2002	$273.7	($10.3)	(3.6%)	5.8%
2003	$376.5	$102.8	37.6%	5.4%
2004	$537.6	$161.1	42.8%	6.1%
2005	$712.6	$175.0	32.6%	3.1%
2006	$365.6	($347.0)	(48.7%)	1.7%
2007	$503.3	$137.7	37.7%	1.6%
2008	$474.3	($29.0)	(5.8%)	1.4%
2009	$322.7	($151.6)	(32.0%)	1.2%
2010	$623.2	$300.5	93.1%	1.8%
2011	$603.4	($19.8)	(3.2%)	1.7%
2012	$649.8	$46.4	7.7%	2.2%
2013	$843.0	$193.2	29.7%	2.5%
2014	$961.2	$118.2	14.0%	1.9%
2015	$312.0	($649.2)	(67.5%)	0.7%
2016	$136.7	($175.3)	(56.2%)	0.4%
2017	$127.3	($9.4)	(6.9%)	0.3%
2018	$198.2	$70.9	55.7%	0.4%
2019	$88.5	($109.7)	(55.3%)	0.2%
2020	$90.9	$2.4	2.7%	0.3%
2021	$178.4	$87.5	96.3%	0.3%
2022	$284.5	$106.1	59.5%	0.3%
2023	$158.7	($125.8)	(44.2%)	0.3%
2024	$270.0	$111.3	70.1%	0.5%
2025 (Jan - Sep)	$660.6	$390.6	144.7%	1.8%

Table 4-8 shows total energy uplift charges by category for the first nine months of 2024 and 2025. The increase of $440.9 million is comprised of an $87.6 million increase in day-ahead uplift (operating reserve) charges, a $355.8 million increase in balancing generator charges, a $0.4 million decrease in reactive service charges, a $1.0 million decrease in synchronous condensing charges, and a $1.2 million decrease in local congestion charges. Starting with the *2024 Annual State of the Market Report for PJM*, cancellation charges, lost opportunity charges, and dispatch differential lost opportunity cost charges are not broken out individually and are included in the category of balancing generator charges, matching PJM's Market Settlements Reporting System.

Table 4-8 Total energy uplift charges by category: January through September, 2024 and 2025[19]

Category	(Jan - Sep) 2024 Charges (Millions)	(Jan - Sep) 2025 Charges (Millions)	Change (Millions)	Percent Change
Day-Ahead Operating Reserves	$93.8	$181.4	$87.6	93.5%
Balancing Operating Reserves	$122.3	$478.1	$355.8	291.0%
Reactive Services	$1.0	$0.6	($0.4)	(41.4%)
Synchronous Condensing	$1.0	$0.0	($1.0)	(100.0%)
Black Start Services	$0.3	$0.4	$0.1	30.4%
Local Congestion Charges	$1.3	$0.1	($1.2)	(90.0%)
Total	$219.7	$660.6	$440.9	200.7%
Energy Uplift as a Percent of Total PJM Billing	0.6%	1.1%	0.8%	147.0%

19 The total PJM billing used in Table 4-8 is different from the total cost shown in Table 1-9. The total PJM billing in Table 4-8 represents the total dollars that pass through the PJM settlement process, while the total cost shown in Table 1-9 is the total cost to load and includes additional costs to load accounted for outside the PJM settlement process.

Table 4-9 compares monthly energy uplift charges by category for January 2024 through September 2025.

Table 4-9 Monthly energy uplift charges: January 2024 through September 2025

	2024 Charges (Millions)						2025 Charges (Millions)

Table 4-10 shows the composition of the balancing operating reserve charges. Balancing operating reserve charges consist of balancing operating reserve reliability charges (credits to generators), balancing operating reserve deviation charges (credits to generators and import transactions), balancing operating reserve charges for economic load response and balancing local constraint charges. Balancing operating reserve charges increased by $355.9 million or 291.3 percent in the first nine months of 2025 compared to the first nine months of 2024.

Table 4-10 Balancing operating reserve charges: January through September, 2024 and 2025[20]

Category	(Jan - Sep) 2024 Charges (Millions)	(Jan - Sep) 2025 Charges (Millions)	Change	Percent Change	2024 Share	2025 Share
Balancing Operating Reserve Reliability Charges	$49.4	$327.3	$277.9	563.1%	40.4%	68.5%
Balancing Operating Reserve Deviation Charges	$72.9	$150.8	$77.9	106.8%	59.6%	31.5%
Balancing Operating Reserve Charges for Load Response			$0.0	NA	0.0%	0.0%
Balancing Local constraint Charges	$1.3	$0.1	($1.2)	(90.0%)	1.1%	0.0%
Total	$122.3	$478.1	$355.8	291.0%	100.0%	100.0%

20 Table 4-9 balancing operating reserve total does not match Table 4-10 because Table 4-10 does not include DDLOC charges of $1.6 million.

Uplift Eligibility

In PJM, units have either a pool scheduled or self scheduled commitment status. Pool scheduled units are committed by PJM while self scheduled units are committed by generation owners. Table 4-11 provides a description of commitment and dispatch status, uplift eligibility and the ability to set price.[21] In the day-ahead energy market only pool scheduled resources are eligible for day-ahead operating reserve credits. A unit may be self scheduled in the day-ahead market and then be pool scheduled and dispatched in subsequent days to remain online, in which case they would be eligible for uplift for the subsequent days. In the real-time energy market only pool scheduled resources that follow PJM's dispatch are defined in the tariff as eligible for balancing operating reserve credits. However, in practice, units receive uplift credits when not following PJM's dispatch signal. Units are paid day-ahead operating reserve credits based on their scheduled operation for the entire day. Balancing operating reserve credits are paid on a segmented basis for each period defined by the greater of the day-ahead schedule and minimum run time. Resources receive day-ahead and balancing operating reserve credits only when they are eligible and unable to recover their operating cost for the day or segment.[22]

Energy Uplift Issues

Uplift Resettlement

Some units have been incorrectly paid uplift despite not meeting uplift eligibility requirements, including not following dispatch, not having the correct commitment status, or not operating with PLS offer parameters. The MMU has requested that PJM correctly resettle the uplift payments in these cases.[24] Since 2018, the cumulative resettlement requests total $17.9 million, of which PJM has agreed and resettled only $3.9 million over the last two years, 22.0 percent, and 1.3 percent are waiting for a PJM response. The remaining 75.8 percent occurred prior to October 2023 and is subject to the OATT's limitation on claims. That limit does not apply and would not have applied if PJM informed the market participant within two years of the occurrence of the issue.[25] PJM should inform market participants of a potential issue when the MMU raises the issue with PJM and the market participant in order to ensure that the issues can be addressed. PJM has refused to accept the voluntary return of incorrectly paid uplift credits by generators when the MMU has identified such cases. The MMU continues to bring new cases to the attention of PJM.

Table 4-11 Dispatch status, commitment status and uplift eligibility[23]

		Commitment Status	
Dispatch Status	Dispatch Description	Self Scheduled (units committed by the generation owner)	Pool Scheduled and following PJM's dispatch signal (units committed by PJM)
Block Loaded	MWh offered to PJM as a single MWh block which is not dispatchable	Not eligible to receive uplift Not eligible to set LMP	Eligible to receive uplift Not eligible to set LMP unless fast start eligible
Economic Minimum	MWh from the nondispatchable economic minimum component for units that offer a dispatchable range to PJM	Not eligible to receive uplift Not eligible to set LMP	Eligible to receive uplift Not eligible to set LMP unless fast start eligible
Dispatchable	MWh above the economic minimum level for units that offer a dispatchable range to PJM.	Only eligible to receive LOC credits if dispatched down by PJM Eligible to set LMP	Eligible to receive uplift Eligible to set LMP

21 PJM has modified the basic rules of eligibility to set price using its CT price setting logic.
22 Resources do not recover their operating cost when market revenues for the day are less than the short run marginal cost defined by the startup, no load, and incremental offer curve.
23 PJM allows block loaded CTs to set LMP by relaxing the economic minimum by 10 to 20 percent using CT price setting logic.
24 To date, the MMU has only requested resettlement of the most egregious cases.
25 OATT § 10.4.

The MMU identifies units that are not following dispatch and that are therefore not eligible to receive uplift payments. These findings are communicated to unit owners and to PJM. The units are identified by comparing their actual generation to the dispatch level that they should have achieved based on the real-time LMP, unit operating parameters (e.g. economic minimum, maximum and ramp rate) and energy offer.

Uplift Forfeiture Rule

The uplift forfeiture rule was introduced in 2000 after PJM observed that in the summer of 1999 units could circumvent the $1,000/MWh offer cap by submitting high offers associated with a long minimum run time (e.g. 24 hours). The rule states that units will not be paid operating reserve credits (uplift) when they are scheduled on their price-based offers during maximum generation conditions and their effective energy offer price exceeds $1,000 per MWh.[26] Maximum generation conditions include maximum generation emergencies, maximum generation emergency alerts, and when PJM schedules units based on the anticipation of a maximum generation emergency or maximum generation emergency alert.

In 2022 and 2023, PJM declared maximum generation conditions on five separate days. During these days, some units received uplift payments in violation of the uplift forfeiture rule. The five days in question are December 23 through 25 of 2022 (Winter Storm Elliott) and July 27 and 28 of 2023. The MMU has determined that, based on the uplift forfeiture rule, balancing operating reserves paid on December 23 and 24 of 2022 should be forfeited. PJM resettled the operating reserve credits paid to units that exceeded an effective offer price of $1,000 per MWh on December 23 and 24, 2022. The total balancing operating reserve credits returned totaled $1.7 million. In the first nine months of 2025, PJM declared maximum generation conditions for January 22, June 22-24, July 14-15, 23-24, and 27-29. The uplift forfeiture rule was triggered on June 23 and 24 because units received uplift with an effective energy price-based offer that exceeded $1,000 per MWh. The uplift payments under the uplift forfeiture rule on June 23 and 24 are under review.

26 See OA Schedule 1 Section 3.2.3 (m) Operating Reserves

The uplift forfeiture rule was also triggered on all of the maximum generation dates in July and analysis and results are pending.

Regulation Market Offsets

PJM does not include regulation market payments as an offset like other market revenues in the operating reserve calculations. Including regulation market revenues would result in lower uplift calculations. Table 4-12 shows that the regulation market revenues in the first nine months of 2025 were $111.5 million and that the balancing generator credits for those units receiving regulation revenues were $39.4 million. The table shows that if the regulation market revenues had been incorporated in the operating reserve calculation as an offset, the balancing generator payment for those units would have been $37.0 million instead of $39.4 million, 6.1 percent lower.

Table 4-12 Adjusted operating reserve credits: January through September, 2025

Month	Regulation Market Revenues (Millions)	Balancing Generator Credits (Millions)	Adjusted Balancing Generator Credits (Millions)	Difference
Jan	$19.8	$25.8	$25.1	($0.7)
Feb	$11.1	$3.4	$3.1	($0.3)
Mar	$11.0	$2.1	$1.8	($0.2)
Apr	$8.5	$2.8	$2.6	($0.2)
May	$8.7	$1.7	$1.5	($0.2)
Jun	$16.5	$1.3	$1.1	($0.2)
Jul	$14.4	$1.3	$0.9	($0.3)
Aug	$9.8	$0.4	$0.3	($0.1)
Sep	$11.8	$0.6	$0.5	($0.1)
Total	$111.5	$39.4	$37.0	($2.4)

Concentration of Energy Uplift Credits

The recipients of uplift payments are highly concentrated by unit and by company. This concentration results from a combination of unit operating parameters, PJM's persistent need to commit specific units out of merit in particular locations and the fact that a lack of full transparency has made it more difficult for competition to affect these payments.[27] Table 4-13 shows the concentration of energy uplift credits. The top 10 units received 37.5

27 As a result of FERC Order No. 844, PJM began publishing total uplift credits by unit by month for credits paid on and after July 1, 2019, on September 10, 2019.

percent of total energy uplift credits in the first nine months of 2025. The top 10 companies received 70.3 percent of total energy uplift credits in the first nine months of 2024.

Table 4-13 Top 10 units and organizations energy uplift credits: January through September, 2025

		Top 10 Units		Top 10 Organizations

Total		$247.5	37.5%	$464.7	70.3%

Unit Specific Uplift Payments

FERC Order No. 844 allows PJM and the MMU to publish unit specific uplift payments by category by month. Table 4-14 through Table 4-18 show the top 10 recipients of total uplift, day-ahead operating reserve credits and lost opportunity cost credits.

Chalk Point 3 and 4 are non-coal steam units in the PEPCO Zone with an ICAP of 582 MW each. In the first nine months of 2025, the Chalk Point 3 and 4 units received a combined $152.2 million in uplift, 23.0 percent of total uplift payments. In the first nine months of 2024, the Chalk Point 3 and 4 units received a combined $32.4 million in uplift, 14.8 percent of total uplift payments.

Brandon Shores 1 and Brandon Shores 2 and Wagner 3 and Wagner 4 submitted retirement notifications to PJM and the MMU in April and October of 2023. Brandon Shores 1 and 2 are coal units in BGE with an ICAP of 635 MW and 638 MW. Wagner 3 and 4 are oil units in BGE with an ICAP of 305 MW and 397 MW. PJM determined that these resources were needed for reliability until transmission upgrades can be completed. In the first nine months of 2025, the Brandon Shores 1 and 2 units received a combined $37.4 million in uplift, 5.7 percent of total uplift payments.

Table 4-14 Top 10 recipients of total uplift: January through September, 2025

Uplift Credits and Market Power Mitigation

Absent effectively implemented market power mitigation, unit owners that submit noncompetitive offers or offers with inflexible operating parameters, can exercise market power, resulting in noncompetitive and excessive uplift payments.

The three pivotal supplier (TPS) test is the test for local structural market power in the energy market.[28] If the TPS test is failed, market power mitigation is applied by offer capping the resources of the owners identified as having local market power to their cost-based offer. Offer capping is designed to set offers at competitive levels.

Table 4-19 shows day-ahead operating reserve credits paid to committed and dispatched units called on during the first nine months of 2025, classified by commitment schedule type. Units using parameter limited schedules received $113.1 million or 62.3 percent of day-ahead operating reserve credits in the first nine months of 2025, units using price-based offers received $30.3 million or 16.7 percent, and units using cost-based offers received $38.1 or 21.0 percent.

Table 4-19 Day-ahead operating reserve credits by Offer Type: January through September, 2025

Offer Type	Day Ahead Operating Reserve Credits (Millions)	Share of DAOR
Cost	$38.1	21.0%
Price	$30.3	16.7%
PLS	$113.1	62.3%
Total	$181.5	100.0%

Table 4-20 shows day-ahead operating reserve credits paid to units called on days with hot and cold weather alerts, classified by commitment schedule type. On weather alert days, PJM can require the use of parameter limited schedules (PLS) to prevent the exercise of market power through the use of inflexible parameters. Of all the day-ahead credits received during days with weather alerts, 1.1 percent went to units that were committed on cost schedules, which are parameter limited, 97.3 percent went to units that were committed on price PLS schedules and 1.5 percent went to units committed on price schedules less flexible than PLS. These results indicate a significant change in PJM's commitment approach during weather alerts. PJM committed only 1.5 percent of units on schedules less flexible than PLS during weather

28 See the MMU Technical Reference for PJM Markets, at "Three Pivotal Supplier Test" for a more detailed explanation of the three pivotal supplier test. <http://www.monitoringanalytics.com/reports/Technical_References/references.shtml>.

alert days in 2025 compared to 17.2 percent during weather alert days in 2024.

Table 4-20 Day-ahead operating reserve credits during weather alerts by commitment schedule: January through September, 2025

Commitment Type During Hot and Cold Weather Alerts	Day Ahead Operating Reserve Credits	Share of DAOR during emergency alerts
Committed on cost (cost capped)	$1,267,761	1.1%
Committed on price schedule as flexible as PLS	$59,921	0.1%
Committed on price schedule less flexible than PLS	$1,775,677	1.5%
Committed on price PLS	$113,117,800	97.3%
Total	$116,221,159	100.0%

Gas fired generators may request temporary exceptions to parameter limits such as minimum run time based on restrictions imposed by natural gas pipelines, including ratable takes.[29] Table 4-21 shows the day-ahead operating reserve uplift credits received from 2018 through the first nine months of 2025 by units that submitted parameter exception requests for a 24 hour minimum run time based on gas pipeline restrictions. In the first nine months of 2025, 93 units requested an exception for a 24 hour minimum run time and 60 units received uplift payments amounting to $147.7 million of day-ahead operating reserves and $30.9 million in balancing operating reserves, or 81.4 percent of total day-ahead operating reserves and 6.9 percent of total balancing operating reserves, corresponding to 22.4 percent and 4.7 percent of total uplift.

Table 4-21 Uplift credits for units with 24 hour minimum run times due to gas pipeline restrictions: 2018 through September 2025

Year	Day-Ahead Operating Reserve Credits (Millions)	Balancing Generator Credits (Millions)	Number of Units with 24 Hour Min Run Time Exceptions	Number of Units with 24 Hour Min Run Time Exceptions that Received Uplift
2018	$4.9	$0.7	25	2
2019	$0.2	$0.6	37	12
2020	$0.2	$0.2	13	2
2021	$0.7	$0.6	61	42
2022	$14.4	$9.8	81	38
2023	$10.7	$1.5	75	23
2024	$30.2	$2.4	79	41
2025 (Jan - Sep)	$147.7	$30.9	93	60

Polar Vortex 2025 (January 19 – 23, 2025)

The commitment and dispatch of units by PJM during Polar Vortex 2025 (January 19 through 23, 2025), resulted in significant uplift payments Table 4-22 summarizes the uplift payments by category during Polar Vortex 2025. During Polar Vortex 2025, generating units received $125.8 million in day-ahead operating reserve credits, 69.3 percent of total day-ahead operating reserves during the first nine months of 2025, and 37.1 percent of total uplift during Polar Vortex 2025. During Polar Vortex 2025, generating units received $207.6 million in balancing generator credits, 46.4 percent of total balancing generator credits during the first nine months of 2025 and 61.2 percent of total uplift during Polar Vortex 2025. Total uplift payments during Polar Vortex 2025 were $339.1 million, 51.3 percent of total uplift during the first nine months of 2025.

29 See OA Schedule 1 Section 6.6 (C) Minimum Generator Operating Parameters – Parameter Limited Schedules.

Table 4-22 Energy uplift credits by category during Polar Vortex 2025

Category	Type	2025 Polar Vortex Credits (Millions)	(Jan - Sep) 2025 Credits (Millions)	Polar Vortex Share of uplift (Jan - Sep) 2025	Share of Polar Vortex Uplift
Day-Ahead	Generators	$125.8	$181.5	69.3%	37.1%
Balancing	Generators	$207.6	$447.7	46.4%	61.2%
	Canceled Resources	$0.0	$0.0	0.0%	0.0%
	Lost Opportunity Cost	$5.7	$28.9	19.6%	1.7%
	Dispatch Differential Lost Opportunity Cost	$0.1	$2.0	3.0%	0.0%
Synchronous Condensing	Synchronous Condensing	$0.0	$0.0	NA	0.0%
	Synchronous Condensing Lost Opportunity Cost	$0.0	$0.0	NA	0.0%
Reactive Services	Generators	$0.0	$0.0	NA	0.0%
	Lost Opportunity Cost	$0.0	$0.5	0.0%	0.0%
	Condensing	$0.0	$0.0	0.0%	0.0%
	Condensing Lost Opportunity Cost	$0.0	$0.0	NA	0.0%
Total		$339.1	$660.6	51.3%	100.0%

Uplift during Polar Vortex 2025 was a result of out of market commitments made by PJM in anticipation of the cold weather. PJM committed units on Friday, January 17 for the January 19, 20 and 21 operating days. These commitments were made in advance of the Day-Ahead Energy Market, before offers were due. Some of the units cleared the Day-Ahead Energy Market economically and did not require uplift payments because their offers were covered by the day-ahead LMP. The rest of the units committed in advance that did not clear the Day-Ahead Market received balancing operating reserves credits because their offers were not covered by the real-time LMP. PJM made these commitments to mitigate generator performance risks based on available information about startup and operating uncertainty due to expected cold temperatures and gas supply illiquidity, including the need for 24 hour minimum run times to meet pipeline requirements for ratable takes.[30] PJM also committed specific units in advance to ensure transmission system reliability. That information was available because in 2024, in order to improve preparations for cold weather, PJM requested that all generators provide their cold weather operating limits, including the operating temperature limit (i.e. lowest ambient temperature at which the plant was designed to operate reliably) and starting temperature limit (i.e. lowest ambient temperature at which the plant could reliably start).

As a result of the low temperatures expected on Monday, January 20 and subsequent days, PJM committed units before temperatures reached the expected low levels. On Friday, January 17 natural gas traded for multiple days, referred to as the weekend package. The weekend package included gas days January 18, 19, 20 and 21, covering the period from Saturday, January 18, 10:00 to Wednesday, January 21, 10:00. PJM committed units on Friday to ensure that they could procure gas over the period of weekend package, reducing the risks of not being able to procure gas during individual days. The same actions were taken on Tuesday, January 21 for gas day January 22 (which covered the period from Wednesday, January 22, 10:00 to Thursday, January 23, 10:00).

The out of market commitments resulted primarily from conservative operations, which PJM declared from January 20 through January 23, but also included unit commitments for transmission constraints.[31] These commitments were made to ensure that supply that in previous events had performed poorly due to cold temperatures and gas supply issues, did not face the same risks. These commitments were not made to meet reserve requirements.

The day-ahead operating reserve credits were the result of units committed for transmission reliability in the day-ahead market (rather than conservative operations), these payments were made to a very small number of units.

Balancing operating reserve credits were the result of multiday commitments to minimize generation performance risk under conservative operations. Those units, mostly gas-fired combined cycle units, were committed ahead of time but did not clear the day-ahead market.

31 See PJM "Manual 13: Emergency Operations," Section 3.2 Conservative Operations Rev. 95 (Feb. 20, 2025).

Table 4-23 summarizes the total energy uplift credits by unit type during Polar Vortex 2025. Combined cycles received $140.1 million in uplift payments, non-coal steam units received $132.4 million and combustion turbines received $63.0 million.

Table 4-23 Total energy uplift credits by unit type during the 2025 Polar Vortex

Unit Type	2025 Polar Vortex Credits (Millions)	(Jan - Sep) 2025 Credits (Millions)	Polar Vortex Share of Uplift (Jan - Sep)	Share of Polar Vortex Uplift
Combined Cycle	$140.1	$156.9	89.3%	41.3%
Combustion Turbine	$63.0	$261.1	24.1%	18.6%
Diesel	$0.4	$2.7	13.4%	0.1%
Hydro	$0.0	$0.9	0.3%	0.0%
Nuclear	$0.0	$0.0	0.0%	0.0%
Solar	$0.0	$0.8	0.0%	0.0%
Steam - Coal	$0.2	$47.6	0.3%	0.0%
Steam - Other	$132.4	$184.6	71.8%	39.0%
Wind	$3.1	$6.0	51.0%	0.9%
Total	$339.1	$660.6	51.3%	100.0%

PJM chose to prepare for the weather related risks of Polar Vortex 2025 in very different ways than for Winter Storm Elliott. Rather than rely on PAI incentives to provide assurance that generators would be ready for cold weather, PJM took direct steps to ensure a reliable outcome. The results of Polar Vortex 2025 vindicated PJM's strategy. PJM took conservative measures to ensure reliability by scheduling resources well in advance of the day-ahead energy market. PJM took additional advance actions to ensure transmission reliability. As there is no multiday market, out of market actions taken before the market starts generally result in uplift. Based on this experience, the rules governing PJM's actions should be more transparent and clearly documented, including defined criteria for taking such actions. In addition, there should be rules about energy offers used for these commitments, and uplift rules should be revised to account for the multiday nature of these commitments. The lessons learned include that conservative operations are preferred to the Winter Storm Elliott approach of assuming that generators would respond, that increased uplift is the expected result and that the process of conservative operations and advance commitments needs to be improved, formalized and made as market oriented as possible in order to minimize uplift and make it as predictable as possible.

Summer Heat Waves in 2025

During the June Heat Wave, lasting June 22 - 26, generating units received $5.8 million in balancing generator credits, 1.3 percent of total balancing generator credits during the first nine months of 2025, and 54.8 percent of total uplift during the June Heat Wave. During the June Heat Wave, generating units received $4.0 million in lost opportunity cost credits, 13.7 percent of total lost opportunity cost credits during the first nine months of 2025 and 37.2 percent of total uplift during the June Heat Wave. Total uplift payments during the June Heat Wave were $10.6 million, 1.6 percent of total uplift during the first nine months of 2025. Of the balancing operating reserve credits during the June Heat Wave, which totaled $5.8 million, $3.1 million was paid to combustion turbines and diesels, $2.6 million was paid to steam units, and $0.9 million was paid to combined cycle units. Of the lost opportunity costs credits paid during the June Heat Wave, which totaled $4.0 million, $3.0 million was paid to flexible resources scheduled day ahead and not committed in real time for the full day-ahead schedule and $1.0 million was paid to units manually dispatched down.

PJM experienced multiple heat waves in July, resulting in periods of high demand, specifically July 14-17 and 23-30. Uplift credits during those days accounted for 6.0 percent of the increase in uplift credits during the first nine months of 2025 compared to the first nine months of 2024.

Capacity Market

In PJM, the capacity market exists to make the energy market work. Energy powers lights and computers and air conditioners. Capacity does not power anything. The capacity market needs to define the total MWh of energy that are needed to reliably serve load. The capacity market needs to provide the missing money. A primary reason to have a capacity market is that the energy market does not provide adequate net revenues to provide incentives for entry and for maintaining existing units. The obligation of load serving entities (LSEs) to own capacity equal to the peak demand plus a reserve margin was a longstanding feature of the PJM Operating Agreement before the creation of the PJM markets. The initial impetus to a capacity market in PJM, a request by the Pennsylvania PUC, was to support retail competition by ensuring that small new entrant competitive LSEs would have access to capacity at a competitive price without having to build capacity or purchase capacity bilaterally from incumbent generation owners at monopoly prices. The first, the daily capacity market, created in 1999, was replaced in 2007 by the current design based on the recognition that the energy market resulted in a shortfall in net revenues compared to that necessary to attract and retain adequate resources for the reliable operation of the energy market. The exogenous reliability requirement to have a level of capacity in excess of the level that would result from the operation of an energy market alone reduces the level and volatility of energy market prices and reduces the duration of high energy market prices. This reduces net revenue to generation owners which reduces the incentive to invest. In order for the PJM markets to be self sustaining, the net revenues from PJM energy, ancillary services and capacity markets must be adequate for those resources. That adequacy requires a capacity market. The capacity market plays the essential role of equilibrating the revenues necessary to incent competitive entry and exit of the resources needed for reliability, with the revenues from the energy and ancillary services markets.

The only goal of the detailed design of the capacity market is to ensure that the opportunity for that revenue equilibration exists through a competitive process.

The Capacity Performance (CP) design was a radical change to the capacity market paradigm. The CP design is a failed experiment. The fundamental mistake of the CP design was to attempt to recreate energy market incentives in the capacity market. The CP model was an explicit attempt to bring energy market shortage pricing into the capacity market design. The CP model was designed on the assumption that shortage prices in the energy market were not high enough and needed to be increased via the capacity market.

PJM's introduction of its significantly modified ELCC method in the 2025/2026 BRA was another radical change to the capacity market design. While it is a good idea to evaluate unit specific performance and a good idea to recognize that risk occurs in the winter as well as the summer and that risks may be correlated, ELCC was implemented before it could be fully tested and unintended consequences evaluated. The results of the 2025/2026 BRA illustrate the extreme sensitivity of the market outcomes to a range of assumptions and decisions about market design details that were not adequately tested or reviewed with stakeholders.[1]

The challenge is to create a straightforward capacity market design that meets the simple objectives of a capacity market and that does not become a vehicle for energy market incentives or rent seeking or attempts to limit the ways in which specific types of generation participate in PJM markets. Energy market incentives should remain in the energy market.

The PJM market design is based on the must offer and must buy obligations of capacity resources. All capacity resources are required to offer into the capacity auctions. The categorical exemption for intermittent resources, capacity storage resources, and hybrid resources from the RPM must offer requirement was eliminated for all resources except demand resources in February 2025.[2] All LSEs must buy capacity equal to their peak load plus a reserve margin.

Each organization serving PJM load must meet its capacity obligations through the PJM Capacity Market, where load serving entities (LSEs) must pay

1 The MMU prepared a series of reports on the 2025/2026 BRA results which can be found here: <https://www.monitoringanalytics.com/reports/Reports/2024.shtml> and here <https://www.monitoringanalytics.com/reports/Reports/2025.shtml>
2 FERC approved extending the RPM must offer requirement to intermittent resources, capacity storage resources, and hybrid resources but not to demand resources on February 20, 2025. 190 FERC ¶ 61,117.

the locational capacity price for their zone. LSEs can also construct generation and offer it into the capacity market, enter into bilateral contracts, develop demand resources and offer them into the capacity market, or construct transmission upgrades and offer them into the capacity market.

There are significant market design issues in the PJM Capacity Market that currently prevent the market from achieving competitive results.

One of the most important issues currently facing the PJM Capacity Market is the addition of data center load. The MMU concludes that the failure to recognize and address the role of large data center loads is a direct cause of higher prices and will continue to result in even higher prices unless the related issues are addressed. PJM should not simply permit the interconnection of large data center loads if it cannot do so reliably, with adequate generation capacity to meet those loads.

The Market Monitoring Unit (MMU) analyzed market design, market structure, participant conduct and market performance in the PJM Capacity Market, including supply, demand, concentration ratios, pivotal suppliers, volumes, prices, outage rates and reliability.[3] The conclusions are a result of the MMU's evaluation of the 2026/2027 Base Residual Auction.[4] [5] [6] [7] [8] [9] [10] [11]

3 The values stated in this report for the RTO and LDAs refer to the aggregate level including all nested LDAs unless otherwise specified. For example, RTO values include the entire PJM market and all LDAs. Rest of RTO values are RTO values net of nested LDA values.

Table 5-1 The capacity market results were not competitive

Market Element	Evaluation	Market Design
Market Structure: Aggregate Market	Not Competitive	
Market Structure: Local Market	Not Competitive	
Participant Behavior	Not Competitive	
Market Performance	**Not Competitive**	**Mixed**

- The aggregate market structure was evaluated as not competitive. For almost all auctions held from 2007 to the present, the PJM Capacity Market failed the three pivotal supplier test (TPS), which is conducted at the time of the auction.[12] Structural market power is endemic to the capacity market.
- The local market structure was evaluated as not competitive. For almost every auction held, all LDAs have failed the TPS test, which is conducted at the time of the auction.[13]
- Participant behavior was evaluated as not competitive in the 2026/2027 BRA. Effective with the 2026/2027 Delivery Year, the market seller offer cap definition was modified to include unit specific standalone Capacity Performance Quantifiable Risk (CPQR) and segmented unit specific offer caps.[14] The offers in the 2026/2027 BRA included those based on standalone CPQR offer caps. Market power mitigation measures were applied when the capacity market seller failed the market power test for the auction, the submitted sell offer exceeded the defined offer cap, and the submitted sell offer, absent mitigation, would increase the market clearing price.

12 In the 2008/2009 RPM Third Incremental Auction, 18 participants in the RTO market passed the TPS test. In the 2018/2019 RPM Second Incremental Auction, 35 participants in the RTO market passed the test. In the 2023/2024 RPM Third Incremental Auction, 36 participants in the RTO passed the TPS test.
13 In the 2012/2013 RPM Base Residual Auction, six participants included in the incremental supply of EMAAC passed the TPS test. In the 2014/2015 RPM Base Residual Auction, seven participants in the incremental supply in MAAC passed the TPS test. In the 2021/2022 RPM First Incremental Auction, two participants in the incremental supply in EMAAC passed the TPS test. In the 2021/2022 RPM Second Incremental Auction, two participants in the incremental supply in EMAAC passed the TPS test. In the 2023/2024 RPM Third Incremental Auction, eight participants in MAAC passed the TPS test.
14 190 FERC ¶ 61,117 (2025).

- Market performance was evaluated as not competitive based on the 2026/2027 Base Residual Auction as a result of the flaws in the Effective Load Carrying Capability (ELCC) design including the failure to correctly define the reliability contribution of thermal resources in the winter, and the failure to recognize and address the role of large data center loads is a direct cause of higher prices and will continue to result in even higher prices unless the related issues are addressed.
- Market design was evaluated as mixed because while there are many positive features of the capacity market design and some of the MMU's recommendations were implemented in the 2026/2027 BRA, there are several features of the RPM design which still threaten competitive outcomes. These include the lack of a queue for the addition of large new data center loads, details of PJM's ELCC implementation, the definition of market seller offer caps, the failure to apply the RPM must offer requirement to demand resources, the inclusion of performance assessment interval (PAI) penalties, the use of gross CONE as the maximum price on the VRR curve, the definition of DR which permits inferior products to substitute for capacity, the replacement capacity issue, the definition of unit offer parameters, and the inclusion of imports which are not substitutes for internal capacity resources.[15]

15 While PJM filed for and FERC accepted the inclusion of RMR resources Brandon Shores and Wagner plants in the 2026/2027 BRA and 2027/2028 BRA, that does not require that RMR resources be included in capacity market auction clearing in future auctions for these or other RMR resources. See Letter Order, FERC Docket No. ER25-682-001 (April 29, 2025).

Overview

RPM Capacity Market

Market Design

The Reliability Pricing Model (RPM) Capacity Market is a three year forward looking, annual, locational market, with a must offer requirement for Existing Generation Capacity Resources and a must buy requirement for load, with performance incentives, that includes clear market power mitigation rules and that permits the direct participation of demand side resources.[16] PJM introduced the Capacity Performance design for the 2017/2018 BRA. PJM introduced a new ELCC method for defining capacity MW offered in the 2025/2026 BRA.[17]

Under RPM, capacity obligations are annual.[18] By design, Base Residual Auctions (BRA) are held for delivery years that are three years in the future despite recent auction delays. First, Second and Third Incremental Auctions (IA) are held for each delivery year.[19] First, Second, and Third Incremental Auctions are conducted 20, 10, and three months prior to the delivery year although some incremental auctions have not been held as a result of delays in holding BRAs.[20] A Conditional Incremental Auction may be held if there is a need to procure additional capacity resulting from a delay in a planned large transmission upgrade that was modeled in the BRA for the relevant delivery year.[21] A Reliability Backstop Auction may be conducted if tariff defined criteria are met to resolve reliability criteria violations caused by lack of sufficient capacity procured through RPM auctions.[22] If the installed reserve margin resulting from the total UCAP committed through self supply or BRAs for three consecutive years is more than one percentage point lower than the approved PJM installed reserve margin, PJM will make a filing with FERC to conduct a Reliability Backstop Auction. If the total UCAP committed

16 The terms *PJM Region*, *RTO Region* and *RTO* are synonymous in this report and include all capacity within the PJM footprint.
17 See 186 FERC ¶ 61,080 (2024), *reh'g order*, 189 FERC ¶ 61,043 (2024).
18 Effective for the 2020/2021 and subsequent delivery years, the RPM market design incorporated seasonal capacity resources. Summer period and winter period capacity must be matched either through commercial aggregation or through the optimization in equal MW amounts in the LDA or the lowest common parent LDA.
19 See 126 FERC ¶ 61,275 at P 86 (2009).
20 See Letter Order, FERC Docket No. ER10-366-000 (January 22, 2010).
21 See 126 FERC ¶ 61,275 at P 88 (2009). There have been no Conditional Incremental Auctions.
22 See OATT Attachment DD § 16.

for all base load generation resources in BRAs for three consecutive years is less than the forecasted minimum hourly load, PJM will make a filing with FERC to conduct a Reliability Backstop Auction.

The 2025/2026 RPM Third Incremental Auction and the 2026/2027 RPM Base Residual Auction were conducted in the first nine months of 2025.

Market Structure

- **RPM Installed Capacity.** In the first nine months of 2025, RPM installed capacity increased 2,072.3 MW or 1.2 percent, from 179,656.2 MW on January 1, to 181,728.5 MW on June 30. Installed capacity includes net capacity imports and exports and can vary on a daily basis.
- **Reserves.** Total reserves on June 1, 2025, were 19,999.9 MW, which is 205.1 MW (UCAP) short of the required reserve level of 20,205.0 MW (UCAP). On June 1, 2025, the target installed reserve margin was 17.8 percent, and the actual reserve margin was only 17.6 percent.
- **RPM Installed Capacity by Fuel Type.** Of the total installed capacity on September 30, 2025, 48.9 percent was gas; 20.7 percent was coal; 17.7 percent was nuclear; 4.5 percent was hydroelectric; 2.2 percent was oil; 1.2 percent was wind; 0.3 percent was solid waste; and 4.4 percent was solar.
- **Market Concentration.** In the 2025/2026 RPM Third Incremental Auction and the 2026/2027 RPM Base Residual Auction, all participants in the total PJM market as well as the LDA RPM markets failed the three pivotal supplier (TPS) test.[23] Offer caps were applied to all sell offers for resources which were subject to mitigation when the capacity market seller did not pass the test, the submitted sell offer exceeded the defined offer cap, and the submitted sell offer, absent mitigation, increased the market clearing price.[24] [25] [26]

23 There are 27 Locational Deliverability Areas (LDAs) identified to recognize locational constraints as defined in "Reliability Assurance Agreement Among Load Serving Entities in the PJM Region," Schedule 10.1. PJM determines, in advance of each BRA, whether the defined LDAs will be modeled in the given delivery year using the rules defined in OATT Attachment DD § 5.10(a)(ii).
24 See OATT Attachment DD § 6.5.
25 Prior to November 1, 2009, existing DR and EE resources were subject to market power mitigation in RPM Auctions. See 129 FERC ¶ 61,081 at P 30 (2009).
26 Effective January 31, 2011, the RPM rules related to market power mitigation were changed, including revising the definition for Planned Generation Capacity Resource and creating a new definition for Existing Generation Capacity Resource for purposes of the must offer requirement and market power mitigation, and treating a proposed increase in the capability of a generation capacity resource the same in terms of mitigation as a Planned Generation Capacity Resource. See 134 FERC ¶ 61,065 (2011).

- **Imports and Exports.** Of the 1,281.7 MW of imports offered in the 2026/2027 RPM Base Residual Auction, 1,281.7 MW cleared. Of the cleared imports, 697.4 MW (54.4 percent) were from MISO.
- **Demand Resources.** Committed DR was 5,782.9 MW for June 1, 2025, as a result of cleared capacity for demand resources in RPM auctions for the 2025/2026 Delivery Year (6,265.9 MW) less replacement capacity (483.0 MW).
- **Energy Efficiency Resources.** EE is not a capacity resource but is paid the capacity market clearing price as a subsidy through the 2025/2026 Delivery Year. Committed EE was 1,481.6 MW for June 1, 2025, as a result of MW offered at a price less than or equal to the RPM auction clearing price in RPM auctions for the 2025/2026 Delivery Year (1,493.2 MW) less replacement MW (11.6 MW).

Market Conduct

- **2025/2026 RPM Third Incremental Auction.** Of the 307 generation resources that submitted Capacity Performance offers, unit specific offer caps were calculated for two generation resources (0.7 percent).
- **2026/2027 RPM Base Residual Auction.** Of the 1,293 generation resources that submitted Capacity Performance offers, unit specific offer caps were calculated for 82 generation resources (6.3 percent).

Market Performance

- The 2025/2026 RPM Third Incremental Auction and the 2026/2027 RPM Base Residual Auction were conducted in the first nine months of 2025. The weighted average capacity price for the 2025/2026 Delivery Year is $296.98 per MW-day, including all RPM auctions for the 2025/2026 Delivery Year. The weighted average capacity price for the 2026/2027 Delivery Year is $329.17 per MW-day, including all RPM auctions for the 2026/2027 Delivery Year.
- For the 2025/2026 Delivery Year, RPM annual charges to load are $14.8 billion.

- In the 2026/2027 RPM Base Residual Auction, the market performance was determined to be not competitive.

Part V Reliability Service (RMR)

- Of the nine companies (28 units) that have provided service following deactivation requests, two companies (seven units) filed to be paid under the deactivation avoidable cost rate (DACR), the formula rate. The other seven companies (21 units) filed to be paid under the cost of service recovery rate.

Generator Performance

- **Forced Outage Rates.** The average PJM EFORd in the first nine months of 2025 was 6.6 percent, an increase from 4.5 percent in the first nine months of 2024.[27]
- **Generator Performance Factors.** The PJM aggregate equivalent availability factor in the first nine months of 2025 was 83.7 percent, a decrease from 86.3 percent in the first nine months of 2024.

Recommendations[28]

Definition of Capacity

- The MMU recommends elimination of the key remaining components of the CP model because they interfere with competitive outcomes in the capacity market and create unnecessary complexity and risk. (Priority: High. First reported 2022. Status: Not adopted.)
- The MMU recommends the enforcement of a consistent definition of capacity resources. The MMU recommends that the tariff requirement to be a physical resource be enforced and enhanced. The requirement to be a physical resource should apply at the time of auctions and should also constitute a commitment to be physical in the relevant delivery year. The requirement to be a physical resource should be applied to all resource types, including planned generation, demand resources, and imports.[29] [30] (Priority: High. First reported 2013. Status: Not adopted.)
- The MMU recommends that DR providers be required to have a signed contract with specific customers for specific facilities for specific levels of DR at least six months prior to any capacity auction in which the DR is offered. (Priority: High. First reported 2016. Status: Not adopted.)
- The MMU recommends that Energy Efficiency Resources (EE) not be included in the capacity market construct because PJM's load forecasts have accounted for EE since the 2016 load forecast for the 2019/2020 delivery year. EE is not a capacity resource as defined in the tariff, and there is no reason to continue to pay large subsidies to EE providers.[31] (Priority: Medium. First reported 2016. Status: Adopted 2024.)[32]
- The MMU recommends that PJM require all market participants to meet their deliverability requirements under the same rules. PJM should end the practice of giving away winter CIRs to intermittent resources that appear to exist because other resources paid for the supporting network upgrades. (Priority: High. First reported 2017. Status: Not adopted.)[33]
- The MMU recommends that the must offer rule in the capacity market apply to all capacity resources. There is no reason to exempt intermittent and capacity storage resources, including hydro, and demand resources from the must offer requirement. The same rules should apply to all capacity resources in order to ensure open access to the transmission system and prevent the exercise of market power through withholding. (Priority: High. First reported 2021. Status: Partially adopted.)
- The MMU recommends that PJM require all market sellers of proposed generation capacity resources, including thermal and intermittent, to submit a binding notice of intent to offer at least six months prior to the base residual auction. This is consistent with the overall MMU

27 The generator performance analysis includes all PJM capacity resources for which there are data in the PJM generator availability data systems (GADS) database. Data was downloaded from the PJM GADS database on October 22, 2025. EFORd data presented in state of the market reports may be revised based on data submitted after the publication of the reports as generation owners may submit corrections at any time with permission from PJM GADS administrators.

28 The MMU has identified serious market design issues with RPM and the MMU has made specific recommendations to address those issues. These recommendations have been made in public reports. See Table 5-2.

32 See 189 FERC ¶ 61,095 (2024).

33 This recommendation was first made in the 2020/2021 BRA report in 2017. See the "Analysis of the 2020/2021 RPM Base Residual Auction," <http://www.monitoringanalytics.com/reports/Reports/2017/IMM_Analysis_of_the_20202021_RPM_BRA_20171117.pdf> (November 11, 2017).

recommendation that all capacity resources have a must offer obligation in the capacity market auctions. (Priority: High. First reported 2023. Status: Partially adopted.)

- The MMU recommends that PJM's application of the ELCC approach be replaced with an ELCC approach that is based on the actual hourly availability of all individual generators for accreditation and for payment. The MMU recommends short term modifications to PJM's approach to include hourly data that would permit unit specific ELCC ratings, to weight summer and winter risk in a more balanced manner, to eliminate PAI risks, and to pay for actual hourly performance rather than based on inflexible class capacity accreditation ratings derived from a small number of nonrepresentative hours of poor performance from PV1 and WSE. (Priority: High. First reported 2023. Status: Not adopted.)

Market Design and Parameters

- The MMU recommends that PJM establish a load queue for large new data center loads to ensure that such loads are not added until there is adequate generation capacity to serve them. The MMU recommends that an expedited queue option that would permit both the load and the generation to be added without delays be available to large data centers if they bring their own new generation with locational and temporal characteristics reasonably matched to their load profile. (Priority: High. First reported Q2, 2025. Status: Not adopted.)
- The MMU recommends that PJM reevaluate the shape of the VRR curve. The shape of the VRR curve directly results in load paying substantially more for capacity than load would pay with a vertical demand curve. More specifically, the MMU recommended that the VRR curve be rotated half way towards the vertical demand curve at the reliability requirement in the 2022 Quadrennial Review. (Priority: High. First reported 2021. Status: Partially adopted.)
- The MMU recommends that the maximum price on the VRR curve be defined as 1.5 times Net CONE, capped at Gross CONE. (Priority: Medium. First reported 2019. Status: Not adopted.)
- The MMU recommends that the reference resource be a CT rather than a CC. The MMU recommends that the ELCC value used to convert the gross CONE in ICAP terms for a CT to the gross CONE in UCAP terms be the ELCC based on winter ratings. (Priority: High. First reported 2024. Status: Adopted 2025.)
- The MMU recommends that the test for determining modeled Locational Deliverability Areas (LDAs) in RPM be redefined. A detailed reliability analysis of all at risk units should be included in the redefined model including transmission constraints inside LDAs. The market design should clear and pay units that are needed for reliability per PJM's transmission reliability analysis in order to forestall RMRs. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that PJM clear the capacity market based on nodal capacity resource locations and the characteristics of the transmission system inside and outside LDAs consistent with the actual electrical facts of the grid. Absent a fully nodal capacity market clearing process, the MMU recommends that PJM use a non-nested model with all LDAs modeled including VRR curves for all LDAs. Each LDA requirement should be met with the capacity resources located within the LDA and exchanges from neighboring LDAs up to the transmission limit. LDAs should be allowed to price separate if that is the result of the LDA supply curves and the transmission constraints between LDAs. (Priority: Medium. First reported 2017. Status: Not adopted.)
- The MMU recommends that the net revenue offset calculation used by PJM to calculate the net Cost of New Entry (CONE) and net ACR be based on a forward looking calculation of expected energy and ancillary services net revenues using historical net revenues that are scaled based on forward prices for energy and fuel. (Priority: High. First reported 2014. Status: Not adopted.)[34]
- The MMU recommends that PJM reduce the number of incremental auctions to a single incremental auction held three months prior to the start of the delivery year and reevaluate the triggers for holding

34 This recommendation was first made during the Quadrennial Review in 2014, including the PJM Capacity Senior Task Force (CSTF), the MRC and the MC. <https://www.pjm.com/committees-and-groups/closed-groups/cstf>.

conditional incremental auctions. (Priority: Medium. First reported 2013. Status: Not adopted.)

- The MMU recommends that PJM not sell back any capacity in any IA procured in a BRA. If PJM continues to sell back capacity, the MMU recommends that PJM offer to sell back capacity in incremental auctions only at the BRA clearing price for the relevant delivery year. (Priority: Medium. First reported 2017. Status: Not adopted.)
- The MMU recommends that PJM not buy any capacity in any IA if PJM has already procured excess reserves. (Priority: Medium. First reported 2023. Status: Not adopted.)
- The MMU recommends changing the RPM solution method to explicitly incorporate the cost of uplift (make whole) payments in the objective function. (Priority: Medium. First reported 2014. Status: Not adopted.)
- The MMU recommends that the Fixed Resource Requirement (FRR) rules, including obligations and performance requirements, be revised and updated to ensure that the rules reflect current market realities and that FRR entities do not unfairly take advantage of those customers paying for capacity in the PJM capacity market. (Priority: Medium. First reported 2019. Status: Not adopted.)
- The MMU recommends that the value of CTRs be defined by the total MW cleared in the capacity market, the internal MW cleared and the imported MW cleared, and not redefined later prior to the delivery year. (Priority: Medium. First reported 2021. Status: Not adopted.)
- The MMU recommends that the market clearing results be used in settlements rather than the reallocation process currently used, or that the process of modifying the obligations to pay for capacity be reviewed. (Priority: Medium. First reported 2021. Status: Not adopted.)[35]
- The MMU recommends that PJM improve the clarity and transparency of its CETL calculations. The MMU also recommends that CETL for capacity imports into PJM be based on the ability to import capacity only where PJM capacity exists and where that capacity has a must offer requirement in the PJM Capacity Market. (Priority: Medium. First reported 2021. Status: Partially adopted 2022.)

Offer Caps, Offer Floors, and Must Offer

- The MMU recommends using the lower of the cost or price-based energy market offer to calculate energy costs in the calculation of the historical net revenues which are an offset to gross ACR in the calculation of unit specific capacity resource offer caps based on net ACR. (Priority: Medium. First reported 2021. Status: Not adopted.)
- The MMU recommends that modifications to existing resources, including relatively small proposed increases in the capability of a Generation Capacity Resource be treated as an existing resource and subject to the corresponding market power mitigation rules and no longer be treated as planned and exempt from offer capping. (Priority: Medium. First reported 2012. Status: Not adopted.)[36]
- The MMU recommends that the RPM market power mitigation rules be modified to apply offer caps in all cases when the three pivotal supplier test is failed and the sell offer is greater than the offer cap. This will ensure that market power does not result in an increase in uplift (make whole) payments for seasonal products. (Priority: Medium. First reported 2017. Status: Not adopted.)
- The MMU recommends that any combined seasonal resources be required to be in the same LDA and at the same location, in order for the energy market and capacity market to remain synchronized and reliability metrics correctly calculated. (Priority: Medium. First reported 2021. Status: Not adopted.)
- The MMU recommends that the definition of avoidable costs in the tariff be corrected to be consistent with the economic definition. Avoidable costs are costs that are neither short run marginal costs, like fuel or consumables, nor fixed costs like depreciation and rate of return. Avoidable costs are the marginal costs of capacity and therefore the competitive

35 This recommendation was first made in the 2023/2024 BRA report in 2022. See "Analysis of the 2023/2024 RPM Base Residual Auction Revised," <http://www.monitoringanalytics.com/reports/Reports/2022/IMM_Analysis_of_the_20232024_RPM_Base_Residual_Auction_20221028.pdf> (October 28, 2022).

36 This recommendation was first made in the 2014/2015 BRA report in 2012. See "Analysis of the 2014/2015 RPM Base Residual Auction," <http://www.monitoringanalytics.com/reports/Reports/2012/Analysis_of_2014_2015_RPM_Base_Residual_Auction_20120409.pdf> (April 9, 2012).

offer level for capacity resources and therefore the market seller offer cap. Avoidable costs are the marginal costs of capacity for both new resources and existing resources. (Priority: Medium. First reported 2017. Status: Not adopted.)[37]

- The MMU recommends that major maintenance costs be included in the definition of avoidable costs and removed from energy offers because such costs are avoidable costs and not short run marginal costs. (Priority: High. First reported 2019. Status: Not adopted.)
- The MMU recommends that capacity market sellers be required to explicitly request and support the use of minimum MW quantities (inflexible sell offer segments) and that the requests only be permitted for defined physical reasons. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that, as part of the MOPR unit specific standard of review, all projects be required to use the same basic modeling assumptions. That is the only way to ensure that projects compete on the basis of actual costs rather than on the basis of modeling assumptions.[38] (Priority: High. First reported 2013. Status: Not adopted.)

Performance Incentive Requirements of RPM

- The MMU recommends that any unit not capable of supplying energy equal to its day-ahead must offer requirement (ICAP) be required to reflect an appropriate outage and associated performance penalty. (Priority: Medium. First reported 2009. Status: Not adopted.)
- The MMU recommends that retroactive replacement transactions associated with a failure to perform during a PAI not be allowed and that, more generally, retroactive replacement capacity transactions not be permitted. (Priority: Medium. First reported 2016. Status: Not adopted.)
- The MMU recommends that there be an explicit requirement that capacity resource offers in the day-ahead energy market be competitive, where competitive is defined to be the short run marginal cost of the units, including flexible operating parameters. (Priority: Low. First reported 2013. Status: Not adopted.)
- The MMU recommends that Capacity Performance resources be required to perform without excuses. Resources that do not perform should not be paid regardless of the reason for nonperformance. (Priority: High. First reported 2019. Status: Not adopted.)
- The MMU recommends that PJM require actual seasonal tests as part of the Summer/Winter Capability Testing rules, that the number of tests be limited, and that the ambient conditions under which the tests are performed be defined to reflect seasonal extreme conditions. (Priority: Medium. First reported 2022. Status: Not adopted.)
- The MMU recommends that PJM select the time and day that a unit undergoes Net Capability Verification Testing, not the unit owner, and that this information not be communicated in advance to the unit owner. (Priority: Medium. First reported 2022. Status: Not adopted.)

Capacity Imports and Exports

- The MMU recommends that all capacity imports be required to be deliverable to PJM load in an identified LDA, zonal or subzonal, or defined combinations of specific zones, e.g. MAAC, prior to the relevant delivery year to ensure that they are full substitutes for internal, physical capacity resources. Pseudo ties alone are not adequate to ensure deliverability to PJM load. (Priority: High. First reported 2016. Status: Not adopted.)
- The MMU recommends that all costs incurred as a result of a pseudo tied unit be borne by the unit itself and included as appropriate in unit offers in the capacity market. (Priority: High. First reported 2016. Status: Not adopted.)

37 This recommendation was first made in the 2023/2024 BRA report in 2022. See "Analysis of the 2023/2024 RPM Base Residual Auction Revised," <http://www.monitoringanalytics.com/reports/Reports/2022/IMM_Analysis_of_the_20232024_RPM_Base_Residual_Auction_20221028.pdf> (October 28, 2022).

38 See 143 FERC ¶ 61,090 (2013) ("We encourage PJM and its stakeholders to consider, for example, whether the unit-specific review process would be more effective if PJM requires the use of common modeling assumptions for establishing unit-specific offer floors while, at the same time, allowing sellers to provide support for objective, individual cost advantages. Moreover, we encourage PJM and its stakeholders to consider these modifications to the unit-specific review process together with possible enhancements to the calculation of Net CONE."); see also, Comments of the Independent Market Monitor for PJM, Docket No. ER13-535-001 (March 25, 2013); Complaint of the Independent Market Monitor for PJM v. Unnamed Participant, Docket No. EL12-63-000 (May 1, 2012); Motion for Clarification of the Independent Market Monitor for PJM, Docket No. ER11-2875-000, et al. (February 17, 2012); Protest of the Independent Market Monitor for PJM, Docket No. ER11-2875-002 (June 2, 2011); Comments of the Independent Market Monitor for PJM, Docket Nos. EL11-20 and ER11-2875 (March 4, 2011).

Deactivations/Retirements

- The MMU recommends that the notification requirement for deactivations be extended from the current one quarter prior (See Table 5-29) to 12 months prior to an auction in which the unit will not be offered due to deactivation; and no less than 12 months prior to the date of deactivation (Priority: Low. First reported 2012. Status: Partially adopted.)
- The MMU recommends that the same reliability standard be used in capacity auctions as is used by PJM transmission planning. One result of the current design is that a unit may fail to clear in a BRA, decide to retire as a result, but then be found to be needed for reliability by PJM planning and paid under Part V of the OATT (RMR) to remain in service while transmission upgrades are made. (Priority: High. First reported 2023. Status: Not adopted.)
- The MMU recommends elimination of both the cost of service recovery rate option and the deactivation avoidable cost rate option for providing Part V reliability service (RMR), and their replacement with clear language that provides for the recovery of 100 percent of the actual incremental costs required to operate to provide the service plus a defined incentive. (Priority: High. First reported 2017. Status: Not adopted.)
- The MMU recommends that units recover all and only the incremental costs, including incremental investment costs without a cap, required to provide Part V reliability service (RMR service) that the unit owner would not have incurred if the unit owner had deactivated its unit as it proposed, plus a defined incentive payment. Customers should bear no responsibility for paying previously incurred (sunk) costs, including a return on or of prior investments. (Priority: High. First reported 2010. Status: Not adopted.)
- The MMU recommends that if units that are paid under Part V of the OATT (RMR) are included in the calculation of CETO and/or reliability in the relevant LDA, the capacity of the RMR resources should also be included in capacity market supply at zero cost, but without all the obligations of a capacity resource, in order to ensure that the capacity market price signal reflects the appropriate supply and demand conditions. (Priority: High. First reported 2023. Status: Partially adopted.)
- The MMU recommends that units that are paid under Part V of the OATT (RMR) not be included in the calculation of CETO or reliability in the relevant LDA, in order to ensure that the capacity market price signal reflects the appropriate supply and demand conditions, until a decision is made to build transmission as a replacement, and then should be included. (Priority: High. First reported 2023. Status: Not adopted.)
- The MMU recommends that all CIRs be returned to the pool of available interconnection capability on the retirement date of generation resources in order to facilitate timely and competitive entry into the PJM markets, open access to the transmission system and maintain the priority order defined by the queue process. (Priority: High. First reported 2023. Status: Not adopted.)

Conclusion

The analysis of the PJM Capacity Market begins with market design and market structure, which provide the framework for the actual behavior or conduct of market participants. The analysis examines participant behavior within that market design and market structure. Regardless of the ownership structure of a market, the market design can result in noncompetitive outcomes. In a good market design and a competitive market structure, market participants are constrained to behave competitively. In a market with endemic structural market power like the PJM Capacity Market, effective market power mitigation rules are required in order to constrain market participants to behave competitively. The analysis examines market performance, measured by price and the relationship between price and marginal cost, that results from the interaction of market structure and participant behavior. The analysis also examines the impact of market design choices on market performance.

The MMU concludes that the results of the 2026/2027 RPM Base Residual Auction were significantly affected by flawed market design elements including the lack of a queue for the addition of large new data center loads, by the performance assessment interval (PAI) penalties that are part of the CP design, by PJM's ELCC approach, by the definition of market seller offer caps, by the failure to extend the RPM must offer requirement to demand resources, and by the product definition and lack of market power mitigation for demand resources. The BRA prices do not reflect supply and demand fundamentals but reflect, in significant part, PJM decisions about the definition of supply and demand. PJM filed changes that were approved by FERC and included in the 2026/2027 BRA to adopt two of the MMU's recommendations, the inclusion of specific RMR resources as supply in the next two BRAs and the elimination of the categorical exemption to the RPM must offer requirement for all but demand resources.[39] [40]

The capacity market is, by design, always tight in the sense that total supply is generally only slightly larger than demand. While the market may be long at times, that is not the equilibrium state. Market power is and will remain endemic to the structure of the PJM Capacity Market. Nonetheless, a competitive outcome can be assured by appropriate market power mitigation rules within an effective market design. Detailed market power mitigation rules are included in the PJM Open Access Transmission Tariff (OATT or Tariff). Reliance on the RPM design for competitive outcomes means reliance on the market power mitigation rules.

