2592. ZYSS, R., & BOCYNSKI, W. (1972), *Otolaryngol. Pol.*, 26(4):398-406, (In Pol. with Engl. Summary), "Morphological changes in the cells of the organ of Corti following exposure to microwaves", [Developmental and morphological changes observed in the cells of the organ of Corti following exposure of Guinea pigs to 10 cm rad. at a level of 2 mw/cm<sup>2</sup> for 4 hrs/day over 25 or 50 days. Reported are: swelling or vacuolar degeneration of cytoplasm, pyknosis or swelling of nuclei, decreased content of glycogen and nucleic acid, and congestion and extravasations in the vascular stria. The authors suggest these changes have an influence on the decrease of bioelectric activity of the cochlea. The changes regressed within 30 days following cessation of the irradiation.]

#### UNSIGNED REPORTS AND ARTICLES

1877. Opening (and Closing) Speech made by the regent at the First Meeting of the S. I. R. B. (Soc. Internat. of Electro-Radio-Biology). Abstr. of the 1st Internat. Congress of Electro-Radio-Biology, Venice, (Cappelli, L., ed., Bologna, Italy), pp. 82-85, (1934) (English Translation)
1878. "Those most sensitive to electricity stand shock best", *Arch. of Physical Therapy* 16:625-626, (1935), (Abstr. in: *Science NewsLetter*, date?)
1879. "Ultrashort waves in medicine and biology", *Proc. of the 1st Ukrainian Conf. on Shortwave Studies*, Kharkov, *Comedizdat* (1936)
1880. Problems of the Metrics and Dosimetry and Ultrahigh Frequency in Biology and Medicine, Moscow (1937)
1881. Materials of the Leningrad Conference on VHF-MF Waves, Leningrad, (1937)
1882. Proceedings of First All-Union Conference (of Physicians, Biologists, & Physiologists) on the Problems of the Use of short and Ultrashort Waves in Medicine, Mediz, (Moscow), (1940)
1883. "Biological and therapeutic effect of a magnetic field and strictly-periodical vibrations", Perm, Molotov (1948)
1884. "Radar and cataracts", *J. Amer. Medical Assoc.*, 150(3):528 (4 Oct. 1952), (Also, *Nuc. Sci. Abs.* 4:339 (1957))
1885. "Health hazards in microwave radiation", *U. S. Military Air Transport Service Medical Information Letter*, No. 113, pp. 10-12 (1953)
1886. "Council on Physical, Medical, and Rehabilitation Therapy: Illegal Operations of Medical Diathermy Equipment", *J. Amer. Medical Assoc.* 156:1583-, (1954)
1887. "Critique of the biological hazards of microwave radiation", *Geo. Washington Univ., Washington, D. C.*, Rept. 36-21, (Nov. 1956)
1888. "Electromagnetic radiation hazards" (Classified), *Naval Air Defense Center, Proj. 4554*, (Oct. 1956)
1889. "Biomedical aspects of microwave radiation", (Classified), *School of Aviation Medicine, U. S. Air Force, Proj. 7783*, (Mar. 1956)

1890. "Symposium on Physiologic and Pathologic Effects of Microwaves", Institute of Radio Engineers Trans. on Medical Electronics PGME-4, 52 pages, (Feb. 1956)
1891. "Radar death calls for caution", Electronics (Business Edition), p. 26, (20 June 1957)
1892. "Health hazards; Information on microwave radiation (including ionizing radiation from electronic equipment)", Environmental and Occupational Health Information Letter No. 58; Headquarters Air Materiel Command, Wright-Patterson AF Base, Ohio, (Nov. 1957)
1893. Conference on Radio-Frequency Hazards; Minutes, Sponsored by Navy Dept., Bureau of Ships, Electronics Div. (Code 960), (Aug. 1957), (Also Minutes of 1958 Conf.)
1894. "Bibliography of microwaves and their biological effects", Prepared in cooperation with the Directorate of Technical Services, Rome Air Defense Center; Appendix E, p. 111-114, Proc. 1st Tri-Service Conf. on Biological Hazards of Microwave Radiation, (Pattishall, E. C., ed.) 1, (1957) (AF 1860011, AD 115603)
1895. "The biological effect of a SEF-CMF electromagnetic field, Trudy Voy. Med. Akad. i Kiroi, USSR, Leningrad (1957)
1896. "Microwave (radar) health hazards; health precautions for prevention of", Bureau of Medicine and Surgery, Department of Navy, Bused Notice 6260, (1958)
1897. "Radar radiation hazards", Electronics (Business Edition) 15-, (April 18, 1958)
1898. "Hazards of microwave electromagnetic radiation", New York Univ. College of Engineering, N. Y., (1958) 8 pages, (AD 624221; SETE-210-14)
1899. "Control of potential hazards to health from microwave energy", Army Regulation (A.R.) No. 40-583, (Sept. 1958), Superseded by Regulations of Sept. 1961)
1900. "Radio frequency hazards handbook", Bur. of Aeronautics of U. S. Air Force, T. O. 31-1-80, (Apr. 1958), (Revised Jan. 1959)
1901. "Hazards of microwave electromagnetic radiation", Report, N. Y. Univ. School of Eng. Sci. (AD 624221), (1958)
1902. "Health Hazards Information: Microwave radiation", U. S. Air Force Rept. AFP 160-613, pp. 1-10, (May 1958)
1903. "New biological effects of E-F radiation", Electronics 32:38-39, (1959), (From Proc. of the 12th Annual Conf. on Electrical Tech. in Med. and Biology)
1904. "Investigator's Conference on Biological Effects of Electronic Radiating Equipments", Tech. Report on Proj. 5543, RADC-TR-59-67, 45 pages, (AD 214693), (Jan. 1959)
1905. "Biological, Clinical, and Research Aspects of the New Bio-Electrical Approach to the Treatment of the Whole Patient", The Abraham J. Ginsberg Foundation, Invitational Symposium, New York, (June 1959)
1906. "Medical considerations of exposure to microwaves (radar)", Medical News Letter (Navy) 34(7):35-40, (Oct. 1959)
1907. "Radar hazards", National Safety News, Data Sheet 461, (1959)
1908. "Blood coagulation changes due to electromagnetic microwave irradiations", Report, St. Louis Univ., (DA-36039, SC-78122), (AD 229267), (1959)
1909. "Labor hygiene and the biological effect of radio frequency electromagnetic waves, summaries of reports", Moscow (1959)
1910. Digest of Technical Papers of 12th Annual Conf. on "Electrical Techniques in Medicine and Biology", (Schwan, H. P., Chm.), Rome Air Development Center, N. Y., TR-59-227, (Sponsored by Institute of Radio Engineers, AIEE, and Instrument Soc. of America; Phila., Pa.), (Nov. 1959)
1911. "Biological effects of radio frequency radiation: bibliography", Prepared by Rome Air Development Center and Midwest Research Institute, Kansas City, Mo., (ZADC TR 60205), (AD 244003), (1960)
1912. "How dangerous are microwaves?", British Medical J., pp. 1420-1421, (1960)
1913. Discussion on Ultrasonics and Microwave Radiation (at 3rd Internat. Conf. on Medicine & Electronics), Proc. of the Internat. Conf. on Med. Electronics in Medicine & Biol. Engineering 3:459-461, (1960);
1914. "Safety precautions relating to intense radio-frequency radiation", Her Majesty's Stationery Office, London (1960); Reprinted in: Radiation Control for Health and Safety Act of 1957 ("To provide for the protection of the public health from radiation emissions"), Hearings before the Committee on Commerce, United States Senate, 90th Congress, Second Session, Part 2, Serial No. 90-49, pp. 1571-1574, (May, 1958)
3350. "Hi-fi and living cells", Think. (Int. Bus. Mach.), pps. June 31-32, 1960, [unable to verify].
2299. "Important areas of electronic research; Compilation of statements by leaders in the field", (AD 253881), (1961).
1915. "Interim standard definitions of terms related to radio frequency radiation hazards", Prepared under Navy, Bureau of Ships, Contract with Midwest Research Institute, Contract No. NCB5-77142, (May 1961)
1916. "Electromagnetic radiation hazards", U. S. Air Force T. O. 31E-10-4, (Oct. 1961), Superseded by: "Ground Electronics Engineering - Installation Agency Standard", Tech. Manual, (May 1957)

3078. Report of "near-fatalities...directly or indirectly attributed to microwave energy" (p.2), and as described on pages 30-34 of the General Electric Report, Light Military Electronics Dept., Utica, entitled "RADHAZ (RF radiation hazard) Instrumentation", Approx. date 1962.
1918. "Questions of the Biological Effect of a SHF-UHF Electromagnetic Field, Summaries of Reports", Kirov Order of Lenin Military Medical Academy, Leningrad (1962)
1919. Methods of Protection Against the Action of Electromagnetic Fields with the Use of High-Frequency Generators, Moscow, (1962) (In Russian)
1920. "Bulletin on health hazards due to radar and similar installations and their prevention", Dusseldorf, (1962), (In German)
1921. In: The Biological Action of Ultrahigh Frequencies, Letavet, A. A., & Gordon, Z. V., (Eds.), (JPRS 12471), (N62-11902), (Feb. 1962), "Recommendations for conducting preliminary and periodic medical examination of workers using UHF sources", pp. 123-125; "Sanitary regulations in work with generators of centimeter waves", pp. 126-130; "Instructions on the method of measuring the power flux density of UHF energy at working positions", Appendix, pp. 131-133; "Bibliography of biological effects of UHF", pp. 134-142
1922. "Microwave effects on the human body: bibliography", (AD/46950), (1962) [Not presently avail. from DDC; "withdrawn by controlling agency"]
1917. "Final report: on biological effects of R-F radiation on macromolecules", Melpar, Inc., Falls Church, Va., (AD 284373), (Aug. 1962)
1923. "The 'Hyfrecator' for electro-desiccation, fulguration, and coagulation", Symposium on Electrodesiccation and Bi-active Coagulation; The Birtcher Corp., Los Angeles, 32 pages, (1963)
1924. "Neurological responses to external electromagnetic energy (A critique of available data and hypotheses)", Compilation of Material Presented at the Conf. at the Brain Research Inst., UCLA, (Adey, W. R., Chm.), 101 pages, (July 1963)
1925. Abstracts of the Conference on "Industrial Hygiene and the Biological Action of Radio Frequency Electromagnetic Fields", Inst. of Indust. Hygiene and Occup. Diseases, Acad. of Med. Sci., Moscow, (1963)
1926. Protection Against the Action of Electromagnetic Fields and Electric Current in Industry, Leningrad, (1963) (In Russian)

MITTLER, S. (Northern Illinois Univ., DeKalb), "Low frequency electromagnetic radiation and genetic aberrations in *Drosophila melanogaster*".

COHEN, B.H. (Johns-Hopkins University School of Hygiene and Public Health, Baltimore, MD), "Paternal radiation, radar exposure and mongolism".

3368. Institute of Electrical & Electronics Engineers G-AP Internat. Symposium and USNC/URSI Meeting, Boulder, Colorado, August 21-24, 1973 (relevant presentations):

- BELDEN, L.H. "Diode probe for detection of microwave leakage".
- BOWMAN, R.R., & BELSHER, D.R. (National Bureau of Standards, Boulder), "Isotropic electric-field probes: Three new models".
- CHEN, K.H. (Michigan State U., E. Lansing), & HOOPINGARNER, T. "Cytological damage to chromosomes of living cells due to microwave radiation".
- CRAWFORD, M.L. (Nat'l Bureau of Standards, Boulder), "Generation of standard EM fields using TEM transmission cells".
- DURNEY, C.H. (U. of Utah, Salt Lake City), GROW, R.W., SORENSON, K.L., & URE, R.W., Jr. "A microwave cumulative radiation personnel dosimeter".
- ECKER, H.A., & CAIN, F.L. (Georgia Inst. of Technology, Atlanta), "Illumination systems for research on biological effects of electromagnetic radiation".
- GIAROLA, A.H., KRUEGER, W.F., BRADLEY, J.W., & SHREKENHAMER, A. (Texas A&M Univ., College Station), "Preliminary results of the effect of electromagnetic fields on fecundity in birds".
- GREENE, F.H. (Nat'l Bureau of Standards, Boulder), & FRAZER, J.W. (USAF School of Aerospace Medicine, Brooks AFB, TX), "Development and construction of an electromagnetic near-field synthesizer for the HF band".
- GUY, A.W. (U. of Washington, School of Medicine, Seattle), "Electromagnetic interactions with biological materials".
- HERMAN, W.A., & BASSEN, H.I. (Bureau of Radiological Health, Rockville, MD), "Microwave power density calibration utilizing the power equation concept".
- JOHNSON, C.C., & DURNEY, C.H. (U. of Utah, Salt Lake City), "A theoretical estimation of tissue anisotropy effects on electromagnetic power deposition (0.1 to 100 MHz)".
- OLSEN, R.G., JOHNSON, C.C. (U. of Utah, Salt Lake City), ROZZELL, T.C. (Office of Naval Research, Arlington, VA), DURNEY, C.H., & LORDS, J.L. (U. of Utah, Salt Lake City), "Microwave transparent temperature sensor".

3111. "Third Internat. Cong. of the International Radiation Protection Association (IRPA), Washington, D.C., Sept. 9-14, 1973.

Session 2A. "Non-Ionizing Radiation", (JANNET, H. (France) Chmn.)

- CARPENTER, R.L., FERRI, E.S., & HAGAN, G.J. (Bureau of Radiological Health), "Pitfalls in the assessment of microwave radiation as a hazard".
- MICHAELSON, S.M. (Univ. of Rochester), "Biological effects and exposure standards for non-ionizing electromagnetic energies".
- SUESS, M.J. (World Health Organization), "The long-term programme on non-ionizing radiation protection of the World Health Organization, Regional Office for Europe".

Session 2A. Rapporteur Presentations, (CLEARY, S. (USA) Rapporteur)

- IIDA, H., & KOSHIJIMA, T. (Japan), "Public health and control of non-ionizing radiation in Japan".
- LEITH, I.S. (Australia), "A calibration facility for microwave monitors; design and operating experience".
- LIBERMAN, A.N., BRONSHTEYN, I.E., OROBEY, V.V., SAKOVSKAYA, M.S., CHESNOKOVA, A.P., & SHUBIK, V.M. (USSR), "Combined effect of ionizing radiation and a superhigh-frequency field on the body".
- WUKASCH, M.C., & THIEL, J.F. (USA), "Progress in the reduction of microwave exposure from microwave ovens, used in commercial food vending operations".

Plenary Session. (VILLFORTH, J.C. (USA), Chmn.)

- JANNET, H. (France), "Protection problems involved by non-ionizing radiation".

3112. International Microwave Power Institute (IMPI) "Symposium on Microwave Power", Sept. 10-13, Univ. of Technology, Loughborough, U.K.

Session 1B. "Biomedical Applications and Effects" (VOSS, W.A.G., Univ. of Alberta, Canada, Chmn.)

- ALMASSY, G., & MISIK, S. (TKI, Budapest, Hungary), "Determination of the properties of the bound water in biological samples by microwave methods".
- BAILLIE, H.D. (Ancoats & Crumpsall Hospitals, Manchester, UK), "A limited review of the recent biological effects of microwave radiation".
- FERRI, E.S., CARPENTER, R.L., & HAGAN, G.J. (Northeastern Radiological Health Laboratory, Winchester, MA), "Use of a dielectric lens in microwave irradiation of animal subjects".
- GRANT, E.H. (Queen Elizabeth College, London, UK), "Dielectric studies on biological materials near 1 GHz: Biophysical and medical implications".

(Continued)

3112. (Continued)

Session 2A. "Microwave Heating Applications" (Relevant to this Biblio.), (TINGA, W.R., Univ. of Alberta, Canada, Chmn.)

KASHYAP, S.C., & LEWIS, J.E. (Univ. of New Brunswick, Fredericton, Can.), "Microwave processing of tree seeds", [for germination enhancement].

Session 2B. "Biomedical Effects I", (ROSENTHAL, S.W., Polytechnic Inst. of Brooklyn, NY, Chmn.)

CZERSKI, P., & PAPROCKA-SLONKA, E. (National Res. Inst. of Mother & Child, Warsaw, Poland), "Microwave irradiation and the circadian rhythm of bone marrow cell mitoses".

GINNS, E.I., RUGH, R., HO, H.S., LEACH, W., GILLESPIE, L., BUDD, R., & HAZZARD, D.D.G. (U.S. Dept. of Health Education & Welfare, Rockville, MD), "Microwave biological effects under reproducible dosimetric environmental conditions".

ROZZELL, T.C. (Office of Naval Research, Arlington, VA), JOHNSON, C.C., DURNEY, C.H., LORDS, J.L., & OLSEN, R.G. (Univ. of Utah, Salt Lake City), "A nonperturbing temperature sensor for measurements in electromagnetic fields".

TOLER, J.C. (Georgia Institute of Technology, Atlanta), "Accurate measurement of microwave fields for medical and biological applications".

Session 3A. "Microwaves In the Food Industry" (KENT, M., Torry Res. Station, Aberdeen, UK, & DECAREAU, R.V., U.S. Army Natick Labs., Natick, MA, Chmn.)

ALEXANDER, D.W. (US Army Natick Labs.), "Process parameters for continuous microwave sterilization".

ARMBRUSTER, G., & ECROYD, L. (Cornell Univ., Ithaca, NY), "The use of pulsed heating periods in 915 MHz and 2450 MHz microwave cooking of meat".

MUDGETT, R.E., TO, E., WANG, D.I.C., & GOLDBLITH, S.A. (Massachusetts Inst. of Technology, Cambridge), & DECAREAU, R.V. (US Army Natick Labs, Natick, MA), "Dielectric measurements of food materials".

OHLSSON, T., & BENGTSSON, N. (Swedish Institute for Food Preservation Res., Goteborg, Sweden), "Development of a Pilot-Plant microwave food sterilizer and results of preliminary experiments".

OHLSSON, T., BENGTSSON, N. (Swedish Inst. for Food Preservation Res., Goteborg, Sweden), & RISMAN, P.O. (Husqvarna AB, Husqvarna, Sweden), "Dielectric data of foods at 915 MHz and 2.8 GHz as a function of temperature: A comparison".

RZEPECKA, M.A., & PEREIRA, R.R. (Univ. of Manitoba, Winnipeg, Can.), "Dielectric properties of dairy products at 2450 MHz".

Session 3B. "Biomedical Effects II", (RICKETTS, C.R., Medical Res. Council, UK; & MICHAELSON, S.M., Univ. of Rochester, N.Y., Chmn.)

BIGU del BLANCO, J., ROMERO-SIERRA, C. (Queen's Univ., Ontario, Can.), & TANNER, J.A. (National Res. Council, Ottawa, Can.), "Effect of microwave radiation on the nastic response of some sensitive plants".

LANGLEY, J.B., YEARGERS, E.K., SHEPPARD, A.P., & HUDDLESTON, G.K. (Georgia Inst. of Technology, Atlanta), "Effects of microwave radiation on enzymes".

LAWRENCE, J.C. (Medical Res. Council Unit, Birmingham, UK), "Effect of microwaves on isolated skin".

McAFEE, R.D., CAZENAVETTE, L.L., & HOLLAND, M.G. (University School of Medicine, New Orleans, LA), "Screening for cataracts".

MILROY, W.C., O'GRADY, T.C., & PRINCE, E.T. (Naval Weapons Laboratory, Dahlgren, VA), "Electromagnetic pulse radiation: A potential biological hazard?".

PHILLIPS, R.D., KING, N.W., HUNT, E.L. (Battelle Northwest Labs, Richland, WA), "Thermoregulatory, cardiovascular and metabolic response of rats to single or repeated exposures to 2450 MHz microwaves".

Session 4B. "Equipment Safety and Interference", (OSEPCHUK, J.M., Raytheon Company, Waltham, MA, Chmn.)

ASLAN, E. (Narda Microwave Corp., Plainview, NY), "A broad-band isotropic probe for microwave power density measurements".

McREE, D.I. (National Inst. of Environmental Health Sciences, Res. Triangle Park, NC), "Determination of energy absorption of microwave radiation using the cooling curve system".

MOBLEY, M.C. (Federal Communications Commission, Laurel, MD), "Revisions of Federal Communications Commission type-approval test procedures".

OSEPCHUK, J.M. (Raytheon Res. Division, Waltham, MA), FOERSTNER, R.A., & McCONNELL, D. (Amana Refrigeration, Inc., Amana, IA), "Computation of personnel exposure in microwave leakage fields and comparison with personnel exposure standards".

(Continued)

3114. (Continued)

ROHL, D., LAUN, H.M., HAUBER, M.E.T., VOIGT, H., & STAUNCH, M. (Univ. of Ulm & AEG-Telefunken Co., Ulm, Ger.), "Susceptibility of cardiac pacemakers to radar interference".

VAN de GRIEK, A., & BRITAIN, R.G. (U.S. Department of Health, Education, & Welfare, Rockville, MD), "Amendments to the US Department of Health, Education, and Welfare microwave oven performance standard".

Panel Discussion. "Biological Effects - Radiation Standards - Equipment Limitations", (GALLAGHER, J.C., Univ. of Bradford, UK, Chmn.).

3113. "Conference on Electrically Mediated Growth Mechanisms in Living Systems", The New York Academy of Sciences, Sept. 19-21, 1973, New York, (LIBOFF, A.R., & RINALDI, R.A., Conf. Chmn.).

Session I. "Biological Studies", (MINKIN, C., Univ. of Southern Calif., Los Angeles, CA, Chmn.)

BASSETT, C.A.L., PAWLUK, R.J., & PILLA, A.A. (Columbia Univ., NY), "Electrical effects in biological systems".

BECKER, R. (Veterans Administration Hospital, Syracuse, NY), "The basic biological data transmission and control system influenced by electrical forces".

BECKER, R., CONE, C.C., JAFFEE, L.F., PARSEGLIAN, V.A., POHL, H., & WEISS, L. "Panel Discussion: The role of electrical potential at the cellular level in growth and development".

BRICK, I., SHAEFFER, B., SHAEFFER, H., & GENARO, J.F. (New York Univ.), "Electrokinetic properties and morphological characteristics of amphibian embryo gastrula cells".

BRIGHTON, C., & FRIEDENBERG, Z. (Univ. of Pennsylvania, Phila.), "Electrical stimulation and oxygen tension".

CONE, C.D. (Eastern Virginia Medical School, Hampton), "The role of the surface electrical transmembrane potential in normal and malignant mitogenesis".

ERIKSSON, C. (Karolinska Institutet, Stockholm, Sweden), "On electrically induced bone formation".

FREY, A.H. (Randomline, Inc., Willow Grove, PA), "Differential biological effects of pulsed vs. continuous electromagnetic fields of the same carrier frequency".

GENSLER, W. (Univ. of Arizona, Tucson), "Bioelectric potentials in higher plants and their relation to growth factors".

GUZELSU, A.M. (Scientific & Technical Res. Council), & AKCASU, A. (Univ. of Istanbul, Turkey), "A piezoelectric model for nerve conduction".

HARRINGTON, D.B. (New York Univ.), "Effects of small amounts of electric current at the cellular level".

JAFFEE, L.F., NUCCITELLI, R., & ROBINSON, K.R. (Purdue Univ., Lafayette, IN), "Transcellular currents, self-electrophoresis and cell development".

PARSEGLIAN, V.A. (National Inst. of Health, Bethesda, MD), "Changes in electrostatic potential expected from cell contact".

RINALDI, R.A., SHAMOS, M.H. (New York Univ.), & LAVINE, L. (S.U.N.Y. Downstate Medical Center, Brooklyn, NY), "Uptake of tritiated thymidine during electrical stimulation of living tissue".

ROMERO-SIERRA, C. (Queen's Univ., Kingston, Can.), & TANNER, J.A. (National Res. Council, Ottawa, Can.), "Biological effects of non-ionizing radiation: An outline of fundamental laws".

TANNER, J.A. (National Res. Council, Ottawa, Can.), & ROMERO-SIERRA, C. (Queen's Univ., Kingston, Can.), "Beneficial and harmful accelerated growth induced by the action of non-ionizing radiation".

TELFER, W., & WOODRUFF, R. (Univ. of Pennsylvania, Phila.), "Electrical potential and transport across inter-cellular bridges".

WEISS, L. (Roswell Park Memorial Inst., Buffalo, NY), "Electrical heterogeneity of cell surfaces".

Session II. "Physical and Chemical Studies", (ROSENBERG, B., Michigan State Univ., Chmn.)

ATHENSTADT, H.A. (Inst. of Physical Chemistry, Julich, W. Germany), "Pyro and piezoelectric properties of vertebrates".

BLACK, J. (Univ. of Pennsylvania, Phila.), "Strain related potentials in living bone".

DIGBY, P.S.B. (McGill Univ., Montreal, Can.), "Electric fields in calcifying tissue".

FUKADA, E. (Inst. of Physical & Chemical Res., Saitama, Japan), "Piezoelectric properties of organic polymers".

FUKADA, E., LANG, S.B., MASCARENHA, S., PILLA, A., SHAMOS, M.H., & STANLEY, H.E., "Panel Discussion: The electro-physical and electrochemical properties of living tissue".

(Continued)

3113. Session **II** (Continued)

- LANG, S.B. (Univ. of The Negev, Beersheba, Israel), SOREMI, E.A., & STIPANICH, N. (McGill Univ., Montreal, Can.), "Mass transfer of bone in vitro under the effect of applied stress".
- LIBOFF, A.R. (Oakland Univ., Rochester, Mich.), & FURST, M. (Hunter College, C.U.N.Y., New York), "Pyroelectric effect in collagenous structures".
- MASCARENHAS, S. (Inst. of Physics & Chemistry, San Carlos, Brazil), "The electret effect in bone and biopolymers and the bound water problem".
- MENEFEFEE, E. (U.S. Dept. of Agriculture, Berkeley, Calif.), "Charge separation associated with dipole disordering in protein".
- OSTROWSKI, K. (Medical School, Warsaw, Poland), "Electromagnetic phenomena of normal and pathological mineralized tissues".
- PILLA, A. (Electric Storage Battery Co., Yardley, Pa.), "Electrochemical phenomena at platinum junctions".
- ROYCE, B.S.H. (Princeton Univ., NJ), "Field induced transport mechanisms in hydroxyapatite".
- SHAMOS, M.H., RINALDI, R.A. (New York Univ.), & LAVINE, L. (S.U.N.Y. Downstate Medical Center, Brooklyn, NY), "Passive electric properties of tissue in vivo".
- STOCKEM, W., HABEREY, M., & BRAATZ-SCHADE, K. (Univ. of Bonn, W. Germany), "Electrophysiological studies of amoeboid movement".
- WILLIAMS, W., & BREGER, L. (Univ. of Illinois, Urbana), "Analysis of stress distribution and piezoelectric response in cantilever bending of bone and tendon".

Session III. "Clinical Studies", (RADIN, E.L., Harvard Univ., Cambridge, MA, Chmn.)

- BAKER, B., SPODARO, J.A., & MARINO, A. (S.U.N.Y. Upstate Medical Center, Syracuse, NY), "Electrical stimulation of articular cartilage regeneration".
- BASSETT, C.A.L., BECKER, R., BRIGHTON, C., FRIEDENBERG, Z.B., & LAVINE, L. "Panel Discussion: To what extent can electrical stimulation be used in treatment of human disorders?".
- FRIEDENBERG, Z.B., & BRIGHTON, C. (Univ. of Pennsylvania, Phila.), "Electrical fracture healing".
- HAMBURY, H.J. (Singleton & Morriston Hospitals, Swansea, UK), & WATSON, J. (Univ. College, Swansea), "Effect of microamp electrical currents on bone in vivo".
- KLAPPER, L., & STALLARD, R. (Boston Univ., MA), "Investigation into the mechanism of electrical stimulation of bone growth".

- LEVY, D.D. (Hydron Labs, Inc., New Brunswick, NJ), "A pulsed stimulation electrical technique for inducing bone growth".
- NORTON, L.A. (Univ. of Kentucky, Lexington), "Bone growth in a controlled electric field".
- ORTIZ, J., CONNOLLY, J., BAYUZICK, R.J., & PRICE, R. (Vanderbilt Univ., Nashville, TN), "Effect of electrical stimulation on physical properties of healed fractures".
- ROWLEY, B.A., MCKENNA, J.M., CHASE, G.R., & WOOLCOTT, L.E. (Texas Tech. Univ., School of Medicine, Lubbock), "The influence of electric current on infecting microorganisms in wounds".
- SMITH, S.D. (Univ. of Kentucky, Lexington), "Electrically induced morphogenesis".
- YASUDA, I. (Kyoto Second Red Cross Hospital, Kyoto, Japan), "Mechanical callus and electrical callus".

3369. 26th Annual Conference on Engineering in Medicine and Biology; Sponsored by the Alliance for Engineering in Medicine and Biology, Minneapolis, Minnesota, September 30 - October 4, 1973 (relevant presentations):

- BIGU DEL LANCO, J. (Queen's U., Kingston, Ont., Canada), "Active and passive properties of bird feathers: Their role as piezoelectric transducers and as receptors of microwave radiation".
- SCHWAN, H.P. (U. of Pennsylvania, Philadelphia), "Selective heating, localized heating, and scaling theory".
- STACK, D.B. "Microwave sterilization of water".
- SUESS, M.J. (World Health Organization, Copenhagen, Denmark), "Overview of standards for safety from exposure to nonionizing radiation".

3115. Seventh Annual Winter Conference on Brain Research, held Jan. 19-26, 1974, in Steamboat Springs, Colorado, sponsored by Barrow Neurological Inst., Michigan State Univ., and the Univ. of California at L.A. (Relevant presentations)

Session 10. "The Effects of Low Intensity Microwaves Upon the Brain", (WACHTEL, H., Chmn.)

BARNES, F.S. (Univ. of Colorado, Boulder), "Threshold effects of microwave radiation on embryo cell systems".

GAMOW, I. (Univ. of Colorado, Boulder), "An analysis of a heat sensor via microwave stimulation".

POSTOW, E. (Bureau of Medicine & Surgery (Navy), Washington, DC), "Two views of microwave effects on the CNS: East and West".

WACHTEL, H. (Duke Univ., Durham, NC), "Immediate effects of low intensity microwaves on isolated neurons".

3116. San Diego Biomedical Symposium, "Innovations in Biomedicine", held Feb. 6-8, 1974, Mission Valley, San Diego, California, (Relevant presentations)

EDRICH, J., & HARDEE, P.C. (Denver Res. Inst., CO), "Thermograms of the human body from millimeter wavelength signals".

GIAROLA, A.J., KRUEGER, W.F., BRADLEY, J.W., & SHREKENHAM, A. (Texas A&M Univ., College Station), "Effect on fecundity in birds exposed to various electromagnetic fields".

3117. Conference on the Biological Effects of Non-Ionizing Radiation, Sponsored by the New York Academy of Sciences, Feb. 12-15, 1974, New York, (TYLER, P.E., Conf. Chmn.)

Introductory Remarks

TYLER, P.E. (Bureau of Medicine & Surgery (Navy), Washington, DC), "Overview of electromagnetic radiation research: Past, present, and future".

Session I. "Electromagnetic Radiation Effect on the Nervous System", (ADEY, W.R., Chmn.)

ALBERT, E.N. (G. Washington Univ. Medical Center, Washington, DC), & DeSANTIS, M.E. (Georgetown Univ. Medical & Dental School, Washington, DC), "Do microwaves alter nervous system structure?".

BARANSKI, S., & EDELWEJN, Z. (Inst. of Aviation Medicine, Warsaw, Poland), "Experimental morphologic and electroencephalographic studies on microwave effects on the nervous system".

BAWIN, S.M., CAVALAS-MEDICI, R., ADEY, W.R., & KACZMAREK, L. (Brain Res. Inst., UCLA, Los Angeles, CA), "Effects of modulated VHF fields on the central nervous system".

GRODSKY, I.T. (Cleveland State Univ., OH), "Possible physical substrates for the interaction of electromagnetic fields with biological membranes".

GUY, A.W. (Univ. of Washington, Seattle), "Microwave interactions with the auditory systems of humans and cats".

LEBOVITZ, R.M. (Univ. of Texas, Dallas), "Detection of weak electromagnetic radiation by the mammalian vestibulo-cochlear complex".

MALCOLM, J.E. (Central Med. Establishment, London, UK), "A new theory of the action of the organ of corti and of the cochlea".

MICHAELSON, S.M., LU, S.-T., HOUK, W., LEBDA, N., & MAGIN, R. (Univ. of Rochester, NY), "Biochemical and neuroendocrine aspects of exposure to microwaves".

SERVANTIE, B., SERVANTIE, A.-M., & ETIENNE, J. (ESSAM-CERB/Hopital I.A. Sainte Anne, Toulon, France), "Synchronization of cortical neurons by a pulsed microwave field: Evidenced by spectrum analysis of electrocorticogram of the white rat".

TAYLOR, E.M., ASHLEMAN, B.T., & GUY, A.W. (Univ. of Washington, Seattle), "Some effects of electromagnetic radiation on the brain and spinal cord of cats".

WACHTEL, H., SEAMAN, R., & JOINES, W. (Duke Univ., Durham, NC), "The effects of microwaves on isolated neurons".

Session II. "Electromagnetic Radiation Effect on Special Senses", (DONALDSON, D.D., Chmn.)

APPLETON, B., & HIRSCH, S. (Walter Reed Army Medical Center, Washington, DC), "Experimental microwave cataractogenesis".

CARPENTER, R.L., FERRI, E.S., HAGAN, G.J. (Northeast Radiological Lab., Winchester, MA), "Some current studies on microwave ocular effects".

KRAMAR, P. (Univ. of Washington, Seattle), "Theoretical and experimental studies of microwave cataracts in rabbits".

3117. Session II. (Continued)

MCAFEE, R.D., CAZENAVETTE, L.L. (Veterans Admn. Hospital, New Orleans, LA), & HOLLAND, M.G. (Tulane Univ. School of Medicine, New Orleans), "Screening for cataracts".

WEITER, J.J., FINCH, E.D., SCHULTZ, W., & FRATTALI, V. (Naval Medical Res. Inst., Bethesda, MD), "Ascorbic acid changes in cultured rabbit lenses following microwave irradiation".

WILLIAMS, R.J., MCKEE, A., & FINCH, L.D. (Naval Medical Res. Inst., Bethesda, MD), "Ultrastructural changes in the rabbit lens induced by microwave radiation".

Session III. "Biochemical and Biophysical Effects", (STRAUB, K.D., Chmn.)

ALLIS, J.W. (Nat'l Environmental Res. Center, Res. Triangle Park, NC), "Discussion Paper: The effects of cross-illumination".

CZERSKI, P. (National Res. Inst. of Mother & Child, Warsaw, Poland), "Microwave effects on the blood-forming system with particular reference to lymphocytes".

ELDER, J.A., & ALI, J.S. (Nat'l Environmental Res. Center, Res. Triangle Park, NC), "The effect of microwaves on isolated rat liver mitochondria".

FRAZER, J.W., RUPP, T., & MONTET, J. (USAF School of Aerospace Med., Brooks AFB, TX), "A comparison of thermal and RF exposure effects on trace metal content of blood plasma and liver cell fractions of rodents".

ROTKOVSKA, D., & VACEK, A. (Czechoslovak Academy of Sciences, Brno, Czech.), "The effect of electromagnetic radiation on the hematopoietic stem cells of mice".

STRAUB, K.D. (Univ. of Arkansas Med. School, Little Rock), "Effects on microsomal and mitochondria preparations".

SZMIGIELSKI, S. (Inst. of Aviation Medicine, Warsaw, Poland), & JELJASZEWICZ, J. (Nat'l Inst. of Hygiene, Warsaw, Poland), "Acute staphylococcal infections in animals irradiated with 3 GHz microwaves".

SZMIGIELSKI, S. (Inst. of Aviation Medicine, Warsaw, Poland), & LUCZAK, M. (Univ. Medical School, Warsaw, Poland), "Effect of microwaves (3 GHz) on cell function and virus replication in cell cultures irradiated *in vitro*".

YEARGERS, E.K. (Georgia Inst. of Technology, Atlanta), "Effects of microwaves on enzymes".

Session IV. "Electromagnetic Radiation Effects on Genetics and Development", (LEACH, W.M., Chmn.)

BLACKMAN, C.F., BENANE, S.G., WEIL, C.M., & ALI, J.S. (Nat'l Environmental Res. Center, Res. Triangle Park, NC), "Effects of non-ionizing electromagnetic radiation on single cell biological systems".

DIETZEL, F. (Wilhelm-Conrad-Rontgen-Klinik, Giessen, Fed. Republic of Germany), "Effects of electromagnetic radiation on implantation and intra-uterine development of the rat".

KRUEGER, W.F., GIAROLA, A.J., BRADLEY, J.W., & SHREKENHAMER, A. (Texas A&M Univ., College Station), "The effect of electromagnetic fields on fecundity in the chicken".

MCREE, D.I., HAMRICK, P., ZINKL, J. (Nat'l Inst. of Environmental Health Sciences, Res. Triangle Park, NC), THAXTON, P., & PARKHURST, C. (North Carolina Univ., Raleigh), "Some effects of exposure of the coturnix quail embryo to 2.45 GHz microwave radiation".

PYLE, S., NICHOLS, D., GAMOW, E., & BARNES, F.S. (Univ. of Colorado, Boulder), "Threshold effects of microwave radiation on embryo cell systems".

WEBB, S.J. (Univ. of Saskatchewan, Saskatoon, Canada), "Genetic continuity and metabolic regulation as seen by the effects of various frequencies of microwaves on these phenomena".

Session V. "Behavioral Effects of Electromagnetic Radiation", (JUSTESEN, D.R., Chmn.)

FREY, A.H. (Randomline, Inc., Willow Grove, PA), "Neural function and behavior: Defining the relationship".

GALLOWAY, W.D. (Bureau of Radiological Health, Rockville, MD), "Microwave dose-response relations on two behavioral tasks".

HEEBELS, G.H. (Lab. of the Armed Forces, Oegstgeest, The Netherlands), ROBERTI, B., & WOLTHUIS, O.L. (Medical Biological Lab. (TNO), Rijswijk, The Netherlands), "Preliminary investigations of the influence of low-level microwave irradiation on the spontaneous motor activity of rats".

HUNT, E.L., KING, N.W., & PHILLIPS, R.D. (Battelle Pacific NW Labs., Richland, WA), "Behavioral effects of pulsed microwave irradiation".

THOMAS, J.R., FINCH, E.D., & FULK, D.W. (Naval Medical Res. Inst., Bethesda, MD), "Effects of microwave radiation on behavioral baselines".

Session VI. "Dosimetry of Electromagnetic Radiation", (BAIRD, R.C., Chmn.)

ALLEN, S.J. (USAF School of Aerospace Medicine, Brooks AFB, TX), "Measurement of power absorption by human phantoms immersed in radiofrequency fields".

BEISCHER, D.E., & RENO, V.R. (Naval Aerospace Medical Res. Lab., Pensacola, FL), "Microwave energy distribution measurements in the proximity of man and their practical application".

3117. Session VI. (Continued)

- BOWMAN, R.R., & BELSHER, D.R. (Nat'l Bureau of Standards, Boulder, CO), "A discussion of three new models of isotropic electromagnetic hazard meters".
- GHANDI, O.P. (Univ. of Utah, Salt Lake City), "Discussion Paper: Polarization and frequency effects".
- HO, H.S. (Bureau of Radiological Health, Rockville, MD), "Contrast of dose distribution in phantom heads due to aperture and plane wave sources".
- RUDDLESTON, G.K. (Georgia Inst. of Technology, Atlanta), & McREE, D.I. (Nat'l Inst. of Environmental Health Sciences, Res. Triangle Park, NC), "A pyroelectric probe for measurement of microwave power density under far-field conditions".
- JOHNSON, C.C. (Univ. of Utah, Salt Lake City), "Discussion Paper: Fiberoptic liquid crystal probe for absorbed RF power measurement".
- PHILLIPS, R.D., HUNT, E.L., & KING, N.W. (Battelle Pacific NW Labs., Richland, WA), "Field measurements, absorbed dose, and biological dosimetry of microwaves".
- SWICORD, M.L., BASSEN, H. (Bureau of Radiological Health, Rockville, MD), & ABITA, J. (Johns Hopkins Applied Physics Lab., Silver Spring, MD), "A broadband, miniature electric field probe".

Panel Discussions

- CZERSKI, P., GUY, A.W., JUSTESEN, D.R., SERVANTIE, B., & STRAUB, K.D. "Future research directions and needs in biological electromagnetic radiation research".
- APPLETON, B., BARANSKI, S., BOWMAN, R.C., ELDER, R.L., MICHAELSON, S.M., SHORE, M.L. "Results of the Polish conference".

3118. Proceedings of Conference on "Biomedical Aspects of Non-ionizing Radiation", held 10 July 1973 in conjunction with the opening and dedication of the Biomedical Research Lab., U.S. Naval Weapons Laboratory, Dahlgren, VA, (MILROY, W.C., (ed.)), (NWL Tech. Rpt. TR-3110, Mar. 1974)

- BAUM, S.J., SKIDMORE, W.D., & EKSTROM, M.E. (Armed Forces Radiobiology Res. Inst., Bethesda, MD), "Continuous exposure of rodents to  $10^8$  pulses of electromagnetic radiation".
- DIACHENKO, J.A., ELLIS, R.L., LAWTON, L.E., MILROY, W.C., O'GRADY, T.C., & PRINCE, E.T. (Naval Weapons Laboratory, Dahlgren, VA), "Biomedical aspects of non-ionizing radiation: An overview of the NWL effort".
- MICHAELSON, S.M. (Univ. of Rochester, NY), "Comparative biology in assessment of electromagnetic bioeffects".
- RENO, V.R., & BEISCHER, D.E. (Naval Aerospace Med. Res. Lab., Pensacola, FL), "Microwave reflection, diffraction, and transmission by man".
- ROSE, M.F. (Naval Weapons Laboratory, Dahlgren, VA), "High power pulse transmitters".
- SCHWANN, H.P. (Univ. of Pennsylvania, Philadelphia), "Some guidelines for the development of EM radiation standards".
- TYLER, P.E. (Bureau of Medicine & Surgery, Washington, DC), "Where are we and where are we going?".

3370. Aerospace Medical Association 45th Annual Meeting, held in Washington, D.C., May 6-9, 1974 (relevant sessions):

Panel: "Aerospace Medical Implications of Non-Ionizing Radiation", (PICKERING, J.E., Moderator)

- APPLETON, B. (Walter Reed Army Med. Ctr., Washington, D.C.), "Ocular status of personnel occupationally exposed to microwaves", (not presented).
- BEISHER, D.E. (Naval Aerospace Med. Res. Lab., Pensacola, FL), "Results of human exposure to non-ionizing radiation"
- FRAZER, J.W. (U.S. Air Force School of Aerospace Med., Brooks AFB, TX), "Interactions of man and animals with radio-frequency fields".
- MITCHELL, J.C. (U.S. Air Force School of Aerospace Med., Brooks AFB, TX), "Special problems of general public exposure to RF radiation".
- PICKERING, J.E. (USAF School of Aerospace Med., Brooks AFB, TX), "Overview of the problem".
- TYLER, P.E. (Naval Med. R&D Command, Bethesda, MD), "U.S. and Eastern standards for exposure to electromagnetic radiation".

Session: "Electromagnetic Radiation", (FRIEDBERG, W., & BURNER, A.M., Co-Chan)

- GRISSETT, J.D. (Naval Aerospace Med. Res. Lab., Pensacola, FL), "Exposure of man to magnetic fields alternating at extremely low frequency".
- HOUK, W.M. (Naval Aerospace Med. Res. Lab., Pensacola, FL), "Metabolic and thermoregulatory responses to microwave radiation in young male rats".

3119. Ninth Annual Symposium on Microwave Power, Sponsored by the Internat. Microwave Power Inst., 28-31 May 1974, Marquette Univ. Milwaukee, Wisconsin, (BOSISIO, R.G., Tech. Prog. Chmn.), (Bio-medically relevant presentations)

Plenary Session. (OSEPCHUK, J.M., Chmn.)

NELSON, S.O., & STETSON, L.E. (Univ. of Nebraska, Lincoln), "Use of microwave and lower frequency RF energy for improving alfalfa seed germination".

Session B2. "Biological Effects of Microwaves", (BIGU DEL BLANCO, J., Chmn.)

ALBERT, E.N. (The G. Washington Univ., Washington, DC), & DeSANTIS, M.E. (Georgetown Univ., Washington, DC), "Histological alterations in central nervous system after microwave irradiation".

FANSLON, G.E., TOLLEFSON, J.J., & OWENS, J.C. (Iowa State Univ., Ames), "Ovicidal effects of electromagnetic energy at 2.45 GHz on eggs Diabrotica undecimpunctata howardi barber".

GANDHI, O.P. (Univ. of Utah, Salt Lake City), "A method of measuring RF absorption of whole animals and bodies of prolate spheroidal shapes".

GLASER, Z.R. (Bureau of Medicine & Surgery, Washington, DC), "Studies on the bio-medical effects of microwave radiation: Past, present, and future". (Invited paper)

KING, N.W., HUNT, E.L., & PHILLIPS, R.D. (Battelle Pacific NW Labs., Richland, WA), "Biological dosimetry of 2450 MHz microwave irradiation with mice".

LASZLO, T.S., & STEPHENS, W.K. (Philip Morris (USA) Res. Center, Richmond, VA), "The effect of microwaves on the tobacco beetle".

Session No. A3. "Medical and Biological Applications", (BAILLIE, H.D., Chmn.)

BIGU DEL BLANCO, J., ROMERO-SIERRA, C. (Queen's Univ., Kingston, Ont., Can.), & TANNER, J.A. (National Res. Council of Canada, Ottawa), "Colour-thermography: A powerful technique in the evaluation of microwave field radiation patterns in biological systems. Its use as a microwave energy density monitor".

CARTER, J.L., FLEISCHPRESSER, D.A., & ISHII, T.K. (Marquette Univ., Milwaukee, WI), "Microwave oven techniques for biological solids determination of wastewater samples".

LENOX, R.H. (Walter Reed Army Inst. of Res., Wash., DC), GANDHI, O.P. (Univ. of Utah, Salt Lake City), MEYERHOFF, J.L., & BROWN, P.V.K. (Walter Reed Army Inst. of Res.), "Modifications of in vivo rapid microwave inactivation of enzymes in the central nervous system".

THOUREL, L., PAREILLEUX, A., THOUREL, B., & AUGE, C. (Department d'Etudes et de Recherches en Micro-Ondes, Toulouse, France), "Microwaves specific effects on beer yeast".

Session No. B3. "Microwaves in the Food Industry", (DECAREAU, R.V., Chmn.)

STONE, W.R. (Raytheon Company, Waltham, MA), "Multi-energy source cooking device (oven) with programming means", [incorporating 915 and 2450 MHz microwave energy, infrared, and steam].

TO, E.C., GOLDBLITH, S.A., WANG, D.I.C., & DECAREAU, R.V. (Massachusetts Inst. of Technology, Cambridge), "Dielectric properties of food stuffs".

WATANABE, M. (Hitachi, Ltd.), SUZUKI, M. (Hokkaido Univ.), KIKUCHI, I. (Hitachi Heating Appliance Co.), FUKUI, Y. (Hitachi, Ltd.), & HIRAKAWA, K. (Bunmeido Ltd., Yokohama, Japan), "A means of detecting temperature of food in microwave electromagnetic field".

Session No. B5. "Microwave Applicators", (HAMID, M.A.K., Chmn.)