The basic conclusion of Part A of the MMU's analysis of the 2026/2027 BRA is that data center load growth is the primary reason for recent and expected capacity market conditions, including total forecast load growth, the tight supply and demand balance, and high prices. But for data center growth, both actual and forecast, the PJM Capacity Market would not have seen the same tight supply demand conditions, the same high prices observed in the 2025/2026 BRA and 2026/2027 BRA or the currently expected tight supply conditions and high prices for subsequent capacity auctions. The combined total increase in capacity market revenues resulting from data center load, both actual and forecast, for the 2025/2026 BRA and the 2026/2027 BRA was $16,603,301,829.[41] [42] This total will continue to grow until the issues associated with the additions of large data center loads are addressed. The impact will increase significantly in the 2028/2029 BRA currently scheduled for June 2026, when the maximum and minimum prices defined by the Agreement are no longer effective.

It is misleading to assert that the capacity market results are simply just a reflection of supply and demand. The current conditions are not the result of organic load growth. The current conditions in the capacity market are almost entirely the result of large load additions from data centers, both actual historical and forecast. The growth in data center load and the expected future growth in data center load are unique and unprecedented and uncertain and require a different approach than simply asserting that it is just supply and demand.

It is equally misleading to assert that the PJM Capacity Market does not work as a result of the impact of existing and forecast large data center load additions. Despite all the issues with PJM's changes to the capacity market design, the PJM Capacity Market would have provided for reliability at prices consistent with organic load growth and the cost of new capacity were it not for the paradigm shift represented by the almost inexhaustible demand for power from data centers.

Data center load growth is the core reliability issue facing PJM markets at present. There is still time to address the issue but failure to do so will result in very high costs for other PJM customers and could also result in a switch from competitive markets to cost of service regulation. Customers are already bearing billions of dollars in higher costs as a direct result of existing and forecast data center load as the Market Monitor demonstrated in Part G of the 2025/2026 BRA Analysis report and Part A of the 2027/2027 BRA Analysis Report.[43] [44]

PJM should not continue to interconnect large new data center load if it cannot be served reliably. The goal should be to serve all load that can be served reliably. The MMU recommends that PJM establish a load queue for

large new data center loads to ensure that such loads are not added until there is adequate generation capacity to serve them. The MMU recommends that an expedited queue option that would permit both the load and the generation to be added without delays be available to large data centers if they bring their own new generation with locational and temporal characteristics reasonably matched to their load profile

For the first time since the introduction of the RPM capacity market design, the 2026/2027 BRA used a VRR curve with both a defined maximum price and a defined minimum price. The maximum and minimum prices were based on the Agreement between Governor Shapiro of Pennsylvania and PJM that was incorporated in a PJM filing with FERC.[45] That VRR curve with the defined maximum and minimum price is referred to in this report as the restricted VRR curve. The VRR curve that would have been used absent the Agreement is referred in this report as the unrestricted VRR curve.

The Agreement resulted in a reduction of BRA revenues of $3,169,915,210, or 16.4 percent, compared to the revenues that would have resulted from the unrestricted VRR curve, holding everything else constant. If the 2026/2027 BRA had been run with an unrestricted VRR curve, total revenues would have been $19,294,286,100, an increase of $3,169,915,210, or 19.7 percent, compared to the actual auction revenues of $16,124,370,889 (Scenario 1).

The demand for capacity includes expected peak load plus a reserve margin, and points on the demand curve, called the Variable Resource Requirement (VRR) curve, exceed peak load plus the reserve margin. The maximum price on the VRR curve has a significant impact on market prices particularly when the market is tight. The shape of the VRR curve results in the purchase of excess capacity and higher payments by customers. The VRR curves used in the 2025/2026 BRA included a maximum price equal to gross CONE for most LDAs that resulted in a significant increase in customer payments for load as a result of paying a price above the competitive level. Demand for capacity is almost entirely inelastic because the market rules require loads to purchase their share of the system capacity requirement. The VRR demand curve is everywhere inelastic. The result is that any supplier that owns more capacity than the typically small difference between total supply and the defined demand is individually pivotal and therefore has structural market power.

For the 2026/2027 RPM Base Residual Auction, total reserves were 21,353.2 MW, which is 208.7 MW (UCAP) short of the required reserve level of 21,561.9 MW (UCAP). The level of committed demand resources in the 2026/2027 BRA was 5,530.6 MW, meaning the PJM markets will rely on demand resources as part of the required reserve margin, rather than as excess above the required reserve margin. This is not consistent with the defined obligations of DR compared to other capacity resources. DR capacity resources do not have a must offer obligation in the energy market. DR capacity resources do not have a must offer obligation in the capacity market. The definition of performance for DR is not to provide a defined incremental level of MW when called but is only to be at a defined level of demand. DR capacity resources do not have a defined market seller offer cap. PJM markets for the first time in the 2025/2026 and 2026/2027 Delivery Years will rely on demand response resources as part of the required reserve margin, rather than as excess above the required reserve margin. PJM markets for the first time in the 2025/2026 and 2026/2027 Delivery Years will experience the implications of the definition of demand resources as a purely emergency capacity resource, when demand resources are a significant share of required reserves. Nonetheless, as another significant flaw in the market design, PJM does not include DR in its definition of primary or secondary reserves in the energy market. DR, for all these reasons, is an inferior resource in the capacity market. PJM does not have clear rules defining when the operators must call on DR.

There are currently two important gaps in the market power rules for the PJM Capacity Market related to demand resources. The RPM must offer requirement is not applied to demand resources. There are no market power mitigation rules that apply to demand resources.

For the 2026/2027 BRA, all participants to which the three pivotal supplier (TPS) test was applied (in the RTO RPM market) failed the three pivotal supplier test. The result was that offer caps were applied to all sell offers for Existing

45 On December 30, 2024, in Docket No. EL25-46-000, Governor Josh Shapiro and the Commonwealth of Pennsylvania filed a complaint against PJM asserting that the maximum price for PJM's capacity auctions is unjust and unreasonable. The Governor and PJM reached an Agreement. On February 20, 2025, in Docket No. ER25-1357-000, pursuant to FPA section 205, PJM submitted proposed revisions to its Tariff to establish a specific maximum price and minimum price for all RPM auctions for the 2026/2027 and 2027/2028 Delivery Years, consistent with the Agreement.

Generation Capacity Resources when the capacity market seller did not pass the test, the submitted sell offer exceeded the tariff defined offer cap, and the submitted sell offer, absent mitigation, would have resulted in a higher market clearing price.[46] [47]

The correct definition of a competitive offer in the capacity market is the marginal cost of capacity, net ACR, where ACR includes an explicit accounting for the costs of mitigating risk, including the risk associated with mitigating rational capacity market nonperformance penalties, and the relevant costs of acquiring fuel, including natural gas.

The MMU recommends elimination of the key remaining components of the CP model because they interfere with competitive outcomes in the capacity market and create unnecessary complexity and risk. The use of Net CONE as the basis for the PAI penalty rate is unsupported by economic logic. The use of Net CONE to establish penalties is a form of arbitrary administrative pricing that creates arbitrarily high risk for generators, creates complexity in the calculation of CPQR and increases CPQR above rational levels, and ultimately raises the price of capacity above the competitive level. Given PJM's recent decision to rely on conservative operations during tight market conditions as evidenced during Polar Vortex 2025 in January 2025, the probability of a PAI is extremely small. In addition, PJM tightened the definition of a PAI and capped the total annual penalty at 1.5 times the resource's capacity market BRA clearing price. As a result, there is no effective performance incentive remaining in the capacity market.

Rather than penalizing capacity resources at extremely high levels for nonperformance only during PAI events, capacity resources should be paid the daily price of capacity only to the extent that they are available to produce energy or provide reserves, as required by PJM on a daily/hourly basis, based on their cleared capacity (ICAP). This is a positive performance incentive based on the market price of capacity rather than a penalty based on an arbitrary assumption. This would mean that capacity resources are paid to provide energy and reserves based on their full ICAP and are not paid a bonus for doing so. The reduced payments for capacity would directly reduce customers' bills for capacity. This would also end the pretense that there will be penalty payments to fund bonus payments. This would also end the need for complex CPQR calculations based on the penalty rate and assumptions about the number and timing of PAI events. CP has not worked as the theory suggested. PAI events are high impact, low probability events. The failure of the PAI incentives to prevent a very high level of outages during Winter Storm Elliott illustrates the weakness of incentives based on this type of event. In addition, the actual performance standards were unacceptably weakened in the CP model. The standard of performance in the CP model is (B) * (ELCC accredited UCAP factor for a unit), where B is the balancing ratio and the ELCC accredited UCAP factor is the derating factor. For example, if B were 80 percent, the actual required performance for a unit with an 80 percent ELCC accredited UCAP factor would be only 64 percent of ICAP (.80 * .80). For units with low ELCC accredited UCAP factors, the required performance is even lower. The obligation to perform should equal the full ICAP value of a unit, consistent with the associated must offer obligation in the energy market for capacity resources.

The MMU is required to identify market issues and to report them to the Commission and to market participants. The Commission decides on any action related to the MMU's findings.

The MMU has identified serious market design issues with RPM and the MMU has made specific recommendations to address those

46 Prior to November 1, 2009, existing DR and EE were subject to market power mitigation in RPM Auctions. See 129 FERC ¶ 61,081 (2009) at P 30.
47 Effective January 31, 2011, the RPM rules related to market power mitigation were changed, including revising the definition for Planned Generation Capacity Resource and creating a new definition for Existing Generation Capacity Resource for purposes of the must-offer requirement and market power mitigation, and treating a proposed increase in the capability of a Generation Capacity Resource the same in terms of mitigation as a Planned Generation Capacity Resource. See 134 FERC ¶ 61,065 (2011).

issues.[48] [49] [50] [51] [52] [53] [54] [55] [56] [57] [58] [59] [60] In the first nine months of 2025, the MMU prepared a number of RPM related reports and testimony, shown in Table 5-2.

The PJM markets have worked to provide incentives to entry and to retain capacity. A majority of capacity investments in PJM were financed by market sources. Of the 57,618.3 MW of additional capacity that cleared in RPM auctions for the 2007/2008 through 2024/2025 Delivery Years, 43,653.8 MW (76.0 percent) were based on market funding. Of the 5,661.6 MW of additional capacity that cleared in RPM auctions for the 2025/2026 and 2026/2027 Delivery Years, 4,487.6 MW (79.3 percent) were based on market funding. Those investments were made based on the assumption that markets would be allowed to work and that inefficient units would exit.

It is essential that any approach to the PJM markets incorporate a consistent view of how the preferred market design is expected to provide competitive results in a sustainable market design over the long run. A sustainable market design means a market design that results in appropriate incentives to competitive market participants to retire units and to invest in new units over time such that reliability is ensured as a result of the functioning of the market.

In order to attract and retain adequate resources for the reliable operation of the energy market, revenues from PJM energy, ancillary services and capacity markets must be adequate for those resources. That adequacy requires a capacity market. The capacity market plays the essential role of equilibrating the revenues necessary to incent competitive entry and exit of the resources needed for reliability, with the revenues from the energy market that are directly affected by nonmarket sources.

Market Design

With the earlier introduction of the Capacity Performance model and the recent introduction of the ELCC model, combined with a tightening of the capacity supply and demand balance in ICAP terms, it is clear that PJM's choices about the details of market design have a potentially dominant impact on capacity market outcomes in PJM. The ongoing decision to allow the addition of a significant number of large new data center loads that cannot be served reliably due to inadequate capacity is the most recent and most significant example.

RPM prices are locational by LDA and may vary depending on transmission constraints into LDAs and local supply and demand conditions.[61] The capacity market is not fully locational. The capacity market locational differences exist only between and among LDAs. The capacity market design assumes that there are no transmission or operational constraints within LDAs and treats all capacity resources within an LDA as perfect substitutes even when they are not. The lack of a fully locational design is a market design flaw that has resulted in the designation of units as RMRs based on internal constraints that were not recognized in the market clearing process. Existing generation that qualifies as a capacity resource must be offered into RPM auctions, except for categorically exempt demand resources, and except for resources in a fixed resource requirement (FRR) plan. All load is required to pay for capacity. Participation by LSEs is mandatory, except for those entities that elect the FRR option. There is an administratively determined demand curve that defines scarcity pricing levels and that, with the supply curve derived from capacity offers, determines market prices in each BRA. There are explicit market power mitigation rules that define structural market power, that define offer caps based on the marginal cost of capacity, and that have flexible criteria for competitive offers by new entrants. Demand resources may be offered directly into RPM auctions but do not have a requirement to be identifiable physical resources, do not have a must offer obligation, and do not have market seller offer caps and receive the clearing price.

The results of the 2026/2027 RPM Base Residual Auction were significantly affected by flawed market design elements including the lack of a queue for the addition of large new data center loads, by the performance assessment interval (PAI) penalties that are part of the CP design, by PJM's ELCC approach, by the definition of market seller offer caps, by the failure to extend the RPM must offer requirement to demand resources, and by the product definition and lack of market power mitigation for demand resources. The BRA prices do not reflect supply and demand fundamentals but reflect, in significant part, PJM decisions about the definition of supply and demand. PJM filed changes that were approved by FERC and included in the 2026/2027 BRA to adopt two of the MMU's recommendations, the inclusion of specific RMR resources as supply in the next two BRAs and the elimination of the categorical exemption to the RPM must offer requirement for all but demand resources.

The fundamental mistake of the CP design was to attempt to recreate energy market incentives in the capacity market. The CP model was an explicit attempt to bring energy market shortage pricing into the capacity market design. The CP model was designed on the unsupported assumption that shortage prices in the energy market were not high enough and needed to be increased via the capacity market. The CP design focused on a small number of critical hours (performance assessment hours or PAH, translated into five minute intervals as PAI) and imposed large penalties on generators that failed to produce energy only during those hours. The use of capacity market penalties rather than energy market incentives created a new risk. While there are differences of opinion about how to value the risk, this CP risk is not risk that is fundamental to the operation of a wholesale power market. This is risk created by the CP design in order to provide an incentive to produce energy during high demand hours that is even higher than the energy market incentive, amplified by an operating reserve demand curves (ORDC). The risk created by CP is not limited to risk for individual generators, but extends to the viability of the market. If penalties create bankruptcies that threaten the viability of required energy output from the affected units, there is a risk to the market.

61 Transmission constraints are local capacity import capability limitations (low capacity emergency transfer limit (CETL) margin over capacity emergency transfer objective (CETO)) caused by transmission facility limitations, voltage limitations or stability limitations.

The CP PAI incentives are not effective market incentives. PAI incentives are administrative and nonmarket incentives that are not compatible with an effective market design. The energy market clearing, in contrast, is transparent and efficient and timely. While there are issues with the details of energy market pricing that must be addressed, including shortage pricing, the energy market does not include or create the significant and long lasting uncertainty created by the PAI rules as exhibited most dramatically by the results of Winter Storm Elliott. The PAI design creates an administrative process that adds unacceptable uncertainty to the process and that can never approach the effectiveness of the energy market in providing price signals and timely settlement. In addition, the imposition of PAI penalties on intermittent resources when those resources cannot perform is illogical.

The MMU recommends that PJM's application of the ELCC approach be replaced with an ELCC approach that is based on the actual hourly availability of all individual generators for accreditation and for payment. The MMU recommends short term modifications to PJM's approach to include hourly data that would permit unit specific ELCC ratings, to weight summer and winter risk in a more balanced manner, to eliminate PAI risks, and to pay for actual hourly performance rather than based on inflexible class capacity accreditation ratings derived from a small number of nonrepresentative hours of poor performance from PV1 and WSE. In the short run capacity accreditation should eliminate the performance during PV1 and WSE and should recognize the winter capability of thermal resources rather than limiting such resources to summer ratings. Most of the risk recognized in the ELCC model is winter risk but the ELCC accreditation values for thermal resources are capped at the summer ratings. That unnecessarily limits supply and changes the ELCC values for all other resources and changes the system accredited unforced capacity and therefore AUCAP, the maximum level of load that can be served by the existing resources and therefore the reliability requirement. The CIRs of such resources are currently limited by the summer ratings but those rules can and should be changed given the use of the ELCC approach. There is no reason that excess winter CIRs cannot be assigned to these resources immediately.

The initial VRR curve, introduced in 2007, had a maximum price equal to 1.5 times the Net Cost of New Entry (Net CONE), determined annually based on the fixed cost of new generating capacity, or Gross Cost of New Entry (Gross CONE), net of the three year average energy and ancillary service revenues. That VRR curve was structured to yield auction clearing prices equal to the 1.5 times Net CONE when the amount of capacity cleared was less than 99 percent of the target reserve margin, and below 1.5 times Net CONE when the amount of capacity cleared was greater than 99 percent of the target reserve margin. The use of Net CONE was based on the logic of the capacity market, to ensure that the cost of entry was covered between the energy and capacity markets. Net CONE was the missing money that needed to be recoverable in the capacity market. Net CONE was the equilibrating factor between the capacity market and energy market. The use of Gross CONE is inconsistent with that basic capacity market logic. Gross CONE was introduced as the maximum price based on concerns that Net CONE would be too low. The maximum point on the VRR curve for the 2025/2026 BRA was the higher of Gross CONE or 1.5 times Net CONE and Gross CONE was used. For the first time since the introduction of the RPM capacity market design, the 2026/2027 BRA used a VRR curve with both a defined maximum price and a defined minimum price.[62] However, if the logic of the markets implies a low Net CONE, that is the right answer. There is nothing inherently wrong with a low Net CONE that requires abandoning the basic capacity market logic. Gross CONE was an intervention designed to increase capacity market prices despite the fact that the basic economic logic did not support that increase. If there is an issue with the calculation of Net CONE, it should be addressed directly rather than by ignoring its central role in the design of the capacity market. As Gross CONE numbers are reasonably well defined, much more focus on getting the net revenues used in the forward auctions is required in order to ensure that market participants have confidence in the Net CONE values used in the auctions.

PJM ended the long standing categorical exemption of intermittent resources, capacity storage resources, and hybrid resources from the RPM must offer requirement. Consistent with the MMU's recommendations, that exemption

62 On April 21, 2025, FERC issued an order accepting PJM's proposal to establish a temporary capacity market price cap and floor for the 2026/2027 and 2027/2028 Delivery Years. 191 FERC ¶ 61,066 (April 21, 2025).

was eliminated for all but demand resources. There is no reason to continue to exempt demand resources from the RPM must offer requirement. The same rules should apply to all capacity resources. The purpose of the RPM must offer rule, which has been in place since the beginning of the capacity market in 1999, is to ensure that the capacity market works, and therefore that the energy market works, based on the inclusion of all demand and all supply, to ensure competitive entry, to ensure open access to the transmission system, and to prevent the exercise of market power via withholding of capacity supply.

For these reasons, existing resources are required to return CIRs to the market within one year after retirement. The MMU recommends that resources return CIRs to the market on the day of retirement.[63]

Consistent with the must offer obligation, performance penalties should not be applied to solar and wind resources when they are not capable of performing based on ambient conditions. For example, solar resources should be subject to performance penalties if they fail to perform when the sun is shining but should not be subject to performance penalties in the middle of the night. That would be the result under the incentive approach recommended by the MMU. If PAI is retained, this would be a rational application of the PAI penalties that recognizes the physical capabilities of resources and is therefore not discriminatory.

Demand resources (DR) have always been treated more favorably than generation capacity resources. Demand resources do not have an RPM must offer requirement. Demand resources, unlike all other capacity resources, are not subject to market seller offer caps to protect against the exercise of market power in the capacity market. When demand resources are pivotal, as they were for the 2026/2027 BRA, they have structural market power and can and do exercise market power. That conclusion does not depend on whether withholding directly benefits those resources through a portfolio effect. The result of the failure to offer can be a significant increase in the market price of capacity above the competitive level when that supply is pivotal. If the resources clear, it benefits the resources directly. Even if the resources do not clear, higher prices can benefit the owners of capacity portfolios that include such resources as well as resources with an RPM must offer requirement. The MMU recommends that demand resources have defined and enforced market seller offer caps in the capacity market, like all other capacity resources.

PJM filed tariff changes that transfer risk caused by the volatile ELCC ratings from generation owners to the load. ELCC ratings may increase or decrease significantly between the time a generator clears in the RPM Base Residual Auction and the final ELCC rating just prior to the start of the delivery year. Under the new tariff rules, generators will be excused from paying the Capacity Resource Deficiency Charge for a deficiency caused by a decrease in the final ELCC rating. Under the prior rules, a Capacity Market Seller was required to cover its short position by acquiring additional capacity or pay a deficiency penalty equal to 20 percent of the base residual auction clearing price for each MW of shortage. The tariff change was filed by PJM on April 18, 2025, and approved by FERC on June 17, 2025.[64] [65] The MMU opposed the change because the new rule does not mitigate the risk as asserted by PJM but simply transfers the ELCC rating volatility risk to the load.[66] The change is inconsistent with basic market logic under which investors bear the risk associated with the ownership of generation.

Installed Capacity

On January 1, 2025, RPM installed capacity was 179,656.2 MW (Table 5-3).[67] Over the next nine months, new generation, unit deactivations, facility reratings, plus import and export shifts resulted in RPM installed capacity of 181,728.5 MW on September 30, 2025, an increase of 2,072.3 MW or 1.2 percent from the January 1 level.[68] [69] The 2,072.3 MW increase was the net result of new or reactivated generation (2,020.0 MW), net capacity modifications (2,293.5 MW), decreases in exports (520.8 MW), and increases in imports (12.9 MW), offset by derates (1,906.0 MW), and deactivations or changes in capacity resource status (868.9 MW).

At the beginning of the new delivery year on June 1, 2025, RPM installed capacity was 181,221.6 MW, an increase of 4,056.0 MW or 2.3 percent from the May 31, 2025, level of 177,165.6 MW. This change occurred as a result of deactivations, derates, capacity modifications, and import/export contracts beginning and/or ending at the start of the new delivery year.

Table 5-3 Installed capacity (By fuel source): January 1, May 31, June 1, and September 30, 2025[70] [71]

	01-Jan-25		31-May-25		01-Jun-25		30-Sep-25	
	MW	Percent	MW	Percent	MW	Percent	MW	Percent

Wind	3,594.8	2.0%	1,717.1	1.0%	2,265.7	1.3%	2,265.7	1.2%
Total	179,656.2	100.0%	177,165.6	100.0%	181,221.6	100.0%	181,728.5	100.0%

Figure 5-1 shows the share of installed capacity by fuel source for the first day of each delivery year, from June 1, 2007, to June 1, 2025, as well as the expected installed capacity for the 2026/2027 Delivery Year. On June 1, 2007, coal comprised 40.7 percent of the installed capacity, reached a maximum of 42.9 percent in 2012, decreased to 20.71 percent on June 1, 2025, and is projected to decrease to 17.5 percent on June 1, 2026. The share of gas increased from 29.1 percent on June 1, 2007, reached a maximum of 50.2 percent in 2024, decreased to 49.0 percent on June 1, 2025, and is projected to increase to 49.9 on June 1, 2026.

67 Percent values shown in Table 5-3 are based on unrounded, underlying data and may differ from calculations based on the rounded values in the tables.
68 Unless otherwise specified, the capacity described in this section is the summer installed capacity rating of all PJM generation capacity resources, as entered into the Capacity Exchange system, regardless of whether the capacity cleared in the RPM auctions.
69 Wind resources accounted for 2,265.7 MW, and solar resources accounted for 8,073.6 MW of installed capacity in PJM on September 30, 2025. Prior to the 2023/2024 Delivery Year, PJM administratively reduced the capabilities of all wind generators to 14.7 percent for wind farms in mountainous terrain and 17.6 percent for wind farms in open terrain, and solar generators to 42.0 percent for ground mounted fixed panel, 60.0 percent for ground mounted tracking panel, and 38.0 percent for other than ground mounted solar arrays, of nameplate capacity when determining the installed capacity because wind and solar resources cannot be assumed to be available on peak and cannot respond to dispatch requests. As data became available, unforced capability of wind and solar resources was to be calculated using actual data. There are additional wind and solar resources not reflected in total capacity because they are energy only resources and do not participate in the PJM Capacity Market. See "PJM Manual 21B: PJM Rules and Procedures for Determination of Generating Capability," § 4 Calculations of ELCC Class Rating, ELCC Resource Performance Adjustment, Accredited UCAP, and Accredited UCAP Factor, Rev. 02 (July 23, 2025). The derating approach has been replaced with ELCC starting in the 2023/2024 Delivery Year.
70 The data for hybrid solar/battery resources are included in the solar data for confidentiality reasons.
71 Installed capacity is based on imports, exports, and PJM's capacity modification ("capmod") database that tracks new and reactivated generation, unit uprates and derates, and deactivations/changes to capacity resource status. Demand Resources are not tracked in this way and are not included here. For analysis of Demand Resources in the capacity market, see the Demand Resources discussion later in this section.

Figure 5-1 Percent of installed capacity (By fuel source): June 1, 2007 through June 1, 2026

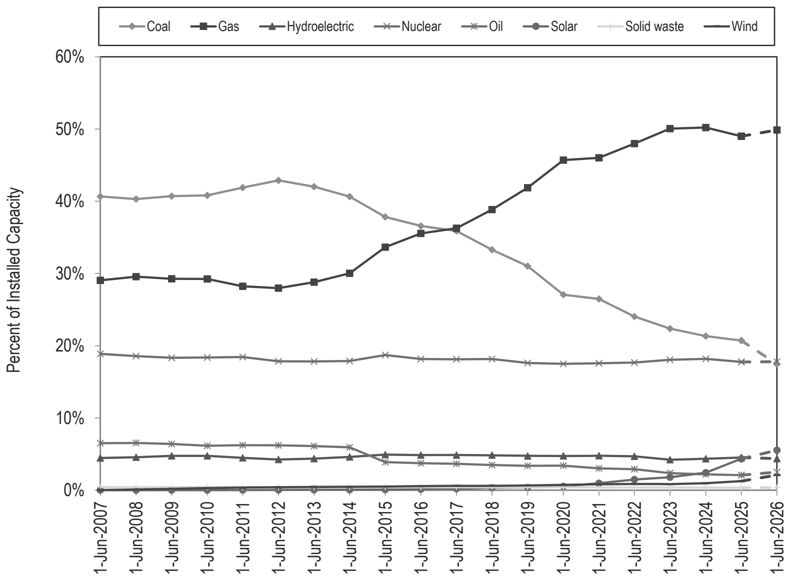

Table 5-4 shows the RPM installed capacity on January 1, 2025, through September 30, 2025, for the top five generation capacity resource owners, excluding FRR committed MW. Dominion Resources, Inc. was an FRR entity for the 2022/2023 through 2024/2025 Delivery Years and shifted their participation from FRR to RPM with the 2025/2026 Delivery Year.

Table 5-4 Installed capacity by parent company: January 1, May 31, June 1, and September 30, 2025

The sources of funding for generation owners can be categorized as one of two types: market and nonmarket. Market funding is from private investors bearing the investment risk without guarantees or support from any public sources, subsidies or guaranteed payment by ratepayers. Providers of market funding rely entirely on market revenues. Nonmarket funding is from guaranteed revenues, including cost of service rates for a regulated utility and subsidies. Table 5-5 shows the RPM installed capacity on January 1, 2025, to September 30, 2025, by funding type.

Table 5-5 Installed capacity by funding type: January 1, May 31, June 1, and September 30, 2025

	01-Jan-25		31-May-25		01-Jun-25		30-Sep-25	
Funding Type	ICAP (MW)	Percent of Total ICAP	ICAP (MW)	Percent of Total ICAP	ICAP (MW)	Percent of Total ICAP	ICAP (MW)	Percent of Total ICAP
Market	131,485.2	73.2%	128,508.7	72.5%	131,492.5	72.6%	131,893.0	72.6%
Nonmarket	48,171.0	26.8%	48,656.9	27.5%	49,729.1	27.4%	49,835.5	27.4%

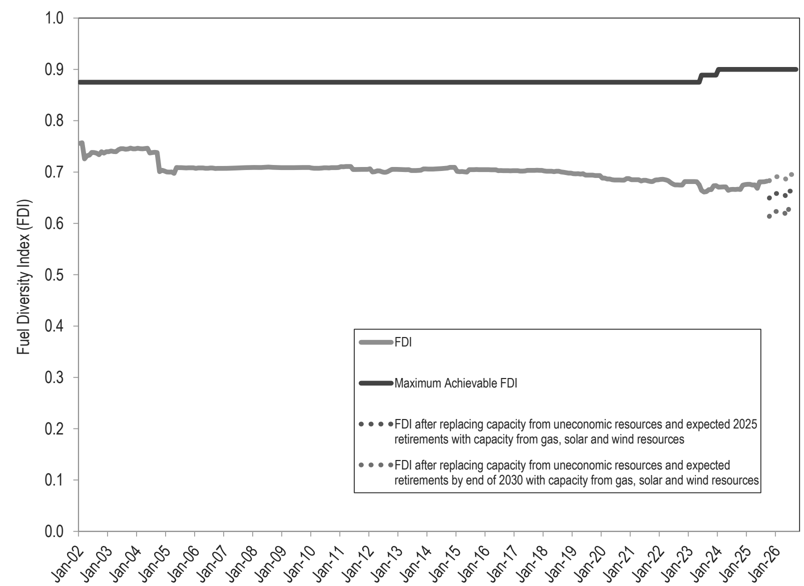
Fuel Diversity

Figure 5-2 shows the fuel diversity index (FDI_c) for RPM installed capacity.[72] The FDI_c is defined as $1-\sum_{i=1}^{N} s_i^2$, where s_i is the percent share of fuel type i. The minimum possible value for the FDI_c is zero, corresponding to all capacity from a single fuel type. The maximum possible value for the FDI_c is achieved when each fuel type has an equal share of capacity. For a capacity mix of eight fuel types, the maximum achievable index is 0.875. The fuel type categories used in the calculation of the FDI_c are in Table 5-3. FDI_c calculations prior to June 1, 2023 included eight fuel types. Batteries were added to the resource mix on June 1, 2023, and hybrid solar resources were added on January 1, 2024. The maximum achievable index with nine fuel types is 0.889. The maximum achievable index with ten fuel types is 0.900. The FDI_c is stable and does not exhibit any long-term trends. The only significant deviation occurred with the expansion of the PJM footprint. On April 1, 2002, PJM expanded with the addition of Allegheny Power System, which added about 12,000 MW of generation.[73] The reduction in the FDI_c resulted from an increase in coal capacity resources. A similar but more significant reduction occurred in 2004 with the expansion into the COMED, AEP, and DAY Control Zones.[74] The FDI_c on September 30, 2025 increased 2.4 percent in comparison with the FDI_c on September 30, 2024. Figure 5-2 also includes the expected FDI_c through September 30, 2026. The expected FDI_c is indicated in Figure 5-2 by the dotted orange line.

The FDI_c is used to measure the impact on fuel diversity of potential retirements in 2025 through 2030. A total of 34,733 MW of capacity are at risk of retirement, consisting of 4,684 MW currently planning to retire, 16,786 MW expected to retire for regulatory reasons and 13,264 MW expected to be uneconomic.[75] The dotted green line in Figure 5-2 shows the FDI_c assuming that the capacity from the expected 2025 retirements were replaced by gas, wind and solar capacity.[76] The counterfactual FDI_c on September 30, 2026 under these assumptions is 4.6 percent lower than the expected FDI_c on September 30, 2026. The dotted blue line in Figure 5-2 shows the FDI_c assuming that the capacity from the expected retirements through 2030 was replaced by gas, wind and solar capacity.[77] The counterfactual FDI_c on September 30, 2026 in this scenario is 9.7 percent lower.

Figure 5-2 Fuel Diversity Index for installed capacity: January 1, 2002 through September 30, 2026



72 The MMU developed the FDI to provide an objective metric of fuel diversity. The FDI metric is similar to the HHI used to measure market concentration. The FDI is calculated separately for energy output and for installed capacity. The FDI_c includes derated capacity values for intermittent capacity subject to derating.

73 On April 1, 2002, the PJM Region expanded with the addition of Allegheny Power System under a set of agreements known as "PJM-West." See page 4 in the *2002 Annual State of the Market Report for PJM* for additional details.

74 See the *2019 Annual State of the Market Report for PJM*, Volume 2, Appendix A, "PJM Geography" for an explanation of the expansion of the PJM footprint. The integration of the COMED Control Area occurred in May 2004 and the integration of the AEP and DAY Control Zones occurred in October 2004.

75 See the *2024 Annual State of the Market Report for PJM*, Volume 2, Section 7: Net Revenue.

76 It is assumed that 519.1 MW of replacement capacity is from solar units and 439.2 MW from wind units, with the remaining replacement capacity coming from gas units. This is the amount of derated wind and solar capacity needed to produce 8,962.7 GWh of generation in the first nine months of 2026 assuming the applicable PJM ELCC capacity derate factors and the average capacity factors for wind and solar capacity resources in Table 8-33 and Table 8-37. This level of GWh represents the increase in renewable generation required by RPS in the first nine months of 2026 over the level of renewable generation that was required by RPS in the first nine months of 2025. The split between solar and wind is based on queue data.

77 It is assumed that 1,658.4 MW of replacement capacity is from solar units and 1,960.1 MW from wind units, with the remaining replacement capacity coming from gas units. This is the amount of derated wind and solar capacity needed to produce 33,840.5 GWh of generation in the first nine months of 2030 assuming the applicable PJM ELCC capacity derate factors and the average capacity factors for wind and solar capacity resources in Table 8-33 and Table 8-37. This level of GWh represents the increase in renewable generation required by RPS in the first nine months of 2030 over the level of renewable generation that was required by RPS in the first nine months of 2025. The split between solar and wind is based on queue data.

RPM Capacity Market

The RPM Capacity Market, implemented June 1, 2007, is a three year forward looking, annual, locational market, with a must offer requirement for existing generation capacity resources, except for demand response resources, and except for resources owned by entities that elect the fixed resource requirement (FRR) option, and mandatory participation by load, with performance incentives, that includes clear market power mitigation rules and that permits the direct participation of demand side resources.

The standard schedule is that annual base residual auctions are held in May for delivery years that are three years in the future. Effective January 31, 2010, First, Second, and Third Incremental Auctions are conducted 20, 10, and three months prior to the delivery year.[78] In the first nine months of 2025, the 2026/2027 RPM Base Residual Auction and 2026/2027 RPM Base Residual Auction were conducted. The auction schedule has diverged significantly from the standard schedule in recent years.

Market Structure

Supply

Table 5-6 shows generation capacity changes since the implementation of the Reliability Pricing Model through the 2024/2025 Delivery Year. The 13,506.2 MW increase was the result of new generation capacity resources (46,491.1 MW), reactivated generation capacity resources (1,380.4 MW), uprates (9,746.8 MW), integration of external zones (21,967.5 MW), a net decrease in capacity exports (538.9 MW), offset by a net decrease in capacity imports (1,513.1 MW), deactivations (58,847.3 MW) and derates (6,258.1 MW).

Table 5-7 shows the calculated RPM reserve margin and reserve in excess of, or short of, the target installed reserve margin (IRM) for June 1, 2022, through June 1, 2026, and accounts for cleared capacity, replacement capacity, and deficiency MW for all auctions held and the most recent peak load forecast for each delivery year. The completion of the replacement process using cleared buy bids from RPM incremental auctions includes two transactions. The first step is for the entity to submit and clear a buy bid in an RPM incremental auction. The next step is for the entity to complete a separate replacement transaction using the cleared buy bid capacity. Prior to the 2025/2026 Delivery Year, replacement capacity transactions can be completed only after the EFORds for the delivery year are finalized, on November 30 in the year prior to the delivery year, but before the start of the delivery day. Effective with the 2025/2026 Delivery Year, replacement capacity transactions can be completed only after the accredited UCAP factors for the delivery year are finalized, but before the start of the delivery day. Early replacement transactions can be approved for defined physical replacements.

Changes in Generation Capacity[79]

As shown in Table 5-6, for the period from the introduction of the RPM capacity market design in the 2007/2008 Delivery Year through the 2024/2025 Delivery Year, internal installed capacity decreased by 7,487.1 MW after accounting for new capacity resources, reactivations, and uprates (57,618.3 MW) and capacity deactivations and derates (65,105.4 MW).[80]

For the current year (2025/2026), new generation capacity is defined as capacity that cleared an RPM auction for the first time for the specified delivery year. Based on expected completion rates of cleared new generation capacity (2,752.8 MW) and pending deactivations (760.0 MW), PJM capacity is expected to increase by 1,992.8 MW through the 2025/2026 Delivery Year.

78 See Letter Order, Docket No. ER10-366-000 (January 22, 2010).

79 For more details on future changes in generation capacity, see "2020 PJM Generation Capacity and Funding Sources 2007/2008 through 2021/2022 Delivery Years," <http://www.monitoringanalytics.com/reports/Reports/2020/IMM_2020_PJM_Generation_Capacity_and_Funding_Sources_20072008_through_20212022_DY_20200915.pdf> (September 15, 2020).

80 These results are for internal capacity only and do not include, for example, imports or exports or the impact of integrations of new areas.

Table 5-6 Generation capacity changes: 2007/2008 through 2024/2025[81]

	ICAP (MW)								
	New	Reactivations	Uprates	Integration	Net Change in Capacity Imports	Net Change in Capacity Exports	Deactivations	Derates	Net Change
2007/2008	45.0	0.0	691.5	0.0	70.0	15.3	380.0	417.0	(5.8)
2008/2009	815.4	238.3	987.0	0.0	473.0	(9.9)	609.5	421.0	1,493.1

2017/2018	4,127.3	5.0	562.1	0.0	(1,025.1)	(695.1)	2,657.4	148.5	1,558.5
2018/2019	8,127.5	4.0	330.9	2,120.0	(3,217.0)	212.7	6,730.0	89.2	333.5
2019/2020	4,612.0	13.3	494.9	165.0	(1,196.6)	401.3	3,296.0	116.8	274.5
2020/2021	403.1	11.6	575.4	0.0	(37.9)	(111.6)	3,572.0	206.4	(2,714.6)
2021/2022	3,309.3	6.0	412.2	0.0	38.5	1,066.1	2,197.6	125.5	376.8
2022/2023	4,743.2	0.0	417.0	0.0	(469.3)	(868.0)	7,460.5	302.0	(2,203.6)
2023/2024	2,696.8	0.0	420.5	0.0	(47.9)	1,067.8	5,149.2	1,441.1	(4,588.7)
2024/2025	1,724.3	0.0	919.5	0.0	17.1	212.0	1,068.0	737.7	643.2
Total	46,491.1	1,380.4	9,746.8	21,967.5	(1,513.1)	(538.9)	58,847.3	6,258.1	13,506.2

As shown in Table 5-7, total reserves on June 1, 2025, were 19,999.9 MW, which is 205.1 MW (UCAP) short of the required reserve level of 20,205.0 MW (UCAP). In the 2026/2027 BRA, total reserves were 21,353.2 MW, which is 208.7 MW (UCAP) short of the required reserve level of 21,561.9 MW (UCAP). The level of committed demand resources in the 2026/2027 BRA was 5,530.6 MW, meaning the PJM markets will rely on demand resources as part of the required reserve margin, rather than as excess above the required reserve margin.

The fact that one quarter (25.6 percent of total reserves) of the PJM reserves depend on demand resources that are not subject to the RPM must offer requirement, a core part of the capacity market design, means that reliability is significantly less certain than the stated reserve margins indicate.

81 The capacity changes in this report are calculated based on June 1 through May 31.

Table 5-7 RPM reserve margin: June 1, 2022, to June 1, 2026[82] [83]

	01-Jun-22	01-Jun-23	01-Jun-24	01-Jun-25	01-Jun-26	
Forecast peak load ICAP (MW)	149,263.6	149,382.2	151,631.1	154,534.1	159,329.1	A

Projected reserve margin	20.4%	19.9%	20.6%	17.6%	18.9%	V=(J-U/(1-E))/K-1 or V=(J-U/F)/K-1

Sources of Funding[84]

Developers use a variety of sources to fund their projects, including Power Purchase Agreements (PPA), cost of service rates, and private funds (from internal sources or private lenders and investors). PPAs can be used for a variety of purposes and the use of a PPA does not imply a specific source of funding.

New and reactivated generation capacity from the 2007/2008 Delivery Year through the 2024/2025 Delivery Year totaled 47,871.5 MW (83.1 percent of all additions), with 36,670.1 MW from market funding and 11,201.4 MW from nonmarket funding. Uprates to existing generation capacity from the 2007/2008 Delivery Year through the 2024/2025 Delivery Year totaled 9,746.8 MW (16.9 percent of all additions), with 6,983.7 MW from market funding and 2,763.1 MW from nonmarket funding. In summary, of the 57,618.3 MW of additional capacity from new, reactivated, and uprated generation that cleared in RPM auctions for the 2007/2008 through 2024/2025 Delivery Years, 43,653.8 MW (76.0 percent) were based on market funding.

Of the 5,661.6 MW of the additional generation capacity (new resources, reactivated resources, and uprates) that cleared in RPM auctions for the 2025/2026 and 2026/2027 Delivery Years, 357.6 MW are not yet in service, all of which have market funding. Applying the historical completion rates, 65.5 percent of all the projects in development are expected to go into service, 234.4 MW of the 357.6 MW in development market funded projects.[85]

82 The calculated reserve margins in this table do not include EE on the supply side or the EE addback on the demand side. The EE excluded from the supply side for this calculation includes annual EE and summer EE. This is how PJM calculates the reserve margin. Effective with the 2026/2027 Deliver Year, EE resources no longer participate in the PJM Capacity Market. See 189 FERC ¶ 61,095 (November 5, 2024).
83 These reserve margin calculations do not consider Fixed Resource Requirement (FRR) load.
84 For more details on sources of funding for generation capacity, see "2020 PJM Generation Capacity and Funding Sources 2007/2008 through 2021/2022 Delivery Years," <http://www.monitoringanalytics.com/reports/Reports/2020/IMM_2020_PJM_Generation_Capacity_and_Funding_Sources_20072008_through_20212022_DY_20200915.pdf> (September 15, 2020).
85 See the *2024 Annual State of the Market Report for PJM*, Volume 2, Section 12: Generation and Transmission Planning.

Of the 5,304.0 MW of the additional generation capacity that cleared in RPM auctions for the 2025/2026 and 2026/2027 Delivery Years and are already in service, 4,130.0 MW (77.9 percent) are based on market funding and 1,174.0 MW (22.1 percent) are based on nonmarket funding.

In summary, 4,487.6 MW (79.3 percent) of the additional generation capacity (357.6 MW not yet in service and 4,130.0 MW in service) that cleared in RPM auctions for the 2025/2026 and 2026/2027 Delivery Years are based on market funding. Capacity additions based on nonmarket funding are 1,174.0 MW (22.1 percent) of generation that cleared the RPM auctions for the 2025/2026 and 2026/2027 Delivery Years.

Demand

The MMU analyzed market sectors in the PJM Capacity Market to determine how they met their load obligations. The PJM Capacity Market was divided into the following sectors:

- **PJM EDC.** EDCs with a franchise service territory within the PJM footprint. This sector includes traditional utilities, electric cooperatives, municipalities and power agencies.
- **PJM EDC Generating Affiliate.** Affiliate companies of PJM EDCs that own generating resources.
- **PJM EDC Marketing Affiliate.** Affiliate companies of PJM EDCs that sell power and have load obligations in PJM, but do not own generating resources.
- **Non-PJM EDC.** EDCs with franchise service territories outside the PJM footprint.
- **Non-PJM EDC Generating Affiliate.** Affiliate companies of non-PJM EDCs that own generating resources.
- **Non-PJM EDC Marketing Affiliate.** Affiliate companies of non-PJM EDCs that sell power and have load obligations in PJM, but do not own generating resources.
- **Non-EDC Generating Affiliate.** Affiliate companies of non-EDCs that own generating resources.
- **Non-EDC Marketing Affiliate.** Affiliate companies of non-EDCs that sell power and have load obligations in PJM, but do not own generating resources.

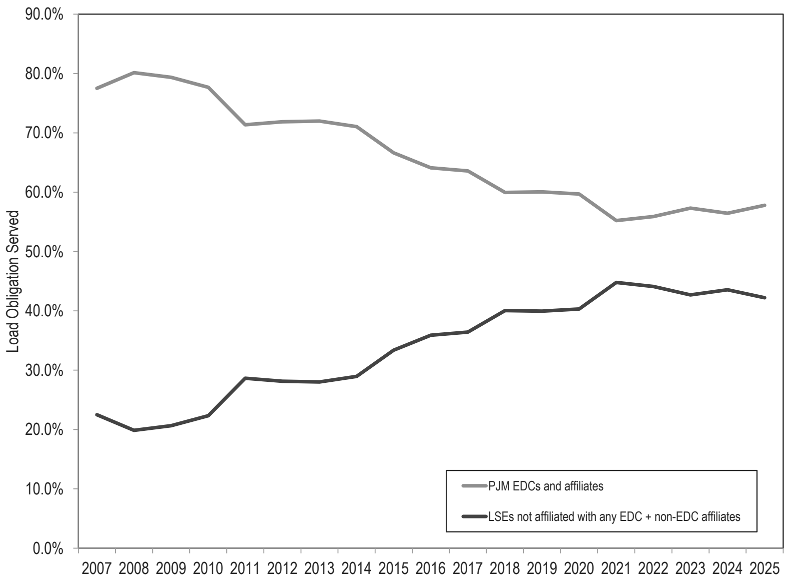
On June 1, 2025, PJM EDCs and their affiliates maintained a majority market share of load obligations under RPM, together totaling 57.8 percent (Table 5-8), up from 56.4 percent on June 1, 2024. The combined market share of LSEs not affiliated with any EDC and of non-PJM EDC affiliates was 42.2 percent, down from 43.6 percent on June 1, 2024. The share of capacity market load obligation fulfilled by PJM EDCs and their affiliates, and LSEs not affiliated with any EDC and non-PJM EDC affiliates from June 1, 2007, to June 1, 2025, is shown in Figure 5-3. PJM EDCs' and their affiliates' share of load obligation has decreased from 77.5 percent on June 1, 2007, to 57.8 percent on June 1, 2025. The share of load obligation held by LSEs not affiliated with any EDC and non-PJM EDC affiliates increased from 22.5 percent on June 1, 2007, to 42.2 percent on June 1, 2025.[86]

86 Prior to the 2012/2013 Delivery Year, obligation was defined as cleared and make whole MW in the Base Residual Auction and the Second Incremental Auction plus ILR forecast obligations. Effective with the 2012/2013 Delivery Year, obligation is defined as the sum of the unforced capacity obligations satisfied through all RPM auctions for the delivery year.

Table 5-8 Capacity market load obligation served: June 1, 2024 and June 1, 2025

	01-Jun-24		01-Jun-25		Change	
	Obligation (MW)	Percent of total obligation	Obligation (MW)	Percent of total obligation	Obligation (MW)	Percent of total obligation
PJM EDCs and Affiliates	106,462.1	56.4%	86,471.6	57.8%	(19,990.5)	1.4%
LSEs not affiliated with any EDC + non EDC Affiliates	82,180.1	43.6%	63,166.5	42.2%	(19,013.6)	(1.4%)
Total	188,642.2	100.0%	149,638.1	100.0%	(39,004.1)	0.0%

Figure 5-3 Capacity market load obligation served: June 1, 2007 through June 1, 2025



Capacity Transfer Rights (CTRs)

Capacity Transfer Rights (CTRs) are used to return capacity market congestion revenues to load. Load pays congestion. Capacity market congestion revenues are the difference between the total dollars paid by load for capacity and the total dollars received by capacity market sellers. The MW of CTRs available for allocation to LSEs in an LDA are equal to the Unforced Capacity imported into the LDA, less any MW of CETL paid for directly by market participants in the form of Qualifying Transmission Upgrades (QTUs) cleared in an RPM Auction, and Incremental Capacity Transfer Rights (ICTRs). There are two types of ICTRs, those allocated to a New Service Customer obligated to fund a transmission facility or upgrade and those associated with Incremental Rights-Eligible Required Transmission Enhancements.

The total required capacity in an LDA is provided by a mix of internal capacity and imported capacity. The imported capacity equals the total required capacity minus the internal capacity. The value of CTRs is based on the fact that load in an LDA pays the clearing price for all cleared capacity but that generators who provide imported capacity are paid a lower price based on the LDA in which they are located. The value of CTRs equals the imported MW times the price difference. This excess is paid by load and is returned to load using CTRs. CTRs are intended to permit customers to receive the benefit of importing cheaper capacity using transmission capability.

But PJM does not use the actual MW cleared in the BRA and three incremental auctions, the actual internal MW and the actual imported MW, when defining what customers pay and when defining the value of CTRs. Under the current rules, PJM defines the total MW needed for reliability in an LDA when clearing the BRA based on forecast demand at the time of the BRA. But PJM actually charges customers for the total MW needed for reliability based on forecast demand three years later, prior to the actual delivery year, and applies a zonal allocation. PJM also defines the internal capacity as the internal capacity after the final incremental auction conducted three years after the BRA, when auctions follow the traditional schedule. The difference between the updated MW needed for reliability and the updated internal capacity is the updated imported MW, adjusted for the final zonal allocation. In cases where the updated imported MW are smaller than the imported MW from the actual auction clearing, the total value of CTRs is lower that it would be if the actual auction clearing MW were used.

The actual load charges are allocated to each zone based on the ratio of the zonal forecast peak load to the RTO forecast peak load used for the third incremental auction conducted three months prior to the delivery year.

The CTR issue implies a broader issue with capacity market clearing and settlements. The capacity market is cleared based on a three year ahead forecast of load and offers of capacity. Payments to capacity resources in the delivery year are based on the capacity market clearing prices and quantities. But payments by customers in the delivery year are not based on market clearing prices and quantities. Payments by customers in each zone are based on the ratio of zonal forecast peak load to the RTO forecast peak load used for the Third Incremental Auction, run three months prior to the delivery year when auctions follow the traditional schedule.[87] The allocation sometimes creates significant differences between the capacity cleared to meet the reliability requirement and the capacity obligation allocated to the customers in a zone. For example, ComEd Zone, which is identical to ComEd LDA, cleared 27,932.1 MW including 5,574.0 MW of imports in the 2021/2022 RPM BRA. The ComEd Zone's capacity obligation, immediately after the clearing of the Base Residual Auction was 24,983.0 MW. The final ComEd Zone's capacity obligation for the 2021/2022 Delivery Year after the Third Incremental Auction was 22,721.2 MW.

As with CTRs, the underlying reasons for not using the market clearing results are not clear. Although not stated explicitly, the goal appears to be to reflect the fact that actual loads change between the auction and the delivery year. But the simple reallocation of capacity obligations based on changes in the load forecast does not reflect the BRA market results. The MMU recommends that the market clearing results be used in settlements rather than the reallocation process currently used or that the process of modifying the obligations to pay for capacity be reviewed.

For LDAs in which the RPM auctions for a delivery year resulted in a positive average weighted Locational Price Adder, an LSE with CTRs corresponding to the LDA is entitled to a payment or charge equal to the Locational Price Adder multiplied by the MW of the LSEs' CTRs. The definition of the MW does not reflect auction clearing MW.

In the 2025/2026 RPM Third Incremental Auction, BGE had 5,024.2 MW of CTRs with a total value of $360.6 million and DOM had 1,752.6 MW of CTRs with a total value of $112.8 million. BGE had 65.7 MW of customer funded ICTRs with a total value of $4.7 million. BGE had 306.0 MW of ICTRs due to Incremental Rights Eligible Required Transmission Enhancements with a value of $22.0 million.

The 2026/2027 RPM Base Residual Auction cleared at $329.17 with no price separation and therefore the value of CTRs is $0.

Demand Curve

A central feature of PJM's Reliability Pricing Model (RPM) design is that the demand curve, or Variable Resource Requirement (VRR) curve, has a downward sloping segment. In the RPM market design, the supply of three year forward capacity is cleared against this VRR curve. A VRR curve is defined for each Locational Deliverability Area (LDA). This shape replaced the vertical demand curve at the reliability requirement. The downward sloping segment begins at the MW level that is approximately 1.0 percent less than the reliability requirement.[88] Figure 5-4 shows the shape of the VRR curve for the 2026/2027 RPM Base Residual Auction.

The initial VRR curve, introduced in 2007, had a maximum price equal to 1.5 times the Net Cost of New Entry (Net CONE), determined annually based on fixed cost of new generating capacity, which is the Gross Cost of New Entry (Gross CONE), net of the three year average energy and ancillary service revenues. That VRR curve was structured to yield auction clearing prices equal to 1.5 times Net CONE when the amount of capacity cleared was less than 99 percent of the target reserve margin and below 1.5 times Net CONE when the amount of capacity cleared was greater than 99 percent of the target reserve margin.

87 See "PJM Manual 18: PJM Capacity Market," § 7.2.3 Final Zonal Unforced Capacity Obligations, Rev. 61 (July 23, 2025).

88 The formula for the MW level where the VRR curve begins the downward slope is given by *(Reliability Requirement) x [1 – 1.2% / (Installed Reserve Margin)]*.

Effective for the 2018/2019 through 2021/2022 Delivery Years, a revised VRR curve was implemented after PJM conducted a triennial review.[89] [90] PJM defines the reliability requirement as the capacity needed to satisfy the one event in ten years loss of load expectation (LOLE) for the RTO and capacity needed to satisfy the one event in 25 years loss of load expectation for the each LDA. The maximum price on the VRR curve was increased to be the greater of Gross CONE or 1.5 times Net CONE for all unforced capacity MW between 0 and 99.8 percent of the reliability requirement. The first downward sloping segment was from 99.8 percent and 102.5 percent of the reliability requirement. The second downward sloping segment was from 102.5 percent and 107.6 percent of the reliability requirement.

Effective for the 2022/2023 through 2025/2026 Delivery Years, a revised VRR curve was implemented after PJM conducted a quadrennial review.[91] The maximum price on the VRR curve was the greater of Gross CONE or 1.5 times Net CONE for all unforced capacity MW between 0 and 98.9 percent of the reliability requirement. The first downward sloping segment was from 98.9 percent and 101.6 percent of the reliability requirement. The second downward sloping segment was from 101.6 percent and 106.8 percent of the reliability requirement (Figure 5-4).

Effective for the 2026/2027 through 2029/2030 Delivery Years, a revised VRR curve was implemented after PJM conducted a quadrennial review.[92] The maximum price on the VRR curve is the greater of Gross CONE or 1.75 times Net CONE for all unforced capacity MW between 0 and 99.0 percent of the reliability requirement. The first downward sloping segment is from 99.0 percent and 101.5 percent of the reliability requirement. The second downward sloping segment is from 101.5 percent and 104.5 percent of the reliability requirement.

The VRR curve was then changed significantly based on PJM's filing to establish the maximum price point on the VRR curve equal to "approximately" $325/MW-day in UCAP with a new MW point that is inconsistent with the tariff definition, a new minimum price point on the VRR curve of "approximately" $175/MW-day in UCAP for an unlimited number of MW that is inconsistent with the tariff, and a VRR curve shape not consistent with the tariff definition, for all Reliability Pricing Model ("RPM") Auctions, including Base Residual Auctions and Incremental Auctions, for the 2026/2027 and 2027/2028 Delivery Years.[93] The VRR curve has always had a maximum price. The VRR curve has always had a minimum price equal to zero. The proposal would set the maximum price level at somewhat higher than 1.5 times Net CONE. The Market Monitor's position is that the maximum price should be equal to the lesser of 1.5 times Net CONE or Gross CONE.[94] The MMU opposed the imposition of a completely unsupported floor price that is inconsistent with the longstanding VRR curve design.

The initial VRR curve, introduced in 2007, had a maximum price equal to 1.5 times the Net Cost of New Entry (Net CONE). The use of Net CONE was based on the logic of the capacity market, to ensure that between the energy and capacity markets the cost of entry was covered. Net CONE was the missing money that needed to be recoverable in the capacity market. Net CONE was the equilibrating factor between the capacity market and energy market. The use of Gross CONE is inconsistent with that basic capacity market logic as is the use of 1.75 times Net CONE which is frequently greater than Gross CONE. Gross CONE was introduced as the maximum price based on concerns that Net CONE would be too low. The maximum point on the VRR curve for the 2025/2026 BRA was the higher of Gross CONE or 1.5 times Net CONE, and Gross CONE was actually used. However, if the logic of the markets implies a low Net CONE, that is the right answer. There is nothing inherently wrong with a low Net CONE that requires abandoning the basic capacity market logic. Gross CONE was an intervention designed to increase capacity market prices based on a judgment about what prices should be despite the fact that the basic economic logic did not support that increase. If there is an issue with the calculation of Net CONE, it should be addressed directly rather than by ignoring its central role in the design of the capacity market. As Gross CONE numbers are reasonably well defined, much more focus on getting

89 "Third Triennial Review of PJM's Variable Resource Requirement Curve," The Brattle Group, May 15, 2014, <http://www.pjm.com//media/library/reports-notices/reliability-pricing-model/20140515-brattle-2014-pjm-vrr-curvereport.ashx?la=en>.

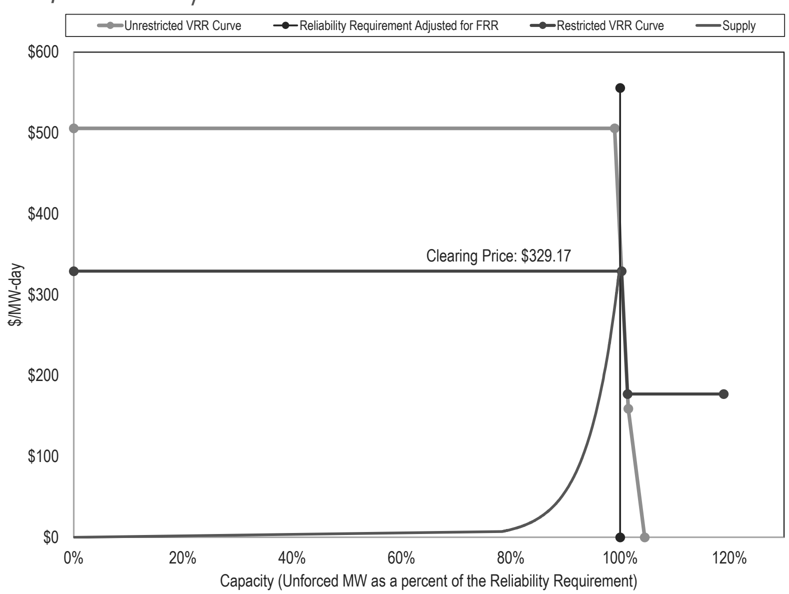
94 See Answer and Motion for Leave to Answer of the Independent Market Monitor for PJM, (April 16, 2025). <https://www.monitoringanalytics.com/filings/2025/IMM_Answer_to_Answer_Docket_No_ER25-1357_20250416.pdf>.

the net revenues used in the forward auctions is required in order to ensure that market participants have confidence in the Net CONE values used in the auctions.

Figure 5-4 shows the RTO VRR curve and RTO reliability requirement for the 2026/2027 RPM BRA.

Figure 5-4 Shape of the VRR curve relative to the reliability requirement: 2026/2027 Delivery Year



Market Concentration

Auction Market Structure

As shown in Table 5-9, in the 2025/2026 RPM Third Incremental Auction and the 2026/2027 RPM Base Residual Auction, all participants in the total PJM market as well as the LDA RPM markets failed the three pivotal supplier (TPS) test.[95] Offer caps were applied to all sell offers for resources which were subject to mitigation when the capacity market seller did not pass the test, the submitted sell offer exceeded the defined offer cap, and the submitted sell offer, absent mitigation, increased the market clearing price.[96] [97] [98]

In applying the market structure test, the relevant supply for the RTO market includes all supply offered at less than or equal to 150 percent of the RTO cost-based clearing price. The relevant supply for the constrained LDA markets includes the incremental supply inside the constrained LDAs which was offered at a price higher than the unconstrained clearing price for the parent LDA market and less than or equal to 150 percent of the cost-based clearing price for the constrained LDA. The relevant demand consists of the MW needed inside the LDA to relieve the constraint.

Table 5-9 presents the results of the TPS test. A generation owner or owners are pivotal if the capacity of the owners' generation facilities is needed to meet the demand for capacity. The results of the TPS are measured by the residual supply index (RSI_x). The RSI_x is a general measure that can be used with any number of pivotal suppliers. The subscript denotes the number of pivotal suppliers included in the test. If the RSI_x is less than or equal to 1.0, the supply owned by the specific generation owner, or owners, is needed to meet market demand and the generation owners are pivotal suppliers with a significant ability to influence market prices. If the RSI_x is greater than 1.0, the supply of the specific generation owner or owners is not needed to meet market demand and those generation owners have a reduced ability to unilaterally influence market price.

95 The market definition used for the TPS test includes all offers with costs less than or equal to 1.50 times the clearing price. See *MMU Technical Reference for PJM Markets*, at "Three Pivotal Supplier Test" for additional discussion.
96 See OATT Attachment DD § 6.5.
97 Prior to November 1, 2009, existing DR and EE resources were subject to market power mitigation in RPM Auctions. See 129 FERC ¶ 61,081 at P 30 (2009).
98 Effective January 31, 2011, the RPM rules related to market power mitigation were changed, including revising the definition for planned generation capacity resource and creating a new definition for existing generation capacity resource for purposes of the must offer requirement and market power mitigation, and treating a proposed increase in the capability of a generation capacity resource the same in terms of mitigation as a planned generation capacity resource. See 134 FERC ¶ 61,065 (2011).

Locational Deliverability Areas (LDAs)

Under the PJM Tariff, PJM determines, in advance of each BRA, whether defined Locational Deliverability Areas (LDAs) will be modeled in the auction. Effective with the 2012/2013 Delivery Year, an LDA is modeled as a potentially constrained LDA for a delivery year if the Capacity Emergency Transfer Limit (CETL) is less than 1.15 times the Capacity Emergency Transfer Objective (CETO), such LDA had a locational price adder in one or more of the three immediately preceding BRAs, or such LDA is determined by PJM in a preliminary analysis to be likely to have a locational price adder based on historic offer price levels. The rules also provide that starting with the 2012/2013 Delivery Year, EMAAC, SWMAAC, and MAAC LDAs are modeled as potentially constrained LDAs regardless of the results of the above three tests.[100] In addition, PJM may establish a constrained LDA even if it does not qualify under the above tests if PJM finds that "such is required to achieve an acceptable level of reliability."[101] A reliability requirement and a Variable Resource Requirement (VRR) curve are established for each modeled LDA. Effective for the 2014/2015 through 2016/2017 Delivery Years, a Minimum Annual and a Minimum Extended Summer Resource Requirement were established for each modeled LDA. Effective for the 2017/2018 Delivery Year, Sub-Annual and Limited Resource Constraints, replacing the Minimum Annual and a Minimum Extended Summer Resource Requirements, were established for each modeled LDA.[102] [103] Effective for the 2018/2019 and the 2019/2020 Delivery Years, a Base Capacity Demand Resource Constraint and a Base Capacity Resource Constraint, replacing the Sub-Annual and Limited Resource Constraints, were established for each modeled LDA.

Imports and Exports

Units external to the metered boundaries of PJM can qualify as PJM capacity resources if they meet the requirements to be capacity resources. Generators on the PJM system that do not have a commitment to serve PJM loads in the given delivery year as a result of RPM auctions, FRR capacity plans, locational

100 Prior to the 2012/2013 Delivery Year, an LDA with a CETL less than 1.05 times CETO was modeled as a constrained LDA in RPM. No additional criteria were used in determining modeled LDAs.
101 OATT Attachment DD § 5.10 (a) (ii).
102 146 FERC ¶ 61,052 (2014).
103 Locational Deliverability Areas are shown in maps in the *2021 Annual State of the Market Report for PJM*, Volume 2, Section 5, "Capacity Market" at "Locational Deliverability Areas (LDAs)".

UCAP transactions, and/or are not designated as a replacement resource, are eligible to export their capacity from PJM.[104]

The market rules in other balancing authorities should also not create inappropriate barriers to the import or export of capacity. The PJM market rules should ensure that the definition of capacity is enforced including physical deliverability, recallability and the obligation to make competitive offers into the PJM Day-Ahead Energy Market equal to ICAP MW. Physical deliverability can only be assured by requiring that all imports are deliverable to PJM load to ensure that they are full substitutes for internal capacity resources. Selling capacity into the PJM Capacity Market but making energy offers daily of $999 per MWh would not fulfill the requirements of a capacity resource to make a competitive offer, but would constitute economic withholding. This is one of the reasons that the rules governing the obligation to make a competitive offer in the day-ahead energy market should be clarified for both internal and external resources. The PJM market rules should also not create inappropriate barriers to either the import or export of capacity.

The calculation of CETL should only include capacity imports into PJM where the capacity has an explicit must offer requirement in the PJM Capacity Market. These could include pseudo tied units or resources with a grandfathered obligation. The external capacity that does not have a must offer requirement in the PJM capacity market is not obligated to serve PJM load under all conditions and therefore should not be assumed to be a source of capacity. This capacity should not be included in PJM's power flow calculations used to deriver CETL values between PJM's LDAs. PJM has modified its CETL calculations to exclude such capacity.

The establishment of a pseudo tie is one requirement for an external resource to be eligible to participate in the PJM Capacity Market. Pseudo tied external resources, regardless of their location, are treated as only meeting the reliability requirements of the rest of RTO and not the reliability requirements of any specific locational deliverability area (LDA). All imports offered in the auction from areas external to PJM are modeled as supply in the rest of RTO and not in any specific zonal or subzonal LDA. The fact that pseudo tied external resources cannot be identified as equivalent to resources internal to specific LDAs illustrates a fundamental issue with capacity imports. Capacity imports are not equivalent to, nor substitutes for, internal resources. All internal resources are internal to a specific LDA.[105]

Effective May 9, 2017, significantly improved pseudo tie requirements for external generation capacity resources were implemented.[106] The rule changes include: defining coordination with other Balancing Authorities when conducting pseudo tie studies; establishing an electrical distance requirement; establishing a market to market flowgate test to establish limits on the number of coordinated flowgates PJM must add in order to accommodate a new pseudo tie; a model consistency requirement; the requirement for the capacity market seller to provide written acknowledgement from the external Balancing Authority Areas that such pseudo tie does not require tagging and that firm allocations associated with any coordinated flowgates applicable to the external Generation Capacity Resource under any agreed congestion management process then in effect between PJM and such Balancing Authority Area will be allocated to PJM; the requirement for the capacity market seller to obtain long-term firm point to point transmission service for transmission outside PJM with rollover rights and to obtain network external designated transmission service for transmission within PJM; establishing an operationally deliverable standard; and modifying the nonperformance penalty definition for external generation capacity resources to assess performance at subregional transmission organization granularity.

Generation external to the PJM region is eligible to be offered into an RPM auction if it meets specific requirements.[107] [108] [109] Firm transmission service must be acquired from all external transmission providers between the unit and border of PJM and generation deliverability into PJM must be demonstrated prior to the start of the delivery year. In order to demonstrate generation deliverability into PJM, external generators must obtain firm point

104 OATT Attachment DD § 5.6.6(b).

105 External resources are not assigned to any of the five global LDAs or 22 zonal and subzonal LDAs. PJM's current practice is to model external resources in the rest of RTO. The practice is not currently documented by PJM. It was previously documented in "PJM Manual 18: PJM Capacity Market," § 2.3.4 Capacity Import Limits, Rev. 39 (Dec. 21, 2017).

106 161 FERC ¶ 61,197 (2017).

107 See "Reliability Assurance Agreement Among Load Serving Entities in the PJM Region," Schedule 9 & 10.

108 "PJM Manual 18: PJM Capacity Market," § 4.2.2 Existing Generation Capacity Resources – External, Rev. 61 (July 23, 2025).

109 "PJM Manual 18: PJM Capacity Market," § 4.6.4 Importing an External Generation Resource, Rev. 61 (July 23, 2025).

to point transmission service on the PJM OASIS from the PJM border into the PJM transmission system or by obtaining network external designated transmission service. In the event that transmission upgrades are required to establish deliverability, those upgrades must be completed by the start of the delivery year. The following are also required: the external generating unit must be in the resource portfolio of a PJM member; 12 months of NERC/GADs unit performance data must be provided to establish an EFORd; the net capability of each unit must be verified through winter and summer testing; and a letter of non-recallability must be provided to assure PJM that the energy and capacity from the unit is not recallable to any other balancing authority.

All external generation resources that have an RPM commitment or FRR capacity plan commitment or that are designated as replacement capacity must be offered in the PJM day-ahead energy market.[110]

Planned External Generation Capacity Resources are eligible to be offered into an RPM Auction if they meet specific requirements.[111] [112] Planned External Generation Capacity Resources are proposed Generation Capacity Resources, or a proposed increase in the capability of an Existing Generation Capacity Resource, that is located outside the PJM region; participates in the generation interconnection process of a balancing authority external to PJM; is scheduled to be physically and electrically interconnected to the transmission facilities of such balancing authority on or before the first day of the delivery year for which the resource is to be committed to satisfy the reliability requirements of the PJM region; and is in full commercial operation prior to the first day of the delivery year.[113] An External Generation Capacity Resource becomes an Existing Generation Capacity Resource as of the earlier of the date that interconnection service commences or the resource has cleared an RPM Auction for a prior delivery year.[114]

110 OATT Schedule 1 § 1.10.1A.
111 See "Reliability Assurance Agreement among Load Serving Entities in the PJM Region," Section 1.69A.
112 "PJM Manual 18: PJM Capacity Market," § 4.2.4 Planned Generation Capacity Resources – External, Rev. 61 (July 23, 2025).
113 Prior to January 31, 2011, capacity modifications to existing generation capacity resources were not considered planned generation capacity resources. See 134 FERC ¶ 61,065 (2011).
114 Effective January 31, 2011, the RPM rules related to market power mitigation were changed, including revising the definition for Planned Generation Capacity Resource for purposes of the must-offer requirement and market power mitigation. See 134 FERC ¶ 61,065 (2011).

As shown in Table 5-10, of the 1,281.7 MW of imports offered in the 2026/2027 RPM Base Residual Auction, 1,281.7 MW cleared. Of the cleared imports, 697.4 MW (54.4 percent) were from MISO.

Demand Resources

The level of DR products that buy out of their positions after the BRA means that the treatment of DR has a negative impact on generation investment incentives and that the rules governing the requirement to be a physical resource should be more clearly stated and enforced.[115] If DR displaces new generation resources in BRAs, but then buys out of the position prior to the delivery year, this means potentially replacing new entry generation resources at the high end of the supply curve with other existing but uncleared capacity resources available in Incremental Auctions at reduced offer prices. This

115 See "Analysis of Replacement Capacity for RPM Commitments: June 1, 2007 to June 1, 2019," <http://www.monitoringanalytics.com/reports/Reports/2019/IMM_Analysis_of_Replacement_Capacity_for_RPM_Commitments_June_1_2007_to_June_1_2019_20190913.pdf> (September 13, 2019).

suppresses the price of capacity in the BRA compared to the competitive result because it permits the shifting of demand from the BRA to the Incremental Auctions, which is inconsistent with the must offer, must buy rules, and the requirement to be an actual, physical resource, governing the BRA. PJM's sell back of capacity in Incremental Auctions exacerbates the incentive for DR to buy out of its BRA positions in IAs.

Effective with the 2020/2021 Delivery Year, DR includes annual and summer products. Annual Demand Resources are required to be available on any day during the delivery year for an unlimited number of interruptions between the hours of 10:00 a.m. and 10:00 p.m. EPT for the months of June through October and the following May and between the hours of 6:00 a.m. and 9:00 p.m. EPT for the months of November through April unless there is a PJM approved maintenance outage during the October through April period.

Summer-Period Demand Resources are required to be available on any day from June through October and the following May of the delivery year for an unlimited number of interruptions between the hours of 10:00 a.m. to 10:00 p.m. EPT.

As shown in Table 5-11, and Table 5-12, committed DR was 5,782.9 MW for June 1, 2025, as a result of cleared capacity for demand resources in RPM auctions for the 2025/2026 Delivery Year (6,265.9 MW) less replacement capacity (483.0 MW).

116 See OATT Attachment DD § 8.4. The reported DR cleared MW may reflect reductions in the level of committed MW due to relief from Capacity Resource Deficiency Charges.
117 Pursuant to OA § 15.1.6(c), PJM Settlement shall attempt to close out and liquidate forward capacity commitments for PJM Members that are declared in collateral default. The reported replacement transactions may include transactions associated with PJM members that were declared in collateral default.
118 EE resources are fully reflected in PJM load forecasts starting with the 2016 load forecast for the 2019/2020 Delivery Year, and EE resources are not defined to be capacity resources in any way as a result. EE resources do not clear in the capacity auctions.
119 See OATT Attachment DD § 5.14E. The reported DR cleared MW for the 2016/2017, 2017/2018, and 2018/2019 Delivery Years reflect reductions in the level of committed MW due to the Demand Response Legacy Direct Load Control Transition Provision.

ELCC: The Capacity Value of Resources

Given that many PJM states have aggressive renewable energy targets, a core goal of a competitive market design should be to ensure that the resources required to provide reliability receive appropriate competitive market incentives for entry and for ongoing investment and for exit when uneconomic. A significant level of renewable resources, operating with zero or near zero marginal costs, will result in very low energy prices at times of high intermittent output. Since renewable resources are intermittent, the contribution of renewables to meeting reliability targets must be analyzed carefully to ensure that the capacity value of renewables is calculated correctly.

120 See OATT Attachment DD § 8.4. The reported DR adjustments to cleared MW include reductions in the level of committed MW due to relief from Capacity Resource Deficiency Charges.

121 See OATT Attachment DD § 5.14C. The reported DR adjustments to cleared MW for the 2015/2016 and 2016/2017 Delivery Years include reductions in the level of committed MW due to the Demand Response Operational Resource Flexibility Transition Provision.

122 See OATT Attachment DD § 5.14E. The reported DR adjustments to cleared MW for the 2016/2017, 2017/2018, and 2018/2019 Delivery Years include reductions in the level of committed MW due to the Demand Response Legacy Direct Load Control Transition Provision.

The units of measurement for the PJM capacity market auctions are unforced capacity (UCAP). PJM uses conversion factors to convert installed capacity MW (ICAP) into UCAP MW and this process is known as capacity accreditation. Prior to the 2023/2024 Delivery Year, EFORd values for thermal generators were used to convert ICAP to UCAP. Conversion factors for wind and solar generators were based on energy output during summer peak hours. Conversion factors for storage resources were equal to the maximum capability during 10 continuous hours of operation. The conversion factor for Demand Resources was equal to the forecast pool requirement (FPR). On July 30, 2021, FERC approved new PJM rules for defining/derating the capacity value of intermittent and storage resources, based on PJM's interpretation of the effective load carrying capability (ELCC) method.[123] PJM's average ELCC accreditations for intermittent and storage resources relied on the average capability by resource class for the 2023/2024 and 2024/2025 Delivery Years. Revisions, filed in October 2023, changed the capacity accreditation calculation to a marginal ELCC approach, applicable to all resource types. Beginning with the 2025/2026 Delivery Year, capacity accreditations are based on the revised marginal ELCC approach. The PJM marginal ELCC approach was accepted by FERC in January 2024.[124]

PJM's approach to ELCC is based on the correct high level insight that there is a need to calculate the availability of different resource types, but the actual implementation does not do that correctly and results in a set of illogical outcomes. For example, PJM assigned penalties to solar resources during Winter Storm Elliott in December 2022 when solar resources did not generate power after dark. PJM's ELCC calculations rely on a significant overweighting

123 See 176 FERC ¶ 61,056.

124 186 FERC ¶61,080 (January 30, 2024).

of generator performance during the Polar Vortex in 2014 and Winter Storm Elliott in 2022 that results in artificially suppressed ELCC values for thermal resources and other resource types.

Under the PJM ELCC approach a solar resource is assigned a derating factor, and the derated MW are asserted to be equivalent to a perfect resource accredited at that MW level. PJM assigned penalties to solar resources during Elliott when they did not generate power after dark. This is clearly not correct and illustrates one of the flaws in the ELCC logic. The solar resource is available for sunny hours and not for unsunny hours. A solar resource is not expected to generate at night and should not face penalties for failing to do what it obviously cannot. ELCC does not convert intermittent resources, or any resource, into a perfect resource, or even the equivalent of a perfect resource. This illogical implication of PJM's ELCC means that there is a significant flaw in the ELCC approach. The penalties were assessed because the ELCC method determined that 1 MW of solar nameplate capacity was equivalent to 0.54 MW of perfect capacity, meaning capacity that is always available at the derated level, even in the middle of the night.[125]

The MMU opposes PJM's ELCC rules because they are an administrative determination by PJM based on a black box model of the capacity value of resources, they rely on significant counterfactual behavioral assumptions for storage and demand response resources, are not unit specific, are not hourly, are not locational, introduce significant volatility to the capacity accreditations, do not recognize the winter capability of thermal resources, overweight unit performance during Winter Storm Elliott, do not recognize actual performance in the delivery year and are an ex ante approach that must assume a capacity resource fleet for determining the ELCC marginal class ratings.[126] PJM does not check the actual cleared capacity in capacity market auctions to verify if the cleared capacity is expected to provide the target reliability.

125 "ELCC Class Ratings for 2024-2025 BRA," PJM Interconnection L.L.C. (December 28, 2021) <https://www.pjm.com/planning/resource-adequacy-planning/effective-load-carrying-capability>.
126 See Protest of the Independent Market Monitor for PJM, Docket ER24-99-000, et al. (November 9, 2023); Comments on Response to Deficiency Notice, Answer and Motion for Leave to Answer of the Independent Market Monitor for PJM, Docket No. ER24-99-000 (December 21, 2023); Answer and Motion for Leave to Answer of the Independent Market Monitor for PJM, Docket No. ER24-99-000 (January 12, 2024); Answer and Motion for Leave to Answer of the Independent Market Monitor for PJM, Docket No. ER24-99-000 (January 24, 2024).

The ELCC approach is not an appropriate way to define the MW capacity value for intermittent and storage resources, or for thermal resources, in a market. ELCC was developed as, and remains, a utility planning tool rather than a market design tool. ELCC was attractive as a possible analytical basis for the derating of intermittent and storage resources to a MW level consistent with their actual availability. The impetus made sense but the actual application of the ELCC planning tool cannot work in markets that include intermittent or thermal resources. The underlying logic makes sense but PJM's implementation does not.

As a result of all these issues, the MMU has concluded that ELCC is not a viable method for determining the reliability contributions of capacity resources. The MMU has proposed a replacement for the PJM ELCC approach that is based on the actual hourly availability of all individual generators.[127] [128] [129]

The ELCC ratings produced by the marginal approach in general, and by PJM's specific marginal approach specifically, are inherently volatile. PJM has calculated the marginal ELCC class ratings for the 2025/2026 Delivery Year on five separate occasions. Table 5-13 shows the results of each calculation. Each calculation is dependent upon the load forecast model, the combination of actual historical performance and changes in experienced weather, and the assumed forward looking resource mix. The PJM 2024 load forecast model was used to produce the February 2024, March 2024 and January 2025 ELCC ratings. The ELCC ratings posted on December 31, 2024, used an interim 2025 load forecast model. In early January, PJM removed the posted ELCC ratings from December 31, 2024, and posted recalculated ratings using the 2024 load forecast model. The modified ELCC ratings were posted on January 23, 2025. The January 23, 2025, ratings are the final ELCC ratings for 2025/2026 Delivery Year.[130] The ELCC rating changes have significant impacts on the

127 For additional details on the MMU proposal see "Executive Summary of the IMM Capacity Market Design Proposal: Sustainable Capacity Market (SCM)", Independent Market Monitor for PJM (August 16, 2023) <http://www.monitoringanalytics.com/reports/Presentations/2023/IMM_RASTF-CIFP_SCM_Executive_Summary_20230816.pdf>.
128 Any generation from a resource in excess of its CIR value is equivalent to generation from an energy only resource and should not be included in the calculation of the capacity value of the resource or in the calculation of the derated ELCC class ratings that define the capacity value of the resource. Updated rules beginning with the 2025/2026 Delivery Year require that ELCC accreditations exclude energy in excess of a generator's CIR. See 183 FERC ¶ 61,009 (April 7, 2023).
129 New rules beginning with the 2025/2026 Delivery Year correctly limit the delivered energy to the CIR level in the ELCC calculations. The new rules also include a complex transition process that allocates available headroom to intermittent resources with understated CIRs. The new rules apply to Delivery Year 2025/2026 BRA and subsequent delivery years. *See* 183 FERC ¶ 61,009 (April 7, 2023).
130 See Item 5 in Markets and Reliability Committee Meeting Materials, *Installed Reserve Margin (IRM), Forecast Pool Requirement (FPR), and Effective Load Carrying Capability (ELCC) for 2025/2026 3IA* at 2, PJM Interconnection L.L.C. (January 23, 2025) <https://www.pjm.com/committees-and-groups/committees/mrc>.

amount of cleared capacity. Table 5-14 shows the difference between capacity that cleared the 2025/2026 Base Residual Auction and the updated capacity MW value based on the final ELCC ratings for 2025/2026 posted on January 23, 2025. In total, the capacity values decreased by 928.5 MW (UCAP) or 0.7 percent. Capacity market sellers are obligated to obtain additional capacity prior to the delivery year if they are short as a result of a reduction in ELCC rating between the BRA and the final ELCC rating from PJM's ELCC rating changes. Had PJM used the ELCC ratings posted on December 31, 2024, the capacity values would have decreased by 3,793.3 MW or 2.8 percent.

Table 5-13 Marginal ELCC ratings for the 2025/2026 Delivery Year

	2025/2026 Delivery Year				
ELCC Class	December 2023	February 2024	March 2024	December 2024	January 2025
Onshore Wind	21%	35%	35%	42%	38%
Offshore Wind	39%	60%	60%	71%	62%
Solar Fixed	15%	9%	9%	8%	10%
Solar Tracking	25%	14%	14%	11%	14%
Landfill Intermittent	56%	55%	54%	51%	51%
Hydro Intermittent	41%	36%	37%	37%	37%
4-hr Storage	76%	59%	59%	44%	55%
6-hr Storage	85%	67%	67%	53%	65%
8-hr Storage	89%	69%	68%	58%	68%
10-hr Storage	92%	78%	78%	67%	77%
Demand Response	95%	77%	76%	68%	77%
Nuclear	96%	96%	95%	95%	95%
Coal	86%	85%	84%	83%	83%
Gas Combined Cycle	87%	80%	79%	77%	78%
Gas Combustion Turbine	74%	62%	62%	59%	63%
Gas Combustion Turbine Dual Fuel	90%	78%	79%	78%	79%
Diesel Utility	91%	90%	92%	92%	92%
Steam	78%	70%	75%	73%	74%

Table 5-14 Impact of ratings changes on cleared capacity[131]

	MW (UCAP)	Reduction in capacity value compared to Base Residual Auction	Percent change in capacity value compared to Base Residual Auction
2025/2026 Base Residual Auction Cleared Capacity	135,684.0		
Updated Cleared Capacity based on Jan 23, 2025 ELCC Ratings	134,755.5	(928.5)	(0.7%)
Updated Cleared Capacity based on Dec 31, 2024 ELCC Ratings	131,890.7	(3,793.3)	(2.8%)

131 PJM stated that the 2024 load forecast model was used because it is the "most recently finalized PJM load forecast." The January 23, 2025, ELCC Ratings are based on the PJM 2024 load forecast model. The December 31, 2024, ELCC Ratings are based on an interim PJM 2025 load forecast model.

The ELCC volatility also affects the reliability requirement calculation. Table 5-15 shows the reliability requirement calculation for the 2025/2026 RPM Base Residual Auction and the update for the Third Incremental Auction for 2025/2026. The pool wide accredited UCAP factor for the Third IA is based on the January 23, 2025, ELCC ratings which use the PJM 2024 load forecast model. These updated ELCC ratings reduced the pool wide accredited UCAP factor from 0.7969 to 0.7963. The reliability requirement and the FRR obligation both increase, resulting in an increase of 395.7 MW (UCAP) to the reliability requirement adjusted for FRR. PJM needs to procure an additional 395.7 MW (UCAP) of capacity in the Third Incremental Auction.

Table 5-15 PJM Reliability Requirement[132 133 134]

	2025/2026 Base Residual Auction	2025/2026 Third Incremental Auction	Change
ICAP	191,693.0	188,920.0	
Solved Load	160,624.0	158,357.0	(2,267.0)
Installed Reserve Margin	17.800%	17.800%	0.0%
Accredited UCAP	152,765.0	150,438.0	(2,327.0)
Pool Wide Accredited UCAP Factor	0.797	0.796	(0.001)
Forecast Pool Requirement	0.939	0.938	(0.001)
Preliminary Forecast Peak Load	153,883.0	154,534.1	651.0
Reliability Requirement	144,450.0	144,953.0	503.0
Fixed Resource Requirement (FRR)	10,886.4	10,993.7	107.3
Reliability Requirement Adjusted for FRR	133,563.6	133,959.3	395.7

PJM filed tariff changes that transfer risk caused by the volatile ELCC ratings from generation owners to the load. ELCC ratings may increase or decrease significantly between the time a generator clears in the RPM Base Residual Auction and the final ELCC rating just prior to the start of the delivery year. Under the new tariff rules, generators will be excused from paying the Capacity Resource Deficiency Charge for a deficiency caused by a decrease in the final ELCC rating. Under the prior rules, a Capacity Market Seller was required to cover its short position by acquiring additional capacity or pay a deficiency penalty equal to 20 percent of the base residual auction clearing price for each MW of shortage. The tariff change was filed by PJM on April 18, 2025, and approved by FERC on June 17, 2025.[135] [136] The MMU opposed the change because the new rule does not mitigate the risk as asserted by PJM but simply transfers the ELCC rating volatility risk to the load.[137] The change is inconsistent with basic market logic under which investors bear the risk associated with the ownership of generation.

PJM has calculated and posted marginal ELCC ratings on nine occasions for the 2025/2026 through 2027/2028 Delivery Years. Figure 5-5 shows the ELCC class ratings for intermittent resources. The horizontal axis shows the delivery year to which the ratings apply and the month the ratings were posted. The ratings change each time they are recalculated. The original rating for onshore wind for the 2025/2026 Delivery Year was 21 percent and the final rating for 2025/2026 Delivery year was 38 percent, an 80.9 percent increase. The onshore wind rating for the 2027/2028 Delivery Year is 41 percent, a 95.2 percent increase over the initial 2025/2026 rating. Solar has decreased. Solar with tracking technology has decreased from the initial 2025/2026 rating of 25 percent to 8 percent for the 2027/2028 Delivery Year, a 68.0 percent decrease. Solar with fixed panels has decreased 53.3 percent over the same period.

Figure 5-5 Marginal ELCC Class Ratings for Intermittent Resources

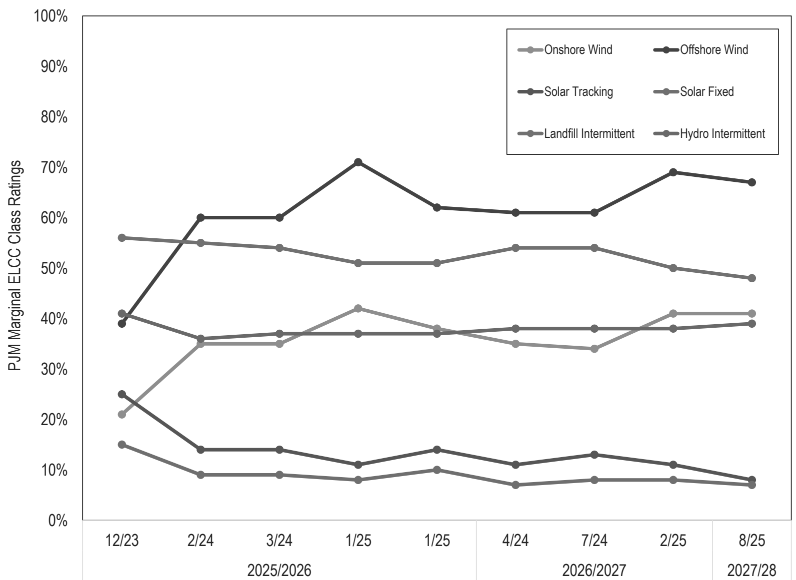

Figure 5-6 shows the ELCC rating for thermal resources. Combined cycle resource and combustion turbine ratings have decreased from their initial 2025/2026 ratings. The original rating for combined cycle resources for the 2025/2026 Delivery Year was 87 percent and the final rating for 2025/2026 Delivery Year was 78 percent, a 10.3 percent decrease. The combined cycle rating for the 2027/2028 Delivery Year is 74 percent, a 14.9 percent decrease over the initial 2025/2026 rating. Combustion turbine ratings have also decreased. Ratings for combustion turbines with dual fuel capability have decreased from the initial 2025/2026 rating of 90 percent to 77 percent for the 2027/2028 Delivery Year, a 14.4 percent decrease. Ratings for combustion turbines without dual fuel capability have decreased 17.6 percent over the same period. The change in UCAP for combined cycle and combustion turbine resources from the initial 2025/2026 ELCC ratings to the latest 2027/2028 ratings is a decrease of 11.5 GW. The corresponding change in ICAP is a decrease of 1.2 GW.

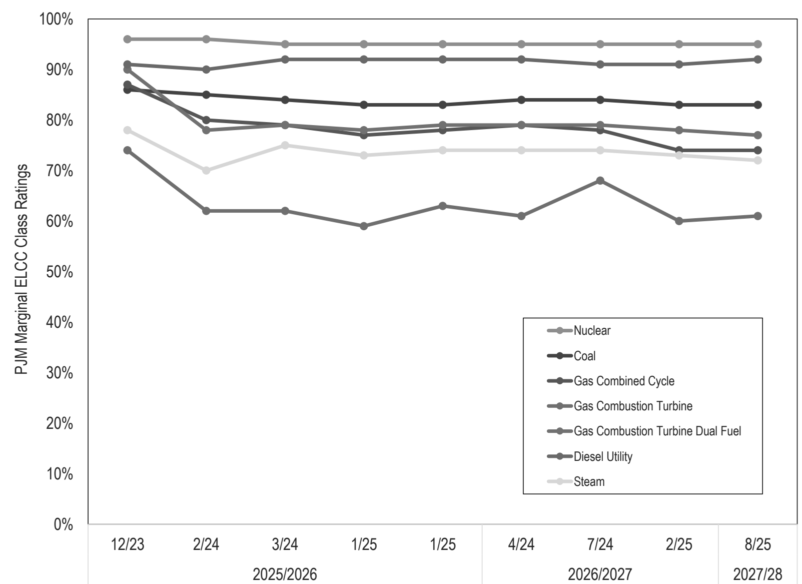
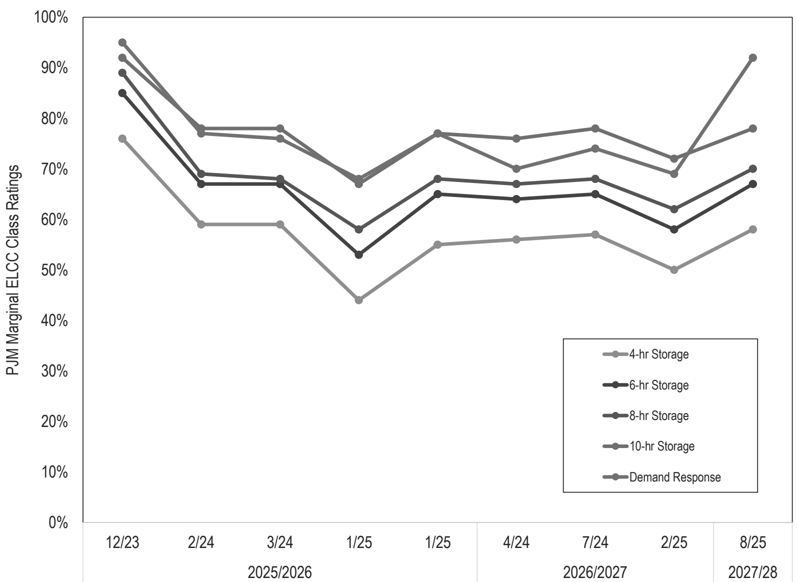
PJM could partially offset this loss of capacity in the short run by recognizing the winter capability of thermal resources rather than limiting such resources to summer ratings. Most of the risk recognized in the ELCC model is winter risk but the ELCC accreditation values for thermal resources are capped at the summer ratings. That unnecessarily limits supply and changes the ELCC values for all other resources and changes the system accredited unforced capacity and therefore AUCAP, the maximum level of load that can be served by the existing resources and therefore the reliability requirement. The CIRs of such resources are currently limited by the summer ratings but those rules can and should be changed given the use of the ELCC approach. There is no reason that excess winter CIRs cannot be assigned to these resources immediately.

Figure 5-6 Marginal ELCC Class Ratings for Thermal Resources



Marginal ELCC ratings for storage and demand response resources have also exhibited volatility. Figure 5-7 shows that the storage resource ratings have decreased. On average across all durations, storage ELCC ratings have decreased 20.4 percent from the initial 2025/2026 Delivery Year ratings to the 2027/2028 Delivery Year ratings. The initial rating for demand response for the 2025/2026 Delivery Year was 95 percent and final rating for the 2025/2026 Delivery Year was 77 percent, an 18.9 percent decrease. Due to recent rule change, the demand response rating for the 2027/2028 Delivery Year is 92 percent.[138]

Figure 5-7 Marginal ELCC Class Ratings for Storage and Demand Resources



138 191 FERC ¶61,103 (May 5, 2025).

Market Conduct

Offer Caps

Market power mitigation measures were applied to capacity resources such that the sell offer was set equal to the defined offer cap when the capacity market seller failed the market structure test for the auction, the submitted sell offer exceeded the defined offer cap, and the submitted sell offer, absent mitigation, would have increased the market clearing price.[139] [140] [141] For Capacity Performance Resources, for RPM auctions prior to September 2, 2021, offer caps were defined in the PJM Tariff as the applicable zonal Net Cost of New Entry (CONE) times (B) where B is the average of the Balancing Ratios (B) during the Performance Assessment Hours in the three consecutive calendar years that precede the base residual auction for such delivery year, unless net avoidable costs exceed this level, or opportunity costs based on the potential sale of capacity in an external market exceed this level. The Commission issued an order eliminating the prior offer cap and establishing a competitive market seller offer cap set at Net ACR, effective September 2, 2021.[142] The Commission rejected an attempt by PJM to undermine the Market Seller Offer Cap rules by order issued February 6, 2024.[143] The Commission approved changes to the Market Seller Offer Cap that allow Capacity Market Sellers to offer the higher of the net ACR and the Capacity Performance Quantifiable Risk (CPQR)[144] and to submit resource specific segmented offer caps.[145] Both changes to the Market Seller Offer Cap give Capacity Market Sellers the ability to offer in excess of the competitive offer and exercise market power as a result.

For RPM Third Incremental Auctions prior to September 2, 2021, capacity market sellers may elect an offer cap equal to the greater of the Net CONE for

139 See OATT Attachment DD § 6.5.
140 Prior to November 1, 2009, existing DR and EE resources were subject to market power mitigation in RPM Auctions. See 129 FERC ¶ 61,081 at P 30 (2009).
141 Effective January 31, 2011, the RPM rules related to market power mitigation were changed, including revising the definition for Planned Generation Capacity Resource and creating a new definition for Existing Generation Capacity Resource for purposes of the must offer requirement and market power mitigation, and treating a proposed increase in the capability of a Generation Capacity Resource the same in terms of mitigation as a Planned Generation Capacity Resource. See 134 FERC ¶ 61,065 (2011).

the relevant LDA and delivery year or 1.1 times the BRA clearing price for the relevant LDA and delivery year. For RPM Third Incremental Auctions after September 2, 2021, capacity market sellers may elect an offer cap of 1.1 times the BRA clearing price for the relevant LDA and delivery year.

Avoidable costs are costs that are neither short run marginal costs, like fuel or consumables, nor fixed costs like depreciation and rate of return. Avoidable costs are the costs that a generation owner incurs as a result of operating a generating unit for one year, in particular the delivery year.[146] As a result, the tariff defines avoidable costs as the costs that a generation owner would not incur if the generating unit did not offer for one year. Although the term mothball is used in the tariff to modify the term ACR, the term mothball is not defined in the tariff. Mothball is an informal term better understood as a metaphor for the cost to operate for one year. Avoidable costs are the costs to operate the unit for one year, regardless of whether the unit plans to retire. Although the tariff includes different mothball and retirement values, the distinction is based on a misunderstanding of the meaning of avoidable costs and should be eliminated. PJM never explained exactly how it calculated mothball and retirement avoidable cost levels. The MMU recommends that major maintenance costs be included in the definition of avoidable costs and removed from energy offers because such costs are avoidable costs and not short run marginal costs.[147] The tariff states that avoidable costs may also include annual capital recovery associated with investments required to maintain a unit as a Generation Capacity Resource, termed Avoidable Project Investment Recovery (APIR), despite the fact that these are not actually avoidable costs, particularly after the first year.

Avoidable cost based offer caps are defined to be net of revenues from all other PJM markets and unit-specific bilateral contracts, including RECs, and expected bonus performance payments/nonperformance charges.[148] Capacity resource owners could provide ACR data by providing their own unit-specific data or, for auctions for delivery years prior to 2020/2021 and auctions held after September 2, 2021, by selecting the default ACR values. The specific components of avoidable costs are defined in the PJM tariff.[149]

Effective for the 2018/2019 and subsequent delivery years, the ACR definition includes two additional components, Avoidable Fuel Availability Expenses (AFAE) and Capacity Performance Quantifiable Risk (CPQR).[150] AFAE is available for Capacity Performance Resources. AFAE is defined to include expenses related to fuel availability and delivery. CPQR is available for Capacity Performance Resources and, for the 2018/2019 and 2019/2020 Delivery Years, Base Capacity Resources. CPQR is defined to be the quantifiable and reasonably supported cost of mitigating the risks of nonperformance associated with submission of an offer.

The opportunity cost option allows capacity market sellers to offer based on a documented price available in a market external to PJM, subject to export limits. If the relevant RPM market clears above the opportunity cost, the generation capacity resource is sold in the RPM market. If the opportunity cost is greater than the clearing price and the generation capacity resource does not clear in the RPM market, it is available to sell in the external market.

Effective with the 2026/2027 Delivery Year, the market seller offer cap definition was modified to include unit specific standalone Capacity Performance Quantifiable Risk (CPQR) and segmented unit specific offer caps.[151] For standalone CPQR, the offer cap is defined as the unit specific CPQR with no net revenue offset applied. For segmented unit specific offer caps, the capacity market seller can request that the first segment of the segmented unit specific offer cap be based on either unit specific standalone CPQR or net unit specific ACR. The remaining segments from the second segment up to the tenth segment are defined to be based on standalone CPQR.[152]

Allowing offers based on gross CPQR when net revenues are greater than total gross ACR, including CPQR, permits offers greater than the competitive level by allowing resources with a competitive offer of $0 per MW-day to make positive offers equal to one component of ACR, the gross CPQR component,

ignoring net revenues entirely. The rule also permits offers greater than the competitive level by allowing resources with a competitive offer greater than $0 per MW-day but less than gross CPQR to make offers equal to one standalone component of ACR, the gross CPQR component, also ignoring EAS entirely.

The decision to allow segmented offer caps means allowing the exercise of market power. This is the case first because the segmented offer caps require that all avoidable costs be spread over a first MW segment that is smaller than the full resource, thus inflating the MSOC, and allow offer caps for all segments after the first segment based on gross CPQR with no net revenue offsets. If avoidable costs can be assigned to the first, self defined MW offer segment, and the later MW segments are not defined in the rules, MSOCs are meaningless. Assigning gross CPQRs and no net revenues to one or more undefined MW tail blocks would permit offers that exceed the correctly calculated MSOC by multiples and would permit the exercise of market power. The rule does not use any net revenue offset for the CPQR segments. The competitive level is defined as total gross avoidable costs, net of net revenues, divided by the total MW in the offer.

On October 17, 2024, the Commission issued a final rule, Order No. 904, eliminating separate payments for reactive in all jurisdictional markets, including PJM.[153] As a result, effective with the 2026/2027 Delivery Year, reactive revenues will not be included in the net revenue offset for RPM purposes including the VRR curve, market seller offer caps, and MOPR floors.[154]

Competitive Offers

The competitive offer of a capacity resource is based, regardless of tariff requirements, on a market seller's expectations of the resource's net going forward costs (net ACR) which are the net of the resource's gross ACR and the resource's forward looking net revenues. The gross ACR includes the cost to mitigate the resource's risk of incurring performance assessment penalties (CPQR).

153 *Compensation for Reactive Power within the Standard Power Factor Range*, Order No. 904, 189 FERC ¶ 61,034 (2024) ("Order No. 904").
154 See Letter Order, FERC Docket No. ER25-682-001 (April 29, 2025).

The competitive offer is based on a forward looking energy and ancillary services (E&AS) net revenue offset rather than the backward looking E&AS net revenue offset currently in the tariff. Forward prices for energy prices and fuel prices are a better guide to market expectations than historical energy and fuel prices but both sources of information should be incorporated. This is particularly important in years, like 2022, when there is a significant change from the historical level of energy market prices. The forward curves reflect this change, but the historical prices do not. However, the PJM method for calculating forward looking net revenues is significantly flawed and overestimates net revenues.

PJM had a forward looking net revenue calculation in the tariff that applied to RPM Auctions for the 2022/2023 Delivery Year.[155] FERC subsequently reversed its approval of that method as part of rejecting PJM's ORDC filing.[156] PJM's method for calculating forward looking E&AS net revenues was flawed for several reasons. PJM's method included an adjustment based on the prices of long term FTRs for the planning period closest in time to the delivery year which requires an adjustment for monthly average day-ahead congestion price differentials and an adjustment for loss component differentials of historical LMPs. Use of the adjustment based on the prices of long term FTRs adds unnecessary complexity, fails to make the result more accurate, makes the results less transparent, and in some cases make the results less accurate. PJM's use of long term FTRs in the forward energy market price calculation does not use the FTR auction for the desired delivery year as a result of the timing of capacity auctions and FTR auctions when PJM is on its defined three year capacity market auction schedule. It would be simpler, more accurate and more transparent to use forward LMPs calculated using real-time monthly on and off peak forward prices for the delivery year at the PJM Western Hub, adjusted to the zone and hour using the historical zonal, nodal and hourly real-time price differentials for each of the last three years. The MMU and PJM have been implementing this method for years in the calculation of the

155 171 FERC ¶ 61,153 (May 21, 2020) and 173 FERC ¶ 61,134 (November 12, 2020).
156 Forward energy and ancillary services (E&AS) revenue offsets were applicable from November 12, 2020, as approved in the FERC Order on compliance in Docket Nos. EL19-58-002 and EL19-58-003 until December 22, 2021, when the Commission issued an Order on Voluntary Remand in Docket Nos. EL19-58-006 and ER19-1486-003 reversing its prior determination that PJM should use a forward looking energy E&AS revenue offset and directing PJM to submit a compliance filing restoring the tariff provisions defining the historical E&AS revenue offset.

opportunity costs associated with environmental limits on the operation of generating units.[157]

More fundamentally, PJM's forward looking net revenue calculation tends to overestimate forward net revenues. The PJM method is based on a theoretical, unit by unit perfect dispatch based on unit parameters and forward fuel costs and LMPs. The PJM method fails to account for the realities of committing and dispatching units. Nonetheless, it remains correct that generation owners look forward and not backwards when calculating net revenues. The goal is an approach that retains the reality of historical commitment and dispatch while recognizing that future conditions will be different. A better approach would calculate unit forward looking expected energy and ancillary services net revenues using historical revenues that are scaled based on a comparison of forward prices for energy and fuel to the historical prices for energy and fuel.

The competitive offer of a capacity resource is based on a market seller's expectations of market variables during the delivery year, the impact of these variables on the resource's risk, and the cost to mitigate that risk. These market variables are: the number of performance assessment intervals (PAI) in a delivery year where the resource is located; the level of performance required to meet its capacity obligation during those performance assessment intervals, measured as the average Balancing Ratio (B); and the level of the bonus performance payment rate (CPBR) compared to the nonperformance charge rate (PPR). The total capacity revenues earned by a resource are the sum of revenues earned in the forward capacity auctions and additional bonus revenues earned (or penalties paid) during the delivery year, which are a function of unit performance during PAI (A). The level of the bonus performance payment rate depends on the level of underperforming MW net of the underperforming MW excused by PJM during performance assessment intervals for reasons defined in the PJM OATT.[158]

The September 2, 2021, Commission order addressed the definition of the market seller offer cap by eliminating the net CONE times B offer cap and establishing a competitive market seller offer cap of net ACR.[159] The Commission rejected a more recent attempt by PJM to undermine the Market Seller Offer Cap rules by order issued February 6, 2024.[160]

In February 2025, PJM filed, and FERC approved, changes to the Market Seller Offer Cap that allow Capacity Market Sellers to offer the higher of the net ACR and the Capacity Performance Quantifiable Risk (CPQR).[161] The changes also allow Capacity Market Sellers to submit resource specific segmented offer caps.[162] Both changes to the Market Seller Offer Cap give Capacity Market Sellers the ability to offer in excess of the competitive offer.

Allowing offers based on gross CPQR when net revenues are greater than total gross ACR, including CPQR, permits offers greater than the competitive level by allowing resources with a competitive offer of $0 per MW-day to make positive offers equal to one component of ACR, the gross CPQR component, ignoring net revenues entirely. The rule also permits offers greater than the competitive level by allowing resources with a competitive offer greater than $0 per MW-day but less than gross CPQR to make offers equal to one standalone component of ACR, the gross CPQR component, also ignoring EAS entirely.

The decision to allow segmented offer caps means allowing the exercise of market power. This is the case first because the segmented offer caps require that all avoidable costs be spread over a first MW segment that is smaller than the full resource, thus inflating the MSOC, and allow offer caps for all segments after the first segment based on gross CPQR with no net revenue offsets. If avoidable costs can be assigned to the first, self defined MW offer segment, and the later MW segments are not defined in the rules, MSOCs are meaningless. Assigning gross CPQRs and no net revenues to one or more undefined MW tail blocks would permit offers that exceed the correctly calculated MSOC by multiples and would permit the exercise of market power.

162 Id. at 123.

The rule does not use any net revenue offset for the CPQR segments. The competitive level is defined as total gross avoidable costs, net of net revenues, divided by the total MW in the offer.

2025/2026 RPM Third Incremental Auction

As shown in Table 5-16, 307 generation resources submitted Capacity Performance offers in the 2025/2026 RPM Third Incremental Auction. Unit specific offer caps were calculated for two generation resources (0.7 percent). Of the 307 generation resources, 238 generation resources elected the offer cap option of 1.1 times the BRA clearing price (77.5 percent), five generation resources had default ACR based offer caps (1.6 percent), two generation resource had a unit specific opportunity cost based offer cap (0.7 percent), five Planned Generation Capacity Resources had uncapped offers (1.6 percent), and the remaining 57 generation resources were price takers (18.6 percent). Market power mitigation was applied to zero Capacity Performance sell offers.

2026/2027 RPM Base Residual Auction

As shown in Table 5-16, 1,293 generation resources submitted Capacity Performance offers in the 2026/2027 RPM Base Residual Auction. Unit specific offer caps were calculated for 82 generation resources (6.3 percent). Of the 1,293 generation resources, 735 generation resources had default ACR based offer caps (56.8 percent), 26 generation resources had unit specific ACR based offer caps (2.1 percent), 48 resources had unit specific standalone CPQR offer caps (3.7 percent), 6 generation resources had unit specific opportunity cost based offer caps (0.5 percent), 2 generation resources had unit specific opportunity cost based offer caps and default ACR based offer caps (0.2 percent), 26 Planned Generation Capacity Resources had uncapped offers (2.0 percent), and the remaining 450 generation resources were price takers (34.8 percent). Market power mitigation was applied to 23 Capacity Performance sell offers.

Table 5-16 ACR statistics: RPM auctions held through the first nine months, 2025

	2025/2026 Third Incremental Auction		2026/2027 Base Residual Auction	
Offer Cap/Mitigation Type	Number of Generation Resources	Percent of Generation Resources Offered	Number of Generation Resources	Percent of Generation Resources Offered
Default ACR	5	1.6%	735	56.8%
Unit specific ACR (APIR)	0	0.0%	4	0.3%

Total Generation Capacity Resources offered	307	100.0%	1,293	100.0%

MOPR

By order issued December 19, 2019, the RPM Minimum Offer Price Rule (MOPR) was modified.[163] The rules applying to natural gas fired capacity resources without state subsidies were retained. The changes included expanding the MOPR to new or existing state subsidized capacity resources; establishing a competitive exemption for new and existing resources other than natural gas fired resources while also allowing a resource specific exception process for those that do not qualify for the competitive exemption; defining limited categorical exemptions for renewable resources participating in renewable portfolio standards (RPS) programs, self supply, DR, EE, and capacity storage; defining the region subject to MOPR for capacity resources with state subsidy as the entire RTO; and defining the default offer price floor for capacity resources with state subsidies as 100 percent of the applicable Net CONE or net ACR values.

The Commission convened a Technical Conference on March 23, 2021, in order to consider whether MOPR should be retained and to consider possible alternative approaches.[164] The MMU testified at the Technical Conference and provided comments and responses to the Commission's questions following the conference.[165]

On September 29, 2021, PJM's FPA section 205 filing in Docket No. ER21-2582-000 revising the Minimum Offer Price Rule (MOPR) was made effective by operation of law.[166] The revised MOPR in OATT Attachment DD § 5.14(h-2) is effective for RPM auctions for the 2023/2024 and subsequent delivery years. Under the revised MOPR, a generation resource would be subject to an offer floor if the capacity is deemed to meet the definition of Conditioned State Support or if the capacity market seller plans to use the resource to exercise Buyer-Side Market Power as the term is defined in the tariff through either self certification or a fact specific review initiated by the MMU or PJM. Whether a state program or policy qualifies for Conditioned State Support would be the result of a Commission determination.

163 169 FERC ¶ 61,239 (2019), *order denying reh'g*, 171 FERC ¶ 61,035 (2020), *aff'd* PJM Power Providers Group, et al. v. FERC, Case No. 21-3068 (3rd Cir. December 1, 2023), *cert denied.*
164 Technical Conference regarding Resource Adequacy in the Evolving Electricity Sector, Docket No. AD21-10 (March 23, 2021).
165 *Modernizing Electricity Market Design*, Comments of the Independent Market Monitor for PJM, Docket No. AD21-10 (April 26, 2021).
166 *PJM Interconnection, L.L.C*, Notice of Filing Taking Effect by Operation of Law, Docket No. ER21-2582 (September 29, 2021).

The MMU's filing in response to PJM's proposal was clear. The PJM markets would be better off, more competitive, and more efficient with no MOPR than with PJM's proposed approach. PJM's proposal would effectively eliminate the MOPR while creating a confusing and inefficient administrative process that effectively makes it both unnecessary and impossible to prove buyer side market power as PJM has defined it.[167]

The Commission approved PJM's proposed revisions to the PJM market rules to implement a forward looking E&AS offset to include forward looking energy and ancillary services revenues rather than historical. The change in the offset affected MOPR floor prices and the results of unit specific reviews under MOPR in the 2023/2024 BRA. This decision was reversed in the Commission's order related to the ORDC matter.

MOPR Statistics

Under the applicable MOPR rules, market power mitigation measures were applied to MOPR Screened Generation Resources such that the sell offer is set equal to the MOPR Floor Offer Price when the submitted sell offer is less than the MOPR Floor Offer Price and an exemption or exception was not granted, or the sell offer is set equal to the agreed upon minimum level of sell offer when the sell offer is less than the agreed upon minimum level of sell offer based on a Unit-Specific Exception or Resource-Specific Exception.

As shown in Table 5-17, there were no unit specific exception requests for MOPR under OATT Attachment DD § 5.14(h-2) for the 2025/2026 RPM Third Incremental Auction or for the 2026/2027 RPM Base Residual Auction. Of the 583.9 MW offered in the 2025/2026 RPM Third Incremental Auction that were subject to MOPR, 583.9 MW cleared and 0.0 MW did not clear. Of the 267.6 MW offered in the 2026/2027 RPM Base Residual Auction that were subject to MOPR, 237.4 MW cleared and 30.2 MW did not clear.

Replacement Capacity[168]

When a capacity resource is not available for a delivery year, the owner of the capacity resource may purchase replacement capacity. Replacement capacity is the vehicle used to offset any reduction in capacity from a resource which is not available for a delivery year. But the replacement capacity mechanism may also be used to manipulate the market.

Table 5-18 shows the committed and replacement capacity for all capacity resources for June 1 of each year from 2007 through 2026.

Sellers of demand resources in RPM auctions disproportionately replace those commitments on a consistent basis compared to sellers of other resource types. External generation and internal generation not in service had high rates of replacement in some years and those are also of concern.

The dynamic that can result is that the speculative DR suppresses prices in the BRA and displaces physical generation assets. Those generation assets then have an incentive to offer at a low price, including offers at zero and below cost, in IAs in order to ensure some capacity market revenue for long lived physical resources which the owners expect to maintain for multiple years. The result is lower IA prices which permit the buyback of the speculative DR at prices below the BRA prices which encourages the greater use of speculative DR.

PJM's sale of capacity in IAs at very low prices, given that PJM announces the MW quantity and the sell offer price in advance of the auctions, further reduces IA prices and increases the incentive of DR sellers to speculate in the BRAs. The MMU recommends that if PJM sells capacity in incremental auctions, PJM should offer the capacity for sale at the BRA clearing price in order to avoid suppressing the IA price below the competitive level. If the PJM sell offer price is not the BRA clearing price, PJM should not reveal its proposed sell offer price or the MW quantity to be sold prior to the auction.

It has been asserted that selling at a high price in the BRA and buying back at a low price in the IA is just a market transaction and therefore does not constitute a problem. But permitting DR to be an option in the BRA rather than requiring DR to be a commitment to provide a physical asset gives DR an unfair advantage and creates a self fulfilling dynamic that incents more of the same behavior. Only DR is permitted to be an option in the BRA. Generation resources must have met physical milestones in order to offer in the BRA. It is not reasonable to permit DR capacity resources to have a different product definition than generation capacity resources. Even if DR is treated as an annual product, this unique treatment as an option makes DR an inferior resource and not a complete substitute for generation resources. The current approach to DR is also inconsistent with the history of the definition of capacity in PJM, which has always been that capacity is physical and unit specific. The current approach to DR effectively makes DR a virtual participant in the PJM Capacity Market. That option should be eliminated.

The definition of demand side resources in PJM capacity markets is flawed in a variety of ways. The current demand side definition should be replaced with a definition that includes demand on the demand side of the market. There are

168 For more details on replacement capacity, see "Analysis of Replacement Capacity for RPM Commitments: June 1, 2007 to June 1, 2019," <http://www.monitoringanalytics.com/reports/Reports/2019/IMM_Analysis_of_Replacement_Capacity_for_RPM_Commitments_June_1_2007_to_June_1_2019_20190913.pdf> (September 13, 2019).

ways to ensure and enhance the vibrancy of demand side without negatively affecting markets for generation.

Market Performance

Figure 5-8 shows cleared MW weighted average capacity market prices on a delivery year basis including base and incremental auctions for each delivery year, and the weighted average clearing prices by LDA in each Base Residual Auction for the entire history of the PJM capacity markets.

Table 5-19 shows RPM clearing prices for the 2021/2022 through 2026/2027 Delivery Years for all RPM auctions held through the first nine months of 2025, and Table 5-20 shows the RPM cleared MW for the 2021/2022 through 2026/2027 Delivery Years for all RPM auctions held through the first nine months of 2025.

Figure 5-9 shows the RPM cleared MW weighted average prices for each LDA from the 2022/2023 Delivery Year to the current delivery year, and all results for auctions for future delivery years that have been held through the first nine months of 2025. A summary of these weighted average prices is given in Table 5-21.

Table 5-22 shows RPM revenue by delivery year for all RPM auctions held through the first nine months of 2025 based on the unforced MW cleared and the resource clearing prices. For the 2024/2025 Delivery Year, RPM revenue is $2.6 billion. For the 2025/2026 Delivery Year, RPM revenue is $14.9 billion.

Table 5-23 shows RPM revenue by calendar year for all RPM auctions held through the first nine months of 2025. In 2024, RPM revenue is $2.5 billion. In 2025, RPM revenue is $9.8 billion.

Table 5-24 shows the RPM annual charges to load. For the 2024/2025 Delivery Year, annual charges to load are $2.5 billion. For the 2025/2026 Delivery Year, annual charges to load are $14.8 billion.