HAMID, M.A.K., MOSTOWY, N.J. (Univ. of Manitoba, Winnipeg, Can.), & BHARTIA, P. (Univ. of Saskatchewan, Regina, Can.), "Microwave bean roaster", ["to destroy the anti-trypsin enzyme (or growth inhibitor), thus facilitating safe nutritional consumption by humans and animals"].

3120. "Fundamental and Applied Aspects of Non-Ionizing Radiation", Seventh Rochester International Conference on Environmental Toxicity, June 5-7, 1974, Univ. of Rochester, Rochester, N.Y., (Proceeding to be pub. by Plenum Publishing Corp., N.Y., NY), (MICHAELSON, S.M., Conf. Chmn.).

Session I. "Biophysics & Dosimetry", (BEISCHER, D.E., Chmn.)

BABIJ, T.M. (Technical Univ. of Wroclaw, Poland), "Synthesis of frequency response of electric field probes".

BOWMAN, R.R. (Nat'l Bureau of Standards, Boulder, CO), "Dosimetry of electromagnetic Radiation".

DUNN, F. (Univ. of Illinois, Urbana), "Acoustic properties of biological materials".

SCHWAN, H.P. (Univ. of Pennsylvania, Philadelphia), "Dielectric properties of biological materials".

STEWART, H.F. (Bureau of Radiological Health, Rockville, MD), "Dosimetry of ultrasound".

(Continued)

3120. (Continued)

Session II. "Energy Absorption", (HARDY, J.D., Chmn.)

BLIGH, J. (Inst. of Animal Physiology, Babraham, Cambridge, UK), "Physiological responses to heat".

LELE, P.P. (Massachusetts Inst. of Technology, Cambridge), "Ultrasonic heating of tissues".

PORTELA, A., et al. (National Council of Scientific & Technical Investigations, Buenos Aires, Argentina), "Transient effects of low-level microwave radiation on bioelectric properties of muscle".

Session III. "Microwaves — Biological Effects", (LOWY, K., Chmn.)

GUY, A.W., & LIN, J. (Univ. of Washington, Seattle), "Electrophysiological effects in animals".

LEHMANN, J.F. (Univ. of Washington, Seattle), "Therapeutic heat".

MICHAELSON, S.M. (Univ. of Rochester, New York), "Review of the biological effects of microwaves".

Session IV. "Ultrasound — Biological Effects", (CASARETT, G.W., Chmn.)

HILL, C.R. (Inst. of Cancer Res., Belmont, Sutton, Surrey, UK), "Effects of ultrasound on isolated cells and cell cultures".

NYBORG, W., GERSHOY, A., & MILLER, D. (The Univ. of Vermont, Burlington), "Effects of ultrasound on plant tissues".

SAVAGE, J.R.K. (MRC Radiobiology Unit, Harwell, Didcot, Berks, UK), "Are chromosomal aberrations reliable indicators of environmental hazards?".

TAYLOR, K.J.W. (The Royal Marsden Hospital, London, UK), "The biological effects of ultrasound on intact tissues".

Session V. "Medical Applications", (GRAMIAK, R., Chmn.)

HILL, C.R. (Inst. of Cancer Res., Belmont, Sutton, Surrey, UK), "Safety of ultrasound in diagnosis".

LELE, P.P. (Massachusetts Inst. of Technology, Cambridge), "Uses of ultrasound in surgery".

MITCHELL, J.C., HURT, W.D., & STEINER, T.O. (USAF School of Aerospace Med., Brooks AFB, TX), "EMR design effectiveness in electronic medical prosthetic devices".

Session VI. "Occupational Aspects", (TYLER, P.E., Chmn.)

CZERSKI, P., & SIEKIERZYNSKI, M. (Nat'l Res. Inst. of Mother & Child, Warsaw, Poland), "Analysis of occupational exposure to microwave radiation".

ELY, T. (Eastman Kodak Company, Rochester, NY), "Control of occupational exposure to non-ionizing radiation".

ODLAND, L.T. (Wright-Patterson Air Force Base, Dayton, Ohio), "Military role in safe use of microwaves".

Session VII. "Future Applications and Controls", (TOMPkins, E., Chmn.)

MAYNARD, O., & GLASER, P.E. (A.D. Little, Inc., Cambridge, MA), "Satellite solar power station: An option for large scale power generation on earth".

OSEPCHUK, J.M. (Raytheon Company, Waltham, MA), "Prospects for expansion of industrial and consumer uses of microwaves".

SUESS, M.J. (World Health Organization, Regional Office for Europe, Copenhagen, Denmark), "Overview of standards for safety from exposure to non-ionizing radiation".

(Presents: underlined)

3121. "International Microwave Symposium, 1974 IEEE S-MIT", June 12-14, 1974, Georgia Inst. of Technology, Atlanta, Georgia, (Bio-Medically Related Presentations).

Special Session. "Technical Forecasting and Assessment"

GUARRERA, J.J. (Guide Scientific Inds., Sun Valley, CA), "Microwave sensors for military and civil use", (Invited).

SAAD, T.S. (Sage Labs., E. Natick, MA), "Microwave applications for material and food processing", (Invited).

(Continued)

3121. (Continued)

Session 2: "Analysis and Application of Microwaves in Biology and Medicine", (ECKER, H.A., Chmn.)

- BIGU DEL BLANCO, J., ROMERO-SIERRA, C. (Queen's Univ., Kingston, Ont., Can.), & TANNER, J.A. (NRC of Canada, CSL, Ottawa), "Some theory and preliminary experiments on microwave radiometry of biological systems".
- BURNS, C.P., & BURDETTE, C.E. (Georgia Inst. of Technology, Atlanta), "Multi-frequency electromagnetic thawing of frozen kidneys".
- JOHNSON, C.C., DURNEY, C.H., & LORDS, J.L. (Univ. of Utah, Salt Lake City), "Liquid crystal fiberoptic temperature probe for the measurement of electromagnetic power absorption in tissue".
- JOHNSON, C.C., LORDS, J.L., & COOMBS, M.A. (Univ. of Utah, Salt Lake City), "Nerve stimulation by implanted diode".
- LIVESAY, D., & CHEN, K.-M. (Michigan State Univ., East Lansing), "Electromagnetic fields induced inside of biological bodies".
- NELSON, S.O. (Univ. of Nebraska, Lincoln), "Insect control possibilities using microwaves and lower frequency RF energy".
- OSEPCCHUK, J.M. (Raytheon Co., Waltham, MA), "A survey of the potential for beneficial applications of microwaves in medicine and biology", (Invited).

Session 5. "Biological Effects of Microwaves", (GUY, A.W., Chmn.)

- CHRISTMAN, C.L., HO, H.S., & YARROW, S. (Bureau of Radiological Health, Rockville, MD), "A microwave dosimetry system for measuring sampled integral dose rate".
- COURTNEY, K., LIN, J.C., GUY, A.W., & CHOU, C.K. (Univ. of Washington School of Med., Seattle), "Microwave effect on rabbit superior cervical ganglion".
- CZERSKI, P. (Nat'l Inst. of Mother & Child, Warsaw, Poland), "Experimental models for the evaluation of microwave biological effects", (Invited).
- LIN, J.C., GUY, A.W., & CALDWELL, L.R. (Univ. of Washington Med. School, Seattle), "Behavioral changes of rats exposed to microwave radiation".
- LU, S.-T., BOGARDUS, R., COHEN, J., JONES, J., KINNEN, E., MICHAELSON, S., & MAGIN, R. (Univ. of Rochester, NY), "Thermogenetic and cariodynamic regulation in dogs cranially exposed to 2450 MHz (cw) microwaves".
- MICHAELSON, S.M. (Univ. of Rochester, NY), & SUESS, M.J. (World Health Organization, Regional Office for Europe, Copenhagen, Denmark), "An international program for microwave exposure protection".
- WEIL, C.M. (Environmental Protection Agency, Res. Triangle Park, NC), "Absorption characteristics of multi-layered sphere models exposed to UHF/microwave radiation".

(Presente: Underlined)

3122. Conference on Precision Electromagnetic Radiation Measurements, London, England, July 1-5, 1974.

- BASSEN, H. (Bureau of Radiological Health, Rockville, MD), "An optically-linked telemetry system for use with electromagnetic hazard probes".

3371. 19th Annual Meeting of the Health Physics Society, Houston, TX, July 7-11, 1974 (relevant presentation):

- BANKIN, N.N., TELL, R.A., & JAMES, D.E. (U.S. Environmental Protection Agency, Silver Spring, MD), "Assessing the potential for exposure to hazardous levels of microwave radiation from high power sources".

3123. Fifth International Congress of Radiation [including non-ionizing] Research, Seattle, Washington, July 14-20, 1974.

- CUNITZ, R.J., GALLOWAY, W.D., & BERMAN, C.M. (Bureau of Radiological Health, Rockville, MD), "Behavioral suppression by 383 MHz radiation".
- ANDERSEN, F.A., & PAY, T.L. (Bureau of Radiological Health, Rockville, MD), "Survival of drosophila eggs exposed to microwave energy and to heat".
- EDWARDS, W.P., & HO, H.S. (Bureau of Radiological Health, Rockville, MD), "Microwave cavity irradiation dosimetry".

3372. "The Physics of Nonionizing Radiation"; summer school conference sponsored by the Amer. Assoc. of Physicists in Medicine, U. of Colorado, Boulder, July 21-26, 1974 (relevant presentations):

- BARNES, F.S. (U. of Colorado, Boulder), & CENKOVIICH, F. "Clinical applications and bio-effects of microwaves".
- CHANNEY, E.L. (U. of Colorado Medical Center, Denver), "Fundamental principles of microwaves".

3373. Conference on "Biological Effects, Hazards, and Medical Uses of Non-Ionizing Radiation", held at the Massachusetts Inst. of Technology, Cambridge, July 29 - August 2, 1974.

3374. "Earth Environment and Resources Conference (EERC)"; sponsored by the Institute of Electrical and Electronics Engineers, Philadelphia, PA, Sept. 12, 1974:

CORY, W.E., & FREDERICK, C.L. (Southwest Res. Inst., San Antonio, TX), "Environmental health effects caused by non-ionizing electromagnetic energy".

3375. National Academy of Science/National Research Council, 1974 Annual U.S. National Committee/International Union of Radio Science (USNC/URSI) Meeting, University of Colorado, Boulder, October 14-17, 1974:

Session #34 - URSI Commission I, Sess. 5 (ROSENTHAL, S.W., Chmn.)

BOWMAN, R.R. (National Bureau of Standards, Boulder), "Electromagnetic field measurements for bioeffects experiments and the control of potential hazards".

GUY, A.W. (University of Washington, Seattle), "Measurement of power absorbed in the tissues of man and animals exposed to electromagnetic fields".

DURNEY, C.H., JOHNSON, C.C., & MASSOUDI, H. (University of Utah, Salt Lake City), "Long wavelength analysis of plane-wave electromagnetic power absorption by a prolate spheroidal tissue body".

BARBER, P.W. (U. of Utah, Salt Lake City), "Electromagnetic fields in a homogeneous model of man".

3376. Meeting of the Electromagnetic Radiation Management Advisory Council (ERMAC), Executive Office of the President, Washington, D. C., October 31 - November 1, 1974:

Work Session on: "Nervous System and Behavioral Effects of Nonionizing EM Radiation".

GALLOWAY, D. (Bureau of Radiological Health, Rockville, MD)

BAWIN, S.M. (Brain Research Inst., UCLA, Los Angeles, CA)

FRASER, J., STAVINOHAN, & MITCHELL, J. (USAF School of Aerospace Medicine, Brooks AFB, TX)

GUY, A.W., & LOVELY, R. (U. of Washington, Seattle)

HAWKINS, T.D. (Walter Reed Army Inst. for Res., Washington, DC)

THOMAS, J. (Naval Medical Res. Inst., Bethesda, MD)

JUSTESEN, D. (Veterans Admn. Hospital, Kansas City, MO)

HUNT, E.L. (Battelle Pacific NW Labs., Richland, WA)

FREY, A. (Randomline Inc., Huntington Valley, PA)

SEAMAN, R. (Duke University, Durham, NC)

ALBERT, E. (G. Washington University, Washington, DC)

3377. Neurosciences Research Program of the Mass. Inst. of Tech., Boston, Work Session on "Brain interactions with weak electric and magnetic fields", November 10-12, 1974.

3378. The University of New Orleans School of Engineering Short Course on "The Biological Effects of Microwave Radiation: Sense and Nonsense", New Orleans, LA, February 18-21, 1975:

SCHWAN, H.P. (U. of Pennsylvania), "Biological effects of microwave radiation".

MICHAELSON, S.M. (U. of Rochester, New York), "The Tri-Service Conferences: Basis of the presently accepted microwave radiation safety recommendations of the Armed Services", "A comparison of soviet and western microwave bioeffects research".

JUSTESEN, D.D. (Veterans' Administration Hospital, Kansas City, MO), "Behavioral effects of microwave radiation".

CARPENTER, R. (Bureau of Radiological Health NE Lab, Winchester, MA), "Cataractogenic effects of microwave radiation".

OSEPCHUCK, J. (The Raytheon Co., Waltham MA), "The 'microwave controversy': Congressional investigation and federal regulation".

3124. 1975 Microwave Power Symposium, sponsored by the International Microwave Power Institute, May 28-30, 1975, to be held at the Univ. of Waterloo, Ontario, Canada.

3713. Proceedings of the 1975 International IEEE/AP-S Symposium and URSI Meeting, University of Illinois, Urbana, 2-5 June 1975.

CHUNG, A. (Univ. of Maryland), & SWICORD, M.L. (Div. of Electronic Products, DHEW), "Development of electromagnetic modeling materials for X-band dosimetry studies."

KANTOR, G., SWICORD, M.L., & BLAIR, M.J. (Div. of Electronic Products, DHEW), "Heating patterns of enclosed and direct contact microwave diathermy applicators."

KELLOGG, R. (Univ. of Maryland), & NEUDER, S. (Div. of Electronic Products, DHEW), "A finite element method for calculating electromagnetic fields in complex geometries."

3714. North Atlantic Treaty Organisation/Advisory Group for Aerospace Research and Development (AGARD) Lecture Series No. 78 on "Radiation Hazards," presented in the Netherlands (22-23 Sept. 1975), Germany (25-26 Sept. 1975), and Norway (29-30 Sept. 1975). (In: AGARD-LS-78, August, 1975, 158 pps.)

- WELLS, P.N.T. (Bristol General Hospital, Bristol, UK), "Physical aspects—ultrasound," p. 3, 1-7.
- Bibliography, p. B, 1-22.

3715. Proceedings of the 5th European Microwave Conference, held 1-4 Sept. 1975 in Hamburg, Federal Republic of Germany.

Session B6—Medical/Biological Applications

- AGARWAL, R., HANNAH, S., HARTNAGEL, H., & KENNAIR, J.T. (U. of Newcastle upon Tyne, UK), "A pocket-sized monitor of dangerous microwave power levels."
- DEFICIS, A. (O.N.E.R.A.-C.E.R.T., Toulouse, France), "Use of dielectric microprobes for electromagnetic fields measurement."
- EDRICH, J. (U. of Denver, CO), "Microwave absorption of living human skin between 8 and 96 GHz."
- GRANT, E.H., SHEPPARD, R.J. (Queen Elizabeth College, London), & SOUTH, G.P. (Bradfield College, UK), "The importance of bound water studies in the determination of energy [absorption] by biological tissue."
- GUY, A.W., & LOVELY, R.H. (U. of Washington School of Medicine, Seattle), "A system for quantitative chronic exposure of a population of rodents to UHF fields."
- ROZZELL, T.C. (Office of Naval Research, Arlington, VA), "Measurement of temperature and microwave power using liquid crystal/optic fiber probes."

Session A3—Invited Papers

- CZERSKI, P., & SZMIGIELSKI, S. (Dept. of Human Genetics, National Research Inst. of Mother and Child, Warsaw, Poland), "Microwave bioeffects: Current status and concepts" (p. 348-357).

3716. Proceedings of the Eighteenth Navy Occupational Health Workshop, held October 6-10, 1975, San Diego, Calif.

- BAKER, \_\_\_, "Medical Aspects of ionizing and non-ionizing radiation."

3717. Proceedings of 1975 IEEE International Symposium on Electromagnetic Compatibility, San Antonio, TX, 7-9 Oct. 1975.

Session 2A - II. EMC and Spectrum Management in Electro-Optics; A Panel Discussion (AASEN, M.D., & ATKINSON, J.H. (co-chmn)).

- HAM, W.T., Jr. (Medical College of VA, Richmond), "Hazards: The effects of optical radiation on biological environments and materials."
- RICHARDS, W. (Naval Electronics Laboratory Center, San Diego, CA), "Standards: Systems, components, safety, etc."

(Continued)

3717. (Continued)

Session 5B - II. EMC Related Bio-Instrumentation (MITCHELL, J.C., Chmn.).

- BASSEN, H.I. (Bureau of Radiological Health, Rockville, MD), "A broadband miniature, isotropic electric field measurement system."
- BRONAUGH, E.L., & KERNS, D.R. (Southwest Research Institute, San Antonio, TX), "Calibration of a multimode microwave exposure chamber."
- HOFF, R.J. (McDonnell Douglas Astronautics Co., St. Louis, MO), "EMC measurements in hospitals."
- RUGGERA, P.S. (Bureau of Radiological Health, FDA, Rockville, MD), "Radiofrequency E-field measurements within a hospital environment."
- TOLER, J.C. (Georgia Institute of Technology, Atlanta), "Electromagnetic interference levels in hospitals."

3718. National Academy of Science/National Research Council, 1975 Annual U.S. National Committee/International Union of Radio Science (USNC/URSI) Meeting, University of Colorado, Boulder, October 20-23, 1975: (Relevant Presentations)

Session B-1a: Auditory Effects (FREY, A.H., Chmn.)

- CAIN, C.A., & RISSMANN, W.J. (U. of Illinois, Urbana), "Microwave hearing in mammals at 3.0 GHz."
- CHOU, C.K., GUY, A.W. (U. of Washington School of Medicine, Seattle), & GALAMBOS, R. (U. of California, San Diego, CA), "Microwave-induced auditory response—cochlear microphonics."
- EICHERT, E.S., & FREY, A.H. (Randomline, Inc., Huntingdon Valley, PA), "RF sound: possible mechanisms as defined by recent research." (withdrawn)
- JOHNSON, R.B., MEYERS, D., GUY, A.W., LOVELY, R.H. (U. of Washington, Seattle), & GALAMBOS, R. (U. of California, San Diego, CA), "Discriminative control of appetitive behavior by pulsed microwave radiation in rats."
- LIN, J.C., & LAM, C-K. (Wayne State U., Detroit, MI), "A theoretical study of microwave-generated auditory phenomena in mammalian cranial structures."

Session B-1b: Microwave Cataractogenesis (ROSENTHAL, S., Chmn.)

- AL-BADWAIHY, K.A., & YOUSSEF, A-B. (Cairo U., Egypt), "Biological thermal effect of microwave radiation on human eyes." (not given)
- BIRENBAUM, L. (Polytechnic Institute of New York, Brooklyn), KAPLAN, I.T. (Zaret Foundation, CUNY, New York), METLAY, W. (Hofstra U., Hempstead, NY), ROSENTHAL, S.W. (Polytechnic Institute of New York, Farmingdale), & ZARET, M.M. (Zaret Foundation, Scarsdale, NY), "Effects of 35 and 107 GHz CW microwaves on the rabbit eye."
- KRAMAR, P., HARRIS, C., GUY, A.W., & EMERY, A. (U. of Washington School of Medicine, Seattle), "Mechanism of microwave cataractogenesis in rabbits."
- RABINOWITZ, J.R. (New York U. Medical Center, New York), "The effect of cataractogenic doses of microwave radiation on lenticular transport."

Combined Session: (RICHARDSON, J.M., Chmn.)

- JUSTESEN, D.R. (V.A. Hospital, Kansas City, MO), "A rose by another name is a cabbage."

Session B-2a: Therapeutic Applications (LEHMANN, J.F., Chmn.)

- AL-BADWAIHY, K.A., & YOUSSEF, A-B.A. (Cairo Univ., Egypt), "Steady state temperature profiles in microwave diathermy" [paper not presented].
- GORDON, G.A., LIVINGSTON, G., & DETHLEFSEN, L.A. (Univ. of Utah, Salt Lake City), "Microwave-induced hyperthermia and radiation sensitivity of mouse intestine."
- GUY, A.W., McDUGALL, J.A., & WEBB, M.D. (Univ. of Washington, Seattle), "Shortwave diathermy applicators."
- KANTOR, G., BASSEN, H., & SWICORD, M. (BRH, Rockville, MD), "Mapping of free space and scattered fields in microwave diathermy."
- LEHMANN, J.F., GUY, A.W., & STONEBRIDGE, J.B. (Univ. of Washington, Seattle), "Physiologic design criteria for therapeutic applicators operating at 915 MHz."
- WEST, B., & REGELSON, W. (M.C.V./V.C.U., Richmond, VA), "Biologic effects of pulsed high frequency electromagnetic radiation" [using a Diapulse Machine].

Session B-2b: Diagnostic Applications (JOHNSON, C.C., Chmn.)

- LANDT, J.A. (U. of California, Los Alamos, NM), "Antenna design for a passive temperature monitoring and identification system for livestock."
- PEDERSEN, P.C., JOHNSON, C.C., DURNEY, C.H., & BRAGG, D.G. (U. of Utah, Salt Lake City), "Microwave radiation as a diagnostic tool."
- SPELMAN, F.A., KINDT, C.W., BOWDEN, D.M., SACKETT, G.P., SPILLANE, J.E. (Regional Primate Research Center at the U. of Washington, Seattle), & BLATTMAN, D.A. (RACON, Inc., Seattle), "Remote measurement of respiration in infant primates using an X-band doppler radar."

(Continued)

3718. (Continued)

Session B-3: Field Survey Instruments (BOWMAN, R., Chmn.)

- ASLAN, E. (Narda Microwave, Plainview, NY). "A low frequency H-field radiation monitor."
- BASSEN, H., & PETERSON, R. (BRH, Rockville, MD). "Complete measurement of hazardous electromagnetic fields with electro optical crystals."
- CONOVER, D.L., PARR, W.H., SENSINTAFFAR, E.L., & MURRAY, W.E., Jr. (NIOSH, Cincinnati, OH). "Measurement of electric and magnetic field strengths from industrial radiofrequency (10-40 MHz) power sources."
- RUGGERA, P.S. (BRH, Rockville, MD). "E- and H-field instrumentation and calibration below 500 MHz."
- SWICORD, M.L., BASSEN, H.I., HERMAN, W.A., DUFF, J.E., & BING, J.R. (FDA, Rockville, MD). "Methods and instrumentation for the evaluation and calibration of microwave survey instruments."
- SWICORD, M.L. (FDA, Rockville, MD), & CHEUNG, A.Y. (U. of Maryland, College Park). "Mutual coupling between linear antennas."
- TRZASKA, H. (Technical U. of Wroclaw, Wroclaw, Poland). "Magnetic field standard at frequencies above 30 MHz."

Session B-4: Cellular and Mutagenetic Effects (McREE, D., Chmn.)

- BLACKMAN, C.F., SURLES, M.C., & BENANE, S.G. (EPA, Research Triangle Park, NC). "The effect of microwave exposure on bacteria: mutation induction."
- ELDER, J.A., ALI, J.S., & LONG, M.D. (EPA, Research Triangle Park, NC). "Respiratory activity of mitochondria exposed in a coaxial airline to 2000-4000 MHz microwave radiation."
- FRAZER, J.W. (USAF School of Aerospace Medicine, Brooks AFB, TX). "A summary of cell and tissue level events produced by RF fields predicted from consideration of regional hyperthermia."
- HSIEH, S.T., & SETO, Y.J. (Tulane U., New Orleans, LA). "Microwave perturbation on cellular enzymatic reactions."
- LIN, J.C., & CHEN, K.C. (Wayne State U., Detroit, MI). "Effects of microwave radiation on mammalian cells *in vitro*."
- SMIALOWICZ, R.J. (EPA, Research Triangle Park, NC). "The effect of microwaves (2450 MHz) on lymphocyte blast transformation *in vitro*."
- VARMA, M.M., DAGE, E.L., & JOSHI, R. (Howard U., Washington DC). "Mutagenicity induced by non-ionizing radiation in Swiss male mice."
- VARMA, M.M., & TRABULAY, E.A., Jr. (Howard U., Washington, DC). "Evaluation of dominant lethal test and DNA studies in measuring mutagenicity caused by non-ionizing radiation."

Session B-5: Exposure Systems (SHORE, M., Chmn.)

- GRAF, E.R., BURKS, D.G. (Auburn U., AL), & COLE, F.E. (Ochsner Medical Foundation, New Orleans, LA). "A unique electromagnetic environmental simulator."
- GUY, A.W., CHOU, C.K., & LOVELY, R.H. (U. of Washington School of Medicine, Seattle). "Chronic exposure of a rat population by circularly polarized guided waves."

17. Alterations in the Biocurrents (EEG?) of the Cerebral Cortex (in animals)
18. Changes in the Rate of Clearance of Tagged Ions from Tissue
19. Reversible Structural Changes in the Cerebral Cortex and the Diencephalon
20. Electrocardiographic (EKG) Changes
21. Alterations in Sensitivity to Light, Sound, and Olfactory Stimuli
19. Reversible Structural Changes in the Cerebral Cortex and the Diencephalon
20. Electrocardiographic (EKG) Changes
21. Alterations in Sensitivity to Light, Sound, and Olfactory Stimuli
22. Functional (a) and Pathological (b) Changes in the Eyes: (a) decrease in size of blind spot, altered color recognition, changes in intraocular pressure, lacrimation, trembling of eyelids; (b) lens opacity and coagulation, altered tissue respiration, and altered reduction-oxidation processes
23. Myocardial Necrosis
24. Hemorrhage in Lungs, Liver, Gut, and Brain
25. Generalized Degeneration of all Body Tissue
26. Loss of Anatomical Parts
27. Death
28. Dehydration
29. Altered Rate of Calcification of Certain Tissue

} At Fatal Levels  
of Radiation

#### C. Central Nervous System Effects

1. Headaches
2. Insomnia
3. Restlessness (Awake and During Sleep)
4. Electroencephalographic (EEG) Changes
5. Cranial Nerve Disorders
6. Pyramidal Tract Lesions
7. Conditioned Reflex Disorders
8. Vagomimetic Action of Heart; Sympaticomimetic Action
9. Seizures, Convulsions

#### D. Autonomic Nervous System Effects

1. Neuro-vegetative Disorders (e.g., alteration of heart rhythm)
2. Fatigue
3. Structural Alterations in the Synapses of the Vagus Nerve
4. Stimulation of Parasympathetic Nervous System (Bradycardia), and Inhibition of the Sympathetic Nervous System

#### E. Peripheral Nervous System Effects

Effects on Locomotor Nerves

F. Psychological Disorders ("Human Behavioral Studies") - the so-called "Psychophysiologic (and Psychosomatic) Responses"

1. Neurasthenia - (general "bad" feeling)
2. Depression
3. Impotence
4. Anxiety
5. Lack of Concentration
6. Hypochondria
7. Dizziness
8. Hallucinations
9. Sleepiness
10. Insomnia
11. Increased Irritability
12. Decreased Appetite
13. Loss of Memory
14. Scalp Sensations
15. Increased Fatigability
16. Chest Pain
17. Tremor of the Hands

G. Behavioral Changes (Animal Studies)

Reflexive, Operant, Avoidance, and Discrimination Behaviors

H. Blood Disorders

(V = in vivo)  
(v = in vitro)

Changes in:

1. Blood and Bone Marrow
2. Phagocytic (polymorphs) and Bactericidal Functions of Blood (V,v)
3. Hemolysis Rate (increase), (a shortened lifespan of cells)
4. Sedimentation Rate (increase), (due to changes in serum protein levels or amount of fibrinogen (??))
5. Number of Erythrocytes (decrease), also number of Lymphocytes
6. Blood Glucose Concentration (increase)
7. Blood Histamine Content
8. Cholesterol and Lipids
9. Gamma (also  $\alpha$  and  $\beta$ ) Globulin, and Total Protein Concentration
10. Number of Eosinophils
11. Albumin/Globulin Ratio (decrease)
12. Hemopoiesis (rate of formation of blood corpuscles)
13. Leukopenia (increase in number of white cells), and Leukocytosis
14. Reticulocytosis

I. Vascular Disorders

1. Thrombosis
2. Hypertension

## J. Enzyme and Other Biochemical Changes

### Changes in activity of:

1. Cholinesterase (V,v)
2. Phosphatase (v)
3. Transaminase (v)
4. Amylase (v)
5. Carboxydismutase
  
6. Protein Denaturation
7. Toxin, Fungus, and Virus Inactivation (at high radiation dose levels), Bacteriostatic Effect
8. Tissue Cultures Killed
9. Alteration in Rate of Cell Division
10. Increased Concentration of RNA in Lymphocytes, and Decreased Concentration in Brain, Liver, and Spleen
11. Changes in Pyruvic Acid, Lactic Acid, and Creatinine Excretions
12. Change in Concentration of Glycogen in Liver (Hyperglycemia)
13. Alteration in Concentration of 17- Ketosteroids in Urine

## K. Metabolic Disorders

1. Glycosuria (sugar in urine; related with blood sugar?)
2. Increase in Urinary Phenol (derivatives? DOPA?)
3. Alteration of Rate of Metabolic Enzymatic Processes
4. Altered Carbohydrate Metabolism

## L. Gastro-Intestinal Disorders

1. Anorexia (loss of appetite)
2. Epigastric Pain
3. Constipation
4. Altered Secretion of Stomach "Digestive Juices"

## M. Endocrine Gland Changes

1. Altered Pituitary Function
2. Hyperthyroidism
3. Thyroid Enlargement
4. Increased Uptake of Radioactive Iodine by Thyroid Gland
5. Altered Adrenal Cortex Activity
6. Decreased Corticosteroids in Blood
7. Decreased Glucocorticoidal Activity
8. Hypogonadism (usually decreased testosterone production)

## N. Histological Changes

1. Changes in Tubular Epithelium of Testicles
2. Gross Changes

O. Genetic and Chromosomal Changes

1. Chromosome Aberrations (e.g., linear shortening, pseudochiasm, diploid structures, amitotic division, bridging, "sticky" chromosomes, irregularities in chromosomal envelope)
2. Mutations
3. Mongolism
4. Somatic Alterations (changes in cell not involving nucleus or chromosomes, cellular transformation)
5. Neoplastic Diseases (e.g., tumors)

P. Pearl Chain Effect (Intracellular orientation of subcellular particles, and orientation of cellular and other (non-biologic) particles)

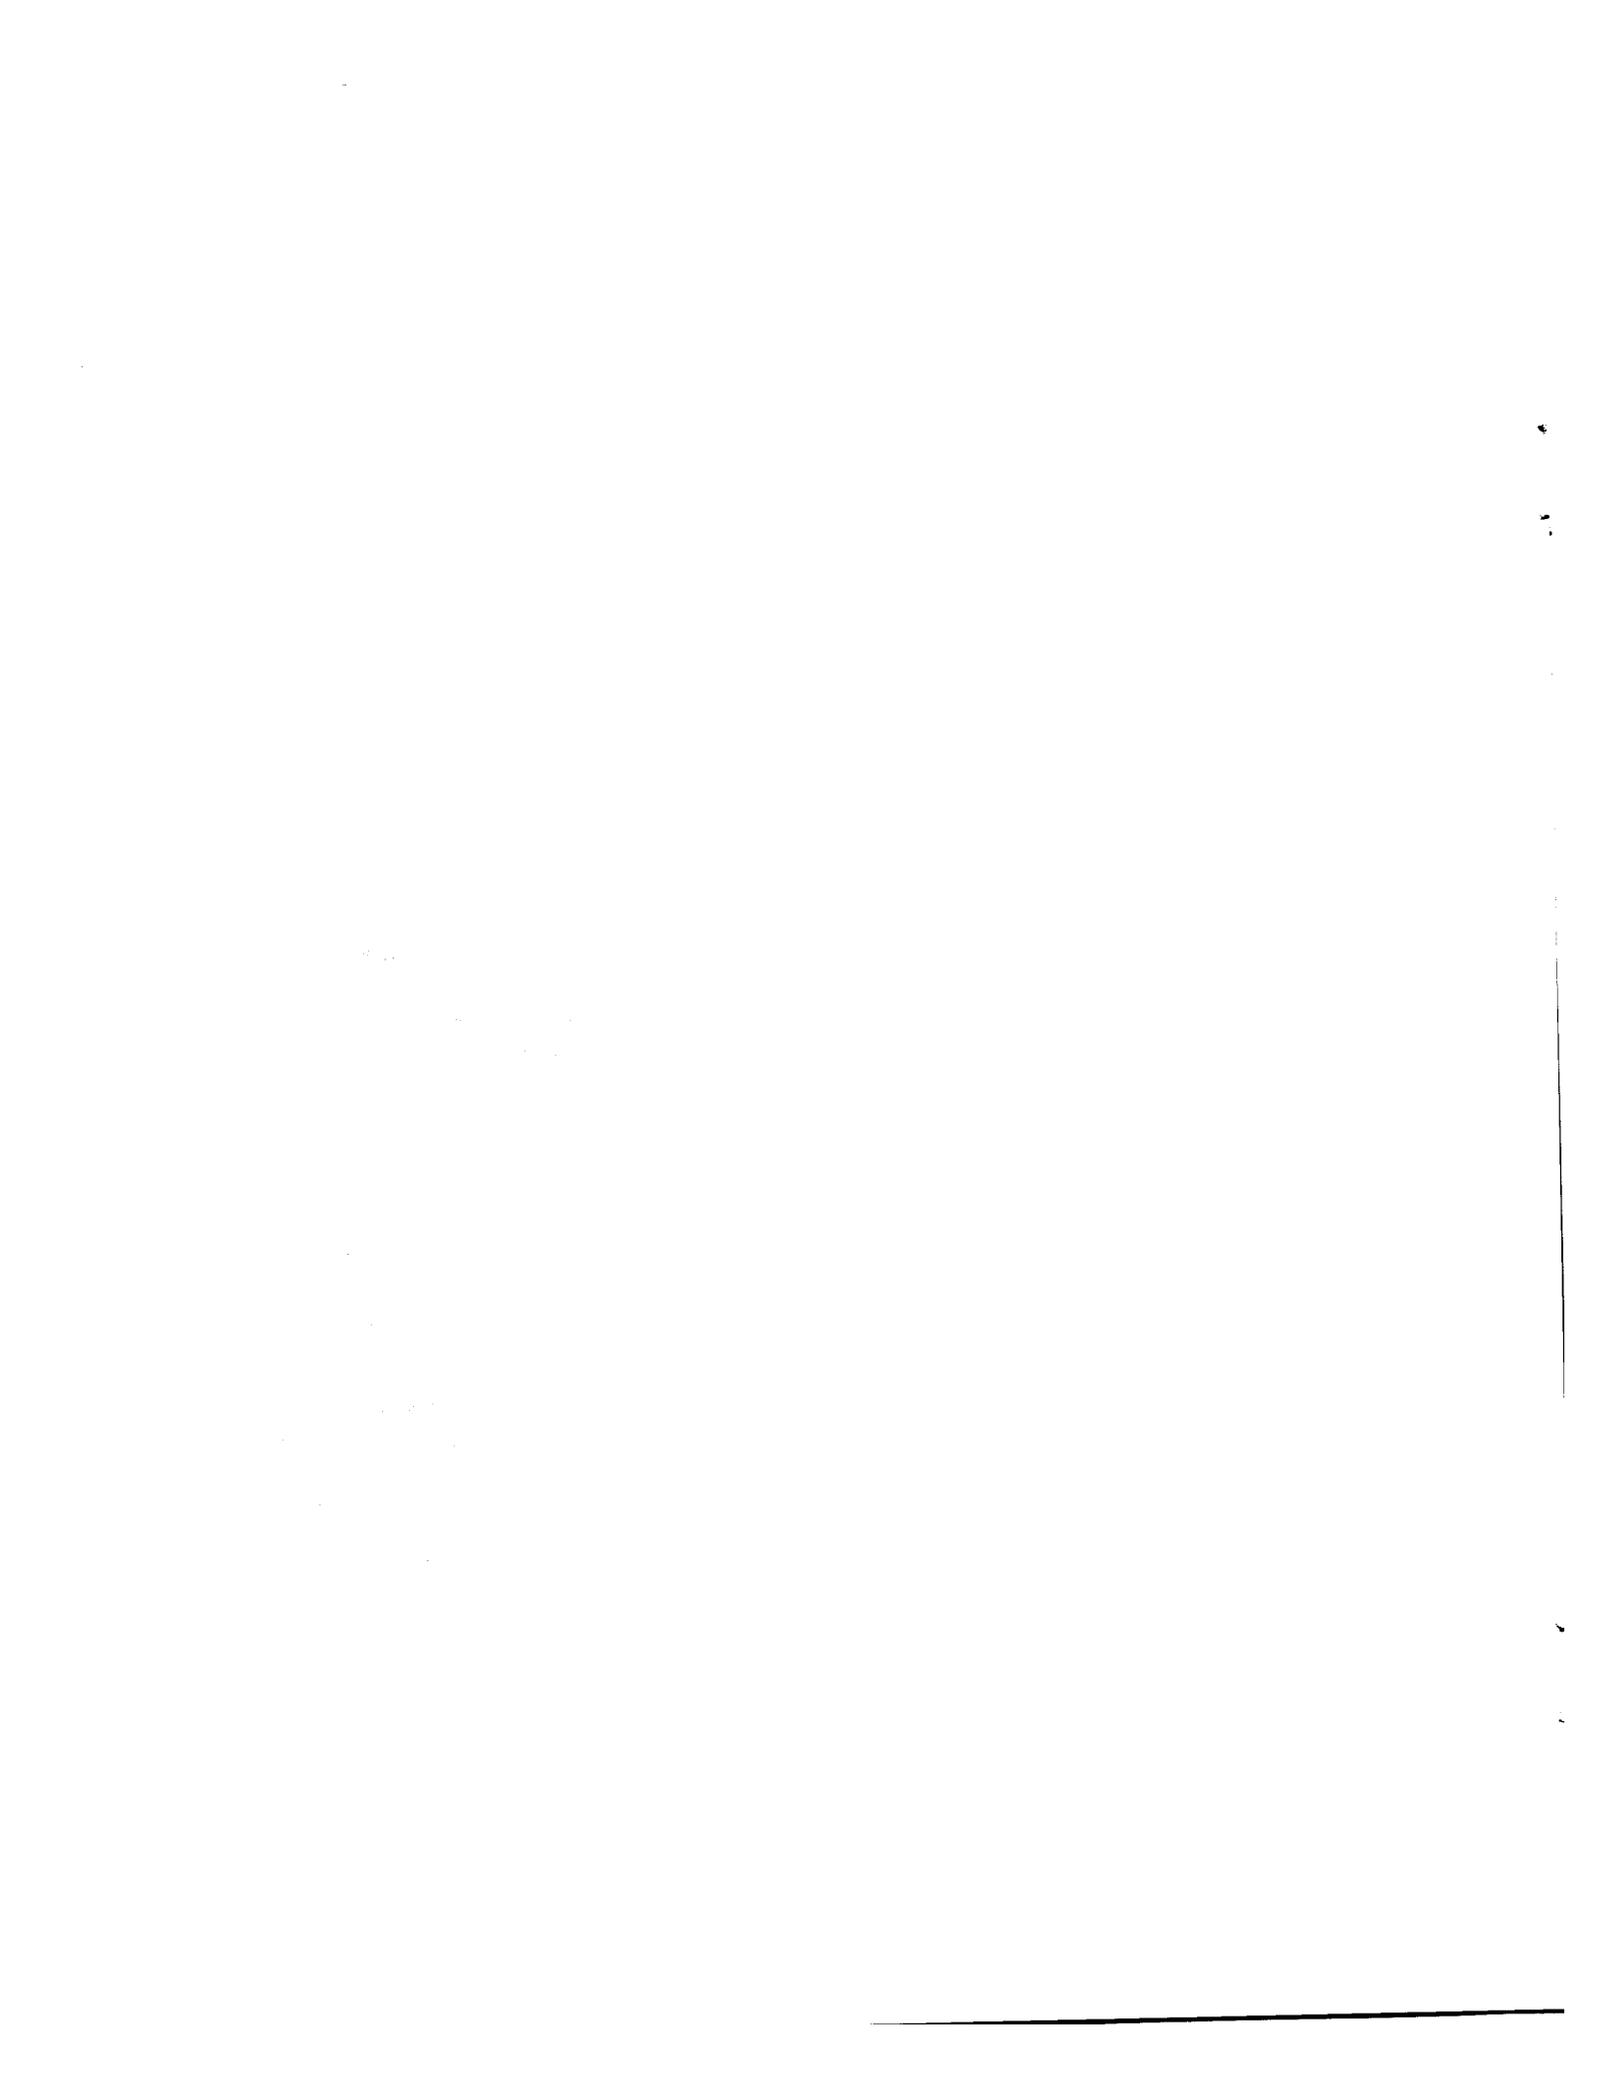

Also, orientation of animals, birds, and fish in electromagnetic fields

Q. Miscellaneous Effects

1. Sparking between dental fillings
2. Peculiar metallic taste in mouth
3. Changes in Optical Activity of Colloidal Solutions
4. Treatment for Syphilis, Poliomyelitis, Skin Diseases
5. Loss of Hair
6. Brittleness of Hair
7. Sensations of Buzzing Vibrations, Pulsations, and Tickling About the Head and Ears
8. Copious Perspiration, Salivation, and Protrusion of Tongue
9. Changes in the Operation of Implanted Cardiac Pacemakers
10. Changes in Circadian Rhythms

---

The Outline of Reported Biological Phenomena ('Effects') and Clinical Manifestations Attributed to Microwave and Radio-Frequency Radiation, is patterned after that given by R. Murray, et al., in an article entitled, "How safe are microwaves", which appeared in Non-Ionizing Radiation 1(1):7-8 (1969). Some of the "effects" were listed in the report by S. F. Cleary and W. T. Ham, Jr., entitled, "Considerations in the evaluation of the biological effects on exposure to microwave radiation", (Background document, Part I, 1969, for the Task Force on Research Planning in Environmental Health, Subtask Force on Physical Factors in the Environment). The discussion and suggestions offered by Byron McLees, Edward Finch, Lewis Gershman, and Christopher Dodge relating to the Outline are also gratefully acknowledged.

 Stress Physiology  
 Radar Safety

## 20. ABSTRACT (cont'd)

This report is a compilation and integration of the first seven supplements, and the alphabetical addenda (appended to the original bibliography), with the revised bibliography of April 1972. The report is a successor to Naval Medical Research Institute (NMRI, Bethesda, MD 20014) Research Report No. 2, completed under Research Work Unit MF12.524.015-0004B in October 1971, by the senior author, and available from National Technical Information Service (Springfield, VA 22151) as AD #734-391. The original report was revised and reprinted in April 1972, and also contains the first three supplements; No. 1 dated October 1971, No. 2 dated November 1971, and No. 3 dated April 1972. The revised report which consists of more than 2300 literature citations, is available from NTIS as AD #750-271, and includes, as the first chapter, an outline of the effects which have been attributed to radio frequency and microwave radiation. Supplement No. 4 (containing 327 citations) was completed in June 1973, as an Electromagnetic Radiation (EMR) Project Office Report, Bureau of Medicine and Surgery (Navy), (Washington, DC 20372), and is available from NTIS as AD #770-621. Supplement No. 5 (containing 497 citations) was completed in July 1974 as an EMR Project Office Report, Naval Medical Research and Development Command (NMR&DC, Bethesda, MD 20014), and is available from NTIS as AD #784-007. The sixth Supplement (containing 241 citations) was completed in June 1975 (also as an EMR Project Office, NMR&DC Report), and is available from NTIS as AD #A015-622. The seventh Supplement (containing 345 citations) was completed in May 1976 as a NMRI Report, and is available from NTIS as AD #A025-354. Supplement No. 8 (not included in this report, but containing 331 citations), was completed in August 1976 as a NMRI Report, and is available from NTIS as AD #A029-430.

Relevant presentations made at technical meetings are included in a separate section.

The "outline of bio-effects" which appeared in the original Bibliography has been included in this report as an Appendix.

## A Basic Summary of the Neurological Effects of Radiofrequency Sickness

Utility companies nationwide are moving toward installing transmitting electrical, gas, and water meters at each customer's service. The new digital meters being installed on electrical services are a type of meter being called "smart" meters because they can do time of day metering, keep very close track of energy usage, and potentially perform other functions. In the case of We Energies, and most other utilities, the "smart" meters selected are **transmitting** "smart" meters. The transmitting electrical rate meters We Energies is using transmit in strong bursts every 6 seconds 24 hours per day 7 days a week. The other utility meters also transmit similarly. This is potentially dangerous in the long-term for everyone; however, for people who already have radiofrequency sickness this exposure can cause disability nearly immediately.

Radiofrequency sickness results from overexposure to radiofrequency radiation. (See Appendix 1 for symptoms.) Radiofrequency sickness is not a disease. It is an environmentally induced functional impairment. Radiofrequency sickness has real and disabling consequences. People with radiofrequency sickness experience illness (or even death) upon exposure to radiofrequency radiation.<sup>1,2,3,4</sup> The most common sources are electrical pollution – high frequencies that travel on building wiring – and transmitters – all wireless devices.

Detrimental biological effects, distinct from tissue heating effects, have been extensively documented in studies at a range of different frequencies and at levels below the current United States safety standard.<sup>5</sup>

**Our current safety regulations are not designed to protect people from the non-thermal hazards posed by transmitting meters or other devices.** The FCC "safety" guidelines are solely designed to protect a 6 ft 185 lb man from tissue heating during a short (6 minute) exposure. They are not designed to protect even a 6 ft man from biological effects during a continuous exposure.<sup>6,7</sup> Exposures from transmitting utility meters and other transmitters are continuous, so these "safety" standards are meaningless. Transmitting devices compliant with current safety standards should not be allowed to portray themselves as "safe". The fact that these transmitters are represented as being "safe" because they comply with FCC guidelines is part of the reason that people are being required to have transmitting utility meters. Additional studies are now available. The data warrant complying with the precautionary principle and establishing lower exposure standards for safe levels of exposure for chronic exposures to radio frequency radiation for the population as a whole.<sup>8</sup> Exposure is often involuntary. For instance, exposure to radiofrequency radiation from neighbors often causes sensitive people in town to be chronically ill, unable to recover.

Microwave and radiofrequency radiation are now being associated with attention deficit disorder, autism, sleep disorders, multiple sclerosis, Alzheimer's disease and epilepsy, as well as asthma, diabetes, malignant melanoma, breast cancer, and other illnesses that have become increasingly more common. Please see [www.bioinitiative.org](http://www.bioinitiative.org)<sup>1</sup> to read a 2007 review of the peer-reviewed science on the long-term risks of exposure to transmitted microwave and radio frequency

radiation. Studies finding no health effects are predominantly industry funded.<sup>9</sup> A report by Hallberg and Johansson<sup>10</sup> published recently in *Pathophysiology* asks the provocative question about whether the recent (1997 and later) increase in exposure to microwave frequencies may be responsible for the recent decline in public health in Sweden. The data seem to say that public exposure to microwave frequencies is a likely culprit.