Table 5-19 Capacity market clearing prices: 2021/2022 through 2026/2027 RPM Auctions[169]

		RPM Clearing Price ($ per MW-day)

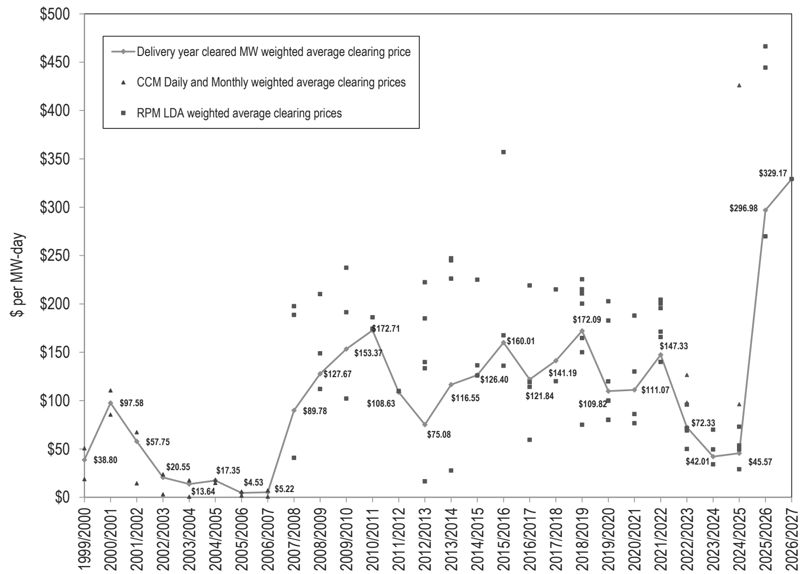
Figure 5-8 History of capacity prices: 1999/2000 through 2026/2027[173]



172 The results for the ATSI Integration Auctions are not included in this table.

173 The 1999/2000 through 2006/2007 capacity prices are CCM combined market, weighted average prices. The 2007/2008 through 2025/2026 capacity prices are RPM weighted average prices. The CCM data points plotted are cleared MW weighted average prices for the daily and monthly markets by delivery year. The RPM data points plotted are RPM LDA clearing prices. For the 2014/2015 and subsequent delivery years, only the prices for Annual Resources or Capacity Performance Resources are plotted.

Figure 5-9 Map of RPM capacity prices: 2023/2024 through 2026/2027

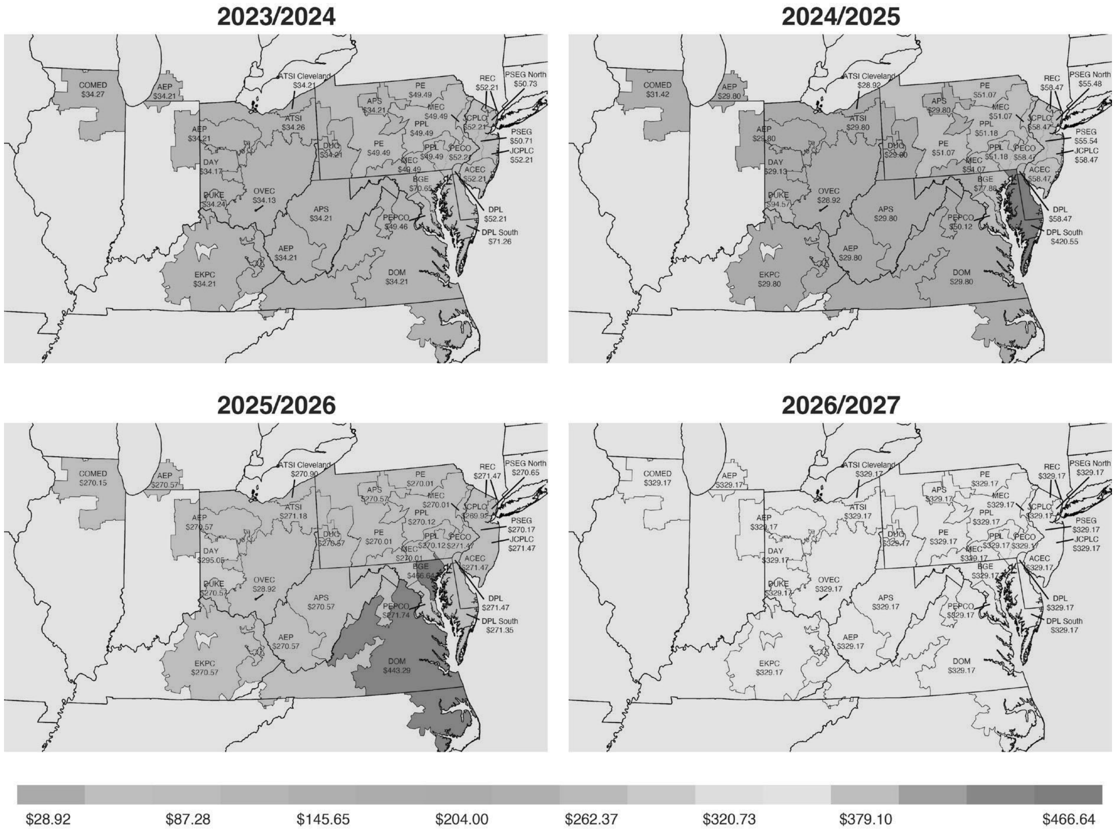


Table 5-24 RPM cost to load: 2023/2024 through 2026/2027 RPM Auctions[174 175]

	Net Load Price ($ per MW-day)	UCAP Obligation (MW)	Annual Charges
2023/2024			
Rest of RTO	$34.18	78,896.5	$986,982,057
EMAAC	$50.96	30,972.7	$577,657,195
WMAAC	$49.58	22,401.9	$406,535,572

Total		150,111.7	$2,497,161,960
2025/2026			
Rest of RTO	$270.43	108,328.9	$10,692,932,080
BGE	$306.84	6,005.7	$672,628,585
DOM	$432.48	21,570.5	$3,405,010,751
		135,905.1	$14,770,571,416
2026/2027			
Rest of RTO	$329.17	134,205.3	$16,124,370,889
		134,205.3	$16,124,370,889

174 The RPM annual charges are calculated using the rounded, net load prices as posted in the PJM RPM auction results.
175 There is no separate obligation for DPL South as the DPL South LDA is completely contained within the DPL Zone. There is no separate obligation for PSEG North as the PSEG North LDA is completely contained within the PSEG Zone. There is no separate obligation for ATSI Cleveland as the ATSI Cleveland LDA is completely contained within the ATSI Zone.

FRR

The states have authority over their generation resources and can choose to remain in PJM capacity markets or to create FRR entities. The existing FRR approach remains an option for utilities with regulated revenues based on cost of service rates, including both privately and publicly owned (including public power entities and electric cooperatives) utilities. Such regulated utilities have had and continue to have the ability to opt out of the capacity market and provide their own capacity. The existing FRR rules were created in 2007 primarily for the specific circumstances of AEP as part of the original RPM capacity market design settlement. The MMU recommends that the FRR rules be revised and updated to ensure that the rules reflect current market realities and that FRR entities do not unfairly take advantage of those customers paying for capacity in the PJM Capacity Market.

The MMU has prepared reports with analysis of the potential impacts on states pursuing the FRR option. In separate reports for Illinois, Maryland, New Jersey, Ohio, Virginia, and the District of Columbia, the cost impacts of the state choosing the FRR option are computed under different FRR capacity price assumptions and different assumptions regarding the composition of the FRR service area.[176 177 178 179 180 181] The reports showed that the FRR approach is likely to lead to significant increases in payments by customers if it were to replace participation in the PJM markets. The impact on the remaining PJM capacity market footprint is also computed for each scenario. In all but a few scenarios the MMU finds that the FRR leads to higher costs for load included in the FRR service area. In all scenarios the MMU finds that prices in what remains of the PJM Capacity Market would be significantly lower.

Both FERC and the states have significant and overlapping authority affecting wholesale power markets. While the FERC MOPR approach was designed to ensure that subsidies did not affect the wholesale power markets, the states have ultimate authority over the generation choices made in the states. The FRR explorations by multiple states illustrated a possible path forward. Under that path, the FERC regulated markets would be unaffected by subsidies but many states would withdraw from the FERC regulated markets and create higher cost nonmarket solutions rather than be limited by MOPR. That would not be an efficient outcome and would not serve the interests of customers or generators.

With the elimination of the prior MOPR rules, the capacity market design must accommodate the choices made by states to subsidize renewable resources in a way that maximizes the role of competition to ensure that customers pay the lowest amount possible, consistent with state goals and the costs of providing the desired resources. Such an approach can take several forms, but none require the dismantling of the PJM capacity market design. The PJM capacity market design can adapt to a wide range of state supported resources and state programs. As a simple starting point, states can continue to support selected resources using a range of payment structures and those resources could participate in the capacity auctions. As a broader and more comprehensive option, PJM could create a central PJM RECs market to facilitate the competitive sale and purchase of RECs.

Dominion Energy Virginia elected the FRR option for the 2022/2023 through 2024/2025 Delivery Years but returned to the capacity market for the 2025/2026 BRA.

CRF Issue[182]

As a result of the significant changes to the federal tax code in December 2017, the capital recovery factor (CRF) tables in PJM OATT Attachment DD § 6.8(a) and Schedule 6A were not correct. These tables should have been updated in 2018. Correct CRFs ensure that offer caps and offer floors in the capacity market are correct. On May 4, 2021, PJM filed updates to the OATT under FPA Section 205.[183] In the filing, PJM proposed new CRFs based on the new tax law and new financial assumptions. The new financial assumptions are identical to the assumptions used in the PJM quadrennial review for the calculation of the cost of new entry (CONE) for the PJM reference resource. The MMU, in comments to the Commission, asked that the following formula be included in the tariff as an efficient alternative to use of tables which require updates whenever tax laws or financial assumptions change:[184] [185]

$$\mathrm{CRF} = \frac{r(1+r)^N\left[1 - \frac{sB}{\sqrt{1+r}} - s(1-B)\sqrt{1+r}\sum_{\mathrm{j}=1}^{\mathrm{L}}\frac{\mathrm{m_j}}{(1+\mathrm{r})^{\mathrm{j}}}\right]}{(1-s)\sqrt{1+\mathrm{r}}\,[(1+r)^N - 1]}$$

The MMU also proposed that PJM discontinue the practice of using an average state tax rate in the CRF calculation. The CRF formula allows for the quick and efficient calculation of a unit's CRF using the state tax rate that is applicable to a specific unit.

FERC accepted PJM's filing but also required that the CRF formula be included in the tariff.[186] FERC rejected the MMU's unit specific state tax recommendation. Going forward, PJM will post the CRFs on their website. Table 5-26 shows the CRFs that are currently posted. The values in Table 5-26 were calculated using the formula above and the financial assumptions in Table 5-27. Bonus depreciation assumptions vary by delivery year with

182 See related filing on CRF issue in black start: Comments of the Independent Market Monitor for PJM, Docket No. ER21-1635 (April 28, 2021).
183 "Revisions to Capital Recovery Factor for Avoidable Project Investment Cost Determinations and Request for Waiver of Sixty-Day Notice Requirement," PJM Interconnection L.L.C., Docket No. ER21-1844-000 (May 4, 2021).
184 See "Comments of the Independent Market Monitor for PJM," Docket No. ER21-1844-000 (May 25, 2021).
185 The formula was first introduced in a related Section 205 filing regarding CRFs for black start service. See "Comments of the Independent Market Monitor for PJM" (April 28, 2021) and "Answer and Motion to Answer of the Independent Market Monitor for PJM" (May 19, 2021) in Docket No. ER21-1635-000.
186 176 FERC ¶61,003 (2021).

100 percent bonus depreciation assumed in the 2022/2023 Delivery Year. The bonus depreciation in each subsequent delivery year is reduced by 20 percent.

Table 5-25 Variable descriptions for the CRF formula

Formula Symbol	Description
r	After tax weighted average cost of capital (ATWACC)
s	Effective tax rate
B	Bonus depreciation percent
N	Cost Recovery Period (years)
L	Lesser of N or 16 (years)
mj	Modified Accelerated Cost Recovery System (MACRS) depreciation factor for year j = 1, ..., 16

The MMU supports the changes to the tariff to correct the application of CRF to the capacity market but there are still unresolved issues. The tariff revisions lack clarity about how CRF values will be determined in the future and to which projects they apply, and lack clarity about how CRF values would be applied to APIR for project costs that are currently being recovered. For example, Table 5-26, which is identical to the table posted by PJM, includes CRF values for projects that go into service for four identified delivery years but fails to note that these CRF values for a later delivery year would not apply for investments made in prior delivery years that will still be in service in the later delivery year.[187] For example, a project that can use the depreciation provisions relevant for the 2023/2024 Delivery Year uses the depreciation provisions once and those provisions affect the project's CRF for its entire life, regardless of the CRF values in the table for subsequent delivery years. However, changes in the tax rate apply each year and if the tax rate changes the applicable CRF values would change for all projects, regardless of vintage. As a result, the CRF values in Table 5-26 for delivery years after 2023/2024 would not apply to the calculation of APIR values for projects that go into service for the 2023/2024 Delivery Year. A similar issue exists for projects that were assigned a CRF under the previous tariff rules. The change in the tax rate should be reflected in the CRF going forward. PJM does not plan to do this and the Commission stated that the issue is beyond the scope of the PJM filing.[188]

187 See "Capital Recovery Factors ("CRF") for Avoidable Project Investment Cost ("APIR") Determinations," <https://pjm.com/-/media/markets-ops/rpm/rpm-auction-info/crf-values-for-apir-determination.ashx>.
188 176 FERC ¶61,003 at P 28 (2021).

On July 4, 2025, with the enactment of the One Big Beautiful Bill Act ("OBBBA"), the bonus depreciation rules changed again. Section 70301 of OBBBA (I.R.C. § 168(k)) allows 100 percent bonus depreciation for "qualified production property ("QPP") acquired and placed in service on or after January 20, 2025.[189] QPP means nonresidential real property used in manufacturing, production, or refining of tangible personal property in the United States.[190] To be eligible, construction must begin after January 19, 2025, and before January 1, 2029, and the property must be placed in service before January 1, 2031.[191] The formula rate calculation of the CRF values in Paragraph 18 of OATT Schedule 6A for units entering service after June 6, 2021, must be implemented to reflect the correct bonus depreciation. It is essential that PJM not repeat its earlier mistake when it ignored the tax law changes in 2017.

Table 5-26 Levelized CRF values: Delivery Year 2023/2024 through Delivery Year 2026/2027

	Cost	2023/2024	2024/2025	2025/2026	2026/2027

191 *Id.*

The 2021 update to the CRF values was calculated using the weighted average cost of capital (WACC) model. The original CRF values, prior to 2021, were calculated using a flow to equity (FTE) model. The WACC model assumes a constant debt to equity ratio during the capital recovery period and therefore assumes that debt holders are paid more quickly than is required. The FTE model recognizes that the debt is repaid according to a predetermined payment schedule with all revenue in excess of taxes and debt payments going to the equity investor. The FTE model accurately reflects the cash flows that occur during capital recovery. Table 5-28 compares CRFs calculated under the two approaches using the assumptions in Table 5-27. The difference between the WACC CRF and FTE CRF is dependent upon the capital recovery term and the level of bonus depreciation. The WACC CRF exceeds the FTE CRF by 16.4 percent under 100 percent bonus depreciation with a 30 year cost recovery term. The FTE model is the correct approach because it accurately captures the cash flows during capital recovery over the defined financial life of the asset.

Timing of Unit Retirements

Generation owners that want to deactivate a unit, either to mothball or permanently retire, must provide notice to PJM and the MMU prior to the proposed deactivation date. Prior to September 2022, generation owners were required to provide deactivation notices at least 90 days before the proposed deactivation date. Beginning in September 2022, PJM and the MMU began reviewing deactivation requests quarterly, and the desired deactivation date is now based on the quarter the request was submitted (Table 5-29). The result is no change to the effective period between the notice and the retirement if notice is provided on the last day of the submittal period, and an increase to six months notice if notice is given on the first day of the submittal period. The MMU recommends that participants be required to provide a notice of deactivation 12 months prior to an auction in which the unit will not be offered due to the deactivation; and no less than 12 months prior to the date of deactivation.

Table 5-29 Earliest deactivation dates allowed based on quarterly submission

Date Request Submitted	Earliest Deactivation Date Permitted
January 1 to March 31	July 1
April 1 to June 30	October 1
July 1 to September 30	January 1 (following calendar year)
October 1 to December 31	April 1 (following calendar year)

Generation owners seeking a capacity market must offer exemption for a delivery year must submit their deactivation request no later than the December 1 preceding the Base Residual Auction or 120 days before the start of an Incremental Auction for that delivery year.[192] If no reliability issues are found during PJM's analysis of the retirement's impact on the transmission system, and the MMU finds no market power issues associated with the proposed deactivation, the unit may deactivate at any time thereafter.[193]

Table 5-30 shows the timing of actual deactivation dates and the initially requested deactivation date, for all deactivation requests submitted from January 2018 through September 2025. Of the 222 deactivation requests submitted, 32 units (14.4 percent) deactivated an average of 153 days earlier than their initially requested date; 34 units (15.3 percent) deactivated an average of 120 days later than the originally requested deactivation date; and 87 units (39.2 percent) deactivated on their initially requested date. Thirty six (16.2 percent) of the unit deactivations were cancelled an average of 298 days (approximately 42 weeks) before their scheduled deactivation date, and 33 (14.9 percent) of the unit deactivations have not yet reached their target retirement date. Table 5-31 shows this information broken out by fuel types.

Due to the significant increase in the capacity price for the 2025/2026 Delivery Year, several units that were scheduled to deactivate rescinded their deactivation request. In 2024, Middle River Power, LLC, rescinded the deactivation of 483 MW from the Elgin CT 1-4 units. In the first nine months of 2025, 11 other units that were slated to deactivate (108 MW from Gen On Energy Management, LLC rescinding Morgantown CT 3 & 4; 54.9 MW from Constellation Energy Co. rescinding Perryman 6 unit 1; 15 MW from Tenaska Power Services, Co. rescinding Kenilworth; 272.1 MW from NRG Business Marketing LLC rescinding Fisk CT 31- 34 and Waukegan CT 31 & 32), accounting for 450.0 MW, rescinded their deactivation requests as a result of the 2025/2026 BRA clearing prices.

Table 5-30 Timing of actual unit deactivations compared to requested deactivation date: Requests submitted January 2018 through September 2025[194]

Status	Number of Units	Percent	Average Days Deviation from Originally Requested Date

Part V Reliability Service (RMR)

PJM must make out of market payments to units that want to retire (deactivate) but that PJM requires to remain in service, for limited operation, for a defined period because the unit is needed for reliability.[195] This provision has been known as Reliability Must Run (RMR) service but RMR is not defined in the PJM tariff, and the PJM market design has important distinguishing features relative to other regions where arrangements referred to as RMR are used. Here the term Part V reliability service is used. The need to retain uneconomic units in service reflects a flawed market design and/or planning process problems. The current capacity market design fails to include transmission constraints inside LDAs with the result that units needed for reliability do not clear in capacity auctions and that prices are suppressed and an RMR is then required. The current approach does not adequately look forward and attempt to address foreseeable unit retirements, whether for economic or regulatory reasons. The result is the wrong price signal for either investing in the existing resource or investing in new resources to provide locational reliability. The answer is not to artificially increase prices during the RMR while the transmission alternative is under construction but to provide an actionable price signal in advance of retirement as a signal to new generation to enter and compete with the transmission solution. It is essential that the deactivation provisions of the tariff be evaluated and modified, both to provide rules that better anticipate deactivations in the markets and rules that reasonably compensate Part V reliability service if it is still needed. Recent changes to the rules fail to address these issues.[196] It is also essential that queue processes that effectively prevent competition from new generation to replace the old generation be modified.

To improve coordination of deactivations and PJM transmission system planning, the MMU recommends that the same reliability standard be used in capacity auctions as is used by PJM transmission planning which means recognizing transmission constraints inside LDAs when they create reliability issues. One result of the current design is that a unit may fail to clear in a BRA, decide to retire as a result, but then be found to be needed for reliability by PJM planning and paid under Part V of the OATT (RMR) to remain in service while transmission upgrades are made. This result indicates a significant market design flaw.

The MMU recommends that PJM treat the inclusion of RMR resources in the capacity market consistently. PJM currently includes RMR units in the reliability analysis for RPM auctions but does not include the RMR units in the supply curves. This approach is internally inconsistent. It would be internally consistent to leave the RMR units out of the CETO/CETL analysis. It would also be internally consistent to include the RMR units in the supply of capacity and in the CETO/CETL analysis. Including RMR resources in the capacity supply curve does not mean forcing unit owners to offer or to take on PAI risk, for example. It simply means that PJM would recognize the fact that PJM treats RMR resources as a source of reliability. The goal is to ensure that the underlying supply and demand fundamentals are included in the capacity market prices. These two options have very different implications for capacity market prices. There are times early in the process when a price signal for the entry of generation is appropriate, e.g. when the goal is to allow generation to compete to replace the transmission option, in whole or in part, and there is enough time to permit such new entry. There are times later in the process when a price signal for the entry of generation is not needed or appropriate, e.g. when PJM has committed to the construction of new transmission that will eliminate the price signal when complete or when there is not enough time to permit such new entry. The relevant rules can and should be changed.[197]

The planning process should, to the extent possible, evaluate the impact of the loss of units at risk and determine in advance whether transmission upgrades are required.[198] It is essential that PJM look forward and attempt to plan for foreseeable unit retirements, whether for economic or regulatory reasons. While not all retirements are completely foreseeable, improvement is needed

195 OATT Part V §114.

196 See Deactivation Enhancements Senior Task Force (DESTF), which can be accessed at: <https://www.pjm.com/committees-and-groups/task-forces/destf>.

197 While PJM filed for and FERC accepted the inclusion of RMR resources Brandon Shores and Wagner plants in the 2026/2027 BRA and 2027/2028 BRA, that does not require that RMR resources be included in capacity market auction clearing in future auctions for these or other RMR resources. See Letter Order, FERC Docket No. ER25-682-001 (April 29, 2025).

198 *See, e.g.*, 140 FERC ¶ 61,237 at P 36 (2012) ("The evaluation of alternatives to an SSR designation is an important step that deserves the full consideration of MISO and its stakeholders to ensure that SSR Agreements are used only as a 'limited, last-resort measure.'"); 118 FERC ¶ 61,243 at P 41 (2007) ("the market participants that pay for the agreements pay out-of-market prices for the service provided under the RMR agreements, which broadly hinders market development and performance.[footnote omitted] As a result of these factors, we have concluded that RMR agreements should be used as a last resort."); 110 FERC ¶ 61,315 at P 40 (2005) ("The Commission has stated on several occasions that it shares the concerns . . . that RMR agreements not proliferate as an alternative pricing option for generators, and that they are used strictly as a last resort so that units needed for reliability receive reasonable compensation.").

in the process for ensuring that planning is looking at the probability of retirements, especially of resources that are critical to locational reliability in order to minimize the duration of any RMR requirement.

The actual implementation of Part V of the tariff has resulted in overpayment of the RMR resources. It is essential that the compensation provisions of Part V of the tariff be modified to ensure payment of all but only the actual costs incurred by the generation owner to provide the service, plus an incentive. Generators operating in competitive markets should be required, as an obligation of receiving interconnection service and having the ability to participate in competitive markets, to provide service under Part V on an incremental cost plus incentive basis when they are needed for reliability.

When notified of an intended deactivation, the MMU performs a market power study to ensure that the deactivation is economic, not an exercise of market power through withholding, and consistent with competition.[199] If the MMU determines that expected revenues exceed avoidable costs and therefore that the deactivation is not economic, the MMU will inform the unit owner that there is a market power issue. The MMU has no authority to prevent the retirement. The MMU can pursue the matter at FERC. Part V status by itself creates market power for the retiring resource. The owners of Part V resources have threatened to shut down the resources and put the grid at risk if they do not receive their requested level of Part V payments. Such exercises of market power have been effective in increasing payments to Part V units during the settlement proceedings that have resolved all Part V filings, generally on a black box basis.

PJM performs a system study to determine whether the system can accommodate the deactivation on the desired date, and if not, when it could.[200] If PJM determines that it needs a unit for a period beyond the intended deactivation date, PJM will request a unit to remain in service for a defined period.[201] The PJM market rules do not require an owner to remain in service. Owners must provide notice of a proposed deactivation at least twelve months prior to the desired deactivation date, although the advance notice can be too short to permit new generation to enter (See Table 5-29).[202] [203] The owner of a generation capacity resource must provide notice of a proposed deactivation in order to avoid a requirement to offer in RPM auctions.[204] In order to avoid submitting an offer for a unit in the next three-year forward RPM base residual auction based on retirement, an owner must submit a preliminary RPM must offer exception request no later than September 1 preceding the BRA and a final RPM must offer exception request demonstrating "a documented plan in place to retire the resource," including a notice of deactivation filed with PJM no later than December 1 preceding the BRA.[205]

Under the current rules, a unit remaining in service at PJM's request can recover its costs of continuing to operate under either the deactivation avoidable cost rate (DACR), which is a formula rate, or the cost of service recovery rate. The deactivation avoidable cost rate is designed to permit the recovery of the costs of the unit's "continued operation," termed "avoidable costs," plus an incentive adder.[206] Avoidable costs are defined to mean "incremental expenses directly required for the operation of a generating unit."[207] The incentives escalate for each year of service (first year, 10 percent; second year, 20 percent; third year, 35 percent; fourth year, 50 percent).[208] The rules provide terms for the repayment of project investment by owners of units that choose to keep units in service after the defined period ends.[209] The amount of project investment recovered cannot exceed the actual amount of the PI.[210] The cost of service rate is designed to permit the recovery of the unit's "cost of service rate to recover the entire cost of operating the generating unit" if the generation owner files a separate rate schedule at FERC.[211]

The DACR is unnecessarily prescriptive about the nature of the incremental costs needed to provide service, and includes unsupported escalation to extremely high incentive rates.

Table 5-32 shows units that have provided Part V reliability service to PJM, including the Indian River 4 unit, which began providing RMR service on June 1, 2022, and ended on February 24, 2025.[212] Only two of nine owners have used the deactivation avoidable cost rate approach. The other seven owners used the cost of service recovery rate. For units using the cost of service recovery rate option, revenues have averaged about 2.9 times the corresponding market price of capacity while for units using the deactivation avoidable cost rate, revenues have averaged about 1.6 times the corresponding market price of capacity.[213]

In each of the cost of service recovery rate filings for Part V reliability service, the scope of recovery permitted under the cost of service approach defined in Section 119 has been a significant issue. Owners have sought to recover fixed costs, incurred prior to the noticed deactivation date, in addition to the cost of operating the generating unit. Owners have cited the cost of service reference to mean that the unit is entitled to file to recover sunk costs that it was unable to recover in the competitive markets, in addition to recovery of costs of actually providing the Part V reliability service.

The cost of service recovery rate approach has been interpreted by the companies using that approach to allow the company to develop the type of rate case filing used by regulated utilities, using a test year with adjustments, to establish a rate base including investment in the existing plant and new investment necessary to remain in service and to earn a return on that rate base and receive depreciation of that rate base, plus guarantee recovery of estimated operation and maintenance expenses without verification of actual expenses. Despite the asserted reliance on traditional cost of service ratemaking principles, in practice generators seek approval of high rates that have weak or non existent support in law and fact relative to what has been traditionally required to justify of cost of service rates. Companies developing the cost of service recovery rate have ignored the tariff's limitation to the costs of operating the unit during the Part V reliability service period and have included costs incurred prior to the decision to deactivate and costs associated with closing the unit that would have been incurred regardless of the Part V reliability service period.[216] In some cases, the filing included costs that already had been written off, or impaired, on the

214 Actual cost data includes RMR charges through August 31, 2025.
215 The actual cost data for Indian River 4 include a refund of the difference between the filed rate that was collected pending resolution and the RMR settlement amount.
216 See, e.g., FERC Dockets Nos. ER10-1418-000, ER12-1901-000 and ER17-1083-000.

company's public books.[217] [218] In another case, the filing ignored evidence of actual book value based on market purchase of the asset.[219] The cost of service recovery rates substantially exceed the actual costs of operating to provide the reliability required by PJM. The costs are generally not subject to review, audit and verification. The Commission has approved black box settlement rates (i.e., no explicit basis for the rate is stated) that included arbitrarily inflated asset values and costs, despite protests.[220]

Because such units are needed by PJM for reliability reasons, and the provision of the service is voluntary in PJM, owners of units that PJM needs to remain in service after the desired retirement date have significant market power in establishing the terms of this reliability service which have generally been set through settlements.

This reliability service should be provided to PJM customers at reasonable rates, which reflect the relatively low risk nature of providing such service to owners, the reliability need for such service and the opportunity for owners to be guaranteed recovery of 100 percent of the actual incremental costs required to operate to provide the service plus an incentive.

The MMU recommends elimination of both the cost of service recovery rate in OATT Section 119 and the deactivation avoidable cost rate in Part V, and their replacement with clear language that provides for the recovery of 100 percent of the actual incremental costs required to operate to provide the service plus an incentive.

The MMU recommends that units recover all and only the incremental costs, including incremental investment costs without a cap, required to provide Part V reliability service (RMR service) that the unit owner would not have incurred if the unit owner had deactivated its unit as it proposed, plus a defined incentive payment. Customers should bear no responsibility for paying previously incurred (sunk) costs, including a return on or of prior investments.

Department of Energy (DOE) 202(c) Orders

Eddystone

On May 30, 2025, the Department of Energy (DOE) issued an order under Section 202(c) of the Federal Power Act stating that the operational availability and economic dispatch of Eddystone units 3 and 4 is necessary to meet an emergency and serve the public interest.[221] The order requires that Constellation Energy, LLC and PJM take measures to ensure that Eddystone units 3 and 4 are available to operate from May 30, 2025, through 5:03 PM EDT on August 28, 2025.[222] Eddystone Units 3 and 4 were previously scheduled to retire on May 31, 2025.

PJM and Constellation notified the Commission by letter dated June 26, 2025, that they had agreed to a rate for service under Section 202(c) based on a modified version of the Deactivation Avoidable Cost Credit method included in Section 114 of the OATT. The modified approach ensure rates based on the actual fuel costs for operating the units and a reasonable approximation of actual avoidable costs rather than the arbitrary regulated cost of service model in recent RMR cases.

On June 9, 2025, the PJM Board of Managers initiated a Critical Issue Fast Path (CIFP) stakeholder process to address the allocation of costs associated with the payments to Constellation for continuing to operate Eddystone units 3 and 4.[223] On June 26, 2025, PJM filed a cost allocation methodology related to the retention of Eddystone units 3 and 4.[224] On August 15, 2025, FERC issued an order accepting PJM's cost allocation methodology related to the retention of Eddystone units 3 and 4.[225]

On August 28, 2025, the DOE issued a subsequent order under Section 202(c) of the Federal Power Act extending the directive that Constellation Energy,

LLC and PJM take measures to ensure that Eddystone units 3 and 4 are available to operate from August 28, 2025, through November 26, 2025.[226]

Generator Performance

Generator performance results from the interaction between the physical characteristics of the units and the level of expenditures made to maintain the capability of the units, which in turn is a function of incentives from energy, ancillary services and capacity markets. Generator performance indices include those based on total hours in a period (generator performance factors) and those based on hours when units are needed to operate by the system operator (generator forced outage rates).

Capacity Factor

Capacity factor measures the actual output of a power plant over a period of time compared to the potential output of the unit had it been running at full nameplate capacity for every hour during that period. Table 5-34 shows the capacity factors by unit type for the first nine months of 2024 and 2025. In the first nine months of 2025, nuclear units had a capacity factor of 95.5 percent, compared to a capacity factor of 95.0 percent in the first nine months of 2024; combined cycle units had a capacity factor of 65.7 percent in the first nine months of 2025, compared to a capacity factor of 67.9 percent in the first nine months of 2024; coal units had a capacity factor of 44.8 percent in the first nine months of 2025, compared to a capacity factor of 37.5 percent in the first nine months of 2024.

226 Department of Energy, Order No. 202-25-8 (August 28, 2025) <https://www.energy.gov/sites/default/files/2025-08/202c%20Order%20No.%20202-25-8.pdf>.

Dual Fuel	8,788.5	28.1%	9,453.0	28.5%	0.4%
Oil	877.0	4.1%	874.6	4.5%	0.4%
Wind	21,812.4	17.5%	22,206.5	19.0%	1.6%
Total	636,584.1	49.2%	653,687.0	50.0%	0.8%

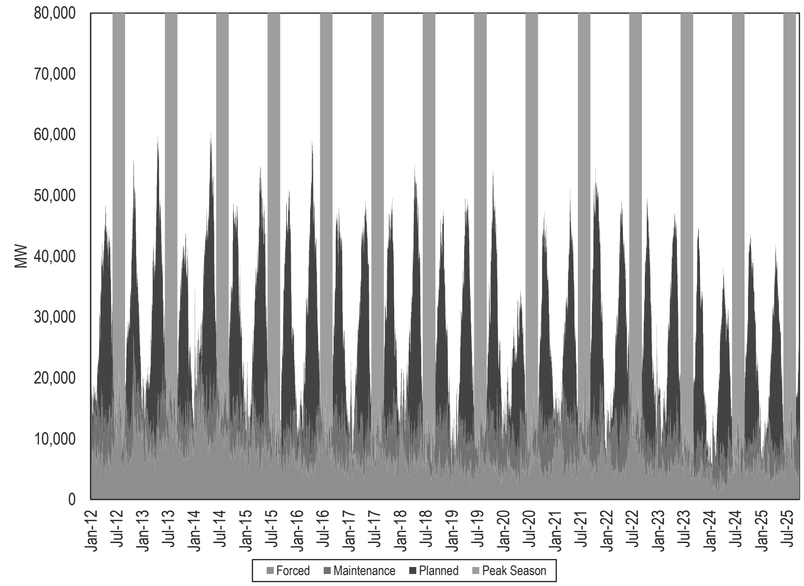
227 The capacity factors in this table are based on nameplate capacity values, and are calculated based on when the units come on line.
228 The subcategories of steam units are consolidated consistent with confidentiality rules. Coal is comprised of coal and waste coal. Natural gas is comprised of natural gas and propane. Oil is comprised of both heavy and light oil. Biomass is comprised of biomass, landfill gas, and municipal solid waste.
229 Hours in which batteries have net negative generation do not count toward their runtime.

Generator Performance Factors

Generator outages fall into three categories: planned, maintenance, and forced. The scheduling of planned and maintenance outages must be approved by PJM. The approval may be withdrawn in order to maintain system reliability.[230] The PJM Market Rules do not specify any consequences if the planned outage continues after PJM withdraws approval. If PJM withdraws approval for a maintenance outage during the outage and the unit cannot operate, the outage is defined to be a forced outage.[231] Outages that are approved by PJM may be extended. An extension to a planned outage that enters the peak period is treated as a forced outage. A maintenance outage that is extended to more than nine days during the peak period is treated as a forced outage.

The MW on outage vary during the year. For example, the MW on planned outage are generally highest in the spring and fall, as shown in Figure 5-10, as a result of restrictions on planned outages during the winter and summer. The Peak Period Maintenance Season, shown in Figure 5-10 as the peak season, runs from the weeks containing the twenty-fourth through thirty-sixth Wednesdays of the year. Planned outages cannot start in nor extend into this period. In 2025, the period runs from Monday, June 9 until Friday, September 5. The effect of the seasonal variation in outages can be seen in the monthly generator performance metrics in Figure 5-13.

Figure 5-10 Outages (MW): 2012 through September 2025



230 "PJM Manual 10: Pre-Scheduling Operations," § 2.3.2 Maintenance Outage Rules, Rev. 45 (Nov. 21, 2024).
231 OATT, Attachment K (Appendix) § 1.9.3 (b).

Table 5-35 shows the total MWh by outage type. In the first nine months of 2025, forced outages were 32.6 percent higher, planned outages were 0.2 percent lower, and maintenance outages were 4.2 percent lower than in the first nine months of 2024.

Table 5-35 Outages (MWh): January through September, 2012 through 2025

Jan-Sep	Forced MWh	Planned MWh	Maintenance MWH
2012	2,125,736	3,004,765	1,603,872
2013	2,583,519	3,375,484	1,286,707
2014	3,153,661	3,407,915	1,451,684
2015	2,216,942	3,198,529	1,162,199

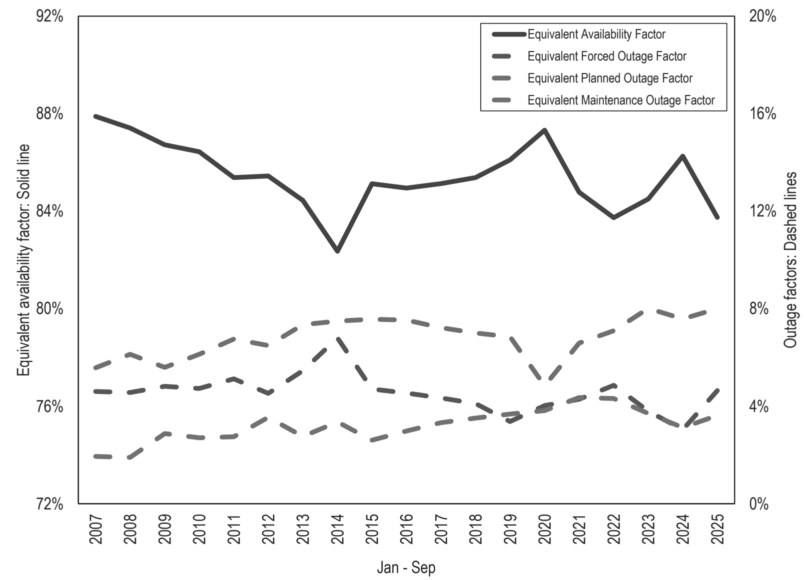
Performance factors include the equivalent availability factor (EAF), the equivalent maintenance outage factor (EMOF), the equivalent planned outage factor (EPOF) and the equivalent forced outage factor (EFOF). These four factors add to 100 percent for any generating unit. The EAF is the proportion of hours in a year when a unit is available to generate at full capacity while the three outage factors include all the hours when a unit is unavailable. The EMOF is the proportion of hours in a year when a unit is unavailable because of maintenance outages and maintenance deratings. The EPOF is the proportion of hours in a year when a unit is unavailable because of planned outages and planned deratings. The EFOF is the proportion of hours in a year when a unit is unavailable because of forced outages and forced deratings.

The PJM aggregate EAF, EFOF, EPOF, and EMOF are shown in Figure 5-11. Metrics by unit type are shown in Table 5-36

Figure 5-11 Equivalent outage and availability factors: January through September, 2007 through 2025



The PJM aggregate equivalent availability factor in the first nine months of 2025 was 83.7 percent, a decrease from 86.3 percent in the first nine months of 2024.

Generator Outage Rates

The most fundamental forced outage rate metric is the equivalent demand forced outage rate (EFORd). EFORd is a measure of the probability that a generating unit will fail, either partially or totally, to perform when it is needed to operate. EFORd measures the forced outage rate during periods of demand, and does not include planned or maintenance outages. A period of demand is a period during which a generator is running or needed to run. EFORd calculations use historical performance data, including equivalent forced outage hours, service hours, average forced outage duration, average run time, average time between unit starts, available hours and period hours.[232] The EFORd metric includes all forced outages, regardless of the reason for those outages.

The average PJM EFORd in the first nine months of 2025 was 6.6 percent, an increase from 4.5 percent in the first nine months of 2024. Figure 5-12 shows the average EFORd since 1999 for all units in PJM.[233]

Figure 5-12 Equivalent demand forced outage rates (EFORd): 1999 through September, 2025

Table 5-37 shows the class average EFORd by unit type.

232 Equivalent forced outage hours are the sum of all forced outage hours in which a generating unit is fully inoperable and all partial forced outage hours in which a generating unit is partially inoperable, prorated to full hours.
233 The universe of units in PJM changed as the PJM footprint expanded and as units retired from and entered PJM markets. See the *2024 State of the Market Report for PJM*, Appendix A: "PJM Overview" for details.

EFORd vs EAF

EFORd is not an adequate measure of unit availability because EFORd measures only forced outages and does not account for planned or maintenance outages. Forced outage rates can be managed under the existing outage rules. A unit with significant planned and/or maintenance outages is considered to have identical reliability properties in capacity planning, transmission planning and in the sale of capacity in the capacity market.[234] The EAF (Equivalent Availability Factor), which reflects all forced, planned, and maintenance outages, is a more accurate measure of the capacity actually available to meet load.

Table 5-38 shows the differences between EFORd and EAF by unit type.

Table 5-38 EFORd and EAF by unit type: January through September, 2012 through 2025

Outage Analysis

The MMU analyzed the causes of outages for the PJM system. The metric used was lost generation, which is the product of the duration of the outage and the size of the outage reduction. Lost generation can be converted into lost system equivalent availability.[235] On a system wide basis, the resultant lost equivalent availability from forced outages is equal to the equivalent forced outage factor (EFOF), the resultant lost equivalent availability from maintenance outages is equal to the equivalent maintenance outage factor (EMOF), and the resultant lost equivalent availability from planned outages is equal to the equivalent planned outage factor (EPOF).

The PJM EFOF was 4.6 percent in the first nine months of 2025. Table 5-39 shows the causes of EFOF by unit type. Forced outages for boiler tube leaks, 15.1 percent of the system EFOF, were the largest single contributor to average system EFOF across all unit types.

Table 5-39 Contribution to PJM EFOF by unit type by cause: January through September, 2025

235 For any unit, lost generation can be converted to lost equivalent availability by dividing lost generation by the product of the generating units' capacity and period hours. This can also be done on a system basis.

The PJM EMOF was 3.6 percent in the first nine months of 2025. Table 5-40 shows the causes of EMOF by unit type. Maintenance outages for boiler tube leaks, 12.1 percent of the system EMOF, were the largest single contributor to average system EMOF across all unit types, although miscellaneous gas turbine issues were the largest contributors to EMOF for combustion turbines.

Table 5-40 Contribution to EMOF by unit type by cause: January through September, 2025

PJM EPOF was 8.0 percent in the first nine months of 2025. Table 5-41 shows the causes of EPOF by unit type. Planned outages for miscellaneous balance of plant, 19.8 percent of the system EPOF, were the largest single contributor to average system EPOF across all unit types, although miscellaneous gas turbine issues were the largest contributors to EPOF for combustion turbines.

Table 5-41 Contribution to EPOF by unit type and cause: January through September, 2025

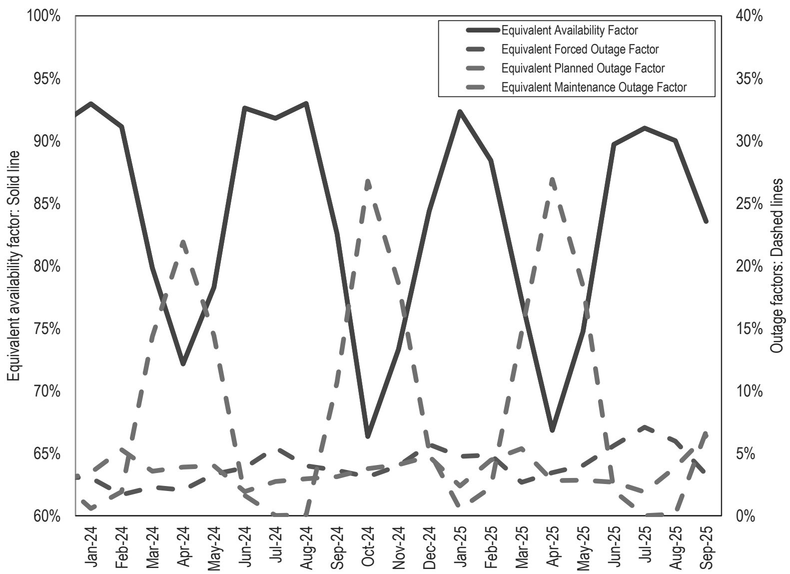
Performance by Month

Monthly values for EAF, EFOF, EMOF and EPOF are shown in Figure 5-13.

Figure 5-13 Monthly generator performance factors: January through September, 2024 through 2025



Generator Testing Issues

PJM Manual 21: Rules and Procedures for Determination of Generating Capability describes how generators are to be tested. PJM's testing requirements are not well designed, permit excessive generator discretion, and do not require adequate winter testing. As a result of the introduction of ELCC, winter capability is much more significant in defining the value of capacity that can be sold in the capacity market, especially for thermal resources. That fact makes it even more essential that PJM require winter testing and include the results of that testing in the calculation of ELCC values.

Net Capability Verification Testing data, meant to demonstrate that a unit has the ICAP claimed, are submitted for the summer and winter testing periods.[236] These periods run from the start of June until September and the start of December until March. If a unit is on a planned or maintenance outage for the entire testing period, it is expected to perform an out of period test once the outage ends. Out of period tests can be performed from the start of September until December for summer tests and from the start of March until June for winter tests. Hydroelectric generators only perform summer tests.[237] Wind and solar resources do not perform verification tests to prove capability.[238]

While data must be submitted for the winter testing period, PJM permits the use of summer test data adjusted for ambient winter conditions in lieu of actual winter test data. The MMU recommends that PJM require actual seasonal tests as part of the Summer/Winter Capability Testing rules and that the ambient conditions under which the tests are performed be defined.

Results, including failed test results, must be submitted to PJM via eGADS. Failing to submit data before the deadline can result in a Data Submission Charge of $500 per day late.[239]

Failure to demonstrate the claimed net capability results in a forced outage or derating effective from the beginning of the testing period and lasting until either a reduced claimed ICAP is in effect, the beginning of the next testing period, or, except for failures due to environmental constraints or a lack of resources, a successful out of period test.

Failed test results must be accompanied by a derating or outage in eGADS and in eDART. Failure to report failed tests and failure to derate the unit can result in a Generation Resource Rating Test Failure Charge, equal to the Daily Deficiency Rate multiplied by: the daily ICAP shortfall multiplied by one minus the effective EFORd for unlimited resources; the UCAP for the daily ICAP shortfall, for limited duration resources and combination resources.[240] Nine resources were assessed for generation resource rating test failure charges

239 "Reliability Assurance Agreement Among Load Serving Entities in the PJM Region," Schedule 12, Section A.
240 PJM. "PJM Manual 18: PJM Capacity Market," § 9.1.5 Generation Resource Rating Test Failure Charge, Rev. 59 (June 27, 2024).

in 2024. No resources were assessed for generation resource rating test failure charges in the first nine months of 2025.

The Daily Deficiency Rate in dollars per MW-day is equal to the weighted average capacity resource clearing price from the RPM auction that resulted in the resource's commitment plus the greater of 20 percent of that clearing price or 20 dollars per MW-day.[241]

While generation owners are required to report failed tests and to derate their unit in eGADS, owners can perform an unlimited number of tests before submitting a successful result. The MMU recommends that PJM limit the number of tests that can be made before submitting final results and that the data be collected by PJM's Power Meter instead of being submitted in eGADS. The MMU recommends that PJM select the time and day for testing a unit, not the unit owner, and that this testing not be communicated in advance. Instead, a unit would be tested by how well it follows its dispatch signal. Under the current testing rules, generation owners have the opportunity to perform tests during more favorable conditions to achieve better performance.

Generator output is also assessed during Performance Assessment Intervals (PAIs), which occur when PJM declares an emergency action as listed in Manual 18, Section 8.4A. If a unit fails to perform as expected, generators may incur a Non-Performance Charge, which is equal to the performance shortfall multiplied by the Non-Performance Charge Rate.[242] In 2022, PAIs occurred on June 13, June 14, June 15, December 23, and December 24. For the December 23 and 24 PAIs, PJM total nonperformance charges were approximately $1.796 billion, reduced to $1.226 billion in a settlement agreement.[243] There were no such charges assessed in 2023 or 2024 or the first nine months of 2025

For each day of a delivery year, generators are required to meet their daily unforced capacity commitments. Generation owners have the option to buy replacement capacity that satisfies the same locational requirements.[244] [245] Failure to meet this commitment can result in a Daily Capacity Resource Deficiency Charge.[246] [247] This charge is equal to the Daily Deficiency Rate multiplied by the difference between a resource's daily commitments and daily position. Thirty resources were assessed for deficiency charges in 2021, 65 resources were assessed for deficiency charges in 2022, 176 resources were assessed for deficiency charges in 2023, 432 resources were assessed for deficiency charges in 2024, and 576 resources were assessed for deficiency charges in the first nine months of 2025. The increase in the number of resources subject to deficiency charges is a result of the implementation of class average ELCC in the 2023/2024 Delivery Year and marginal ELCC starting in the 2025/2026 Delivery Year.

Changing Outage Types

Capacity resource owners have an incentive to minimize their forced outages to maximize capacity revenue and minimize penalties. Generation owners have had the ability to change the designation of the outage type after the initial submission to the eGADS database since 2014. Table 5-42 shows that from 2014 through September 2025, of all the changes in outage status, 96.2 percent of the outages and 86.5 percent of the outage MW were changed from either planned or maintenance to forced outage status. Of those changes to forced outage status, 41.3 percent of the outages and 84.1 percent of the MW were for coal and hydro plants.

248 Year describes the year in which the outage started and not the year in which the outage designation was changed.

Demand Response

Markets require both a supply side and a demand side to function effectively. The demand side of wholesale electricity markets is underdeveloped. Wholesale power markets will be more efficient when the demand side of the electricity market becomes fully functional without depending on special programs as a proxy for full participation. The current PJM demand side programs do not result in a functional demand side of the electricity market.

Overview

- **Demand Response Activity.** Demand response resources include economic demand response (energy market demand resources), emergency demand response, pre-emergency demand response and price responsive demand (PRD) (capacity market demand resources), synchronized reserves and regulation.[1]

  Total demand response revenue increased by $221.8 million, 194.2 percent, from $114.2 million in the first nine months of 2024 to $336.0 million in the first nine months of 2025, primarily due to increases in capacity market revenue. Emergency demand response revenue accounted for 85.9 percent of all demand response revenue, economic demand response for 6.1 percent, demand response in the synchronized reserve market for 4.2 percent and demand response in the regulation market for 3.8 percent.

  Total emergency demand response revenue increased by $201.5 million, 231.5 percent, from $87.0 million in the first nine months of 2024 to $288.5 million in the first nine months of 2025.[2] This increase was primarily a result of higher capacity market prices and capacity market revenue.

  Economic demand response revenue increased by $11.8 million, 134.4 percent, from $8.7 million in the first nine months of 2024 to $20.5 million in the first nine months of 2025.[3] Demand response revenue in the synchronized reserve market increased by $5.9 million, 70.7 percent, from $8.3 million in the first nine months of 2024 to $14.2 million in the first nine months of 2025. Demand response revenue in the regulation market increased by $2.7 million, 26.5 percent, from $10.1 million in the first nine months of 2024 to $12.8 million in the first nine months of 2025.

- **Demand Response Energy Payments are Uplift.** Energy payments to emergency and economic demand response resources are uplift. LMP does not cover energy payments to demand response resources although emergency demand response and economic demand response can and do set LMP. Energy payments to emergency demand resources are paid by PJM market participants in proportion to their net purchases in the real-time energy market. Energy payments to economic demand resources are paid by real-time exports from PJM and real-time loads in each zone for which the load-weighted, average real-time LMP for the hour during which the reduction occurred is greater than or equal to the net benefits test price for that month.[4]

- **Demand Response Market Concentration.** The ownership of economic demand response resources was highly concentrated in the first nine months of 2024 and 2025. The HHI for economic demand response resource reductions decreased by 46 points from 8846 in the first nine months of 2024 to 8800 in the first nine months of 2025.

  The ownership of emergency demand response resources is highly concentrated. The HHI for emergency demand response resources committed MW was 2387 for the 2024/2025 Delivery Year. In the 2024/2025 Delivery Year, the four largest CSPs owned 88.5 percent of all committed emergency demand response UCAP MW. The HHI for emergency demand response committed MW is 2517 for the 2025/2026 Delivery Year. In the 2025/2026 Delivery Year, the four largest CSPs own 86.7 percent of all committed demand response UCAP MW.

- **Limited Locational Dispatch of Demand Resources.** With full implementation of the Capacity Performance rules in the capacity market in the 2020/2021 Delivery Year, PJM should be able to individually dispatch any capacity performance resource, including demand resources. PJM cannot dispatch demand resources by node with the current rules because demand resources are not registered to a node. In addition, aggregation rules allow

1 Emergency demand response refers to both emergency and pre-emergency demand response.
2 The total credits and MWh numbers for demand resources were downloaded as of October 14, 2025, and may change as a result of continued PJM billing updates.
3 Economic credits are synonymous with revenue received for reductions under the economic load response program.
4 "PJM Manual 28: Operating Agreement Accounting," § 11.2.2, Rev. 102 (Oct. 1, 2025).

a demand resource that incorporates many small End Use Customers to span an entire zone, which is inconsistent with nodal dispatch.

- **Energy Efficiency.** Energy efficiency payments have been eliminated from PJM markets effective June 1, 2026. Energy efficiency resources are not capacity resources in PJM and do not clear in the capacity market. The total MW of energy efficiency resources paid decreased by 80.6 percent, from 7,716.0 MW in the 2024/2025 Delivery Year to 1,493.2 MW in the 2025/2026 Delivery Year. In the 2025/2026 Delivery Year, payments to EE are $148 million.
- **Energy Efficiency Payments are a Subsidy and Uplift.** Payments from the buyers of capacity to energy efficiency providers are a subsidy and uplift. Energy efficiency is not a capacity resource and does not contribute to reliability.
- **Energy Efficiency Market Concentration.** The HHI for energy efficiency on an aggregate market basis shows that ownership is highly concentrated. The four largest companies own 90 percent or more of all paid Energy Efficiency MW. The HHI for Energy Efficiency resources also shows that ownership is highly concentrated for the 2025/2026 Delivery Year, with an HHI value of 2804. In the 2025/2026 Delivery Year, the four largest companies own 96.0 percent of all paid Energy Efficiency MW.

Recommendations

- The MMU recommends that PJM report the response of emergency demand response resources to dispatch by PJM as the actual change in load rather than simply the difference between the amount of capacity purchased by the customer and the actual metered load. The current approach significantly overstates the expected response to PJM dispatch. (Priority: High. First reported 2023. Status: Not adopted.)
- The MMU recommends that emergency demand response resources offering as supply in the capacity market be required to offer a guaranteed load drop (GLD) below their PLC to ensure that demand resources provide an identifiable MW resource to PJM when called. (Priority: High. First reported 2023. Status: Not adopted.)
- The MMU recommends, as an alternative to including emergency demand response resources as supply in the capacity market, that demand resources have the option to be on the demand side of the markets, that customers be able to avoid capacity and energy charges by not using capacity and energy at their discretion, that customer payments be determined only by metered load, and that PJM forecasts immediately incorporate the impacts of demand side behavior. (Priority: High. First reported 2014. Status: Not adopted.)
- The MMU recommends that the option to specify a minimum dispatch price (strike price) for emergency demand response resources be eliminated and that participating resources receive the hourly real-time LMP less any generation component of their retail rate.[5] (Priority: Medium. First reported 2010. Status: Not adopted.)
- The MMU recommends that the maximum offer for emergency demand response resources and price response demand resources be the same as the maximum offer for generation resources and that the same cost verification rules applied to generation resources apply to demand resources. (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends that the emergency demand response resources be treated as economic resources, responding to economic price signals like other capacity resources. The MMU recommends that emergency demand response resources not be treated as emergency resources. The MMU recommends that emergency demand response resources be available for every hour of the year. (Priority: High. First reported 2012. Status: Partially adopted.)
- The MMU recommends that the Emergency Program Energy Only option be eliminated because the opportunity to receive the appropriate energy market prices is already provided in the economic program. (Priority: Low. First reported 2010. Status: Not adopted.)
- The MMU recommends that, if emergency demand response resources remain in the capacity market, a daily energy market must offer requirement apply to emergency demand response resources, comparable

5 See "Complaint and Motion to Consolidate of the Independent Market Monitor for PJM," Docket No. EL14-20-000 (January 28, 2014), "Comments of the Independent Market Monitor for PJM," Docket No. ER15-852-000 (February 13, 2015).

to the rule applicable to generation capacity resources.[6] (Priority: High. First reported 2013. Status: Not adopted.)

- The MMU recommends that emergency demand response resources be required to provide their nodal location, comparable to generation resources. (Priority: High. First reported 2011. Status: Not adopted.)
- The MMU recommends that PJM require nodal dispatch of emergency demand response resources with no advance notice required or, if nodal location is not required, subzonal dispatch of demand resources with no advance notice required. The MMU recommends that, if PJM continues to use subzones for any purpose, PJM clearly define the role of subzones in the dispatch of demand response. (Priority: High. First reported 2015. Status: Not adopted.)
- The MMU recommends that PJM not remove any defined subzones and maintain a public record of all created and removed subzones. (Priority: Low. First reported 2016. Status: Not adopted.)
- The MMU recommends that PJM eliminate the measurement of compliance across zones within a compliance aggregation area (CAA). The multiple zone approach is less locational than the zonal and subzonal approach and creates larger mismatches between the locational need for the resources and the actual response. (Priority: High. First reported 2015. Status: Not adopted.)
- The MMU recommends that measurement and verification methods for all demand resources be modified to reflect compliance more accurately. (Priority: Medium. First reported 2009. Status: Not adopted.)
- The MMU recommends that compliance rules be revised to include submittal of all necessary hourly load data, and that negative values be included when calculating event compliance across hours and registrations. (Priority: Medium. First reported 2012. Status: Not adopted.)
- The MMU recommends that PJM adopt the ISO-NE five-minute metering requirements in order to ensure that operators have the necessary information for reliability and that market payments to demand resources be calculated based on interval meter data at the site of the demand reductions.[7] (Priority: Medium. First reported 2013. Status: Not adopted.)
- The MMU recommends demand response event compliance be calculated on a five minute basis for all emergency demand response resources and that the penalty structure reflect five minute compliance. (Priority: Medium. First reported 2013. Status: Partially adopted.)
- The MMU recommends that demand response testing be initiated by PJM with advance notice to CSPs identical to the actual lead time required in an emergency in order to accurately represent the conditions of an emergency event. (Priority: Low. First reported 2012. Status: Partially adopted.)
- The MMU recommends that shutdown cost be defined as the cost to curtail load for a given period that does not vary with the measured reduction or, for behind the meter generators, be the start cost defined in Manual 15 for generators. (Priority: Low. First reported 2012. Status: Not adopted.)
- The MMU recommends that the Net Benefits Test be eliminated and that economic demand response resources be paid LMP less any generation component of the applicable retail rate. (Priority: Low. First reported 2015. Status: Not adopted.)
- The MMU recommends that the tariff rules for emergency demand response resources clarify that a resource and its CSP, if any, must notify PJM of material changes affecting the capability of the resource to perform as registered and must terminate or modify registrations that are no longer capable of responding to PJM dispatch directives at defined levels because load has been reduced or eliminated, as in the case of bankrupt and/or out of service facilities. (Priority: Medium. First reported 2015. Status: Not adopted.)
- The MMU recommends that there be only one demand response product in the capacity market, with an obligation to respond when called for

6 See "Complaint and Motion to Consolidate of the Independent Market Monitor for PJM," Docket No. EL14-20-000 (January 27, 2014) at 1.