In addition to transmitting in strong bursts, transmitting “smart” meters can also overexpose the general population to high frequencies by putting high frequencies on home and building wiring, either deliberately through signaling or inadvertently through poor engineering. High frequency signals on power lines are also biologically active. Milham and Morgan found a dose-response relationship between high frequencies present on building wiring and cancer<sup>11</sup>. Recent analysis of historical epidemiological data indicates a relationship to cancer, diabetes, heart disease, and suicide<sup>12</sup>. Removing high frequencies on building wiring has improved MS symptoms, blood sugar levels, asthma, sleep quality, teacher health, student attentiveness, headaches, ADD, and numerous other health problems<sup>13,14,15</sup>. Technical papers provide a solid electrical and biomolecular basis for these effects. A recent paper by Ozen showed that transients induce much stronger current density levels in the human body than does the powerline 60Hz signal<sup>16</sup>. A technical paper by Vignati and Giuliani discusses the authors’ findings that high frequency communication signals on power lines also induce much stronger electrical currents in the human body than a low frequency signal of the same strength<sup>17</sup>. The induced currents disturb normal intercellular communications. This causes harmful short-term and long-term effects. Additional information can be found on [www.electricalpollution.com](http://www.electricalpollution.com). Information necessary to properly measure the high frequencies causing these health problems can be found on the Technical page. A simple meter is also available that can provide accurate measurements of electrical pollution levels in most situations.

The precautionary principle dictates that only utility meters that do not increase public exposure to microwave and radiowave radiation and “dirty” power should be used while conservative standards to protect the health of the general population during continuous exposure are researched and established. Safe technology is available that can be used to perform the same functions as transmitting “smart” meters. There are non-transmitting meters that can do variable rates and meter both incoming and outgoing power. Meters can easily be engineered that do not put high frequencies on electrical wiring either inadvertently or deliberately, while still performing all necessary functions. Directly wired connections could be used to shut off key loads. Alternate technologies may cost a bit more up front, but the precautionary principle should apply. In fact, the Health Department in New Mexico agrees. They recently persuaded a local water utility to use wired connections between monitoring stations, instead of wireless, based on the precautionary principle. If you have questions, you can contact John McPhee, Childhood Injury Prevention Coordinator for the New Mexico Department of Health (505-827-2582).

The only “cure” for radiofrequency sickness is not to be exposed to radiofrequency radiation. People with radiofrequency sickness often become ill almost immediately upon exposure, although the severity of the illness depends on how often the exposure occurs, the frequency and amplitude of the radiation signal and the duration of the exposure. Studies show pulsed microwaves, as utilized by modern communication devices, including transmitting electrical meters, are very potent biologically.<sup>1,2,3,4</sup>

In fact, data presented at the recent conference “Electromagnetic Radiation Impacts on Human Health” sponsored by The EMR Policy Institute showed that radiofrequencies, specifically pulsed modulated microwaves from a DECT cordless telephone base unit can have an instantaneous effect on heart rhythm in susceptible individuals. This technology is the same as that used by cellphones, WiFi internet access, and transmitting utility meters. See: <http://www.youtube.com/user/EMRPolicyInstitute> presentation of Prof. Magda Havas in three segments.

A number of studies show that electromagnetic radiation, including radiofrequency radiation, alters heart rate variability, blood pressure (including inducing hypertension with microwave exposure – smart meters transmit in the microwave range) and increases risk of arrhythmia related heart disease and heart attack.<sup>4,5</sup>

There is extensive documentation in the literature of alterations of  $\text{Ca}^{2+}$  homeostasis.<sup>5</sup> This is likely to be responsible at least in part for the profound effects that radiofrequency radiation has on the heart and neurological function.  $\text{Ca}^{2+}$  regulates gap junction opening. Gap junctions are key in many intercellular communications.

Exposure to radiofrequency radiation also interferes with the action of enzymes, signaling pathways, and makes the immune system simultaneously hyperactive and less effective.<sup>5,18</sup> Immune impairment results in part from the disruptive effect of radiofrequency radiation on calcium ion homeostasis. In addition to radiofrequency radiation-induced immune impairment increasing risk of various types of infection, it is likely to increase the risk of getting cancer from the DNA breakages radiofrequency radiation is well-documented to induce.<sup>5</sup> While radiofrequency radiation is non-ionizing, the metabolic changes it can cause result in oxidative damage to DNA and subsequent breakage. Direct interactions between radiofrequency radiation and DNA can have similar results, as well as causing changes in gene transcription, through changes in electron flows induced by the radiation.<sup>19</sup>

Neurological function can be seriously impaired by radiofrequency radiation. Cholinesterase enzyme activity is impaired by exposure to radiofrequency radiation in a manner similar to impairment caused by organophosphate pesticides often rendering a person with radiofrequency sickness particularly sensitive to small amounts of chemicals.<sup>20</sup> Radiofrequency radiation can lower the pain threshold, slow reaction times, cause fatigue, muscle weakness, headaches, difficulty concentrating, short-term memory problems and even memory loss.<sup>1,2,3,4</sup> These may be caused by disruption of  $\text{Ca}^{2+}$ , disruption of various enzyme pathways, induction of the stress response and associated effects, increased permeability of the blood-brain barrier, or various other effects of over exposure to radiofrequency radiation.<sup>4,5,20</sup>

Radiofrequency radiation significantly decreases melatonin levels and decreases the ability of existing melatonin to fight cancer.<sup>5</sup> Good sleep is essential for good mental and physical health. Good sleep is very difficult, if not impossible to obtain if your melatonin levels are abnormally low. Sleep deprivation along with impaired neurological function and enzyme impairment are likely to be behind the brain fog and cognitive difficulties those with radiofrequency sickness experience.

More detailed information can be found in the following references, in *The BioInitiative Report* at [www.bioinitiative.org](http://www.bioinitiative.org), and at [www.electricalpollution.com](http://www.electricalpollution.com).

**Appendix 1- Symptoms of Radio Wave Sickness** (excerpted from *No Place To Hide* April 2001):

- **Neurological:** headaches, dizziness, nausea, difficulty concentrating, memory loss, irritability, depression, anxiety, insomnia, fatigue, weakness, tremors, muscle spasms, numbness, tingling, altered reflexes, muscle and joint pain, leg/foot pain, "Flu-like" symptoms, fever. More severe reactions can include seizures, paralysis, psychosis and stroke.
  - **Cardiac:** palpitations, arrhythmias, pain or pressure in the chest, low or high blood pressure, slow or fast heart rate, shortness of breath.
  - **Respiratory:** sinusitis, bronchitis, pneumonia, asthma.
  - **Dermatological:** skin rash, itching, burning, facial flushing.
  - **Ophthalmologic:** pain or burning in the eyes, pressure in/behind the eyes, deteriorating vision, floaters, cataracts.
- Others:** digestive problems; abdominal pain; enlarged thyroid, testicular/ovarian pain; dryness of lips, tongue, mouth, eyes; great thirst; dehydration; nosebleeds; internal bleeding; altered sugar metabolism; immune abnormalities; redistribution of metals within the body; hair loss; pain in the teeth; deteriorating fillings; impaired sense of smell; ringing in the ears.

## New Best Practices Optimize Wi-Fi

By Joe Zeto

*For The Record*

Vol. 26 No. 2 P. 8

With the rapid growth of mobile computing and Wi-Fi-enabled devices, today's medical institutions have gone from viewing wireless as a matter of convenience to a matter of life and death.

Medical staffs now routinely use wireless networks and devices to communicate and gain instant access to EMRs, test results, and provider information throughout a facility. Wireless local area networks support mobile patient monitoring, infusion pumps, medical imaging systems, and other specialized devices and applications. And the bring-your-own-device trend continues to gain steam among clinicians, patients, and visitors who favor using smartphones, tablets, laptops, and the like.

All in all, Wi-Fi networks in health care facilities are being pushed to their limits while the risks associated with poor performance—dropped calls, choppy videos, low patient satisfaction ratings—are on the rise. The modernization of facility networks to comply with health care reform introduces still more risk that must be monitored and mitigated.

With user expectations higher than ever and applications growing in complexity, the health care industry as a whole is adopting new best practices for approaching major Wi-Fi product launches and initiatives. As the volume and diversity of mobile devices continue to grow, health care facility IT teams and medical device manufacturers alike must become more proactive and aggressive in guaranteeing performance out of the gate and over time.

### The Challenge

Patient care depends on the secure exchange of accurate, actionable information. Many hospitals have become full-service facilities, offering emergency and intensive care to thousands of patients per month and requiring hospital IT staff to ensure high quality and availability of that care. Doing so is rife with challenges, including the following:

- verifying network capacity;
- providing high bandwidth in all areas requiring wireless connectivity;
- measuring individual Wi-Fi client device performance (eg, roaming, coexistence, throughput);

- assessing the quality of experience users can expect for voice, video, and other real-time mobile applications (eg, determining the voice quality at nurses' stations where voice-over Internet protocol handsets are concentrated); and
- evaluating future upgrades needed to support industry regulations and individual hospital IT road maps.

For hospital IT departments and their integration partners, the pressure to achieve hospital-grade Wi-Fi connectivity translates into the need to thoroughly assess environments and measure the impact of new mobile medical devices on existing hospital wireless local area networks and vice versa. As the sheer volume and diversity of mobile devices continue to grow, facility administrators must know how each new system, device, or application will perform; interact with other devices; and impact existing ecosystems before they're deployed.

Fortunately, the quality challenge does not rest solely with IT staff. Manufacturers of life-critical mobile devices must work in conjunction with hospital teams to optimize device and application performance for specific needs and environments.

With many medical devices going mobile for the first time, manufacturers new to Wi-Fi must adopt strategies for ensuring products can maintain wireless connectivity in challenging health care environments and under diverse traffic and environmental scenarios.

Even with strict compliance to standards and routine certification by the Wi-Fi Alliance, deployments in health care facilities face unique complexities and challenges that must be modeled early in development. Manufacturers must validate in advance that new devices will meet user and regulatory expectations for intended use or risk an adverse event. For example, missed alerts resulting in a delay in patients receiving critical care can lead to financial loss, liability, regulatory recalls, and damage to brand reputation.

Both device makers and those deploying Wi-Fi networks in health care environments are adopting new strategies for evaluating performance prior to introducing products and applications.

### **Prepare for Increased Traffic**

In many hospitals, wireless local area networks already support hundreds of devices used by nurses, clinicians, and other staff members as well as patients and guests. In optimizing networks to support these and other life-critical devices, the best practice is to assess network readiness for additional clients and services, and the quality each is likely to expect. The following factors must be addressed to help ensure success:

- **Capacity vs. coverage:** When wireless access first was introduced into health care environments, any connectivity was considered better than none, and virtually any level of application performance was deemed acceptable. Focusing primarily on connectivity, network architects attempted to minimize installation costs by using the minimum number of access points required to blanket an area. Unfortunately, this typically created an unsatisfactory user experience. Modern health care networks must be designed with actual network capacity in mind to ensure the necessary quality in high-density, heavily trafficked areas.
- **Device selection and interoperability:** During network design and vendor/device selection, site surveys must be conducted using actual devices to measure their impact on each other and the existing or intended network and applications. Those designing Wi-Fi networks must determine the best choices for both

wireless local area network infrastructure equipment and specialized wireless medical devices based on their individual performance requirements.

- **Optimal roaming:** Because people and devices both are constantly on the move, roaming tests must be conducted. Actual traffic and devices should be used to benchmark the impact of various roaming procedures on users and applications.
- **Target rates and service-level agreements:** A comprehensive evaluation of an intended site should be conducted during the planning stages to help set and gauge performance against target rate and service-level agreements for each traffic type. Traditional site surveys conducted prior to embarking on Wi-Fi initiatives must evolve into comprehensive site assessments.

Modern site assessments eclipse traditional surveys with their ability to generate real application traffic to measure the quality of the experience from the user perspective instead of inferring it from rudimentary signal strength measurements; replicate live network environments, including facilities' unique traffic mixes, environmental challenges, and peak conditions; assess true network capacity to allow IT teams to determine optimal repositioning of access points and the power configurations needed to maximize capacity; and model what-if scenarios to assess growth and future upgrades.

Fortunately, modern site assessments can be conducted quickly and cost-effectively, often assessing multiple devices and variables impacting performance during a single sweep through a facility.

### **Increased Mobility on the Horizon**

For health care device makers, the new best practices center chiefly on re-creating live network conditions in development and quality assurance labs. By simulating deployment conditions, various access points, and traffic from numerous other devices, manufacturers can fine-tune the capabilities of new devices to roam, interoperate with existing Wi-Fi networks, and deliver a high-quality user experience.

Early evaluation of real-world performance in the design and development cycles aids in choosing the appropriate radio-frequency components that play a pivotal role in determining a device's ultimate performance. Manufacturers also can tweak and recommend configurations that are optimized for specific application and service-level requirements.

### **The Future of Mobile Health Care**

If the risks associated with poor performance can be effectively mitigated, innovations in mobility will continue to revolutionize health care. With network and data system health affecting patient health like never before, reliability precludes liability. But armed with actionable insights gleaned from new best practices, the industry can look forward to leaps in speed, efficiency, and accuracy that only new degrees of mobility can deliver.

## NIH STUDY FINDS CELL PHONE/SMART METER RADIATION CAUSES BRAIN & HEART CANCERS

The National Toxicology Program (NTP) under the National Institutes of Health has completed the largest-ever animal (rats and mice) study on nonionizing radiation and cancer. Partial results released on May 26th confirm whole body exposures to low level radiofrequency radiation (RFR) of the type emitted by cell phones, smart meters and other wireless devices and within currently allowable safety limits, are the “*likely cause*” of brain and heart cancers in these animals, according to Dr. John Bucher, Associate Director of the NTP.

The \$25 million dollar study planned since 1999 showed one in twelve (12) male rats (8.3%) developed either malignant cancer (brain and rare heart tumors) or pre-cancerous lesions that can lead to cancer. Tumors called schwannomas were induced in the heart, and in the same kind of brain cells that have led to acoustic neuromas seen in human studies. The NTP says it is important to release these completed findings now given the implications to global health. No cancers occurred in the control group.

Dr. Lennart Hardell, MD, PhD of Sweden’s Orebro University and an expert witness in the Maine Smart Meter Health Investigation says “(T)he animal study confirms our findings in epidemiological studies of an increased risk for glioma and acoustic neuroma among people that use wireless phones, both cell phones and cordless phones (DECT). Acoustic neuroma is a type of Schwannoma, so interestingly this study confirms findings in humans of increased risk for glioma and acoustic neuroma. In 2013 we called for upgrading the risk in humans to Group 1, the agent is carcinogenic to humans. It is now time to re-evaluate both the cancer risk and other potential health effects in humans from radiofrequency radiation and also inform the public,” says Hardell. “This NTP evidence is greatly strengthening the evidence of risk, is sufficient to reclassify cell phone radiation as a known cancer-causing agent, and confirms the inadequacy of existing public safety limits.”

Dr. Christopher Portier, formerly with the NTP commented this is not just an associated finding—but that the relationship between radiation exposure and cancer is clear. “I would call it a causative study, absolutely. They controlled everything in the study. It’s [the cancer] because of the exposure. This is by far—far and away—the most carefully done cell phone bioassay, a biological assessment. This is a classic study that is done for trying to understand cancers in humans”.

We have written in Merrymeeting News since 2011 about the dangers of radiofrequency radiation from wireless devices, particularly smart meters which bring exposures to rural Maine. Birds, bees, other insects and mammals all show adverse responses to low-level electromagnetic field exposures. As levels of “electrosmog” grow with wireless proliferation not only from land sources but now also space-based platforms, the harbinger of an “Electronic Silent Spring” should alarm anyone who cares about our wildlife and civilization, much the same as Rachel Carson’s alarm did in bringing the effects of pesticide exposure to the public eye.

Dr. Jerry Phillips, PhD, is biochemist and director of the Excel Science Center at the University of Colorado at Colorado Springs. An educator and research scientist, Phillips conducted Motorola-funded research into the potential health impacts of cell phones during the 1990s while he was with the U.S. Department of Veterans Affairs’ Pettis VA Medical Center in Loma Linda, California. Phillips and his colleagues looked at the effects of different radiofrequency signals on rats, and on cells in a dish. Phillips also testified for health advocates in Maine’s smart meter investigation.

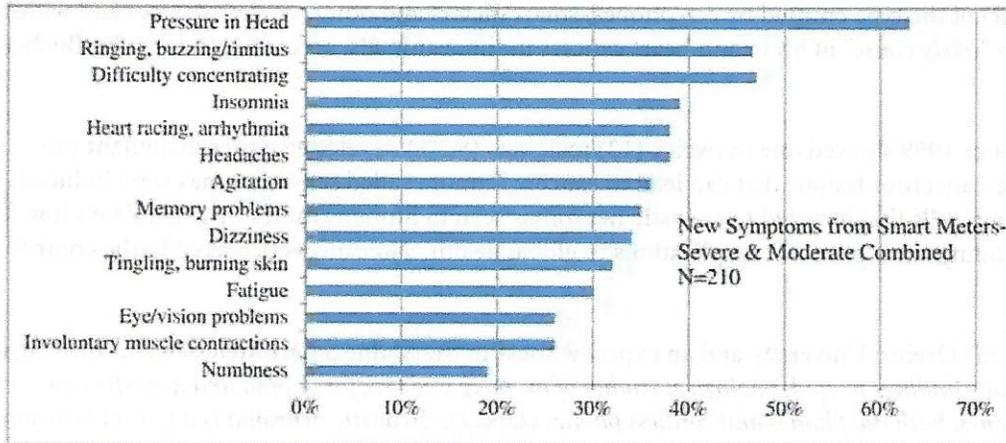

“The most troublesome finding to Motorola at the time is that these radiofrequency signals could interact with living tissues, which is what we saw in the rats,” he said in a recent [Scientific American](#) interview, adding:

“But you have to realize that this issue opens up a much bigger can of worms than cell phones. If this radiation, this form of energy can interact with biological tissue then it’s going to reopen a lot of what were supposedly settled issues regarding the safety of wireless communications. If we’re going to be bathed in a whole new electromagnetic environment, how safe is it?”

While cancers from RFR are certainly of great concern, perhaps of greater concern are debilitating non-cancer symptoms disorienting and causing avoidance behavior and other biological and behavioral responses in wildlife and humans. In people,

## NTP STUDY (CONTINUED)

relationships have commonly been stressed and destroyed, jobs have been lost and homes of many years sold or abandoned as a result of sensitivities to RFR. Consider if you suffer any or a number of the common RFR symptoms found in an international survey of those affected by smart meters as shown in this chart:

Conrad & Friedman, 2013. Smart Meter Health Effects Survey & Report

Smart meters in particular have sensitized many to any wireless device including routers and cell phones. The inability to use these common tools severely inhibits folks in their personal and economic lives. Their ability to live normal lives in the 21st century has been severely compromised immediately versus 10-30 year latency periods typical in cancer development. This change in ability to use these devices is directly correlated to smart meter exposure.

The suffering and the social and economic effects of chronic debilitating symptoms victims have experienced since smart meter exposure simply cannot be ignored, and provides ample evidence there is something about smart meters (evidence suggests the RF from up to 170,000 transmissions/day is conducted on home wiring) causing extreme harm to at least some, and possibly eventually all persons. While there is obviously only a portion of our population manifesting acute electromagnetic hypersensitivity (EHS) symptoms now (the canaries), and even fewer recognizing their source, we are all being exposed and are all susceptible.

*"This is a game changer, there is no question,"* said Dr. David Carpenter, MD, PhD, director of the Institute for Health and the Environment at the University of Albany and also an expert witness in Maine. *"It confirms what we have been seeing for many years — though now we have evidence in animals as well as in humans."* Quoted in *Microwave News*, Carpenter went on to add, *"The NTP has the credibility of the federal government. It will be very difficult for the naysayers to deny the association any longer."*

## KENNEBEC AND ANDROSCOGGIN PROPOSED CRITICAL HABITAT FOR ATLANTIC STURGEON

NOAA Fisheries announced June 2, two proposed rules designating critical habitat for five distinct population segments [DPS] of federally listed Atlantic sturgeon. The proposed areas provide important protected river habitats for the threatened Gulf of Maine population segment and the endangered population segments of the New York Bight, Chesapeake Bay, Carolina and South Atlantic. NOAA Fisheries listed the Atlantic sturgeon under the Endangered Species Act in 2012. The two local designations include the Kennebec to Lockwood dam in Waterville and the Androscoggin to the Brunswick-Topsham dam.

The ESA requires NOAA Fisheries [formerly and often still known as the National Marine Fisheries Service or NMFS] designate critical habitat when a species is listed as threatened or endangered. Under the ESA, critical habitat is defined as geographic areas occupied by the species, and containing features essential to the conservation of that species. Critical habitat can also include geographical areas that are not currently occupied by the species, but that are essential to its conservation, historical habitat for example.

Critical habitat does not create preserves or refuges. Instead, when a federal agency is carrying out funding or authorizing an activity that may affect the critical habitat, the federal agency works with NOAA NOAA Fisheries to avoid or minimize

## Abstract

Ionising radiation can transfer sufficient energy to ionise molecules, and this can lead to chemical changes, including DNA damage in cells. Key evidence for the carcinogenicity of ionising radiation comes from: follow-up studies of the survivors of the atomic bombings in Japan; other epidemiological studies of groups that have been exposed to radiation from medical, occupational or environmental sources; experimental animal studies; and studies of cellular responses to radiation. Considering exposure to environmental ionising radiation, inhalation of naturally occurring radon is the major source of radiation in the population – in doses orders of magnitude higher than those from nuclear power production or nuclear fallout. Indoor exposure to radon and its decay products is an important cause of lung cancer; radon may cause approximately one in ten lung cancers in Europe. Exposures to radon in buildings can be reduced via a three-step process of identifying those with potentially elevated radon levels, measuring radon levels, and reducing exposure by installation of remediation systems. In the 4th Edition of the European Code against Cancer it is therefore recommended to: “Find out if you are exposed to radiation from naturally high radon levels in your home. Take action to reduce high radon levels”. Non-ionising types of radiation (those with insufficient energy to ionise molecules) – including extremely low-frequency electric and magnetic fields as well as radiofrequency electromagnetic fields – are not an established cause of cancer and are therefore not addressed in the recommendations to reduce cancer risk.

## Keywords

- Radon;
- Ionizing radiation;
- Cancer;
- Radiation-induced cancer;
- Electromagnetic fields;
- Primary prevention;
- Europe

## Abbreviations

- AGIR, Advisory Group on Ionising Radiation;
  - CT, computerised tomography;
  - EMF, electromagnetic fields;
  - IARC, International Agency for Research on Cancer;
  - ICRP, International Commission on Radiological Protection;
  - ICNIRP, International Commission on Non-Ionising Radiation Protection;
  - RF, radiofrequency;
  - UVR, ultraviolet radiation;
  - UNSCEAR, United Nations Scientific Committee on the Effects of Atomic Radiation
-

# 1. Sources and physical and biological properties of radiation

## 1.1. Introduction

Natural and man-made sources generate radiant energy in the form of electromagnetic waves; these are characterised by their wavelength, frequency and photon energy. The electromagnetic spectrum includes static (non-alternating) electric and magnetic fields, low-frequency electric and magnetic fields (low energy, long wavelengths), intermediate and radiofrequency (RF) electromagnetic fields (EMF), microwaves, optical radiation (infrared, visible light, ultraviolet radiation) and gamma- and X-rays (ionising radiation with high energy and very short wavelengths) (Fig. 1). In addition to electromagnetic waves, ionising radiations include particulate sources: notably neutrons, electrons (beta particles) and alpha particles. While non-ionising and ionising electromagnetic waves and neutrons can penetrate the body from external sources, charged particles – including alpha and beta particles – have limited ability to penetrate body tissues, and risks are generally associated with their entry into the body by inhalation or ingestion.

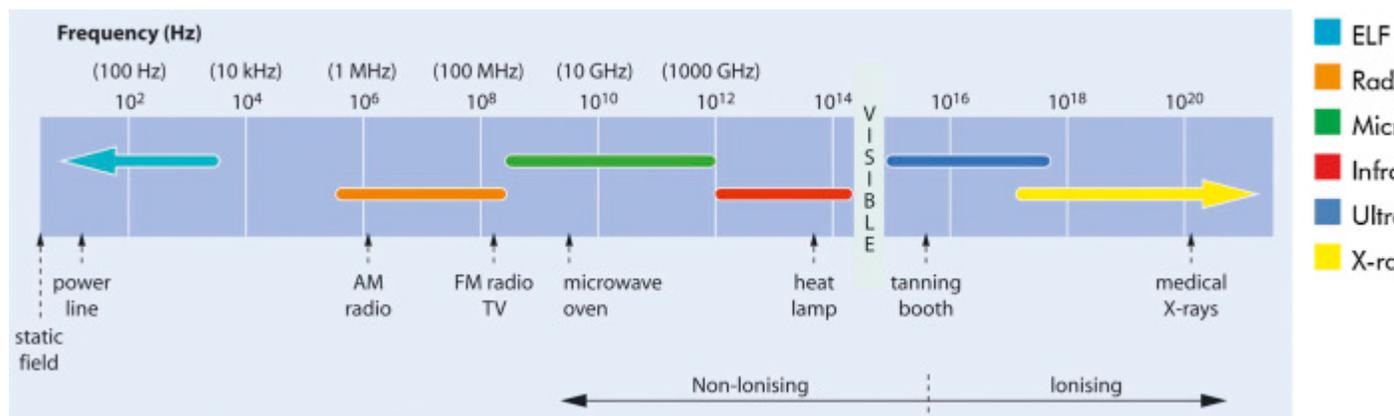

Fig. 1.

Electromagnetic spectrum. The electromagnetic spectrum extends from below the low frequencies used for modern radio communication to gamma radiation at the shortest wavelength and highest frequency. Reproduced from the European Commission, Research Directorate-General, European Communities (2005). Health and Electromagnetic Fields: EU-funded research into the impact of electromagnetic fields and mobile telephones on health. © European Communities, 2005.

### [Figure options](#)

Ionising radiation and ultraviolet radiation (UVR) are known to cause cancer [1] and [2], but the evidence regarding non-ionising radiation is equivocal [3] and [4]; while there is a mechanistic understanding of the cellular effects of ionising radiation and UVR, plausible mechanisms have not been established for the effects of non-ionising radiation. The cancer risk from ionising radiation, in particular radon, justifies the recommendation of the 4th edition of the European Code against Cancer (Box 1). Ionising radiation from medical diagnostics and treatment is discussed elsewhere, together

with other medical exposures [5]. UVR, also subject to a recommendation, is discussed elsewhere [6]. In this paper, we also cover non-ionising radiation (the EMF part), for which the scientific evidence has been evaluated and shows that it is not an established cause of cancer, and is therefore not addressed by a recommendation of the Code.

Box 1.

European Code Against Cancer.

## EUROPEAN CODE AGAINST CANCER

### **12 ways to reduce your cancer risk**

1. Do not smoke. Do not use any form of tobacco
2. Make your home smoke free. Support smoke-free policies in your workplace
3. Take action to be a healthy body weight
4. Be physically active in everyday life. Limit the time you spend sitting
5. Have a healthy diet:
  - Eat plenty of whole grains, pulses, vegetables and fruits
  - Limit high-calorie foods (foods high in sugar or fat) and avoid sugary drinks
  - Avoid processed meat; limit red meat and foods high in salt
6. If you drink alcohol of any type, limit your intake. Not drinking alcohol is better for cancer prevention
7. Avoid too much sun, especially for children. Use sun protection. Do not use sunbeds
8. In the workplace, protect yourself against cancer-causing substances by following health and safety instructions
9. Find out if you are exposed to radiation from naturally high radon levels in your home; take action to reduce high radon levels
10. For women:
  - Breastfeeding reduces the mother's cancer risk. If you can, breastfeed your baby
  - Hormone replacement therapy (HRT) increases the risk of certain cancers. Limit use of HRT
11. Ensure your children take part in vaccination programmes for:
  - Hepatitis B (for newborns)
  - Human papillomavirus (HPV) (for girls)
12. Take part in organised cancer screening programmes for:
  - Bowel cancer (men and women)
  - Breast cancer (women)
  - Cervical cancer (women)

The European Code Against Cancer focuses on actions that individual citizens can take to help prevent cancer. Successful cancer prevention requires these individual actions to be supported by governmental policies and actions.

### **1.2. Exposure to sources of ionising radiation**

Radioactive substances are a source of ionising radiation. An important characteristic of these radioactive materials is the rate at which they decay, either into another radioactive nuclide or into a stable (i.e. non-radioactive) nuclide. The decay rate is normally expressed in terms of the nuclide's half-life, namely, the time taken for the radioactivity of any given amount of the particular radionuclide to decay to half of its initial value. The amount of a radioactive substance is generally measured in terms of its activity or radioactive decay rate, with units of becquerel (Bq); 1 Bq equals one nuclear decay event per second. Each radionuclide, depending on its degree of nuclear instability, has a characteristic radioactive half-life, and nuclear decay is accompanied by a specific yield of energy depending on the radiations emitted (e.g. alpha, beta).

Many radioactive materials exist naturally. Primordial radioactive elements include uranium-238 that has a radioactive half-life of around  $4.5 \times 10^9$  years leading to the radioactive decay chain that includes radon-222 (which together with its progeny/daughter isotopes/decay products is referred to as 'radon' below). Some human activities create radioactive materials either deliberately or as a by-product. Nuclear fission of uranium-235 in nuclear reactors is a source of man-made radionuclides. Some devices, such as x-ray sets used in medicine and in industrial inspection, generate and emit ionising radiation without the presence of radioactive material.

Radioactive materials external to the body can result in radiation exposure and cancer risk if the emitted radiations can penetrate to body organs and tissues, as is the case for gamma rays, X-rays and neutrons [7]. Entry of radioactive materials into the body, mainly by inhalation or ingestion, can lead to their deposition and retention in body organs and tissues, resulting in continued irradiation. For so-called non-penetrating radiations – including beta and alpha particles – risk to health is largely the result of such internal exposures. The extent to which specific organs and tissues are exposed from a radionuclide within the body depends on various factors: the mode of entry into the body; the physical and chemical properties of the incorporated radionuclides; the radiations emitted; the radioactive half-lives of the incorporated radionuclide and its decay products; and the distribution within and elimination from the body [7]. A short-lived, insoluble, alpha-emitting radionuclide that is ingested would irradiate the gut more than other tissues. In contrast, a long-lived, highly soluble, gamma-emitting radionuclide that is inhaled may be distributed around and irradiate most of the body's tissues before being excreted.

For all types of ionising radiation exposure, radiation dose is defined as the energy deposited as a result of ionisations and excitations per unit mass of material. This quantity is referred to as the absorbed dose and has the unit of gray (Gy), where 1 Gy equals 1 J/kg. At sufficiently high doses, the predominant effect is cell killing, leading to gross organ damage and potentially to death. If an individual escapes death (from exposure-related cell killing) and at all lower doses, the predominant effect of concern is an increased probability of cancer (see below). For radiological protection purposes, the International Commission on Radiological Protection (ICRP) has defined the quantity, the effective dose (unit of Sievert, Sv), as a risk-adjusted dosimetric quantity for use in the control of radiation exposures. The effective dose is calculated from absorbed dose, adjustments being made for differences between radiation types in their ability to cause cancer (per Gy) and differences between

organs and tissues in their sensitivity to the induction of cancer. For example, alpha particles are more effective in causing cancer per Gy of radiation than gamma rays, and this is recognised for protection purposes using a radiation weighting factor of 20. The greater sensitivity of the colon than the liver to radiation-induced cancer (as suggested, for instance, by the higher risk of colon cancer than liver cancer in the atomic bomb survivors in Japan, shown in [Fig. 2](#)), for example, is recognised in tissue weighting factors of 0.12 and 0.04, respectively [\[7\]](#). It should be appreciated, however, that these are simplified risk adjustments applied for protection purposes and they do not fully reflect our scientific understanding and would not be used in the calculation of risks to specific population groups or individuals. Thus, for example, radiation effectiveness is known to be dependent on cancer type and organ/tissue sensitivity and is age- and sex-dependent [\[8\]](#) and [\[9\]](#).

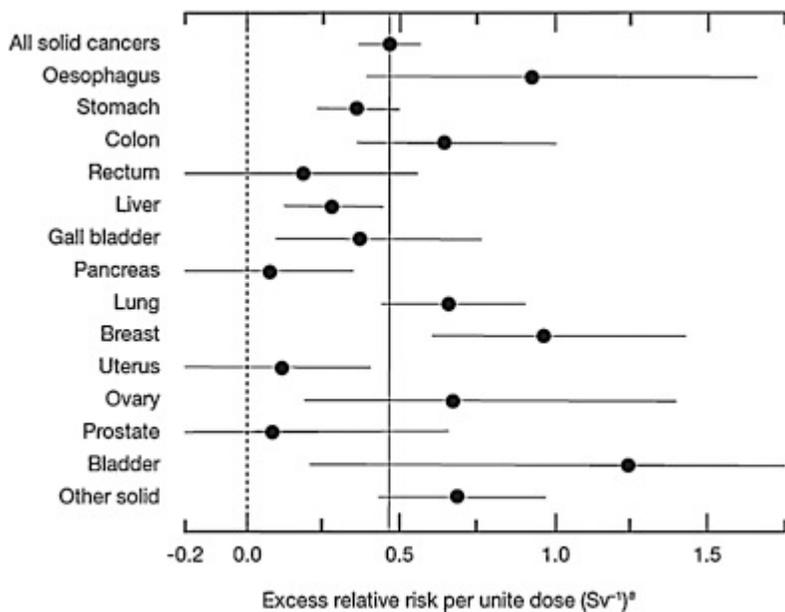

Fig. 2.

Estimates of solid cancer mortality risk for different organs from studies of the survivors of the atomic bombings in Japan. The figure shows the excess relative risk per unit dose ( $\text{Sv}^{-1}$ ) of various cancer types from radiation exposure among the survivors of the atomic bombings in Japan. Reproduced with permission from United Nations/UNSCEAR [\[18\]](#). <sup>a</sup>While the absorbed dose is expressed in gray (Gy), because radiations differ in their ability per Gy to cause cancer, a radiation-weighted quantity, equivalent dose, is used, expressed in Sievert (Sv) (see Section [1.2](#)). The horizontal bars represent 90% confidence intervals.

### [Figure options](#)

Estimates are made, nationally and internationally, of the sources and distribution of radiation exposures of populations. According to the latest periodic review of radiation exposures by the United Nations Scientific Committee on the Effects of Atomic Radiation (UNSCEAR) [\[10\]](#), reference individuals receive an average of about 3 mSv effective dose annually but, within a population, there may be a wide range of individual exposures from less than 1 to more than several tens of mSv. For any individual, the absolute and relative contributions of different sources of radiation exposure will depend on many factors, including their home location (e.g. radon and cosmic ray exposure), exposure

as patients during medical diagnostic procedures (e.g. X-rays, computerised tomography (CT) scans) or radiotherapy, their job (workplace exposure), and dietary choices (ingestion of radionuclides). However, everybody is exposed to ionising radiation to some extent owing to the abundance of natural sources. [Fig. 3](#) shows the relative contributions from different sources to the estimated average annual exposure estimated for the global population. Much of the radiation exposure of a typical individual comes from natural radiation sources, including internal exposure from inhaling radon decay products when indoors, external exposure from gamma-emitting radionuclides in rocks, soil and building materials, and internal exposure from ingestion of natural radionuclides in food and drink [\[10\]](#).

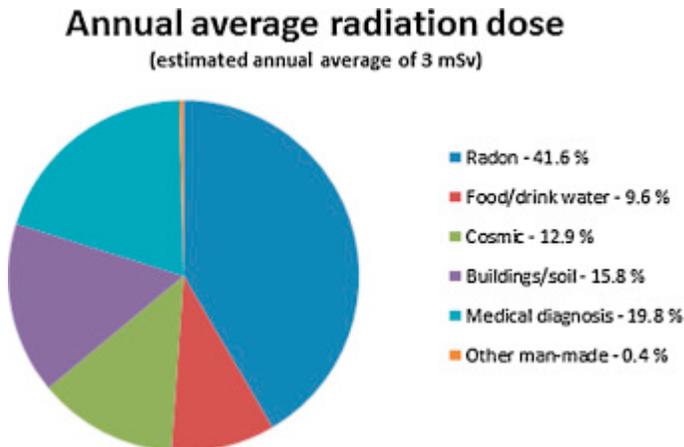

Fig. 3.

Components of worldwide annual average individual radiation dose. The pie chart shows the annual average dose to the representative individual from the different radiation sources. Inhalation of radon (=Radon); ingestion of radionuclides in food and drink (=food/drink water); external irradiation from cosmic rays (=Cosmic); external irradiation from radionuclides in building materials and soil (=Buildings/soil); external and internal irradiation from medical diagnosis (=Medical diagnosis); external radiation and ingestion/inhalation from other man-made sources (=Other man-made). Reproduced from [\[10\]](#).

#### [Figure options](#)

The predominant source of man-made radiation exposure is the use of radiation for medical diagnostic and therapeutic purposes [\[10\]](#); medical exposure to ionising radiation will be discussed in a separate article [\[5\]](#). Other anthropogenic sources include: external and internal exposure of the public to radionuclides released into the environment from nuclear power plants, both low-level releases during normal operations and exposures resulting from past accidents (such as those at Chernobyl and Fukushima); exposures to fallout from nuclear weapons testing; and occupational radiation exposures of workers including those in the health care, nuclear industry, airline pilots and some miners [\[10\]](#). Together, these non-medical man-made sources make only a minor contribution to the overall population exposure. For most people, radon is the largest individual component of exposure to ionising radiation.

### 1.3. Exposure to radon

Radon is an inert gas with several radioactive isotopes. Radon-222 is formed by the radioactive decay of uranium-238 that is present in small quantities in all soils and rocks. Other radon isotopes are generally less important for health than radon-222 because their short half-lives limit their presence in inhaled air. Radon-222 has a 3.8-day half-life, sufficient to allow time for accumulation above ground in homes and other buildings. In outdoor air, it is generally diluted to negligible concentrations [11].

Buildings, including homes, have slightly reduced air pressure relative to outdoor air, due to indoor heating and air movement. Soil air, containing radon, is drawn from the ground into a building through openings and minor defects in the foundations such as in seams and utility entry points. It may be retained within the building unless removed by ventilation, and this can lead to elevated concentrations in indoor air which can reach hundreds or thousands of becquerels per cubic metre ( $\text{Bq m}^{-3}$ ) [12]. As an inert gas, inhaled radon is mostly exhaled. However, radon has a number of radioactive decay products with very short half-lives which include alpha-particle-emitting isotopes of polonium (218 and 214) which are deposited within the lungs and are a recognised cause of lung cancer.

Radon is present in most rocks and soil. The concentrations in homes and workplaces depend on a number of factors, including: the abundance of radium-226 (a long-lived intermediate decay product of uranium-238) in the ground; the permeability of the soil; the openings in the foundations of the building through which radon can enter a building from the ground; and the extent to which a particular building retains radon. These variations can result in a wide range of indoor radon concentrations even in a small geographical area. Two apparently identical adjacent homes can have very different indoor radon levels. UNSCEAR [13] estimated a worldwide population-weighted geometric mean indoor level of  $30 \text{ Bq m}^{-3}$ . Fig. 4 shows the geographical distribution means of long-term radon concentrations in ground floors across Europe. A small proportion of radon exposure arises from its presence in and emanation from building materials and water supplies.

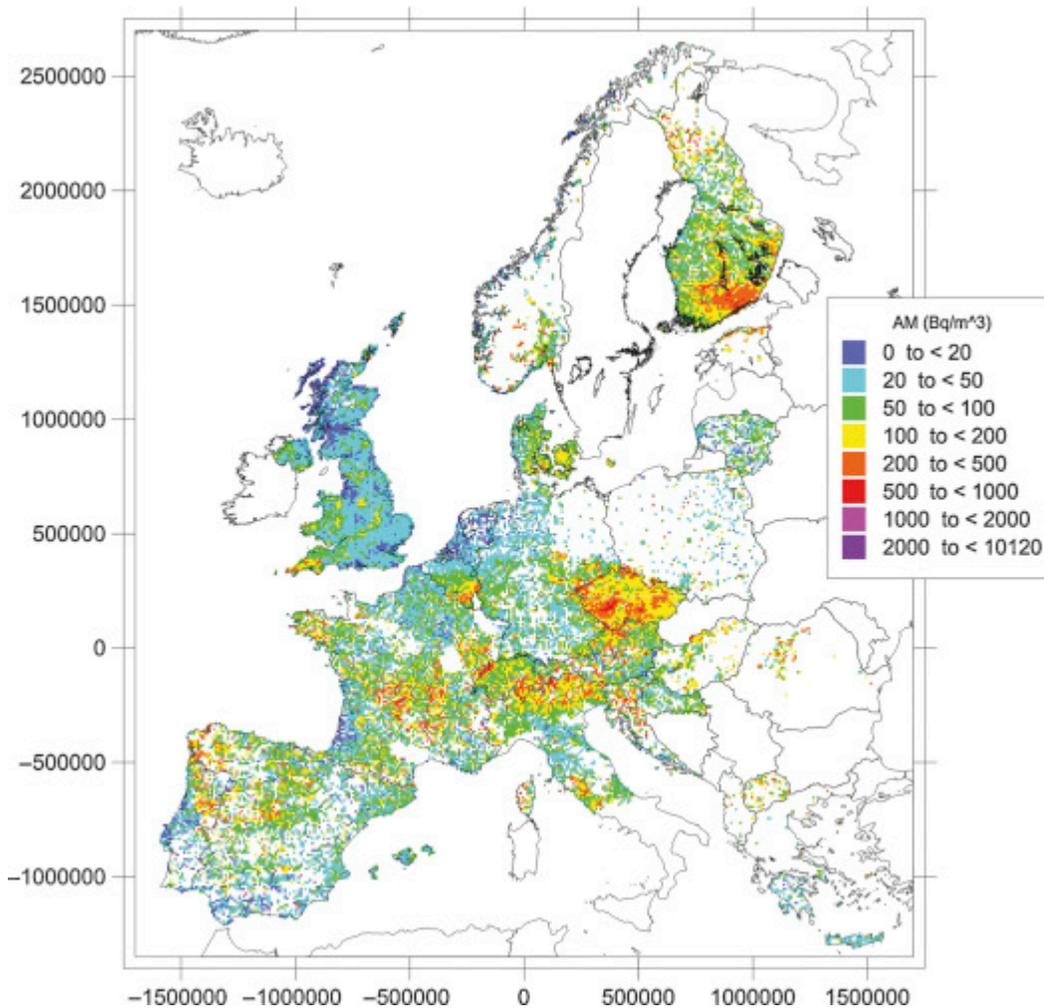

Fig. 4.

Map of radon in Europe. Arithmetic means over  $10 \text{ km} \times 10 \text{ km}$  cells of long-term radon concentration in ground-floor rooms. Data available up until May 2014 included. Reproduced with permission of Oxford University Press [52].

[Figure options](#)

## 1.4. Exposure to non-ionising radiation

Exposure to static and to extremely low-frequency electric and magnetic fields is ubiquitous due to natural phenomena and power transmission and the use of electrical appliances. Examples of natural sources of exposure include the geomagnetic field of the earth and, as extreme phenomena, thunder and lightning. Normal residential background exposure to extremely low-frequency magnetic fields is usually below  $0.1 \mu\text{T}$  (flux density or magnetic field strength) [14]. A small fraction of households located very close to high-voltage power lines or other sources (including indoors) can have higher exposures, but usually well below protection limits – defined by the International Commission for Non-Ionising Radiation Protection (ICNIRP) – for the general population [15]. Higher but short-term exposures occur in particular jobs such as those of electricians.

For the majority of people, highest exposures to radiofrequency electromagnetic fields occur when using mobile phones because the source of emission is held close to the head. Much lower levels of exposure arise from high-power TV and radio transmitters, but the electric field strength may exceed 1 V/m even at points several kilometres from transmitters [16]. Exposures from smaller transmitters – such as mobile phone base station antennas – are normally even lower except in their immediate vicinity [17]. The number of sources continues to increase with further utilisation of the whole electromagnetic frequency spectrum and further development of new wireless technologies.

## 2. Cancer risk from ionising radiation

### 2.1. Ionising radiation and cancer

Large numbers of studies have investigated the effects of ionising radiation exposure as a cause of haematological malignancies and solid cancers. Ionising radiation has been classified by the International Agency for Research on Cancer (IARC) as an established or class I carcinogen [1]. Key evidence for the carcinogenicity of ionising radiation has been reviewed by IARC, the United Nations Scientific Committee on the Effects of Atomic Radiation [11], and the International Commission on Radiological Protection [7]; it includes: the Life Span Study of survivors of the atomic bombings in Japan exposed at the end of the second world war; other epidemiological studies of groups that have been exposed to radiation from medical, occupational or environmental sources; experimental animal studies; and studies of cellular responses to radiation including DNA damage.

[Fig. 2](#) illustrates some of the evidence for radiation-associated cancer and the magnitude of risk to different tissues. It shows the excess relative risk per dose unit (Sv) of various cancer types among the survivors of the atomic bombings in Japan.

In its 2011 summary report of low-dose radiation effects on health [18], UNSCEAR stated that “... the energy deposited in the cell after irradiation can damage all subcellular components. The main subcellular targets for radiation-associated cellular change are the DNA molecules residing in the chromosomes... The cell may survive but with DNA mutations that affect cellular behaviour. A small fraction of such mutations can contribute to cancer development... Complex DNA damage is difficult to repair correctly, and even at low doses of radiation it is likely that there is a very small but non-zero chance of the production of DNA mutations that increase the risk of cancer developing. Thus, the current balance of available evidence tends to favour a non-threshold response for the mutational component of radiation-associated cancer induction at low doses and dose-rates.”

ICRP judges [7] that the weight of evidence supports the view that it is “scientifically plausible to assume that the incidence of cancer... will rise in direct proportion to an increase in the equivalent dose in the relevant organs and tissues.”

These conclusions from UNSCEAR and ICRP embody what is generally referred to as the linear, no-threshold (LNT) dose–response model. It implies that there is no level at which the risk is zero, but any additional exposure to ionising radiation increases the lifetime cancer risk, adding to the underlying cancer risk from other causes. The ICRP risk factor [7] for cancer induction in a mixed age population is 5.5% per Sv of effective dose delivered at low dose and dose rate.

## 2.2. Radon and cancer

There is substantial epidemiological evidence that indoor exposure to radon and its decay products is an important cause of lung cancer, second only to tobacco smoking. Several large-scale epidemiological studies – including pooled analyses of uranium miners and populations exposed to elevated radon levels at home [19], [20], [21] and [22] – have demonstrated that long-term exposure to radon increases the risk of lung cancer. Pooled case–control studies have also shown that the excess relative risk of lung cancer is proportional to long-term radon exposure levels for smokers, non-smokers and ex-smokers, as illustrated in Fig. 5[20] and [23]. The UK independent Advisory Group on Ionising Radiation (AGIR) reported a 16% excess relative risk from long-term (30 years) exposure to radon in air at a concentration of  $100 \text{ Bq m}^{-3}$ , with a 95% confidence interval of 5–31% [23]. The results provide direct evidence of increased lung cancer risk at radon levels below  $200 \text{ Bq m}^{-3}$ . The greatest absolute lung cancer risks from radon exposure were to continuing smokers, primarily because smoking induces a much higher baseline lung cancer risk, and radon acts multiplicatively with other lung cancer risks. In other words, the vast majority of radon-induced cancers develop among smokers as a joint effect of radon and smoking. Darby et al. [19] and [20] estimated the fraction of the lung cancer burden attributable to indoor radon in Europe to be about 9%. The World Health Organization (WHO) [12] reported estimates ranging from 3% to 14% across some selected populations around the world, including some from Europe, based on a large pooling study for the UK (3.3%), Germany (5%), France (5%), and Switzerland (8.3%).