7 See ISO-NE Tariff, Section III, Market Rule 1, Appendix E1 and Appendix E2, "Demand Response," <http://www.iso-ne.com/regulatory/tariff/sect_3/mr1_append-e.pdf>. (Accessed October 17, 2017) ISO-NE requires that DR have an interval meter with five-minute data reported to the ISO and each behind the meter generator is required to have a separate interval meter. After June 1, 2017, demand response resources in ISO-NE must also be registered at a single node.

any hour of the delivery year. (Priority: High. First reported 2011. Status: Partially adopted.[8])

- The MMU recommends that all demand resources register as Pre-Emergency and that the Emergency Program be eliminated. (Priority: High. First reported 2020. Status: Not adopted.)
- The MMU recommends that the lead times for emergency demand response resources be shortened to 30 minutes with a one hour minimum dispatch for all resources. (Priority: Medium. First reported 2013. Status: Partially adopted.)
- The MMU recommends setting the baseline for measuring capacity compliance under winter compliance at the customers' PLC, similar to GLD, to avoid double counting. (Priority: High. First reported 2010. Status: Partially adopted.)
- The MMU recommends the Relative Root Mean Squared Test be required for all demand resources with a CBL. (Priority: Low. First reported 2017. Status: Partially adopted.)
- The MMU recommends that 30 minute pre-emergency and emergency demand response be considered to be 30 minute reserves. (Priority: Medium. First reported 2018. Status: Not adopted.)
- The MMU recommends that energy efficiency resources (EE) not be included in the capacity market mechanism and that PJM should ensure that the impact of EE measures on the load forecast is incorporated immediately. (Priority: Medium. First reported 2018. Status: Adopted 2024.)[9] [10]
- The MMU recommends that demand reductions based entirely on behind the meter generation be capped at the lower of economic maximum or actual generation output. (Priority: High. First reported 2019. Status: Not adopted.)
- The MMU recommends that DER aggregations that clear in a capacity auction not be permitted to change status from homogeneous demand response to any other status for any additional auctions for the same delivery year, or for the delivery year. (Priority: High. New recommendation. Status: Not adopted.)
- The MMU recommends that EDCs not be allowed to participate in markets as DER aggregators in addition to their EDC role. (Priority: High. First reported 2021. Status: Not adopted.)
- The MMU recommends that PJM include a 5.0 MW maximum size cap on DER aggregations. (Priority: Medium. First reported 2021. Status: Not adopted.)
- The MMU recommends that PJM use a nodal approach for DER participation in PJM markets that excludes multinodal aggregation. (Priority: Medium. First reported 2022. Status: Partially adopted.)
- The MMU recommends that the Commission require PJM to include in OATT Attachment M the explicit statement that the Market Monitor's role includes the right to collect information from EDCs and DERA related to actions taken on the distribution system related to DERs. (Priority: Medium. First reported 2023. Status: Not adopted.)
- The MMU recommends that net metering resources be prohibited from participating in wholesale ancillary services markets if they are compensated for the service at the retail level. (Priority: Medium. First reported Q2, 2025. Status: Not adopted.)
- The MMU recommends that PJM revise the requirements for reporting expected real time energy load reductions by CSPs to PJM to improve the accuracy and usefulness to PJM's system operators. (Priority: Medium. First reported 2023. Status: Not adopted.)
- The MMU recommends that PJM define when operators can and should call on demand resources, given that a call on demand resources no longer triggers a PAI. The MMU recommends that PJM revise the performance requirements for demand resources to include an event specific measurement for dispatch occurring outside of Performance Assessment Events and penalties for nonperformance. (Priority: Medium. First reported 2023. Status: Not adopted.)

8 PJM's Capacity Performance design requires resources to respond when called for any hour of the delivery year, but demand resources still have a limited mandatory compliance window.
9 See 189 FERC ¶ 61,095.
10 Originally incorporated with auctions conducted in 2016 for the 2016/2017 Delivery Year and forward. The mechanics of the EE addback mechanism were modified beginning with the 2023/2024 Delivery Year.

- The MMU recommends that PRD be required to respond during a PAI, regardless of whether the real-time LMP at the applicable location meet or exceeds the PRD strike price, to be consistent with all CP resources. (Priority: Medium. New recommendation. Status: Not adopted.)

Conclusion

A fully functional demand side of the electricity market means that End Use Customers or their designated intermediaries will have the ability to see real-time energy price signals in real time, will have the ability to react to real-time prices in real time and will have the ability to receive the direct benefits or costs of changes in real-time energy use. In addition, customers or their designated intermediaries will have the ability to see current capacity prices, will have the ability to react to capacity prices and will have the ability to receive the direct benefits or costs of changes in the demand for capacity in the same year in which demand for capacity changes. A functional demand side of these markets means that customers will have the ability to make decisions about levels of power consumption based both on how customers value the power and on the actual cost of that power.

In the energy market, if there is to be a demand side program, demand resources should be paid the value of energy, which is LMP less any generation component of the applicable retail rate. There is no reason to have the net benefits test. The necessity for the net benefits test is an illustration of the illogical approach to demand side compensation embodied in paying full LMP to demand resources. The benefit of demand side resources is not that they suppress market prices, but that customers can choose not to consume at the current price of power, that individual customers benefit from their choices and that the choices of all customers are reflected in market prices. If customers face the market price, customers should have the ability to not purchase power and the market impact of that choice does not require a test for appropriateness.

If demand resources are to continue competing directly with generation capacity resources in the PJM Capacity Market, the product must be defined such that it can actually serve as a substitute for generation. This is a prerequisite to a functional market design. Demand resources do not have a must offer requirement into the day-ahead energy market, are able to offer above $1,000 per MWh without providing a fuel cost policy, or any rationale for the offer. Demand resources do not have telemetry requirements similar to other Capacity Performance resources. Until July 30, 2023, including Winter Storm Elliott, PJM automatically, and inappropriately, triggered a PAI when demand resources were dispatched.

In order to be a substitute for generation, demand resources offering as supply in the capacity market should be required to offer a guaranteed load drop (GLD) below their PLC to ensure that demand resources provide an identifiable MW resource to PJM when called.

In order to be a substitute for generation, the ELCC for demand resources should be based on data about actual reductions in demand during high expected loss of load hours, like other capacity resources. The current DR ELCC is significantly overstated because the DR ELCC value is based on the unsupported assumption that the full amount of capacity sold will respond when called rather than on actual response data. In other words, the actual response is assumed to be perfect. The amount of capacity sold equals the PLC – the FSL for the resource. PJM has proposed to make this problem worse rather than to correct it, by increasing the ELCC of demand resources based on assumptions rather than actual performance data.

In order to be a substitute for generation, demand resources should be defined in PJM rules as an economic resource, as generation is defined. Demand resources should be required to offer in the day-ahead energy market and should be called when the resources are required and prior to the declaration of an emergency. Demand resources should be available for every hour of the year. The fact that demand resources are only obligated to respond for defined time periods meant that PJM could not fully use demand resources during Winter Storm Elliott (Elliott). Demand resources should be treated as economic resources like any other capacity resource. Demand resources should be called whenever economic and paid the LMP rather than an inflated strike price up to $1,849 per MWh that is set by the seller.

In order to be a substitute for generation, demand resources should be subject to robust measurement and verification techniques to ensure that transitional DR programs incent the desired behavior. The methods used in PJM programs today are not adequate to determine and quantify deliberate actions taken to reduce consumption.

In order to be a substitute for generation, demand resources should provide a nodal location and should be dispatched nodally to enhance the effectiveness of demand resources and to permit the efficient functioning of the energy market. Both subzonal and multi-zone compliance should be eliminated because they are inconsistent with an efficient nodal market.

In order to be a substitute for generation, compliance by demand resources with PJM dispatch instructions should include both increases and decreases in load. Compliance of demand resources for capacity purposes during a Performance Assessment Event is measured relative to either Peak Load Contribution or Winter Peak Load, which are static values. If a demand resource's metered load increases above these reference values during a PAI, the current method applied by PJM simply ignores increases in load and thus artificially overstates compliance.[11]

In order to be a substitute for generation, Actual Performance of demand resources during a Performance Assessment Event should be determined consistent with that of generation and should not be netted across the Emergency Action Area (EAA). The Capacity Market Seller's Performance Shortfalls for Demand Resources in the EAA are netted to determine a net EAA Performance Shortfall for the Performance Assessment Interval. Any net positive EAA Performance Shortfall is allocated to the Capacity Market Seller's demand resources that under complied within the EAA on a prorata basis based on the under compliance MW, and such seller's demand resources will be assessed a Performance Shortfall for the Performance Assessment Interval. Any net negative EAA Performance Shortfall is allocated to the Market Seller's Demand Resources that over complied within the EAA on a prorata basis based on over compliance MW, and such Market Seller's Demand Resources will be assessed Bonus Performance. Netting of performance of Demand Resources across the EAA is inconsistent with the performance measurement of other Capacity Performance resources.

In order to be a substitute for generation, any demand resource and its Curtailment Service Provider (CSP), should be required to notify PJM of material changes affecting the capability of the resource to perform as registered and to terminate or modify registrations that are no longer capable of responding to PJM dispatch directives at the specified level, such as in the case of bankrupt and out of service facilities. Generation resources are required to inform PJM of any change in availability status, including outages and shutdown status.

As an alternative to being a substitute for generation in the capacity market, demand response resources should have the option to be on the demand side of the capacity market rather than on the supply side. Rather than detailed demand response programs with their attendant complex and difficult to administer rules, customers would be able to avoid capacity and energy charges by not using capacity and energy at their discretion and the level of usage paid for would be defined by metered usage rather than a complex and inaccurate measurement protocol, and PJM forecasts would immediately incorporate the impacts of demand side behavior.

The MMU peak shaving proposal at the Summer-Only Demand Response Senior Task Force (SODRSTF) is an example of how to create a demand side product that is on the demand side of the market and not on the supply side.[12] The MMU proposal was based on the BGE load forecasting program and the Pennsylvania Act 129 Utility Program.[13] [14] Under the MMU proposal, participating load would inform PJM prior to an RPM auction of the MW participating, the months and hours of participation and the temperature humidity index (THI) threshold at which load would be reduced. PJM would reduce the load forecast used in the RPM auction based on the designated reductions. Load would agree to curtail demand to at or below a defined

12 See the MMU package within the *SODRSTF Matrix*, <http://www.pjm.com/-/media/committees-groups/task-forces/sodrstf/20180802/20180802-item-04-sodrstf-matrix.ashx>.

13 *Advance signals that can be used to foresee demand response days*, BGE, <https://www.pjm.com/-/media/committees-groups/task-forces/sodrstf/20180309/20180309-item-05-bge-load-curtailment-programs.ashx> (March 9, 2018).

14 *Pennsylvania ACT 129 Utility Program*, CPower, <https://www.pjm.com/-/media/committees-groups/task-forces/sodrstf/20180413/20180413-item-03-pa-act-129-program.ashx> (April 13, 2018).

FSL, less than the customer PLC, when the THI exceeds a defined level or load exceeds a specified threshold. By relying on metered load and the PLC, load can reduce its demand for capacity and that reduction can be verified without complicated and inaccurate metrics to estimate load reductions. Under PJM's weakened version of the program, performance is measured under the current economic demand response CBL rules which means relying on load estimates rather than actual metered load.[15] PJM's proposal includes only a THI curtailment trigger and not an overall load curtailment trigger.

The long term appropriate end state for demand resources in the PJM markets should be comparable to the demand side of any market. Customers should use energy as they wish, accounting for market prices in any way they like, and that usage will determine the amount of capacity and energy for which each customer pays. There would be no counterfactual measurement and verification.

Under this approach, customers that wish to avoid capacity payments would reduce their load during expected high load hours, not limited to a small number of peak hours. Capacity costs would be assigned to LSEs and by LSEs to customers, based on actual load on the system during these hours. Customers wishing to avoid high energy prices would reduce their load during high price hours. Customers would pay for what they actually use, as measured by meters, rather than relying on flawed measurement and verification methods. No measurement and verification estimates are required. No promises of future reductions which can only be verified by inaccurate and biased measurement and verification methods are required. To the extent that customers enter into contracts with CSPs or LSEs to manage their payments, measurement and verification can be negotiated as part of a bilateral commercial contract between a customer and its CSP or LSE. But the system would be paid for actual, metered usage, regardless of which contractual party takes that obligation.

This approach provides more flexibility to customers to limit usage at their discretion. There is no requirement to be available year round or every hour of every day. There is no 30 minute notice requirement. There is no requirement to offer energy into the day-ahead market. All decisions about interrupting are up to the customers only and they may enter into bilateral commercial arrangements with CSPs at their sole discretion. Customers would pay for capacity and energy depending solely on metered load.

A transition to this end state should be defined in order to ensure that appropriate levels of demand side response are incorporated in PJM's load forecasts and thus in the demand curve in the capacity market. That transition should be defined by the rules proposed by the MMU.

This approach would work under the CP design in the capacity market. This approach is entirely consistent with the Supreme Court decision in *EPSA* as it does not depend on whether FERC has jurisdiction over the demand side.[16] This approach will allow FERC to more fully realize its overriding policy objective to create competitive and efficient wholesale energy markets. The decision of the Supreme Court addressed jurisdictional issues and did not address the merits of FERC's approach. The Supreme Court's decision has removed the uncertainty surrounding the jurisdictional issues and created the opportunity for FERC to revisit its approach to demand side.

Any discussion of demand resource performance during a PAI must recognize the significant problems with the definition of performance for demand resources. As defined by PJM rules, performance, contrary to intuition, does not mean actually reducing load in response to a PJM request for demand resources. Performance means only that, on a net portfolio basis, the amount of capacity paid for in the capacity market (PLC) minus actual metered load is equal to the amount of demand side capacity sold in the capacity market (ICAP). If a demand resource location was already at a reduced load level when PJM called a PAI, the demand resource would be deemed to have performed if the PLC less the metered load level was equal to the ICAP sold in the capacity market. The standard reporting of demand side response is therefore misleading because it includes loads that were already lower for any reason as a response. That is exactly what happened during Elliott. In addition, PRD is not required to respond if the LMP is less than the PRD strike price. This flawed rule meant that PRD did not fully respond during Winter Storm Elliott because PRD offered at the maximum price of $1,849 per MWh.

15 The PJM proposal from the SODRSTF weakened the proposal but was approved at the October 25, 2018 Members Committee meeting and PJM filed Tariff changes on December 7, 2018. See "Peak Shaving Adjustment Proposal," Docket No. ER19-511-000 (December 7, 2018).

16 577 U.S. 260 (2016).

PJM Demand Response Programs

All PJM demand response programs can be grouped into economic demand response (energy market demand resources), emergency demand response, pre-emergency demand response and price responsive demand (PRD) (capacity market demand resources), synchronized reserves and regulation.[17] Table 6-1 provides an overview of the key features of PJM demand response programs.

Based on FERC Order No. 719 PJM implemented rules that require PJM to verify with EDCs that no law or regulation of a RERRA prohibits End Use Customers' participation.[18] [19]

Table 6-1 Overview of demand response programs

	Emergency and Pre-Emergency Demand Response Program			Economic Demand Response Program	Price Responsive Demand
	Capacity Market Demand Response			Economic Demand Response	
Product Types	Capacity Performance, Summer-Period Capacity Performance OATT Attachment DD § 5.5A	Capacity Performance,Summer-Period Capacity Performance OATT Attachmend DD § 5.5A		OATT Attachment K § 1.5A	
Market	Capacity Only OATT Attachment K § 8.1	Full Program Option (Capacity and Energy) OATT Attachemnt K § 8.1	Energy Only OATT Attachemnt K § 8.1	Energy Only	Capacity Only
Capacity Market	DR cleared in RPM	DR cleared in RPM	Not included in RPM	Not included in RPM	PRD cleared in RPM
Dispatch Requirement	Mandatory Curtailment	Mandatory Curtailment	Voluntary Curtailment	Dispatched Curtailment	Price Threshold
Capacity Payments	Capacity payments based on RPM clearing price	Capacity payments based on RPM clearing price	NA	NA	LSE PRD Credit RAA Schedule 6.1.G
Capacity Measurement and Verification	Firm Service Level Guaranteed Load Drop	Firm Service Level Guaranteed Load Drop	NA	NA	Firm Service Level

17 Emergency demand response refers to both emergency and pre-emergency demand response.
18 *Wholesale Competition in Regions with Organized Electric Markets*, Order No. 719, FERC Stats. & Regs. ¶ 31,281 at P 154 (2008), *order on reh'g*, Order No. 719-A, FERC Stats. & Regs. ¶ 31,292, *order on reh'g*, Order No. 719-B, 129 FERC ¶ 61,252 (2009).
19 The evidence supplied by LDCs must take the form of an order, resolution or ordinance of the RERRA, an opinion of the RERRA's legal counsel attesting to existence of an order, resolution, or ordinance, or an opinion of the state attorney general on behalf of the RERRA attesting to existence of an order, resolution or ordinance.

Non-PJM Demand Response Programs

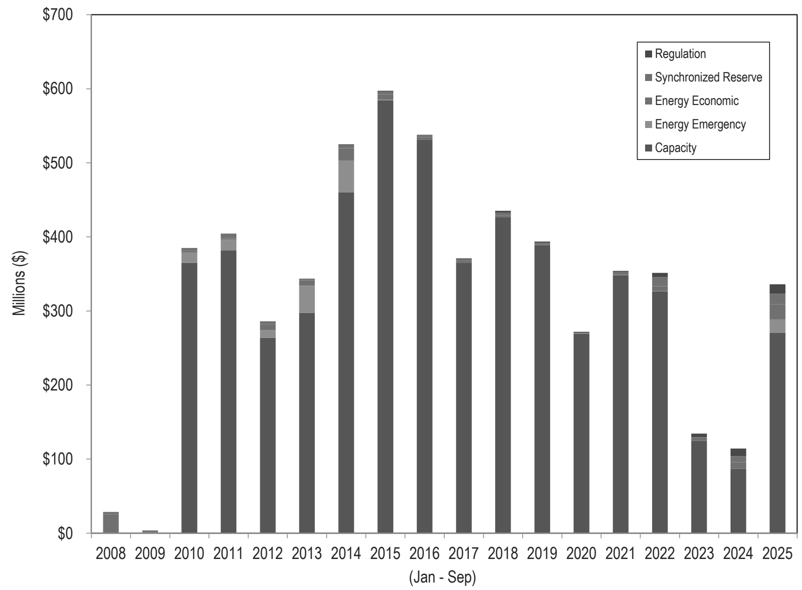
Within the PJM footprint, states may have additional demand response programs as part of a Renewable Portfolio Standard (RPS) or a separate program. Indiana, Ohio, Pennsylvania (e.g. Pennsylvania ACT 129 Utility Program) and North Carolina include demand response in their RPS. If demand response is dispatched by a state run program, the demand response resources are ineligible to receive payments from PJM during the state dispatch.[20]

PJM Demand Response Programs

Figure 6-1 shows all revenue from PJM demand response programs by market for each year, 2008 through September 2025. Since the implementation of the RPM Capacity Market on June 1, 2007, the capacity market has been the primary source of demand response revenue.[21] In the first nine months of 2025, total demand response revenue increased by $221.8 million, 194.2 percent, from $114.2 million in the first nine months of 2024 to $336.0 million in the first nine months of 2025, primarily due to increases in capacity market prices and revenue. Total emergency demand response revenue increased by $201.5 million, 231.5 percent, from $87.0 million in the first nine months of 2024 to $288.5 million in the first nine months of 2025. This increase was primarily a result of higher capacity market prices and capacity market revenue.[22] In the first nine months of 2025, emergency demand response revenue, which includes capacity and energy revenue, accounted for 85.9 percent of all revenue received by demand response providers, the economic program for 6.1 percent, synchronized reserve for 4.2 percent and the regulation market for 3.8 percent.

Economic demand response revenue increased by $11.8 million, 134.4 percent, from $8.7 million in the first nine months of 2024 to $20.5 million in the first nine months of 2025.[23] Demand response revenue in the synchronized reserve market increased by $5.9 million, 70.7 percent, from $8.3 million in the first nine months of 2024 to $14.2 million in the first nine months of 2025. Demand response revenue in the regulation market increased by $2.7 million, 26.5 percent, from $10.1 million in the first nine months of 2024 to $12.8 million in the first nine months of 2025.

Figure 6-1 Demand response revenue by market: January through September, 2008 to 2025



20 "PJM Manual 11: Energy & Ancillary Services Market Operations," § 10.1, Rev. 136 (October 1, 2025).
21 This includes both capacity market revenue and emergency energy revenue for capacity resources.
22 The total credits and MWh for demand resources were downloaded as of October 14, 2025, and may change as a result of continued PJM billing updates.
23 Economic credits are synonymous with revenue received for reductions under the economic load response program.

Table 6-2 shows the monthly demand response cleared volumes and revenues in the synchronized reserve market.

Table 6-2 Demand response synchronized reserve market MWh and revenue: January 2024 through September 2025

	MWh			Revenue		
Month	2024	2025	Percent Change	2024	2025	Percent Change
Jan	299,469	188,234	(37.1%)	$719,294.50	$528,551.11	(26.5%)
Feb	312,394	192,247	(38.5%)	$544,082.82	$569,852.48	4.7%
Mar	340,047	339,478	(0.2%)	$1,370,683.73	$2,228,065.08	62.6%
Apr	213,888	226,206	5.8%	$877,390.11	$2,013,303.75	129.5%
May	344,696	404,918	17.5%	$1,577,366.27	$1,673,752.10	6.1%
Jun	210,675	415,556	97.2%	$606,492.40	$2,119,535.48	249.5%

CSPs provide for each registered location the load reduction method and the associated load reduction capability. Load reduction methods indicate the type of electrical equipment that is controlled to provide the demand response activity and include: heating, ventilation and air conditioning (HVAC), lighting, refrigeration, manufacturing, water heaters, batteries, plug load, computing and generation. A plug load represents an electronic device that is plugged into a socket, which is not already represented by the methods described above. Examples of plug load include IT peripherals such as large computers, monitors, printers, routers, copiers and scanners or appliances such as washers, dryers or dishwashers.[24]

Table 6-4 shows the demand response capability registered to provide synchronized reserves by load reduction method.

Table 6-4 Demand response synchronized reserve load reduction methods: January through September, 2025

Method	MW	Percent
Generator	139.1	5.7%
HVAC	78.9	3.2%
Lighting	165.3	6.8%
Refrigeration	16.0	0.7%
Manufacturing	1,362.0	55.7%
Water Heaters	0.0	0.0%
Batteries	14.1	0.6%
Plug Load	1.6	0.1%
Computing	670.3	27.4%
Total	2,447.2	100.0%

Table 6-5 shows the demand response capability registered to provide regulation by load reduction method.

Table 6-5 Demand response regulation load reduction methods: January through September, 2025

Water Heaters	143.8	63.1%
Batteries	84.2	36.9%
Total	228.0	100.0%

24 "PJM Manual 11: Energy & Ancillary Services Market Operations," § 10.2.2, Rev. 136 (October 1, 2025).

Emergency and Pre-Emergency Demand Response Programs

Pre-Emergency is the default status for capacity market demand response resources. Emergency status is only for resources that use behind the meter generation and that generation has environmental restrictions that limit the resource's ability to operate only in emergency conditions.[25] All demand resources must register as pre-emergency unless the participant qualifies for emergency. PJM also uses the term Load Management Program to refer to the emergency and pre-emergency demand response resources.

Capacity demand response resources may be dispatched both as part of, and absent, a PAI. While demand resources dispatched during a PAI continue to be subject to Non-Performance Assessment charges, demand resources dispatched outside of a PAI are not subject to any event specific penalties.[26] If a demand resource is dispatched only outside of Performance Assessment Events for the delivery year, its performance for the delivery year is determined based on the better of actual performance or a test.[27] There are no penalties or consequences for demand response nonperformance.

For example, if a demand resource is called upon five times during the delivery year only outside of Performance Assessment events and fails to perform each time, its delivery year performance will be based only on a test. If the performance under the test is better than the actual performance, no penalties would be levied even though the resource failed to perform each time it was needed.

The MMU recommends that PJM define when operators can and should call on demand resources, given that a call on demand resources no longer triggers a PAI. The MMU recommends that PJM revise the performance requirements for demand resources to include an event specific measurement for dispatch occurring outside of Performance Assessment Events and penalties for nonperformance.

25 OA Schedule 1 § 8.5.
26 "PJM Manual 18: PJM Capacity Market," § 8.6, Rev. 61 (July 23, 2025).
27 "PJM Manual 18: PJM Capacity Market," § 8.7, Rev. 61 (July 23, 2025). Load Management Test.

In all demand response programs, CSPs are companies that sign up end use retail customers that have the ability to reduce load. CSPs satisfy cleared RPM commitments by registering end use retail customers as Nominated MW.[28] After a demand response event occurs, PJM compensates CSPs for their participants' load reductions and CSPs in turn compensate their participants. Only CSPs are eligible to participate in the PJM demand response programs, but a participant can register as a PJM special member and become a CSP without any additional cost.

All emergency or pre-emergency demand resources must be registered as annual capacity resources. Summer period demand response resources are allowed to aggregate with winter period capacity resources to fulfill the annual requirement.[29]

The rules applied to demand resources (DR) in the current market design do not treat demand resources in a manner comparable to generation capacity resources, even though demand resources are sold in the same capacity market, are treated as a substitute for other capacity resources and displace other capacity resources in RPM auctions. PJM will not measure compliance for DR, and the resources will not face penalties, in a PAI unless the product type and lead time type are dispatched by PJM. PJM does not dispatch DR nodally like other capacity resources. DR can only be dispatched on a zonal or subzonal basis. PJM will not measure compliance for DR, and the resources will not face penalties, in a PAI if the area dispatched is not a defined subzone or control zone. With the dispatch of DR no longer triggering a PAI, demand resources dispatched outside of a PAI are no longer subject to any event specific penalties or consequences for nonperformance.

Demand resources are not subject to the same rules as other capacity resources related to the definition of response. Increases in load are ignored when calculating the response of DR to a PJM dispatch.

28 See RAA Schedule 6. Since 2010, the PJM tariff definition of "End User Customer" limits the scope of the term to mean only PJM Members. Letter Order, Docket No. ER11-1909-000 (December 20, 2010). Recently, PJM has asserted that the reference in RAA Schedule 6 § L.1 and OATT Attachment DD-1 § L.1 to the defined term, "End Use Customer," was a mistake, and proposed to discontinue use of the defined term in the February 8, 2024, meeting of the PJM Governing Document Enhancement and Clarification Subcommittee (GDECS). The proposed change would remove the current requirement in the filed tariff that End Use Customers be PJM Members. The proposed change is substantive and not a correction of a typographical error.
29 Summer period demand response must be available for June through October and the following May between 10:00AM and 10:00PM EPT. *See* PJM OATT RAA Article 1.

Demand resources are not required to meet the same must offer requirements as other capacity resources. All other capacity resources must offer in the capacity market and all other capacity resources must offer their ICAP MW daily in the day-ahead energy market.

The MMU has made recommendations that would provide a capacity market supply side and a demand side option and that would result in treating demand resources in a manner comparable to other capacity and energy resources and in a way that would ensure that the demand side contribution to reliability is accurately measured.

Market Structure

The HHI for demand resources shows that ownership was highly concentrated for the 2024/2025 Delivery Year, with an HHI value of 2387. In the 2024/2025 Delivery Year, the four largest companies contributed 88.5 percent of all committed demand response UCAP MW. The HHI for demand resources shows that ownership is highly concentrated for the 2025/2026 Delivery Year, with an HHI value of 2517. In the 2025/2026 Delivery Year, the four largest companies own 86.7 percent of all committed demand response UCAP MW.

Table 6-6 shows the HHI value for committed Demand Response UCAP MW and the market share of the four largest suppliers by delivery year.

Table 6-6 Demand Response HHI: 2019/2020 through 2025/2026

Delivery Year	HHI	Structure	Top 4 Market Share
2019/2020	1840	Highly Concentrated	79.1%
2020/2021	2523	Highly Concentrated	88.4%
2021/2022	2070	Highly Concentrated	85.3%
2022/2023	2051	Highly Concentrated	82.8%
2023/2024	2295	Highly Concentrated	85.6%
2024/2025	2387	Highly Concentrated	88.5%
2025/2026	2517	Highly Concentrated	86.7%

Table 6-7 shows the HHI value for committed UCAP MW by LDA by delivery year. The HHI values are calculated by the committed UCAP MW in each delivery year for demand resources.

Table 6-7 HHI value for committed UCAP MW by LDA by delivery year: 2024/2025 and 2025/2026 Delivery Years[30]

Market Performance

Table 6-8 shows the cleared Demand Resource UCAP MW by delivery year. Total cleared demand response UCAP MW in PJM decreased by 1,798.8 MW, or 22.3 percent, from 8,064.7 MW in the 2024/2025 Delivery Year to 6,265.9 MW in the 2025/2026 Delivery Year. The DR percent of capacity decreased by 0.7 percentage points, from 5.2 percent in the 2024/2025 Delivery Year to 4.5 percent in the 2025/2026 Delivery Year.

30 The RTO LDA refers to the rest of RTO.

Table 6-8 Cleared Demand Resource UCAP MW: 2007/2008 through 2025/2026 Delivery Year

2025/2026	6,265.9	137,733.6	4.5%

Table 6-9 shows zonal monthly capacity market revenue to demand resources for the first nine months of 2025. Capacity market revenue increased in the first nine months of 2025 by $183.6 million, 211.0 percent, from $87.0 million in the first nine months of 2024 to $270.6 million in the first nine months of 2025. The increase in capacity market revenue was a result of the increase in capacity market clearing prices between the 2024/2025 and 2025/2026 Delivery Years. The RTO clearing price in the 2024/2025 BRA was $28.92/MW-Day compared to $269.92/MW-Day in the 2025/2026 BRA.

Table 6-9 Zonal monthly demand resource capacity revenue: January through September, 2025

Product Definition

Pre-Emergency and Emergency Load Response resources must register all resources with a specific response time. The options are to respond within 30, 60 or 120 minutes of a PJM dispatched event. The 30 minute prior notification is the default and applies unless a CSP obtains an exception from PJM due to physical operational limitations that prevent the Demand Resource Registration from reducing load within that timeframe.

Table 6-10 shows the amount of nominated MW and locations by product type and lead time for the 2024/2025 Delivery Year. Nominated MW are Pre-Emergency or Emergency Load Response registrations used to satisfy a CSP's committed MW position for a delivery year. PJM approved 2,681 locations, or 16.1 percent of all locations, which have 3,287.5 nominated MW, or 45.6 percent of all nominated MW, for exceptions to the 30 minute lead time rule for the 2024/2025 Delivery Year.

Table 6-10 Nominated MW and locations by product type and lead time: 2024/2025 Delivery Year

	Pre-Emergency		Emergency			
Lead Type	MW	Percent	MW	Percent	Total	Percent of Total
30 Minutes	3,797.5	96.7%	130.4	3.3%	3,927.9	54.4%

120 Minutes	4,436	99.1%	42	0.9%	4,478	21.3%
Total	20,860	99.1%	196	0.9%	21,056	100.0%

The alternative notification times are 60 minutes and 120 minutes. The CSP must request an exception in writing, including the reason(s) for the requested exception. Once a location is granted a longer lead time, the resource does not need to resubmit for a longer lead time each delivery year.

The request for an exception must demonstrate one of four defined reasons:[31]

- The manufacturing processes for the Demand Resource Registration require gradual reduction to avoid damaging major industrial equipment used in the manufacturing process, or damage to the product generated or feedstock used in the manufacturing process;
- Transfer of load to backup generation requires time intensive manual process taking more than 30 minutes;
- Onsite safety concerns prevent location from implementing reduction plan in less than 30 minutes; or,
- The Demand Resource Registration is comprised of mass market residential customers or Small Commercial Customers which collectively cannot be notified of a Load Management Event within 30 minutes due to unavoidable communications latency, in which case the requested notification time shall be no longer than 120 minutes.

Table 6-12 shows the nominated MW and locations by product type and lead time of granted lead time exceptions for the 2025/2026 Delivery Year.[32]

Table 6-12 Nominated MW and locations of granted lead time exceptions: 2025/2026 Delivery Year

	60 Minutes		120 Minutes			
Reason	MW	Percent	MW	Percent	Total	Percent
Generation Start Time	50.4	1.2%	475.2	10.9%	525.6	12.1%
Manufacturing Damage	208.6	4.8%	2,257.4	51.8%	2,466.1	56.6%
Safety Problem	240.0	5.5%	1,126.2	25.8%	1,366.3	31.4%
Total	499.1	11.5%	3,858.8	88.5%	4,357.8	100.0%

Prior to participating in the PJM Markets, CSPs must complete a registration in DR Hub which identifies the specific location(s) based on the unique EDC

31 OATT Attachment DD-1, Section A.2(a).
32 Data for generation start time and mass market communication categories were combined based on confidentiality rules.

account number that will participate and their associated load reduction capability. Locations are identified by zone, street address and zip code and are not nodal. CSPs must maintain the accuracy of the registration information provided to PJM for each demand resource and each time the CSP registers the location or extends the registration, the CSP must review all information to ensure it is accurate and update as necessary. In order to register demand resources, the CSPs must classify locations according to the location's primary purpose or business use. CSPs first determine if the location's business use falls under one of the following primary categories: Hospitals, Industrial / Manufacturing, Multiple Dwelling Unit, Office Building, Residential, Retail Service, Correctional Facilities, Data Center, Data Center with Crypto Mining, or Schools. In cases where the location does not fit into one of the primary categories, the CSP selects from one of the following categories: Agriculture, Forestry and Fishing, Mining, Transportation, Communications, Electric, Gas and Sanitary Services or Services.[33] PJM had previously not been explicitly identifying demand response associated with data center load in the registration process. PJM was instead including nominated capacity and load reductions from data centers with crypto mining as a load reduction method under the plug load category. At the April 23, 2025, Markets and Reliability Committee, PJM members endorsed changes to Manual 11 to discontinue this practice. The adopted changes relocated the reference to data centers in the registration process from the load reduction method/plug load section to the business segment section and separately identifies data centers and data centers with crypto mining.[34]

Table 6-13 shows the nominated MW and locations by business segment for the 2025/2026 Delivery Year.

Correctional Facilities	35.7	0.4%	40	0.2%
Total	7,999.6	100.0%	21,056	100.0%

There are two ways to measure the load reductions of emergency demand response resources. The Firm Service Level (FSL) method for the summer period, measures the difference between a customer's peak load contribution (PLC) and its real-time load, multiplied by the loss factor (LF) to account for transmission and distribution line losses.[35] The Guaranteed Load Drop (GLD) method measures the minimum of: the comparison load minus real-time load multiplied by the loss factor; or the PLC minus the real-time load multiplied by the loss factor. The comparison load estimates what the load would have been if PJM did not declare a Load Management Event, similar to a CBL, by using a comparable day, same day, customer baseline, regression analysis or backup generation method. Limiting the GLD method to the minimum of the two calculations ensures reductions occur below the PLC, thus avoiding double counting of load reductions.[36]

With the introduction of the Winter Peak Load (WPL) concept, effective for the 2017/2018 Delivery Year, both the FSL and GLD methods are modified for the non-summer period. The FSL method measures compliance during the non-summer period as the difference between a customer's WPL multiplied by the

35 Real-time load is hourly metered load.
36 See 135 FERC ¶ 61,212 (2011).

Zonal Winter Weather Adjustment Factor (ZWWAF) and the loss factor (LF), rather than the PLC, and real-time load, multiplied by the LF. PJM calculates and posts on the PJM website the ZWWAF as the zonal winter weather normalized peak divided by the zonal average of the five coincident peak loads in December through February.[37] The Winter Peak Load is determined based on the average of the Demand Resource customer's specific peak hourly load between hours ending 7:00 EPT through 21:00 EPT on the PJM defined five coincident peak days from December through February two delivery years prior to the delivery year for which the registration is submitted. The Winter Peak Load is adjusted up for transmission and distribution line loss factors (LF) because one MW of load would be served by more than one MW of generation to account for transmission losses. The Winter Peak Load is normalized based on the winter conditions during the five coincident peak loads in winter using the ZWWAF to account for an extreme temperatures or a mild winter. The GLD method measures compliance during the non-summer period as the minimum of: the comparison load minus real-time load multiplied by the loss factor; or the WPL multiplied by the ZWWAF and the LF, rather than the PLC, minus the real-time load multiplied by the LF.[38]

The capacity market is an annual market. A Capacity Performance resource has an annual commitment. Effective with the 2020/2021 Delivery Year, the capacity market design also includes the ability to offer Seasonal Capacity Performance Resources directly into the RPM Auction as an alternative to entering into a commercial arrangement to establish and offer an Aggregate Resource.[39]Capacity Market Sellers may submit sell offers of either Summer Period Capacity Performance Resources or Winter Period Capacity Performance Resources and the auction clearing optimization algorithm is designed to clear equal quantities of offsetting seasonal capacity sell offers thereby creating an annual capacity commitment by matching a Summer Period Capacity Performance Resource with a Winter Period Capacity Performance Resource. Load is allocated capacity obligations based on the annual peak load which is a summer load. The amount of capacity MW allocated to load does not vary based on winter demand. The principle is that a customer's actual use of capacity should be compared to the level of capacity that a customer is required to pay for. Capacity costs are allocated to LSEs by PJM based on the single coincident peak load method. In PJM, the single coincident peak occurs in the summer.[40] LSEs generally allocate capacity costs to customers based on the five coincident peak method.[41] The allocation of capacity costs to customers uses each customer's PLC. Customers pay for capacity based on the PLC, not the WPL. If an end customer has 3 MW of load during the coincident peak load hour, but only 1 MW during the coincident winter peak load hour, the End Use Customer must pay for 3 MW of capacity for the entire delivery year, but can only participate as a 1 MW demand response resource. Using PLC to measure compliance for the entire delivery year would allow the customer to fully participate as a 3 MW demand response resource. FERC allowed the use of the WPL for calculating compliance for non-summer months effective June 1, 2017.[42] The MMU recommends setting the baseline for measuring capacity compliance under summer and winter compliance at the customer's PLC, similar to GLD, to avoid double counting, to avoid under counting and to ensure that a customer's purchase of capacity is calculated correctly. The FSL and GLD equations for calculating load reductions are:

$$FSL\ Compliance_{Summer} = PLC - (Load \cdot LF)$$

$$FSL\ Compliance_{Non-Summer} = (WPL \cdot ZWWAF \cdot LF) - (Load \cdot LF)$$

$$GLD\ Compliance_{Summer} = Minimum\{(comparison\ load - Load) \cdot LF; PLC - (Load \cdot LF)\}$$

$$GLD\ Compliance_{Non-Summer} = Minimum\{(comparison\ load - Load) \cdot LF; (WPL \cdot ZWWAF \cdot LF) - (Load \cdot LF)\}$$

37 "PJM Manual 18: PJM Capacity Market," § 4.3.7, Rev. 61 (July 23, 2025).
38 "PJM Manual 18: PJM Capacity Market," § 8.7A, Rev. 61 (July 23, 2025).
39 An Aggregate Resource is created by a Capacity Market Seller that owns or controls one or more Capacity Storage Resources, Intermittent Resources, Demand Resources or Environmentally Limited Resources by submitting a Sell Offer which represents the aggregated Unforced Capacity value of such resources, where such Sell Offer is considered to be located in the smallest modeled LDA common to the aggregated resources.

42 162 FERC ¶ 61,159 (2018).

For Demand Resources prior to the 2025/2026 Delivery Year, PJM calculated UCAP as the product of the FPR and the Demand Resource's Nominated Value, which depends on the peak load contribution of customers on the Demand Resource registration and their committed Firm Service Level or Guaranteed Load Drop.[43]

Similarly, the UCAP of an Energy Efficiency Resource is the product of the FPR and the resource's Nominated Energy Efficiency Value, which is the resource's expected average load reduction during the EE Performance Hours defined in the RAA.[44] The current accreditation practice for Demand Resources and Energy Efficiency Resources assumes they provide 100 percent performance at any time they are required to perform. Beginning with the 2025/2026 Delivery Year, PJM instituted an ELCC approach for generation and emergency demand response resources. This accreditation change does not apply to Energy Efficiency Resources whose UCAP value continues to be determined using FPR. For Demand Resources, PJM calculates Accredited UCAP as the product of the resource's Nominated Value and its ELCC Class Rating. Unlike generation, PJM does not apply a resource specific performance adjustment for Demand Resources. The Demand Resource availability window, defined in the RAA for Annual Demand Resources and Summer-Period Demand Resources, does not align with the projected hours with a loss of load risk in the winter period.[45] The ELCC class rating for Demand Resources for the 2025/2026 BRA is 76 percent.[46]

PJM makes several unsupported assumptions when calculating ELCC for demand response resources. The PJM ELCC calculations do not account for the actual historical performance of DR in same way as thermal resources. PJM analysis showed that the ELCC reduction capability is overstated compared to the metered DR reduction capability.[47] This overstatement of performance is consistent with the observed performance of DR during Winter Storm Elliott. There was a significant disparity between the reported expected reduction capability provided by the CSPs and the actual observed energy reduction during Winter Storm Elliott. As a general matter, these resources are rarely used.

Beginning in May 2024 the MIC worked on a problem statement and issue charge regarding the alignment of demand response capacity availability hours with periods of reliability risk.[48] PJM proposed to expand the window to all hours. PJM also proposed to use coincident peak demand rather than the sum of noncoincident peak demands to measure the level of demand resources. The MMU supported the extension of availability to all hours, consistent with all other capacity resources. The MMU supported the proposal to measure all DR for the same coincident peak demand hour as a more accurate measure of the level of actual DR potential rather than the overstatement that has resulted from adding together all the DR from individual non coincident peak hours.

PJM also proposed to increase the ELCC derating factor from 76 percent to 94 percent, an increase of 24 percent in the value of demand resource MW. PJM's proposed ELCC value for DR is not consistent with the method PJM uses for generation resources. PJM's proposed ELCC for DR is based on assumed behavior and not based on the actual performance of demand resources during the same high EUE (expected unserved energy) hours used for other capacity resources. The current ELCC value for demand response is already overstated. As currently demand resources are inferior resources in the capacity market and the ELCC values, both existing and proposed, significantly overstate their contribution to reliability. The demand resources are rarely used. While PJM may call on demand resources as part of its emergency actions, there are no PJM rules governing the overall commitment and dispatch of demand resources as there are for all other capacity resources.[49] Demand resources do not have a must offer obligation in the energy market as all other capacity resources do. PJM rules do not indicate if, when and how demand resources should be called on for nonemergency events. PJM rules do not require the use of demand resources under defined conditions. PJM rules do not require that demand resources be called on during emergency events but leave all emergency actions to the discretion of PJM dispatchers. The proposed changes

47 See PJM, DR Availability Window: Additional DR ELCC Information, <https://pjm.com/-/media/committees-groups/committees/mic/2024/20240807/20240807-item-08b---pjm-dr-education.ashx> (August 7, 2024).
48 See *Approved Minutes from the Markets & Reliability Committee*, <https://pjm.com/-/media/committees-groups/committees/mrc/2024/20240627/20240627-consent-agenda-a---draft-mrc-minutes---05222024.ashx>.
49 See PJM Manual 13: Emergency Operations, §2.3.2. Rev. 96 (Sept. 25, 2025).

would increase the value of demand resources by almost a billion dollars ($880.7M) without any actual change in the physical reality and without the type of detailed analysis applied to other capacity resources.[50] The proposed changes would simply pay demand response more for capacity without any increase in use and without any rules governing when demand response can or will be used for economic reasons and without a must offer obligation in the energy or capacity markets, and without any market power mitigation rules, without resource specific performance adjustments, and without addressing the fact that demand side performance metrics simply ignore increases in load above the WPL when called. PJM did not propose consistent changes to the treatment of demand resources in the summer. PJM proposed to make these changes to the ELCC value of demand response resources while ignoring significant issues with the treatment of other resource technologies. The result of this administrative change would also be to affect the ELCC of other classes and to make it appear that PJM is more reliable than it is. PJM filed these proposed changes on March 6, 2025, in Docket No. ER25-1525-000.[51] The MMU filed an answer and motion for leave to answer on April 14, 2025.[52] On May 5, 2025, in Docket No. ER25-1525-000, FERC accepted PJM's section 205 proposal to revise the RAA, effective with the 2027/2028 Delivery Year, that extends the Demand Resource availability window to 24 hours a day throughout the year and revises the definition of Winter Peak Load used in calculating Demand Resources' Winter Nominated Value in PJM's ELCC method, effective May 6, 2025.[53]

Table 6-14 shows the MW registered by measurement and verification method and by technology type for the 2025/2026 Delivery Year. For the 2025/2026 Delivery Year, 99.75 percent of the MW use the FSL method and 0.25 percent of the MW use the GLD measurement and verification method.

53 191 FERC ¶ 61,103

Table 6-14 Nominated MW by each demand response method: 2025/2026 Delivery Year

	Technology Type								
Measurement and Verification Method	On-site Generation MW	HVAC MW	Refrigeration MW	Lighting MW	Manufacturing MW	Water Heating MW	Other, Batteries or Plug Load MW	Total	Percent by type
Firm Service Level	1,258.3	1,892.9	210.8	792.0	3,659.3	24.4	141.6	7,979.3	99.75%
Guaranteed Load Drop	5.1	1.1	0.0	0.0	14.1	0.0	0.0	20.3	0.25%
Total	1,263.4	1,894.0	210.8	792.0	3,673.4	24.4	141.6	7,999.6	100.0%
Percent by method	15.8%	23.7%	2.6%	9.9%	45.9%	0.3%	1.8%	100.0%	

Table 6-15 shows the fuel type used in the onsite generators for the 2025/2026 Delivery Year in the emergency and pre-emergency programs. For the 2025/2026 Delivery Year, 1,263.4 MW of the 7,999.6 nominated MW, 15.8 percent, used onsite generation. Of the 1,263.4 MW, 84.5 percent used diesel and 15.5 percent used natural gas, gasoline, oil, propane or waste products. Some DR registrations reflect a participant's reliance on behind the meter generation having environmental restrictions that limit the resource's ability to operate only in emergency conditions. Demand resources relying on behind the meter generation having environmental restrictions limiting the resource's ability to operate only in emergency conditions must register as emergency DR. EPA regulations require that Reciprocating Internal Combustion Engines (RICE) that do not meet EPA emissions standards (stationary emergency RICE) may operate for only 100 hours per year and only to provide emergency DR during an Energy Emergency Alert 2 (EEA2), or if there are five percent voltage/frequency deviations. PJM does not prevent emergency stationary RICE that does not meet emissions standards from participating in PJM markets as DR. Some emergency stationary RICE that does not meet emissions standards are now included in DR portfolios. PJM's DR Hub does not explicitly identify Reciprocating Internal Combustion Engines (RICE) generators, only whether it is an internal combustion engine. For the 2025/2026 Delivery Year, of the 253.5 MW registered as generation backed emergency DR, 251.4 MW, or 19.9 percent of all onsite generation, are backed by internal combustion engines. Stationary emergency RICE should be prohibited from participation as DR either when registered individually or as part of a portfolio if it cannot meet its capacity market obligations as a result of emissions standards.

Table 6-15 Onsite generation fuel type (MW): 2025/2026 Delivery Year

	2025/2026	
Fuel Type	MW	Percent
Diesel	1,068.1	84.5%
Natural Gas, Gasoline, Oil, Propane, Waste Products	195.3	15.5%
Total	1,263.4	100.0%

Table 6-16 shows the MW registered by measurement and verification method and by technology type for the 2024/2025 Delivery Year. For the 2024/2025 Delivery Year, 99.99 percent use the FSL method and 0.01 percent use the GLD measurement and verification method.

Table 6-16 Nominated MW by each demand response method: 2024/2025 Delivery Year

	Technology Type								
Measurement and Verification Method	On-site Generation MW	HVAC MW	Refrigeration MW	Lighting MW	Manufacturing MW	Water Heating MW	Batteries and Plug Load MW	Total	Percent by type
Firm Service Level	1,050.5	1,731.0	192.5	663.3	3,438.5	22.3	116.5	7,214.7	99.99%
Guaranteed Load Drop	0.0	0.7	0.0	0.0	0.1	0.0	0.0	0.8	0.01%
Total	1,050.5	1,731.7	192.5	663.3	3,438.6	22.3	116.5	7,215.5	100.0%
Percent by method	14.6%	24.0%	2.7%	9.2%	47.7%	0.3%	1.6%	100.0%	

Table 6-17 shows the fuel type used in the onsite generators for the 2024/2025 Delivery Year in the emergency and pre-emergency programs. For the 2024/2025 Delivery Year, 1,050.5 MW of the 7,215.5 nominated MW, 14.6 percent, use onsite generation. Of the 1,050.5 MW, 84.1 percent use diesel and 15.9 percent use natural gas, gasoline, oil, propane or waste products.

Table 6-17 Onsite generation fuel type (MW): 2024/2025 Delivery Year

	2024/2025	
Fuel Type	MW	Percent
Diesel	883.5	84.1%
Natural Gas, Gasoline, Oil, Propane, Waste Products	167.0	15.9%
Total	1,050.5	100.0%

Emergency and Pre-Emergency Event Reported Compliance

Capacity resources measure performance nodally, except for demand resources. PJM cannot dispatch demand resources by node with the current rules because demand resources are not registered to a node. Demand resources can be dispatched by subzone only if the subzone is defined before dispatch. Aggregation rules allow a demand resource that incorporates many small End Use Customers to span an entire zone, which is inconsistent with nodal dispatch.

Subzonal dispatch became mandatory for emergency demand resources in the 2014/2015 Delivery Year.[54] A subzone is defined by zip code, not by nodal location. If a registration has any location in the dispatched subzone, as defined by the zip code of the enrolled End Use Customer's address, the entire registration must respond. There are currently nine defined dispatchable subzones in PJM: APS_EAST, DOM_CHES, DOM_YORKTOWN, AECO_ENGLAND, JCPL_REDBANK, DOM_ASHBURN, DOM_DCA, DOM_PRINWILM and AEP_MARION.[55] The AEP_MARION subzone was added as a result of the June 14-16, 2022, performance assessment event in the Columbus, Ohio area of the AEP Zone.

PJM can remove a defined subzone, and make changes to the subzone, at their discretion. Subzones should not be removed once defined, as the subzone may need to be dispatched again in the future. The METED_EAST, PENELEC_EAST, PPL_EAST and DOM_NORFOLK Subzones were removed by PJM. The MMU recommends that, if PJM continues to use subzones for any purpose, PJM clearly define the role of subzones in the dispatch of demand response.

The subzone design and closed loop interfaces are related. PJM implemented closed loop interfaces with the stated purpose of improving the incorporation of reactive constraints into energy prices and to allow emergency DR to set

54 OATT Attachment DD, Section 11.
55 See "Load Management Subzones," <https://www.pjm.com/-/media/markets-ops/demand-response/subzone-definition-workbook.ashx> (Accessed January 13, 2023).

price.[56] PJM applies closed loop interfaces so that it can use units needed for reactive support to set the energy price when they would not otherwise set price under the LMP algorithm. PJM also applies closed loop interfaces so that it can use emergency DR resources to set the real-time LMP when DR would not otherwise set price under the fundamental LMP logic. Of the 20 closed loop interface definitions, 11 (55 percent) were created for the purpose of allowing emergency DR to set price.[57] The closed loop interfaces created for the purpose of allowing emergency DR to set price are located in the Rest of RTO, MAAC, EMAAC, SWMAAC, DPL-SOUTH, ATSI, ATSI-CLEVELAND and BGE LDAs. These interfaces correspond to LDAs as defined in RPM.[58]

Demand resources can be dispatched for voluntary compliance during any hour of any day, but dispatched resources are not measured for compliance outside of the mandatory compliance window for each demand product. This will change beginning in the 2027/2028 Delivery Year when the mandatory compliance window will expand to 24 hours per day. A demand response event during a product's mandatory compliance window also may not result in a compliance score. When demand response events occur for partial hours under 30 minutes, the event is not measured for compliance.

Demand resources currently estimate five minute compliance with an hourly interval meter during PAIs. To accurately measure compliance on a five minute basis, a five minute interval meter is required. All other capacity resources require five minute interval meters, and demand resources should be no different. Demand resources are paid based on the average performance by registration for the duration of a demand response event. Demand response should measure compliance on a five minute basis to accurately report reductions during demand response events. Measuring compliance on a five minute basis would provide accurate information to the PJM system. The MMU recommends demand response event compliance be calculated on a five minute basis for all capacity resources and that the penalty structure reflect five minute compliance.[59]

Under the capacity performance design of the capacity market, compliance for potential penalties is measured for DR only during performance assessment intervals (PAI).[60]

The MMU recommended that demand response resources be treated as economic resources like all other capacity resources and therefore that the dispatch of demand response resources not automatically trigger a performance assessment interval (PAI) for CP compliance. Emergencies should be triggered only when PJM has exhausted all economic resources including demand response resources. For the first seven months of 2023, PJM declared an emergency if pre-emergency or emergency demand response were dispatched. But in an order issued July 28, 2023, effective July 30, 2023, FERC approved proposed revisions to PJM's Tariff to eliminate the dispatch of demand response as a trigger for calling an emergency and for defining a Performance Assessment Interval (PAI).[61] Table 6-18 shows the amount of nominated demand response MW, the required reserve margin and actual reserve margin for the 2024/2025 and 2025/2026 Delivery Years. There are 8,137.5 nominated MW of demand response for the 2025/2026 Delivery Year, 32.1 percent of the required reserve margin and 29.4 percent of the actual reserve margin for the 2025/2026 Delivery Year.[62]

Table 6-18 Demand response nominated MW compared to reserve margin: 2024/2025 and 2025/2026 Delivery Years[63]

Delivery Year	Demand Response Nominated MW	Required Reserve Margin	Demand Response Percent of Required Reserve Margin	Actual Reserve Margin	Demand Response Percent of Actual Reserve Margin
2024/2025	7,220.0	21,398.4	33.7%	24,856.8	29.0%
2025/2026	8,137.5	25,381.0	32.1%	25,116.0	32.4%

62 See *2025 Quarterly State of the Market Report for PJM: January through September*, Section 5: Capacity Market, Table 5-7.
63 Nominated MW totals are Demand Response ICAP corresponding to Demand Response UCAP cleared in RPM auctions for each delivery year. The total nominated MW values do not reflect replacement transactions.

PJM will dispatch demand resources by zone or subzone, or within a PAI area. When PJM dispatches all demand resources in multiple connecting zones, PJM further degrades the nodal design of electricity markets. In that case, PJM allows compliance to be measured across zones within a compliance aggregation area (CAA) or an Emergency Action Area (EAA).[64] [65] A CAA, or EAA, is an electrically connected area that has the same capacity market price. This changes the way CSPs dispatch resources when multiple electrically contiguous areas with the same RPM clearing prices are dispatched. The compliance rules determine how CSPs are paid and thus create incentives that CSPs will incorporate in their decisions about how to respond to PJM dispatch. The multiple zone approach is even less locational than the zonal and subzonal approaches and creates larger mismatches between the locational need for the resources and the actual response. If multiple zones within a CAA are called by PJM, a CSP will dispatch the least cost resources across the zones to cover the CSP's obligation. This can result in more MW dispatched in one zone that are locationally distant from the relief needed and no MW dispatched in another zone, yet the CSP could be considered 100 percent compliant and pay no penalties. More locational deployment of load management resources would improve efficiency. With full implementation of capacity performance, demand response will be dispatched by registrations within an area for which an Emergency Action is declared by PJM. PJM does not have the nodal location of each registration, meaning PJM will need to guess as to the useful demand response registration by registered location. The MMU recommends that demand resources be required to provide their nodal location. Nodal dispatch of demand resources would be consistent with the nodal dispatch of generation.

Definition of Compliance

PJM's reporting of load management events overstates the performance of demand side capacity resources. Limiting reported compliance to only positive values incorrectly reports compliance. Settlement locations with a negative load reduction value (load increase) are not included in compliance reporting by PJM within registrations or within demand response portfolios. A resource that has load above their PLC during a demand response event has a negative performance value. But PJM does not include the negative performance values in the net performance calculation. PJM limits reported compliance shortfall values to zero MW.

The MMU recommends that PJM correctly report compliance for demand side capacity resources to include negative values above PLC when calculating event compliance across hours and registrations.[66]

Emergency demand response resources that are also registered as economic resources have a calculated CBL for the emergency event days. Demand resources that are not registered as Economic Resources use the three day CBL type with the symmetrical additive adjustment for measuring energy reductions without the requirements of a Relative Root Mean Squared Error (RRMSE) Test required for all economic resources.[67] The CBL must use the RRMSE test to verify that it is a good approximation for real-time load usage.

The MMU recommends that PJM Manual 11 be revised to require, rather than recommend, that the RRMSE test be applied to all demand resources with a CBL.[68]

The CBL for a customer is an estimate of what load would have been if the customer had not responded to LMP and reduced load. The difference between the CBL and real-time load is the energy reduction. When load responds to LMP by using a behind the meter generator, the energy reduction should be capped at the generation output. Any additional energy reduction is a result of inaccuracy in the CBL estimate rather than an actual reduction. The MMU recommends capping demand reductions based entirely on behind the meter generation at the lower of the generator's economic maximum or actual generation output.

64 CAA is "a geographic area of Zones or sub-Zones that are electrically contiguous and experience for the relevant Delivery Year, based on Resource Clearing Prices of, for Delivery Years through May 31, 2018, Annual Resources and for the 2018/2019 Delivery Year and subsequent Delivery Years, Capacity Performance Resources, the same locational price separation in the Base Residual Auction, the same locational price separation in the First Incremental Auction, the same locational price separation in the Second Incremental Auction, or the same locational price separation in the Third Incremental Auction." OATT § 1.