Fig. 5.

Relative risk of lung cancer in relation to long-term residential radon concentrations in the European pooling study (with 95% confidence intervals). Relative risks and 95% confidence intervals are shown for categorical analyses and also the best-fitting straight line. Risks are relative to that at  $0 \text{ Bq m}^{-3}$ . [Figure options](#)

### 2.3. Other relevant sources of ionising radiation and cancer

Studies of nuclear workers exposed mainly to low doses of external radiation under relatively well controlled conditions demonstrated a small increase in cancer mortality associated with exposure at work [24] and [25]. In a study of nuclear workers from 15 countries, 1–2% of deaths from solid cancers were considered to be possibly related to their occupational exposure [24]. Analysis of cancer incidence in the very large cohort of workers included in the UK National Registry for Radiation Workers showed a significant dose–response relationship consistent with the extrapolation of the A-bomb risk factors to low doses [25]. Studies of cancer incidence in plutonium workers at the Russian Mayak plant have shown plutonium-239-related excesses of lung and liver cancers [26] and [27]. Comparisons of lung cancer incidences following exposures to radon progeny (uranium miners), plutonium and external gamma rays show that risk estimates are consistent when account is taken of the relative biological effectiveness (RBE) of alpha particles and gamma rays [28]. The data are consistent with alpha particle RBE values of around 10–20, although Marsh et al. [28] noted the considerable uncertainties associated with these estimates.

Excesses of childhood leukaemia incidence in populations near nuclear installations in the UK, Germany and other countries have been recorded, but a number of similar studies have failed to show any increased risks [9] and [29]. The radiation doses in these populations are well below the levels that might cause any discernible excess risk of cancer in the light of current understanding, particularly as doses from natural sources have been shown to dominate and exceed any contributions from radioactive discharges from nuclear facilities. Overall there is no good evidence that any step in the production of nuclear power under controlled conditions is related to any cancer excess in the populations of the adjacent areas. However, nuclear accidents such as that at the Ukrainian Chernobyl plant can result in exposure to radiation doses resulting in elevated cancer risks, depending on the release of radionuclides and the location [10]. In addition, radioactive discharges from the Mayak plant into the Techa River were sufficiently high in the early years of operation to lead to increases in both haematological malignancies and solid cancers [30] and [31]. The recent accident at the Fukushima plant in Japan resulted in exposures that were an order of magnitude or more below those experienced following the Chernobyl reactor, and discernible increases in cancer incidence are not expected [32] and [33].

### 2.4. Non-ionising radiation and cancer

Epidemiological studies have consistently shown a positive association of extremely low-frequency magnetic fields with an approximately two-fold higher childhood leukaemia risk at average exposure levels exceeding 0.3–0.4  $\mu\text{T}$  [15]. A causal relationship, however, has not been established due to the potential for bias and confounding in the studies and because supporting evidence from experimental studies and mechanistic data are lacking. The 2002 IARC Monograph [3] on extremely low-frequency magnetic fields classified them as possibly carcinogenic to humans (group 2B) based on the findings for childhood leukaemia; the evidence for other types of malignancy was evaluated to be inadequate. This view was recently confirmed by the European Commissions' Scientific Committee on Emerging and Newly Identified Health Risks [34]. Radiofrequency electromagnetic fields (group 2B) have also been classified by the IARC [4] as possibly carcinogenic to humans on the basis of findings for glioma and acoustic neuroma. Case–control studies on mobile phone use and cancer have reported increased risks of glioma and acoustic neuroma in heavy users of mobile phones, based on self-reported mobile

phone use [35] and [36]. Cohort studies have shown no associations, but had fewer data on heavy users [37] and [38]. Time trends in glioma incidence based on Nordic countries excluded any significant increased incidence attributable to mobile phone usage of up to 10 years [39]. With regard to environmental exposures from transmitters – including television, radio, and military transmissions as well as mobile phone base stations – the evidence is inadequate due to paucity of high-quality studies with accurate individual exposure assessment [40]. Some large studies on childhood cancer and fields generated by high-output TV and/or radio transmitters reported no associations [15]. Overall, currently available information does not provide unequivocal evidence that non-ionising radiation at low and high frequencies is a cause of cancer.

### **3. Scientific justification of the recommendation on radon**

The carcinogenicity of ionising radiation is well documented [1]. Ionising radiation can cause many types of cancer and haematological malignancies. Some exposure to ionising radiation is unavoidable – for instance that from cosmic radiation or terrestrial radiation. The major source of man-made radiation is medical exposure; the exposure is intentional and brings benefit through diagnoses or treatment. Therefore controlled and judicious use of radiation in medicine is associated with risks that are counterbalanced with benefits [5]. Man-made radiation also occurs in some occupational settings for which regulations are in place, such as the Euratom 2014 Basic Safety Standards [41]. These regulations provide a range of controls, including: risk assessment; control of radiation use and procedures for radiation safety and protection; and personal and environmental radiation monitoring where appropriate. The recommendation of the Code to follow health and safety advice to reduce occupational exposure defined elsewhere also applies to ionising radiation [42]. Other man-made exposures – such as for example those related to the use of nuclear energy under normal conditions – are sometimes of concern in the population. Nevertheless, they generally contribute little to overall radiation exposure (Fig. 3). This does not apply to major nuclear accidents with major radionuclide releases.

The major source of exposure to ionising radiation, modifiable by the individual, comes from naturally occurring radon. While this naturally occurring exposure cannot be eliminated, it can be substantially reduced at places where people spend much of their time, namely in their own homes or at their workplaces. Radon is estimated to account for about one in ten lung cancers in Europe [18], therefore causing a major cancer burden. The respective recommendation is: “Find out if you are exposed to radiation from naturally high radon levels in your home. Take action to reduce high radon levels”.

#### **3.1. Individual action for protection against radon**

##### **3.1.1. Variation in radon exposure**

Radon concentrations in homes and other buildings vary substantially, as discussed in Section 1.3. The radon exposures of building occupants depend primarily on the proportion of time they spend in the building. Over the course of a year, most people spend a majority of their time in their home, mostly in living rooms and bedrooms. Homes are therefore the primary source of indoor radon exposure, with workplaces presenting the second most important source of exposure with radon concentrations typically similar to or slightly lower than those in homes (although high concentrations can occur in particular workplaces, especially underground).

It is not generally possible to accurately predict the indoor radon concentration in a specific building, and measurements are required. However, a number of countries (see for example [43], [44] and [45]) have used radon or related measurements or geological information to identify radon-prone areas where high radon levels are more common. Maps indicating radon-prone areas are used in some countries to provide guidance on whether radon measurements should be made in existing properties to inform remediation decisions (Fig. 4).

### 3.1.2. Measuring radon in the home

Indoor radon levels vary considerably over short periods (hours and days) [46], and seasonally through the year [47]. Within any home, there is often a variation in concentration between rooms. Measurements of radon are generally intended to represent the long-term average concentration in the home. For this reason, radon measurements in homes are often made using two detectors placed in regularly occupied rooms, including a bedroom, for several weeks. Measurements made during different times of the year can be adjusted to reflect seasonal variations [47]. Shorter duration measurements may be made but the results are less accurate and have greater uncertainties.

### 3.1.3. Managing individual risks from radon exposure

The distribution of residential radon exposures in a population reflects the geometric mean of indoor radon concentrations with a log-normal distribution. A large proportion of the population exposure to radon will therefore arise from the many homes that have relatively modest indoor radon concentrations [12]. The modest cost of including radon preventative measures in new buildings is sufficiently low as to support preventive measures in new buildings [12]. Maps of radon-prone areas can be used to support policies on radon preventative measures in new buildings, such as requiring the installation of impermeable membranes at the building foundation level.

Most radon strategies focus on identifying and managing the homes with the highest radon concentrations. International guidance is available from the ICRP [48] and the WHO [12] on radon concentration levels (termed “reference levels” by the ICRP), above which action should be taken to reduce indoor radon concentrations, and below which concentrations should be reduced as far as is reasonably achievable. The WHO and ICRP have advised that relevant national authorities should establish radon reference levels for homes in the range 100–300 Bq m<sup>-3</sup>. The ICRP system of radiological protection [7] advises that reference levels of radiation dose for “existing exposure situations” such as radon in buildings, should be implemented using dose criteria in the range 1–20 mSv y<sup>-1</sup>. ICRP has advised [48] that a derived reference level of 300 Bq m<sup>-3</sup> for homes is consistent with this aspect of its system of radiological protection.

A European Union directive, setting out requirements for protection against ionising radiation [41], has established criteria for managing indoor radon, setting an upper limit of 300 Bq m<sup>-3</sup> on national reference levels unless there are extenuating circumstances. Means to manage high individual radon exposures in the home include provision of resources and funding for radon risk assessments, measurements or remediation [49] and provision of information to the householder [50]. The European Code Against Cancer recommendation concerning radon in the home expects the householder to take responsibility for managing the radon risk in their home. Such an approach complements programmes

to encourage or support householders in radon management and complements responsibilities that landlords have to provide safe housing for their tenants.

### 3.1.4. Reducing high indoor radon levels

Practical methods are available for reducing high radon levels in existing properties [12], usually at modest cost. These generally work by either reducing the radon concentration at the point where it enters the building from the ground, or reducing the air pressure differential between the building and the ground that is the driving force for soil air and radon to enter the home. Experience to date [51] suggests that the most effective solutions are based on low-power electrical air pumps, typically consuming a few tens of watts that work continuously and can achieve reductions in radon concentration to a tenth of the original level. The most commonly used remediation systems include: (1) a “radon sump” – a small, engineered, partially depressurised void beneath the building from which soil air and radon are continually pumped through pipes and expelled to atmosphere; and (2) positive pressure ventilation, in which air is pumped into a central area of the home to reduce the pressure differential between indoor air and soil air. Some passive (non-powered) methods are available but these generally result in smaller concentration reductions and are therefore not suitable for reducing the highest radon levels [52] and [53].

## 4. Conclusions

Ionising radiation has been shown to be carcinogenic and everyone is exposed to a range of natural and man-made sources. Radon is the single biggest source of ionising radiation exposure for most people, with most exposure occurring in the home. Radon is the second leading cause of lung cancer after smoking, with long-term exposure shown to result in excess lung cancers. Radon levels vary between regions and even between neighbouring buildings. A suitable radon measurement is needed to determine the radon level in any specific property. National agencies can prepare maps indicating the geographical variation of indoor radon. In areas where high indoor radon levels are more common, radon measurements should be made comprehensively, particularly in homes. International organisations, including the WHO, have advised that countries should establish reference levels of indoor radon in the range 100–300 Bq m<sup>-3</sup>, above which steps should be taken to reduce concentrations. Minor building modifications can be made to reduce high indoor radon levels. For new buildings, techniques should be employed to minimise radon levels, as this can be achieved easily and also reduces other hazards such as moisture damage.

Householders should:

- - take ownership of the radon issue for their home;
- - use the available national information to decide whether to test their home for radon;
-

test their home for radon where this is advised, reduce high radon levels in the home.

## Conflict of interest

The authors declare no conflicts of interest.

# Novartis Pharmaceuticals announces a joint investment company with Qualcomm, leading innovation in digital medicines for physicians and patients

Jan 12, 2015

- Novartis establishing a joint investment company with Qualcomm Ventures, the venture investment group of Qualcomm Incorporated, of up to USD 100 million to support early stage companies with technologies, products or services that "go beyond the pill"
- Digital technologies can optimize the value of innovative medicines by providing integrated solutions for physicians and patients and advancing the practice of medicine
- Qualcomm Ventures, is a leading global investor in wireless technologies and one of the most active strategic investors in digital health

**Basel, January 12, 2015** - Novartis Pharmaceuticals announced today the plans to establish of a joint investment company with Qualcomm Ventures, the investment arm of Qualcomm Incorporated, to target early stage companies who offer technologies, products or services that "go beyond the pill" to benefit physicians and patients.

"By working with Qualcomm Ventures, Novartis sees the opportunity to take a greater leadership role in introducing new mobile or digital technologies that have the potential to change the practice of medicine and bring more breakthroughs with real benefits to patients and society," said David Epstein, Division Head, Novartis Pharmaceuticals. "We are excited by the potential of digital medicines to further enhance our mission of the right drug for the right patient at the right time helping people live longer with a better quality of life giving more time to do the things that matter to them."

Digital and mobile technologies are expected to make a significant difference in the pharmaceutical industry. New technologies are emerging such as telephone enabled devices, mobile applications, wearable devices, and technologies for big and small data to enable delivery of the right medicine to the right patients and more robust pharmacoeconomic analyses. The plan to establish the joint investment company combines the knowledge of Novartis' innovation in the research, development and manufacturing of innovative medicines with Qualcomm's expertise in digital and mobile technologies.

## Disclaimer

This press release contains expressed or implied forward-looking statements, including statements that can be identified by terminology such as "can," "target," "opportunity," "potential," "mission," "expected," or similar expressions. Such forward-looking statements reflect the current views of the Group regarding future events, and involve known and unknown risks, uncertainties and other factors that may cause actual results to be materially different from any future results expressed or implied by such statements. These expectations could be affected

by, among other things, risks and factors referred to in the Risk Factors section of Novartis AG's current Form 20-F on file with the US Securities and Exchange Commission. Novartis is providing the information in this press release as of this date and does not undertake any obligation to update it in the future.

### **About Novartis**

Novartis provides innovative healthcare solutions that address the evolving needs of patients and societies. Headquartered in Basel, Switzerland, Novartis offers a diversified portfolio to best meet these needs: innovative medicines, eye care, cost-saving generic pharmaceuticals, preventive vaccines and over-the-counter products. Novartis is the only global company with leading positions in these areas. In 2013, the Group achieved net sales of USD 57.9 billion, while R&D throughout the Group amounted to approximately USD 9.9 billion (USD 9.6 billion excluding impairment and amortization charges). Novartis Group companies employ approximately 130,000 full-time-equivalent associates and sell products in more than 150 countries around the world. For more information, please visit <http://www.novartis.com>.

## **Introduction and summary**

---

### **What are electric and magnetic fields?**

Electric and magnetic fields are produced by any wiring or equipment carrying electric current. This includes overhead and underground power lines carrying electricity, wiring in buildings, and electrical appliances. The strengths of the fields decrease rapidly with increasing distance from the source.

Electric and magnetic fields are fundamentally different, in their physical nature and in the way they interact with the body, from true electromagnetic radiation such as radio waves and microwaves. Information on the health effects of these radiations is available in other National Radiation Laboratory publications. This booklet relates only to electric and magnetic fields around power lines, electrical wiring and appliances.

### **Do they present health risks?**

Most research into this question has concentrated on finding out whether the magnetic fields can cause cancer or could assist the development of a cancerous condition. Other effects investigated include miscarriages, Alzheimer's disease and depression.

In spite of all the studies that have been carried out over the past thirty years there is still no persuasive evidence that the fields pose any health risks. The results obtained show that if there are any risks, they must be very small. A review published by the World Health Organization in June 2007 recommended using exposure guidelines published by the International Commission on Non-Ionizing Radiation Protection, along with low cost measures to reduce exposures where this can be readily achieved. The National Radiation Laboratory and Ministry of Health support these recommendations.

## What are electric and magnetic fields?

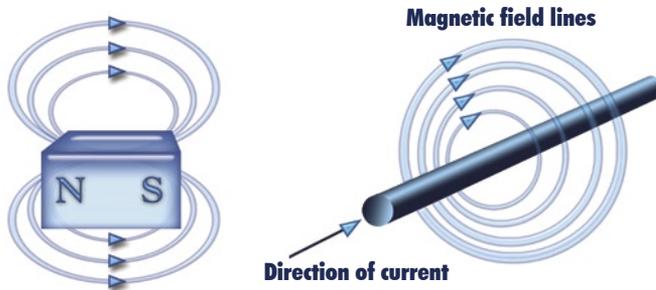

---

### Magnetic fields

A small piece of iron held near a magnet will move towards and attach itself to that magnet. The magnet produces a magnetic field around it, which attracts the iron. The field can be pictured by sprinkling iron filings on a sheet of paper and holding the sheet over the magnet. When the sheet is tapped gently the filings align themselves in a pattern around the magnet.

The earth is a natural magnet, which enables a compass to be used for direction finding.

Magnetic fields are also produced by an electric current. The magnetic field encircles the current-carrying wire, as illustrated in the diagram.

Magnetic field lines around a bar magnet (left) and a current-carrying wire (right)

If the current through the wire is not steady, but changes in strength and direction, these changes cause changes in the strength and direction of the magnetic field.

Mains electricity in New Zealand houses, and in almost all power lines, is an *alternating current* (AC)\*. An alternating current does not flow steadily in one direction, but oscillates backwards and forwards, making 50 complete cycles every second. Therefore, the magnetic field produced by such a current also oscillates at the same rate. This frequency is commonly

expressed as 50 Hertz (Hz), and falls into a range referred to as *extremely low frequency* (ELF). The magnetic fields can be referred to as *ELF magnetic fields*.

### **Electric fields**

The voltage on a current-carrying wire or electrically charged surface produces an electric field around it.

Like the current, the voltage on a cable or appliance carrying mains electricity is not constant but alternates 50 times every second. Therefore, the electric field also alternates and can be referred to as an *ELF electric field*.

### **Units of measurement**

ELF magnetic fields are normally quantified in terms of the *magnetic flux density*. The international (SI) unit of measurement is the tesla (T) or microtesla ( $\mu\text{T}$ ). 1 tesla = 1,000,000 microtesla. Some literature on the subject uses an older unit, the milligauss (mG). There is a factor of 10 difference between the microtesla and milligauss units:  $1 \mu\text{T} = 10 \text{ mG}$ ,  $0.1 \mu\text{T} = 1 \text{ mG}$ , etc. In this booklet, magnetic flux densities are given in microtesla, with the equivalent value in milligauss given in brackets.

Electric field strengths are measured in units of volts per metre (V/m) or kilovolts per metre (kV/m), where  $1 \text{ kV/m} = 1000 \text{ V/m}$ .

\* The exception is the power line linking the north and south islands. This is discussed in the section about static fields near the end of this booklet.

## **Sources of ELF electric and magnetic fields**

---

Electric and magnetic fields are present around all wires carrying electricity, whether they are high voltage power lines, house wiring, or wires inside domestic appliances. The strength of the electric field depends on the voltage, while the strength of the magnetic field depends on the size of the current carried. The strengths of the fields reduce rapidly with distance from the wires.

### **ELF electric fields**

Electricity transmission and distribution lines in New Zealand operate at voltages between 230 volts (normal household voltage) and 220,000 volts (220 kV). Lines operating at 400 kV have also been proposed. In other countries, high voltage (HV) transmission lines at voltages up to or above a million volts (1000 kV) are in use.

Under the highest voltage transmission lines currently used in New Zealand, the electric field strength can reach 3 kV/m\*. Trees and buildings shield electric fields, which can reduce their strength considerably. Field strengths inside buildings may be only a small fraction of the field strength outside, and be lower than the fields around electrical appliances.

Typical ELF electric field levels in different situations are presented over the page.

### **ELF magnetic fields**

The strength of the ELF magnetic field beneath a high voltage transmission line may reach up to around 5 microtesla (50 milligauss). The field may vary over the day and through the year as more or less current flows through the line.

\* 400 kV lines are discussed in the *Frequently Asked Questions* section at the end of this booklet.

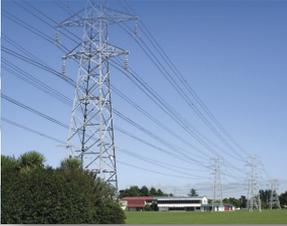

The field strength decreases quite rapidly with increasing distance from the line. Typically, within 50 to 100 metres of the line the magnetic field decreases to the levels found in many houses which are far away from any power lines.

Under low voltage (LV) distribution lines (that is, overhead street wires) the magnetic field may reach 2 microtesla (20 milligauss). Here too, the strength of the field decreases with increasing distance from the line. Magnetic fields are not shielded by trees, buildings or iron roofs. Magnetic fields around small “kiosk” transformers sited on the ground decrease to low levels within 2–3 metres.

Within a few centimetres of some electrical appliances, ELF magnetic fields may be much stronger than those under power lines. However, the fields normally decrease to much lower levels within a metre. The fields are strongest near appliances which contain an electric motor, such as hair dryers and food processors. For most people, their principal sources of exposure to ELF magnetic fields are electrical appliances and house wiring.

Typical magnetic field levels found in various locations are presented over the page.

## High voltage transmission lines

### Directly beneath line:

Electric fields: 0.3–3 kV/m

Magnetic fields: 0.5–5  $\mu\text{T}$  (5–50 mG)

### 40 metres from line:

Electric fields: 0.01–0.1 kV/m

Magnetic fields: 0.1–1  $\mu\text{T}$  (1–10 mG)

Generally, magnetic fields decrease to around 0.1  $\mu\text{T}$  (1 mG) within 50–100 metres of the line.

## Near street distribution lines

Electric fields: 0.01–0.1 kV/m

Magnetic fields: 0.05–2  $\mu\text{T}$  (0.5–20 mG)

## Substations

Electric fields: generally less than 0.1 kV/m except near where overhead supply lines enter or leave the station.

Magnetic fields: generally decrease to around 0.1  $\mu\text{T}$  (1 mG) within 5 metres of equipment except near where supply lines enter or leave the station.

## Local supply ('kiosk') transformers

Electric fields: less than 0.1 kV/m

Magnetic fields:

300 mm from transformer: 1–10  $\mu\text{T}$  (10–100 mG)

2–3 metres from transformer: around 0.1  $\mu\text{T}$  (1 mG)

### Near switchboard

#### Electric fields:

300 mm away: 20–100 V/m  
1–2 metres away: 10–30 V/m

#### Magnetic fields:

300 mm away: 1–3  $\mu\text{T}$  (10–30 mG)  
1–2 metres away: 0.1  $\mu\text{T}$  (1 mG)

### Inside a house or office (away from transmission lines and appliances)

Electric fields: 0.003–0.03 kV/m

Magnetic fields: 0.05–0.15  $\mu\text{T}$  (0.5–1.5 mG)

### Near appliances

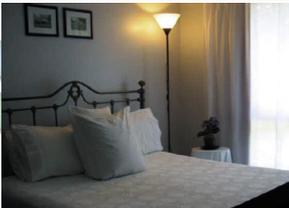

Electric fields: 0.01–0.05 kV/m

#### Magnetic fields:

300 mm away: 0.05–5  $\mu\text{T}$  (0.5–50 mG)  
1 metre away: 0.05–0.3  $\mu\text{T}$  (0.5–3 mG)

### Above electric blanket

Electric fields: 0.06–0.6 kV/m

Magnetic fields: 0.02–0.5  $\mu\text{T}$  (0.2–5 mG)

## **Health effects of ELF electric and magnetic fields**

---

The principal hazard to be avoided with electrical equipment is fatal electric shock from direct contact with conductors. Particular care should be taken by crane and yacht operators and agricultural contractors near power lines.

### **ELF electric fields**

When a person is in an ELF electric field, an alternating electric current flows in the body. Even in fields of 50 kV/m (well above the highest fields present under AC transmission lines), the induced currents are so small they cannot be felt.

In fields of several kV/m, sensitive individuals might feel minute vibrations of skin, hair or clothing. Some people may experience small shocks when touching large ungrounded objects (eg, a large bus) in these fields. These effects are harmless but can be irritating, especially if experienced persistently. However, they can be avoided by simple means such as earthing and screening, and normally people do not feel any sensation, even under even the highest voltage lines.

Studies of people and animals who have been exposed to ELF electric fields show that, at the strengths normally encountered in the home and under power lines, ELF electric fields do not cause health problems.

### **ELF magnetic fields**

ELF magnetic fields also induce very small electric currents in the body. The minute currents produced by fields near transmission and distribution lines and domestic appliances are far too weak to be felt, and are much lower than currents which occur naturally in the body.

Most laboratory studies have found that exposure to ELF magnetic fields has no effect on a wide range of biological processes. However, a few effects have been reported, such as changes in the flow of calcium in and out of cells, changes in hormone production and cell growth.

Although these changes are interesting to study, it is not clear whether they have any implications for health. Some of the effects reported only occurred under conditions quite different from everyday exposures, and many could not be replicated in other laboratories.

### **ELF magnetic fields and cancer**

A lot of research has been carried out to determine whether ELF magnetic fields might be a potential cause of cancer. This work has involved laboratory experiments with cell cultures and animals, and epidemiological studies of people who, because of where they live or work, may have higher exposures to magnetic fields than other people.

Overall, there is a wide consensus that there is a weak but relatively consistent association (correlation) between prolonged exposure to relatively strong magnetic fields and childhood leukemia. For example, a pooled analysis of the results from several studies, published in 2000, found that there was an increased incidence of childhood leukemia associated with exposure to time-averaged magnetic fields greater than 0.4  $\mu\text{T}$ . The fact that there is a correlation does not necessarily mean that there is a cause and effect relationship. The authors of the pooled analysis commented that “the explanation for the elevated risk estimates is unknown, but selection bias may have accounted for some of the increase.” (Selection bias is an artefact arising from the way the studies were carried out.)

The research findings have been reviewed by several panels of experts around the world\*, including the World Health Organization (WHO). Overall, these groups doubt that long term exposure to magnetic fields causes cancer. Although the relationship between childhood leukemia and magnetic field exposures suggests that there may be a link, laboratory research does not indicate any effect of magnetic fields on cancer. This includes several studies on animals exposed over their lifetimes. There are also considerable doubts that ELF magnetic fields, at the levels found around power lines and electrical appliances, could produce any effect at all.

\* Findings from recent reviews are summarised in the section *Summary of Conclusions from Recent Reviews*.

Other research has looked at cancer in adults who may be exposed to relatively high levels of ELF magnetic fields at home or in the course of their work. The review groups have concluded that there is no consistent evidence of a relationship between adult exposure and cancer risk.

### **ELF magnetic fields and other health effects**

There have been some studies of other health effects (such as Alzheimer's disease, suicide, depression, or altered melatonin levels) to see whether they might be related to magnetic field exposure. The findings from these studies, too, have been reviewed and found to give no persuasive evidence of any effects.

## Exposure guidelines

---

The National Radiation Laboratory recommends the use of guidelines published by the International Commission on Non-Ionizing Radiation Protection (ICNIRP). ICNIRP is an international scientific body and is recognised by the World Health Organization (WHO) for its expertise in this area.

The ICNIRP guidelines are based on a careful examination of the research data on the health effects of exposure to ELF fields, and include margins for safety. They were first proposed in 1990, and reconfirmed in 1993 and 1998 after consideration of more recent research. ICNIRP has continued to review new research published since 1998, but has not seen any need to amend their guidelines.

ICNIRP concluded that the only effects clearly evident in the research data were those caused by currents induced in the body by ELF electric and magnetic fields. In very strong fields, these induced currents could interfere with the body's nervous system, and so should be limited to levels where no effects can occur. For electric fields, ICNIRP also wished to limit the possibility of experiencing small shocks in strong electric fields.

While acknowledging the results of studies which found a weak association between ELF magnetic field exposures and the risk of childhood leukemia, ICNIRP considered that the results were too tenuous, and lacking support from other sources, to form the basis for exposure guidelines. Other recent reviews, including the 2007 WHO review, came to the same conclusion, and found that the data currently available did not justify setting more stringent exposure limits. The 2007 WHO review supported use of the ICNIRP guidelines.

The ICNIRP guidelines set a *basic restriction* on the density of electric current induced in the body by ELF fields. As induced current density is difficult to measure in the body, the guidelines also prescribe *reference levels* in terms of the more easily measured field strengths. Compliance

with the reference levels ensures compliance with the basic restrictions, and in most applications the reference levels can effectively be regarded as “exposure limits” (although this term is not used as such). If exposures exceed the reference levels, this does not necessarily mean that the basic restriction is also exceeded. However, a more comprehensive analysis is required in order to verify compliance with the basic restrictions.

**Basic restrictions and reference levels for occupational and public exposures to 50 Hz ELF electric and magnetic fields**

Exposure characteristics	Basic restriction Induced current density (mA/m <sup>2</sup> )	Reference levels		
		Electric field strength (kV/m)	Magnetic flux density	
			microtesla	milligauss
Occupational	10	10	500	5000
General public	2	5	100	1000

Note: All values are rms (root-mean-square, a kind of average)

Different limits are set for persons exposed occupationally and for the general public. The main reason for this is that people exposed occupationally are adults, exposed under controlled conditions, who should receive training to inform them of potential risks, and precautions they should be taking. They should be aware, for example, of the possibilities of receiving small shocks when touching objects in a strong electric field. Occupational exposures are limited to the duration of the working day and over the working lifetime.

The general public, on the other hand, includes individuals of all ages and in all states of health, who will not normally be aware of the exposure they are receiving. They can be exposed for twenty-four hours per day, and over a whole lifetime, and should not be expected to accept effects such as annoyance or pain due to small shocks and discharges.

The National Radiation Laboratory recommends that the occupational limits should only be applied to people like electricians or others who are aware of their exposures. In offices and most other work sites, the public limits should apply. In practice, exposures exceeding the public limits are extremely rare.

Compliance with the ICNIRP guidelines has been recommended in many countries. In countries where other recommendations are used, they generally have the same basis as ICNIRP, and recommend very similar exposure limits.

In New Zealand, a *National Policy Statement on Electricity Transmission* published in 2008 under the Resource Management Act requires that planning provisions dealing with ELF fields be based on the ICNIRP Guidelines and the 2007 WHO recommendations.

ICNIRP plans to publish revised Guidelines in 2009. While there may be changes in the detail, it is not anticipated that there will be significant changes to the basis of the Guidelines or the Reference Levels. Information on the changes will be posted on the NRL website ([www.nrl.moh.govt.nz](http://www.nrl.moh.govt.nz)) when it is available.

## **Should I be worried about ELF fields affecting my health?**

---

After some thirty years of research, there is still only weak evidence suggesting that ELF fields might be linked with childhood leukemia. The recent WHO review considered that if there were a true cause and effect relationship, there would be a “limited impact on public health”. Assuming a link does exist, worldwide the fields might be responsible for 0.2–4.9% of all childhood leukemia.

Put another way, although research may never give an absolute yes or no answer about the safety of ELF magnetic fields, we can say with some assurance that if a link is eventually proved, almost all cases of childhood leukemia would be caused by other factors. The pooled analysis of leukemia studies referred to previously included a New Zealand study, and found that none of 86 cases of childhood leukemia reported over a four year period had been exposed to strong magnetic fields (ie, average fields greater than 0.4  $\mu$ T). While this does not prove that there is no risk from magnetic fields, it does give an idea of the magnitude of any risk which may exist.

There is no persuasive evidence that magnetic fields which comply with the ICNIRP guidelines are associated with other health effects.

### **Prudent avoidance**

Different perceptions of risks can lead to different actions. Some people conclude that the current evidence for health risks from ELF fields is so tenuous, and the possible risks so small, that no action is necessary. They feel that there are plenty of known risks in life, and that it would be more worthwhile to direct their energies towards reducing these. Others find even the slight possibility of a risk sufficiently disturbing that they would like to take precautions anyway, just in case.

The idea of *prudent avoidance* has been suggested as a means to control exposures to ELF fields if there is any doubt that they are harmless. Prudent avoidance involves limiting exposures which can be avoided with small investments of money and effort, but not doing anything drastic or expensive.

For example, ELF magnetic fields within 50 centimetres of the switchboard in the house may reach one to three microtesla (10–30 milligauss). If someone's bed is situated very close to the switchboard, they may decide to move the bed a little further away to reduce their exposure while they sleep. However, deciding to switch off electricity at the mains every night or to rewire the house would not be seen as necessary.

When buying a new house, proximity to power lines might be one of many things considered. However, even if ELF fields were eventually shown to pose a health risk, factors such as traffic patterns in nearby streets, air quality, and hazards such as open fires, pools and common household appliances are likely to be more important for the health and safety of adults and children. Moving home to get away from power lines goes beyond what would be considered prudent avoidance.

The National Radiation Laboratory and Ministry of Health encourage the use of low or no cost measures to reduce or avoid exposures, and also promote this approach for the siting of new electrical facilities. This is consistent with a recommendation in the 2007 WHO review of ELF fields to take very low cost precautionary measures to reduce exposures, which has effectively been mandated in planning provisions by the 2008 *National Policy Statement on Electricity Transmission* made under the Resource Management Act.

### **Cardiac pacemakers**

A very small proportion of cardiac pacemakers has been found to be sensitive to 50/60 Hz electric and magnetic fields close to the ICNIRP limits for public exposure. (These same devices are also likely to be sensitive to other sources of electromagnetic interference, such as car ignition systems.) It is most likely that they will revert to a fixed pacing mode, which poses no immediate threat to the wearer. Since the field levels at which these effects occur are close to the ICNIRP limits for public exposure, the risk to members of the general public is thought to be extremely small. However, in workplaces where field strengths approaching the occupational limits are expected, precautions may need to be taken to alert or exclude pacemaker wearers.

There are no known instances of adverse effects on pacemaker users around power lines, or in other areas where exposure limits comply with the ICNIRP reference levels for the public.

## FREQUENTLY ASKED QUESTIONS

---

**Q** *Do power lines and electrical appliances emit radiation?*

**A** The electric and magnetic fields around power lines and electrical appliances are not a form of radiation. The word “radiation” is a very broad term, but generally refers to the propagation of energy away from some source. For example, light is a form of radiation, emitted by the sun and light bulbs.

ELF fields do not travel away from their source, but are fixed in place around it. They do not propagate energy away from their source. They bear no relationship, in their physical nature or effects on the body, to true forms of radiation such as x-rays or microwaves.

**Q** *Are ELF fields strongest around power line pylons?*

**A** On flat ground, ELF fields are weaker near the pylons than between them, because the cables are at their highest point above the ground. The fields are produced by the voltage on, and electric current through, the cables supported by the pylons. The pylons are simply there to keep the cables well above the ground.

**Q** *Does lead shield against ELF fields?*

**A** Lead is very good at shielding x-rays, but has no special shielding properties for ELF fields. Like other metals, lead is a conductor and so can shield electric fields. However, it does not shield magnetic fields. Special grades of steel or alloys are required to shield magnetic fields.

**Q** *In the past, it was thought that things like asbestos or smoking were safe, but many years later they were found to be harmful. How do we know that some time from now ELF fields are not going to pose the same problems that, say, asbestos does today?*

**A** Research on ELF fields shows that if they do pose a health risk, it must be very much lower than that due to asbestos or smoking. The health risks of both asbestos and smoking showed very strongly in initial investigations, and were confirmed by subsequent studies. Similar studies on ELF fields have not shown any clear, unambiguous evidence of health risks.

**Q** *How do the New Zealand exposure guidelines compare with those in other countries?*

**A** The International Commission on Non-Ionizing Radiation Protection exposure guidelines recommended by the National Radiation Laboratory have been adopted by many overseas bodies, including the European Union. All these bodies have considered research investigating the possibility that there may be an association between exposure to weak ELF magnetic fields and some types of cancer. However, they have concluded that, taken together, the evidence does not demonstrate a cause and effect relationship, and does not form a basis from which exposure guidelines can be formulated.

In the United States, there are no national guidelines. However, some individual states have set limits on the ELF magnetic field levels at the edges of power line rights of way. These vary from 15 to 25 microtesla (150 to 250 milligauss).

Some countries, in addition to adopting the ICNIRP guidelines, have also proposed lower “precautionary” limits in what are considered “sensitive areas”. Such areas generally include places like houses, parks and schools. The levels adopted tend to be based on what is

technically achievable (based on existing levels), and apply to new installations. Switzerland, for example, has set an “installation limit value” of 1  $\mu\text{T}$  (ie, the maximum field from any one installation should be less than 1  $\mu\text{T}$ ), and Italy has set an “attention value” of 10  $\mu\text{T}$  and a “quality goal” of 3  $\mu\text{T}$ . All these are time-averaged values.

The Ministry of Health and National Radiation Laboratory do not support the adoption of arbitrary limits which have no basis in the research data. On the one hand, they risk creating unnecessary alarm should exposures exceed the arbitrary level chosen. On the other, if there are genuine adverse health effects, an arbitrarily chosen exposure limit could create a false sense of security if those effects actually occur at a lower exposure level. Some research suggests that “precautionary limits” such as these can actually heighten concerns rather than alleviate them. The WHO does not support such arbitrary reductions either.

**Q** *Aren't exposures greater than 0.4  $\mu\text{T}$  quite common?*

**A** While there are many places where exposures might exceed 0.4  $\mu\text{T}$  (near an electric range, near many appliances, beneath low or high voltage power lines), these periods of high exposure are normally quite short. Research shows that when exposures are averaged over periods of a day or more, very few people have average exposures greater than 0.4  $\mu\text{T}$ .

**Q** *If I am concerned about possible health effects, what simple steps can I take to reduce my exposures to ELF fields?*

**A** In the home, fields are elevated near operating electrical appliances and meter boards and switchboards. The strength of the fields decreases quite rapidly with increasing distance from these sources, and generally decreases to levels found elsewhere in the home

within 0.5 to 1 metre. Simple means to reduce exposures (especially prolonged exposures) include the following:

- Keep beds more than one metre away from fuse boards, meter boards and electric heaters which operate at night.
- If you have a mains-powered motor driven bedside clock (eg. an older style clock with hands), keep it at arm's length from the bed.
- Switch off electric blankets when in bed (unless the electric blanket is used to remedy health problems).
- Switch off appliances when not in use.

**Q** *If I live near a high voltage transmission line, am I exposed to dangerous field levels?*

**A** Measurements on power lines in New Zealand have shown that even directly beneath the line, the electric and magnetic fields are well below the recommended exposure limits. Typically, the field levels decrease to the background levels found in many houses (from house wiring and domestic appliances) within 50–100 metres of the line.

**Q** *What about the proposals for new 400 kV transmission lines in New Zealand?*

**A** Transpower (the owner and operator of the national high voltage electricity grid) have made a commitment to comply with the ICNIRP guidelines in all publicly accessible areas near new transmission lines. They have also stated that the conductors will be arranged so as to ensure a rapid decrease in field strengths with distance from the line (an arrangement referred to as “reverse phasing”, generally regarded as a prudent avoidance measure). Calculations of the fields based on Transpower’s design confirm that they will comply with the ICNIRP guidelines.

**Q** *Does a transformer on the street affect exposures in my house?*

**A** Magnetic field levels around small “kiosk” transformers decrease to low levels within 2–3 metres, and have no effect on field levels in nearby houses.

**Q** *Who is monitoring the research in New Zealand?*

**A** The National Radiation Laboratory, a unit of the Ministry of Health, monitors research and briefs the Minister of Health on significant developments. Research is also reviewed regularly by the *Inter-Agency Committee on the Health Effects of Non-ionising Fields*, which includes representatives from government agencies, local government, health researchers, consumer groups and industry.

**Q** *When will we know whether ELF fields are safe or not?*

**A** It is actually very hard to prove that something is safe. Experiments can prove whether there are harmful effects, and the levels at which these effects occur. However, the absence of some effect under particular exposure conditions does not necessarily prove safety for all possible exposure conditions. If there were harmful effects from exposure to ELF fields, it is not at all clear what feature of the field – average level, exposure added up over time, variations in exposure, etc – might be important.

Nevertheless, the absence of a wide range of potentially harmful effects over a variety of exposure conditions gives good grounds for believing that adverse effects are unlikely.

## **Static electric and magnetic fields around DC lines**

---

For some long-distance transmission lines it is more economic to transmit electrical power as *direct current* (DC), where the current flows steadily in one direction. These lines produce static electric and magnetic fields.

The Benmore-Haywards line which links the North and South Islands via the Cook Strait cable is a High Voltage DC (HVDC) line.

### **Naturally occurring static fields**

Magnetic and electric fields which are largely unchanging or static over time, occur naturally. The most significant magnetic field is the geomagnetic field of the earth which varies between 35 and 70 microtesla (350 to 700 milligauss) depending on location.

In fair weather the lower atmosphere contains a static electric field of approximately 0.15 kV/m. During a thunderstorm the electric field strength between the ground and clouds can reach up to a few kV/m.

Static fields and charges are also commonly created by friction through the movement of clothing. Their presence can be felt when a small shock is experienced on touching a bare metal surface, as when touching a metal object after walking on some carpets. These shocks can be unpleasant but are harmless, even though voltages of up to 20 kilovolts may be generated.

### **Artificial static fields**

The static electric field strengths below the HVDC line in open country may reach up to about 30 kV/m. However, in built-up or wooded areas the field strengths can be much lower because of screening by trees, vegetation and buildings. The electric field is due to both the voltage on the line, and also due to the production of air ions (groups of molecules with a small electric charge) around it. The production and movement of air ions is greatly influenced by weather conditions, particularly the presence of wind and rain, so that the electric field under the line also varies.

Air ions are also produced by storms, waterfalls and flames, and as a result of air movement. The maximum ion concentration under the DC line is similar to higher levels found in some natural circumstances.

The static magnetic field beneath the HVDC line linking the North and South Islands has a strength of about half that of the earth's natural magnetic field. Similar static magnetic fields are usually present in electrified trolley buses, suburban rail systems, and much larger fields are experienced by operators in processes such as electrolytic smelting. Patients undergoing diagnostic magnetic resonance imaging examinations are exposed to even stronger fields, about 50,000 times greater than those present under DC lines.

### **Health effects of static fields**

Large metal objects beneath the line, such as vehicles or long fence wires, may build up enough electric charge to cause small shocks when they are touched. Often, however, car tyres and fence posts conduct enough electricity to keep these effects to a minimum.

Extensive overseas studies have not produced any good evidence of adverse health effects attributable to either DC electric fields or air ions associated with HVDC lines.

The static magnetic field beneath the HVDC line is smaller than the earth's magnetic field of around 50 microtesla. No health effects are expected at this level.

## Further reading

---

This booklet has given only a brief coverage of a complex subject. Below are some further references which provide additional information.

- ***ELF electromagnetic fields and the risk of cancer***  
This report was published in 2001 by the British National Radiological Protection Board Advisory Group on Non-Ionising Radiation (v 12, no. 1 in the series *Documents of the NRPB*). It updates previous reviews by that group published between 1992 and 1994 and is quite technical, but includes simpler summaries.
- ***Exposure to electromagnetic fields (0 Hz–10 MHz)***  
The Health Council of the Netherlands has set up an Electro-magnetic Fields Committee to review research on ELF fields. They published this report in March 2000 and it is available on the internet at [www.gr.nl/engels/welcome/frameset.htm](http://www.gr.nl/engels/welcome/frameset.htm) – follow links to publications and reports. Updates, also available at the same site, were published in 2001 and 2004.
- ***Interagency advisory committee on the health effects of electromagnetic fields: Report to Ministers. November 2004***  
This report reviews the health research available through to 2004, covering both ELF and radiofrequency fields, and sets out the Ministry of Health's recommendations on protection measures. It is available at <http://www.nrl.moh.govt.nz/publications/elf-rfreporttoministers.pdf>.

- ***Guidelines for limiting exposure to time-varying electric, magnetic and electromagnetic fields (up to 300 GHz)***

This document presents the ICNIRP exposure guidelines which are recommended for use in New Zealand. It is very technical and not an easy read. Originally published in the journal Health Physics volume 74, No 4, p. 494-522, 1998. It can also be downloaded on the internet at [www.icnirp.de](http://www.icnirp.de) – select “downloads”.

- ***Exposure to static and low frequency electromagnetic fields, biological effects and health consequences (0–100 kHz)***

This report was published by ICNIRP in 2003 and is a comprehensive review of laboratory and epidemiological studies of exposures to static and ELF fields.

- ***Fields from electric power. What are they? What do we know about possible health risks? What can be done?***

This is a set of three brochures prepared in 1995 by the Department of Engineering and Public Policy at Carnegie Mellon University, Pittsburgh, USA. Although not covering the most recent research, much of the discussion (on the nature and occurrence of ELF fields, possible health effects, and possible courses of action) is still relevant. They are written in non-technical language.

Publications not available on the internet may be available from local libraries. If your library does not hold them, they can be borrowed from the National Radiation Laboratory through the library interloan service.

Information is also available on the internet at:

- [www.who.int/peh-emf/](http://www.who.int/peh-emf/)  
This is the home page of the International EMF project, set up by the WHO in 1996 to coordinate a programme to review the scientific literature on health effects of electric and magnetic fields, encourage focused research to fill gaps in knowledge, assess possible health risks and encourage internationally acceptable, uniform exposure standards. A series of fact sheets is available.
- <http://www.microwavenews.com/www.html>  
This site, operated by Microwave News, contains links to many other sites of interest.
- [www.nrl.moh.govt.nz](http://www.nrl.moh.govt.nz)  
This is the web site of the National Radiation Laboratory.
- [www.emf-portal.de](http://www.emf-portal.de)  
This site, set up and operated by the University of Aachen, provides a database of information on studies into the effects of electromagnetic fields. It also covers the radiofrequency fields from radio transmitters.

## **Appendix: Summary of conclusions from recent reviews**

---

### **World Health Organization (2007)**

- There are established short-term effects of exposure to ELF fields, and compliance with existing international guidelines provides adequate protection.
- Epidemiological studies suggest an increased risk of childhood leukemia for chronic exposures greater than 0.3–0.4  $\mu\text{T}$ . Some aspects of the methodology of these studies introduce uncertainties in the hazard assessment. Laboratory evidence and mechanistic studies do not support a causal relationship, but the evidence is sufficiently strong to remain a concern. If the relationship is causal, the global impact on public health, if any, is limited and uncertain.
- Scientific data suggesting a linkage with other diseases (other childhood and adult cancers, depression, suicide, reproductive problems, developmental and immunological disorders, and neurological disease) is much weaker, and in some cases (eg, cardiovascular disease, breast cancer) sufficient to rule out a causal relationship.
- Exposure limits such as those recommended by ICNIRP should be implemented to protect against the established acute effects of exposure to ELF fields. In view of the conclusions on childhood leukemia, the use of precautionary approaches is reasonable and warranted but exposure limits should not be reduced arbitrarily in the name of precaution.
- Precautionary approaches should not compromise the health, social and economic benefits of electric power. Given the weakness of the link between exposures to ELF fields and childhood leukemia, and the limited impact on public health if the relationship is causal, the benefits of exposure reductions are unclear, so the cost of precautionary measures should be very low.

- Very low cost measures should be implemented when constructing new facilities and designing new equipment (including appliances). When contemplating changes to existing ELF sources, ELF field reduction should be considered alongside safety, reliability and economic aspects.

The WHO report can be downloaded from [http://www.who.int/peh-emf/publications/elf\\_ehc/en/index.html](http://www.who.int/peh-emf/publications/elf_ehc/en/index.html). An information sheet is available at <http://www.who.int/mediacentre/factsheets/fs322/en/index.html>.

### **International Agency for Research on Cancer (2001)**

- There is a fairly consistent statistical association between childhood leukemia and exposure to comparatively high ELF fields. This is unlikely to have been due to chance, but may be affected by selection bias.
- There is no consistent relationship between exposures to ELF fields and the incidence of other childhood cancers, or adult cancers.
- Laboratory studies have shown no consistent enhancement of tumours in experimental animals, and other results have been generally negative.
- Overall, ELF magnetic fields fall within Class 2B (“possibly carcinogenic to humans”) of the IARC classification scheme. This puts them in the same class as car exhaust, coffee and pickled vegetables. Class 2A (probably carcinogenic) includes diesel exhaust, sun lamps and PCBs, and Class 1 (carcinogenic) includes alcoholic drinks, benzene and asbestos.

### **(British) National Radiological Protection Board (2004)**

- Studies on the effects of ELF fields on the central nervous system provide a basis for setting quantitative exposure limits.
- Evidence on other possible effects, mostly from studies into possible effects on cancer, are insufficient to make a conclusive judgement on causality or to provide quantitative exposure limits. However, such studies taken together with people's concerns provide a basis for considering the possible need for further precautionary measures in addition to quantitative restrictions on exposures.
- The ICNIRP basic restrictions and reference levels should be used for controlling exposures.

The report can be downloaded from [www.hpa.org.uk/radiation/publications/documents\\_of\\_nrpb/abstracts/absd15-3.htm](http://www.hpa.org.uk/radiation/publications/documents_of_nrpb/abstracts/absd15-3.htm). Related publications produced by the NRPB (now the Radiation Protection Division of the Health Protection Agency) include *Advice on Limiting Exposure to Electromagnetic Fields (0-300 GHz)* (which was based on the review discussed above), available at [http://www.hpa.org.uk/radiation/publications/documents\\_of\\_nrpb/abstracts/absd15-2.htm](http://www.hpa.org.uk/radiation/publications/documents_of_nrpb/abstracts/absd15-2.htm), and *Power Frequency Electromagnetic Fields, Melatonin and the Risk of Breast Cancer*, published in 2006 and available at <http://www.hpa.org.uk/publications/PublicationDisplay.asp?PublicationID=31>.

### **National Radiation Laboratory**

The National Radiation Laboratory (NRL) is a unit of the Ministry of Health. It is based in Christchurch.

Its role is to provide a regulatory function in the radiation health area, and to provide independent radiation protection advice.

*Received for publication November 29, 2005; accepted for publication March 7, 2006.*

It is still under debate whether occupational exposure to radio frequency/microwave electromagnetic fields (RF/MW-EMF) contributes to the development of brain tumors. This analysis examined the role of occupational RF/MW-EMF exposure in the risk of glioma and meningioma. A population-based, case-control study including 381 meningioma cases, 366 glioma cases, and 1,494 controls aged 30–69 years was performed in three German regions in 2000–2003. An exposure matrix for occupational activity was constructed by using information on RF/MW-EMF exposure collected in a computer-assisted personal interview. “High” exposure was defined as an occupational exposure that may exceed the RF/MW-EMF exposure limits for the general public recommended by the International Commission on Non-Ionizing Radiation Protection. Multiple conditional logistic regressions were performed separately for glioma and meningioma. No significant association between occupational exposure to RF/MW-EMF and brain tumors was found. For glioma, the adjusted odds ratio for highly exposed persons compared with persons not highly exposed was 1.21 (95% confidence interval: 0.69, 2.13); for meningioma, it was 1.34 (95% confidence interval: 0.64, 2.81). However, the slight increase in risk observed with increasing duration of exposure merits further research with larger sample sizes.

brain neoplasms; case-control studies; electromagnetic fields; occupations; radiation

Abbreviations: CI, confidence interval; RF/MW-EMF, radio frequency/microwave electromagnetic fields.

The question of whether occupational exposure to radio frequency/microwave electromagnetic fields (RF/MW-EMF) contributes to the development of brain tumors is still under debate. Interest in this specific frequency of RF/MW-EMF in the whole range of EMF, including extremely low frequency EMF or static fields, has risen, particularly because of cellular telephones. In 1988, Milham et al. (1) reported a nonsignificantly increased standardized mortality ratio of 1.39 (95 percent confidence interval (CI): 0.93, 2.00)

for amateur radio operators. In subsequent years, several ad hoc analyses on this issue were published (2). As of now, seven cohort studies (1, 3–8) are known to have been published, but results are not consistent (table 1). A study of military personnel in Poland showed a significantly increased relative risk of several nervous system tumors, including brain cancer, in persons exposed to RF/MW-EMF (7). However, few details were given on the study methods used, and the increased risk of so many cancer types

† Included malignant neoplasm of the brain and malignant neoplasm of other parts of the nervous system.

associated with radio frequency radiation has raised concerns about the validity of the results (9). In two case-control studies, a significant association between occupational exposure to RF/MW radiation and the risk of brain cancer was found (10, 11). One of these studies (10) even found a significant dose-response relation between duration of exposure and brain cancer risk. The other case-control study was nested in a cohort study of male members of the US Air Force. An increased risk for persons ever exposed to occupational RF/MW-EMF was reported, with an odds ratio of 1.39 (95 percent CI: 1.01, 1.90). However, there was no trend with either intensity of exposure or duration of exposure (11).

None of these studies analyzed the association between occupational RF/MW-EMF and nonmalignant brain tumors. Experimental, up-to-date research provides no convincing evidence that low-level RF/MW-EMF exposure is involved in carcinogenesis. However, most of the discussion on the effect of RF/MW-EMF exposure refers to the hypothesis of a possible promoting effect of the exposure but not on the genetic mutation itself (12).

The aim of this analysis of the German part of the international Interphone Study was to investigate the association between RF/MW-EMF exposure and the risk of brain tumors in glioma and meningioma patients and in population controls. This paper focuses especially on occupational exposure

to RF/MW-EMF, which was assessed by using information from a comprehensive personal interview including questions about job titles and specific occupational activities.

## MATERIALS AND METHODS

### Study population

A population-based, case-control study (the German part of the international Interphone Study) was performed in line with the core protocol of the international Interphone Study (13). Incident meningioma and glioma cases aged 30–59 years (later extended to age 69 years) at the date of diagnosis were selected from four neurosurgical clinics located in Bielefeld, Heidelberg/Mannheim, and Mainz (covering some 6.6 million inhabitants). These four large clinics cover the metropolitan and rural areas surrounding these cities. Cases were eligible if their tumor was diagnosed between October 1, 2000, and October 31, 2003. On October 1, 2001, after receiving additional funding for the German part of the Interphone Study, the study was extended to include cases and controls aged 60–69 years at the date of diagnosis. Cases were all patients with histologically confirmed diagnoses of primary glioma or meningioma (benign or malignant) to ensure that no other brain tumors—for example, metastases, embryonic tumors, or tumors of the hemopoietic system—were included in the study. Therefore, 22 cases without histologic confirmation of their diagnosis were excluded. The following types of brain tumors (*International Classification of Diseases for Oncology*, Third Edition) were included for glioma: topography codes C71.0–C71.9 and morphology codes 9380–9383, 9390–9393, 9400–9401, 9410–9411, 9420–9421, 9424, 9440–9442, and 9450–9451. For meningioma, *International Classification of Diseases for Oncology*, Third Edition, topography code C70.0 and morphology codes 9530–9539 were included.

In total, 891 eligible patients were identified for the study. All were contacted by an interviewer after approval by the physician responsible for their treatment. The overall response rate for cases was 83.8 percent ( $n = 747$ ) and was slightly lower for glioma patients (79.6 percent) than for meningioma cases (88.4 percent). For the analysis, data for 366 glioma patients and 381 meningioma patients were available. For glioma patients, the causes for not participating were death ( $n = 42$ ), being too ill to answer the questions ( $n = 24$ ), refusal ( $n = 22$ ), or loss of contact after discharge from the hospital ( $n = 6$ ). For some patients who were not able to answer, proxy interviews with relatives were performed ( $n = 40$ ). The reasons for nonparticipation of meningioma patients were refusal ( $n = 21$ ), being too ill to answer the questions ( $n = 16$ ), loss of contact after discharge from the hospital ( $n = 9$ ), and death ( $n = 4$ ). Proxy interviews were performed for five meningioma cases.

A total of 2,449 eligible controls frequency matched to the cases by sex, age, and center were drawn from the compulsory population registries in the three regions. Participating in the study were 62.7 percent of them ( $n = 1,535$ ). Contact by letter and telephone was made several times to improve the response rate. The reasons for nonparticipation in the study were refusal ( $n = 747$ ), loss of contact ( $n =$

118), being too ill ( $n = 48$ ), and death ( $n = 1$ ). At the end of the data collection phase, a post hoc 1:2-person matching was performed by assigning two controls to each case matched by sex, birth year ( $\pm 2$  years), and region (Bielefeld, Heidelberg/Mannheim, Mainz; few exceptions) to adjust for the time lag in interviewing cases and controls. By using this method, the exposure period for the controls was censored at the date of diagnosis of the matched case. Two corresponding controls were matched to each case. For the analyses, data for 732 individually matched controls for the 366 glioma cases and 762 controls for the 381 meningioma cases were available. More details on the materials and methods are published elsewhere (14).

### Data collection

Computer-assisted personal interviews were conducted by trained interviewers and included questions on demographic characteristics; use of cellular telephones, transmitters, and ham radios; smoking and medical histories; diagnostic treatment; and occupational activities related to EMF and ionizing radiation. Most cases were interviewed during their stay in the hospital or, if this option was not possible, at home, after their surgery. The controls were mostly interviewed at home. Each interviewer questioned cases as well as controls. The duration of the interview was compared between cases and controls. Mean duration was 52.0 minutes for controls (standard deviation, 18.9) and 55.1 minutes for cases (standard deviation, 19.7). At the beginning of the study, the computer-assisted personal interview was not available. Therefore, a printed version was used for the first 7 months for interviews with 122 cases and 202 controls. However, unlike the computer-assisted personal interviews, the printed version did not include all details of occupational history. For these first 7 months, only so-called screening questions on occupational history were asked. Persons who reported any of the activities listed in these screening questions were approached later for a more detailed telephone interview when the computer program was available. Sensitivity analyses were performed to test for differences in the results by data collection method.

### Occupational exposure assessment

A detailed questionnaire on occupational activities related to RF/MW-EMF and the whole range of EMF, including static fields and very low frequency EMF, as well as ionizing radiation, was constructed by the International Exposure Assessment Committee of the Interphone Study. In this analysis, only RF/MW-EMF details were assessed. Information on the following occupational activities was derived from this questionnaire; screening questions about possible activities with RF/MW-EMF exposure asked about 1) using industrial heating equipment to process food; to bond, seal, and weld materials; or to melt, dry, and cure materials; 2) manufacturing semiconductor chips or microelectronic devices; 3) using radar; 4) maintaining electromagnetic devices used to treat or diagnose diseases; 5) working with or nearby broadcasting and telecommunications antennae and masts; 6) using different kinds of transmitters; and 7) using

a ham radio. The following screening questions were not considered because the activities mentioned were not related to RF/MW-EMF exposure: 1) working next to electrical motors; 2) being employed by an electric company; 3) working directly on or around any electric transport; 4) constructing, maintaining, or repairing electrical machinery or equipment; 5) using industrial machinery powered by electric motors; 6) using other electrical equipment not mentioned before; 7) working with ionizing radiation; and 8) being employed as an airline pilot or crew member.

Occupations associated with the following frequency ranges were considered: radio transmission (30–300 MHz); cellular and personal communication, including ham radio use (800 MHz–2GHz); and industrial applications such as microwave heating and medical applications, and rarely for ham radio use (up to 2.45 GHz) (15). Because of the small numbers of observations, we included all frequency ranges in one exposure category. However, most of the considered exposures were related to personal communication devices (800 MHz–2 GHz).

The following procedure was used to estimate exposure to RF/MW-EMF. First, all persons who marked one of the activities listed in the above-mentioned screening questions were selected.

Second, all activities mentioned by at least one person were classified with regard to possible exposure to RF/MW-EMF. The computer-assisted personal interviews included some detailed questions to determine whether the occupation led to a measurable exposure to RF/MW-EMF. All activities were classified into four categories based on the scientific literature (16–26) as well as on a review by two German industrial hygienists. Some occupational activities mentioned in these screening questions were categorized as “no RF/MW-EMF” exposure. Examples included a physician working with an electrocardiogram, a cook working in a kitchen, all types of metal welding, and binding and gluing plastic and nylon without microwave heating.

The remaining activities were classified according to the degree or the likelihood of exposure. If the exposure existed and was probably present continuously during the mentioned working hours, the activity was categorized as “probable” exposure. If the exposure surely existed continuously during the mentioned working hours and sometimes exceeded 0.08 W/kg (which corresponds to the exposure limits of RF/MW-EMF for the general population (27)), this activity was categorized as “high” exposure. The International Commission on Non-Ionizing Radiation Protection guidelines allow these exposure limits for the general public to be exceeded by a factor of five for occupational exposures (27). A certain exposure that did not exceed the general exposure limits was considered a probable exposure because it occurred only rarely. Finally, activities were grouped as “not probable” when the activity mentioned was related to RF/MW-EMF but it was presumed that the person was not exposed to RF/MW-EMF. For example, the use of a transmitter inside a car was regarded as an exposure to RF/MW-EMF only when it was mentioned that the transmitter antenna was located inside the car.

Third, the different activities were grouped together for each person, and duration of exposure in each summarized

category was calculated. For example, a person who worked from 1980 to 1989 in an RF/MW-EMF exposed job categorized as probable exposure and from 1990 to 1995 in an RF/MW-EMF exposed job categorized as high exposure was considered RF/MW-EMF exposed for 15 years, including 5 years with high RF/MW-EMF exposure. Only those activities up to 2 years prior to the date of diagnosis of the tumor or the reference date for controls, respectively, were taken into account.

A description of probable and high exposure activities is presented in table 2, and a flow chart of the exposure categorization used is shown in figure 1. The activities were categorized without knowledge of the disease status of the participant. The activity exposure matrix includes 277 activities; among those, 130 are classified as high exposure, 147 as probable exposure, and 212 as not probable exposure.

### Statistical analysis

Conditional logistic regression was performed to account for frequency matching by using SAS software (version 9.1; SAS Institute, Inc., Cary, North Carolina). All regression models were stratified for the three regions and for sex. Adjusting variables were socioeconomic status, urban ( $\geq 100,000$  inhabitants) vs. rural ( $< 100,000$  inhabitants) area, corresponding age at diagnosis, smoking history, and ionizing radiation exposure. Socioeconomic status was based on educational and occupational training in Germany, yielding three levels. Smoking history was considered current smoker, former smoker, or nonsmoker. Ionizing radiation was categorized into four groups: (0) no exposure; (1) at least five lifelong radiographic examinations but no computed tomography (excluding radiographic examinations of a single tooth); (2) more than five radiographic examinations or at least one computed tomography, angiography, and/or szintigraphy; and (3) occupational exposure to ionizing radiation for at least 5 years, or any radiation therapy. Only those examinations considering the head and neck were included. The use of cellular telephones was not deemed a confounder. Sensitivity analyses were performed to consider the use of cellular telephones as a confounder. However, the results were very similar to those presented here and are therefore not shown. Occupational exposure was analyzed with three different models:

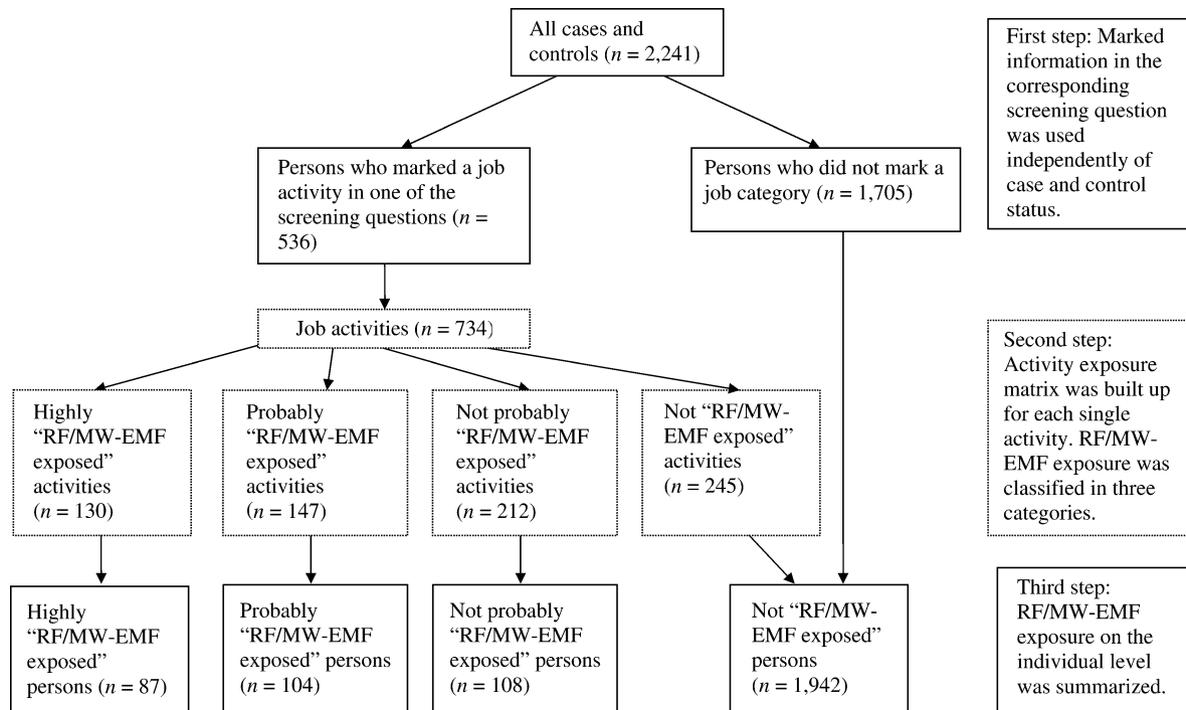

1. Model 1: any RF/MW-EMF exposure (no/yes).
2. Model 2: four categories—no exposure, not probable, probable, and high.
3. Model 3: three categories considering duration of exposure—no high exposure (including no exposure, not probable, and probable), less than 10 years of high exposure, and 10 or more years of high exposure. The category of high exposure was introduced to increase sensitivity by taking into account duration of exposure. All other potential exposure categories were considered not exposed because they do not exceed the exposure limits for the general population. By doing so, a potential threshold above the limits of the general population was examined.

**TABLE 2. Job activities and their grouping according to intensity of RF/MW-EMF\* exposure, German Interphone Study (Bielefeld, Heidelberg/Mannheim, and Mainz), 2000–2003**

Activity and gradient†	Activity title	No. of activities	Reference no(s).
Industrial heating			
Probable	Wood veneer with glue heat curer	4	23
Probable	Vulcanization of rubber	3	19
Probable	Rubber glued, bonded, sealed, welded, or cured with microwave heating equipment	2	16, 18, 19
Probable	Heating of rubber with pressure-sealed applicator	1	18, 19
Probable	Heating of metal with dielectric heating equipment	1	16, 26
High	Dielectric radio frequency heating equipment	1	16, 19, 22, 23, 25, 26
Treatment or diagnosis of disease			
Probable	Use of microwave therapy equipment	4	23
Probable	Use of shortwave therapy equipment	3	19
Probable	Operator of hyperthermia devices (e.g., electrocautery)	1	26
High	Use of microwave therapy or diathermy equipment	2	24
Radar			
Probable	Use of radar during military service, at the airport, or in other civil services; no adjusting, no technical work with the radar equipment	27	16, 19, 20, 22
Probable	Radar used by hand or by a technician maintaining and controlling radar	3	16, 18
Broadcasting			
Probable	Working in civil and military telecommunication services, but not working on the antenna while operating antennas and not for home or private use	14	16, 20, 26
Probable	Technician for cellular telephone base stations or for personal communication services	2	16, 26
High	Telecommunication in telecommunication/mobile communication services, military, and radio broadcasting, working one third of the time on the antenna while operating it	9	16, 21, 26
Ham radio			
Probable	Ham radio operator using private equipment less than 5 hours per week	11	17
High	Ham radio operator and working on the antenna while operating it	4	17
Transmitter			
Probable	Use of walkie-talkies	71	17, 19, 24
High	Use of communication devices (CB* radios, satellite telephones, UHF/VHF* used on boats and other marine vessels' radios on ships, other personal radios for professional use, for example, aviation and private security, with antennas held in the hand, beside the head, or inside the car)	114	17, 19, 24
Total			
Probable	Number of "probable" "RF-EMF exposed" activities	147	
High	Number of "high" "RF-EMF exposed" activities	130	

\* RF/MW-EMF, radio frequency/microwave electromagnetic fields; CB, citizens band; UHF/VHF, ultra high frequency/very high frequency.

† Gradient: probable means probable RF/MW-EMF exposure, high means high RF/MW-EMF exposure.

**FIGURE 1.** Flow chart of the structure of the exposure matrix for specific activities involved in occupations. Data were derived from the German Interphone Study (Bielefeld, Heidelberg/Mannheim, and Mainz), 2000–2003. Boxes with solid lines indicate individual data, boxes with broken lines indicate data based on each mentioned activity. RF/MW-EMF, radiofrequency/microwave electromagnetic fields.

The analyses were repeated after excluding data from proxy interviews. The results were very similar to those presented here and are therefore not shown. Sensitivity analyses were conducted after excluding persons for whom the full computerized personal interview was impossible. For gliomas, the results were very similar to those presented here. For meningioma, possibly because of small numbers, differences within the random variation of the results were found.

## RESULTS

The distribution of major characteristics of the study population is presented in table 3. The median age was 53 years for glioma cases and 55 years for meningioma cases and did not differ between cases and controls. Nearly 60 percent of glioma cases were male, whereas only 27 percent of meningioma cases were male. Compared with that for cases, socioeconomic status of controls in both diagnostic groups was slightly higher. Most of the cases and controls were recruited from urban areas.

Overall, 104 persons were considered probably exposed to RF/MW-EMF and 87 as highly exposed. The results of the crude and adjusted conditional logistic regressions are presented in table 4 for glioma and in table 5 for meningioma. RF/MW-EMF exposure was not associated with occurrence of glioma or meningioma in the total study population. For glioma (table 4), the adjusted odds ratio

was 1.04 (95 percent CI: 0.68, 1.61). However, when we included duration of RF/MW-EMF exposure and focused solely on high exposure, the odds ratios for gliomas increased slightly. For persons who worked less than 10 years, the adjusted odds ratio for high exposure compared with not high exposure was 1.11 (95 percent CI: 0.48, 2.56); for persons who worked 10 years or more, the corresponding odds ratio was 1.39 (95 percent CI: 0.67, 2.88).

The results of the conditional logistic regressions with regard to the association between RF/MW-EMF exposure and occurrence of meningioma were similar (table 5). The adjusted odds ratio for exposure to RF/MW-EMF was 1.12 (95 percent CI: 0.66, 1.87). The adjusted odds ratios for high exposure compared with not high exposure were 1.14 (95 percent CI: 0.37, 3.48) for an exposure of less than 10 years and 1.55 (95 percent CI: 0.52, 4.62) for an exposure of 10 years or more.

## DISCUSSION

To our knowledge, our case-control study is the first in which exposure to RF/MW-EMF has been investigated among a large number of persons by using a detailed interview on occupational history and particular job activities. No significant association between occupational exposure to RF/MW-EMF and brain tumors was found in the data from the German part of the Interphone case-control study.

Regular use	138	37.7	283	38.7	104	27.3	234	30.7

A slightly increased risk was observed for high exposure in comparison with probable exposure as well as an increasing odds ratio with increasing duration of years in high-exposure jobs. However, this result should be interpreted with caution, particular because of the small number of exposed persons.

Our results resemble those from the other case-control studies analyzing the association between RF/MW-EMF exposure and development of brain tumors. Thomas et al. (10) found an odds ratio of 1.6 (95 percent CI: 1.0, 2.4) for persons ever exposed to occupational RF radiation and a significant dose-response association between years of working

and brain cancer death. Grayson (11) analyzed persons ever exposed to occupational RF/MW-EMF and found an odds ratio of 1.39 (95 percent CI: 1.01, 1.90). However, in contrast to our results, a dose response, in this study measured by a potential exposure score, was not found in that study (11). Five cohort studies revealed no association between occupational RF/MW-EMF exposure and the occurrence of brain tumors (3–6, 8). For amateur radio operators, a non-significant standardized mortality ratio of 1.39 (95 percent CI: 0.93, 2.00) was found (1). However, there is currently little evidence from cellular and animal studies of the carcinogenicity of RF/MW-EMF (15).

† Conditional logistic regression with frequency matching for center and sex, adjusted for socioeconomic status, urban vs. rural area, ionizing radiation exposure, smoking history, and age at diagnosis.

Measurement of RF/MW-EMF exposure was subject to some methodological discussion; cohort studies that are analyzing a large number of persons acknowledge the difficulty in identifying actually exposed persons rather than occupational groups (28). Thus, no data on individual shielding systems and day-to-day duration of individual exposure were available. This limitation might have led to an exposure classification with high specificity but low sensitivity. This type of nondifferential misclassification in dichoto-

mous exposure assessment is associated mostly with an outcome measure biased toward the null effect (29). The older case-control study (10) used two methods of classifying RF/MW-EMF: first, subjects' occupational history was assigned a three-digit code for industry and a census code for occupations; second, each job listed in the occupational history was categorized by a certified industrial hygienist as high, moderate, or low. In the nested case-control study performed among the US Air Force population, a subgroup

of persons exposed to RF/MW-EMF above permissible exposure limits ( $10 \text{ mW/cm}^2$ ) was identified by a historical list of incidents. All other job titles were assigned to the non-exposed category (11).

Our assessment of occupational exposure was based on individual activities during employment instead of job titles. Doing so enabled us to consider individual exposure to RF/MW-EMF and the use of shielding systems. In particular, the category of high-exposure activities derived from the comprehensive questionnaire was established to consider the specific exposure situation during an activity. This method was used to allow a more sensitive exposure estimation of the real situation and a more specific exclusion of a nonexposure situation during a possible-exposed occupation.

This study has some limitations, which is common in case-control studies. First, recall bias may have been present, particularly because of the extensive questionnaire used. It might be that cases, because of their preoccupation with disease, overestimated their exposure compared with that of controls (recall bias type A). It could also happen that, because of their disease, cases were unable to answer accurately (recall bias type B). Recall bias A might lead to an overestimation of occupational exposure and should be particularly obvious in occupational screening questions. However, because we constructed the activity exposure matrix from given information in the computer-assisted personal interviews, participants did not know which answer was used to determine RF/MW-EMF exposure. Thus, in the high RF/MW-EMF exposed group, recall bias A is unlikely. Recall bias B was also analyzed by performing a sensitivity analysis for all interviews, excluding proxy interviews. As mentioned above, the results for both analyses did not differ. The potential impact of selection bias also needs to be discussed in case-control studies. The response rate differed between cases (83.8 percent) and controls (62.4 percent). Selection bias related to exposure to occupational RF/MW-EMF may not be as obvious in this analysis of the Interphone Study as it is for the exposure in connection with cellular phone use. Analysis of a short nonresponder questionnaire showed that male, but not female, controls were more likely to refrain from regular cellular phone use as well as to refuse to participate in this study (14).

The number of observed cases in cohort studies of RF/MW-EMF exposure is small because brain tumors are rare (table 1). Until now, the number of cases included in this case-control study (366 glioma cases and 381 meningioma cases) is the highest of all published case-control studies investigating occupational RF/MW-EMF exposure. Nevertheless, the number of people with high exposure among cases and controls identified is still small (22 glioma cases and 11 meningioma cases). Hence, there might not be enough statistical power to find a possible small risk, particularly for patients with a long duration of exposure.

All frequency ranges of RF/MW-EMF were included in one exposure category. In the high-exposure group, 114 of 130 activities (table 2: area transmitter) occurred in the context of personal communication devices representing the frequency range of 800 MHz–2 GHz (15). To our knowledge, there is no different etiologic mechanism in discus-

sions of the different frequency ranges of RF/MW-EMF and the stated promoting effect on tumors. Furthermore, in the group with high exposure, we considered the limit among the general public recommended by the International Commission on Non-Ionizing Radiation Protection. These limits are equal for all considered frequency ranges (specific absorption rate of  $0.08 \text{ W/kg}$ ) and are based on the established thermal effect in all of these RF/MW-EMF frequency ranges (27).

To our knowledge, this is the first time that the association between RF/MW-EMF exposure and nonmalignant brain tumors such as meningioma has been considered. The results for meningiomas and gliomas were virtually identical. Meningiomas and gliomas are of different tissue origin; meningiomas arise from meningotheia cells, whereas gliomas arise from glial cells. Compared with gliomas, meningiomas might be associated with a longer latency period. Up to now, no previously published study has been known to show an association between RF/MW-EMF exposure from cellular phone use and meningioma. Positive associations with glioma have been reported in two of six studies, but methodological considerations limited interpretability of the findings (30). Therefore, the similar association we found for long-duration exposure among highly exposed participants concerning both brain tumor types and the exposure of RF/MW-EMF found in our analysis should be discussed. The stated tumor-promoting effect of RF/MW-EMF might be the same for meningiomas and gliomas. In our study, the high-exposure category was defined so we could look for a potential effect of an RF/MW-EMF exposure above the exposure limits for the general population. Although doing so may strengthen the plausibility of the results, it leads to the effect that only a few persons are regarded as "exposed." Furthermore, it cannot be excluded whether potential information bias or selection bias could lead to a similar increase in risk of both brain tumor entities. For confirmation of these results, further analysis of the pooled Interphone data set is awaited.

This study shows the first known results concerning exposure to RF/MW-EMF in the frame of occupational activities and occurrence of glioma and meningioma. We did not find a significant association between occupational exposure to RF/MW-EMF and brain tumors, but odds ratios for both glioma and meningioma were slightly increased for long-duration and high exposure. These results were based on low numbers of exposed participants and need be confirmed by the results of the pooled analyses of the Interphone Study. In a larger data set, it will also be possible to perform a stratified analysis of different types of brain tumors such as high-grade or low-grade gliomas, of gender, of different exposure estimates for activities associated with particular RF/MW-EMF frequency ranges, and of a higher number of expected long-term RF/MW-EMF exposed workers.

## ACKNOWLEDGMENTS

## **“Pandemic is Over” – Former Pfizer Chief Science Officer Says “Second Wave” Faked On False-Positive Tests**

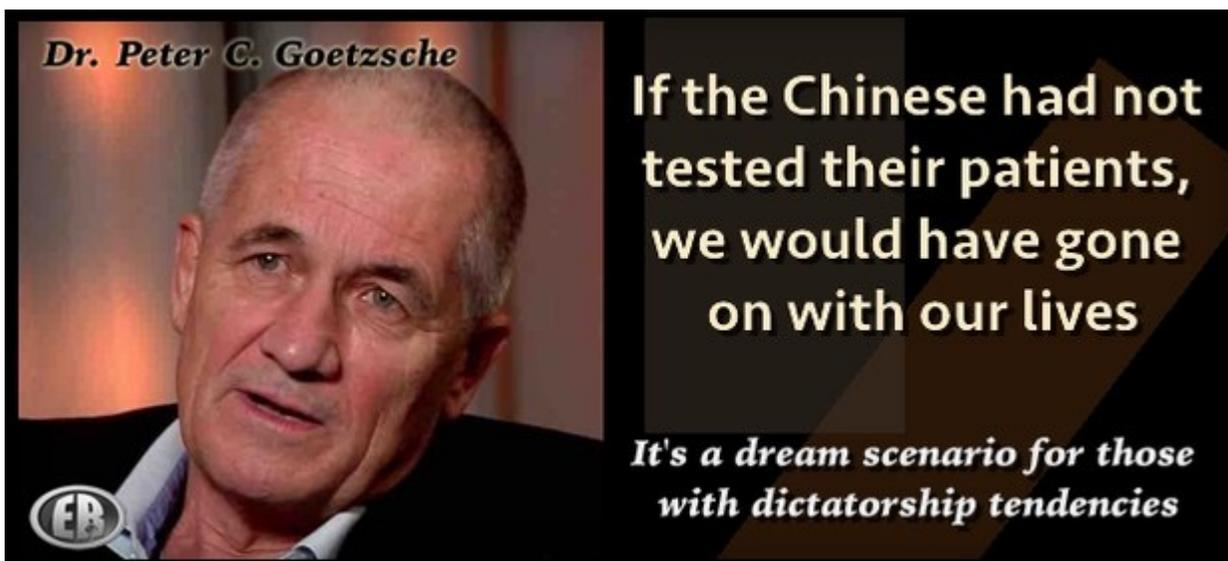

[Mon 9:24 am +00:00, 23 Nov 2020](#)

posted by Weaver

**ER Editor:** We’re linking to a piece we published on April 1, 2020, which brings us full circle, with a boatload of experts back then questioning the virus hype: [TWENTY-TWO Experts Questioning the Coronavirus Panic \[VIDEOS & Scientific Common Sense\]](#). And this from March 30 by the esteemed Dr. Peter Goetsche of the Cochrane Institute: [Coronavirus: An Epidemic of Mass Panic](#).

March was the time of the greatest number of infections, with the greatest number of deaths following on in April. Data experts said we locked down during March when it was already evident that the number of infections were about to decline. As Goetsche said back then, ‘it’s a dream scenario for those with dictatorship tendencies.’

The video by Dr. Mike Yeadon below is well worth listening to closely for his both expert opinion and common sense reasoning about the virus.

\*\*\*\*\*

## **“Pandemic is Over” – Former Pfizer Chief Science Officer Says “Second Wave” Faked On False-Positive COVID Tests**

## TYLER DURDEN

This video provides one of the most erudite and informative looks at Covid-19 and the consequences of lockdowns. As [AIER notes](#), **it was remarkable this week to watch as it appeared on YouTube and was forcibly taken down only 2 hours after posting.**

The copy below is hosted on LBRY, a blockchain video application. In a year of fantastic educational content, this is one of the best we've seen.

Consider the presenter's [bio](#):

**Dr. Michael Yeadon is an Allergy & Respiratory Therapeutic Area expert with 23 years in the pharmaceutical industry. He trained as a biochemist and pharmacologist, obtaining his PhD from the University of Surrey (UK) in 1988.**

Dr. Yeadon then worked at the Wellcome Research Labs with Salvador Moncada with a research focus on airway hyper-responsiveness and effects of pollutants including ozone and working in drug discovery of 5-LO, COX, PAF, NO and lung inflammation. With colleagues, he was the first to detect exhaled NO in animals and later to induce NOS in lung via allergic triggers.

**Joining Pfizer in 1995**, he was responsible for the growth and portfolio delivery of the Allergy & Respiratory pipeline within the company. He was responsible for target selection and the progress into humans of new molecules, **leading teams of up to 200 staff across all disciplines** and won an Achievement Award for productivity in 2008.

Under his leadership the research unit invented oral and inhaled NCEs which delivered multiple positive clinical proofs of concept in asthma, allergic rhinitis and COPD. He led productive collaborations such as with Rigel Pharmaceuticals (SYK inhibitors) and was involved in the licensing of Spiriva and acquisition of the Meridica (inhaler device) company.

**Dr. Yeadon has published over 40 original research articles** and now consults and partners with a number of biotechnology companies. **Before working with Apellis, Dr. Yeadon was VP and Chief Scientific Officer (Allergy & Respiratory Research) with Pfizer.**

What likely triggered the Silicon Valley censor-mongers is the fact that a former Chief Science Officer for the pharmaceutical giant Pfizer says **“there is no science to suggest a second wave should happen.”** The “Big Pharma” insider asserts that false positive results from inherently unreliable COVID tests are being used to manufacture a “second wave” based on “new cases.”

[As Ralph Lopez write at HubPages](#), Yeadon warns that half or even “almost all” of tests for COVID are false positives. Dr. Yeadon also argues that the threshold for herd immunity may be much lower than previously thought, and may have been reached in many countries already.

[In an interview last week](#) (see below) Dr. Yeadon was asked:

**“we are basing a government policy, an economic policy, a civil liberties policy, in terms of limiting people to six people in a meeting...all based on, what may well be, completely fake data on this coronavirus?”**

Dr. Yeadon answered with a simple “yes.”

Even more significantly, even if all positives were to be correct, Dr. Yeadon said that given the “shape” of all important indicators in a worldwide pandemic, such as [hospitalizations](#), ICU utilization, and deaths, “the pandemic is fundamentally over.”

Yeadon said in the interview:

**“Were it not for the test data that you get from the TV all the time, you would rightly conclude that the pandemic was over, as nothing much has happened. Of course people go to the hospital, moving into the autumn flu season...but there is no science to suggest a second wave should happen.”**

In a paper published this month, which was co-authored by Yeadon and two of his colleagues, [“How Likely is a Second Wave?”](#), the scientists write:

**“It has widely been observed that in all heavily infected countries in Europe and several of the US states likewise, that the shape of the daily deaths vs. time curves is similar to ours in the UK. Many of these curves are not just similar, but almost super imposable.”**

In the data for UK, Sweden, the US, and the world, it can be seen that in all cases, deaths were on the rise in March through mid or late April, then began tapering off in a smooth slope which flattened around the end of June and continues to today. The case rates however, **based on testing**, rise and swing upwards and downwards wildly.

**Media messaging in the US is already [ramping up expectations](#) of a “second wave.”**

The survival rate of COVID-19 has been upgraded since May to [99.8% of infections](#). This comes close to ordinary flu, the survival rate of which is 99.9%. Although COVID can have serious after-effects, [so can flu](#) or any respiratory illness. The present survival rate is far higher than initial grim guesses in March and April, cited by Dr. Anthony Fauci, of 94%, or 20 to 30 times deadlier. The Infection Fatality Rate (IFR) value accepted by Yeadon *et al* in the paper is .26%. The survival rate of a disease is 100% minus the IFR.

**Dr. Yeadon pointed out that the “novel” COVID-19 contagion is novel only in the sense that it is a new type of coronavirus. But, he said, there are presently four strains which circulate freely throughout the population, most often linked to the common cold.**

In the scientific paper, Yeadon *et al* write:

**“There are at least four well characterised family members (229E, NL63, OC43 and HKU1) which are endemic and cause some of the common colds we experience, especially in winter. They all have striking sequence similarity to the new coronavirus.”**

The scientists argue that much of the population already has, if not antibodies to COVID, some level of **“T-cell” immunity from exposure to other related coronaviruses**, which have been circulating long before COVID-19.

The scientists write:

“A major component of our immune systems is the group of white blood cells called T-cells whose job it is to memorise a short piece of whatever virus we were infected with so the right cell types can multiply rapidly and protect us if we get a related infection. Responses to COVID-19 have been shown in dozens of blood samples taken from donors before the new virus arrived.”

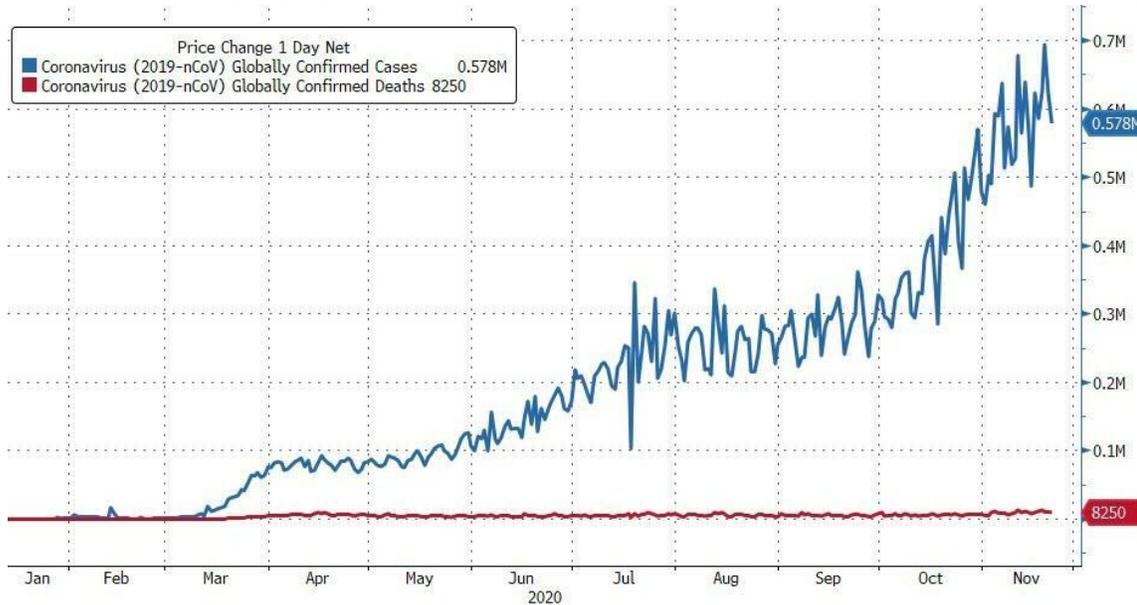

Introducing the idea that some prior immunity to COVID-19 already existed, the authors of “How Likely is a Second Wave?” write:

**“It is now established that at least 30% of our population already had immunological recognition of this new virus, before it even arrived...COVID-19 is new, but coronaviruses are not.”**

They go on to say that, because of this prior resistance, **only 15-25% of a population being infected may be sufficient to reach herd immunity:**

“...epidemiological studies show that, with the extent of prior immunity that we can now reasonably assume to be the case, only 15-25% of the population being infected is sufficient to bring the spread of the virus to a halt...”

In the US, accepting a death toll of 200,000, and a survival rate of 99.8%, this would mean for every person who has died, there would be about 400 people who had been infected, and lived. This would translate to around 80 million Americans, or 27% of the population. **This touches Yeadon’s and his colleagues’ threshold for herd immunity.**

**Finally, the former Pfizer executive and scientist singles out one former colleague for withering rebuke for his role in the pandemic, Professor Neil Ferguson (pictured). Ferguson taught at Imperial College while**

**Yeadon was affiliated.** Ferguson's [computer model](#) provided the rationale for governments to launch draconian orders which turned free societies into virtual prisons overnight. Over what is now estimated by the CDC to be a 99.8% survival rate virus.

Dr. Yeadon said in the interview that “no serious scientist gives any validity” to Ferguson’s model.

Speaking with thinly-veiled contempt for Ferguson, Dr. Yeadon took special pains to point out to his interviewer:

**“It’s important that you know most scientists don’t accept that it [Ferguson’s model] was even faintly right...but the government is still wedded to the model.”**

Yeadon joins other scientists in castigating governments for following Ferguson’s model, the assumptions of which all worldwide lockdowns are based on. One of these scientists is [Dr. Johan Giesecke](#), former chief scientist for the European Center for Disease Control and Prevention, who **called Ferguson’s model “the most influential scientific paper” in memory, and also “one of the most wrong.”**

It was Ferguson’s model which held that “mitigation” measures were necessary, i.e. social distancing and business closures, in order to prevent, for example, over 2.2 million people dying from COVID in the US.

**Ferguson predicted that Sweden would pay a terrible price for no lockdown, with 40,000 COVID deaths by May 1, and 100,000 by June. Sweden’s death count is under 6,000.** The [Swedish government says](#) this corresponds to a mild flu season. Although initially higher, Sweden now has a lower death rate per-capita than the US, which it achieved without the terrific economic damage still ongoing in the US. [Sweden never closed](#) restaurants, bars, sports, most schools, or movie theaters. The government never ordered people to wear masks.

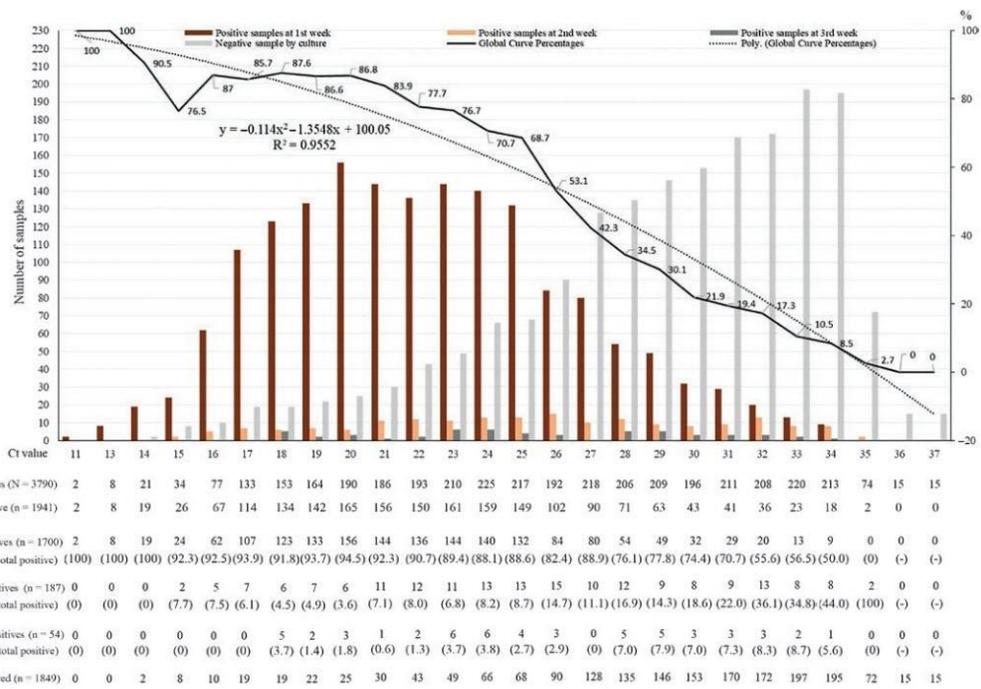

**Dr. Yeadon speaks bitterly of the lives lost as a result of lockdown policies, and of the “saveable” countless lives which will be further lost, from important surgeries and other healthcare deferred, should lockdowns be reimposed.**

Watch the full discussion below:

Yeadon’s warnings are confirmed by a new study from [the Infectious Diseases Society of America](#)., summarized succinctly in the following [twitter thread from al gato malo \(@boriquagato\)](#)

**Anyone still presuming that a Positive PCR test is showing a COVID case needs to read this very carefully:**

- even with 25 cycles of amplification, 70% of “positives” are not “cases.” Virus cannot be cultured; it’s dead.
- by 35: 97% non-clinical.
- the US runs at 40, 32X the amplification of 35. (*ER: France is using cycle thresholds of 35-40*)

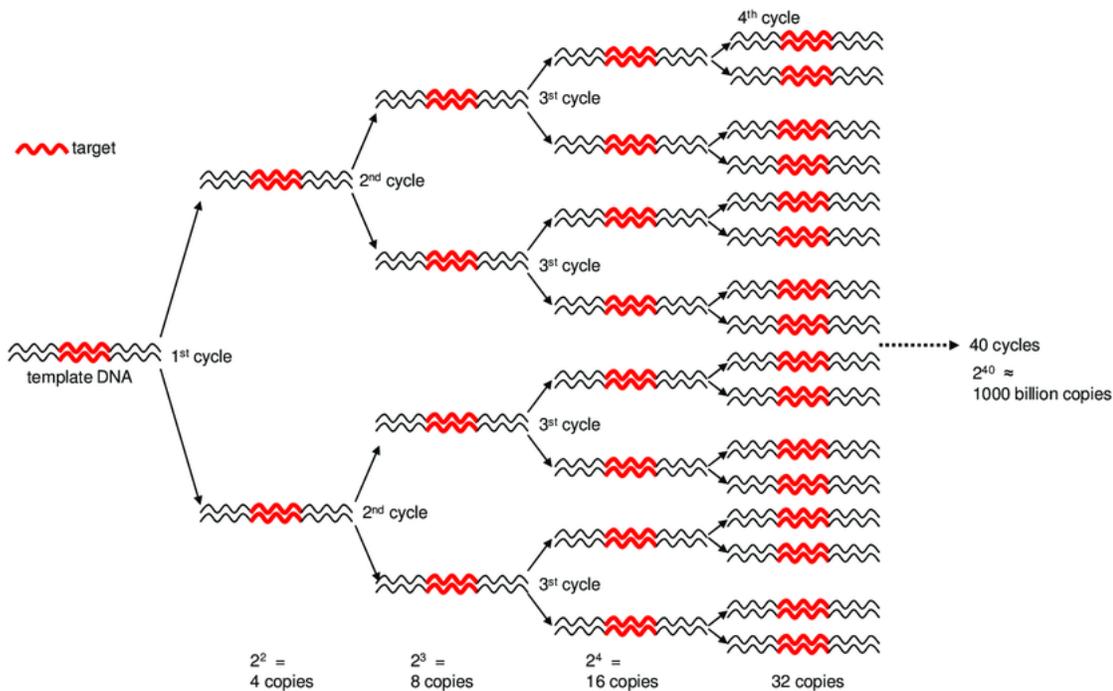

**Figure 1.** Percentage of positive viral cultures of severe acute respiratory syndrome coronavirus 2 polymerase chain reaction–positive nasopharyngeal samples from coronavirus disease 2019 patients, according to Ct value (plain line). The dashed curve indicates the polynomial regression curve. Abbreviations: Ct, cycle threshold; Poly., polynomial.