An extreme example makes clear the fundamental problems with the use of measurement and verification methods to define the level of power that would have been used but for the DR actions, and the payments to DR customers that result from these methods. The current rules for measurement and verification for demand resources make a bankrupt company, a customer that no longer exists due to closing of a facility or a permanently shut down company, or a company with a permanent reduction in peak load due to a partial closing of a facility, an acceptable demand response customer under some interpretations of the tariff, although it is the view of the MMU that such customers should not be permitted to be included as registered demand resources. Companies that remain in business, but with a substantially reduced load, can maintain their pre-bankruptcy FSL (firm service level to which the customer agrees to reduce in an event) commitment, which can be greater than or equal to the post-bankruptcy peak load. The customer agrees to reduce to a level which is greater than or equal to its new peak load after bankruptcy. When demand response events occur the customer would receive credit for 100 percent reduction, even though the customer took no action and could take no action to reduce load. This problem exists regardless of whether the customer is still paying for capacity. To qualify and participate as a demand resource, the customer must have the ability to reduce load. "A participant that has the ability to reduce a measurable and verifiable portion of its load, as metered on an EDC account basis."[69] Such a customer no longer has the ability to reduce load in response to price or a PJM demand response event. CSPs in PJM have and continue to register bankrupt customers as emergency or pre-emergency load response customers. PJM finds acceptable the practice of CSPs maintaining the registration of customers with a bankruptcy related reduction in demand that are unable, as a result, to respond to emergency events. Three proposals that included language to remove bankrupt customers from a CSP's portfolio failed at the June 7, 2017, Market Implementation Committee.[70] The registered customers that are bankrupt and the amount of registered MW cannot be released for reasons of confidentiality.

69 OA Schedule 1 § 8.2.
70 There was one proposal from PJM, one proposal from a market participant and one proposal from the MMU. See *Approved Minutes from the Market Implementation Committee*, <http://www.pjm.com/-/media/committees-groups/committees/mic/20170607/20170607-minutes.ashx>.

The metering requirement for demand resources is outdated, and has not kept up with the changes to PJM's market design. PJM moved to five minute settlements, but the metering requirement for demand resources remained at an hourly interval meter. It is impossible to measure energy usage on a five minute basis using an hourly interval meter. PJM will estimate real-time usage by prorating the hourly interval meter and assume if load is less than the CBL, that the reduction occurred during the required dispatch window. The meter reading is not telemetered to PJM in real time. The resource is allowed up to 60 days to report the data to PJM.[71] The MMU recommends that PJM adopt the ISO-NE five-minute metering requirements in order to ensure that dispatchers have the necessary information for reliability and that market payments to demand resources be calculated based on interval meter data at the site of the demand reductions so that they can accurately measure compliance and that data be provided to PJM within 24 hours.[72]

On September 19, 2024, the Commission issued an order denying the complaint by Enerwise Global Technologies seeking to use statistical sampling for measuring demand response performance when interval metering is available.[73] Commissioner Chang concurred with the Commission's determination and agreed that using actual metered interval data is the ideal method to measure and verify performance for demand-side resources. Commissioner Chang further noted that it is essential that resources that are procured and compensated in the markets actually deliver on their reliability and economic commitments.[74]

When demand resources are not dispatched during a mandatory response window, each CSP must test their portfolio to the levels of capacity commitment, but the testing requirements have been inadequate.[75]

71 "PJM Manual 11: Energy & Ancillary Services Market Operations," § 10.4.1, Rev. 136 (October 1, 2025).
72 See ISO-NE Tariff, Section III, Market Rule 1, Appendix E1 and Appendix E2, "Demand Response," <http://www.iso-ne.com/regulatory/tariff/sect_3/mr1_append-e.pdf>. (Accessed October 17, 2017) ISO-NE requires that DR have an interval meter with five-minute data reported to the ISO and each behind the meter generator is required to have a separate interval meter. After June 1, 2017, demand response resources in ISO-NE must also be registered at a single node.
73 See "Order Denying Complaint re Enerwise Global Technologies, LLC v. PJM Interconnection," EL23-104-000 (July 28, 2023).
74 *Id*, Commissioner Chang Statement Concurring at 1.
75 The mandatory response time for Capacity Performance DR is June through October and the following May between 10:00AM to 10:00PM EPT and November through April between 6:00AM through 9:00PM EPT. *See* PJM. "Manual 18: PJM Capacity Market," Rev. 61 (July 23, 2025).

For the 2023/2024 Delivery Year and subsequent delivery years, if a Demand Resource registration is not dispatched by PJM for a Load Management event in a delivery year, then the registration must be tested for a two-hour period between the hours of 11:00 EPT and 18:00 EPT of a non-NERC holiday weekday during June through October or November through March of the relevant delivery year, where the date and time are selected by PJM.[76] All registrations in a zone are tested simultaneously for two hours for each product type. Registration performance is calculated as the two hour average reduction.

If less than 25 percent (by MW) of a CSP's total Demand Resources in a zone fail the test, the CSP may conduct re-tests limited to all registrations that failed to meet their seasonal nominated ICAP in the prior test, provided that such re-test(s) must be during the same season, at the same time of day and under approximately the same weather conditions as the prior test. If 25 percent or more (by MW) of a CSP's Demand Resources fail the test, the CSP may request PJM to schedule a one time retest limited to all registrations that failed to meet their seasonal nominated ICAP in the prior test. The request must be made before the 46th day after the test. PJM will select the date and time of the retest during the same season. For the initial PJM scheduled test, PJM schedules, on an alternating basis, one test during June through October or November through March for each delivery year that a test is required. On the first business day of a week, PJM provides notice of all zones to be tested during the following two week test window. The test window opens the first business day of the week following the notice. By 10:00 EPT the day before the test, PJM posts on its website, and notifies the CSPs directly, the test date and zones.[77] On the test date, CSPs are notified of the start time of the test through the same notification protocol used for an actual event. For any scheduled retest by PJM, by 10:00 EPT the day before the retest, PJM will posts on its website, and notifies the CSPs directly, the retest date. On the retest date, CSPs are notified of the start time of the retest through the same notification protocol used for an event.

While the testing revisions implemented with the 2023/2024 Delivery Year are an improvement, the MMU recommends that load management testing be initiated by PJM with advance notice to CSPs identical to the actual lead time required in an emergency in order to accurately represent the conditions of an emergency event.

Beginning in the 2024/2025 Delivery Year and subsequent delivery years, CSPs may elect to use performance data from a Load Management event that was not subject to a Non-Performance Assessment (a non-PAI LM event) as performance data for a PJM zonal test event.[78] Elections are made on or after June 1 and no later than July 14 after the delivery year in the DR Hub system. Data required for compliance evaluation must be submitted no later than July 14 after the delivery year. Only one event result (either test event or non-PAI LM event) for each end-use customer site will be used in the zonal test evaluation. The duration of the non-PAI LM event must be at least 30 minutes of a clock hour. The election of non-PAI LM events to be used as zonal test performance will be done at registration lead time level. The non-PAI LM event must have occurred in the same season as the PJM scheduled test. For purposes of this election, the calculated reduction value for a registration in the non-PAI LM event is the average of the registration's hourly reductions within the product period hourly window.

The ability for test performance to be a substitute for event performance, coupled with the absence of nonperformance penalties, weakens the incentive to perform during non-PAI events. Emergency demand response resources have the same obligation to perform when called upon, regardless of whether the dispatch event occurs as part of a PAI or not.[79] There is no reason therefore to allow CSPs the optionality of testing in lieu of using non-PAI event performance.

Table 6-19 shows the test penalties by delivery year by product type for the 2021/2022 Delivery Year through the 2024/2025 Delivery Year.[80] The shortfall MW are calculated for each CSP by zone. The weighted rate per MW is the average penalty rate paid per MW. Testing shortfalls increased dramatically beginning with the 2023/2024 Delivery Year. The testing shortfall for the

76 "PJM Manual 18: PJM Capacity Market," § 8.7, Rev. 61 (July 23, 2025).

78 "PJM Manual 18: PJM Capacity Market," § 8.7, Rev. 61 (July 23, 2025).
79 OATT Attachment K, § 8.5.
80 Not all products received penalties or existed in every delivery year. For example, the Base and Capacity Performance products were not an option for the 2020/2021 Delivery Year.

2024/2025 Delivery Year increased by 134 percent compared to the 2023/2024 Delivery Year. Total Load Management Test Compliance penalties were 15.5 percent of total DR capacity revenues in the 2024/2025 Delivery Year.

The daily load management test failure charge rate for a zonal testing shortfall is equal to the provider's weighted daily revenue rate in such zone plus the greater of 0.20 times the provider's weighted daily revenue rate in such zone, or $20/MW-day. A daily load management test failure charge, equal to the net testing shortfall in the zone times the daily load management test failure charge rate, is applied for each day in the delivery year that the resource was committed. The load management test failure charge is assessed in the August monthly bill, issued in September, after the conclusion of the delivery year.[81] The ex-post nature of the load management test penalty, coupled with a high test failure rate, creates the potential for credit issues. Planned demand resource positions in RPM have a collateral requirement only until such time that a nominated MW quantity of customers are registered in DRHUB sufficient to cover the RPM zonal MW quantity committed.[82] These registrations occur prior to the start of the delivery year. Following the delivery year, at the time the testing penalty is levied, these resources are no longer collateralized. Providers subject to test failure penalties would nonetheless be subject to a retroactive disgorgement of revenues proportional to the shortfall quantity plus the higher of 20 percent of their weighted daily revenue rate or $20/MW-day.

Table 6-19 Test penalties by delivery year: 2021/2022 through 2024/2025 Delivery Years

	2021/2022			2022/2023			2023/2024			2024/2025		
Product Type	Shortfall MW	Weighted Rate per MW	Total Penalty	Shortfall MW	Weighted Rate per MW	Total Penalty	Shortfall MW	Weighted Rate per MW	Total Penalty	Shortfall MW	Weighted Rate per MW	Total Penalty
Capacity Performance	23.1	$176.79	$1,487,430	7.1	$97.07	$250,346	391.4	$56.45	$8,087,631	933.4	$53.50	$18,225,318

When describing overall test performance, PJM nets the over and under performance of all resources. Netting overstates the performance and capability of the underlying resources. A resource that tests short of its RPM commitment is subject to a penalty. That penalty is offset neither by the over performance of the provider's other resources nor that of other provider's resources. Additionally, during an actual dispatch event, a resource is only required to perform up to its RPM commitment to avoid penalties. While a resource may demonstrate excess capability during testing, there is no obligation for that capability to be provided during an actual event.

Test results for the 2024/2025 Delivery Year when netted, demonstrate an overall capability of 103 percent of the RPM commitment. Underlying this are 933 MW UCAP of testing deficiencies assessed to individual resources. Testing results for the 2024/2025 Delivery Year also showed a marked difference in performance between CSP and EDC or utility-operated programs. As a general matter, the overall over performance of the EDC program resources offset the overall under performance of non-utility providers in the 2024/2025 Delivery Year. Table 6-20 contrasts the testing performance of resources from utility versus non-utility providers for the 2024/2025 Delivery Year.

Table 6-20 Testing Performance: CSP vs EDC Providers

Provider Type	RPM Commitment MW UCAP	Test Performance MW UCAP	Percent
CSP	6,782.6	6,396.5	94%
EDC	920.4	1,540.8	167%
Overall	7,703.1	7,937.3	103%

81 "PJM Manual 18: PJM Capacity Market," § 9.1.6, Rev. 61 (July 23, 2025).
82 "PJM Manual 18: PJM Capacity Market," § 4.8.2, Rev. 61 (July 23, 2025).

Emergency and Pre-Emergency Load Response Energy Payments

Emergency and pre-emergency demand response dispatched during a load management event by PJM are eligible to receive emergency energy payments if registered under the full program option. The full program option includes an energy payment for load reductions during a pre-emergency or emergency event for demand response events and capacity payments.[83] There are 98.7 percent of nominated MW for the 2025/2026 Delivery Year registered under the full program option. There are 1.3 percent of nominated MW for the 2025/2026 Delivery Year registered as capacity only option. Demand resources clear the capacity market like all other capacity resources and the dispatch of demand resources should not trigger a scarcity event. The strike price is set by the CSP before the delivery year starts and cannot be changed during the delivery year. The demand resource energy payments are equal to the higher of hourly zonal LMP or the strike price energy offer made by the participant, including a dollar per MWh minimum dispatch price and an associated shutdown cost. Demand resources should not be permitted to offer above $1,000 per MWh without cost justification or to include a shortage penalty in the offer. FERC has stated clearly that demand resources in the capacity market must verify costs above $1,000 per MWh, unless they are capacity only: "We clarify, however, that reforms adopted in this Final Rule, which provide that resources are eligible to submit cost-based incremental energy offers in excess of $1,000/MWh and require that those offers be verified, do not apply to capacity-only demand response resources that do not submit incremental energy offers in energy markets."[84] PJM interprets the scarcity pricing rules to allow a maximum DR energy price of $1,849 per MWh for the 2021/2022 Delivery Year.[85] [86] Demand resources registered with the full option should be required to verify energy offers in excess of $1,000 per MWh. PJM does not require such verification.[87] The MMU recommends that the maximum offer for demand resources be the same as the maximum offer for generation resources and that the same cost verification rules applied to generation resources apply to demand resources.

Shutdown costs for demand response resources are not adequately defined in Manual 15. PJM's Cost Development Subcommittee (CDS) approved changes to Manual 15 to eliminate shutdown costs for demand response resources participating in the synchronized reserve market, but not demand resources or economic resources.[88]

Table 6-21 shows the distribution of registrations and associated MW in the emergency full option across ranges of minimum dispatch prices for the 2024/2025 Delivery Year. The majority of participants, 83.3 percent of locations and 52.8 percent of nominated MW, had a minimum dispatch price between $1,550 and $1,849 per MWh, the maximum price allowed for the 2024/2025 Delivery Year. Almost all registrations, 99.7 percent of locations and 98.1 percent of nominated MW have a dispatch price above $1,000 per MWh. The shutdown cost of resources with $1,000 to $1,275 per MWh strike prices had the highest average at $137.74 per location and $109.14 per nominated MW.

Table 6-21 Distribution of registrations and associated MW in the full option across ranges of minimum dispatch: 2024/2025 Delivery Year

Ranges of Strike Prices ($/MWh)	Locations	Percent of Total	Nominated MW (ICAP)	Percent of Total	Shutdown Cost per Location	Shutdown Cost Per Nominated MW (ICAP)
$0-$1,000	49	0.3%	132.6	1.9%	$7.14	$2.64
$1,000-$1,275	2,323	14.3%	2,931.6	41.2%	$137.74	$109.14
$1,275-$1,550	340	2.1%	293.6	4.1%	$0.31	$0.36
$1,550-$1,849	13,534	83.3%	3,755.3	52.8%	$15.37	$55.40
Total	16,246	100.0%	7,113.2	100.0%	$32.53	$74.29

Table 6-22 shows the distribution of registrations and associated MW in the emergency full option across ranges of minimum dispatch prices for the 2025/2026 Delivery Year. The majority of participants, 76.0 percent of locations and 43.8 percent of nominated MW, have a minimum dispatch price between $1,550 and $1,849 per MWh, the maximum price allowed for the 2025/2026 Delivery Year. Almost all registrations, 99.7 percent of locations

88 "PJM Manual 15: Cost Development Guidelines," § 8.1, Rev. 47 (Oct. 1, 2025).

and 98.0 percent of nominated MW have a dispatch price above $1,000 per MWh. The shutdown cost of resources with $0 to $1,000 per MWh strike prices have the highest average at $175.34 per location, while the shutdown cost of resources with $1,000 to $1,275 per MWh strike prices have the highest average at $87.73 per nominated MW.

Table 6-22 Distribution of registrations and associated MW in the full option across ranges of minimum dispatch: 2025/2026 Delivery Year

Ranges of Strike Prices ($/MWh)	Locations	Percent of Total	Nominated MW (ICAP)	Percent of Total	Shutdown Cost per Location	Shutdown Cost Per Nominated MW (ICAP)
$0-$1,000	59	0.3%	156.1	2.0%	$175.34	$66.25
$1,000-$1,275	4,459	21.5%	3,784.9	47.9%	$74.47	$87.73
$1,275-$1,550	447	2.2%	497.1	6.3%	$0.21	$0.19
$1,550-$1,849	15,738	76.0%	3,460.2	43.8%	$11.15	$50.70
Total	20,703	100.0%	7,898.4	100.0%	$25.02	$65.57

PRD

Price Responsive Demand, or PRD, in the capacity market is capacity based on a firm commitment to reduce load in response to a defined level of real-time energy prices. A PRD offer is a commitment to reduce energy usage by a defined amount in response to real time energy prices during the delivery year. A PRD offer includes MW quantities that the seller will reduce at defined capacity market reservation prices ($/MW-day). PRD offers change the shape of the VRR Curves used in the capacity market auctions.

PRD is provided by a PJM member that represents retail customers that have the ability to reduce load in response to price. In order to be eligible as PRD, the End Use Customer load must be served under a dynamic retail rate or contractual arrangement linked to, or based upon, a PJM real-time LMP trigger at a substation as electrically close as practical to the applicable load. In order for load to be eligible to be considered as PRD, the end-use customer load must be subject to Supervisory Control as defined in the RAA.[89] End Use Customer loads identified may not sell any other form of demand side management in PJM markets.

PRD must also be curtailed once PJM has declared a Performance Assessment Interval but only if the real-time LMP at the applicable location meets or exceeds the price on the submitted PRD curve at which the load has committed to curtail. The high PRD strike prices mean that PRD could avoid a performance requirement even during a PAI.

In order to commit PRD for a delivery year, a PRD Provider must submit a PRD Plan in advance of the Base Residual Auction which indicates the Nominal PRD Value in MW that the PRD Provider is willing to commit at different reservation prices expressed in ($/MW-day). Additional PRD may participate in the Third Incremental Auction only if the LDA final peak load forecast for the delivery year increases relative to the LDA preliminary peak load forecast used for the Base Residual Auction.

Unlike other capacity resources, once committed, PRD may not be uncommitted or replaced by available capacity resources or Excess Commitment Credits. A PRD Provider may transfer the PRD obligation to another PRD Provider bilaterally. The PRD Provider will receive a Daily PRD Credit ($/MW-day) during the delivery year. A PRD Provider under the FRR Alternative will not be eligible to receive a Daily PRD Credit ($/MW-day) during the delivery year. PRD first cleared the capacity market in the BRA for the 2020/2021 Delivery Year.[90] Table 6-23 shows the Nominated MW of Price Responsive Demand for the 2020/2021 through 2025/2026 Delivery Years.

Table 6-23 Nominated MW of price responsive demand: 2020/2021 through 2025/2026 Delivery Year

Delivery Year	RTO	MAAC	EMAAC	SWMAAC	DPL SOUTH	PEPCO	BGE
2020/2021	558.0	558.0	58.0	500.0	27.0	170.0	330.0
2021/2022	510.0	510.0	75.0	435.0	35.7	195.0	240.0
2022/2023	230.0	230.0	40.0	190.0	19.6	110.0	80.0
2023/2024	235.0	235.0	38.0	197.0	15.4	110.0	87.0
2024/2025	305.0	305.0	35.0	270.0	13.0	110.0	160.0

89 "PJM Manual 18: PJM Capacity Market," § 3A.3, Rev. 61 (July 23, 2025).

90 There were a total of 558 MW of cleared PRD in the 2020/2021 Delivery Year. See PJM Auction Results, <https://www.pjm.com/-/media/markets-ops/rpm/rpm-auction-info/2020-2021-base-residual-auction-results.ashx?la=en>.

The cleared PRD is credited the adjusted zonal clearing price of the LDA in which they cleared. The PRD credits are charged to the load of those LDAs by inclusion in the RPM net load price A PRD Provider receives a PRD Credit for each approved Price Responsive Demand registration on a given day. PRD Credits are determined as:[91]

$$
\begin{aligned}
&\textit{PRD Credit}\\
&= [(\textit{Share of Zonal Nominal PRD Value committed in Base Residual Auction}\\
&* (\textit{Zonal Weather}\\
&- \textit{Normalized Peak Load for the summer concluding prior to the commencement of the Delivery Year}\\
&/ \textit{Final Zonal Peak Load Forecast for the Delivery Year})\\
&* \textit{Final Zonal RPM Scaling Factor} * \textit{FPR} * \textit{Final Zonal Capacity Price})\\
&\\
&\textit{plus}\\
&\\
&(\textit{Share of Zonal Nominal PRD Value committed in Third Incremental Auction}\\
&* (\textit{Zonal Weather}\\
&- \textit{Normalized Peak Load for the summer concluding prior to the commencement of the Delivery Year}\\
&/ \textit{Final Zonal Peak Load Forecast for the Delivery Year})\\
&* \textit{Final Zonal RPM Scaling Factor} * \textit{FPR} * \textit{Final Zonal Capacity Price}\\
&* \textit{Third Incremental Auction Component of Final Zonal Capacity Price stated as a Percentage})]
\end{aligned}
$$

Effective with the 2022/2023 Delivery Year, the factor equal to (Zonal Weather-Normalized Peak Load for the summer concluding prior to the commencement of the Delivery Year / Final Zonal Peak Load Forecast for the delivery year) is eliminated in the calculation of the PRD Credit.

Table 6-24 shows the PRD Credits for the 2020/2021 through 2025/2026 Delivery Years.[92]

Table 6-24 PRD Credits for 2020/2021 through 2025/2026 Delivery Year

Delivery Year	PRD Credit
2020/2021	$23,649,865.05
2021/2022	$38,282,769.14
2022/2023	$10,702,158.12
2023/2024	$6,169,725.27
2024/2025	$10,782,581.08
2025/2026	$10,848,835.56

91 PJM. "Manual 18: Capacity Market," § 9.4.4, Rev. 61 (July 23, 2025).
92 The total credits for PRD were downloaded as of October 14, 2025, and may change as a result of continued PJM billing updates.

A PRD Provider with a daily commitment compliance shortfall in a subzone/zone for RPM or FRR is assessed a Daily PRD Commitment Compliance Penalty. The Daily PRD Commitment Compliance Penalty is determined as:

$$\begin{aligned}&\textit{PRD Commitment Compliance Penalty}\\&\quad = \textit{MW shortfall in the Sub} - \textit{zone}/\textit{Zone}\\&\quad * \textit{Delivery Year Forecast Pool Requirement}\\&\quad * \textit{PRD Commitment Compliance Penalty Rate}\end{aligned}$$

The revenue collected from assessment of the PRD Commitment Compliance Penalty is distributed to all entities that committed Capacity Resources in the RPM Auctions for the relevant delivery year, based on each entity's prorata share of daily revenues from Capacity Market Clearing Prices in such auctions, net of any daily compliance charges incurred by such entity.

PRD committed in RPM for the current delivery year bids in the PJM Energy Market. PRD Curves may be submitted by PRD Providers in the PJM Energy Market by 1100 at the closing of the day-ahead bid period. PRD Curves submitted by PRD Providers are identified in the day-ahead market software and user interface. PRD bids are modeled in the real-time energy market only, and are modeled in the real-time dispatch algorithms. PRD curves are not modeled in the day-ahead market clearing process. PRD Curves in the energy market are modeled in the real-time dispatch algorithms and can set real-time LMP. PRD Providers with committed PRD are required to have automation of PRD that is needed to respond to real-time LMPs for the PRD Curves that are submitted. The maximum bid price of the PRD Curve is the applicable energy market offer cap plus the shortage penalty, or $1,849 per MWh. When PRD sellers offer at the cap, they limit the number of times that PRD is called on to respond. The ability to use the strike price which is above the maximum offer for generation resources and above the energy market price for most intervals permits PRD to economically withhold and renders the PRD resources effectively worthless under almost all circumstances.

On February 7, 2019, PJM filed revisions to its Open Access Transmission Tariff and the Reliability Assurance Agreement to update the rules and requirements for PRD to conform to those for Capacity Performance Resources.[93] PJM's filing sought to change the calculation of the Nominal PRD Value used for determining the PRD Credit from the reduction in load during PJM's annual peak to the lesser of summer and winter load reductions. The proposed changes were intended to ensure that PRD will be available to curtail the same quantity of MW in either the summer or the winter consistent with the requirements of Capacity Performance Resources. In an order issued June 27, 2019, the Commission rejected PJM's proposal finding that it was unjust and unreasonable to calculate the Nominal PRD Value in a manner inconsistent with how an LSE's capacity obligation is determined, and therefore saw no need for consistency between the PRD requirements and the requirements for capacity resources.[94] While treated as an annual product, PRD resources are largely comprised of utility retail programs designed to reduce electric load during periods of high load and/or high wholesale energy prices during the summer season. PRD resources consequently performed poorly when called upon during Winter Storm Elliott for the small number of intervals in which LMP exceeded the strike price.[95]

The PRD rules fall short of defining an effective and efficient product that is aligned with the definition of a capacity resource.[96] PJM's initial filing was rejected by the Commission based on the MMU's comments and PJM's modified filing was accepted.[97] PJM's final filing adopted the MMU's recommendation to exclude the use of Winter Peak Load (WPL) when calculating the nominated MW for PRD resources used to satisfy RPM commitments. Load is allocated capacity obligations based on the annual peak load within PJM. The amount of capacity allocated to load is a function solely of summer coincident peak demand and is unaffected by winter demand. Use of the WPL to calculate the nominated MW for PRD resources to satisfy RPM commitments, would incorrectly restrict PRD to less than the total capacity the customer is required to buy. PJM's adoption of the MMU recommendation correctly values PRD nominated MW. FERC required and PJM's filing also adopted the MMU's recommendation that PRD should be eligible for bonus performance payments

97 See "Order Rejecting Tariff Revisions," Docket No. ER19-1012-000 (June 27, 2019).

during Performance Assessment Intervals (PAI) only when PRD resources respond above their nominated MW value. Allowing PRD resources to collect bonus payments at times when they are not even required to meet their basic obligation would be inconsistent with the basic CP construct as it applies to all other CP resources.[98]

PJM's filing still fell short of completely aligning PRD with the definition of capacity. PRD resources do not have to respond during a PAI if the PRD's trigger price is above LMP during the PAI. All other CP resources have the obligation to perform during a PAI, regardless of the real-time LMP, subject to instructions from PJM. PRD should be held to the same standard during a PAI event. The MMU recommends that PRD be required to respond during a PAI, regardless of whether the real-time LMP at the applicable location meet or exceeds the PRD strike price, to be consistent with all CP resources.

June 23-25, 2025 Load Management Event

PJM dispatched pre-emergency load management during a period of hot weather on June 23-25, 2025. Long lead time (120 minute) and short lead-time (60 minute) pre-emergency resources were dispatched each day. PJM never declared a level EEA2 emergency, the requirement for deployment of emergency demand response resources, and therefore only dispatched pre-emergency demand resources.[99]

PJM did not dispatch quick lead time (30 minute) demand resources. PJM used the less flexible 60 and 120 minute lead time resources first. The 60 and 120 minute lead time resources were more economical as they are subject to $1,425 and $1,100 maximum strike prices compared to the $1,849 maximum strike price for 30 minute resources.

On June 23, 2025, PJM dispatched 1,299.3 MW of 120 minute lead time (34.6 percent of total pre-emergency 120 minute resources) and 114.0 MW of 60 minute lead time (24.7 percent of total pre-emergency 60 minute resources). On June 24, 2025, PJM dispatched 3,755.5 MW of 120 minute lead time (100 percent of total pre-emergency 120 minute resources) and 462.0 MW of 60 minute lead time (100 percent of total pre-emergency 60 minute resources). On June 25, 2025, PJM dispatched 1,604.5 MW of 120 minute lead time (42.7 percent of total pre-emergency 120 minute resources) and 123.9 MW of 60 minute lead time (26.8 percent of total pre-emergency 60 minute resources).[100]

Load management compliance data for non-PAI event performance is due 45 days after the month in which the event occurs.[101] Data supporting requested energy settlements is due 60 days after an event.[102]

Table 6-25 through Table 6-27 show the deployment and release times, by lead time, for June 23-25, 2025.

Table 6-25 Demand Resource Deployment and Release Times: June 23, 2025

Deploy Time (EPT)	Release Time (EPT)	Resource Type	Lead Time	Zones

1500	1900	Pre-emergency	60 minute	DOM

The emergency procedures employed during June 23-25, 2025 did not trigger a PAI. There are no penalties for demand resources failing to perform outside of a PAI. In an order issued July 28, 2023, effective July 30, 2023, FERC approved proposed revisions to PJM's Tariff to eliminate the dispatch of demand response as a trigger for calling an emergency and for defining a Performance Assessment Interval (PAI).[103] Under the prior rules, PJM would declare an emergency if pre-emergency or emergency demand response was dispatched. The new rules mean that demand resources may be dispatched both as part of, and absent, a PAI. While demand resources dispatched during a PAI continue to be subject to Non-Performance Assessment charges, demand resources dispatched outside of a PAI are not subject to any event specific penalties.[104] If a demand resource is dispatched only outside of Performance Assessment Events for the delivery year, its performance for the delivery year may be determined based solely on a Load Management Test.[105] Beginning in the 2024/2025 Delivery Year and subsequent delivery years, CSPs may elect to use performance data from a load management event that was not subject to a Non-Performance Assessment (a non-PAI load management event) as performance data for a PJM zonal test event.[106]

Given that calling demand resources no longer triggers a PAI, the MMU recommended in 2023 that PJM revise the performance requirements for demand resources to include an event specific measurement for dispatch occurring outside of Performance Assessment Events and penalties for nonperformance. Load management resources have the same obligation to perform when called upon, regardless of whether the dispatch event occurs as part of a PAI or not.[107] There is no reason therefore to allow CSPs the optionality of testing in lieu of using non-PAI event performance. If demand resources are only subject to non-PAI dispatch events during the delivery year, their ability to meet their obligations are best defined by their actual operational performance rather than through a scripted test.

Load management resources overall failed to perform to their committed ICAP level during the June 23-25, 2025 dispatch event. Load management resources were evaluated based on their ability to reduce load to their nominated Firm Service Level (FSL). Customer Base Line (CBL) is an hourly estimate of the load level of a demand resource in the absence of a demand response event. The expected hourly reduction of each resource is defined as the difference between the CBL and the FSL. The actual hourly reduction is defined as the difference between the CBL and the metered load of the resource adjusted for losses. If a resource reduces to its FSL, then its actual reduction equals its expected reduction. This metric provides a better assessment of demand response performance than simply comparing metered load to FSL. During Winter Storm Elliott, demand resource loads were already at a reduced level when dispatched. While deemed to have generally met their ICAP commitments, there was very little incremental reduction provided in order to reach their FSL. The difference between CBL and FSL provides a better estimate of the expected incremental reduction. If a dispatched registration has a CBL equal to or less than the FSL, the expected incremental reduction is zero. Based on this metric, demand resources provided 69.3 percent of their expected reduction on June 23, 70.6 percent of their expected reduction on June 24 and 68.8 percent of their expected reduction on June 25. Table 6-28 summarizes these results.

103 See "Order Accepting Tariff Revisions Subject to Condition," Docket No. ER23-1996-000 (July 28, 2023).
104 "PJM Manual 18: PJM Capacity Market," § 8.6, Rev. 61 (July 23, 2025).
105 "PJM Manual 18: PJM Capacity Market," § 8.7, Rev. 61 (July 23, 2025).

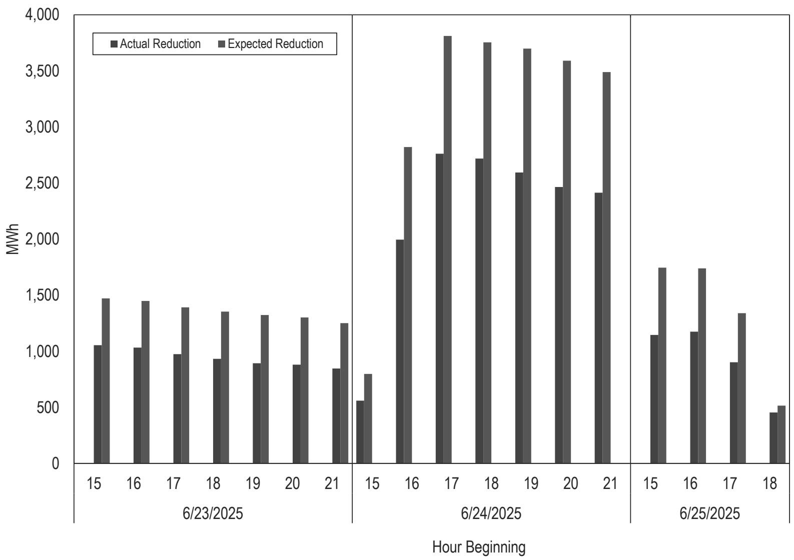
107 OATT Attachment K, § 8.5.

Table 6-28 Demand Resource Expected and Actual Performance: June 23-25, 2025

Date	Actual Reduction (MWh)	Expected Reduction (MWh)	Percent Performance
23-Jun-25	6,614	9,540	69.3%
24-Jun-25	15,506	21,963	70.6%
25-Jun-25	3,675	5,339	68.8%
Total	25,796	36,842	70.0%

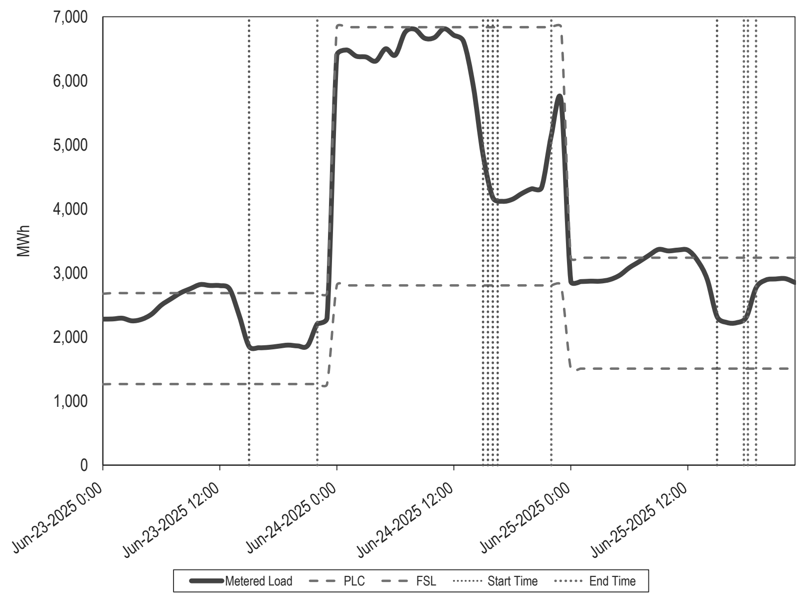
Figure 6-2 shows the hourly expected and actual reduction values for June 23-25, 2025.

Figure 6-2 Hourly demand resource expected and actual performance: June 23-25, 2025



The failure of demand resources overall to perform to their committed ICAP level is further evidenced by observing the metered load relative to the Peak Load Contribution (PLC) and FSL. As shown in Figure 6-3, demand resources overall failed to reduce load to their FSL on all three days that they were dispatched.

Figure 6-3 Demand resource metered load compared to PLC and FSL: June 23-25, 2025



Load management demand resources are compensated at real-time LMP for their actual load reduction determined as the difference between the CBL and the metered load. Load management demand resources are paid an emergency load response energy credit equal to their actual load reduction multiplied by the real-time LMP. Load management demand resources are made whole to their offer value which includes their emergency bid price, or strike price and shutdown costs. If the emergency load response energy credit is insufficient to cover the emergency bid based reduction plus shutdown costs, they will receive an emergency load response make whole credit for the difference.

$$\begin{aligned}&\textit{Total Emergency Energy Revenue}\\&\quad = \textit{Daily Load Response Emergency Credits}\\&\quad + \textit{Emergency Load Response Make Whole Credit}\end{aligned}$$

where,

$$\begin{aligned}&\textit{Emergency Load Response Make Whole Credit}\\&\quad = \textit{Emergency Bid cost} + \textit{Emergency Shutdown cost}\\&\quad - \textit{Daily Load Response Emergency Credits}\end{aligned}$$

Table 6-29 shows the daily emergency energy payments to load management demand resources for June 23-25, 2025. Across the three days, real-time LMP was sufficient to cover 51 percent of the total emergency energy payments with the remainder compensated through make whole credits. These energy payments are in addition to the capacity market revenues received by load management demand resources. For the 2025/2026 Delivery Year, capacity market revenues paid to load management demand resources average $55.5 million per month.

Table 6-29 Demand resource emergency energy payments: June 23-25, 2025

Date	Real-Time Actual Relief (MWh)	Average Emergency Bid Price	Average Emergency Shutdown Cost	Average LMP	Emergency Load Response Energy Credit	Emergency Load Response Energy Make-Whole Credit	Total Emergency Energy Revenue
23-Jun-25	7,397	$1,143	$48	$555	$4,105,528	$3,616,557	$7,722,084
24-Jun-25	19,096	$1,134	$82	$662	$12,639,948	$8,862,562	$21,502,510
25-Jun-25	5,149	$1,132	$72	$212	$1,092,332	$4,347,255	$5,439,587
Total	31,642	$1,136	$67	$564	$17,837,807	$16,826,374	$34,664,181

Economic Demand Response

The Economic Demand Response Program is for demand response customers that offer into the day-ahead or real-time energy market.[108] The estimated load reduction is paid the zonal LMP, as long as the zonal LMP is greater than the monthly Net Benefits Test threshold.

Market Structure

Table 6-30 shows the average hourly HHI for each month and the average hourly HHI for January 1, 2024, through September 30, 2025. The ownership of economic demand response resources was highly concentrated in 2024 and the first nine months of 2025.[109] Table 6-30 lists the share of reported reductions provided by, and the share of credits claimed by the four largest CSPs in each year. The HHI for economic demand response was highly concentrated in the first nine months of 2025. The HHI for economic demand response in the first nine months of 2025 decreased by 46, 0.5 percent, from 8846 in the first nine months of 2024 to 8800 in the first nine months of 2025.

108 Also known in the PJM Market Rules as the Economic Load Response Program.
109 All HHI calculations in this section are at the parent company level.

Table 6-30 Average hourly MWh HHI and market concentration in the economic program: January 2024 through September 2025[110]

	Average Hourly MWh HHI			Top Four CSPs Share of Reduction			Top Four CSPs Share of Credit		
Month	2024	2025	Percent Change	2024	2025	Change in Percent	2024	2025	Change in Percent

Market Performance

Table 6-31 shows the total MW reported reductions made by participants in the economic program and the total credits paid for these reported reductions in the first nine months of 2010 through 2025. The average credits per MWh paid increased by $5.77 per MWh, 10.9 percent, from $52.76 per MWh in the first nine months of 2024 to $58.53 per MWh in the first nine months of 2025. Curtailed energy for the economic program was 350,396 MWh in the first nine months of 2025, an increase of 184,584 MWh, 111.3 percent, as compared to curtailed energy for the economic program in the first nine months of 2024. Total credits paid for the economic load response program in the first nine months of 2025 were $20,508,803, an increase of $11,760,026, 134.4 percent, compared to the total credits paid for the economic load response program in the first nine months of 2024.

110 Omitted reduction and credit share values are based on confidentiality rules that require published data to include more than four owners.

Table 6-31 Credits paid to economic program participants: January through September, 2010 through 2025

(Jan-Sep)	Total MWh	Total Credits	$/MWh
2010	58,280	$2,677,937	$45.95
2011	15,376	$1,943,507	$126.40
2012	121,381	$8,172,654	$67.33
2013	105,299	$7,387,658	$70.16
2014	118,007	$16,510,733	$139.91
2015	103,721	$7,355,263	$70.91
2016	67,516	$3,032,039	$44.91
2017	49,331	$2,167,590	$43.94
2018	44,735	$2,360,007	$52.76
2019	21,163	$860,235	$40.65
2020	8,329	$289,129	$34.71
2021	15,670	$935,370	$59.69
2022	59,370	$6,408,156	$107.94
2023	34,546	$2,342,794	$67.82
2024	165,812	$8,748,777	$52.76
2025	350,396	$20,508,803	$58.53

Economic demand response resources that are dispatched by PJM in both the economic and emergency programs are paid the higher price defined in the emergency rules.[111] For example, assume a demand resource has an economic offer price of $100 per MWh and an emergency strike price of $1,800 per MWh. If this resource were scheduled to reduce in the day-ahead energy market, the demand resource would receive $100 per MWh, but if an emergency event were called during the economic dispatch, the demand resource would receive its emergency strike price of $1,800 per MWh instead. The rationale for this rule is not clear.[112] All other resources that clear in the day-ahead market are financially firm at the clearing price. Payment at a guaranteed strike price and the ability to set energy market prices at the strike price effectively grant the seller the right to exercise market power.

Figure 6-4 shows monthly economic demand response credits and MWh, from January 1, 2010, through September 30, 2025.

111 "PJM. Manual 11: Energy & Ancillary Services Market Operations," § 10.4.5, Rev. 136 (October 1, 2025).
112 *Offer Caps in Markets Operated by Regional Transmission Organizations and Independent System Operators*, Order No. 831, 157 FERC ¶ 61,115 (2016) ("Order No. 831").

Figure 6-4 Economic program credits and MWh by month: 2010 through September 2025

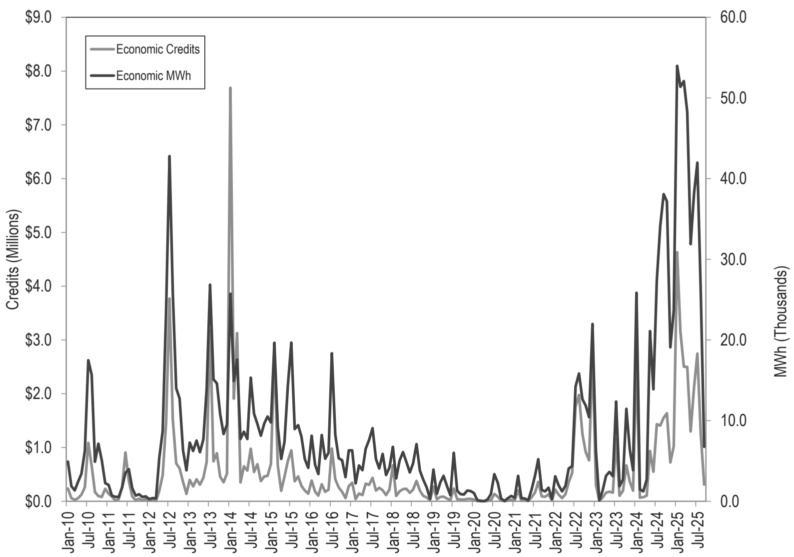

Table 6-32 shows performance for the first nine months of 2024 and 2025 in the economic program by control zone. Total reported reductions under the economic program increased by 184,584 MWh, 111.3 percent, from 165,812 MWh in the first nine months of 2024 to 350,396 MWh in the first nine months of 2025. Total revenue under the economic program increased by $11.8 million, 134.4 percent, from $8.7 million in the first nine months of 2024 to $20.5 million in the first nine months of 2025.[113]

Emergency and economic demand response energy payments are uplift and not compensated by LMP revenues. Economic demand response energy costs are assigned to real-time exports from the PJM Region and real-time loads in each zone for which the load-weighted average real-time LMP for the hour during which the reduction occurred is greater than the price determined under the net benefits test for that month.[114] The zonal allocation is shown in Table 6-32.

113 Economic demand response reductions that are submitted to PJM for payment but have not received payment are not included in Table 6-32. Payments for Economic demand response reductions are settled monthly.

114 "PJM Manual 28: Operating Agreement Accounting," § 11.2.2, Rev. 98 (Dec. 17, 2024).

Table 6-32 Economic program participation by zone: January through September, 2024 and 2025

	Credits			MWh Reductions			Credits per MWh Reduction

Table 6-33 shows average reported MWh reductions and credits by hour for the first nine months of 2024 and 2025. The average LMP during Load Response is the reduction weighted average hourly DA or RT load-weighted LMP during the economic load response hour. In the first nine months of 2024, 71.4 percent of the reported reductions and 73.8 percent of credits occurred in hours ending 0900 EPT to 2100 EPT, and in the first nine months of 2025, 62.9 percent of the reported reductions and 64.4 percent of credits occurred in hours ending 0900 EPT to 2100 EPT. The average LMP during load response increased by $12.98 per MWh, 27.7 percent, from $46.88 per MWh in the first nine months of 2024 to $59.86 per MWh in the first nine months of 2025.

Table 6-34 shows the distribution of economic program reported MWh reductions and credits by ranges of real-time zonal load-weighted average LMP in the first nine months of 2024 and 2025. In the first nine months of 2025, 2.4 percent of reported MWh reductions and 9.7 percent of program credits occurred during hours when the applicable zonal LMP was higher than $175 per MWh.

Economic Load Response revenues are paid by real-time loads and real-time scheduled exports as an uplift charge. Table 6-35 shows the sum of real-time and day-ahead Economic Load Response charges paid in each zone and paid by exports. In the first nine months of 2025, DOM Zone has paid the highest Economic Load Response charges.

Table 6-35 Zonal Economic Load Response charge: January through September, 2025[115]

Table 6-38 shows registered sites and MW for the last day of each month for the period January 1, 2021, through September 30, 2025. Registration is a prerequisite for CSPs to participate in the economic program. Average monthly registrations increased by 85, 17.1 percent, from 496 in the first nine months of 2024 to 581 in the first nine months of 2025. Average monthly registered MW decreased by 14 MW, 0.5 percent, from 3,156 MW in the first nine months of 2024 to 3,142 MW in the first nine months of 2025.

Most economic demand response resources are registered in the emergency demand response program. Resources registered in both programs do not need to register for the same amount of MW. There are 184 economic registrations and 190 capacity registrations in the emergency program that share the same location IDs in both programs. There are 1,616.4 nominated economic MW, 51.4 percent of all economic MW and 1,326.8 nominated capacity MW, 16.6 percent of all nominated capacity MW in the emergency program that share the same location IDs in both programs.

117 Load response charges were downloaded as of October 14, 2025, and may change as a result of continued PJM billing updates. Economic demand response reductions that are submitted to PJM for payment but have not received payment are not included. Payments for Economic demand response reductions are settled monthly.

The registered MW in the economic load response program are not a good measure of the MW available for dispatch in the energy market. Economic resources can dispatch up to the amount of MW registered in the program, but are not required to offer any MW. Table 6-39 shows the sum of maximum economic MW dispatched by registration each month from January 1, 2013, through September 30, 2025. The monthly maximum is the sum of each registration's monthly noncoincident maximum dispatched MW and annual maximum is the sum of each registration's annual noncoincident maximum dispatched MW. The monthly maximum dispatched MW increased 44.4 MW, 19.0 percent, in the first nine months of 2025 compared to 2024.[119]

Issues

FERC Order No. 831 requires that each RTO/ISO market monitoring unit verify all energy offers above $1,000 per MWh.[120] Economic resources offer into the energy market and must provide supporting documentation to offer above $1,000 per MWh. FERC stated, "[t]he offer cap reforms, however, do not apply to capacity-only demand response resources that do not submit incremental energy offers into energy markets."[121] Demand resources participate in both the capacity and energy markets and are not capacity only resources. It is not clear whether FERC intended to exclude demand resources with high strike prices from the requirements of FERC Order No. 831. Demand resources should not be permitted to make offers above $1,000 per MWh without the same verification requirements applied to economic resources or generation resources. The MMU recommends that the rules for maximum offer for the emergency and pre-emergency program match the maximum offer for generation resources.

120 157 FERC ¶ 61,115 at P 139 (2016).
121 *Id.* at 8.

On April 1, 2012, FERC Order No. 745 was implemented in the PJM economic program, requiring payment of full LMP for dispatched demand resources when a net benefits test (NBT) price threshold is exceeded. This approach replaced the payment of LMP minus the charges for wholesale power and transmission included in customers' tariff rates. Following FERC Order No. 745, all ISO/RTOs are required to calculate an NBT threshold price each month above which the net benefits of DR are deemed to exceed the cost to load.

PJM calculates the NBT price threshold by first retrieving generation offers from the same month of the prior calendar year for which the calculation is being performed. PJM then adjusts a portion of each prior year offer, representing the typical share of fuel costs in energy offers in the PJM Region, for changes in fuel prices based on the ratio of the reference month spot fuel price to the study month forward fuel price. To accomplish this adjustment, the ratio of forward prices for the study month to the spot fuel prices for the reference month is used as a scaling factor. If the forward price for the study month was $7.08 and the spot fuel price from the reference month was $6.75, then the ratio is 1.05. The offers of generation units are then adjusted by this scaling factor. The price of fuel typically represents 80 to 90 percent of a generator's offer with the remainder being variable operations and maintenance costs. Where generators offer multiple points on a curve, each point on the curve is adjusted in this manner. The offers are then combined to create daily supply curves for each day in the period. The daily curves are then averaged to form an average supply curve for the study month. PJM then uses a non-linear least squares estimation technique to determine an equation that approximates and smooths this average supply curve. The NBT threshold price is the price at the point where the price elasticity of supply is equal to 1.0 for this estimated supply curve equation.[122] PJM publishes the details of the equation and parameters each month along with the NBT results.

122 "PJM Manual 11: Energy & Ancillary Services Market Operations," §10.3.1, Rev. 136 (October 1, 2025)

The NBT test is a crude tool that is not based in market logic. The NBT threshold price is a monthly estimate calculated from a monthly supply curve that does not incorporate real-time or day-ahead prices. In addition, it is a single threshold price used to trigger payments to economic demand response resources throughout the entire RTO, regardless of their location and regardless of locational prices.

The necessity for the NBT test is an illustration of the illogical approach to demand side compensation embodied in paying full LMP to demand resources. The benefit of demand side resources is not that they suppress market prices, but that customers can choose not to consume at the current price of power, that individual customers benefit from their choices and that the choices of all customers are reflected in market prices. If customers face the market price, customers should have the ability to not purchase power and the market impact of that choice does not require a test for appropriateness nor does it require a payment from PJM markets.

When the zonal LMP is above the NBT threshold price, economic demand response resources that reduce their power consumption are paid the full zonal LMP. When the zonal LMP is below the NBT threshold price, economic demand response resources are not paid for any load reductions.[123]

Table 6-42 shows the NBT threshold price for the historical test from August 2010 through July 2011, and April 2012, when FERC Order No. 745 was implemented in PJM, through September 2025. The historical test was used as justification for the method of calculating the NBT for future months. From 2012 through 2021, the NBT threshold price exceeded the lowest historical test result of $34.07 per MWh one time, in March 2014 when the NBT threshold price was $34.93. The NBT threshold price exceeded the lowest historical test result of $34.07 per MWh in 10 of 12 months of 2022. In the first nine months of 2025, the NBT threshold price did not exceed the lowest historical test result of $34.07 per MWh.

123 "PJM Manual 11: Energy & Ancillary Services Market Operations," §10.3.4, Rev. 136 (October 1, 2025)

Table 6-43 shows the number of hours that at least one zone in PJM had day-ahead LMP or real-time LMP higher than the NBT threshold price.[124] In the first nine months of 2025, the highest zonal LMP in PJM was higher than the NBT threshold price 6,107 hours out of 6,551 hours, or 93.2 percent of all hours. Reductions occurred in 5,166 hours, 84.6 percent, of those 6,107 hours in the first nine months of 2025. The last three columns illustrate how often economic demand response activity occurred when LMPs exceeded NBT threshold prices for January 1, 2024, through September 30, 2025. There are no economic payments when demand response occurs and zonal LMP is below the NBT threshold. Demand response reported reductions occurred in none of the hours in which LMP was below the NBT threshold price in the first nine months of 2024, and none of the hours in which LMP was below the NBT threshold price in the first nine months of 2025.

Table 6-43 Hours with price higher than NBT and economic load response occurrences in those hours: January 2024 through September 2025

	Number of Hours		Number of Hours with LMP Higher than NBT			Percent of NBT Hours with Economic Load Response		
Month	2024	2025	2024	2025	Percent Change	2024	2025	Percentage Change

Total	8,784	6,551	8,092	6,107	(24.5%)	68.3%	84.6%	16.3%

124 The MWh for demand resources were downloaded as of October 14, 2025, and may change as a result of continued PJM billing updates.

Energy Efficiency

Energy Efficiency Resources (EE) are not capacity resources and do not contribute to reliability. FERC ruled on November 5, 2024, that EE should no longer be paid the capacity market clearing price effective with the 2026/2027 Delivery Year.[125] Payments from PJM customers to energy efficiency providers are a subsidy and uplift. The rules described here remain in effect until June 1, 2026.

The MMU had long recommended that Energy Efficiency Resources (EE) be removed from the capacity market mechanism because PJM's load forecasts now account for EE, unlike the situation when EE was first added to the capacity market.[126] EE should not be part of the capacity market mechanism in any way. EE is appropriately and automatically compensated through the markets because to the extent that it actually reduces energy and capacity use, it reduces customer payments for energy and capacity. EE is appropriately incorporated in PJM forecasts, so the original logic for the inclusion of EE in the capacity market is no longer correct.

History

EE is not a capacity resource and is not treated as a capacity resource in the capacity market. EE does not contribute to meeting the RPM Reliability Requirement. EE resources may not serve as a replacement for the commitment of any other RPM Capacity Resource type.

On March 26, 2009, FERC approved Tariff and RAA changes to allow EE Resources to participate in PJM Capacity Markets beginning with the Base Residual Auction conducted in May 2009 which committed capacity for the 2012/2013 Delivery Year.[127] FERC approved PJM's request to allow EE Resource participation beginning June 1, 2011, in the remaining 2011/2012 Incremental Auctions by letter order dated January 22, 2010 in Docket No. ER10-366-000. The only reason that EE was included in the capacity market in the first place was that EE was asserted to not be included in the PJM load forecast used in

125 See 189 FERC ¶ 61,095, *reh'g denied*, 190 FERC ¶ 62,005 (2025).
126 "PJM Manual 19: Load Forecasting and Analysis," § 3.2 Development of the Forecast, Rev. 37 (Dec. 18, 2024).
127 126 FERC ¶ 61,275 (2009)

the capacity market. PJM stated that EE was not fully reflected in the load forecast for four years based on the method in place at the time.

Revisions to the PJM load forecast to incorporate energy efficiency were endorsed at the November 19, 2015, MRC.[128] These revisions included improvements to comprehensively capture energy efficiency impacts through incorporation of projections from the U.S. Energy Information Administration (EIA) Annual Energy Outlook (AEO). The AEO forecast is based on a set of end use models for the residential, commercial, and industrial sectors. EIA accounts for state and utility efficiency programs by mapping regional EE program expenditures to end uses and tracks the number of units sold and associated efficiency information on an ongoing basis.[129]

As soon as PJM explicitly included EE in the load forecast used in the capacity market, PJM should have followed its tariff language and logic and eliminated EE from the capacity market construct entirely. Instead of eliminating EE from the capacity market construct consistent with the tariff and logic, PJM removed EE from capacity resource status and implemented a calculation method (misleadingly termed the addback method) that would pay EE the capacity market clearing price while having no impact, either price or quantity, on the capacity market. Beginning with capacity auctions conducted in 2016 for the 2016/2017 through 2025/2026 Delivery Years, PJM paid EE the capacity market clearing price while completely excluding EE from the actual capacity market. Use of this approach to EE addback did inappropriately require that customers pay for all EE offered at less than the market clearing price as an uplift payment or subsidy to EE sellers.

After the MMU filed a complaint in Docket No. EL24-126 requesting that the Commission require PJM to stop paying EE the uplift/subsidy, PJM filed to confirm removal of the EE from the capacity market construct, including the subsidy. On November 5, 2024, the Commission approved the complete removal of EE effective with the 2026/2027 capacity auction.[130] The MMU subsequently noticed withdrawal of the MMU complaint.[131]

Prior to the MMU complaint filed in Docket No. EL24-126, the MMU filed a complaint in Docket No. EL24-113 against indicated EE sellers for failure to submit post-installation M&V reports sufficient to support payments for EE from PJM for the 2024/2025 Delivery Year.[132] The complaint remains pending.

On May 29, 2025, in Docket No. EL25-87-000, the MMU filed a second complaint against indicated EE sellers who are providers of Energy Efficiency Resources for the 2025/2026 Delivery Year. The complaint alleges that the sellers' post-installation measurement and verification reports for the 2025/2026 Delivery Year are inadequate and capacity payments should be withheld pending further review.[133] The complaint remains pending.

PJM stakeholders initiated a holistic review of Energy Efficiency Resources participation in PJM markets in November of 2023. A sector-weighted super majority of PJM's stakeholders supported elimination of EE from the capacity construct at the MRC and the MC meetings on August 21, 2024.[134] PJM filed the proposal under Section 205 on September 6, 2024.[135] On November 5, 2024, the Commission issued an order approving the proposed Tariff and RAA revisions to remove Energy Efficiency Resource participation from the PJM capacity construct effective with the 2026/2027 Delivery Year.[136] On December 5, 2024, Affirmed Energy LLC filed a motion of a stay and a request for rehearing. An order denying rehearing by operation of law was issued January 6, 2025.[137] On February 7, 2025, the Commission issued an order denying the motion for stay and affirming its earlier denial of rehearing.[138]

On December 16, 2024, the Commission issued an Order to Show Cause and Notice of Proposed Penalty recommending civil penalties against American

Efficient, LLC, a large seller of EE, and its affiliates in connection with an alleged scheme to manipulate the capacity markets operated by PJM and MISO.[139] The Order directs American Efficient to show cause as to why it should not be required to pay a civil penalty of $722 million and disgorge $253 million in unjust profits. On January 29, 2025, American Efficient, et al. filed for review of the show cause order in the United States District Court for the Middle District of North Carolina.[140] The court case is pending.

EE Details

In addition to the fact that EE resources are not capacity resources, the measurement of EE that was required as a condition to receive subsidy payments from PJM were largely unsupported by factual evidence or actual measurements.

An EE Resource is required to be a project that involves the installation of more efficient devices or equipment, or the implementation of more efficient processes or systems, exceeding then current building codes, appliance standards, or other relevant standards, at the time of installation, as known at the time of commitment, and meets the requirements of Schedule 6 (section L) of the Reliability Assurance Agreement. The EE Resource must achieve a permanent, continuous reduction in electric energy consumption at the End Use Customer's retail site during the defined EE Performance Hours that is not reflected in the peak load forecast used for the auction delivery year for which the EE Resource is proposed.[141]

Despite the fact that the EE Resource must be fully implemented at all times during the delivery year, without any requirement of notice, dispatch, or operator intervention, EE accreditation is based only on extremely limited periods. EE is required to demonstrate savings only during three summer months and two winter months and only for extremely limited hours during those months. The EE Performance Hours in the summer are defined as the four hours from the hour ending 15:00 Eastern Prevailing Time (EPT) through the hour ending 18:00 EPT during all days for the three month period from June 1 through August 31, inclusive, of such delivery year, that is not a weekend or federal holiday. For the 2023/2024 Delivery Year, the summer EE Performance hours comprise 256 hours across 64 days. The EE Performance Hours in the winter are defined as the four hours from the hour ending 8:00 EPT and hour ending 9:00 EPT, and from the hour ending 19:00 EPT and hour ending 20:00 EPT during all days for the two month period from January 1 through February 28, inclusive, of such delivery year that is not a weekend or federal holiday, For the 2023/2024 Delivery Year, the winter EE Performance hours comprise 160 hours across 40 days. For the 2023/2024 Delivery Year, the total annual EE Performance hours comprised 416 hours across 104 days, or 4.7 percent of all hours in the year.