**A lot of people still seem to not understand what this means, so let's lay that out for a minute.**

PCR tests look for RNA. There is too little in your swab, so they amplify it using a primer-based heating and annealing process.

**Each cycle of this process doubles the material**

**The US (and much of the world) is using a 40 Ct (cycle threshold). So, 40 doublings, 1 trillion X amplification.**

**This is absurdly high.**

The way that we know this is by running this test, seeing the Ct to find the RNA, and then using the same sample to try to culture virus.

If you cannot culture the virus, then the virus is “dead.” It’s inert. If it cannot replicate, **it cannot infect you or others.** It’s just traces of virus, remnants, fragments, etc.

**PCR is not testing for disease, it’s testing for a specific RNA pattern** and this is the key pivot.

When you crank it up to 25, 70% of the positive results are not really “positives” in any clinical sense.

I hesitate to call it a “false positive” because it’s really not. It did find RNA, but that RNA is not clinically relevant.

**It cannot make you or anyone else sick**

So let’s call this a non-clinical positive (NCP).

- if 70% of positives are NCP’s at 25, imagine what 40 looks like. 35 is 1,000X as sensitive.
- this study found only 3% live at 35
- 40 Ct is 32X 35, 32,000X 25

**No one can culture live virus past about 34** and we have known this since March. yet no one has adjusted these tests.

**This is more very strong data refuting the idea that you can trust a PCR+ as a clinical indicator.**

That is NOT what it’s meant for. At all.

**Using them to do real time epidemiology is absurd.**

At the beginning of the outbreak, we correlated Ct values obtained using our PCR technique based on amplification of the E gene and the results of the culture [8]. Since the beginning of the pandemic, we have performed 250 566 SARS-CoV-2 RT-PCR for 179 151 patients, of whom 13 161 (7.3%) tested positive. Up to the end of May, 3790 of these samples, reported as positive on nasopharyngeal samples, were inoculated and managed for culture as previously described [8]. Of these 3790 inoculated samples, 1941 SARS-CoV-2 isolates could be obtained after the first inoculation or up to 2 blind subcultures. The correlation between the scanner values and the positivity of the culture allows us to observe that the image obtained with 10 times more isolates than in our preliminary work (1941 vs 129) does not change significantly (Figure 1). It can be observed that at Ct = 25, up to 70% of patients remain positive in culture and that at Ct = 30 this value drops to 20%. At Ct = 35, the value we used to report a positive result for PCR, <3% of cultures are positive. Our Ct value of 35, initially based on the results obtained by RT-PCR on control negative samples in our laboratory and initial results of cultures [8], is validated by the results herein presented and is in correlation with what was proposed in Korea [9] and Taiwan [10]. We could observe that subcultures, especially the first one, allow an increasing percentage of viral isolation in samples with Ct values, confirming that these high Ct values are mostly correlated with low viral loads. From our cohort, we now need to try to understand and define the duration and frequency of live virus shedding in patients on a case-by-case basis in the rare cases when the PCR is positive beyond 10 days, often at a Ct >30. In any cases, these rare cases should not impact public health decisions.

The FDA would never do it, the drug companies doing vaccine trials would never do it... it's **because it's nonsense.**

**And this same test is used for “hospitalizations” and “death with covid” (itself a weirdly over inclusive metric)**

PCR testing is not the answer, it's the problem.

**It's not how to get control of an epidemic, it's how to completely lose control of your data picture and wind up with gibberish and we have done this to ourselves before.**

**A quick word what this data does and does not mean.**

Saying “a sample requiring 35 Ct to test + has a 3% real clinical positive rate” does not mean “97% of + tests run at 35 Ct are NCP's”

People seem to get confused on this, so let's explain:

**Most tests are just amplified and run. They don't test every cycle as these academics do. That would make the test slow and expensive, so you just run 40 cycles then test.**

Obviously, a real clinical positive (RCP) that would have been + at 20 is still + at 40.

But when you run the tests each cycle as the academics do, that test would already have dropped out.

So saying that only 3% at 35 are RCP really means that 3% of those samples not PCR + at 34 were PCR and RCP + at 35.

This lets us infer little about overall NCP/RCP rate.

***So we cannot say "at 25 Ct, we have a 70 NCP rate." In fact, it's hard to say much of anything. It depends entirely on what the source material coming in looks like.***

You cannot even compare like to like.

***This is what i mean by "the data is gibberish"***

Today at 40 Ct, 7% PCR positive rate could be 1% RCP prevalence when that same thing meant 6% RCP prev in april.

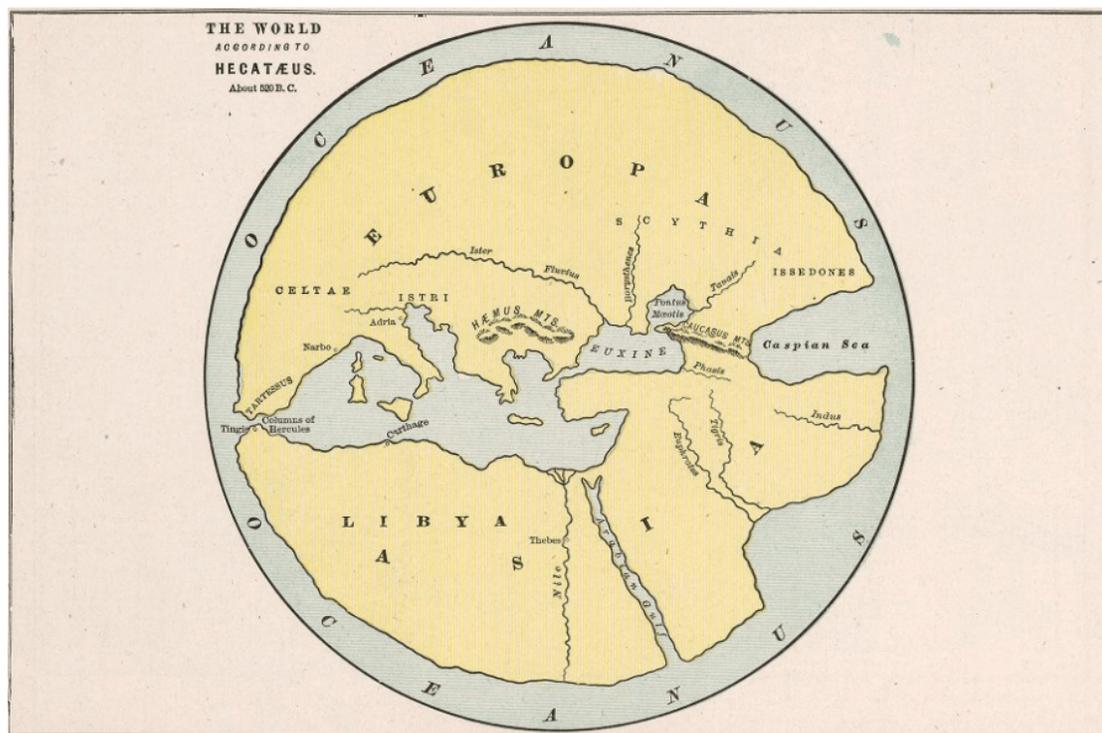

**If there is lots more trace virus around, more people who have recovered and have fragments left over, etc, this test could be finding virus you killed 4 months ago.**

So if we consider RCP rate/PCR+ rate, we would expect that number to drop sharply late in an epidemic because there is more dead virus around for PCR to find, but we have no idea what that ratio is or how it changes.

**This spills over in to deaths, reported hospitalization, etc.**

Testing is being made out to be like the high beams on a car, but when it's snowing like hell at night, that is the LAST thing you want. It is not illuminating our way, it's blinding us.

**A bad inaccurate map is much worse than no map at all, and this is a world class bad map...**

**We're basing policy that is affecting billions of humans on data that is uninterpretable gibberish.**

It's a deranged technocrat's wet dream, but for those of us along for the ride, it's a nightmare.

**Testing is not the solution, it's the problem.**

Any technocrat or scientist that does not know this by now is either unfit for their job or has decided that they just don't care and prefer power to morality.

This is, of course, precisely the kind of person who winds up running a gov't agency... oopsie.

**The head of the NIH is not the best scientist, it's the best politician.**

All this wild and reckless government policy has never been about the science.

**It's politics and panic.**

You can read the whole paper here: <https://academic.oup.com/cid/advance-article/doi/10.1093/cid/ciaa1491/5912603>

# Nobel Laureate, PCR Inventor Said Fauci Was a Liar, Abusing Test Data For An Agenda And Afraid To Debate

Published December 11, 2020 By [David Knight](#)

The Nobel Laureate inventor of the PCR test, Kary Mullis, died at the age of 74 back in August of 2019 but prior to his death, he had a lot of interaction with Fauci.

He'd already gone to war with Fauci for misusing his PCR test. Mullis and other scientists said Fauci was magnifying the retrovirus HIV using PCR to "prove" it was the cause of AIDS. Mullis was furious that Fauci refused to debate him on science but argued from authority.

Does this all sound familiar? It's another reason why this COVID "novel" was not credible from the beginning. In the past, Fauci, CDC, etc, had abused test methods many times to push pandemics and pharmaceuticals.

"The strategy for locking us down again is based on these fraudulent tests. The magnified tests that don't measure the quantity of anything. It's the same strategy Fauci used to make a lot of money for a lot of people. It's not just the PCR test, all these rapid tests, every one of them, they're all NON-QUANTITATIVE tests. There's no such thing as a non-quantitative test, it's a lie, an obvious fraud. We're locking everybody down over brainless lies. The only reason they were able to get away with this is because they've turned us into an idiocracy, that was the whole point of the government schools."

"[Mullis] always said you couldn't use [PCR] to diagnose a disease but in this particular clip, he goes directly after Fauci and tells what a liar he is," reported David Knight on 12/10/2020's show.

Knight then played the clip (here: <https://twitter.com/libertytarian/status/1336993923076665346>) where Mullis said, "These guys like Fauci get up there and start talking to me, you know, he doesn't know anything really about anything, and I'd say that to his face. Nothing. The man thinks you can take a blood sample and stick it in an electron microscope and if it's got a virus in there you'd know it. He doesn't understand electron microscopy, and he doesn't understand medicine, and he shouldn't be in the position he's in. Most of those guys up there on the top are just total administrative people, and they don't know anything about what's going on at the bottom. Those guys have an agenda, which is not what we would like them to have, being that we pay for them to take care of our health in some way. They've got a personal kind of agenda, they make up their own rules, they change them as they go. And Tony Fauci doesn't mind going on television in front of the people who pay his salary and lie directly into the camera."

Knight comments, "Fauci didn't want to have the debate because he only argues from AUTHORITY. Mullis didn't believe that there was a connection between HIV and AIDS and said they're making this connection by misusing his test. He said we all have retroviruses and they're, literally, blowing this way out of proportion. They're amplifying it a TRILLION times, that's what a PCR cycle of 40 does." The FDA requires PCR testing of COVID to be 40 CT (cycle threshold).

"There's an excellent article about Mullis and his conflict with Fauci by Celia Farber (here: <https://uncoverdc.com/2020/04/07/was-the-covid-19-test-meant-to-detect-a-virus/>).

Knight comments, “Mullis didn’t believe that AIDS was caused by HIV, partly because it was barely detectable in AIDS patients. When PCR was used, they were able to see viral particles in quantities they couldn’t see before.”

Farber reports, ”Mullis himself was unimpressed. ‘PCR made it easier to see that certain people are infected with HIV,’ Mullis told Spin in 1992, ‘and some of those people came down with symptoms of AIDS. But that doesn’t begin even to answer the question — Does HIV cause it?’ ”

“Does that sound familiar?” asked Knight. “They misuse the PCR test and all of a sudden we’ve got cases everywhere. They did a complete media blackout of the HIV debate for over 7 years. Just like with vaccines right now.”

“Remember that the first thing Fauci did as director of the NIH was to make sure that BigPharma had legal immunity for any damage from vaccines. And remember, this was less than 10 years after we’d been rushed into a swine flu vaccine over a fake pandemic and a lot of people were injured by it. That was the reason he had to do it, it had nothing to do with science, it’s all about politics and money.”

But Fauci also took the reins of NIH’s infectious diseases as AIDS/HIV was pushed to the front by him and by media.

Mullis said “The mystery of [AIDS] has been generated by the \$2 billion a year they spend on it. You take any other virus, and you spend \$2 billion, and you can make up some great mysteries about it too.”

Knight compares the financial incentives of the AIDS industry in 1990s with GreatReset financial and political incentives with COVID. “What if you spend \$20 billion on it? What if you were to reorder society and take everything from everyone over it? What if the pot at the end of all this is worth TENS of TRILLIONS of dollars to the bankers, globalists, and the politicians who work for them? For TRILLIONS of dollars, they could reset the whole world.” And all it takes is magnifying a virus a trillion times with a PCR of 40 CT.

“There are many parallels between what Fauci did with AIDS and what he’s doing with COVID. Mullis pointed out that the misuse of his test was just being done because there’s money involved. For 7-years the media stopped anyone questioning what Fauci said about AIDS. They’ve been censoring the debate over vaccines for quite some time and they’re going to step it up. YouTube was bragging about how they’re going to pull down any videos of anyone who questions the election now.”

“It’s a clear violation of the First Amendment, they’re taking our right to know, to debate. These people don’t want to debate, Mullis was saying he’d challenged Fauci but he wouldn’t show up. They will control the press, just like they did a blackout on AIDS, they’ll do a blackout on this vaccine,” concluded Knight.

# Peer Reviewed Published Research Studies on Wi-Fi and 2.4 GHz Wireless Frequencies

Many people ask “What research has been done on Wi-Fi frequencies? Do we know that they are as harmful as cell phone radiation frequencies?”

There are several research studies done on W-Fi specifically that have found adverse effects. However it is important to recognize that Wi-Fi is radio frequency radiation. Almost all the wireless frequencies long used by the public are categorized as radio frequency radiation.

People have not been using Wi-Fi for as long as they have been using cell phones, so the research on humans that has looked at long term use of cell phones is very important to understand the long term health risks from wireless and Wi-Fi.

A 2017 study [“Measurements of Radiofrequency Radiation with a body-borne exposimeter in Swedish schools with Wi-Fi”](#) concluded that, “The risk for cancer may be accentuated for children partly because of their likely longer life-time use of wireless devices, but also since their smaller size and thinner skull bone give higher RF radiation to the brain. Children are also growing and have more immature cells which can be more sensible to RF radiation.” This study higher RF levels when students streamed videos.

[Lahham 2019](#) followed adults from the West Bank, Palestine and found their total daily exposure from all radiofrequency electromagnetic field sources varied widely depending on their location, the mobile network they use, their activities, and their mode of transportation. The main contribution to the mean exposure was from WiFi 2G (45%), GSM900 uplink (19%), GSM900 downlink, and FM radiobroadcasting (each by 11%). GSM1800, UMTS2100, WiFi 5G, DECT, TETRA, WiMAX, and TV bands all together contributed 14%. During different activities, participants were exposed to the highest exposure level while traveling and to the lowest exposure while they were sleeping.

A [2019 publication](#) in the industry journal Building and Environment summarizes the scientific evidence showing harmful effects at low levels- well below government limits and details best practices in buildings to reduce radiofrequency as including wired technology instead of Wi-Fi, and corded phones in buildings.

The World Health Organization [International Agency for the Research on Cancer’s classification](#) of wireless radiofrequency frequencies a Class 2B carcinogen includes wireless radiation from any transmitting source such as cellphones, baby monitors, tablets, cell towers, radar, other wifi, etc. The radiofrequency classification applies to RF-EMF in the range of 30 KHz to 300 GHz emitted from any device. Cell phone frequencies commonly start at 900 MHz (with some cell phones having up to 7 antennas all at different frequencies) and Wi-Fi device frequencies are at 2.45 GHz and 5GHz.

A study entitled [Radiofrequency at 2.45 GHz increases toxicity, pro-inflammatory and pre-apoptotic activity caused by black carbon in the RAW 264.7 macrophage cell line](#) published in Science of the Total Environment found a sub thermal exposure of 2.45 GHz – the frequency used in Wi-Fi- combined with fine/coarse black carbon prolong innate and inflammatory immune responses. “Radiofrequency (RF) dramatically increased BC-induced toxicity at high doses in the first 24 h and toxicity levels remained high 72 h later for all doses.” The paper concludes, “Our results indicate that the interaction of BC and RF modifies macrophage immune response, activates apoptosis, and accelerates cell toxicity, by which it can activate the induction of hypersensitivity reactions and autoimmune disorders.”

Many scientists now conclude that the [scientific evidence](#) is [substantial](#) enough to conclude that radiofrequency radiation (including radiation from cell phones, Wi-Fi and other wireless devices) is a human carcinogen.

While cell phones localize the highest microwave exposure to the brain, Wi-Fi exposures are often localized with more intense exposures to the abdomen, leg and chest area. However this is not always the case as some people sleep in rooms with Wi-Fi baby monitors, Wi-Fi routers or Wi-Fi gaming devices near their pillow. Wi-Fi printers may be in offices next to a person's desk and most people are unaware that they transmit continuously.

Wi-Fi devices emit continuous radiation bursts, just like cell phones, as they always stay in contact with their router or base station. The Wi-Fi radiation patterns can be quite erratic when the device is in use and this can further impact biological effects.

### **Compendium of Research studies on Wi-Fi and 2.4 GHz Wireless Frequencies**

Pall M., [Wi-Fi is an important threat to human health](#), Environmental Research Volume 164, July 2018, Pages 405-416

- (Review paper) "Repeated Wi-Fi studies show that Wi-Fi causes oxidative stress, sperm/testicular damage, neuropsychiatric effects including EEG changes, apoptosis, cellular DNA damage, endocrine changes, and calcium overload. Each of these effects are also caused by exposures to other microwave frequency EMFs, with each such effect being documented in from 10 to 16 reviews." Wi-Fi is thought to act via voltage-gated calcium channel activation.

Fahmy, H., & Mohammed, F. (2020). [Hepatic injury induced by radio frequency waves emitted from conventional Wi-Fi devices in Wistar rats.](#) *Human & Experimental Toxicology*. <https://doi.org/10.1177/0960327120946470>

- The present data revealed that Wi-Fi exposure leads to severe oxidative stress in the rat liver. Furthermore, Wi-Fi exposure resulted in deleterious effects in the liver function and alters its molecular structure. Moreover, severe histological and ultrastructural alterations are reported in the hepatic tissues points to hepatotoxic effects induced by Wi-Fi exposure.

Ibitayo, A., Afolabi, O., Akinyemi, A., Ojiezeh, T., Adekoya, K. and Ojewunmi, O., 2017. [RAPD Profiling, DNA Fragmentation, and Histomorphometric Examination in Brains of Wistar Rats Exposed to Indoor 2.5 Ghz Wi-Fi Devices Radiation.](#) BioMed Research International, 2017, pp.1-6.

- The present study was conducted to investigate the injurious effect of radiofrequency emissions from installed Wi-Fi devices in brains of young male rats. Animals were divided into four equal groups; group 1 served as control while groups 2, 3, and 4 were exposed to 2.5 Ghz at intervals of 30, 45, and 60 consecutive days with free access to food and water ad libitum. Alterations in harvested brain tissues were confirmed by histopathological analyses which showed vascular congestion and DNA damage in the brain was assayed using agarose gel electrophoresis. Histomorphometry analyses of their brain tissues showed perivascular congestion and tissue damage as well."

Adejoke Olukayode Obajuluwa, Ayodele Jacob Akinyemi, Olakunle Bamikole Afolabi, Khalid Adekoya, Joseph Olurotimi Sanya, Azeez Olakunle Ishola, [Exposure to radio-frequency electromagnetic waves alters acetylcholinesterase gene expression, exploratory and motor coordination-linked behaviour in male rats.](#) Toxicology Reports, Volume 4, 2017, Pages 530-534, ISSN 2214-7500,

- “The results revealed that WiFi exposure caused a significant increase in anxiety level and affect locomotor function. Furthermore, there was a significant decrease in AChE activity with a concomitant increase in AChE mRNA expression level in WiFi exposed rats when compared with control. In conclusions, these data showed that long term exposure to WiFi may lead to adverse effects such as neurodegenerative diseases as observed by a significant alteration on AChE gene expression and some neurobehavioral parameters associated with brain damage.”

Afolabi Olakunle Bamikole, Obajuluwa Adejoke Olukayode, Tiwa Obajuluwa, Okiki Pius, Oloyede Omotade Ibidun, Fadaka Oluwaseun Adewale, Ojo Oluwafemi Adeleke. [Exposure to a 2.5 GHz Non-ionizing Electromagnetic Field Alters Hematological Profiles, Biochemical Parameters, and Induces Oxidative Stress in Male Albino Rats](#) [J]. *Biomedical and Environmental Sciences*, 2019, 32(11): 860-863.

- In the current study, alterations were noted in hematological and biochemical parameters of groups exposed to a 2.5 GHz EMF emission from an indoor Wi-Fi device over a period of 4-8 weeks.

Hedendahl, Lena K., et al. [“Measurements of Radiofrequency Radiation with a body-borne exposimeter in Swedish schools with Wi-Fi.”](#) *Frontiers in Public Health* 5 (2017): 279.

- The environmental exposure to RF radiation in some schools is higher than reported levels for non-thermal biological effects. In order to reduce children’s exposure to RF radiation, schools should prefer wired network connections, allow laptop, tablets, and mobile phone usage only in flight mode and deactivate Wi-Fi access points when internet is not needed for learning purposes.
- All values were far below International Commission on Non-Ionizing Radiation Protection’s (ICNIRP) reference values, but most mean levels measured were above the precautionary target level of 3–6  $\mu\text{W}/\text{m}^2$  as proposed by the Bioinitiative Report ...however the ICNIRP guidelines are based on short-term heating (thermal) effects, and are therefore not relevant to decide on the appropriateness of long-term exposure.
- “The risk for cancer may be accentuated for children partly because of their likely longer life-time use of wireless devices, but also since their smaller size and thinner skull bone give higher RF radiation to the brain. Children are also growing and have more immature cells which can be more sensible to RF radiation.”

Li ZQ et al., [Testing of behavioral and cognitive development in rats after prenatal exposure to 1800 and 2400 MHz radiofrequency fields.](#) *J Radiat Res.* 2020 Mar 23;61(2):197-206.

- The objective of the study was to explore the effects of behavioral and cognitive development in rats after prenatal exposure to 1800 and 2400 MHz radiofrequency fields. The 1800 MHz + WiFi group displayed an increased trend in path length, duration, entry times and stationary time in the central area. In both the 1800 MHz + WiFi and WiFi groups, NR2A and NR2B expression was down-regulated, while NR2D, NR3A and NR3B were up-regulated. Moreover, NR1 and NR2C in the WiFi group were also up-regulated. Prenatal exposure to 1800 MHz and WiFi radiofrequency may affect the behavioral and cognitive development of offspring rats, which may be associated with altered mRNA expression of NMDARs in the hippocampus.

Siervo, B. [Numerical evaluation of human exposure to WiMax patch antenna in tablet or laptop,](#) *Bioelectromagnetics.* 2018

- This paper reports the estimation of the interaction between an E - shaped patch antenna (3.5 GHz) and human models, by means of finite - difference time - domain (FDTD) method. Specifically, four different human models (young adult male, young adult female, pre - teenager female, male child) in different exposure conditions (antenna at different distances from the human model, in different positions, and

orientations) were considered and whole - body, 10 and 1 g local SAR and magnetic field value (Bmax) were evaluated. From our results, in some worst - case scenarios involving male and female children's exposure, the maximum radiofrequency energy absorption (hot spots) is located in more sensitive organs such as eye, genitals, and breast

Gupta SK, Patel SK, Tomar MS, Singh SK, Mesharam MK, Krishnamurthy S. [Long-term exposure of 2450 MHz electromagnetic radiation induces stress and anxiety like behavior in rats.](#) Neurochemistry International. Publ. online Apr 4, 2019.

- EMR-2450 MHz induces stress and aggravates anxiety-like symptoms in rats. Exposure of EMR-2450 MHz increases plasma corticosterone level and, expression of CRH-2 and GR in amygdala. Increased expression of cytochrome-C and caspase-9 indicating mitochondrial dysfunction and activation of apoptosis. Change in expression of mitochondrial Bax: Bcl2 ratio indicating modulation of apoptosis. EMR-2450 MHz exposure causes both amygdalar necrotic and apoptotic cell death.

Sueiro-Benavides RA, Leiro-Vidal JM, Salas-Sánchez AÁ, Rodríguez-González JA, Ares-Pena FJ, López-Martín ME. [Radiofrequency at 2.45 GHz increases toxicity, pro-inflammatory and pre-apoptotic activity caused by black carbon in the RAW 264.7 macrophage cell line.](#) Sci Total Environ. 2020 Oct 4:142681. doi: 10.1016/j.scitotenv.2020.142681. Epub ahead of print. PMID: 33071139.

- Environmental factors such as air pollution by particles and/or electromagnetic fields (EMFs) are studied as harmful agents for human health.
- We analyzed whether the combined action of EMF with fine and coarse black carbon (BC) particles induced cell damage and inflammatory response in RAW 264.7 cell line macrophages exposed to 2.45 GHz in a gigahertz transverse electromagnetic (GTEM) chamber at sub-thermal specific absorption rate (SAR) levels. Radiofrequency (RF) dramatically increased BC-induced toxicity at high doses in the first 24 h and toxicity levels remained high 72 h later for all doses.
- Our results indicate that the interaction of BC and RF modifies macrophage immune response, activates apoptosis, and accelerates cell toxicity, by which it can activate the induction of hypersensitivity reactions and autoimmune disorders.

Shahin, Saba, et al. [“2.45 GHz Microwave radiation impairs hippocampal learning and spatial memory: Involvement of local stress mechanism induced suppression of iGluR/ERK/CREB signaling.”](#) *Toxicological Sciences* (2017).

- “Our findings led us to conclude that 2.45 GHz MW radiation exposure induced local stress suppresses signaling mechanism(s) of hippocampal memory formation.”

Hassanshahi, A., et al. [“The effect of Wi-Fi electromagnetic waves in unimodal and multimodal object recognition tasks in male rats.”](#) *Neurological Sciences*, 2017, pp. 1-8.

- This study aimed to investigate the effect of 2.4 GHz Wi-Fi radiation (12 h/day for 30 days) on multisensory integration in male rats. Results demonstrated that rats in Wi-Fi exposure groups could not discriminate significantly between the novel and familiar objects in any of the standard SOR, tactile SOR, visual SOR, and CMOR tests and the expression of M1 receptors increased following Wi-Fi exposure. In conclusion, results of this study showed that chronic exposure to Wi-Fi electromagnetic waves might impair both unimodal and cross-modal encoding of information.

Akdag, M.Z., et al. [“Does prolonged radiofrequency radiation emitted from Wi-Fi devices induce DNA damage in various tissues of rats?”](#) *Journal of Chemical Neuroanatomy*, vol. 75, pt. B, 2016, pp. 116-22.

- The purpose of this study was to reveal whether long term exposure (over a year) of 2.4GHz frequency RF radiation will cause DNA damage of different tissues such as brain, kidney, liver, and skin tissue and testicular tissues of rats. Based on the DNA damage results determined by the single cell gel electrophoresis (Comet) method, it was found that the % tail DNA values of the brain, kidney, liver, and skin tissues of the rats in the experimental group increased more than those in the control group. The increase of the DNA damage in all tissues was not significant ( $p>0.05$ ), however the increase of the DNA damage in rat testes tissue was significant ( $p<0.01$ ). In conclusion, long-term exposure to 2.4GHz RF radiation (Wi-Fi) does not cause DNA damage of the organs investigated in this study except testes indicating that testes are more sensitive organ to RF radiation.

Kuybulu, A.E., et al. [“Effects of long-term pre- and post-natal exposure to 2.45GHz wireless devices on developing male rat kidney.”](#) Renal Failure, vol. 38, no. 4, 2016, pp. 571-80.

- The aim of the present study was to investigate oxidative stress and apoptosis in kidney tissues of male Wistar rats that pre- and postnatally exposed to 2.45 GHz wireless electromagnetic field (EMF) for 1 h/day until puberty. Based on this study, it is thought that chronic pre- and post-natal period exposure to wireless internet frequency of EMF may cause chronic kidney damages; staying away from EMF source in especially pregnancy and early childhood period may reduce negative effects of exposure on kidney.

Celik, O., M.C. Kahya and M. Naziroglu. [“Oxidative stress of brain and liver is increased by Wi-Fi \(2.45GHz\) exposure of rats during pregnancy and the development of newborns.”](#) Journal of Chemical Neuroanatomy, vol. 75, pt. B, 2015, pp. 134-9.

- An excessive production of reactive oxygen substances (ROS) and reduced antioxidant defence systems resulting from electromagnetic radiation (EMR) exposure may lead to oxidative brain and liver damage and degradation of membranes during pregnancy and development of rat pups. In the EMR groups, lipid peroxidation levels in the brain and liver were increased following EMR exposure; however, the glutathione peroxidase (GSH-Px) activity, and vitamin A, vitamin E and  $\beta$ -carotene concentrations were decreased in the brain and liver. Glutathione (GSH) and vitamin C concentrations in the brain were also lower in the EMR groups than in the controls; however, their concentrations did not change in the liver. In conclusion, Wi-Fi-induced oxidative stress in the brain and liver of developing rats was the result of reduced GSH-Px, GSH and antioxidant vitamin concentrations. Moreover, the brain seemed to be more sensitive to oxidative injury compared to the liver in the development of newborns.

Ciftci, Z.Z., et al. [“Effects of prenatal and postnatal exposure of Wi-Fi on development of teeth and changes in teeth element concentration in rats.”](#) Biological Trace Element Research, vol.163, no. 1-2, 2015, pp. 193-201.

- The present study determined the effects of prenatal and postnatal exposure to 2.45 GHz Wi-Fi-induced electromagnetic radiation (2h/day for 21 days during pregnancy and 21 days during lactation) on tooth and surrounding tissue development as well as the element levels in growing rats. Histological and immunohistochemical examinations between the experimental and control groups showed that exposure to 2.45 GHz EMR for 2 h per day does not interfere with the development of teeth and surrounding tissues. However, there were alterations in the elemental composition of the teeth, especially affecting such oxidative stress-related elements as copper, zinc, and iron, suggesting that short-term exposure to Wi-Fi-induced EMR may cause an imbalance in the oxidative stress condition in the teeth of growing rats.

Cig, B. and M. Naziroglu. [“Investigation of the effects of distance from sources on apoptosis, oxidative stress and cytosolic calcium accumulation via TRPV1 channels induced by mobile phones and Wi-Fi in breast cancer cells.”](#) *Biochemica et Physica Acta*, vol. 1848, pt B, 2015, pp. 2756-65.

- We aimed to investigate the effects of distance from sources on calcium signaling, cytosolic ROS production, cell viability, apoptosis, plus caspase-3 and -9 values induced by mobile phones and Wi-Fi in breast cancer cells. The cytosolic ROS production, Ca<sup>2+</sup> concentrations, apoptosis, caspase-3 and caspase-9 values were higher in groups exposed to 900 MHz, 1800 MHz and 2450 MHz compared to controls at 0 cm, 1 cm and 5 cm distances although cell viability (MTT) values were increased by the distances. There was no statistically significant difference in the values between control, 20 and 25 cm. Wi-Fi and mobile phone EMR placed within 10 cm of the cells induced excessive oxidative responses and apoptosis via TRPV1-induced cytosolic Ca<sup>2+</sup> accumulation in the cancer cells. Using cell phones and Wi-Fi sources which are farther away than 10 cm may provide useful protection against oxidative stress, apoptosis and overload of intracellular Ca<sup>2+</sup>.

Dasdag, S., et al. [“Effect of long-term exposure of 2.4 GHz radiofrequency radiation emitted from Wi-Fi equipment on testes functions.”](#) *Electromagnetic Biology and Medicine*, vol. 34, no. 1, 2015, pp. 37-42.

- The aim of this study was to investigate long-term effects of 2.4 GHz radiofrequency radiation (24 h/day for 1 year) emitted from a Wireless Fidelity (Wi-Fi) system on the testes of male rats. Results showed that sperm head defects increased in the exposure group ( $p < 0.05$ ) while weight of the epididymis and seminal vesicles, seminiferous tubules diameter and tunica albuginea thickness were decreased in the exposure group ( $p < 0.01$ ,  $p < 0.001$ ,  $p < 0.0001$ ). However, other alterations of other parameters were not found significant ( $p > 0.05$ ). We suggest Wi-Fi users to avoid long-term exposure of RF emissions from Wi-Fi equipment.

Dasdag, S., et al. [“Effects of 2.4 GHz radiofrequency radiation emitted from Wi-Fi equipment on microRNA expression in brain tissue.”](#) *International Journal of Radiation Biology*, vol 91, no. 7, 2015, pp. 555-61.

- The aim of this study was to investigate the long-term effects of 2.4 GHz radiofrequency radiation (24h/day for 12 months) emitted from a Wireless Fidelity (Wi-Fi) system on some of the miRNA in brain tissue in male rats. The results revealed that long-term exposure of RFR radiation can alter expression of some of the miRNAs, indicating that this type of exposure may lead to adverse effects such as neurodegenerative diseases originated from the alteration of some miRNA expression and more studies should be devoted to the effects of RF radiation on miRNA expression levels.

Deshmukh, P.S., et al. [“Cognitive impairment and neurogenotoxic effects in rats exposed to low-intensity microwave radiation.”](#) *International Journal of Toxicology*, vol. 34, no. 3, 2015, pp. 284-90.

- The present study aimed to investigate the effects of chronic low-intensity microwave exposure (900, 1800 or 2450 MHz for 180 days) on cognitive function, heat shock protein 70 (HSP70), and DNA damage in the rat brain. The results showed declined cognitive function, elevated HSP70 level, and DNA damage in the brain of microwave-exposed animals. The results indicated that, chronic low-intensity microwave exposure in the frequency range of 900 to 2450 MHz may cause hazardous effects on the brain.

Megha, K., et al. [“Low intensity microwave radiation induced oxidative stress, inflammatory response and DNA damage in rat brain.”](#) *Neurotoxicology*, vol. 51, 2015, pp. 158-65.

- The present study was undertaken to determine the influence of low intensity microwave radiation (900, 1800, or 2450 MHz for 2h/day, 5days/week, for 60 days) on oxidative stress, inflammatory response and DNA damage in rat brain. Low intensity microwave exposure resulted in a frequency dependent significant increase in oxidative stress markers, reduced levels of GSH and SOD, increased levels of pro-inflammatory cytokines, and significant DNA damage in microwave exposed groups compared to controls. In conclusion, the present study suggests that low intensity microwave radiation induces oxidative stress, inflammatory response and DNA damage in brain by exerting a frequency dependent effect. The study also indicates that increased oxidative stress and inflammatory response might be the factors involved in DNA damage following low intensity microwave exposure.

Misa-Agustiño, M.J. et al. [“Exposure to non-ionizing radiation provokes changes in rat thyroid morphology and expression of HSP-90.”](#) *Experimental Biology and Medicine*, vol. 240, no. 9, 2015, pp. 1123-35.

- Non-ionizing radiation at 2.45 GHz may modify the morphology and expression of genes that codify heat shock proteins (HSP) in the thyroid gland. The present study used a diathermy model – the therapeutic application of non-ionizing radiation – on laboratory rats subjected to maximum exposure non-ionizing radiation (30 min, 10 times in two weeks) in the left front leg, in order to study the effects of radiation on the nearby thyroid tissue. Ninety minutes after radiation with the highest SAR, the central and peripheral follicles presented increased size and the thickness of the peripheral septa had decreased. Twenty-four hours after radiation, only peripheral follicles radiated at 12 W were found to be smaller. Morphological changes in the thyroid tissue may indicate a glandular response to acute or repeated stress from radiation in the hypothalamic-pituitary-thyroid axis.

Misa-Augustiño, M.J., et al. [“EMF radiation at 2450 MHz triggers changes in the morphology and expression of heat shock proteins and glucocorticoid receptors in rat thymus.”](#) *Life Sciences*, vol. 127, 2015, pp. 1-11.

- This study analyzed cellular stress levels in rat thymus after exposure to a 2.45 GHz radio frequency (RF) using an experimental diathermic model in a Gigahertz Transverse Electromagnetic (GTEM) chamber. The thymus tissue presented several morphological changes, including increased distribution of blood vessels along with the appearance of red blood cells and hemorrhagic reticuloepithelial cells, while the glucocorticoid receptors presented greater immunomarking on the thymic cortex in exposed animals. These results indicate that non-ionizing sub-thermal radiation causes changes in the endothelial permeability and vascularization of the thymus, and is a tissue-modulating agent for Hsp90 and GR.

Saili, L., et al. [“Effects of acute exposure to WIFI signals \(2.45GHz\) on heart variability and blood pressure in Albinos rabbit.”](#) *Environmental Toxicology and Pharmacology*, vol. 40, no. 2, 2015, pp. 600-5.

- Electrocardiogram and arterial pressure measurements were studied under acute exposures to WIFI (2.45GHz) during one hour in adult male rabbits. Acute exposure of rabbits to WIFI increased heart frequency (+22%) and arterial blood pressure (+14%). Moreover, analysis of ECG revealed that WIFI induced a combined increase of PR and QT intervals, but failed to alter maximum amplitude and P waves. After intravenously injection of dopamine (0.50ml/kg) and epinephrine (0.50ml/kg) under acute exposure to RF we found that, WIFI alter catecholamines (dopamine, epinephrine) action on heart variability and blood pressure compared to control. These results suggest for the first time, as far as we know, that exposure to WIFI affect heart rhythm, blood pressure, and catecholamines efficacy on cardiovascular system; indicating that radiofrequency can act directly and/or indirectly on cardiovascular system.

Sangun, O., et al. 2015. [“The effects of long-term exposure to a 2450 MHz electromagnetic field on growth and pubertal development in female Wistar rats.”](#)Electromagnetic Biology and Medicine, vol. 34, no. 1, 2015, pp. 63-7.

- The aim of this study was to investigate the effects of prenatal and postnatal 2450 MHz electromagnetic field exposure (1h/day from intrauterine or postnatal period) on the growth and development of female Wistar rats. Birth masses of the groups were similar ( $p > 0.05$ ), however mass gain per day was significantly lower and the puberty was significantly later in the prenatal group. Brain and ovary TOS and OSI values in the prenatal group were significantly increased ( $p < 0.05$ ) compared to the control group and serum LH levels of the prenatal and postnatal groups were increased, although serum FSH, and E2 values did not differ among the groups ( $p > 0.05$ ). Histological examinations of the specimens revealed no statistically significant difference between the groups ( $p > 0.05$ ). Exposure to 2450 MHz EMF, particularly in the prenatal period, resulted in postnatal growth restriction and delayed puberty in female Wistar rats. Increased TOS and OSI values in the brain and ovary tissues can be interpreted as a sign of chronic stress induced by EMF.

Saygin, M., et al. [“Impact of L-carnitine and selenium treatment on testicular apoptosis in rats exposed to 2.45GHz microwave energy.”](#)West Indian Medicine Journal, vol 64, no. 2, 2015, pp. 55-61.

- This study investigated if supplemental selenium (Se) and L-carnitine may reduce the adverse effect 2.45 GHz electromagnetic radiation can have on testicular apoptosis using rats as a study animal. Electromagnetic radiation exposure resulted in testicular apoptosis in rats, mainly by the intrinsic pathways by down-regulated expression of caspase-8. Reduction in the activation of the intrinsic pathway of apoptosis was found higher with selenium administration compared with L-carnitine administration.

Saygin, M. et al. [“Impact of 2.45GHz microwave radiation on the testicular inflammatory pathway biomarkers in young rats: The role of gallic acid.”](#)Environmental Toxicology, 2015.

- The aim of this study was to investigate electromagnetic radiation (EMR) transmitted by wireless devices (2.45 GHz, 3h/day for 30 days), which may cause physiopathological or ultrastructural changes, in the testes of rats and address if the supplemental gallic acid (GA) may reduce these adverse effects. EMR only group was shown to have higher oxidative stress, decreased testosterone and VEGF levels, increased prostaglandin E2 and CGRP, as well as decreased numbers of spermatozoa. Long term EMR exposure resulted in testicular physiopathology via oxidative damage and inflammation. GA may have ameliorative effects on the prepubertal rat testes physiopathology.

Farah Hanan Fathihah Jaffar, Khairul Osman, Nur Hilwani Ismail, Kok-Yong Chin, Siti Fatimah Ibrahim, [Adverse Effects of Wi-Fi Radiation on Male Reproductive System: A Systematic Review](#), The Tohoku Journal of Experimental Medicine, 2019, Volume 248, Issue 3, Pages 169-179, Released July 26, 2019, Online ISSN 1349-3329

- Sperm count, motility and DNA integrity were the most affected parameters when exposed to RF-EMR emitted by Wi-Fi transmitter. Unfortunately, sperm viability and morphology were inconclusive. Structural and/or physiological analyses of the testes showed degenerative changes, reduced testosterone level, increased apoptotic cells, and DNA damage. These effects were mainly due to the elevation of testicular temperature and oxidative stress activity. In conclusion, exposure towards 2.45 GHz RF-EMR emitted by Wi-Fi transmitters is hazardous on the male reproductive system.

Shahin, S., et al. [“2.45GHz microwave radiation impairs learning and spatial memory via oxidative/nitrosative stress induced p53 dependent/independent hippocampal apoptosis: molecular basis and underlying mechanism.”](#) Toxicology Science, vol. 148, no. 2, 2015, pp. 380-99.

- This study was performed to understand the effect of short (15 days) and long-term (30 and 60 days) low-level 2.45 GHz MW radiation exposure on hippocampus with special reference to spatial learning and memory and its underlying mechanism in Swiss strain male mice, *Mus musculus*. We observed that, short-term as well as long-term 2.45 GHz MW radiation exposure increases the oxidative/nitrosative stress leading to enhanced apoptosis in hippocampal subfield neuronal and nonneuronal cells. Present findings also suggest that learning and spatial memory deficit which increases with the increased duration of MW exposure (15 < 30 < 60 days) is correlated with a decrease in hippocampal subfield neuronal arborization and dendritic spines. These findings led us to conclude that exposure to CW MW radiation leads to oxidative/nitrosative stress induced p53-dependent/independent activation of hippocampal neuronal and nonneuronal apoptosis associated with spatial memory loss.

Shokri, S., et al. [“Effects of Wi-Fi \(2.45 GHz\) exposure on apoptosis, sperm parameters and testicular histomorphometry in rats: a time course study.”](#) Cell Journal, vol. 17, no. 2, 2015, pp. 322-31.

- This study aimed to investigate the major cause of male infertility during short- (1h/day for 2 months) and long-term (7h/day for 2 months) exposure of 2.45 GHz Wi-Fi radiation. Both 1-hour and 7-hour groups showed a decrease in sperm parameters in a time dependent pattern and the number of apoptosis-positive cells and caspase-3 activity increased in the seminiferous tubules of exposed rats. The seminal vesicle weight reduced significantly in both 1-hour or 7-hour groups in comparison to the control group. Researchers concluded that there should be a major concern regarding the time dependent exposure of whole-body to the higher frequencies of Wi-Fi networks existing in the vicinity of our living places.

Taheri, M., et al. [“Klebsiella pneumonia, a Microorganism that Approves the Non-linear Responses to Antibiotics and Window Theory after Exposure to Wi-Fi 2.4 GHz Electromagnetic Radiofrequency Radiation.”](#) Journal of Biomedical and Physical Engineering, vol. 5, no. 3, 2015, pp. 115–20.

- This study was aimed at investigating the alteration of antibiotic resistance of *Klebsiella pneumonia*, after exposure to Wi-Fi 2.4 GHz electromagnetic radiofrequency radiation from a Wi-Fi router for 3, 4.5 or 8 hours. The findings of this study show a statistically significant rise in the sensitivity of *Klebsiella pneumoniae* to different antibiotics after 4.5 hours of exposure to 2.4 GHz Wi-Fi radiation, followed by a fall after 8 hours of exposure. These observations can be interpreted by the concept of non-linearity in the responses of *Klebsiella pneumoniae* to different antibiotics after exposure to electromagnetic radiofrequency radiation.

Yildirim, M.E., et al. [“What is harmful for male fertility: Cell phone or the wireless internet?”](#) Kaohsiung Journal of Medical Science, vol 31, no. 9, 2015, pp. 480-4.

- This study aimed to assess the potential harmful effects of radiofrequency-electromagnetic radiation on sperm parameters. There was no significant difference between sperm counts and sperm morphology excluding sperm motility, due to mobile phone usage period, however total motile sperm count and the progressive motile sperm count decreased due to the increase of internet usage and progressive motile sperm count also decreased with wireless Internet usage compared with the wired Internet connection usage.

Yüksel, M. et al. [“Long-term exposure to electromagnetic radiation from mobile phones and Wi-Fi devices decreases plasma prolactin, progesterone, and estrogen levels but increases uterine oxidative stress in pregnant rats and their offspring.”](#) *Endocrine*, vol. 52, no. 2, 2015, pp. 352-62.

- This study investigated the effects of mobile phone (900 and 1800 MHz)- and Wi-Fi (2450 MHz)-induced electromagnetic radiation (EMR) exposure (60 min/day during pregnancy and growth periods) on uterine oxidative stress and plasma hormone levels in pregnant rats and their offspring. Although EMR exposure decreased the prolactin, estrogen, and progesterone levels in the plasma of maternal rats and their offspring, EMR-induced oxidative stress in the uteri of maternal rats increased during the development of offspring. Mobile phone- and Wi-Fi-induced EMR may be one cause of increased oxidative uterine injury in growing rats and decreased hormone levels in maternal rats.

Ghazizadeh, V. and M. Naziroglu. [“Electromagnetic radiation \(Wi-Fi\) and epilepsy induce calcium entry and apoptosis through activation of TRPV1 channel in hippocampus and dorsal root ganglion of rats.”](#) *Metabolic Brain Disease*, vol. 29, no. 3, 2014, pp. 787-99.