Calculating the Nominated MW value for Energy Efficiency (EE) resources is different than calculating the Nominated MW value for actual capacity resources. The maximum amount of Nominated MW a generator can offer into the capacity market is based on the maximum output of a generator that is metered and tested. The Nominated MW for EE resources are not metered or measured or tested, although they could be, but are based on calculations of estimated savings based on a set of largely unverified and unverifiable assumptions. The Nominated Value of an EE Resource is the expected average demand reduction during the summer EE Performance Hours. Qualifying EE Resources must also have an expected average load reduction during the winter EE performance hours that is not less than the Nominated EE Value determine during the summer EE Performance Hours. If the Nominated EE Value determined during the summer EE Performance Hours is greater than the expected average demand during the winter performance hours, the expected demand during the winter performance hours will be the value of the EE Resource. The Nominated EE Value of a Summer-Period Energy Efficiency Resource is the expected average demand reduction during the summer EE Performance Hours.

139 See 189 FERC ¶ 61,196.

140 See American Efficient, LLC, et al. v. FERC, Case No. 1:25-cv-68.

141 See RAA Schedule 6 § L. Since 2010, the PJM tariff definition of "End User Customer" limits the scope of the term to mean only PJM Members. Letter Order, Docket No. ER11-1909-000 (December 20, 2010). Recently, PJM asserted that the reference in RAA Schedule 6 § L.1 and OATT Attachment DD-1 § L.1 to the defined term, "End Use Customer," was a mistake, and proposed to discontinue use of the defined term in the February 8, 2024, meeting of the PJM Governing Document Enhancement and Clarification Subcommittee (GDECS). The defined term was in place for more than 13 years and subject to many reviews. The proposed change removes the current requirement in the filed tariff that EE loads be End Use Customers and therefore be PJM Members. The proposed change is substantive and not a correction of a typographical error. PJM has been operating in violation of that tariff provision since 2010. The proposed change was filed and approved. *PJM Interconnection, L.L.C.*, Letter Order, Docket No. ER24-1987-000 (May 23, 2024).

Prescriptive energy efficiency MW are based on and paid on assumed savings calculated based on an assumed installation rate and on the difference between the assumed electricity usage of what is being replaced and the assumed electricity usage of the new product. All lighting EE is prescriptive. The majority of EE MW offered into the PJM Capacity Market are prescriptive energy efficiency MW. The measurement and verification method for prescriptive energy efficiency projects relies on neither measurement nor verification but instead relies on unverified assumptions and is too imprecise to rely on for the payment of more than $100 million per year. The nonprescriptive measurement and verification methods are also inadequate and rely on samples and assumptions for limited periods that are frequently significantly outdated.[142]

Most EE MW are not directly measured. Savings are calculated based on an assumed installation rate and assumed usage level, compared to the assumed electricity usage of the default. For example, the calculation of the summer period lighting savings for a residential lighting retrofit is generally:

$$\Delta kW = ((WattsBase - WattsEE) / 1000) * ISR * WHFd * CF$$

Where:

ISR = In Service Rate approximating percent of bulbs installed in calculation year

WHFd = Waste Heat Factor for Demand to account for cooling savings from efficient lighting

CF = Summer Peak Coincidence Factor approximating percent of EE Performance Hours device is in use

The inputs to these calculations are based on assumptions and observations over very limited periods and generally rely on data that is significantly out of date. Many EE Providers rely on usage assumptions from industry publications rather than from primary data collected from measurements of their own customers. A commonly referenced document in supporting Measurement & Verification reports is the Maryland/Mid-Atlantic Technical Reference Manual (TRM) facilitated and managed by Northeast Energy Efficiency Partnerships, a 501 (c)(3) non-profit organization funded by various advocacy groups and the federal government.[143] [144] While this manual focuses on a geographic region included in PJM's service territory, EE Providers can and do use assumptions based on installations in locations outside of PJM's service territory. The technical reference manuals (TRM) referenced by EE Providers are generally significantly outdated and therefore cannot reasonably be used to define the actual current baseline conditions that should be used for valuation of projects. Given the development cycle, the data underlying the TRM lags the publishing date by several years. Of TRMs frequently referenced by EE Providers, the Maryland/Mid-Atlantic TRM was published in 2020, the Pennsylvania TRM in 2024 and the Ohio TRM in 2019. The Pennsylvania PUC updates and approves its TRM on a 5-year cycle.[145] As a result, for the normal three year capacity market timing, a three year old TRM, relying on data from as much as five years prior to publication, is used to estimate savings for at least four years into the future. As a result, in the fourth year of the EE resource, its purported savings will be based on data from 15 years earlier. That is not a reasonable basis for calculating savings. Table 6-44 shows the current publishing dates of TRMs frequently referenced in M&V reporting submitted to PJM. In addition to Technical Reference Manuals, other studies and references are cited in EE M&V Plans and Reports. These citations are likewise used to justify the claimed benefits and savings attributed to Energy Efficiency projects. These materials, as with the TRMs, are often several years out of date and commonly 10 years old and in some cases older.

Table 6-44 Publishing dates (Year) of technical resource manuals

State/Region	Current Version
Delaware	2016
Illinois	2024
Maryland	2020
New Jersey	2023
Ohio	2019
Pennsylvania	2024
Tennessee	2015
Mid-Atlantic	2020

142 PJM. "Manual 18B: Energy Efficiency Measurement & Verification," § 2.2 Rev. 05 (Sep. 21, 2022).

143 See *Maryland/Mid-Atlantic Technical Reference Manual Version 10* <https://neep.org/mid-atlantic-technical-reference-manual-trm-v10> (May 27, 2020).

145 66 PA § 2806.1(c)(3)

Another weakness of the methods used to evaluate EE is the failure to recognize that the incremental benefits of EE measures decline over time as improved energy saving technology is adopted by customers. This improvement in technology reduces the baseline energy usage against which incremental savings should be measured. An example of a decreasing baseline in energy usage is in residential lighting. The assumed baseline condition was originally an incandescent bulb but should have evolved to more and more efficient LEDs, which eliminates the incremental savings when replaced by another LED lightbulb.

The mix of EE project types offered should have more quickly reflected the actual technology adopted in the markets. In the 2019/2020 BRA, lighting projects comprised 77 percent of all EE measures. Table 6-45 shows the composition of project types submitted in M&V Plans for the 2019/2020 RPM Base Residual Auction.

Table 6-45 EE Project Types – 2019/2020 Delivery Year

Project Type	2019/2020
Residential Lighting	23%
Residential HVAC	1%
Residential New Construction	<1%
Appliances	<1%
Commercial Lighting	54%
Commercial Prescriptive	8%
Commercial HVAC	<1%
Small Business	4%
Commercial Construction	2%
Other	7%

In the 2024/2025 BRA, lighting dropped to 45 percent of all EE measures. Building envelope measures, which include thermal performance improvements to exterior walls, windows, doors, and roofing to reduce building energy consumption were a growing project type encompassing 33 percent of all EE measures in the 2024/2025 BRA. Table 6-46 shows the composition of project types submitted in EE M&V Plans for the 2024/2025 RPM Base Residual Auction.

Table 6-46 EE Project Types – 2024/2025 Delivery Year

Project Type	2024/2025
Lighting	45%
Building Envelope	33%
Variable Frequency Drives	8%
Appliances	<1%
Other	14%

There is no evidence that the EE programs result in changed behavior or increases in savings. EE Providers may repackage the independent actions of customers that have already occurred. There is no evidence that EE participation in PJM markets causes End Use Customers to reduce their energy consumption beyond what they would have otherwise.

While EE does not affect the capacity market clearing price or quantity, customers do pay for EE at capacity market clearing prices. These direct payments to EE are a subsidy and uplift and an overpayment by customers. Table 6-47 shows the RPM revenues paid, by delivery year, to energy efficiency (EE) resources in PJM.

PJM does not codify eligibility requirements to claim the property rights to energy efficiency installations in the tariff. PJM does not have a registration system to track claims to property rights to energy efficiency installations and document installation periods of energy efficiency installations. The purpose of the registration system is to prevent duplicative claims to property rights and to document installation periods of energy efficiency to verify eligibility for continued participation measures. Energy Efficiency projects should be clearly identified by retail customer account, year of project installation and a description of the Energy Efficiency project.

A registration system would also serve the benefit of preventing multiple Energy Efficiency Providers from claiming property rights to the same project. The Energy Efficiency Resource Provider offering an Energy Efficiency Resource for payment must demonstrate to PJM that it has the legal authority to claim the demand associated with such Energy Efficiency Resource.[146] This demonstration is generally a prepackaged statement, provided by PJM, that

146 EE Post-Installation Measurement & Verification Report Template, <https://www.pjm.com/-/media/markets-ops/rpm/rpm-auction-info/post-installation-measurement-and-verification.ashx> (*Accessed Aug. 5, 2022*).

is never fully verified. PJM should have codified eligibility requirements to claim the property rights to Energy Efficiency installations in the Tariff. These eligibility requirements should specifically define the conditions under which an Energy Efficiency Resource Provider may claim the property rights to Energy Efficiency installations as well as evidentiary requirements such as signed contracts with their customers conferring such rights. PJM does not require contracts between the seller of EE to PJM and the actual owner of the EE. It is not always clear who the owner of the EE property rights actually is.

Table 6-47 shows the amount of energy efficiency (EE) resources paid as of June 1 for the 2011/2012 through 2025/2026 Delivery Years. EE resources may participate in PJM without restrictions imposed by a state unless the Commission authorizes a state to impose restrictions.[147] Only Kentucky has been so authorized by the Commission.[148] The total MW of energy efficiency resources paid decreased by 80.6 percent, from 7,716.0 MW in the 2024/2025 Delivery Year to 1,493.2 MW in the 2025/2026 Delivery Year.

Table 6-47 Energy efficiency resources (MW): 2011/2012 through 2025/2026 Delivery Years

Delivery Year	EE Paid (MW)	Total RPM Cleared (UCAP MW)	EE MW/ Capacity MW	EE Revenue
2011/2012	76.4	134,182.6	0.1%	$139,812
2012/2013	666.1	141,295.6	0.5%	$11,408,552
2013/2014	904.2	159,844.5	0.6%	$21,598,174

Total	$130,780,274	$147,950,487	100.0%	100.0%

As defined in the RAA, each LSE incurs a Locational Reliability Charge, subject to certain offsets and other adjustments as described in Attachment DD, Sections 5.14B through 5.14E and Section 5.15.[149] Locational Reliability Charges are equal to the LSE's Daily Unforced Capacity Obligation in a zone during the Delivery Year multiplied by the applicable Final Zonal Capacity Price in the zone. The Tariff does not define the allocation of EE revenue requirements to load in RPM. In practice, PJM allocates total EE revenue requirements to load prorata based on final zonal UCAP obligations. As a result, the allocation of EE costs to zones is not equal to the revenue requirement of EE resources located in that zone. Zones in which no EE resources are located are allocated a share of total EE revenue requirements based on their share of

149 See PJM, Intra-PJM Tariffs, RAA, Article 7, §2.

the total PJM UCAP obligation. Table 6-49 and Table 6-50 shows the zonal revenue requirement of EE resources compared to the zonal allocation of total EE revenue requirements to load. Where a zone's load charge is greater than the revenue requirement of EE resources located in that zone, the zone's customers are subsidizing the revenue requirement of EE resources located in other zones. Where a zone's load charge is less than the revenue requirement of EE resources located in that zone, the zone's customers are receiving a subsidy from customers located in other zones.

Total		$147,950,487	$147,950,487	($0)

The ownership of Energy Efficiency is highly concentrated. The combined market share of the four largest companies ranges from 90 to 99 percent of all paid Energy Efficiency MW. The HHI for Energy Efficiency resources shows that ownership of EE for the entire market is highly concentrated for each of the last six delivery years. Table 6-51 shows the HHI value for paid Energy Efficiency MW and the market share of the four largest suppliers by delivery year for the entire market.

Table 6-51 Energy Efficiency HHI: 2019/2020 through 2025/2026

Delivery Year	HHI	Structure	Top 4 Market Share
2019/2020	3574	Highly Concentrated	90.6%
2020/2021	3005	Highly Concentrated	89.8%
2021/2022	3409	Highly Concentrated	91.6%
2022/2023	5803	Highly Concentrated	99.1%
2023/2024	6029	Highly Concentrated	99.9%
2024/2025	5749	Highly Concentrated	98.0%
2025/2026	2804	Highly Concentrated	96.0%

The ownership of Energy Efficiency is also highly concentrated on an LDA basis as shown by the HHI levels. The individual LDA HHI values cannot be made public based on PJM's confidentiality rules. Table 6-52 shows the HHI value for paid MW by LDA for the 2024/2025 and 2025/2026 Delivery Years.

Table 6-52 Energy Efficiency HHI by LDA

	Structure	
LDA	2024/2025	2025/2026
ATSI	Highly Concentrated	Highly Concentrated
ATSI-CLEVELAND	Highly Concentrated	Highly Concentrated

RTO	28.6%	5.6%

Peak Shaving Adjustment

Peak Shaving Adjustment (PSA) provides an alternative means for demand response to participate in the Reliability Pricing Model (RPM). Rather than being on the supply side of the capacity market, a PSA participates on the demand side through a modified peak load forecast for the zone in which the Peak Shaving Adjustment resources are located. The peak shaving adjusted load forecast is included in the VRR curve. An important issue is that the resultant reduction in capacity obligation is socialized across all loads in the zone rather than directly benefitting the resources providing the Peak Shaving Adjustment.[150] This eliminates the incentive for individual customers to participate in peak shaving. The solution is a retail rate design that directly assigns the benefits of peak shaving to individual customers. The retail rate design is within the authority of state regulators and not the authority of FERC which has jurisdiction over the wholesale markets.

A PSA plan must include: the basis for the planned reductions; a THI trigger for interruption; the duration of the interruption in hours; the MW value of the curtailment; the months of the offer; all historical addbacks for the nominated programs.[151] Any resource selling a PSA must reduce load on any day in which its trigger is met or exceeded. The trigger is based on the actual maximum daily temperature humidity index (THI) for the relevant PJM zone. When the trigger is met, the PSA must comply with its defined offer parameters including number of hours of interruption. Failure to operate to these parameters will lead to a reduction in the peak shaving adjustment value in future delivery years. Performance is measured based on the aggregated Customer Baseline (CBL). PJM applies a three year rolling average of the annual peak shaving performance ratings to the program's total participating MW in order to determine its peak shaving adjustment.

150 See "Peak Shaving Adjustment Proposal," Docket No. ER19-511-000 (December 7, 2018).
151 "PJM Manual 19: Load Forecasting and Analysis," Attachment D, Rev. 37 (Dec. 18, 2024).

Distributed Energy Resources

Distributed Energy Resources (DER) include generation connected to distribution level facilities, behind the meter generation, and energy storage facilities connected to the distribution grid or to load. FERC issued Order No. 2222 on September 17, 2020, with the goal of removing barriers for small distributed resources to enter the wholesale market by allowing them to aggregate in order to encourage competition, but larger resources, up to 5 MW, can participate.[152] On May 1, 2025, FERC issued an order accepting all of the final elements of PJM's compliance filing including delaying the effective date for the DER Aggregation Participation Model to February 2, 2028. PJM is currently developing implementation details for DER Aggregation Resources (DERAs) at the Distributed Resources Subcommittee (DISRS).

PJM proposed Manual 18 updates for Planned DER Capacity Resource's participation in the 2028/2029 BRA.[153] The changes include detailed business rules for DER Capacity Aggregation Resources, DER plan requirements, RPM commitment compliance, and test failure charges. All DER will be planned resources for the 2028/2029 auction, meaning PJM will not require the CSP to register an actual physical resource prior to the auction. The MMU identified a loophole in the market power mitigation rules applicable to planned DER in PJM's proposed Manual 18 language. The loophole exists because a DER aggregation can change resource types between the time of clearing in an auction and the actual delivery year. For example, a DER aggregation can offer as a homogeneous demand resource and then change to a heterogeneous DER resource in the actual delivery year. This would allow a DER aggregation to avoid market power mitigation rules in the capacity market. Under the proposed rules, if a planned DER Capacity Aggregation Resource consists of only demand response resources (homogeneous DR), it is exempt from the market power mitigation rules. Planned resources can change types between BRAs and IAs, or between capacity auctions and delivery years. The rules allow a planned DER Capacity Aggregation Resource solely comprised of demand response resources that was not subject to market power mitigation rules in a capacity auction to add generation after the auction. This would allow the added generation to avoid market power mitigation rules. This loophole should be closed with a simple rule change to prevent the behavior.

The MMU recommends that DER aggregations that clear in a capacity auction not be permitted to change status from homogeneous demand response to any other status for any additional auctions for the same delivery year, or for the delivery year.

Getting the rules right at the beginning of DER development is essential to the active and effective participation of DER in the wholesale power markets in a manner that enhances rather than undermines the efficiency and competitiveness of the power markets. In addition, getting the implementation details right is critical in keeping the original intention of Order No. 2222 to enhance competition in wholesale markets while removing barriers for small distributed resources. To date, PJM is not meeting these objectives.

Nodal Aggregation and Size

The PJM market is a nodal market. Nodal markets provide efficient price signals to resources in an economically dispatched, security constrained market. Aggregation behind a single node is feasible, is consistent with the nodal market principle, and will encourage competition. The accepted DER Aggregation Participation Model allows multinodal aggregation for small resources that satisfy a few conditions. Energy injection from DERs across multiple nodes, even if it is small, will change congestion patterns that PJM would not have the ability to predict and control. Allowing DER aggregation across nodes even for small resources is not necessary and would distort the nodal market signals that indicate where capacity and energy are needed and their impacts on congestion. The MMU recommends that PJM use a nodal approach for DER participation in PJM markets that excludes multinodal aggregation.

The accepted DER Aggregation Participation Model does not propose a maximum size requirement for DER Aggregation Resources. This loophole would allow larger DERs to divide one larger resource into multiple DERs less than 5 MW and register them as one DER Aggregation Resource, undermining the intent of the DER approach. To avoid this loophole, there

152 See 172 FERC ¶ 61,247 at PP 6–7.
153 See "Manual 18 Revisions - Redline," from the October 9, 2025 meeting of the MIC <https://www.pjm.com/-/media/DotCom/committees-groups/committees/mic/2025/20251009/20251009-item-01-1---manual-18-revisions---redline.pdf>.

should be a maximum size requirement on DER Aggregation Resources. The MMU recommends that PJM include a 5.0 MW maximum size cap on DER aggregations.

EDC Role

The EDCs' dual role as the distribution system operator and as a DER Aggregator is a threat to PJM's competitive market. When an EDC, acting in its proposed role as a market participant, controls its competitors' access to the market, the result is not structurally competitive. The result would be to create barriers to competition, exactly the opposite of FERC's intent. EDCs have a very significant role to play as designers, builders and managers of the local grids, without competing with DER providers. The accepted DER Aggregation Participation Model does not prevent EDCs from serving as DER aggregators or address the market power issues, based on a reference to the provision of Order No. 2222 that prohibits RTOs/ISOs from limiting the business models under which DER aggregators can operate. FERC, however, stated that it could revisit the EDCs' role in the PJM markets, if "evidence of undue discrimination regarding the participation of DER aggregations in RTO/ISO markets" is discovered.[154] The MMU continues to recommend that EDCs not be allowed to participate in markets as DER aggregators in addition to their EDC role.

Cases where EDCs override PJM dispatch instructions should be communicated to PJM and recorded in the PJM market systems for operations and market monitoring purposes. When DER Aggregation Resources update bidding parameters due to override instructions from the EDC, the MMU should be able to check whether the update is due to an override or other operational or economic reasons. When the EDC itself is the DER Aggregator and it overrides its PJM dispatch instruction, it should also be communicated to PJM and recorded. FERC clarified that if an EDC's override actions are discriminatory or involve the exercise of market power such behavior would violate the terms of PJM's tariff and that such actions can be monitored and addressed through existing mechanisms such as Attachment M.[155] However, the proposed tariff language does not explicitly define the MMU's role in monitoring or mitigating the potential exercise of market power by EDCs. To enable efficient and effective market monitoring, EDCs and DERAs should be explicitly required to provide information requested by the MMU. The MMU recommends that the Commission require PJM to include in OATT Attachment M a statement explicitly affirming that the Market Monitor's role includes the right to collect information from EDCs and DERA related to actions taken on the distribution system related to DER Aggregation Resources.

Net Metering Resources

A net metering resource is a single electric customer location that has both generation and load, where the generation can exceed the load, and the customer pays for energy or receives compensation for energy based on the net energy output measured at the customer meter. Retail customers on a net metering tariff with their distribution utility pay the retail rate when consuming and are paid the retail rate when selling energy. These resources cannot participate in the energy or capacity markets, because they already receive full compensation for their output. That retail rate compensation includes credits for ancillary services charges.

According to PJM, no net metering resources in the PJM footprint provide ancillary services as part of a retail program.[156] From PJM's perspective, this means all net metering resources in its territory are eligible to participate in its ancillary services market.[157] PJM argues that even if a resource is compensated for the same service at the retail and the wholesale level, it should not be considered double counting. Under this proposal, a net metered resource that receives credits through its retail rate for reducing its ancillary services purchase can also receive payment from PJM for providing the same ancillary services. That is clearly double counting. The accepted DER Aggregation Participation Model allows EDCs to raise concerns about double counting but neither PJM nor an EDC may preclude a Component DER from providing ancillary services based on the resources being compensated for ancillary services at the retail level. No resource should be paid more than once for its services. If the net energy metering resources receive credits at a rate that includes compensation for ancillary services, that means they are providing

the service and being compensated for it. The MMU recommends that net metering resources be prohibited from participating in wholesale ancillary services markets if they are compensated for the service at the retail level.

Outside the Order No. 2222 rule development, a proposal was developed and approved by PJM stakeholders to allow DERs at net metering sites to be able to inject in the regulation market before February 2, 2028, when the DER Aggregation Participation Model will be effective.[158] This selective implementation of a part of a rule set is unjust and unreasonable. There is no reason to implement a small part of a participation model earlier than the FERC approved effective date, especially, if the expected result is to change the definition of demand response resources and enable them to inject in the regulation market. The MMU opposed the proposal.

158 See "DER Regulation Market Only Participation at NEM Customer Sites," from the October 23, 2025 meeting of the MC <https://www.pjm.com/-/media/DotCom/committees-groups/committees/mc/2025/20251023/20251023-consent-agenda-b---1-der-regulation-market-only-participation-at-nem-customer-sites---presentation.pdf>.

Net Revenue

The Market Monitoring Unit (MMU) analyzed measures of PJM energy market structure, participant conduct and market performance. As part of the review of market performance, the analysis includes the theoretical new entrant net revenues for combustion turbine (CT), combined cycle (CC), coal plant (CP), diesel (DS), nuclear, solar, and wind generating units.

Overview

Net Revenue

- Energy market net revenues are significantly affected by energy prices and fuel prices. Energy prices, gas prices and coal prices increased in the first nine months of 2025 compared to the first nine months of 2024. The net effects were that in the first nine months of 2025, average energy market theoretical net revenues increased by 30 percent for a new combustion turbine (CT), increased by 35 percent for a new combined cycle (CC), increased by 148 percent for a new coal plant (CP), increased by 46 percent for a new nuclear plant, increased by 279 percent for a new diesel (DS), increased by 52 percent for a new onshore wind installation, increased by 49 percent for a new offshore wind installation and increased by 42 percent for a new solar installation.
- The price of natural gas and coal increased in the first nine months of 2025. The marginal costs of a new CT were greater than the marginal cost of a new CP only in January, February and March 2025. The marginal costs of a new CC were greater than the marginal cost of a new CP only in January 2025.
- In the first nine months of 2025, spark spreads and dark spreads and the volatility of spark spreads and dark spreads increased in BGE, COMED and Western Hub compared to the first nine months of 2024. In the first nine months of 2025, spark spreads decreased while dark spreads and the volatility of both spark spreads and dark spreads increased in PSEG compared to the first nine months of 2024.
- Of the 16 PJM nuclear plants analyzed, all are expected to cover their avoidable costs from energy and capacity market revenues in 2025, 2026 and 2027, without any subsidies.

Recommendations

- The MMU recommends that the net revenue calculation used by PJM to calculate the net Cost of New Entry (CONE) and net ACR be based on a forward looking calculation of expected energy and ancillary services net revenues using historical revenues that are scaled based on forward prices for energy and fuel. (Priority: Medium. First reported 2019. Status: Not adopted.)

Conclusion

Wholesale electric power markets are affected by externally imposed reliability requirements. A regulatory authority external to the market makes a determination as to the acceptable level of reliability which is enforced through a requirement to maintain a target level of installed or unforced capacity. The requirement to maintain a target level of installed capacity can be enforced via a variety of mechanisms, including government construction of generation, full requirement contracts with developers to construct and operate generation, state utility commission mandates to construct capacity, or capacity markets of various types. Regardless of the enforcement mechanism, the exogenous requirement to construct capacity in excess of what is constructed in response to energy market signals alone has an impact on energy markets. The reliability requirement results in maintaining a level of capacity in excess of the level that would result from the operation of an energy market alone. The result of that additional capacity is to reduce the level and volatility of energy market prices and to reduce the duration of high energy market prices. This, in turn, reduces net revenue to generation owners which reduces the incentive to invest. The exact level of both aggregate and locational excess capacity is a function of the calculation methods used by RTOs and ISOs. A basic purpose of the capacity market is to allow all cleared capacity resources the opportunity to cover their net avoidable costs on an annual basis to ensure the economic sustainability of the reliable energy market.

PJM's introduction of a form of ELCC for defining available capacity has made the definition of reliability less clear. The ELCC derate factors are volatile and subject to changes for reasons that are not clear to generation owners or other market participants. There are significant issues with PJM's implementation of its approach to ELCC.

Net Revenue

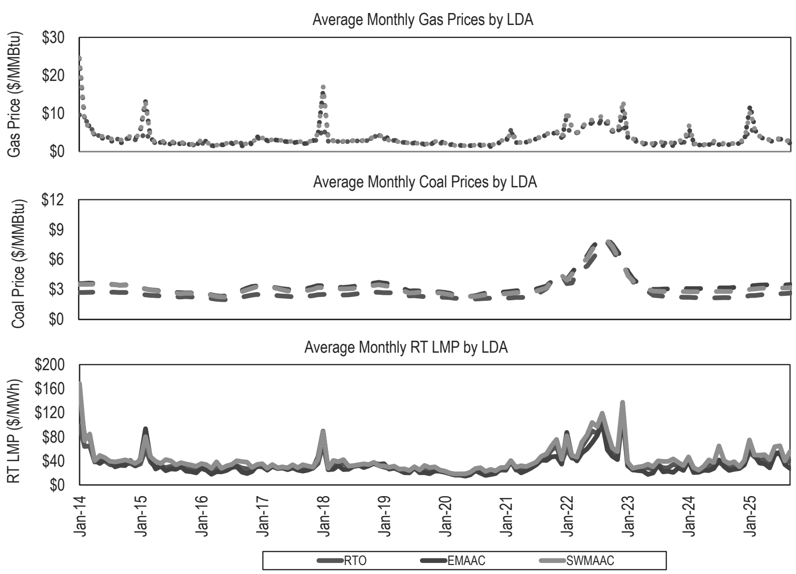
When compared to annualized fixed costs and avoidable costs, net revenue is an indicator of generation investment profitability, and thus is a measure of overall market performance as well as a measure of the incentive to invest in new generation and to maintain existing generation in PJM markets. Net revenue equals total revenue received by generators from PJM energy, capacity and ancillary service markets, including uplift payments, and from the provision of black start and reactive services and capability, and from subsidies like RECs, less the short run marginal costs of energy production. In other words, net revenue is the amount that remains, after the short run marginal costs of energy production have been subtracted from gross revenue. Net revenue is the contribution to fixed costs, which include a return on investment, depreciation and income taxes, and to avoidable costs, which include long term and intermediate term operation and maintenance expenses.[1] Net revenue is the contribution to total fixed and avoidable costs received by generators from all PJM markets.

In a perfectly competitive, energy only market in long run equilibrium, net revenue from the energy market would be expected to equal the annualized fixed and avoidable costs for the marginal unit, including a competitive return on investment. The PJM market design includes other markets that contribute to the payment of fixed and avoidable costs. In PJM, the energy, capacity and ancillary service markets are all significant sources of revenue to cover the fixed and avoidable costs of generators, as are payments for the provision of black start and reactive services. Thus, in a perfectly competitive market in long run equilibrium, with energy, capacity and ancillary service markets, net revenue from all sources would be expected to equal the annualized fixed and avoidable costs of generation for the marginal unit. Net revenue is a measure of whether generators are receiving competitive returns on invested capital and of whether market prices are high enough to encourage entry of new capacity and to encourage maintaining existing capacity. In actual wholesale power markets, where equilibrium seldom occurs, net revenue is expected to fluctuate above and below the equilibrium level based on actual conditions in all relevant markets. The current definition of net revenue is not fully accurate as the FERC ordered definition uses price-based offers at times and does not include revenue from opportunity cost adders for environmentally constrained resources.

Net revenues are significantly affected by energy prices, fuel prices and capacity prices. The real-time load-weighted average LMP in the first nine months of 2025 increased 47.2 percent from the first nine months of 2024, from $34.31 per MWh to $50.51 per MWh. Gas prices and coal prices increased in the first nine months of 2025 compared to the first nine months of 2024. The price of eastern natural gas was 83.4 percent higher, the price of western natural gas was 59.2 percent higher; the price of Northern Appalachian coal was 11.4 percent higher; the price of Central Appalachian coal was 7.8 percent higher; and the price of Powder River Basin coal was 2.5 percent higher (Figure 7-1). The price of ULSD NY Harbor Barge (ultra low sulfur diesel) was 6.4 percent lower in the first nine months of 2025 than in the first nine months of 2024.

1 Avoidable costs are sometimes referred to as going forward costs.

Figure 7-1 Energy market net revenue factor trends: 2014 through September 2025



Spark Spreads and Dark Spreads

The spark or dark spread is defined as the difference between the LMP received for selling power and the cost of fuel used to generate power, converted to a cost per MWh. The spark spread compares power prices to the cost of gas and the dark spread compares power prices to the cost of coal. The spread is a measure of the approximate difference between revenues and marginal costs and is an indicator of net revenue and profitability.

$$Spread\left(\frac{\$}{MWh}\right) = LMP\left(\frac{\$}{MWh}\right) - Fuel\ Price\left(\frac{\$}{MMBtu}\right) * Heat\ Rate\left(\frac{MMBtu}{MWh}\right)$$

Spread volatility is a result of fluctuations in LMP and the price of fuel. Spreads can be positive or negative.

In the first nine months of 2025, spark spreads and dark spreads and the volatility of spark spreads and dark spreads increased in BGE, COMED and Western Hub compared to the first nine months of 2024. In the first nine months of 2025, spark spreads decreased while dark spreads and the volatility of both spark spreads and dark spreads increased in PSEG compared to the first nine months of 2024.

Table 7-1 shows average peak hour spreads by year and Table 7-2 shows the associated standard deviations.

Table 7-1 Peak hour spark and dark spreads ($/MWh)

	BGE		COMED		PSEG		Western Hub	
Jan-Sep	Spark	Dark	Spark	Dark	Spark	Dark	Spark	Dark
2024	$36.35	$24.84	$18.96	$13.59	$18.12	$0.94	$26.32	$15.15
2025	$44.29	$37.38	$24.07	$26.88	$18.85	$15.88	$32.74	$26.72
Percent change	22%	50%	27%	98%	4%	1,584%	24%	76%

Figure 7-2 Hourly spark spread (gas) for peak hours ($/MWh): 2021 through September 2025[2]

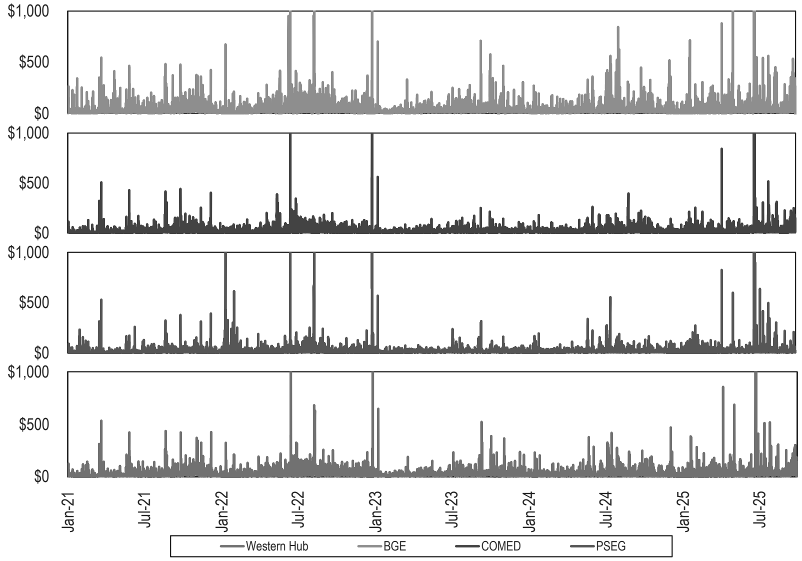

Figure 7-3 Hourly dark spread (coal) for peak hours ($/MWh): 2021 through September 2025[3]

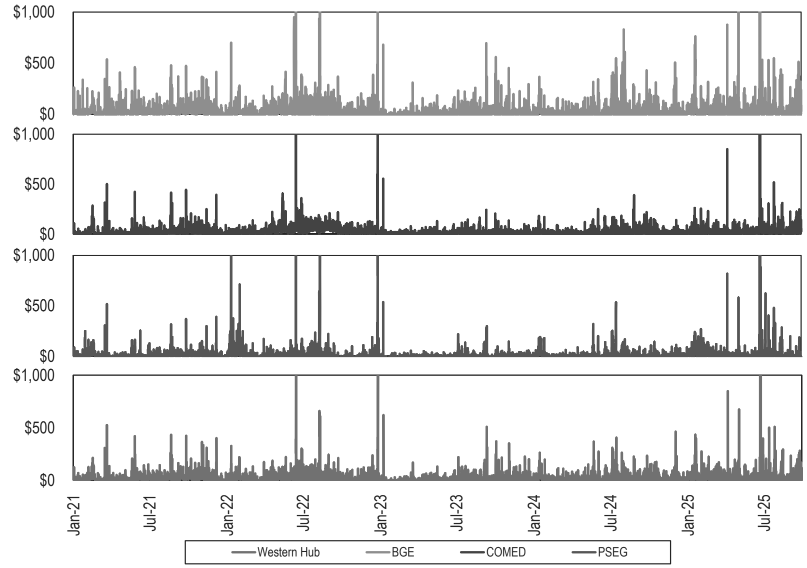


Theoretical Energy Market Net Revenue

The net revenues presented in this section are theoretical as they are based on explicitly stated assumptions about how a new unit with specific characteristics would operate under economic dispatch. The economic dispatch uses technology specific operating constraints in the calculation of a new unit's operations and potential net revenue in PJM markets.

Analysis of energy market net revenues for a new unit includes eight power plant configurations:

- The CT plant is a single GE Frame 7HA.03 CT with an installed capacity of 409.3 MW, equipped with evaporative coolers, and selective catalytic reduction (SCR) for NO_x reduction, and dual fuel capability.

2 Spark spreads use a combined cycle heat rate of 7,000 Btu/kWh, zonal hourly LMPs and daily gas prices; Chicago City Gate for COMED, Zone 6 non-NY for BGE, Zone 6 NY for PSEG, and Texas Eastern M3 for Western Hub.

3 Dark spreads use a heat rate of 10,000 Btu/kWh, zonal hourly LMPs, daily coal prices, and average transportation costs by coal type; Powder River Basin coal for COMED, Northern Appalachian coal for BGE and Western Hub, and Central Appalachian coal for PSEG.

- The CC plant includes two single shaft 1x1 GE Frame 7HA.02 CTs, each with a single combustion turbine, heat recovery steam generator, and steam turbine with a total installed capacity of 1,362 MW, equipped with SCR for NO_x reduction, dry cooling, duct burners, and dual fuel capability.
- The CP is a subcritical steam unit with an installed capacity of 600.0 MW, equipped with selective catalytic reduction system (SCR) for NO_x control, a flue gas desulphurization (FGD) system with chemical injection for SO_x and mercury control, and a baghouse for particulate control.
- The DS plant is a single oil fired CAT 2 MW unit with an installed capacity of 2.0 MW using New York Harbor ultra low sulfur diesel.
- The nuclear plant includes two units and related facilities using the Westinghouse AP1000 technology with an installed capacity of 2,200 MW.
- The onshore wind installation includes 104 Siemens 2.9 MW wind turbines with an installed capacity of 301.6 MW.
- The offshore wind installation includes of 40 Siemens 10.0 MW wind turbines with an installed capacity of 400.0 MW.
- The solar installation is a 472 acre ground mounted tracking solar farm with an installed AC capacity of 200 MW.
- The battery storage unit is a 2.5 MW, 10 hour battery capable of providing 2.5 MWh for 10 hours, or 25 MWh.

Net revenue calculations for the CT, CC and CP include the hourly effect of actual local ambient air temperature on plant heat rates and generator output for each of the three plant configurations.[4] [5] Plant heat rates account for the efficiency changes and corresponding cost changes resulting from ambient air temperatures.

CO_2, NO_x and SO_2 emission allowance costs are included in the hourly plant dispatch cost, the short run marginal cost.[6] CO_2, NO_x and SO_2 emission allowance costs were obtained from daily spot cash prices.[7]

4 Hourly ambient conditions supplied by DTN.
5 Heat rates provided by Pasteris Energy, Inc. No load costs are included in the dispatch price since each unit type is dispatched at full load for every economic hour resulting in a single offer point.
6 CO_2 emission allowance costs only included for states participating in RGGI.
7 CO_2, NO_x and SO_2 emission daily prompt prices obtained from Evolution Markets, Inc.

The class average equivalent availability factor for each type of plant was calculated from PJM data and incorporated into all revenue calculations.[8]

Zonal net revenues reflect average zonal LMP and fuel costs based on locational fuel indices and zone specific delivery charges.[9] The delivered fuel cost for natural gas reflects the zonal, daily delivered price of natural gas from a specific pipeline and is from published commodity daily cash prices, with a basis adjustment for transportation costs.[10] The delivered cost of coal reflects the zone specific, delivered price of coal and was developed from the published prompt month prices, adjusted for rail transportation costs.[11] Net revenues are calculated for all zones except OVEC.[12]

Short run marginal cost includes fuel costs, emissions costs, and the short run marginal component of VOM costs.[13] [14] Average short run marginal costs are shown, including all components, in Table 7-3 and the short run marginal component of VOM is also shown separately.

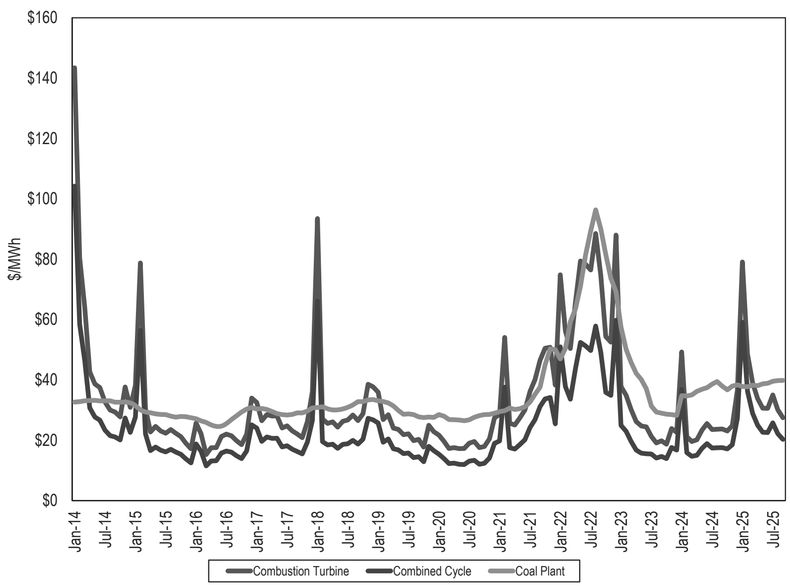
Table 7-3 Average short run marginal costs: January through September, 2025

Unit Type	Short Run Marginal Costs ($/MWh)	Heat Rate (Btu/kWh)	VOM ($/MWh)
CT	$39.36	9,241	$0.54
CC	$29.18	6,369	$0.88
CP	$38.72	9,250	$5.64
DS	$173.01	9,660	$0.25
Nuclear	$0.00	NA	$0.00
Wind	$0.00	NA	$0.00
Wind (off shore)	$0.00	NA	$0.00
Solar	$0.00	NA	$0.00

8 Outage figures obtained from the PJM eGADS database.
9 Startup fuel burns and emission rates provided by Pasteris Energy, Inc. Startup station power consumption costs were obtained from the station service rates published quarterly by PJM and netted against the MW produced during startup at the preceding applicable hourly LMP. All starts associated with combined cycle units are assumed to be warm starts.
10 Gas daily cash prices obtained from Platts.
11 Coal prompt month prices obtained from Platts.
12 The Ohio Valley Electric Corporation (OVEC) includes a generating plant in Ohio and a generating plant in Indiana, and high voltage transmission lines, but does not occupy a single geographic footprint like the other control zones.
13 Fuel costs are calculated using the daily spot price and may not equal what individual participants actually paid.
14 VOM rates provided by Pasteris Energy, Inc.

A comparison of the monthly average short run marginal cost of the theoretical CT, CC and CP plants since 2014 shows that, on average, the short run marginal costs of the CC plant have been less than those of the CP plant but the costs of the CC plant have been more volatile than the costs of the CP plant as a result of the higher volatility of gas prices compared to coal prices (Figure 7-4). The average monthly marginal costs of a new CC and CT were greater than the marginal cost of a new CP only in January 2025 and the average monthly marginal costs of a new CT were greater than the marginal cost of a new CP only in February and March 2025. Marginal costs are based on spot fuel costs. Individual generation plants may have contracts for coal that differ significantly from spot prices.

Figure 7-4 Average short run marginal costs: 2014 through September 2025



The net revenue measure does not include the potentially significant contribution from the explicit or implicit sale of the option value of physical units or from bilateral agreements to sell output at a price other than the PJM day-ahead or real-time energy market prices, e.g., a forward price.

Gas prices, coal prices, and energy prices are reflected in new unit capacity factors. Table 7-4 shows the average capacity factor for new units. The capacity factors for a new CP increased in the first nine months of 2025 compared to the first nine months of 2024.

Table 7-4 Average capacity factor: January through September, 2014 through 2025

New Entrant Combustion Turbine

Energy market net revenue was calculated for a new CT plant economically dispatched by PJM. It was assumed that the CT plant had a minimum run time of two hours. The unit was first committed day ahead in profitable blocks of at least two hours, including start costs. If the unit was not already committed day ahead, it was run in real time in standalone profitable blocks of at least two hours, or any additional profitable hours bordering the profitable day-ahead or real-time block.

The new entrant CT is larger and more efficient than most CTs currently operating in PJM. The new entrant CT energy market net revenue results must therefore be interpreted carefully when comparing to existing CTs which are generally smaller and less efficient than the newest CT technology used by the new entrant CT.

New entrant CT plant energy market net revenues were higher in all zones in the first nine months of 2025 as a result of higher spark spreads (Table 7-5).

15 The energy net revenues presented for the PJM area in this section are calculated using the zonal average LMP.

New Entrant Combined Cycle

Energy market net revenue was calculated for a new CC plant economically dispatched by PJM. It was assumed that the CC plant had a minimum run time of four hours. The unit was first committed day ahead in profitable blocks of at least four hours, including start costs.[16] The unit was allowed to extend its run in real time if it was profitable to do so.

New entrant CC plant energy market net revenues were higher in all zones in the first nine months of 2025 as a result of higher spark spreads (Table 7-6).

16 All starts associated with combined cycle units are assumed to be warm starts.
17 The energy net revenues presented for the PJM area in this section represent the zonal average energy net revenues.

New Entrant Coal Plant

Energy market net revenue was calculated for a new CP plant economically dispatched by PJM. It was assumed that the CP plant had a minimum run time of eight hours. The unit was first committed day ahead in profitable blocks of at least eight hours, including start costs. The unit was allowed to extend its run in real time if it was profitable to do so.

New entrant CP plant energy market net revenues were higher in all zones in the first nine months of 2025 as a result of higher dark spreads (Table 7-7).

18 The energy net revenues presented for the PJM area in this section represent the zonal average energy net revenues.

New Entrant Nuclear Plant

Energy market net revenue was calculated assuming that the nuclear plant was dispatched day ahead by PJM for all available plant hours. The unit runs for all hours and output reflects the class average equivalent availability factor.[19]

New entrant nuclear plant energy market net revenues were higher in all zones in the first nine months of 2025 as a result of higher energy prices (Table 7-8).

Table 7-8 Energy net revenue for a new entrant nuclear plant: January through September, 2014 through 2025 (Dollars per installed MW-year)[20]

19 The annual class average *equivalent availability* factor was used in the calculation of energy market net revenues.
20 The energy net revenues presented for the PJM area in this section represent the zonal average energy net revenues because fuel costs for nuclear units are included in the NEI nuclear costs.

New Entrant Diesel

Energy market net revenue was calculated for a DS plant economically dispatched by PJM in real time.

New entrant DS plant energy market net revenues were higher in all zones in the first nine months of 2025 as a result of higher and more volatile energy prices (Table 7-9).

Table 7-9 Energy market net revenue for a new entrant DS: January through September, 2014 through 2025 (Dollars per installed MW-year)

New Entrant Onshore Wind Installation

Energy market net revenues for an onshore wind installation were calculated hourly by zone assuming the unit generated at the average hourly capacity factor of all operating wind units in the zone with an installed capacity greater than 3 MW.[21]

Onshore wind energy market net revenues excluding RECs in the defined zones were higher in the first nine months of 2025 as a result of increases in energy prices.

Table 7-10 Energy market net revenue for an onshore wind installation (Dollars per installed MW-year): January through September, 2014 through 2025

	Jan-Sep												
Zone	2014	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025	Change in 2025 from 2024
AEP	$80,488	$54,850	$45,842	$48,743	$69,611	$49,912	$30,754	$47,276	$106,828	$46,094	$49,330	$70,634	43%
APS	$83,957	$55,410	$40,843	$51,330	$69,984	$42,199	$32,374	$42,649	$96,708	$45,219	$45,229	$73,998	64%
COMED	$72,887	$46,732	$39,315	$48,121	$46,613	$44,297	$26,061	$46,357	$97,383	$37,238	$41,007	$54,937	34%

21 Net revenues are calculated for zones in which there are sufficient operating units to determine capacity factor for a new entrant unit.
22 RECs prices obtained from Evolution Markets, Inc.

New Entrant Offshore Wind Installation

Energy market net revenues for an offshore wind installation were calculated hourly for relevant zones assuming the unit generated at a 40 percent capacity factor.

Offshore wind energy market net revenues excluding RECs were higher in the first nine months of 2025 as a result of higher energy prices.

Table 7-12 Energy market net revenue for an offshore wind installation (Dollars per installed MW-year): January through September, 2014 through 2025

	Jan-Sep												
Zone	2014	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025	Change in 2025 from 2024
ACEC	$149,772	$96,219	$64,564	$69,660	$90,860	$64,497	$46,801	$76,737	$170,516	$60,970	$71,916	$105,695	47%
DOM	$157,995	$104,655	$79,002	$79,539	$105,879	$72,441	$54,828	$97,137	$231,511	$91,249	$96,009	$153,034	59%

24 Net revenues are calculated for zones in which there are sufficient operating units to determine capacity factor for a new entrant unit.
25 RECs prices obtained from Evolution Markets, Inc.

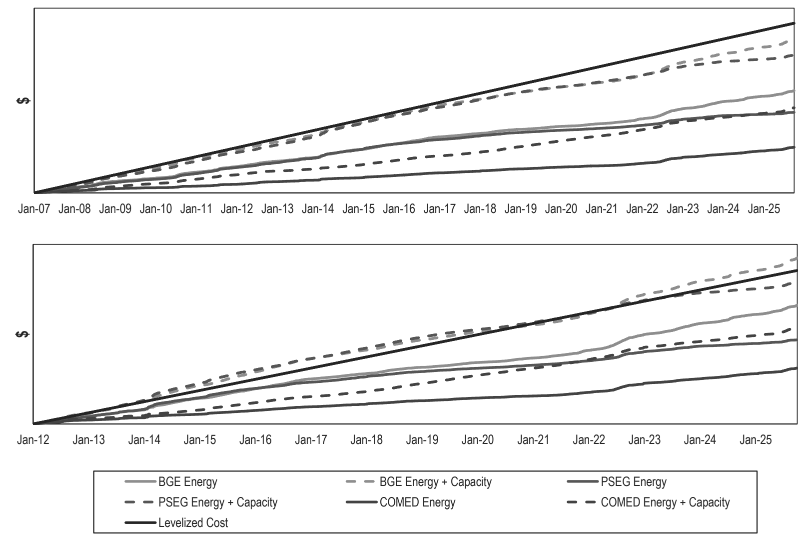
Historical New Entrant CC Revenue Adequacy

Total unit net revenues include energy and capacity market revenues. Analysis of the total unit revenues of theoretical new entrant CCs for three representative locations shows that CC units that entered the PJM markets in 2007 have covered 91 percent of their total costs in the BGE Zone and 81 percent of total costs in the PSEG Zone, and 50 percent of total costs in the COMED Zone, including the return on and of capital, on a cumulative basis through September 2025. The analysis also shows that theoretical new entrant CCs that entered the PJM markets in 2012 have covered over 100 percent of their total costs on a cumulative basis in the BGE Zone, 92 percent of their total costs in PSEG Zone, and 63 percent of total costs in the COMED Zone. Energy market revenues alone were not sufficient to cover total costs in any scenario, which demonstrates the critical role of the capacity market revenue in covering total costs. Covering 100 percent of total costs in this analysis includes earning the assumed rate of return. Units earned a positive rate of return even when earning less than the assumed rate of return.

Under cost of service regulation, units are guaranteed that they will cover their total costs, assuming that the costs were determined to be reasonable. To the extent that units built in the PJM markets did not cover their total costs, investors were worse off and customers were better off than under cost of service regulation, ignoring the benefits of competition on increasing efficiency, reducing costs and improving technology and ignoring the possibility of over earning under cost of service regulation.

Figure 7-5 compares cumulative energy market net revenues and energy market net revenues plus capacity market revenues to cumulative levelized costs for a new entrant CC that began operation on January 1, 2007, and a new entrant CC that began operation on January 1, 2012. The solid black line shows the total net revenue required to cover total costs. The solid colored lines show net energy revenue by zone. The dashed colored lines show the sum of net energy and capacity revenue by zone.

Figure 7-5 Historical new entrant CC revenue adequacy: 2007 through September 2025 and 2012 through September 2025[26]



26 The gas pipeline pricing points used in this analysis are Zone 6 non-NY for BGE, Chicago City Gate for COMED, and Texas Eastern M3 for PSEG.

Table 7-16 shows the percent of levelized total costs recovered from the start date through September 2025. Table 7-16 also shows the return (IRR) earned from the start date through September 2025. For example, for a CC built in BGE in 2012, the resource would have earned a 14 percent IRR compared to the required 12 percent. In contrast, for a CC built in ComEd in 2012, the resource would have earned a 2 percent IRR compared to the required 12 percent.

Table 7-16 Percent of levelized total costs recovered

2007 through September 2025 and 2012 through September 2025	2007 CC	2012 CC
Percent of levelized costs covered at 12% IRR		
BGE	91%	108%
COMED	50%	63%
PSEG	81%	92%
IRR at which levelized costs are covered		
BGE	9%	14%
COMED	0%	2%
PSEG	7%	11%

The assumptions used for this analysis are shown in Table 7-17.

Table 7-17 Assumptions for analysis of new entry in 2007 and 2012

Nuclear Net Revenue Analysis

The analysis of nuclear plants includes annual avoidable costs and incremental capital expenditures from the Nuclear Energy Institute (NEI) based on NEI's calculations of average costs for all U.S. nuclear plants.[27] [28] The analysis includes the most recent operating cost data and incremental capital expenditure data for single unit plants and multi unit plants published by NEI, which is for 2023.[29] NEI average operating costs have decreased since their peak in 2012 (a 7.5 percent decrease from 2012 through 2023 for all plants including single and multiple unit plants in nominal dollars; a 33.0 percent decrease in real 2023 dollars).[30] NEI average incremental capital expenditures have decreased since their peak in 2012 (a 32.8 percent decrease from 2012 through 2023 for all plants including single and multiple unit plants in nominal dollars; a 51.1 percent decrease in real 2023 dollars).[31] NEI's incremental capital expenditures peaked in 2012 as a result of regulatory requirements following the 2011 accident at the Fukushima nuclear plant in Japan.

The results for nuclear plants are sensitive to small changes in PJM energy and capacity prices, both actual and forward prices.[32] When gas prices are high and LMPs are high as a result, net revenues to nuclear plants increase. In 2014, the polar vortex resulted in a significant increase in net revenues to nuclear plants. When gas prices are low and LMPs are low as a result, net revenues to nuclear plants decrease. In 2016, PJM energy prices were then at the lowest level since the introduction of competitive markets on April 1, 1999, and remained low in 2017. As a result, in 2016 and 2017, a significant proportion of nuclear plants did not cover annual avoidable costs based on

27 Operating costs from: Nuclear Energy Institute (February 2025). "Nuclear Costs in Context," <https://www.nei.org/resources/reports-briefs/nuclear-costs-in-context>. Individual plants may vary from the average due to factors such as geographic location, local labor costs, the timing of refueling outages and other unit specific factors. This is the most current NEI data available.

28 The NEI costs for Hope Creek were treated as that of a two unit configuration because the unit is located in the same area as Salem 1 & 2. The net surplus of Hope Creek is sensitive to the accuracy of this assumption.

29 NEI also provides average costs by plant run by operators with one plant or multiple plants, by market, and by type of nuclear reactor. Plants run by operators with multiple plants have lower average costs than plants run by operators with a single plant. Plants participating in wholesale markets have lower average costs than plants in regulated markets. PWR reactors have lower average generating costs than BWR reactors.

30 Operating costs in this paragraph are operating costs as specified by NEI and do not include fuel costs or capital expenditures. Operating costs for single unit plants decreased by 2.6 percent from 2022 to 2023 in nominal dollars. Operating costs for multiple unit plants increased by 6.0 percent from 2022 to 2023 in nominal dollars.

31 Capital expenditures have decreased 20.6 percent since 2012 for single unit plants and 35.0 percent for multiple unit plants in nominal dollars.

32 A change in the capacity market price of $24 per MW-day translates into a change in capacity revenue of $1.00 per MWh for a nuclear power plant operating at a capacity factor of 100 percent. A change in the capacity market price of $24 per MW-day translates into a change in capacity revenue of $1.05 per MWh for a nuclear power plant operating at a capacity factor of 0.951 percent.

current year prices.[33] In 2018, high gas prices and high LMPs resulted in a significant increase in net revenues for nuclear plants in PJM. Energy prices in 2018 were significantly higher than in 2017. Although energy prices in 2019 were lower than in 2016, higher capacity market revenues more than offset the difference. In 2020, PJM energy prices were at the lowest level since the introduction of competitive markets, even lower than in 2016. Average energy prices in 2022 were higher than energy prices in any year since the inception of PJM markets in 1999. Based on forward prices as of September 30, 2025, expected nuclear plant energy revenues for 2025 and 2026 are higher than actual revenues in all years since 2014, with the exception of 2022. The actual net revenue results for individual nuclear plants are a function of the degree to which actual unit costs are less than or greater than the benchmark NEI data.

Table 7-18 shows energy market prices, Table 7-19 and Table 7-20 show capacity market prices and Table 7-21 shows nuclear cost data for the 16 nuclear plants in PJM in addition to Oyster Creek, which retired September 17, 2018, and Three Mile Island, which retired September 20, 2019.[34] [35] The analysis excludes the Catawba 1 nuclear unit. Partial data is provided for the Cook, North Anna, and Surry nuclear units. The AEP Cook nuclear units are designated FRR. North Anna 1 and 2 and Surry 1 and 2 are part of the Dominion FRR for the 2022/2023 and 2023/2024 and 2024/2025 Delivery Years.[36] [37] [38] FRR units receive cost of service revenues and are not subject to PJM market revenues. Duke's Catawba 1 is not in PJM but is pseudo tied to PJM.

For nuclear plants, all calculations are based on publicly available data in order to avoid revealing confidential information. Historical nuclear unit revenue is based on day-ahead LMP at the relevant node. Nuclear unit capacity revenue assumes that the unit cleared its full unforced capacity at the BRA locational clearing price. Unforced capacity is determined using the annual class average EFORd or ELCC rate.[39]

42 Capacity revenue through the 2024/2025 Delivery Year is calculated by adjusting the BRA Capacity Price for calendar year, by the class average EFORd, and by the annual class average capacity factor. Class average EFORd and capacity factor is from *2024 Annual State of the Market Report for PJM*, Volume 2, Section 5: Capacity Market. Capacity revenue beginning the 2025/2026 Delivery Year is calculated by adjusting the BRA Capacity Price for calendar year, by the class average ELCC. See BRA Class Ratings <https://www.pjm.com/planning/resource-adequacy-planning/effective-load-carrying-capability>.