- The present study tested the effects of Wi-Fi (2.45 GHz for 1h) exposure on Ca(2+) influx, oxidative stress and apoptosis through TRPV1 channel in the murine dorsal root ganglion (DRG) and hippocampus of pentylenetetrazol (PTZ)-induced epileptic rats. The cytosolic free Ca(2+), reactive oxygen species production, apoptosis, mitochondrial membrane depolarization, caspase-3 and -9 values in hippocampus were higher in the PTZ group than in the control although cell viability values decreased. The Wi-Fi exposure induced additional effects on the cytosolic Ca(2+) increase. However, pretreatment of the neurons with CPZ, results in a protection against epilepsy-induced Ca(2+) influx, apoptosis and oxidative damages. In conclusion, epilepsy and Wi-Fi in our experimental model is involved in Ca(2+) influx and oxidative stress-induced hippocampal and DRG death through activation of TRPV1 channels, and negative modulation of this channel activity by CPZ pretreatment may account for the neuroprotective activity against oxidative stress.

Gürler, H.S. et al, 2014. [“Increased DNA oxidation \(8-OHdG\) and protein oxidation \(AOPP\) by Low level electromagnetic field \(2.45 GHz\) in rat brain and protective effect of garlic.”](#) *International Journal of Radiation Biology*, vol 90, no. 10, 2014, pp. 892-6.

- The purpose of this study was to investigate the oxidative damage and protective effect of garlic (daily 500 mg/kg during study period) on rats exposed to low level of electromagnetic fields (EMF) at 2.45 GHz Microwave radiation (MWR) for 1 h/day for 30 consecutive days. Researchers concluded that low level EMF at 2.45 GHz MWR increases the DNA damage in both brain tissues and plasma of the rats whereas it increases protein oxidation only in plasma. They also be argued that the use of garlic decreases these effects.

Margaritis, L.H. et al. [“Drosophila oogenesis as a bio-marker responding to EMF sources.”](#) *Electromagnetic Biology and Medicine*, vol. 33, no. 3, 2014, pp. 165-89.

- This study used *Drosophila* as model organisms to assess the effects of various EMF sources (short time daily for 3-7 days) on apoptotic cell death of follicles during oogenesis and reproductive capacity (fecundity) decline. Sources included: 900/1800 MHz mobile phone, 1880-1900 MHz wireless base, wireless handset, mobile phone-handset combination, 2.44 GHz wireless network (Wi-Fi), 2.44 GHz bluetooth, 92.8 MHz FM generator, 27.15 MHz baby monitor, 900 MHz CW RF generator and microwave oven's 2.44 GHz RF and magnetic field components. All EMF sources used created statistically significant effects regarding fecundity and cell death-apoptosis induction, even at very low intensity levels well below

ICNIRP's guidelines, suggesting that *Drosophila* oogenesis system is suitable to be used as a biomarker for exploring potential EMF bioactivity.

Meena, R., et al. [“Therapeutic approaches of melatonin in microwave radiations-induced oxidative stress-mediated toxicity on male fertility pattern of Wistar rats.”](#) *Electromagnetic Biology and Medicine*, vol. 33, no. 2, 2014, pp. 81-91.

- The present study aimed to investigate the protective effects of melatonin against oxidative stress-mediated testicular impairment due to long-term exposure (2 h/day for 45 days) of 2.45 GHz Microwave Radiation. Result shows that melatonin prevented oxidative damage biochemically by significant increase ( $p < 0.001$ ) in the levels of testicular LDH-X, decreased ( $p < 0.001$ ) levels of MDA and ROS in testis ( $p < 0.01$ ). Meanwhile, it reversed the effects of MWs on XO, protein carbonyl content, sperm count, testosterone level and DNA fragmentation in testicular cells. These results concluded that the melatonin has strong antioxidative potential against MW induced oxidative stress mediated DNA damage in testicular cells.

Oksay, T., et al. [“Protective effects of melatonin against oxidative injury in rat testis induced by wireless \(2.45 GHz\) devices.”](#) *Andrologia*, vol. 46, no. 1 2014, pp. 65-72.

- The present study was designed to determine the possible protective effects of melatonin on oxidative stress-dependent testis injury induced by 2.45-GHz electromagnetic radiation exposure (60 min/day for 30 days). Lipid peroxidation levels were shown to be higher in melatonin-supplemented group compared to EMR only and controls, as well as reduced glutathione and glutathione peroxidase levels. Vitamin A and E concentrations decreased in exposure group, and melatonin prevented the decrease in vitamin E levels. In conclusion, wireless (2.45 GHz) EMR caused oxidative damage in testis by increasing the levels of lipid peroxidation and decreasing in vitamin A and E levels. Melatonin supplementation prevented oxidative damage induced by EMR and also supported the antioxidant redox system in the testis.

Senavirathna, M.D., et al. [“Nanometer-scale elongation rate fluctuations in the \*Myriophyllum aquaticum\* \(Parrot feather\) stem were altered by radio-frequency electromagnetic radiation.”](#) *Plant Signal Behavior*, vol. 9, no. 4, 2014.

- This study investigated the effect of 2GHz EMR (1h) on the growth dynamics of *Myriophyllum aquaticum* (Parrot feather) by measuring the nanometric elongation rate fluctuation (NERF) using a statistical interferometry technique. After continuous exposure to EMR, *M. aquaticum* plants exhibited a statistically significant reduction in NERF standard deviation, therefore, the reduced NERF was due to a non-thermal effect caused by EMR exposure. The alteration in NERF continued for at least 2.5 h after EMR exposure and no significant recovery was found in post-EMR NERF during the experimental period.

Shahin, S., et al. [“Microwave irradiation adversely affects reproductive function in male mouse, \*Mus musculus\*, by inducing oxidative and nitrosative stress.”](#) *Free Radical Research*, vol 48, no. 5, 2014, pp. 511- 25.

- This study investigated the long-term effects of low-level 2.45GHz MW irradiation (2h/day for 30 days) on the reproductive function of male mice and its mechanism of action. Researchers observed that MW irradiation induced a significant decrease in sperm count and sperm viability along with the decrease in seminiferous tubule diameter, degeneration of seminiferous tubules, reduction in testicular 3 $\beta$  HSD activity and reduction in plasma testosterone levels. Increased expression of testicular i-NOS was observed in the

MW-irradiated group of mice. These adverse reproductive effects suggest that chronic exposure to nonionizing MW radiation may lead to infertility via free radical species-mediated pathway.

Soran, M.-L., et al. [“Influence of microwave frequency electromagnetic radiation on terpene emission and content in aromatic plants.”](#)Journal of Plant Physiology, vol 171, no. 15, 2014, pp. 1436-43.

- Here we studied the influence of microwave irradiation at bands corresponding to wireless router (WLAN) and mobile devices (GSM) on leaf anatomy, essential oil content and volatile emissions in *Petroselinum crispum*, *Apium graveolens* and *Anethum graveolens*. Microwave irradiation resulted in thinner cell walls, smaller chloroplasts and mitochondria, and enhanced emissions of volatile compounds, in particular, monoterpenes and green leaf volatiles. There was a direct relationship between microwave-induced structural and chemical modifications of the three plant species studied. These data collectively demonstrate that human-generated microwave pollution can potentially constitute a stress to the plants.

Tök, L., et al. [“Effects of melatonin on Wi-Fi-induced oxidative stress in lens of rats.”](#)Indian Journal of Ophthalmology, vol. 62, no. 1, 2014, pp. 12-15.

- The present study was designed to determine the effects of 2.45 GHz Wi-Fi exposure (60min/day for 30 days) on the lens oxidant and antioxidant redox systems of rats, as well as the possible protective effects of melatonin on the lens injury induced by electromagnetic radiation (EMR). Results showed poor oxidative toxic effects of one hour of Wi-Fi exposure on the lens in the animals. However, melatonin supplementation in the lens seems to have protective effects on the oxidant system by modulation of GSH-Px activity.

Aynali, G., et al. [“Modulation of wireless \(2.45 GHz\)-induced oxidative toxicity in laryngotracheal mucosa of rat by melatonin.”](#)European Archives of Otorhinolaryngol, vol. 270, no. 5, 2013, pp. 1695-700.

- The aim of this study was to investigate the possible protective role of melatonin on oxidative stress induced by Wi-Fi (2.45 GHz, 60min/day for 28 days) EMR in laryngotracheal mucosa of rat. In comparison to control and sham groups, RFR-exposed animals had higher lipid peroxidation levels and lower glutathione peroxidase levels, while the RFR-exposed animals treated with melatonin had significantly lower lipid peroxidation levels and increased glutathione peroxidase activity compared with controls. Results show that there is an apparent protective effect of melatonin on the Wi-Fi-induced oxidative stress in the laryngotracheal mucosa of rats by inhibition of free radical formation and support of the glutathione peroxidase antioxidant system.

Desmunkh, P.S., et al. [“Detection of Low Level Microwave Radiation Induced Deoxyribonucleic Acid Damage Vis-a-vis Genotoxicity in Brain of Fischer Rats.”](#)Toxicology International, vol. 20, no. 1, 2013, pp. 19-24.

- The present study was designed to investigate the possible DNA damaging effects of low-level microwave radiation (900, 1800, or 2450 MHz for 30 days) in brain of Fischer rats. Researchers demonstrated DNA damaging effects of low level microwave radiation in brain and concluded that low SAR microwave radiation exposure at these frequencies may induce DNA strand breaks in brain tissue.

Eser, O. [“The effect of electromagnetic radiation on the rat brain: an experimental study.”](#) Turkish Neurosurgery, vol. 23, no. 6, 2013, pp. 707-15.

- The aim of this study was to determine the structural changes in the frontal cortex, brainstem and cerebellum in the male rat brain due to electromagnetic wave exposure (900, 1800, 2450 MHz, 1h/day for 2 months). While the histopathological changes in the frontal cortex and brainstem were normal in the control group, there were severe degenerative changes, shrunken cytoplasm and extensively dark pyknotic nuclei in the EMR groups. Biochemical analysis demonstrated that the Total Antioxidative Capacity level was significantly decreased in the EMR groups and also Total Oxidative Capacity and Oxidative Stress Index levels were significantly increased in the frontal cortex, brainstem and cerebellum. Researchers concluded that EMR causes structural changes in the frontal cortex, brainstem and cerebellum and impairs the oxidative stress and inflammatory cytokine system. This deterioration can cause to disease including loss of these areas function and cancer development.

Ozorak, A., et al. [“Wi-Fi \(2.45 GHz\)- and mobile phone \(900 and 1800 MHz\)- induced risks on oxidative stress and elements in kidney and testis of rats during pregnancy and the development of offspring.”](#) Biological Trace Elements Research, vol. 156, no. 103, 2013, pp. 221-9.

- The present study was designed to determine the effects of both Wi-Fi (2.45 GHz)- and mobile phone (900 and 1800 MHz)-induced electromagnetic radiation (60 min/day during pregnancy and growth) on oxidative stress and trace element levels in the kidney and testis of growing rats from pregnancy to 6 weeks of age. In conclusion, Wi-Fi- and mobile phone-induced EMR caused oxidative damage by increasing the extent of lipid peroxidation and the iron level, while decreasing total antioxidant status, copper, and GSH values. Wi-Fi- and mobile phone-induced EMR may cause precocious puberty and oxidative kidney and testis injury in growing rats.

Salah, M.B., et al. [“Effects of olive leaf extract on metabolic disorders and oxidative stress induced by 2.45 GHz WIFI signals.”](#) Environmental Toxicology and Pharmacology, vol. 36, no. 3, 2013, pp. 826-34.

- We investigated the effect of olive leaves extract administration on glucose metabolism and oxidative response in liver and kidneys of rats exposed to 2.45 GHz radiofrequency radiation (1h/day for 21 days). This exposure was shown to induce a diabetes-like status and also decreased the activities of glutathione peroxidase, catalase, superoxide dismutase, and groups thiol amount in liver and kidneys. Olive leaves extract administration (100 mg/kg, ip) in RF-exposed rats prevented glucose metabolism disruption and restored the activities of GPx, CAT and SOD and thiol group amount in liver and kidneys and was able to bring down the elevated levels of MDA in liver but not in kidneys. Our investigations suggested that RF exposure induced a diabetes-like status through alteration of oxidative response, while olive leaves extract was able to correct glucose metabolism disorder by minimizing oxidative stress induced by RF in rat tissues.

Shahin, S., et al. [“2.45 GHz Microwave Irradiation-Induced Oxidative Stress Affects Implantation or Pregnancy in Mice, Mus musculus.”](#) Applied Biochemistry and Biotechnology, vol. 169, 2013, pp. 1727–51.

The present experiment was designed to study the 2.45 GHz low-level microwave irradiation-induced stress response (continuous wave exposure for 2h/day for 45 days) and its effect on implantation or pregnancy in female mice. Researchers observed that implantation sites were affected significantly in MW-irradiated mice as compared to control and in addition to a significant increase in ROS, hemoglobin, RBC and WBC counts, N/L ratio, DNA damage in brain cells, and plasma estradiol concentration, a significant decrease was observed in NO level and antioxidant enzyme activities of MW-exposed mice. Our findings led us to conclude that a low level of MW

irradiation-induced oxidative stress not only suppresses implantation, but it may also lead to deformity of the embryo in case pregnancy continues. We also suggest that MW radiation-induced oxidative stress by increasing ROS production in the body may lead to DNA strand breakage in the brain cells and implantation failure/resorption or abnormal pregnancy in mice.

Akar A., et al. [“Effects of low level electromagnetic field exposure at 2.45 GHz on rat cornea.”](#) International Journal of Radiation Biology, vol. 89, no. 4, 2012, pp. 243-9.

- The purpose of this study was to investigate the effects of low level electromagnetic field (low level-EMF) exposure, as frequently encountered in daily life (2.45 GHz, 2h/day for 21 days), on the normal adult male rat cornea using histological and stereological method. There was no statistically significant difference in mean corneal thicknesses between the groups ( $p > 0.05$ ), however there were statistically differences between the groups with regard to the thickness of anterior epithelium ( $p < 0.05$ ). Results of this preliminary study show that exposure to MW radiation might cause alterations in the rat cornea.

Atasoy H.I. et al. [“Immunohistopathologic demonstration of deleterious effects on growing rat testes of radiofrequency waves emitted from conventional Wi-Fi devices.”](#) Journal of Pediatric Urology, vol. 9, no. 2, 2012, pp. 223-9.

- The objective of this study was to investigate effects of 2.437 GHz radiofrequency radiation (24h/day for 20 weeks) emitted from indoor Wi-Fi Internet access devices on rat testes using histological and immunohistochemical methods. Researchers observed significant increases in serum 8-hydroxy-2'-deoxyguanosine levels and 8-hydroxyguanosine staining in the testes of the experimental group indicating DNA damage due to exposure ( $p < 0.05$ ) as well as decreased levels of catalase and glutathione peroxidase activity in the experimental group, which may have been due to radiofrequency effects on enzyme activity ( $p < 0.05$ ). These findings raise questions about the safety of radiofrequency exposure from Wi-Fi Internet access devices for growing organisms of reproductive age, with a potential effect on both fertility and the integrity of germ cells.

Avendaño, C., et al. [“Use of laptop computers connected to internet through Wi-Fi decreases human sperm motility and increases sperm DNA fragmentation.”](#) Fertility and Sterility, vol. 97, no. 1, 2012, pp. 39-45.

- The objective of this study was to evaluate the effects of radiofrequency radiation emitted from an internet-connected laptop via Wi-Fi for 4 hours on human sperm motility, viability, and DNA fragmentation. Donor sperm samples, mostly normozoospermic, exposed to a wireless internet-connected laptop showed a significant decrease in progressive sperm motility and an increase in sperm DNA fragmentation. We speculate that keeping a laptop connected wirelessly to the internet on the lap near the testes may result in decreased male fertility.

Ceyhan, A.M., et al. [“Protective effects of  \$\beta\$ -glucan against oxidative injury induced by 2.45-GHz electromagnetic radiation in the skin tissue of rats.”](#) Archives of Dermatological Research, vol. 304, no. 7, 2012, 521-527.

- The aim of the present study was to investigate the effect of 2.45-GHz electromagnetic radiation (60min/day for 4 weeks) on the oxidant and antioxidant status of skin and to examine the possible protective effects of  $\beta$ -glucans (50 mg/kg/day before each EMR exposure) against the oxidative injury in male rats. EMR exposure caused a significant increase in malondialdehyde levels and catalase activity, while the activities of superoxide dismutase and glutathione peroxidase decreased in skin tissues. Systemic

$\beta$ -glucan significantly reversed the elevation of MDA levels and the reduction of SOD activities.  $\beta$ -glucan treatment also slightly enhanced the activity of CAT and prevented the depletion of GSH-Px activity caused by EMR, but not statistically significantly. The present study demonstrated the role of oxidative mechanisms in EMR-induced skin tissue damages and that  $\beta$ -glucan could ameliorate oxidative skin injury via its antioxidant properties.

Kesari, K.K., et al. [“Pathophysiology of microwave radiation: effect on rat brain.”](#) Applied Biochemistry and Biotechnology, vol. 166, no. 2, 2012, pp. 379-88.

This study investigated the effect of 2.45 GHz microwave radiation (2 h/day for 45 days) on biomarkers within Wistar rats. A significant decrease ( $P < 0.05$ ) was recorded in the level of pineal melatonin of exposed group as compared with sham exposed, while a significant increase ( $P < 0.05$ ) in creatine kinase, caspase 3, and calcium ion concentration was observed in whole brain of exposed group of animals as compared to sham exposed. The study concludes that a reduction in melatonin or an increase in caspase-3, creatine kinase, and calcium ion may cause significant damage in brain due to chronic exposure of these radiations. These biomarkers clearly indicate possible health implications of such exposures.

Misa-Augustiño, M.J., et al. [“Electromagnetic fields at 2.45 GHz trigger changes in heat shock proteins 90 and 70 without altering apoptotic activity in rat thyroid gland.”](#)Biology Open, vol. 1, no. 9, 2012, pp. 831-39.

- This study examined the possible ability of 2.45 GHz microwave radiation exposure (30 min) to modify the expression of genes that codify heat shock proteins (HSP) in the thyroid gland. Ninety minutes after radiation, HSP-90 and HSP-70 had decreased significantly ( $P < 0.01$ ); Twenty-four hours after radiation, HSP-90 had partially recovered and HSP-70 had recovered completely. There were few indications of lesions in the glandular structure and signs of apoptosis were negative in all radiated animals. The results suggest that acute sub-thermal radiation at 2.45 GHz may alter levels of cellular stress in rat thyroid gland without initially altering their anti-apoptotic capacity.

Nazıroğlu, M., et al. [“2.45-Gz wireless devices induce oxidative stress and proliferation through cytosolic Ca<sup>2+</sup> influx in human leukemia cancer cells.”](#)International Journal of Radiation Biology, vol. 88, no. 6, 2012, pp. 449–56.

- The present study was designed to determine the effects of 2.45 GHz radiation (1, 2, 12, or 24 hours) on the antioxidant redox system, calcium ion signaling, cell count and viability in human leukemia 60 cells. The extent of lipid peroxidation, cytosolic free Ca<sup>2+</sup> and cell numbers were higher in 2.45 GHz groups than in the controls and was time-dependent. 2.45 GHz electromagnetic radiation appears to induce proliferative effects through oxidative stress and Ca<sup>2+</sup> influx although blocking of transient receptor potential melastatin 2 channels by 2-aminoethyl diphenylborinate seems to counteract the effects on Ca<sup>2+</sup> ions influx.

Nazıroğlu, M., et al. [“Melatonin modulates wireless \(2.45 GHz\)-induced oxidative injury through TRPM2 and voltage gated Ca\(2+\) channels in brain and dorsal root ganglion in rat.”](#)Physiology & Behavior, vol. 105, no. 3, 2012, pp. 683-92.

- We aimed to investigate the protective effects of melatonin and 2.45 GHz electromagnetic radiation (60 min/day for 30 days) on brain and dorsal root ganglion (DRG) neuron antioxidant redox system, Ca(2+)

influx, cell viability and electroencephalography (EEG) records in the rat. Lipid peroxidation (LP), cell viability and cytosolic Ca(2+) values in DRG neurons were higher in EMR-exposed groups than in controls, although their concentrations were increased by melatonin, 2-aminoethyl-diphenyl borinate (2-APB), diltiazem and verapamil supplementation. Lower numbers of EEG spikes were recorded in EMR+melatonin groups than in EMR only, while brain cortex vitamin E concentrations were higher in the melatonin-supplemented group. In conclusion, Melatonin supplementation in DRG neurons and brain seems to have protective effects on the 2.45 GHz-induced increase Ca(2+) influx, EEG records and cell viability of the hormone through TRPM2 and voltage gated Ca(2+) channels.

Chaturvedi, C.M., et al. [“2.45GHz \(CW\) microwave irradiation alters circadian organization, spatial memory, DNA structure in the brain cells and blood cell counts of male mice, \*Mus musculus\*.”](#) Progress in Electromagnetics Research B, vol. 29, 2011, pp. 23-42.

- The present study examined the biological effects of continuous wave 2.45 GHz microwave radiation (2h/day for 30 days) in Parkes strain mice. The results show that microwave radiation caused an increase in erythrocyte and leukocyte counts, a significant DNA strand break in brain cells and the loss of spatial memory in mice. This report for the first time provides experimental evidence that continuous exposure to low intensity microwave radiation may have an adverse effect on the brain function by altering circadian system and rate of DNA damage.

Jorge-Mora, T., et al. [“The effects of single and repeated exposure to 2.45 GHz radiofrequency fields on c-Fos protein expression in the paraventricular nucleus of rat hypothalamus.”](#) Neurochemical Research, vol. 36, no. 12, 2011, pp. 2322-32.

- This study investigated the effects of 2.45 GHz microwave radiation (exposed once or repeatedly – ten times in two weeks) on the cellular activation within the paraventricular nucleus of the hypothalamus, extracted from rat brains. High SAR triggered an increase of the c-Fos marker 90 min or 24 h after radiation, and low SAR resulted in c-Fos counts higher than in control rats after 24 h. Repeated irradiation at 3 W increased cellular activation of PVN by more than 100% compared to animals subjected to acute irradiation and to repeated non-irradiated repeated session control animals. The results suggest that PVN is sensitive to 2.45 GHz microwave radiation at non-thermal SAR levels.

Kumar, S., K.K. Kesari and J. Behari. [“The therapeutic effect of a pulsed electromagnetic field on the reproductive patterns of male Wistar rats exposed to a 2.45-GHz microwave field.”](#) Clinics (Sao Paulo), vol. 66, no. 7, 2011, pp. 1237-45.

- This study aimed to examine the therapeutic effects of a 100 Hz pulsed electromagnetic field (2 h/day for 60 days) on the reproductive systems of male Wistar rats (70 days old). The results showed significant increases in caspase and creatine kinase and significant decreases in testosterone and melatonin in the exposed groups. This finding emphasizes that reactive oxygen species (a potential inducer of cancer) are the primary cause of DNA damage. However, pulsed electromagnetic field exposure relieves the effect of microwave exposure by inducing Faraday currents.

Oni, M.O., D.B. Amuda and C.E. Gilbert. [“Effects of radiofrequency radiation from WiFi devices on human ejaculated semen.”](#) International Journal of Recent Research and Applied Studies, vol. 9, no. 2, 2011, pp. 292-4.

- This study was an in-vitro pilot study which established the effect of radiofrequency radiation from 2.4 GHz laptop antenna on human semen. A test of significance between results of semen parameters using Mann-Whitney U- test at 0.05 level of significance showed a significant effect of RFR exposure on sperm concentration, motility and morphology grading.

Papageorgio, C.C., et al. "[Effects of Wi-Fi signals on the p300 component of event-related potentials during an auditory haying task.](#)" Journal of Integrative Neuroscience, vol. 10, no. 2, 2011, pp. 189-202.

The present study focused on the possible gender-related effects of Wi-Fi electromagnetic fields on these processes in human males and females. P300 amplitude values at 18 electrodes were found to be significantly lower in the response inhibition condition than in the response initiation and baseline conditions and independent of this effect, within the response inhibition condition there was also a significant gender X radiation interaction effect of males in comparison to female subjects only at the presence of EMF. In conclusion, the present findings suggest that Wi-Fi exposure may exert gender-related alterations on neural activity associated with the amount of attentional resources engaged during a linguistic test adjusted to induce WM.

Türker, Y., et al. "[Selenium and L-carnitine reduce oxidative stress in the heart of rat induced by 2.45-GHz radiation from wireless devices.](#)" Biological Trace Element Research, vol 143, no. 3, 2011, pp. 1640-50.

- The aim of this study was to investigate the possible protective role of selenium and L-carnitine on oxidative stress induced by 2.45-GHz radiation (60min/day for 28 days) in heart of rat. Electromagnetic radiation exposure was found to cause oxidative stress in the heart of rats. There is also an apparent protective effect of selenium and L-carnitine by inhibition of free radical formation and support of the antioxidant redox system.

Grigoriev, Y.G., et al. "[Confirmation studies of Soviet research on immunological effects of microwaves: Russian immunology results.](#)" Bioelectromagnetics, vol. 31, no. 8, 2010, pp. 589-602.

- This paper presents the results of a replication study performed to investigate earlier Soviet studies conducted between 1974 and 1991 that showed immunological and reproductive effects of long-term low-level exposure of rats to radiofrequency electromagnetic fields (continuous wave 2450 MHz for 7h/day, 5days/week for 30 days). The RF exposure resulted in minor increases in formation of antibodies in brain tissue extract and the exposure did not appear to be pathological. In addition, a study was conducted to replicate a previous Soviet study on effects from the injection of blood serum from RF-exposed rats on pregnancy and foetal and offspring development of rats, using a similar animal model and protocol. Our results showed the same general trends as the earlier study, suggesting possible adverse effects of the blood serum from exposed rats on pregnancy and foetal development of intact rats, however, application of these results in developing exposure standards is limited.

Kesari, K.K., et al. "[Mutagenic response of 2.45 GHz radiation exposure on rat brain.](#)" International Journal of Radiation Biology, vol. 86, no. 4, 2010, pp. 334-43.

- The purpose of the study was to investigate the effect of 2.45 GHz microwave radiation (2 h/day for 35 days) on the male rat brain. MWR-exposed rats showed significantly increased comet head, tail length and tail movement, as well as decrease of antioxidant enzymes. Researchers conclude that the chronic exposure to these radiations may cause significant damage to brain, which may be an indication of possible tumour promotion.

Kesari, K.K. and J. Behari. [“Effects of microwave at 2.45 GHz radiations on reproductive system of male rats.”](#) Toxicological and Environmental Chemistry, vol. 92, no. 6, 2010, pp. 1135-47.

- The present study was performed to investigate the effect of 2.45 GHz microwave radiation (2 h/day for 35 days) on reproductive pattern of male Wistar rats. Chronic exposure to these radiations produced formation of apoptotic cells in testis. In addition, a significant decrease in the levels of antioxidant enzymes glutathione and superoxide dismutase activities as well as an increase in catalase activity was observed in the exposed group. These results indicate that a low level exposure of microwave radiations exerts a negative impact on male reproductive system function.

Maganioti, A. E., et al. [“Wi-Fi electromagnetic fields exert gender related alterations on EEG.”](#)6th International Workshop on Biological Effects of Electromagnetic fields, 2010.

- The present study investigated the influence of 2.4GHz electromagnetic fields, similar to that emitted by Wi-Fi system, on human brain activity. The presence of radiation had no effect on the energies of alpha and beta band of male subjects, while it reduced these energies of female subjects, resulting in significantly lower energies, as compared to those of males. Delta and theta band energies did not experience any noteworthy effect from gender, radiation condition and their interaction. Conversely, there was a significant interaction effect (gender x radiation) on the energies of alpha and beta rhythms. The present data support the idea that Wi-Fi signal may influence normal physiology through changes in gender related cortical excitability, as reflected by alpha and beta EEG frequencies.

Gumral, N., et al. [“Effects of selenium and L-carnitine on oxidative stress in blood of rat induced by 2.45-GHz radiation from wireless devices.”](#)Biological Trace Elements Research, vol. 132, no. 1-3, 2009, pp. 153-63.

- This study measured the levels of blood lipid peroxidation, glutathione peroxidase, reduced glutathione, and vitamin C to follow the level of oxidative damage caused by 2.45 GHz electromagnetic radiation exposure (60 min/day for 28 days) in rats. The possible protective effects of selenium and L-carnitine were also tested and compared to untreated controls. Researchers found that 2.45 GHz electromagnetic radiation caused oxidative stress in blood of rat. L-carnitine seems to have protective effects on the 2.45-GHz-induced blood toxicity by inhibiting free radical supporting antioxidant redox system although selenium has no effect on the investigated values.

Naziroğlu, M. and N. Gumral. [“Modulator effects of L-carnitine and selenium on wireless devices \(2.45 GHz\)-induced oxidative stress and electroencephalography records in brain of rat.”](#)International Journal of Radiation Biology, vol 85, no. 8, 2009, pp. 680-9.

- The present study was designed to determine the effects of 2.45 GHz EMR (60 min/day for 28 days) on the brain antioxidant redox system and electroencephalography (EEG) records in rat, as well as examine the possible protective effects of selenium and L-carnitine. EMR-exposed animals showed lower concentration of vitamins A, C, and E than controls, although their concentrations were increased by selenium and L-carnitine supplementation. Animals which received selenium and L-carnitine in addition to EMR also showed lower levels of lipid peroxidation. Results indicate that L-carnitine and selenium seem to have protective effects on the 2.45 GHz-induced decrease of the vitamins by supporting antioxidant redox system.

Sinha, R.K. [“Chronic non-thermal exposure of modulated 2450 MHz microwave radiation alters thyroid hormones and behavior of male rats.”](#) International Journal of Radiation Biology, vol. 84, no. 6, 2008, pp. 505-13.

- The purpose of this investigation was to analyze the effects of chronic 2.45 GHz leakage microwave irradiation on thyroid hormones and behavior of male rats. Behavioral changes were found to be significantly changed from controls for immobilization, rearing and ambulation behavior. Changes in behavioral parameters are also correlated with the trend of changes, compared to control animals, in hormonal blood levels of T3 and T4. Researchers concluded that low energy microwave irradiation may be harmful as it is sufficient to alter the levels of thyroid hormones as well as the emotional reactivity of the irradiated compared to control animals.

Paulraj R. and J. Behari. [“Single strand DNA breaks in rat brain cells exposed to microwave radiation.”](#) Mutation Research, vol 596, no. 1-2, 2006, pp. 76-80.

- This investigation concerns with the effect of low intensity microwave (2.45 and 16.5 GHz, SAR 1.0 and 2.01 W/kg, respectively) radiation on developing rat brain when exposed for 35 days. Results showed that the chronic exposure to these radiations caused statistically significant ( $p < 0.001$ ) increase in DNA single strand breaks in brain cells of rat.

Paulraj R. and Behari J. [“Protein kinase C activity in developing rat brain cells exposed to 2.45 GHz radiation.”](#) Electromagnetic Biology and Medicine, vol. 25, no. 1, 2006, pp. 61-70.

- This experiment investigated the effects of 2.45 GHz microwave radiation exposure (2h/day for 35 days) on the developing rat brain. The study revealed a statistically significant ( $p < 0.05$ ) decrease in protein kinase C activity in hippocampus as compared to the remaining portion of the whole brain and the control group, while a similar experiment conducted on hippocampus and the whole brain gave a similar result. Electron microscopic study shows an increase in the glial cell population in the exposed group as compared to the control group. This present study is indicative of a significant change after exposure to the above-mentioned field intensity, which suggests that chronic exposures may affect brain growth and development.

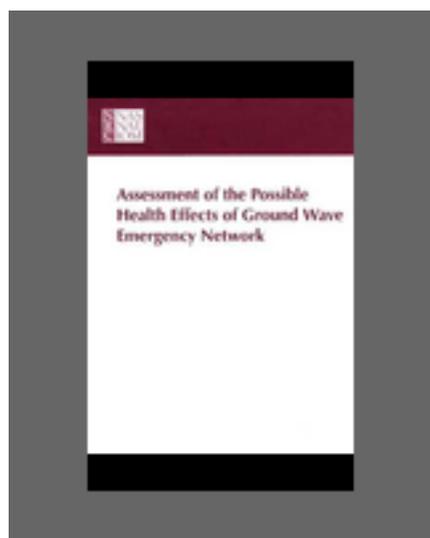

Chou, C.K., et al. [“Long-term, low-level microwave irradiation of rats.”](#) Bioelectromagnetics, vol. 13, no. 6, 1992, pp. 469–96.

- This study investigated the effects of long-term exposure to 2.45 GHz pulsed microwave radiation. The major emphasis was to expose a large sample of experimental animals throughout their lifetimes (21.5h/day for 25 months, starting at 8 weeks) and to monitor them for effects on general health and longevity. Results showed negative overall effects of RFR on general health, longevity, cause of death, or lesions associated with aging and benign neoplasia. Positive findings of effects were found on corticosterone levels and immune system. A statistically significant increase in primary malignancies in exposed rats vs. incidence in control was also found.

Somogyi, Z., et al. [“Effects of modulated and continuous microwave irradiation on the morphology and cell surface negative charge of 3T3 fibroblasts.”](#) Scanning Microscope, vol. 5, no. 4, 1991, pp. 1145-55.

- Mouse embryo 3T3 cells were irradiated with 2450 MHz continuous and low frequency (16 Hz) square modulated waves of absorbed energy. The low frequency modulated microwave irradiation yielded more morphological cell changes than did the continuous microwave fields of the same intensity. The amount of

free negative charges (cationized ferritin binding) on cell surfaces decreased following irradiation by modulated waves but remained unchanged under the effect of a continuous field of the same dose. Modulated waves of 0.024 mW/g dose increased the ruffling activity of the cells, and caused ultrastructural alteration in the cytoplasm. Similar effects were experienced by continuous waves at higher (0.24 and 2.4 mW/g) doses.

## Assessment of the Possible Health Effects of Ground Wave Emergency Network.

# 4 Perception and Behavioral Effects of Electromagnetic Fields

Some animals respond to extremely low levels of electromagnetic fields (EMF), usually at frequencies ranging from DC to extremely-low-frequency (ELF) and usually with specialized receptors.<sup>1</sup> Although the responses have been described and can be demonstrated at will, the mechanisms are not understood. Perceptual and behavioral responses to very low levels of EMFs at low frequency and above have not been reported in humans, and there are no mechanisms at DC or ELF that might imply as yet unreported responses, although they cannot be excluded. There is a considerable literature on perception and behavioral responses to stimulation at magnitudes consistent with direct electrical stimulation of nervous tissues by induced currents in the tissue, but they are limited to the frequency ranges that stimulate excitable membranes.

In the radiofrequency (RF) range of concern for assessment of GWEN sites, there have been many reports of sensory perception. The responses may be organized in the following categories:

- Stimulation of nervous structures by electric and magnetic fields and associated currents in the body. Above a threshold that is frequency-dependent, these currents are perceived as a painful stimulus that increases with current intensity.

Electroencephalographic (EEG) activity in cats and rabbits has been reported to be altered by exposure to amplitude-modulated RF. Exposure to 147-MHz fields, amplitude-modulated between 1 and 25 Hz, altered the ability of cats to produce selected EEG rhythms. Changes in EEG frequency spectrum were also observed in rabbits chronically exposed to 1-10 MHz fields that were amplitude-modulated at 14-16

Hz.<sup>2</sup> Other studies have shown small changes in EEG patterns, particularly desynchronization, in rats and rabbits after exposure to 12.95-GHz field at 1 W/kg.<sup>3,4</sup> In some later studies failed to find an effect. The lowest levels used, in the above studies are 10,000 times that which would be encountered near GWEN installations.

- Shocks and burns. When the human body is in an EMF of suitable frequency and intensity and it makes contact with a conducting body in the same field, an electrical current is produced that can cause perceptible electrical shock, muscular contractions, burns, and possible death.
- Heating. If enough RF power is absorbed in human tissue, especially skin, it can raise the tissue temperature and cause a sensation of warming that will be due to thermal stimulation of temperature receptors. Thermal perception of absorbed RF energy is frequency-dependent: the threshold energy decreases as the frequency increases.<sup>5</sup> There is a delay in the perception of warmth after the start of irradiation; the delay may vary from 5 sec or more at GHz frequencies to as little as 1 sec for infrared radiation.<sup>6</sup> Justesen et al.<sup>7</sup> compared thermal perception in human volunteers who were irradiated on the forearm in a 100-cm<sup>2</sup> area with far-infrared radiation or 2.45-GHz microwave radiation. The thresholds of perception for a 10-sec exposure were 1.7 mW/cm<sup>2</sup> for far infrared radiation and 26.7 mW/cm<sup>2</sup> for microwave radiation.
- Auditory perception. A special effect has been reported in which microwave RF emitted in the form of very short pulses (1-20 μsec) is perceived by humans and animals as clicks or other sounds. This perception could well result when thermal absorption leads to thermoelastic expansion of tissues and fluids in the head and is sensed by auditory receptors. If the energy flux in the pulse exceeds about 40 μJ/cm<sup>2</sup>, delivered in a few microseconds, auditory perceptions occur.<sup>8</sup>

The auditory perception of pulsed microwave fields was first reported in 1947 and has been studied extensively. Frey<sup>9</sup> reported on controlled experimental exposures at frequencies of 0.2-8.9 GHz and pulse widths of 1-1,000 μsec. He found that, depending on the characteristics of the field, sensations were perceived as buzzing, ticking, hissing, or knocking sounds. Sound was perceived at all frequencies up to 8.9 GHz. Guy et al.<sup>10</sup> demonstrated that the threshold for auditory perception was four times higher at 3.75 kHz in subjects with neurosensory deficits compared with normal subjects, thus indicating that the effect was in the acoustic elements involved in hearing.

- Behavioral changes. Epidemiologic studies of groups of people occupationally or environmentally exposed to electromagnetic fields in the RF and ELF range have yielded perceptual and behavioral responses, including fatigue, difficulty in concentrating, and increased frequency of headaches. A number of researchers have used disruption of behavior patterns, such as work stoppage, to study the effect of RF fields on animals, including rodents<sup>11-13</sup> and monkeys.<sup>14</sup> Several carrier frequencies, field zones, and modulation characteristics were used. A relatively narrow range of threshold of specific absorption rates (SARs), about 4-9 W/kg, was found. Lebovitz<sup>15</sup> examined the effect of repeated exposures to a pulsed 1,300-MHz field on behavioral performance in rats. He exposed animals to SARs of 1.6, 3.6, or 6.7 W/kg for 3 h/day, 5 d/wk for 6-9 wk and found that rates of lever-pressing for food were slightly reduced at the highest SAR. However, the ability of the rats to discriminate improved as a positive function of SAR when lever-pressing was not reinforced by the presence of food. DeLorge<sup>16</sup> used a different experimental paradigm and showed a disruption in performance of rats at an SAR of 2.5 W/kg when they were exposed to a pulsed 1,300-MHz field. Behavioral studies performed by Hjeresen et al.<sup>17</sup> showed that rats placed in a shuttlebox tended to remain in the side shielded from pulsed RF fields. Because the rats also tended to avoid pulsed sound waves, the investigators suggested that the rats' avoidance of the RF fields might be related to the hearing of the pulsed fields. The response to a pulsed field is stronger than that to a continuous field. For example, Carroll et al.<sup>18</sup> found that rats exposed to an intense field that was not

pulse-modulated did not readily learn to escape from it. It appears that hearing the pulses is a more effective cue for escaping than is the warming that results from a continuous field.

Studies in Eastern Europe have investigated populations exposed to EMFs ranging from 50 Hz to microwave frequencies.<sup>19</sup> Complaints included irritability, lethargy, insomnia, impotence, headaches, loss of memory, and inability to concentrate. The syndrome was identified as neurasthenia or "microwave sickness." Energy magnitudes associated with the syndrome have been reported for a few microwatts to a few thousand microwatts per square centimeter. An epidemiologic study of the personnel in the American embassy in Moscow found an excess of the same neurasthenic symptoms, but the symptoms were not correlated with measured individual exposures.<sup>20</sup>

Eastern European investigators have also reported on rats and rabbits exposed for one to several hours a day over periods of weeks or months. Power densities ranging from 0.6 to 30,000  $\mu\text{W}/\text{cm}^2$  were reported to alter conditional reflexes<sup>21</sup> and decrease latency of audiogenic seizures.<sup>22</sup> Attempts to confirm the findings were made by several investigators; some effects of exposure to RF fields were found, but most were at higher field intensities, and in general the results did not support the findings from Eastern Europe.

Studies with ELF fields have suggested that behavior can be influenced by exposure to either magnetic or electric fields. Persinger<sup>23</sup> reported that prenatal exposure of rats to 0.5-Hz, 0.05-to 3-mT fields, resulted in changes in juvenile or adult rats' emotionality and ability to perform a conditioned-suppression test. Frey<sup>24</sup> found that prenatal exposure of rats to a 60-Hz field at 3.5 kV/m caused changes in open-field activity.

McGivern et al.<sup>25</sup> studied male rats that had been exposed prenatally on days 15-21 of gestation. Exposures were for 15 min twice a day, to a 15-Hz, 800- $\mu\text{T}$  pulsed magnetic field. Exposed animals showed a significant reduction in scent marking, compared with sham-exposed or caged controls. Exposed males had larger seminal vesicles, prostates, and epididymides than did control males.

Transient neurobehavioral changes in rats exposed prenatally and postnatally to a 60-Hz electric field (65-kV/m effective field) were reported by Sikov et al.<sup>26</sup> Exposed animals showed significantly more motility than did controls. Development of righting reflex and negative geotropism was also delayed in exposed rats; the percentage of pups that failed to show these behaviors was increased on day 14 of postnatal life, but not on day 21.

Lovely et al.<sup>27</sup> exposed gravid Sprague-Dawley rats to a 60-kV/m, 60-Hz electric field and then tested the offspring at the age of 90 days in three tasks: shuttlebox avoidance, a residential maze, and a preference-avoidance test. No differences were noted between exposed and sham-exposed animals.

Changes in learning have been reported in rats exposed to a combination of 60-Hz electric fields (30 kV/m and 0.1 mT) and magnetic fields (10 kV/m and 0.033 mT) throughout gestation and during the first 8 days of postnatal life.<sup>28</sup> Both acquisition and extinction of a schedule-controlled response were affected in the exposed animals. In contrast, other studies failed to find an effect of exposure to ELF fields on behavior.<sup>29,30</sup>

Exposure to 60-Hz electric fields (30 or 60 kV/m) has been reported to affect the social behavior of baboons.<sup>31,32</sup> The investigators used a number of measures of social behavior, but found that passive affinity, tension, and stereotypy performance were significantly increased in exposed groups. The authors suggested that the changes might indicate a stress response to the fields.

Although there is evidence that exposure of experimental animals to electric or magnetic fields can influence neurobehavioral function, there is a paucity of direct observations at the 175-kHz frequency and at the ultra-high frequencies of 200400 MHz used in the GWEN system. Moreover, magnitudes of the exposure usually required to produce an effect are substantially higher than those likely to be encountered as a result of operation of the GWEN system. It therefore seems unlikely that electromagnetic fields from GWEN will affect neurosensory or neurobehavioral function in persons living around GWEN sites.

# Power Takeover: What's Wrong With "Smart" Meters?

September 30, 2013 [Comments](#)

"Under my plan of a cap-and-trade system, electricity rates would necessarily skyrocket"

**Josh del Sol**  
Infowars.com  
Sept. 30, 2013

On January 17, 2008, President Obama famously said, "**Under my plan of a cap-and-trade system, electricity rates would necessarily skyrocket.**" It's now becoming evident that the new so-called "smart" meter your utility is attempting to force on you, is the culprit technology for the government-sponsored extortion that Obama was referring to. But this is just the beginning of a hornet's nest of alarming details unveiled in our new documentary, Take Back Your Power ([now available at the Infowars shop](#)).

**Billions of tax dollars... no benefits?**

**In a time of economic crisis, the US government allocated \$11B of taxpayer funds** from the 2009 bailout package to develop a "smart" grid, including "smart" meters for every home's electricity, gas and water. And recently, the European Union has announced plans to blow a mind-numbing \$700B on building out this centralized control grid. The ostensible reasons for "smart" metering and grid technology:

- a) to save energy and thus aid the environment;
- b) to increase power reliability; and
- c) to give you more control of energy use in your own home.

It is now easily demonstrated that all three of these claims are patently false. “Smart” meters and grids typically use more energy, they are extremely hackable (making the entire power grid vulnerable), and customers suffer increased utility bills virtually across the board immediately following a “smart” meter installation – a fact even acknowledged now by some utilities.

In the words of Dr. Timothy Schoechle, a leading digital technology engineer and author of “Getting Smarter About The Smart Grid:”

“The smart meter is a canard—a story or a hoax based on specious and grandiose claims about energy benefits ostensibly derived from the promise of “two-way” communication with the customer... There is essentially no possibility that most smart meters or meter networks will lead to greater sustainability.”

### **Clear evidence of health damage**

**Tens of thousands of individuals are reporting officially, to governments and utilities, that they are experiencing illness or functional impairments** following the installation of “smart” meters. Reported symptoms include headaches, sleep problems, ear ringing, focus difficulties, fatigue, heart palpitations, nausea and statistically abnormal recurrences of cancer. According to court-ordered documentation, and independent testing, utilities have been proven to be lying about how often “smart” meters transmit bursts of microwave radiation. Depending on the utility their claim is typically something like “4-6 times per day” (Pepco), or “45-60 seconds per day” (PG&E) — whereas courts and independent testing reveal that meters are transmitting in the range of **10,000 to 190,000** pulsed microwave transmissions per day.

The amount of transmitted microwave radiation has been measured up to 200 times greater (if one is standing next to the meter) than the Building Biology standard threshold for “extreme concern.” The radiation standards set by national agencies such as the FCC are literally thousands of times higher than science-based levels, because they actually assume that harm can only be done from electromagnetic radiation (EMR) if cells heat up by a certain amount. This is called a “thermal effect”. The reality is that more than 6,000 peer-reviewed, published studies have indicated functional impairment, symptoms of illness or disease (ie. “non-thermal effects”) from levels of EMR as much as 10,000 times lower than “safety” standards set by organizations such as the FCC, Health Canada, ICNIRP, etc.

But the health effects don’t end with the pulsed microwave radiation – from the meters and all future “smart” appliances – under this multinational plan of total control. Every “smart” digital electric meter has what’s known as a “switching mode power supply”, which is proven to directly create large amounts of dirty electricity – or high-frequency energy radiating throughout your home’s electric circuits, essentially creating an antenna cage. The levels of DE caused by “smart” meters can be several hundred times higher than some international safety standards. When confronted, one government agent would not talk about this on his work phone, but confirmed the awareness and concern of the DE health hazard on a private call.

As stated by Dr. De-Kun Li, a respected Kaiser Permanente scientist whom I interviewed, **utilities and industry simply haven't done any studies to show that "smart" meters are safe. Not one.** In this complete void of responsibility or conscience, independent research is now starting to clearly show negative biological effects. One such example is demonstrated in our film – the effects of a single "smart" meter on live human blood – and the visual results are staggering, to say the least.

Additionally, by many reports there are now **well over a thousand home fires** linked to "smart" meters, and tens of thousands have experienced other appliance breakages in their home. Incredulously, almost none of these meters, made mostly in China, have been tested or approved by UL or an equivalent standards body. Thus, the homeowner has no guarantee of coverage, and is often left to deal with the damage and expense to repair.

### **"Smart" spy state**

As if all this is not enough, "smart" meters – in combination of "smart" appliances also chronically transmitting low-level microwave radiation – are functionally designed to **collect swaths of in-home private data on everyone.**

According to a US Congressional Research Service report, "Police will have access to data that might be used to track residents' daily lives and routines while in their homes, including their eating, sleeping, and showering habits, what appliances they use and when, and whether they prefer the television to the treadmill, among a host of other details."