Hope Creek, Quad Cities, and Salem have all received state subsidies since 2019.[46] [47] The NJ Board of Public Utilities, having received no applications as of December 1, 2023, closed the third eligibility period of the ZEC program for the period beginning June 1, 2025.[48] This was a result of the introduction of a new federal nuclear subsidy under the Inflation Reduction Act. Braidwood, Byron, Dresden, and LaSalle will receive a state subsidy if necessary to meet a target net revenue value, in dollars per MWh, from the energy and capacity markets.[49] All existing nuclear plants will receive a federal subsidy if necessary to meet a target revenue value, in dollars per MWh, from the energy market.[50]

The Inflation Reduction Act added a significant new federal subsidy for existing nuclear power plants.[51] All existing nuclear plants will receive the Zero Emission Nuclear Power Production Credit (Nuclear PTC) if revenues from energy, ancillary, capacity markets, and any state subsidies are between $25.00/MWh and $43.75/MWh, adjusted for inflation. The Nuclear PTC of $3.00/MWh is increased by a factor of five to $15.00/MWh if certain prevailing wage requirements are met. The Nuclear PTC creates a revenue floor of $40.00/MWh and does not create a revenue ceiling. If nuclear revenues are greater than $43.75/MWh, the Nuclear PTC subsidy does not apply and units keep all profits.

Surry	-	-	-	-	-	$8.08	$0.00
Susquehanna	-	-	-	-	-	$13.98	$0.00
Three Mile Island	-	-	-	-	-	-	-

Table 7-23 shows the surplus or shortfall in $/MWh for the 16 nuclear plants in PJM, and Oyster Creek and Three Mile Island, calculated using historic LMP and cost data. In 2020, no nuclear plants covered their fuel costs, operating costs, and incremental capital expenditures as a result of lower energy prices. In 2021 and 2022, all nuclear plants more than covered their fuel costs, operating costs, and capital expenditures as a result of higher energy prices. In 2023, only two nuclear plants covered their fuel costs, operating costs, and incremental capital expenditures as a result of lower energy and capacity prices. In 2024, all nuclear plants with the exception of Davis Besse covered their fuel costs, operating costs, and incremental capital expenditures. The surplus or shortfall assumes that the unit receives the DA LMP, reactive capability revenue, cleared its full unforced capacity at the BRA locational clearing price, receives a subsidy if qualified, and has costs equal to the NEI average costs.[52] Unforced capacity is determined using the annual class average EFORd or ELCC rate.[53]

The market revenues are based in part on the sale of capacity. Some nuclear plants did not clear the capacity market in some years as a result of decisions by plant owners about how to offer the plants in the capacity market auctions. When nuclear plants do not clear in the capacity market, it is a result of the offer behavior of the plants and does not accurately reflect the economic viability of the plants. This analysis is intended to define whether the plants are receiving a retirement signal from the PJM markets. If the plants are viable including both energy and capacity market revenues based on actual clearing prices, then the PJM markets indicate that the plant is economically viable. If plant owners decide to offer so as to not clear in the capacity market, that does not change the market signals to the plants. Such decisions may reflect a variety of considerations. Quad Cities and a portion of Byron's capacity did not clear in the 2019/2020 Auction.[54] Quad Cities did not clear in the 2020/2021 Auction.[55] Dresden and most of Byron did not clear in the 2021/2022 Auction.[56] Beaver Valley, Davis Besse, and Perry did not clear in the 2021/2022 Auction.[57] Byron, Dresden, and Quad Cities did not clear in the 2022/2023 Auction.[58]

Nuclear unit revenue is a combination of energy market revenue, ancillary services market revenue and capacity market revenue. Negative energy market prices do not have a significant impact on nuclear unit revenue. Since 2014, negative energy market prices have affected nuclear plants' annual total revenues by an average of 0.1 percent. Negative LMPs reduced nuclear plant total revenues by an average of 0.0 percent and a maximum of 0.6 percent in 2014, an average of 0.2 percent and a maximum of 1.2 percent in 2015, an

In order to evaluate the expected viability of nuclear plants, analysis was performed based on forward energy market prices for 2025, 2026, and 2027 and known capacity market prices for 2024 and 2025. The purpose of the forward analysis is to evaluate whether current forward prices are consistent with nuclear plants covering their annual avoidable costs over the next three years. While the forward capacity market prices are known through the 2025/2026 Delivery Year, actual energy prices will vary from forward values. Nuclear plants may choose to sell their output at a range of forward prices and for a range of future years.

Table 7-25 shows PJM energy prices (LMP), annual fuel, and operating and capital expenditures used for the analysis of the period 2025 through 2027. Capacity revenues for calendar year 2026 include five months of capacity revenue from the 2025/2026 Delivery Year and seven months of capacity revenue for the 2026/2027 Delivery Year. Capacity revenues for calendar year 2027 include five months of capacity revenue from the 2026/2027 Delivery Year and seven months of capacity revenue assuming a clearing price of $325/MW-Day for the 2027/2028 Delivery Year.[60] The 2027/2028 BRA has not yet been run. The LMPs are based on forward prices with a basis adjustment for the specific plant locations.[61] Forward prices are as of September 30, 2025. The capacity prices are known through May 31, 2027, based on PJM capacity auction results.

60 On February 20, 2025, PJM filed with FERC to establish a maximum price of approximately $325/MW-day in unforced capacity and a minimum price of approximately $175/MW-day, both in unforced capacity (UCAP) terms for all capacity auctions for the 2026/2027 and 2027/2028 delivery years. See Docket No. ER25-1357.

61 Forward prices are reported for PJM trading hubs which are adjusted to reflect the historical differences between prices at the trading hub and prices at the relevant plant locations. The basis adjustment is based on 2024 data.

Table 7-25 Forward prices in PJM energy markets, capacity revenue, and annual costs

The MMU also calculates the capacity price that would be required to cover the net avoidable costs for each nuclear plant.

Based on the FERC order allowing the inclusion of major maintenance in energy offers, major maintenance costs can no longer be included in gross ACR values offered in the capacity market.[62] The MMU calculates the capacity price that would be required to cover the net avoidable costs for each nuclear plant with major maintenance included in avoidable costs and with major maintenance excluded from avoidable costs. For the case including major maintenance, gross ACR is NEI total cost including fuel, operating cost, and incremental capital expenditures. For the case excluding major maintenance, gross ACR is NEI total cost including fuel and operating cost, excluding capital expenditures as a proxy for fixed VOM, given that NEI does not provide a breakout of major maintenance. NEI incremental capital expenditures are likely to be a conservatively low estimate of major maintenance expense.

62 See 167 FERC ¶ 61,030 at P 41 (2019).

All generating plants including nuclear plants must cover their gross avoidable costs, including major maintenance, to remain economically viable. All of the MMU analysis of nuclear plant economics includes gross avoidable costs as reported by NEI unless explicitly stated otherwise.

In Table 7-26, the capacity price required to cover avoidable costs in $/MWh is calculated by taking the total NEI costs in $/MWh and subtracting the total expected energy and ancillary services revenues in $/MWh. Total expected energy revenue is the unit's ICAP multiplied by the average forward LMP multiplied by the class average capacity factor. Total expected ancillary services revenue is unit specific reactive capability revenue.[63] The capacity price required to cover avoidable costs in $/MW-day is calculated by multiplying the required price in $/MWh by 24. Plants may have actual operating costs higher or lower than the NEI average.

In Table 7-26, the capacity price required to cover avoidable costs is $0/MW-day for all units in 2025, 2026 and 2027 using NEI data as reported including capital expenditures, and is $0/MW-day for all plants, excluding capital expenditures as a proxy for major maintenance, in 2025, 2026, and 2027.[64] Net revenues based on forward energy prices alone are greater than or equal to avoidable costs in 2025, 2026, and 2027 without any contribution from capacity market revenues for all plants. The result is that net ACR values for 2025, 2026 and 2027 in Table 7-26 are zero.

63 Reactive Supply & Voltage Control Revenue Requirements available from PJM <https://www.pjm.com/markets-and-operations/billing-settlements-and-credit.aspx>.
64 PJM's tariff definition of avoidable costs excludes major maintenance. PJM includes major maintenance costs in the definition of short run marginal costs in energy offers.

Table 7-27 shows the surplus or shortfall that would be received net of avoidable costs and incremental capital expenditures by year, based on forward prices, on a per MWh basis. The fuel and operating costs are the 2023 NEI fuel, operating, and capital costs. Plants may have operating costs higher or lower than the NEI average. Table 7-27 shows the total dollar surplus or shortfall and adjusts energy revenues and operating costs using the annual class average capacity factor.

The 2025 nuclear unit surplus values are shown in Table 7-27 based on forward prices as of September 30, 2025, NEI average costs, and expected subsidy values.[65] The current analysis, based on forward prices for energy, known forward prices for capacity, and an assumed clearing price of $325/MW-Day for the 27/28 delivery year, shows that all PJM nuclear plants analyzed are expected to have a surplus without any subsidy amount in 2025, 2026 and 2027.[66]

65 Gross receipts used to calculate the unit subsidy include energy revenue, ancillary services revenue, capacity revenue, and state ZECs subsidies, and assumes the unit meets prevailing wage requirements and receives the Zero Emission Nuclear Power Production Credit 5 times multiplier. Effectively, nuclear power plants will receive the higher of the state or federal subsidy amount.
66 On February 20, 2025, PJM filed with FERC to establish a maximum price of approximately $325/MW-day in unforced capacity and a minimum price of approximately $175/MW-day, both in unforced capacity (UCAP) terms for all capacity auctions for the 2026/2027 and 2027/2028 Delivery Years. See Docket No. ER25-1357.

67 The state subsidy value for Braidwood, Byron, Dresden, and LaSalle is calculated by taking the applicable Baseline Cost less forward energy prices and known capacity prices.
68 The federal subsidy value for nuclear plants is defined in the Inflation Reduction Act of 2022, Public Law 117-169 (August 16, 2022).
69 North Anna and Surry are in Dominion FRR beginning with the 2022/2023 Delivery Year. North Anna and Surry rejoined the PJM Capacity Market beginning with the 2025/2026 Delivery Year.

Environmental and Renewable Energy Regulations

Environmental requirements and renewable energy mandates have a significant impact on PJM markets. State and federal environmental regulatory requirements affect the economic viability of resources and will result in the retirement of a significant level of capacity resources by 2030. State and federal environmental policies also affect the viability of new resources and the cost of entry. State and federal subsidies for renewable generation have made new solar resources cost competitive with existing coal resources and contributed to the significant level of wind and solar resources entering the market.

Overview

Federal Environmental Regulation

- **MATS.** The U.S. Environmental Protection Agency's (EPA) Mercury and Air Toxics Standards rule (MATS) applies the Clean Air Act (CAA) maximum achievable control technology (MACT) requirement to new or modified sources of emissions of mercury and arsenic, acid gas, nickel, selenium and cyanide.[1] On April 24, 2024, the EPA finalized a strengthened and updated MATS rule reflecting recent developments in control technologies and the performance of coal fired plants.[2] On June 11, 2025, the EPA proposed to repeal the core changes of the 2024 amendments,[3] including the revised filterable particulate matter (fPM) emission standard, restoring the 0.030 lbs/MMBtu standard.[4]
- **Air Quality Standards (NO_X and SO_2 Emissions).** The CAA requires each state to attain and maintain compliance with fine particulate matter (PM) and ozone national ambient air quality standards (NAAQS). The CAA also requires that each state prohibit emissions that significantly interfere with the ability of another state to meet NAAQS.[5] (Transport Rule) On March 15, 2021, the EPA finalized decreases to allowable emissions under the Cross-State Air Pollution Rule (CSAPR) and the 2008 ozone NAAQS for 10 PJM states.[6] On February 28, 2022, the EPA issued a federal implementation plan for implementation of CSAPR (also known as the Good Neighbor Plan),[7] which applies when no state implementation plan has been approved. On June 27, 2024, the Supreme Court of the United States granted a stay of the federal implementation plan pending judicial review.[8] The effect of the stay is to eliminate the ozone season NO_X emissions budgets for electric generating units in the PJM states. Unless and until the stay is lifted, no federal implementation plan is effective in PJM states and the state emissions budgets are not effective. The EPA had previously rejected all proposed state implementation plans for PJM states. Under the new administration the future of the federal implementation plan is uncertain, and attempts to create state implementation plans are expected to resume.
- **NSR.** The CAA's NSR program is a preconstruction permitting program that requires certain stationary sources of air pollution to obtain permits prior to beginning construction. Parts C and D of Title I of the CAA provide for New Source Review (NSR) in order to prevent new projects and projects receiving major modifications from increasing emissions in areas currently meeting NAAQS or from inhibiting progress in areas that do not.[9] NSR requires permits before construction commences. NSR review applies a two part analysis to projects at facilities such as power plants, some of which involve multiple units and combinations of new and existing units.[10]
- **RICE.** Stationary reciprocating internal combustion engines (RICE) are electrical generation facilities like diesel engines typically used for backup, emergency or supplemental power. RICE must be tested

9 42 U.S.C § 7470 et seq.
10 40 CFR § 52.21.

annually.[11] Environmental regulations allow stationary emergency RICE that do not meet the emissions limits and are participating in demand response programs to operate for up to 100 hours per calendar year when providing emergency demand response when there is a PJM declared NERC Energy Emergency Alert Level 2 or there are five percent voltage/frequency deviations.

PJM does not prevent stationary emergency RICE that cannot meet its capacity market obligations as a result of EPA emissions standards from participating in PJM markets as DR. Some stationary emergency RICE that cannot meet its capacity market obligations as a result of emissions standards are now included in DR portfolios. Stationary emergency RICE should be prohibited from participation as DR either when registered individually or as part of a portfolio if it cannot meet its capacity market obligations as a result of emissions standards.

- **Greenhouse Gas Emissions.** On April 25, 2024, the EPA issued a rule (called "Carbon Emissions Rule" in this report) taking four separate actions under CAA § 111(a)(1) addressing greenhouse gas (GHG) emissions from fossil fuel-fired electric generating units (EGUs):[12] the rule repeals the Affordable Clean Energy (ACE) Rule; the rule finalizes emission guidelines for GHG emissions from existing coal fired and oil/gas fired steam generating EGUs; the rule revises the New Source Performance Standards (NSPS) for GHG emissions from new and reconstructed fossil fuel-fired stationary combustion turbine EGUs; the rule revises the NSPS for GHG emissions from fossil fuel-fired steam generating units that undertake a large modification, based upon the 8-year review required by the CAA. The rule deferred action on emission guidelines for GHG emissions from existing fossil fuel-fired stationary combustion turbines.

  The Carbon Emissions Rule reflects the application of the best system of emission reduction (BSER). The proposal includes emission guidelines for GHG emissions from existing fossil fuel-fired steam generating EGUs (including coal, oil or gas). For coal fired EGUs, compliance is required by January 1, 2030, with standards that vary based on whether the EGU commits to retire before 2032, 2035, 2040, or does not commit to retire before 2040.[13] The Carbon Emissions Rule proposes to repeal the Affordable Clean Energy Rule.[14]

- **Cooling Water Intakes.** An EPA rule implementing Section 316(b) of the Clean Water Act (CWA) requires that cooling water intake structures reflect the best technology available for minimizing adverse environmental impacts.[15]

- **Waters of the United States.** On August 29, 2023, the EPA issued a final rule defining adjacent wetlands consistent with the Supreme Court holding that an adjacent wetland is "… a relatively permanent body of water connected to traditional interstate navigable waters … and … that the wetland has a continuous surface connection with that water."[16] The rule became effective on September 8, 2023.[17]

- **Effluents.** Under the CWA, the EPA regulates (National Pollutant Discharge Elimination System (NPDES)) discharges from and intakes to power plants, including water cooling systems at steam electric power generating stations. Since 2015, the EPA has been strengthening certain discharge limits applicable to steam generating units, and some plant owners have already indicated an intent to close certain generating units as a result. In May 2024, the EPA finalized a rule strengthening regulation of effluent discharges.[18]

- **Coal Ash.** The EPA administers the Resource Conservation and Recovery Act (RCRA), which governs the disposal of solid and hazardous waste.[19] The EPA has adopted significant changes to the implementing regulations that will require closing noncompliant impoundments, and, as a result, the host power plant. The EPA is implementing a process for extensions to as late as October 17, 2028. The EPA is reviewing applications received

from PJM plant owners for extensions of the deadline for compliance with the revised Coal Combustion Residuals Rule.

State Environmental Regulation

- **Regional Greenhouse Gas Initiative (RGGI).** The Regional Greenhouse Gas Initiative (RGGI) is a CO_2 emissions cap and trade agreement among Connecticut, Delaware, Maine, Maryland, Massachusetts, New Hampshire, New Jersey, New York, Rhode Island, and Vermont that applies to power generation facilities. The most recent RGGI auction, held on September 3, 2025, cleared at $22.25 per short ton, or $24.53 per metric tonne.
- **Illinois Climate and Equitable Jobs Act (CEJA).** On September 16, 2021, the Climate and Equitable Jobs Act (CEJA) became effective. CEJA created an expanded nuclear subsidy program. CEJA mandated that all fossil fuel plants close by 2045. CEJA established emissions caps for investor owned, gas-fired units with three years of operating history, effective October 1, 2021, on a rolling 12 month basis. More than 10,000 MW of capacity are currently affected. The CEJA operating hour limits have resulted in significant opportunity cost adders to cost-based energy market offers for affected units.
- **Carbon Price.** If the price of carbon were $50.00 per metric tonne, short run marginal costs would have increased by $24.45 per MWh or 62.1 percent for a new combustion turbine (CT) unit, $16.85 per MWh or 57.7 percent for a new combined cycle (CC) unit and $43.12 per MWh or 111.4 percent for a new coal plant (CP) for the first nine months of 2025.
- **Offshore Wind.** New Jersey and Maryland have taken significant steps to promote offshore wind. Both states enacted legislation for offshore wind renewable energy credits (ORECs) in 2010.[20] On January 20, 2025, the Trump Administration issued a Presidential Memorandum withdrawing "from disposition for wind energy leasing all areas within the Offshore Continental Shelf."[21] The withdrawal effectively puts on hold indefinitely the offshore wind projects in New Jersey and Maryland. On May 5, 2025, the Attorneys General of New Jersey and Maryland, along with the 16 other states, filed suit against the withdrawal of offshore leasing.[22]

20 See Offshore Wind Economic Development Act of 2010, P.L. 2010, c. 57, as amended, N.J.S.A. 48:3-87 to -87.2.
21 *Temporary Withdrawal of all Areas on the Outer Continental Shelf from Offshore Wind Leasing and Review of the Federal Government's Leasing and Permitting Practices for Wind Projects*, Presidential Memorandum (January 20, 2025) <https://www.whitehouse.gov/presidential-actions/2025/01/temporary-withdrawal-of-all-areas-on-the-outer-continental-shelf-from-offshore-wind-leasing-and-review-of-the-federal-governments-leasing-and-permitting-practices-for-wind-projects/>.

State Renewable Portfolio Standards

- **RPS.** In PJM, ten of 14 jurisdictions have enacted legislation requiring that a defined percentage of retail suppliers' load be served by renewable resources, for which definitions vary. These are typically known as renewable portfolio standards, or RPS. As of September 30, 2025, Delaware, Illinois, Maryland, Michigan, New Jersey, North Carolina, Ohio, Pennsylvania, Virginia and Washington, DC have renewable portfolio standards. Indiana has a voluntary renewable portfolio standard. Kentucky, Tennessee and West Virginia do not have renewable portfolio standards.
- **RPS Cost.** The cost of complying with RPS, as reported by the states, is $14.6 billion over the ten year period from 2014 through 2023, an average annual RPS compliance cost of $1.5 billion. The compliance cost for 2023, the most recent year with almost complete data, was $2.9 billion.[23]

Emissions Controls in PJM Markets

- **Regulations.** Environmental regulations affect decisions about emission control investments in existing units, investment in new units and decisions to retire units. As a result of environmental regulations and agreements to limit emissions, many PJM units burning fossil fuels have installed emission control technology.
- **Emissions Controls.** In PJM, as of September 30, 2025, 98.0 percent of coal steam MW had some type of flue-gas desulfurization (FGD) technology to reduce SO_2 emissions, 99.8 percent of coal steam MW had some type of particulate matter (PM) control, and 99.7 percent of coal steam MW had NO_X emission control technology. All coal steam units in PJM are compliant with the state and federal emissions limits established by MATS.

22 State of New York v. Trump, Case No. 1:25-cv-11221 (Dist. of Mass. May 5, 2025).
23 The 2023 compliance cost value for PJM states does not include Delaware, Michigan or North Carolina. Based on past data these states generally account for approximately 2.0 percent of the total RPS compliance cost of PJM states.

Renewable Generation

- **Renewable Generation.** Wind and solar generation was 6.5 percent of total generation in PJM for the first nine months of 2025. RPS Tier I generation was 7.6 percent of total generation in PJM and RPS Tier II generation was 1.9 percent of total generation in PJM for the first nine months of 2025. Only Tier I generation is defined to be renewable but Tier I includes some carbon emitting generation.
- PJM states with RPS rely heavily on imports and generation from behind the meter resources for RPS compliance. In the first nine months of 2025, Tier I generation from PJM generators met only 46.8 percent of the Tier I RPS requirements.

Recommendations

- The MMU recommends that renewable energy credit markets based on state renewable portfolio standards be brought into PJM markets as they are an increasingly important component of the wholesale energy market. The MMU recommends that there be a single PJM operated forward market for RECs, for a single product based on a common set of state definitions of renewable technologies, with a single clearing price, trued up to real-time delivery. (Priority: High. First reported 2010. Status: Not adopted.)
- The MMU recommends that jurisdictions with a renewable portfolio standard make the price and quantity data on supply and demand more transparent. (Priority: Low. First reported 2018. Status: Not adopted.)
- The MMU recommends that the Commission reconsider its disclaimer of jurisdiction over RECs markets because, given market changes since that decision, it is clear that RECs materially affect jurisdictional rates. (Priority: Low. First reported 2018. Status: Not adopted.)
- The MMU recommends that PJM provide a full analysis of the impact of carbon pricing on PJM generating units and carbon pricing revenues to the PJM states in order to permit the states to consider a potential agreement on the development of a multistate framework for carbon pricing and the distribution of carbon revenues. (Priority: High. First reported 2018. Status: Not adopted.)
- The MMU recommends that load and generation located at separate nodes be treated as separate resources in order to ensure that load and generation face consistent incentives throughout the markets. (Priority: High. First reported 2019. Status: Not adopted.)
- The MMU recommends that stationary emergency RICE be prohibited from participation as DR either when registered individually or as part of a portfolio if it cannot meet the capacity market requirements to be DR as a result of emissions standards that impose environmental run hour limitations. (Priority: Medium. First reported 2019. Status: Not adopted.)

Conclusion

Environmental requirements and renewable energy mandates at both the federal and state levels have a significant impact on the cost of energy and capacity in PJM markets.

Environmental requirements and initiatives at both the federal and state levels, and state renewable energy mandates and associated subsidies have resulted in the construction of substantial amounts of renewable capacity in the PJM footprint, especially wind and solar resources, and the retirement of emitting resources. Renewable energy credit (REC) markets created by state programs, federal subsidies, and federal tax credits have significant impacts on PJM wholesale markets. But state renewables programs in PJM are not coordinated with one another, are generally not consistent with the PJM market design or PJM prices, have widely differing objectives, including supporting some emitting resources, have widely differing implied prices of carbon and are not transparent on pricing and quantities. The effectiveness of state renewables programs would be enhanced if they were coordinated with one another and with PJM markets, and if they increased transparency. States could evaluate the impacts of a range of carbon prices if PJM would provide a full analysis of the impact of carbon pricing on PJM generating units and carbon pricing revenues to the PJM states in order to permit the states to consider a potential agreement on the development of a multistate framework for carbon pricing and the distribution of carbon revenues. A single carbon price across PJM, established by the states, would be the most efficient way to reduce carbon output, if that is the goal.

In the absence of a PJM market carbon price, a single PJM market for RECs would contribute significantly to market efficiency and to the procurement of renewable resources in a least cost manner. Ideally, there would be a single PJM operated forward market for RECs, for a single product based on a common set of state definitions of renewable technologies, with a single clearing price, trued up to real-time delivery. States would continue to have the option to create separate RECs for additional products that did not fit the product definition, e.g. waste coal, trash incinerators, or black liquor.

RECs are an important mechanism used by PJM states to implement environmental policy. RECs clearly affect prices in the PJM wholesale power market. Some resources are not economic except for the ability to purchase or sell RECs. RECs provide out of market payments to qualifying renewable resources, primarily wind and solar. The credits provide an incentive to make negative energy offers and more generally provide an incentive to enter the market, to remain in the market and to operate whenever possible. These subsidies affect the offer behavior and the operational behavior of these resources in PJM markets and in some cases the existence of these resources and thus the market prices and the mix of clearing resources.

RECs markets are, as an economic fact, integrated with PJM markets including energy and capacity markets, but are not formally recognized as part of PJM markets. It would be preferable to have a single, transparent market for RECs operated by the PJM RTO on behalf of the states that would meet the standards and requirements of all states in the PJM footprint. This would provide better information for market participants about supply and demand and prices and contribute to a more efficient and competitive market and to better price formation. This could also facilitate entry by qualifying renewable resources by reducing the risks associated with lack of transparent market data.

Existing REC markets are not consistently or adequately transparent. Data on REC prices, clearing quantities and markets are not publicly available for all PJM states. The economic logic of RPS programs and the associated REC and SREC prices are not always clear. The price of carbon implied by REC prices ranges from $10.24 per tonne in Ohio to $65.23 per tonne in Virginia. The price of carbon implied by SREC prices ranges from $69.05 per tonne in Pennsylvania to $832.21 per tonne in Washington, DC. The effective prices for carbon compare to the RGGI clearing price in September 2025 of $24.53 per tonne and to the social cost of carbon which is estimated in the range of $50 per tonne.[24] [25] The impact on the cost of generation from a new combined cycle unit of a $50 per tonne carbon price would be $16.85 per MWh.[26] The impact of an $800 per tonne carbon price would be $269.59 per MWh. This wide range of implied carbon prices is not consistent with an efficient, competitive, least cost approach to the reduction of carbon emissions.

In addition, even the explicit environmental goals of RPS programs are not clear. While RPS is frequently considered to target carbon emissions, Tier 1 resources include some carbon emitting generation and Tier 2 resources include additional carbon emitting generation.

PJM markets provide a flexible mechanism for incorporating the costs of environmental controls and meeting environmental requirements in a cost effective manner. Costs for environmental controls are part of offers for capacity resources in the PJM Capacity Market. The costs of emissions credits are included in energy offers. PJM markets also provide a flexible mechanism that incorporates renewable resources and the impacts of renewable energy credit markets, and ensures that renewable resources have access to a broad market. PJM markets provide efficient price signals that permit valuation of resources with very different characteristics when they provide the same product.

If the states chose this policy option, PJM markets could also provide a flexible mechanism to limit carbon output, for example by incorporating a consistent carbon price in unit offers which would be reflected in PJM's economic dispatch. If there is a social decision to limit carbon output, a consistent carbon price would be the most efficient way to implement that decision. The states in PJM could agree, if they decided it was in their interests,

24 "Technical Update of the Social Cost of Carbon for Regulatory Impact Analysis – Under Executive Order 12899," Interagency Working Group on the Social Cost of Greenhouse Gases, United States Government, (Aug. 2016), <https://19january2017snapshot.epa.gov/sites/production/files/2016-12/documents/sc_co2_tsd_august_2016.pdf>.

25 A recent update by the EPA estimates the social cost of carbon emissions for 2030 to be between $140 and $380 per metric ton (2020 dollars). See Table ES.1 in Report on the Social Cost of Greenhouse Gases, U.S. Environmental Protection Agency (November 2023) <https://www.epa.gov/environmental-economics/scghg>.

26 The cost impact calculation assumes a heat rate of 6.296 MMBtu per MWh and a carbon emissions rate of 52.91 kg per MMBtu. The $800 per tonne carbon price represents the approximate upper end of the carbon prices implied by the 2025 REC and SREC prices in the PJM jurisdictions with RPS. Additional cost impacts are provided in Table 8-9.

with the appropriate information, on a carbon price and on how to allocate the revenues from a carbon price that would make all states better off. A mechanism like RGGI leaves all decision making with the states. The carbon price would not be FERC jurisdictional or subject to PJM decisions. The MMU continues to recommend that PJM provide a full analysis of the impact of carbon pricing on PJM generating units and carbon pricing revenues to the PJM states in order to permit the states to consider a potential agreement on the development of a multistate framework for carbon pricing and the distribution of carbon revenues. The results of the analysis would include the impact on the dispatch of every unit, the impact on energy prices and the carbon pricing revenues that would flow to each state.

For example, states receiving high levels of revenue could shift revenue to states disproportionately hurt by a carbon price if they believed that all states would be better off as a result. A carbon price would also be an alternative to specific subsidies to individual nuclear power plants and to the current wide range of implied carbon prices embedded in RPS programs and instead provide a market signal to which any resource could respond. The imposition of specific and prescriptive environmental dispatch rules would, in contrast, pose a threat to economic dispatch and efficient markets and create very difficult market power monitoring and mitigation issues. The provision of subsidies to individual units creates a discriminatory regime that is not consistent with competition. The use of inconsistent implied carbon prices by state is also inconsistent with an efficient market and inconsistent with the least cost approach to meeting state environmental goals.

The annual average cost of complying with RPS over the ten year period from 2014 through 2023 for the ten jurisdictions that had RPS was $1.5 billion, or a total of $14.6 billion over ten years. The RPS compliance cost for 2023, the most recent year for which there is almost complete data, was $2.9 billion.[27] RPS costs are payments by customers to the sellers of qualifying resources. The revenues from carbon pricing flow to the states.

If all the PJM states participated in a regional carbon market, the estimated revenue returned to the states/customers from selling carbon allowances would be approximately $7.4 billion per year if the carbon price were $22.25 per short ton and emissions levels were five percent below 2024 emission levels. If all the PJM states participated in a regional carbon market, the estimated revenue returned to the states/customers from selling carbon allowances would be approximately $16.5 billion if the carbon price were $50 per short ton and emission levels were five percent below 2024 levels. If only the current RPS states participated in a regional carbon market, the estimated revenue returned to the states/customers from selling carbon allowances at $22.25 per short ton would be about $5.0 billion. The costs of a carbon price are the impact on energy market prices, net of the revenue returned to states/customers.

27 The 2023 compliance cost value for PJM states does not include Delaware, Michigan or North Carolina. Based on past data these states generally account for approximately 2.0 percent of the total RPS compliance cost of PJM states.

Federal Environmental Regulation

The U.S. Environmental Protection Agency (EPA) administers the Clean Air Act (CAA), the Clean Water Act (CWA) and the Resource Conservation and Recovery Act (RCRA), all of which address pollution created by electric power production. The administration of these statutes is relevant to the operation of PJM markets.[28]

The CAA regulates air emissions by providing for the establishment of acceptable levels of emissions of hazardous air pollutants. The EPA issues technology based standards for major sources and area sources of emissions.[29] [30]

The CWA regulates discharges from point sources that affect water quality and temperature.

The Resource Conservation and Recovery Act (RCRA) regulates the disposal of solid and hazardous waste.[31] Regulation of coal ash or coal combustion residuals affects coal fired power plants.

28 For more details, see the *2024 Annual State of the Market Report for PJM*, Appendix H: "Environmental and Renewable Energy Regulations."
29 42 U.S.C. § 7401 et seq. (2000).
30 The EPA defines a "major source" as a stationary source or group of stationary sources that emit or have the potential to emit 10 tons per year or more of a hazardous air pollutant or 25 tons per year or more of a combination of hazardous air pollutants. An "area source" is any stationary source that is not a major source.
31 42 U.S.C. §§ 6901 *et seq.*

The EPA's actions have affected and will continue to affect the cost to build and operate generating units in PJM, which in turn affects wholesale energy prices and capacity prices.

CAA: NESHAP/MATS

Section 112 of the CAA requires the EPA to promulgate emissions control standards, known as the National Emission Standards for Hazardous Air Pollutants (NESHAP), from both new and existing area and major sources. On December 21, 2011, the EPA issued its Mercury and Air Toxics Standards rule (MATS), which applies the CAA maximum achievable control technology (MACT) requirement to new or modified sources of emissions of mercury and antimony, arsenic, beryllium, cadmium, chromium, cobalt, lead, manganese, acid gas, nickel, selenium and cyanide.

The EPA's MATS rule applies the CAA maximum achievable control technology (MACT) requirement to new or modified sources of emissions of mercury and arsenic, acid gas, nickel, selenium and cyanide.[32] On February 13, 2023, the EPA issued a final rule reaffirming that it remains appropriate and necessary to regulate hazardous air pollutants (HAP), including mercury, from power plants after considering cost.[33] This action revokes a 2020 finding that it was not appropriate and necessary to regulate coal and oil fired power plants under CAA § 112, and would restore the basis for the MATS rule.

On April 24, 2024, the EPA finalized a strengthened and updated MATS rule reflecting recent developments in control technologies and the performance of coal fired plants.[34] The EPA allows plants to meet emissions requirements for non-HAP metals under an alternative fPM emission standard as a surrogate, and most use that approach.[35] The core proposal would revise the (non Hg) fPM emission standard, from 0.030 to 0.010 lbs/MMBtu.[36] The EPA "does not project that any EGUs will retire in response to the standards promulgated in this final rule."[37]

The new administration has taken steps to weaken the enforcement of the MATS rule. In April 2025, in an administrative decision by the EPA under Administrator Lee Zeldin, citing Section 112(i)(4) of the CAA, 47 coal-fired power plants were exempted from MATS compliance for two years. The decision was based on a determination of a need to prolong the life of aging coal plants and support national energy interests. This action is temporary and does not repeal the MATS rule. Repeal of the MATS has been identified as an EPA regulatory goal.[38]

Potentially 16,661 MW of generation in PJM is covered by the two year exemption. Most of the units have either not indicated plans to retire or have repowered, so the impact of the extension alone may not be direct and immediate.

On June 11, 2025, the EPA proposed to repeal the core changes of the 2024 amendments, including the revised filterable particulate matter (fPM) emission standard, restoring the 0.030 lbs/MMBtu standard.[39]

CAA: NAAQS/CSAPR

The CAA requires each state to attain and maintain compliance with particulate matter (PM) and ozone national ambient air quality standards (NAAQS).[40] Under NAAQS, the EPA establishes emission standards for six air pollutants, including NO_X, SO_2, O_3 at ground level, PM, CO, and Pb, and approves state plans to implement these standards, known as State Implementation Plans (SIPs).

In January 2015, the EPA began implementation of the Cross-State Air Pollution Rule (CSAPR) to address the CAA's requirement that each state prohibit emissions that significantly interfere with the ability of another state

39 See *National Emission Standards for Hazardous Air Pollutants: Coal- and Oil-Fired Electric Utility Steam Generating Units*, EPA–HQ–OAR–2018–0794; FRL–6716.4–01–OAR, 90 Fed. Reg. 25535 (June 17, 2025).

40 The particulate matter (PM) regulated under the CAA is classified as either PM_{10}, which refers to PM less than 10 microns, and $PM_{2.5}$, which refers PM less than 2.5 microns. $PM_{2.5}$ is referred to as fine particular matter and poses the greatest risk to health. Examples of $PM_{2.5}$ include combustion particles, metals, and organic compounds.

to meet NAAQS. CSAPR requires specific states in the eastern and central United States to reduce power plant emissions of SO_2 and NO_X that cross state lines and contribute to ozone and fine particle pollution in other states. CSPAR requires reductions to levels consistent with the 1997 ozone and fine particle emissions and 2006 fine particle emission NAAQS. CSAPR covers 28 states, including all of the PJM states except Delaware, and also excluding the District of Columbia.

On March 15, 2021, in response to a court holding in Wisconsin v. EPA,[41] the EPA finalized decreases to allowable emissions under the Cross-State Air Pollution Rule (CSAPR) and the 2008 ozone NAAQS for 10 PJM states.[42] On February 28, 2022, the EPA proposed a Federal Implementation Plan (FIP) (at that time termed the Transport Rule) for 26 states that addresses the contribution of those states to problems in other states in attaining and maintaining the 2015 Ozone NAAQS.[43] The proposed FIP requirements would establish ozone season NO_X emissions budgets for electric generating units in the PJM states, excluding North Carolina and the District of Columbia.

On March 15, 2023, the EPA finalized Federal Implementation Plan (FIP) requirements for 23 states that addresses the contribution of those states to problems in other states in attaining and maintaining the 2015 Ozone NAAQS.[44] The FIP, also known as the Good Neighbor Plan, resolves the CAA good neighbor obligations of the affected states and applies when no state implementation plan has been approved. The FIP requirements establish ozone season NO_X emissions budgets for electric generating units in the following PJM states: Illinois, Indiana, Kentucky, Maryland, Michigan, New Jersey, Ohio, Pennsylvania, Virginia and West Virginia. The list of PJM jurisdictions excludes North Carolina, the District of Columbia, Tennessee and Delaware. Electric generating units in the indicated states would be required to participate in a revised version of the CSAPR NO_X Ozone Season Group 3 Trading Program that was previously established in the 2021 CSAPR Update.

The EPA's emissions budgets for each PJM state for each ozone season for 2023 through 2029, and beyond are shown in Table 8-1.

Table 8-1 CSAPR NO_X ozone season group 3 state budgets: 2023 through 2029[45]

	Emissions Budget (Tons)							
PJM State	2023	2024	2025	2026	2027	2028	2029	2030+
Illinois	7,474	7,325	7,325	5,889*	5,363*	4,555*	4,050*	*
Indiana	12,440	11,413	11,413	8,410*	8,135*	7,280*	5,808*	*
Kentucky	13,601	12,999	12,472	10,190*	7,908*	7,837*	7,392*	*
Maryland	1,206	1,206	1,206	842*	842*	842*	842*	*
Michigan	10,727	10,275	10,275	6,743*	5,691*	5,691*	4,656*	*
New Jersey	773	773	773	773*	773*	773*	773*	*
Ohio	9,110	7,929	7,929	7929*	7,929*	6,911*	6,409*	*
Pennsylvania	8,138	8,138	8,138	7,512*	7,158*	7,158*	4,828*	*
Virginia	3,143	2,756	2,756	2,565*	2,373*	2,373*	1,951*	*
West Virginia	13,791	11,958	11,958	10,818*	9,678*	9,678*	9,678*	*

*The budget for these years will be subsequently determined and equal the greater of the value above or that derived from the dynamic budget methodology.

On February 7, 2024, the EPA issued a final rule reducing the primary annual $PM_{2.5}$ standard to 9.0 µg/m^3 from 12.0 µg/m^3.[46] The rule does not change other $PM_{2.5}$ standards. The proposal responds to the directive in Executive Order 13990 for review of a 2020 Particulate Matter NAAQS Decision that left $PM_{2.5}$ standards unchanged.

On June 27, 2024, the Supreme Court of the United States granted a stay of the FIP and therefore the EPA's enforcement of CSAPR pending judicial review.[47] The effect of the stay is to eliminate the ozone season NO_X emissions budgets for electric generating units in the PJM states. Unless and until the stay is lifted, no federal implementation plan is effective in PJM states and the emissions budgets described in Table 8-1 are not effective. The EPA had previously rejected all proposed state implementation plans for PJM states.

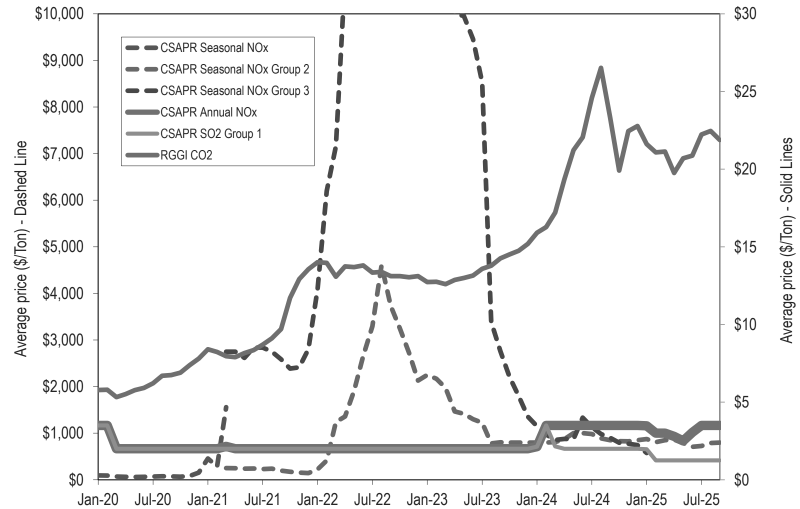
45 *Id.* at 35 (Table I.B-1).
46 *See Reconsideration of the National Ambient Air Quality Standards for Particulate Matter.* Proposed Rule, Docket No. EPA-HQ-OAR-2015-0072; FRL-8635-01- OAR, 89 Fed. Reg. 16202 (March 6, 2024).
47 Ohio v. EPA, Slip Op. No. 23A349. (S. Ct. June 27, 2024).

The new EPA Administrator has indicated plans to terminate the Good Neighbor Plan and revive negotiation of state implementation plans with the affected states.[48] Specific proposals are pending, and likely to result in litigation.

Figure 8-1 shows average, monthly settled prices for NO_X and SO_2 emissions allowances including CSAPR related allowances for 2020 through June 2025. Figure 8-1 also shows the average, monthly settled price for the Regional Greenhouse Gas Initiative (RGGI) CO_2 allowances.

The RGGI CO_2 allowance price averaged $21.30 in the first nine months of 2025, a 2.8 percent increase in comparison with the average price for the first nine months of 2024. The CSAPR annual NO_X allowance price averaged $3.15 in the first nine months of 2025, a 6.0 percent decrease in comparison with the average price for the first nine months of 2024. The group 2 CSAPR Seasonal NO_X allowance price averaged $800.46 in the first nine months of 2025, a 10.0 percent decrease in comparison with the average price for the first nine months of 2024.[49] The components of real-time LMP analysis shows that NO_x cost contributed $0.07 to the load-weighted average real-time LMP in the first nine months of 2025, compared to $0.11 in the first nine months of 2024.[50] CO_2 cost (RGGI) contributed $2.08 to the load-weighted average real-time LMP in the first nine months of 2025, compared to $1.91 in the first nine months of 2024.[51]

Figure 8-1 Spot monthly average emission price comparison: January 2020 through September 2025[52]



CAA: NSR

The CAA's NSR program is a preconstruction permitting program that requires certain stationary sources of air pollution to obtain permits prior to beginning construction. Parts C and D of Title I of the CAA provide for New Source Review (NSR) in order to prevent new projects and projects receiving major modifications from increasing emissions in areas currently meeting NAAQS or from inhibiting progress in areas that do not.[53] NSR requires permits before construction commences. In PJM, permits are issued by state environmental regulators, or in a process involving state and regional EPA regulators.[54]

49 Tennessee is the only PJM state that remains in the CSAPR NOX Ozone Season Group 2 Trading Program.
50 See Components of LMP in the *2025 Quarterly State of the Market Report for PJM: January through September*, Section 3: Energy Market.
51 Id.
52 The CSAPR Seasonal NOx Group 3 price peaked at an average price of $44,826 in March, 2022.
53 42 U.S.C § 7470 et seq.
54 CAA permitting in EPA Region 2 (New Jersey) is the responsibility of the state's environmental regulatory authority; CAA permitting in Region 3 (Delaware, District of Columbia, Maryland, Pennsylvania, Virginia, West Virginia) is the shared responsibility of each state's environmental regulatory authority and EPA Region 3; CAA permitting in Region 4 (Kentucky and North Carolina) is the shared responsibility of each state's environmental regulatory authority and EPA Region 4; CAA permitting in EPA Region 5 (Illinois, Indiana, Michigan and Ohio) is the responsibility of each state's environmental regulatory authority.

NSR review applies a two part analysis to projects at facilities such as power plants, some of which involve multiple units and combinations of new and existing units.[55] The first part considers whether a modification would cause a significant emission increase of a regulated NSR pollutant. The second part considers whether any identified increase is also a significant net emission increase.[56]

CAA: RICE

On January 14, 2013, the EPA signed a final rule amending its rules regulating emissions from a wide variety of stationary reciprocating internal combustion engines (RICE). RICE include certain types of electrical generation facilities like diesel engines typically used for backup, emergency or supplemental power, including facilities located behind the meter.[57] These rules include: National Emission Standard for Hazardous Air Pollutants (NESHAP) for Reciprocating Internal Combustion Engines (RICE); New Source Performance Standards (NSPS) of Performance for Stationary Spark Ignition Internal Combustion Engines; and Standards of Performance for Stationary Compression Ignition Internal Combustion Engines (collectively RICE Rules). The RICE Rules apply to emissions such as formaldehyde, acrolein, acetaldehyde, methanol, CO, NO_X, volatile organic compounds (VOCs) and PM.

EPA regulations require that RICE that do not meet the EPA emissions standards (stationary emergency RICE) may operate for only 100 hours per year and only to provide emergency DR during an Energy Emergency Alert 2 (EEA2), or if there are five percent voltage/frequency deviations.[58] Under PJM rules, an EEA2 is automatically triggered when PJM initiates an emergency load response event. Demand resources that rely on RICE to provide load reductions are constrained to a maximum of 100 hours.

Up to 50 hours of the maximum 100 hours can be operated in limited non emergency conditions.[59] By letter issued February 27, 2025, EPA indicated, in response to an inquiry from Duke Energy, that RICE can be operated for up to 50 hours per year to prevent the interruption of power supply in a local area when under an EEA1 and transition to EEA2 is likely without further action.[60]

PJM does not prevent emergency stationary RICE that does not meet emissions standards from participating in PJM markets as DR. Some emergency stationary RICE that does not meet emissions standards are now included in DR portfolios. Some DR registrations reflect a participant's reliance on behind the meter generation having environmental restrictions that limit the resource's ability to operate only in emergency conditions. PJM's DRHUB does not explicitly identify RICE generators, only whether it is an internal combustion engine. Emergency stationary RICE should be prohibited from participation as DR either when registered individually or as part of a portfolio if it does not meet emissions standards. Emergency RICE with a limit of 100 hours per year cannot comply with the requirement to be available during the entire delivery year to be a capacity resource. PJM should not allow locations that rely upon emergency stationary RICE to register as DR individually or in portfolios. Registration of DR should be based on a finding that registered locations are capable of providing load reductions without an hourly limit. Reliance on the prospect of penalties to deter registration of ineligible resources as DR in lieu of a substantive ex ante review is not appropriate. The MMU recommends that emergency stationary RICE be prohibited from participation as DR either when registered individually or as part of a portfolio if it cannot meet the

57 See *National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines; New Source Performance Standards for Stationary Internal Combustion Engines*, EPA–HQ–OAR–2008–0708, 78 Fed. Reg. 6674 (January 30, 2013); 40 CFR Parts 60 and 63.
58 Emergency Operations, EOP-011-1, North American Electric Reliability Corporation, <https://www.nerc.com/pa/Stand/Reliability%20 Standards/EOP-011-1.pdf> (Accessed March 2, 2020).

59 See 40 CFR 63.6640(f)(4)(ii) (RICE located at area sources of hazardous air pollutants (HAP)1 can operate for up to 50 hours per year in non-emergency situations to supply power as part of a financial arrangement with another entity). The following conditions must be met: (i) The engine is dispatched by the local balancing authority or local transmission and distribution system operator. (ii) The dispatch is intended to mitigate local transmission and/or distribution limitations so as to avert potential voltage collapse or line overloads that could lead to the interruption of power supply in a local area or region. (iii) The dispatch follows reliability, emergency operation or similar protocols that follow specific North American Electric Reliability Corporation (NERC), regional, state, public utility commission or local standards or guidelines. (iv) The power is provided only to the facility itself or to support the local transmission and distribution system. (v) The owner or operator identifies and records the entity that dispatches the engine and the specific NERC, regional, state, public utility commission or local standards or guidelines that are being followed for dispatching the engine. The local balancing authority or local transmission and distribution system operator may keep these records on behalf of the engine owner or operator.
60 EPA letter to Duke Energy <https://www.epa.gov/system/files/documents/2025-05/response-to-duke-energy.pdf>. The EPA describes Duke's program: "the Mandatory 50 program is deployed when forecasted grid reserves fall below Duke Energy's thresholds for maintaining reliable service—specifically, under Energy Emergency Alert (EEA) Level 1 when transition to EEA Level 2 is imminent without further action. The program would fall below other emergency demand response programs in Duke Energy's resource stack and is constrained to 50 hours per calendar year. The letter states that the program prevents the need for rotating load shed, which would create local disturbances that could result in use of all generators throughout the affected areas."

capacity market requirements to be DR as a result of emissions standards that impose environmental run hour limitations.

CAA: Greenhouse Gas Emissions

The EPA regulates CO_2 as a pollutant using CAA provisions that apply to pollutants not subject to NAAQS.[61] [62]

Executive Order 14057 requires the federal government to achieve "100 percent carbon pollution-free electricity on a net annual basis by 2030, including 50 percent 24/7 carbon pollution-free electricity by 2030."[63]

On April 25, 2024, the EPA finalized a rule taking four actions under CAA § 111(a)(1) addressing greenhouse gas (GHG) emissions from fossil fuel-fired electric generating units (EGUs) ("Carbon Emissions Rule").[64] The Carbon Emissions Rule repeals the Affordable Clean Energy (ACE) Rule; finalizes emission guidelines for GHG emissions from existing coal fired and oil/gas fired steam generating EGUs; revises the New Source Performance Standards (NSPS) for GHG emissions from new and reconstructed fossil fuel-fired stationary combustion turbine EGUs; and revises the NSPS for GHG emissions from fossil fuel-fired steam generating units that undertake a large modification, based upon the 8-year review required by the CAA. The rule deferred action on emission guidelines for GHG emissions from existing fossil fuel-fired stationary combustion turbines.

On May 9, 2024, a coalition of PJM states including West Virginia, Indiana, Kentucky, Tennessee, Virginia, and 20 other states, filed a petition for review of the Carbon Emissions Rule by the United Stated Court of Appeals for the D.C. Circuit.[65] PJM joined other RTOs to file an amicus brief in support of petitioners, arguing that the result would result in premature retirements of fossil generation and threaten reliability.[66] The states also sought to stay implementation of the rule, but the motion for stay was denied by the U.S. Supreme Court by order issued October 4, 2024.[67] The petition remains pending at the D.C. Circuit.

On June 11, 2025, the EPA proposed to repeal all GHG emissions standards for fossil fuel-fired power plants.[68] The EPA is further proposing to make a finding that GHG emissions from fossil fuel-fired power plants do not contribute significantly to dangerous air pollution.[69] The EPA is also proposing, as an alternative, to repeal a narrower set of requirements that includes the emission guidelines for existing fossil fuel fired steam generating units, the carbon capture and sequestration/storage (CCS)-based standards for coal-fired steam generating units undertaking a large modification, and the CCS-based standards for new base load stationary combustion turbines.[70]

CWA: WOTUS Definition

The Clean Water Act (CWA) applies to navigable waters, which are defined as waters of the United States (WOTUS).[71] [72] The definition of WOTUS is a threshold issue that determines the hydrological scope of the CWA's applicability. Over the past decade, attempts to define WOTUS have been repeatedly addressed by the Courts, and no durable definition has resulted.[73] Establishing a durable definition is important to the electric industry, which needs to plan for compliance with the CWA and related regulations.

61 See CAA § 111.

62 On April 2, 2007, the U.S. Supreme Court overruled the EPA's determination that it was not authorized to regulate greenhouse gas emissions under the CAA and remanded the matter to the EPA to determine whether greenhouse gases endanger public health and welfare. Massachusetts v. EPA, 549 U.S. 497. On December 7, 2009, the EPA determined that greenhouse gases, including carbon dioxide, methane, nitrous oxide, hydrofluorocarbons, perfluorocarbons, and sulfur hexafluoride, endanger public health and welfare. See *Endangerment and Cause or Contribute Findings for Greenhouse Gases Under Section 202(a) of the Clean Air Act*, 74 Fed. Reg. 66496, 66497 (Dec. 15, 2009). In a decision dated June 26, 2012, the U.S. Court of Appeals for the D.C. Circuit upheld the endangerment finding, rejecting challenges brought by industry groups and a number of states. Coalition for Responsible Regulation, Inc., et al. v. EPA, No 09-1322.

73 See, e.g., Rapanos v. U.S., 547 U.S. 715 (2006); Solid Waste Agency of Northern Cook County v. U.S. Army Corps of Engineers, 531 U.S. 159 (2001); U.S. v. Riverside Bayview Homes, Inc., 474 U.S. 121 (1985).

The scope of the CWA expanded as a result of an April 23, 2020, decision of the U.S. Supreme Court in *County of Maui v. Hawaii Wildlife Fund*, which held that the discharge of pollutants via groundwater requires a CWA permit.[74] Groundwater is not itself WOTUS. However, if pollutants pass through groundwater from a point source to WOTUS, a permit may be required.[75] The Court held that discharge into groundwater "is the functional equivalent of a direct discharge."[76] The existence of a functional discharge will depend on an analysis including time and distance, and other factors.[77] Additional litigation or administrative action may clarify the functional discharge analysis.[78] *County of Maui* reduces the importance of the precise definition of WOTUS because WOTUS is generally part of the watershed.[79]

On December 30, 2022, the EPA and the Army Corps of Engineers announced a final rule revising the definition of WOTUS.[80] The Rule defines WOTUS to include: (i) traditional navigable waters, the territorial seas, and interstate waters; (ii) impoundments of WOTUS; (iii) tributaries to traditional navigable waters, the territorial seas, interstate waters, impoundments when the tributaries meet either the relatively permanent standard or the significant nexus standard; (iv) wetlands, including jurisdictional adjacent wetlands; and (v) intrastate lakes and ponds, streams, or wetlands that meet either the relatively permanent standard or the significant nexus standard.[81] The rule became effective on March 20, 2023, except that, due to preliminary injunctions issued in court proceedings challenging the rule, the rule did not become effective in 26 states, including PJM states Indiana, Ohio, Tennessee, Virginia, West Virginia, and Kentucky.

77 *Id.* at 16 ("The difficulty with this approach, we recognize, is that it does not, on its own, clearly explain how to deal with middle instances. But there are too many potentially relevant factors applicable to factually different cases for this Court now to use more specific language. Consider, for example, just some of the factors that may prove relevant (depending upon the circumstances of a particular case): (1) transit time, (2) distance traveled, (3) the nature of the material through which the pollutant travels, (4) the extent to which the pollutant is diluted or chemically changed as it travels, (5) the amount of pollutant entering the navigable waters relative to the amount of the pollutant that leaves the point source, (6) the manner by or area in which the pollutant enters the navigable waters, (7) the degree to which the pollution (at that point) has maintained its specific identity. Time and distance will be the most important factors in most cases, but not necessarily every case.").

81 See *id.* at 3005-6.

On May 25, 2023, a decision of the U.S. Supreme Court held that "jurisdiction over an adjacent wetland under the CWA" requires "first, … a relatively permanent body of water connected to traditional interstate navigable waters … and second, that the wetland has a continuous surface connection with that water, making it difficult to determine where the 'water' ends and the 'wetland' begins."[82] The Court's definition of adjacent wetlands significantly reduced the range of waters meeting that definition compared to the range covered in the December 30, 2022 rule.

On August 29, 2023, the EPA issued a final rule modifying its 2022 rule to define adjacent wetlands consistent with the Supreme Court holding, and it became effective on September 8, 2023.[83] On March 24, 2025, the EPA and the Army Corps of Engineers issued a memorandum in response to requests for further clarification on the definition of adjacent wetlands, stating: "[A]n interpretation of 'continuous surface connection' which allows for wetlands far removed from and not directly abutting covered waters to be jurisdictional as adjacent wetlands has the potential to violate the direct abutment requirement for 'adjacent wetlands' under the plurality's standard and now *Sackett's* endorsement of that standard.[footnote omitted] Therefore, any components of guidance or training materials that assumed a discrete feature established a continuous surface connection are rescinded."[84]

CWA: Effluents

The EPA regulates under its National Pollutant Discharge Elimination System (NPDES) permitting authority discharges from and intakes to power plants, including water cooling systems at steam electric power generating stations, under the CWA.[85] The regulations, Effluent Limitations Guidelines and Standards (ELGs), are national industry-specific wastewater regulations based on the performance of demonstrated wastewater treatment technologies.

85 See 40 CFR Part 423. For more details, see the *2019 Annual State of the Market Report for PJM*, Appendix H: "Environmental and Renewable Energy Regulations."

On June 9, 2022, the EPA proposed the Water Quality Certification Improvement Rule (WQCIR), which would expand the grounds on which states may condition or block, projects in federal permit proceedings.[86] The WQCIR would provide each state certifying agency a role in determining the "reasonable period of time" to review the request and encourage their adoption of an "activity as a whole" analytical approach that would consider the impacts of the entire project rather than just the specific discharge needing certification.[87]

The EPA has been implementing ELGs established in its 2015 and 2020 rules.[88] [89] The 2015 Rule established limitations and standards applicable to discharges from steam electric generating units from bottom ash (BA) transport water, flue gas desulfurization (FGD) wastewater, fly ash (FA) transport water, flue gas mercury control wastewater, gasification wastewater, combustion residual leachate, and non chemical metal cleaning wastes. The 2020 Rule revised the limitations and standards for BA transport water and FGD wastewater, leaving the other limitations and standards in place. The 2020 Rule applied less stringent effluent limits to three new subcategories of units: High FGD flow plants, low utilization generating units, and generating units that will permanently cease the combustion of coal by 2028.

Units subject to the generally applicable limits had to comply with the 2020 Rule as soon as possible on or after October 13, 2021, but no later than December 31, 2025.[90]

Plants are required to inform regulators of their plans to comply with the new rule by upgrading their plants with pollution control equipment or committing to retiring their units by 2028.[91]

Executive Order 13990 called for review and improvement of the 2020 Rule.

On April 25, 2024, pursuant to CWA, the EPA issued a rule strengthening the 2015 and 2020 ELGs for coal-fired power plants ("2024 Effluents Rule").[92] The 2024 Effluents Rule would reduce discharges by an estimated 660–672 million pounds per year, including toxic and bio accumulative pollutants, such as arsenic, lead, mercury, selenium, chromium, and cadmium.[93]

This 2024 Effluents Rule establishes a zero discharge of pollutants limitation for three wastewaters generated at coal-fired power plants: flue gas desulfurization wastewater, bottom ash transport water, and combustion residual leachate.[94] The regulation also establishes numeric discharge limitations for mercury and arsenic for combustion residual leachate (CRL) that is discharged through groundwater and for a fourth waste stream, called legacy wastewater, that is discharged from certain surface impoundments.[95] The regulation also eliminates less stringent requirements for two subcategories of facilities (high flow facilities and low utilization energy generating units) that were contained in the 2020 regulation.[96]

The 2024 Effluents Rule allows additional time for compliance for some plants that have installed, or are in the process of installing, additional treatment technologies to meet the 2015 and 2020 ELGs.[97] The rule allows some plants to continue to meet the 2015 and 2020 ELGs while they are in the process of closing and converting to use other fuels such as natural gas.[98]