But it gets worse.

Utilities and public utilities commissions (such as California's PUC) are actually **encouraging the sale of this private data** – everything you do in your own home – to 3rd-party corporate interests, for a profit.

And incredulously, even former CIA Director David Patraeus boasted (in Wired, March 2012) that government will be routinely spying on through their "smart" appliances. Thus, with CISPA's focus on legalizing private data transfer deals for corporations to government agencies, the primary motivation behind the push for such legislation starts to become clear.

And not only would every detail of your life be tracked, but your access to electricity would be totally controlled: your appliances or entire home could be shut down at any time – without notice – by any utility, or government agency, or as former CIA director James Woolsey states, "a hacker on a cellphone in China."

Newsflash: the NSA phone spying scandal is just the tip of the globalist iceberg.

The good news: this master plan of control and order-out-of-chaos cannot be achieved if enough people simply refuse to participate in this federally-sponsored voluntary microwave and surveillance program.

### **The rising tide of awakening**

This is the first time in known history that either governments or corporations are attempting to force a device (on entire populations) which has been openly proven to **cause direct harm to health, rights, security and property**. And this agenda rips apart the 4th, 5th and 10th Constitutional Amendments.

The installation of “smart” meters is either underway or planned in virtually all western countries, despite existing foundational laws which have heretofore served as protection for the people. It does, in fact, appear that the corrupted powers-that-be truly are going for broke on this one folks.

However, as documented in *Take Back Your Power*, there is a **growing widespread awareness** and resistance to this anti-freedom, anti-life program. **Hundreds of local governments have issued a moratorium** on the installation of “smart” meters, and in California alone, 15 councils have criminalized the installations. Several such as Sebastopol have additionally issued an ordinance fining PG&E \$500 fine per installed meter in their city.

But PG&E and other utilities around the world still are not backing down. In almost all regions where people are beginning to rise to their feet, utilities are moving toward an extortive “opt-out” program, charging customers through the nose for the privilege of not being microwaved and surveilled in their home. Last week the rogue British Colombian government floated the idea to more than 60,000 hold-outs, to pay them an initial fee of \$100, and then pay them an ongoing fee of \$35 per month, just to keep their analog meter.

According to some legal experts we interviewed, the trick is to realize that it’s just a poker game.

**There is no law** requiring you to accept a so-called “smart” meter on your home, or to participate in extortion, even though utilities and governments are intimidating people into believing they have no choice. Strangely enough, paying criminals to minimize the harm they are doing does not sit well with most people.

Legal actions and claim-of-right processes against installations are sprouting up and becoming almost ubiquitous. In many local governments that are still not listening to the people, individual councilors and mayors are now beginning to be on the receiving end of civil and criminal litigation, and processes based in contract law. As one rights group put it,

“No longer can a department head say they were just following orders. No longer can a mayor or city council member say they didn’t know, especially when an avalanche of information is presented to them indicating their position on an issue is detrimental to the health their constituency.”

Because virtually all of us have utility meters, we all now have direct leverage against a central pillar of the planetary control system, perhaps for the first time in any social movement, ever.

This is why we made *Take Back Your Power*. This is why we put up with two years of corporate witchcraft and BS. To let people know – in a highly credible, inspiring and hugely entertaining way – that you no longer have to be silenced by a faceless, soulless enemy. And to provide a tool that can be used like a light saber of awakening on personal networks – or entire regions.

The curtain’s pulled back. Time to connect-the-dots and turn the tables. Let’s start by reaching the 20% who are more-or-less already awake.

## High stakes, big opportunity

What's at stake is nothing less than our basic rights to life, health, choice and freedom itself. When finally understood, this situation is a crisis, but it is also a **truly momentous opportunity** to claim power back into the hands of the people, by decentralizing energy production within the community, and vetoing the old dinosaurs of leechlike extraction. The insanity of these systems is becoming evident, no matter how well-trained the oligarchy's PR department.

What helps to make sense of this whole thing, is coming to the understanding that governments have become corporate puppets and have been systematically suppressing any tangible solution for decades. The Federation of American Scientists acknowledges that more than 5,000 technology patent applications have been "secretized." And the US Patent Office actually has a publicly-visible internal law for the suppression of inventions. With 6 of the 7 world's richest companies in the oil/gas/energy industry, should it be surprising that corporate governments have (in Spain) actually passed laws to prohibit the "illegal use of sunlight for energy generation," setting a fine of \$30M Euros for violating homeowners?

The fact is, in order for human civilization to make it through this time of terrible corruption – and to realize a world of decentralized power and restoration of rights to health, privacy and life itself – we are now required to transition to higher awareness of our situation. We are being asked to confront our existential fear of authority; to go through the proverbial eye of the needle. This requires a realization of the tremendous magnitude of fraud that has been perpetrated by the corporate-government power centers – and then a willingness to take a stand and move our innate Creative force through this awareness. To commit to a solution that burns off the parasite, and benefits the living.

In the end, there is no other way but to stand against corruption, and reveal who we are.

PRINCETON  
BIOPHARMA  
CAPITAL  
PARTNERS, LLC

## INVESTMENT TEAM

### Michael Wells

Michael is a Managing Director at Princeton Biopharma Capital Partners, LLC a boutique private equity firm focused on providing growth capital and operating expertise to commercial stage healthcare companies. He is a veteran of the pharmaceutical industry with extensive expertise in licensing and commercialization of prescription pharmaceuticals around the world. Prior to forming Princeton Biopharma Capital, LLC, he was the founder and CEO of Aton Pharma, Inc., a specialty pharmaceutical company with products that treated orphan diseases. Michael started the company in 2004 with a blank piece of paper and a dream. By 2010, the company was on track to surpass \$100 million in revenue and \$35 million of EBITDA with 11 products sold in over 30 countries. In 2010 the company was sold to Valeant Pharmaceuticals International for \$330 million. In 2009 Michael was a winner of the Ernst & Young Entrepreneur of the Year Award.

Prior to forming Aton, Michael co-founded Lathian Systems Inc., a venture-backed company that provides online data and marketing services to pharmaceutical and biotech companies. At Lathian, he held several senior management positions, including Vice President of Marketing, Vice President of Sales, Vice President of Operations and Director. His career began at Merck & Co. Inc., where he held positions ranging from hospital sales to brand management. He holds a BS and MS from the University of Pittsburgh and an MBA from The Wharton School.

### George Parise

George is a Managing Director at Princeton Biopharma Capital Partners, LLC with strong experience in the pharmaceutical industry and in private equity. Prior to co-founding Princeton Biopharma Capital Partners, LLC, George was the Chief Financial Officer of Aton Pharma, Inc., a specialty pharmaceutical company with products that treated orphan conditions and ophthalmology. George provided financial leadership to Aton through two acquisitions, a \$30MM credit facility entered into in the difficult credit environment of 2009, and the sale of Aton to Valeant Pharmaceuticals in the Spring of 2010.

Prior to joining Aton, George was an operating executive with Cerberus Operations and Advisory Company, leading diligence efforts and assuming key operating roles within portfolio companies. During his tenure with Cerberus, George's positions included Chief Financial Officer of Velocita Wireless, where he led the complex standalone transition of this Cingular Wireless carve-out and spearheaded the eventual successful sale to Sprint. Prior to his time at Cerberus, Mr. Parise was the Senior VP of Finance for CAI Wireless Systems, a publicly held wireless telecommunication services provider, where he offered financial leadership to the organization through

several business plan changes, a financial restructuring through Chapter 11 of the US Bankruptcy Code, and the successful sale of the company. Prior to CAI, Mr. Parise was the Chief Financial Officer of CellularVision, a pioneer in the development of wireless telecommunication services, where he led the company's successful initial public stock offering. Mr. Parise has also held the position of Staff Vice President of Accounting at TriCon Leasing Corporation (a former subsidiary of Verizon), and has held several progressing positions with Ernst & Young. Mr. Parise holds a BS in Accounting from Seton Hall University and is a CPA (inactive).

## Barry Levinson

Barry is a Managing Director at Princeton Biopharma Capital Partners, LLC with over 25 years of biotech and pharmaceutical industry experience combined with a distinguished scientific career. Prior to joining Princeton Biopharma Capital Partners, LLC, Barry was Vice President of Business Development at Valeant Pharma North America LLC, responsible for the business development activities of its specialty pharmaceutical businesses in dermatology, CNS, orphan conditions and ophthalmology. Before Valeant, Barry was a founding employee of Aton Pharma, Inc., a specialty pharmaceutical company with products that treated orphan conditions and ophthalmology. As its Vice President of Business Development, Barry identified and acquired several key products for Aton and put in place its international partnerships. In addition, he was responsible for recognizing opportunities to expand the application of Aton's products to new medical uses, and spearheaded programs to develop these new indications.

Before Aton, Barry was Founder and President of Park Life Science Advisory, LLC, where he provided outsourced business development capabilities for life science companies. He was previously a Managing Director at CPP Advisors (now Apeiron Partners), a boutique life sciences strategic advisory group and before that a Director in the Life Sciences Group at KPMG Corporate Finance, LLP, an investment bank. For the 10 years prior to KPMG, Dr. Levinson held increasingly senior positions in cardiovascular research and then in business development at Berlex Laboratories, the US subsidiary of Schering A.G. (now Bayer Healthcare Pharmaceuticals), most recently as Associate Director of Schering's Office of Technology. Before Berlex, Dr. Levinson initiated and developed the Protein Biochemistry Group at the biotech startup Ecogen, and served as the company's Radiation Safety Officer. Dr. Levinson received his PhD and Master's degrees in Molecular Biophysics and Biochemistry from Yale University, and was granted his BA, with highest honors, in Biochemistry from Princeton University.

# Self-reporting of symptom development from exposure to radiofrequency fields of wireless smart meters in victoria, australia: a case series.

[Lamech F.](#)

## Abstract

### CONTEXT:

In 2006, the government in the state of Victoria, Australia, mandated the rollout of smart meters in Victoria, which effectively removed a whole population's ability to avoid exposure to human-made high-frequency nonionizing radiation. This issue appears to constitute an unprecedented public health challenge for Victoria. By August 2013, 142 people had reported adverse health effects from wireless smart meters by submitting information on an Australian public Web site using its health and legal registers.

### OBJECTIVE:

The study evaluated the information in the registers to determine the types of symptoms that Victorian residents were developing from exposure to wireless smart meters.

### DESIGN:

In this case series, the registers' managers eliminated those cases that did not clearly identify the people providing information by name, surname, postal address, and/or e-mail to make sure that they were genuine registrants. Then they obtained consent from participants to have their deidentified data used to compile the data for the case series. The author later removed any individual from outside of Victoria.

### PARTICIPANTS:

The study included 92 residents of Victoria, Australia.

### OUTCOME MEASURES:

The author used her medical experience and judgment to group symptoms into clinically relevant clusters (eg, pain in the head was grouped with headache, tinnitus was grouped with ringing in the ears). The author stayed quite close to the wording used in the original entries. She then calculated total numbers and percentages for each symptom cluster. Percentages were rounded to the nearest whole number.

### RESULTS:

The most frequently reported symptoms from exposure to smart meters were (1) insomnia, (2) headaches, (3) tinnitus, (4) fatigue, (5) cognitive disturbances, (6) dysesthesias (abnormal sensation), and (7) dizziness. The effects of these symptoms on people's lives were significant.

## **CONCLUSIONS:**

Review of some key studies, both recent and old (1971), reveals that the participants' symptoms were the same as those reported by people exposed to radiofrequency fields emitted by devices other than smart meters. Interestingly, the vast majority of Victorian cases did not state that they had been sufferers of electromagnetic hypersensitivity syndrome (EHS) prior to exposure to the wireless meters, which points to the possibility that smart meters may have unique characteristics that lower people's threshold for symptom development.

## Amid Health, Privacy Fears, States Are Letting People Reject 'Smart Meters'

- February 05, 2016
- By [Sarah Breitenbach](#)

© The

Associated Press

A Burlington Electric employee checks the radio frequency of a smart meter in Vermont, which in 2012 became the first state to allow electric customers to refuse smart meters at no added cost.

Shortly after Joe Davidson moved into his Cincinnati apartment, he noticed his joints were achy and he wasn't sleeping well. Then he needed two root canals.

Davidson is among a small but outspoken group of people who say the radio frequencies coming from so-called smart meters installed in their homes are making them sick. The wireless devices — designed to measure gas and electricity consumption and help consumers save money — have other critics, such as privacy advocates who argue they could violate customers' privacy and consumer advocates who complain they could lead to higher utility bills.

Driven by these concerns, legislators in several states have moved to give consumers options when it comes to installing smart meters in their homes.

According to the National Conference of State Legislatures, at least 15 states allow customers to opt out of smart meter installation, although many permit utility companies to impose a fee on customers who don't want the meters.

This year, lawmakers in Maryland, [Massachusetts](#), [Ohio](#), Pennsylvania and [Texas](#) are expected to consider bills that would allow consumers to keep their existing analog meters; require customers to opt in to smart meter programs; or allow them to refuse the devices, sometimes at no cost.

Smart meters measure the consumption of energy as customers use it and submit that information to utility companies, eliminating the need to estimate bills and to visit homes and businesses to read meters.

The meters also allow consumers to track their own energy use. And energy industry representatives say the devices make it easier to pinpoint and respond to power outages, and could lead to more accurate pricing that reflects how gas and electricity costs fluctuate throughout the day.

The meters are touted as a way to cut energy use and save customers money by allowing better monitoring of consumption so utilities can adjust production and consumers can change their habits.

Buoyed by \$200 million in federal [funding](#) in 2009, utilities had installed nearly [52 million](#) smart meters by 2013, according to the U.S. Energy Information Administration (EIA). Eighty-nine percent of those were installed in homes.

But opponents say the meters have been forced upon consumers who don't want the digital devices and the fees many utility companies charge those customers are unjust.

"There's no reason to charge someone for something they don't want," said Del. Glen Glass, a Republican from Maryland who plans to introduce legislation that would prevent utility companies from charging extra to customers who refuse smart meters.

Maryland residents who reject smart meters pay a \$75 one-time fee and an additional \$5.50 each month. But few people actually choose to opt out of smart meters, said Marc Harnish, an analyst with the EIA.

## **Expectation of Privacy**

Because smart meters convey information over wireless networks, some opponents worry the data they transmit could be stolen and used by criminals to target individual homes. For example, by looking at when power is being used, a thief could determine when a house is empty, said Bradley Shear, a Maryland-based privacy lawyer.

"I don't see these issues going away. In fact I see them becoming more complex as more utility companies install these technologies," said Shear, who also worries that hackers could steal customers' personal and financial information.

But advocates for smart meters — such as the nonprofit [Smart Grid Consumer Collaborative](#), which is supported by utility companies, and consumer and conservation groups — say those worries are misplaced.

Patty Durand, the group's director, said the meters don't transmit that kind of data and only send information about how much electricity is being used. She said utility companies have had no data breaches, and though she expects they will eventually, she says consumers are at very little risk because the meters aren't transmitting personal financial information such as credit card numbers.

And, proponents say, criminals looking to rob a home are much more likely to lurk outside someone's house than they are to hack their network.

Eventually more people will have appliances that hook into a home's smart meter to use power more efficiently, saving them money on utility bills, Harnish said. For example, a refrigerator could use information from a smart meter to cool down at a point in the day when energy is relatively cheap.

But bringing appliances online will just give utility companies and potential hackers a more intimate portrait of what's going on in a person's home, Shear said. This detailed data could be sold to outside companies for marketing or other purposes, he said.

"I don't expect the minutiae of what I did in my house to be fair game," Shear said.

To avoid that, Pennsylvania state Rep. Mike Reese, a Republican, has introduced [legislation](#) that would reverse a state smart meter mandate and limit how and when utility companies can share information gleaned from the meters.

"This gives a level of confidence to our customers that their information is private," Reese said.

All states have privacy laws that require utility companies to protect consumer data and the companies generally can't share that information without a customer's permission, said Puesh Kumar, engineering and operations director for the American Public Power Association ([APPA](#)), which represents more than 2,000 publicly owned electric utilities. Utility companies aren't sharing data with marketers, he said.

## **Who saves money?**

Utility companies like smart meters because they save money in multiple ways, Harnish said.

Because the devices are on wireless networks, a power company can see exactly where a power outage occurs instead of relying on customer phone calls and dispatching people to look for the outage, he said.

"They're able to get electricity back up quicker," Harnish said. "That's a big revenue saver."

The price of energy also changes throughout the day as demand rises and falls, and smart meters allow utility companies to adjust what they charge customers for energy as they use it.

But most utilities are not using this kind of pricing yet, APPA officials said. Some offer rebates for people who use less energy during times of high demand, but most bill consumers at a flat rate.

## Smart Meters and Health

Davidson is convinced the smart meters made him sick and the wireless radiation they emit continues to make other people sick.

“The two root canals were the biggest issue,” he said. “I never had any dental issues in my life and all of a sudden I need two root canals.”

A doctor certified that Davidson was sensitive to the radio frequency of the meter and it was removed by his power company after he lobbied the Ohio Public Utilities Commission. Slowly, he started to feel better.

Now an Ohio state senator is pushing [legislation](#) that would require that utility companies get permission from property owners before installing smart meters.

Based on surveys from the Smart Grid Consumer Collaborative, worries about safety and health are the biggest consumer qualm about smart meters, director Durand said.

Kate Kheel, the director of Maryland Smart Meter Awareness, a group that opposes smart meters, points to [surveys](#) in which people in the U.S. and Australia say they have had headaches, dizziness and fatigue after being exposed to the meters.

“It’s not right to force this kind of exposure 24/7 on someone’s home without knowledge of the science,” Kheel said.

The International Agency for Research on Cancer reports that the kind of radio frequency given off by the meters may be carcinogenic to humans. But the American Cancer Society says it is [unclear](#) if smart meters put people at risk for developing cancer.

Durand’s group says the meters emit much [weaker](#) radio frequencies than other common devices such as cellphones, baby monitors and microwaves.

“We’re confident there is no health risk associated with electrical pulses that smart meters are sending,” she said.

# RADIATION INHIBITION OF AMINO ACID UPTAKE BY *Escherichia coli*

**ABSTRACT** The inhibition of macromolecular synthesis in *Escherichia coli* by ionizing radiation has been investigated. The survival of the ability to incorporate arginine, leucine, isoleucine, histidine, uracil, and glucose after various doses of gamma radiation, deutron and alpha particle bombardment has been measured. All amino acids are incorporated by processes which show the same radiation sensitivity. The sensitivity of uracil corresponds to a volume which is roughly spherical, of radius about 160A, whereas the amino acids possess sensitive regions which are long and thin in character. The uptake of glucose is concerned with a smaller, roughly spherical unit. The possible identification of the radiation-sensitive targets with cellular constituents is discussed. The long thin character observed for amino acids suggests that the sensitive region affected by radiation is an unfolded form of a ribosome, or alternatively a long nucleic acid molecule. For uracil the sensitive region fits with a 70S ribosome, while for glucose a smaller particle would fit the data.

## INTRODUCTION

Studies on the uptake of amino acids by bacterial cells have begun to reveal some of the aspects of the cellular synthetic mechanism. Roberts and coworkers at the Carnegie Institution, in particular, have exploited the method in a sustained series of studies (Roberts *et al.*, 1957). Recently McQuillen, Roberts, and Britten (1959) have shown, by rapid pulse-labeling methods, that fractions of the particulate structure of *Escherichia coli*, the 70S and 85S ribosomes, are the site of first synthesis of protein in the cell. It is of great interest to determine the actual nature of the macromolecular organelle responsible for this process. It is possible that within the cell the ribonucleoprotein particles do not all possess the character of being spherical. Instead they may be extended in some way, or at least might be expected to be a mixed population, some being unfolded and others not. Alternatively, some of the processes of amino acid uptake may be concerned with large RNA molecules themselves.

Preliminary indications regarding these questions can be made by studying the

way ionizing radiation inhibits the uptake of amino acids. Such studies employ a simple statistical analysis of the inhibition, taking advantage of the fact that ionizing radiation produces energy releases which are largely localized, either in small separate clusters occupying a region not more than a few Angstrom units across, or along lines of relatively dense ionization, with ionizations spread apart to a greater or lesser extent depending on the kind of ionization source used. The technique of such irradiation studies has been under development in this laboratory for some time and the validity of some of the necessary assumptions has also been the subject of much research (Pollard *et al.*, 1955). Recent work supporting this method of analysis may be found in the papers of Pollard (1959), Hutchinson (1957), and Pollard and Barrett (1959).

Comparative studies of various kinds of cell damage by radiation have been made and are briefly reviewed by one of the authors (Pollard, 1960). The uptake of amino acids is quite insensitive, by comparison with cell division or uptake of phosphate, and it therefore seems probable that amino acid uptake (and so probably protein synthesis) is thus a measure of ribosomal damage, or at any event, of a process which does not require the whole organization of the cell. On the other hand, ionizing radiation is not disruptive of the entire cellular contents, as is the case for extractive techniques, and therefore the statistical study of inhibition should be informative of the character of the synthetic units.

Preliminary experiments on the incorporation of certain amino acids have been reported (Hutchinson *et al.*, 1957; Kempner and Pollard, 1958); these have now been extended to include four other amino acids, and glucose and uracil for comparative purposes. In this paper we report the extended work and include a summary of all the findings.

## MATERIALS AND METHODS

Cultures of *Escherichia coli* B (A.T.C.C. No. 11303) were grown with aeration at 37°C in Roberts' (1957) minimal "C" medium containing five gm of glucose per liter. Growth was measured turbidimetrically in a Bausch and Lomb "spectronix 20" colorimeter at 650 m $\mu$ . When the cultures reached a concentration of 3.0 to 5.0  $\times 10^8$  cells/ml, samples were removed and treated as follows:—

1. Irradiation in a cobalt<sup>60</sup> source. Twenty ml samples of the bacterial culture were placed in screw-top culture tubes and placed in a 1500 curie cobalt<sup>60</sup> source. The dose rate was found to be 330,000 r/hr. by ferric sulfate dosimetry. Irradiations were performed at 30°C, and also at dry ice temperatures. For the latter experiments, the bacterial samples were rapidly frozen and then placed in the cooled cobalt source.

2. Cyclotron irradiations. Samples of 1  $\times 10^8$  or 1  $\times 10^9$  cells were drawn through "HA" millipore filters. The excess liquid was removed, and the filters carrying the bacteria were kept moist with a porous backing containing minimal medium with no glucose added. The samples were irradiated in the Yale cyclotron at 2°C as described elsewhere (Kempner and Pollard, 1958; Pollard *et al.*, 1955). After irradiation, the bacteria were resuspended in minimal C medium and equilibrated to 37°C.

3. Incubation with isotopically labeled compounds. Irradiated bacterial suspensions were added to an equal volume of minimal medium containing glucose and  $0.1 \mu\text{c}$  of carbon per 20 ml of incubation medium.

The isotopically labeled compounds used in these studies and their specific activities are listed below. All were commercially available and checked for chromatographic purity.

L—Arginine— $\text{C}^{14}$	13.1 mc/millimole
L—Histidine—2 (ring)— $\text{C}^{14}$	0.284 mc/millimole
L—Isoleucine— $\text{C}^{14}$	12.6 mc/millimole
L—Leucine— $\text{C}^{14}$	5.13 mc/millimole
Uracil—2— $\text{C}^{14}$	2.94 mc/millimole
Glucose— $\text{C}^{14}$	1.0 mc/millimole

Studies on the incorporation of glucose were performed in the same medium without the addition of carrier (C-12) glucose. Incubation was conducted with aeration in a  $37^\circ\text{C}$  water bath. During an incubation period of 15 minutes, 2.0 ml samples were withdrawn after various time intervals. Half of the samples were drawn through individual collodion membrane filters with an average pore size of  $0.85 \mu$ . The filters were washed with 2.0 ml of minimal medium and dried in air. These constituted the "intact cell" samples. The remaining samples were added to 2.0 ml of cold 10 per cent trichloroacetic acid (TCA) and placed at  $2^\circ\text{C}$  for 1 hour. These were then drawn through membrane filters, washed with 2.0 ml cold 5 per cent (TCA), and air-dried. These are referred to as the (TCA) insoluble samples.

The dried filters were counted under a thin-window Geiger tube on an automatic sample changer (Kempner and Bisbee, 1958).

## RESULTS

After various doses of radiation, cultures of *E. coli* all showed increases in optical density during a 90 minute growth period in minimal glucose medium. As an example, after 360,000 r the optical density rose from 0.35 to 0.40. At the doses used in these experiments there is essentially no colony-forming ability left.

To see whether any great redistribution of activity among fractions took place, the proportion of radioactive label in the cold TCA-insoluble material was further extracted with 75 per cent ethanol, ethanol-ether, and hot TCA by the method of Roberts *et al.* (1957). This method of study did not reveal any differential effect in amino acid or uracil uptake.

In Fig. 1 we show the incorporation of  $\text{C}^{14}$ -leucine as a function of time for unirradiated cells and cells which had received various doses of gamma radiation. The control cells show a normal uptake behavior, with a small difference (which we will refer to as the pool) between whole cell and (cold) TCA-insoluble fractions. The tracer quantity of exogenous label is soon exhausted and the activity of each fraction reaches a plateau. After 665,000 r the cellular uptake has been depressed markedly and similarly the labeled TCA-soluble fraction is lower. The pool size is also decreased. After still greater radiation doses (1,110,000 r) the pool size is unmeasurable.

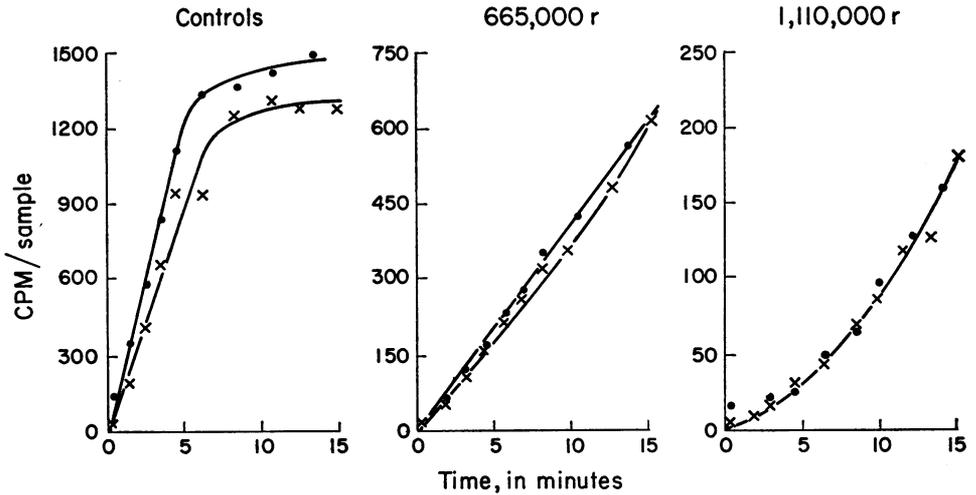

FIGURE 1 Incorporation of L-leucine into the whole cell (upper) and TCA-insoluble (lower curve) fractions as affected by various doses of  $\text{Co}^{60}$  gamma radiation. There is always a steady increase in the TCA-insoluble fraction even after massive radiation dosage.

The data of Fig. 1 are from a single experiment of five different radiation doses. We generally completed at least two or three such experiments and drew conclusions from the average of all.

In Fig. 2, the incorporation of uracil by *E. coli* after irradiation by cobalt<sup>60</sup> is shown. The depression of cellular activity is similar to that shown with leucine in Fig. 1, except that although the pool-forming ability is diminished by radiation, it is not completely destroyed.

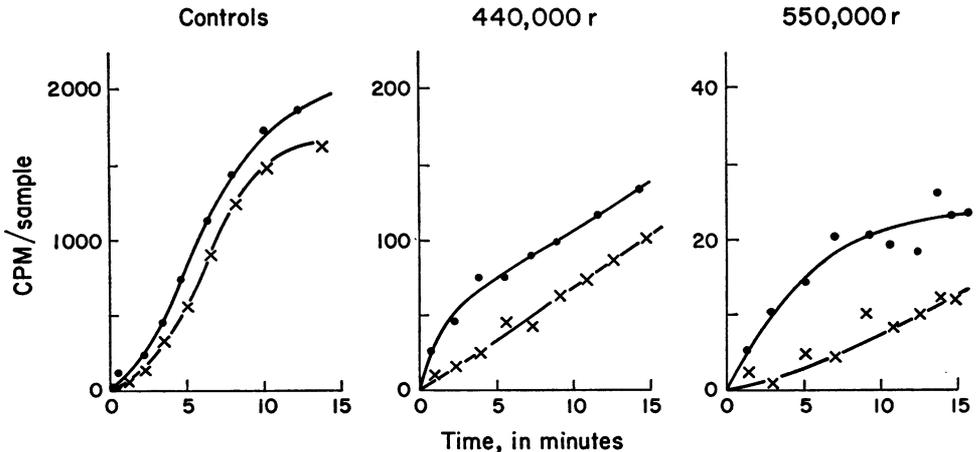

FIGURE 2 Incorporation of  $\text{C}^{14}$ -uracil into the whole cell (upper) and TCA-insoluble (lower curve) fractions as affected by various doses of  $\text{Co}^{60}$  gamma radiation.

In order to have some estimate of the relative effects of different doses, we adopted the procedure of plotting the ratio of uptake to that of the control for several different doses, choosing also several different times. Such a set of points for 7 minutes' incorporation of leucine and uracil into the TCA-insoluble fraction is shown in Fig. 3.

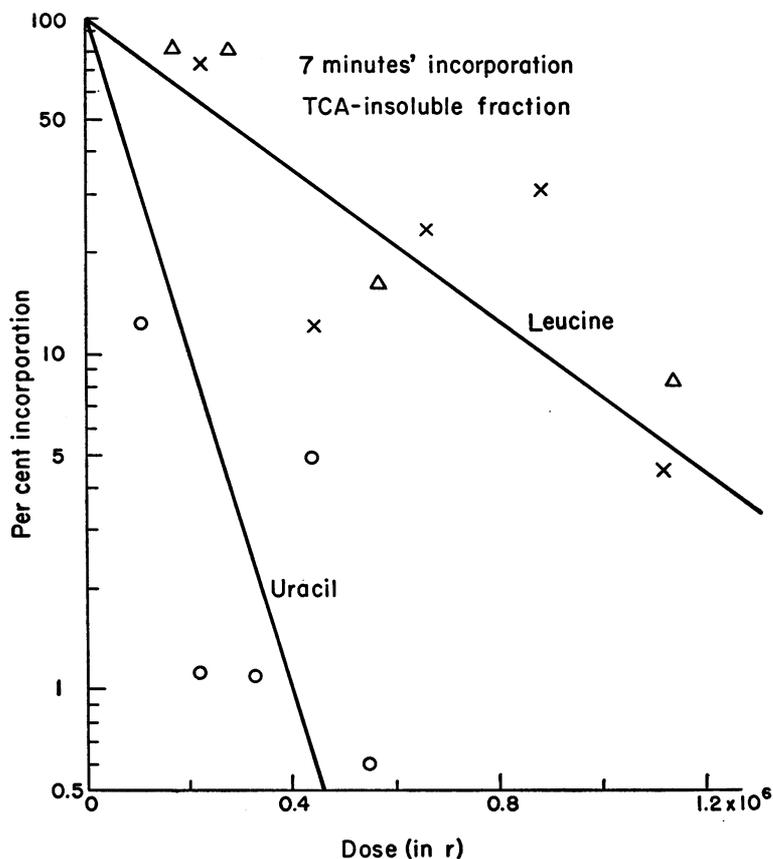

FIGURE 3 The percentage uptake of L-leucine and uracil into the TCA-insoluble fraction at 7 minutes, as a function of gamma radiation dose. Leucine data ( $\times$ ) from experiment shown in Fig. 1. Triangles from a duplicate experiment. The plot of the per cent is on a logarithmic scale and it can be seen that if  $n/n_0$  is the ratio of uptake to original uptake, then the relation  $\ln n/n_0 = \text{constant} \times \text{dose}$  is obeyed.

The ordinate in this graph is plotted logarithmically, and it can be seen that although there is considerable scatter in the points, there is a plausible relationship between the logarithm of the ratio, so plotted, and the dose. If different times are chosen, essentially the same slope is found. The agreement between different times and duplicate experiments was usually 20 per cent or better.

In some experiments the uptake was carried out in the presence of all exogenous

unlabeled amino acids, as well as the labeled one under study. Within 10 per cent, there was no effect on the slope of the line. Nor was there any difference between the effects of radiation at dry ice temperatures and at the normal temperature of the cobalt source within the same limit of error. This is significant, in that it implies that indirect inactivation due to migrating radicals of short half-life must be at a very low value.

Data very similar to the results with leucine were obtained for arginine, isoleucine, cystine, and proline. The radiation-sensitive volumes calculated from these data are shown in Table I.

Bacterial cells were also irradiated in the Yale cyclotron with deuterons at two different energies and also with alpha particles. Subsequent to this treatment, the

**FIGURE 4** Incorporation of L-leucine as affected by various alpha particle bombardments.

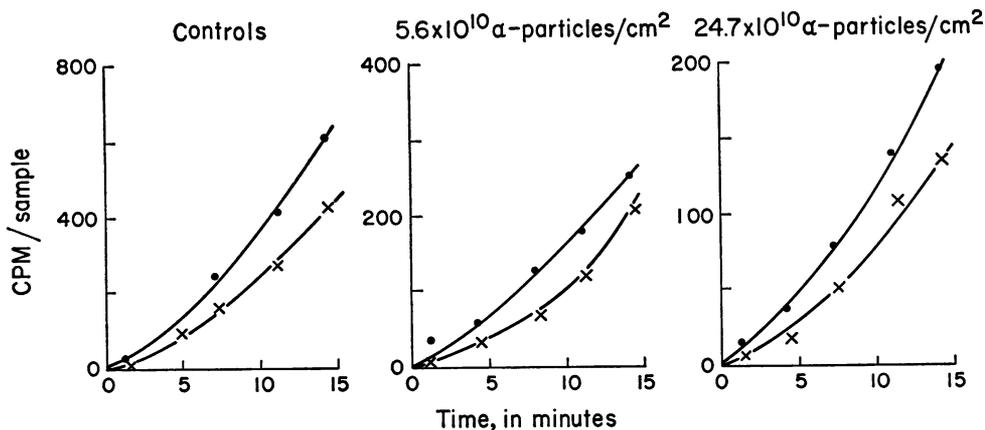

FIGURE 5 Incorporation of uracil as affected by various alpha particle bombardments.

incorporation of the labeled compounds was studied as in the case of gamma ray irradiation. Figs. 4 and 5 show the incorporation of leucine and uracil, respectively, after alpha particle bombardment of *E. coli*. The inhibition of cellular utilization appears to be similar to the results previously shown for gamma ray irradiations. However, the survival curve of the TCA-insoluble fraction, shown in Fig. 6, clearly indicates a distinct difference. The greater sensitivity to gamma rays of cellular incorporation of uracil over leucine is reversed, and the alpha particle radiation shows 37 per cent dose for leucine incorporation to be some 5 times smaller than for uracil. Other amino acids (arginine, isoleucine, and histidine) show the same sensitivity as leucine. Glucose incorporation into a TCA-precipitable form is extremely insensitive to alpha particle bombardment, with a  $D_{37}$  some 40 times greater than that of the amino acids.

#### ANALYSIS

An ionization within, or very near a macromolecule of protein or nucleic acid causes it to lose its function (Pollard, 1959). In material of the density of a bacterial cell (1.05), the number of primary ionizations per  $\text{cm}^3$  per roentgen is  $5.0 \times 10^{11}$ . Since ionization is an "all-or-none" process, one very simple basis for analysis is to inquire as to the probability that a macromolecule of volume  $V$  can wholly escape an ionization when these are distributed randomly such that there is a number of ionizations  $I$  per unit volume. Since  $VI$  is the average number per macromolecule, the application of Poisson's equation yields the probability of no ionization, by purely random occurrence, as  $e^{-VI}$ . Thus we can suggest that the fraction left active, which is an experimental measure of the probability of escape, can be equated to

$e^{-VI}$ . If we denote by  $n$  the number still active and by  $n_0$  the number initially, before radiation, we obtain

$$\frac{n}{n_0} = e^{-VI}$$

or equivalently,

$$\ln \frac{n}{n_0} = -VI$$

The fact that a plausible fit to this relation holds, makes it possible to calculate  $V$  within rather large limits of error. It will be seen that the limits of error are still not

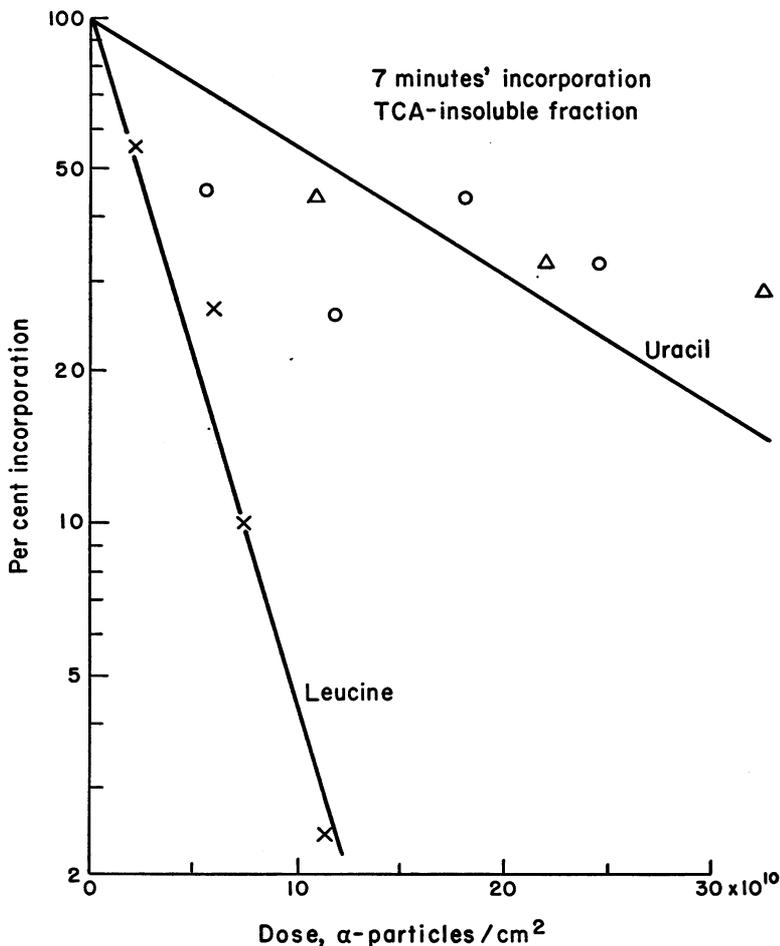

FIGURE 6 The percentage of uptake of L-leucine and uracil into the TCA-insoluble fraction at 7 minutes, as a function of alpha particle dose. Uracil data (o) from experiment shown in Fig. 5. Triangles from a duplicate experiment. The relative sensitivity is seen to be the reverse of that shown in Fig. 3 for gamma radiation.

so great as to preclude interesting deductions, and in fact, the power of the radiation analysis lies in the truth of this last statement.

Before calculating the values of  $V$  we can turn to the case of heavy particle radiation. The heavy charged particle cuts a narrow swath of ionization along its path. The swath is, however, accompanied by secondary ionization by ejected electrons, known as delta rays (Pollard *et al.*, 1955). If, for the moment, we ignore these delta rays, we can approach the "escape probability" by reasoning in terms of the idea that if one of densely ionizing tracks passes through the target, an inactivation will result. If we denote the sensitive area by  $S$  and the number of particles per unit area by  $D$ , then the average number passing through  $S$  is  $SD$ , and the same reasoning leads to the probability of there being a complete escape as  $e^{-SD}$ , so that we obtain

$$\frac{n}{n_0} = e^{-SD}$$

or equivalently,

$$\ln \frac{n}{n_0} = -SD$$

The same kind of logarithmic plot shows that this relation also plausibly holds. Thus a value of  $S$  can be calculated from the experimental data.

The value of  $S$  is found to vary with the ionization density. There are two major reasons for the variation. The first is the effect of delta rays; the second is the possibility of "straddling" a thin target, by which we mean that sometimes, even though a charged particle has gone through the target, the target is so thin that it may have failed to receive an ionization within it. The first can be corrected for by a simple method described by Pollard and Barrett (1959). Straddling effects have been discussed by Ore (1957) and his corrections have also been used in our analysis. After such corrections we can make an estimate of  $V$  from cobalt irradiation,  $S$  the area, and  $t$  the thickness, from heavy particle data. These estimates are only rough, but they are informative.

In Fig. 7 we show the results of plotting the experimentally found (uncorrected) values of  $S$ , which we call the cross-section, *versus* the rate of energy loss for the bombarding particles, for the uptake into the TCA-insoluble fraction of arginine, histidine, isoleucine, leucine, uracil, and glucose, as well as proline and methionine (Kempner and Pollard, 1958). The slopes of the lines near the origin are fixed by the values of  $V$  found from cobalt irradiation as described by Pollard *et al.* (1955). Even without any corrections it is quite apparent that there are three groupings. The cellular "targets" for arginine, histidine, isoleucine, leucine, and proline incorporation show a steady increase in radiation cross-section with the rate of energy loss, while the targets for methionine and uracil do not. The case of glucose is even more striking, in that a clear leveling off at a low cross-section can be seen.

In Table I we show the values of the sensitive volume and the values (corrected

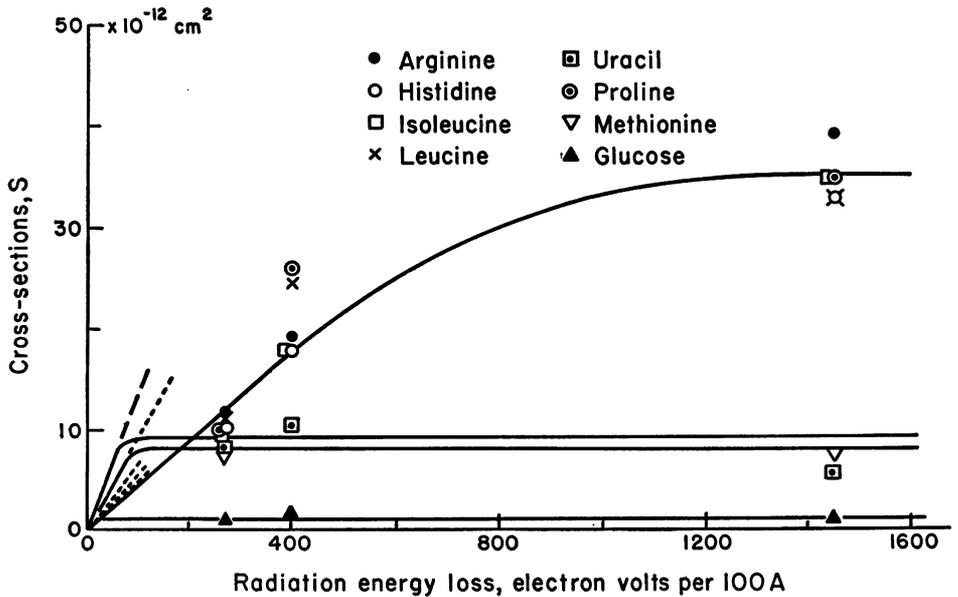

FIGURE 7 A plot of the sensitive cross-section for seven metabolites against the rate of energy loss. The initial slope is found from  $\text{Co}^{60}$  inactivation. Three groupings appear: arginine, histidine, leucine, isoleucine, and proline are all characterized by high sensitivity at high rates of energy loss; methionine and uracil have rather low sensitivities for such radiation and glucose is consistently low. Probably the first grouping are long thin objects, but the others are more nearly spherical.

for delta rays) of  $S_0$ , the maximum cross-section for heavily ionizing particles. In addition, we calculate the appropriate lengths and radii for long cylinders, or spheres according to which is the most suitable approximation. Since the calculation of radii involves  $V^{1/3}$  or  $A^{1/2}$ , a 20 per cent experimental error in the determination of the 37 per cent inhibition dose results in only a 10 per cent error in the linear dimensions of the target.

If we apply the statistical analysis previously used, we can consider the falling aspect of pool size. Roughly speaking, the relation

$$\ln \frac{n}{n_0} = -VI$$

can be held to apply. In most cases the dose necessary to reduce the survival ratio to 0.37 (for which the natural logarithm is  $-1$ ) is very roughly 500,000 r, giving a value of  $V$  of  $4 \times 10^{-18} \text{cm}^3$ , or a molecular weight of

$$4 \times 10^{-18} \times 1.3 \times 6.03 \times 10^{23} = 3.1 \times 10^6$$

assuming material of density 1.3. This is interesting in that it indicates that some rather large, organized molecular structures are responsible for the maintenance of a pool.

## DISCUSSION

The effects of radiation which we have roughly measured can be looked at in two ways. The first is essentially empirical and regards radiation as a kind of stress applied to the cell, which can perhaps produce differential effects on the structures that react with various metabolites. Thus one can look simply at any grouping of effects and consider whether they have any significance. Such grouping shows very clearly in the response to heavy particle irradiation. Data in Table I show that the radiation-sensitive elements associated with the uptake of the amino acids arginine, leucine, isoleucine, histidine, and proline fall into one class, characterized by behavior which radiation analysis associates with long, thin, sensitive units, whereas another amino acid, methionine, differs markedly. Methionine incorporation seems to require the intervention somewhere of a much shorter, thicker structure. Uracil seems to behave in the same way. Glucose, on the other hand, appears to be involved with a still smaller, but thick and roughly spherical object.

A second way of looking at the experiments is to consider the results of cell fractionation to see which of the known cellular structures could be involved with the various operations. Such a method is limited by our knowledge of cell components, which is admittedly imperfect, but it is still a useful viewpoint. An *E. coli* cell has a cell wall, a protoplast membrane, two or more "nuclear bodies," a rather organized complement of DNA within the nuclear bodies, and a large number of ribosomal particles with sedimentation constants ranging from 20 to 100 Svedberg units. These ribosomes contain RNA and protein in a tight bonding. There is in addition an amount of soluble RNA of smaller molecular weight, and a large number of enzymes.

The radiation data enable us to eliminate from this list the whole nucleus, as being too large a radiation target, and the enzymes or soluble RNA as being too small. Interest therefore centers on DNA, large specific RNA, and the ribosomes. The effect of radiation on the uptake of methionine and uracil fits rather remarkably well with the idea that ribosomal particles of sedimentation constant about 80 Svedberg units are involved. On the other hand, the sensitivity found for the five other amino acids studied is much more in agreement with that to be expected from a nucleic acid chain of molecular weight about  $4 \times 10^6$ . Whether this be DNA or RNA, we have no basis for telling. It is possible that a ribonucleoprotein particle, in action, is unrolled in some way, and could therefore result in the long, thin appearance of a radiation target.

Present concepts of protein synthesis postulate the existence of a protein-forming "template." In such a frame of reference, it would be expected that the incorporation of amino acids would be inhibited by destruction of a radiation target identical for all. Our results indicate that at least for five of the six amino acids studied, this indeed is the case. The results for methionine (Kempner and Pollard, 1958) therefore are quite paradoxical. It is extremely difficult to see how these re-

sults could be consistent with any simple model of protein synthesis. Further studies on the radiation inhibition of the incorporation of methionine and other amino acids might be very informative about the mechanism of such synthesis.

The ability of cells to utilize glucose after exposure to each type of radiation used was found to be a simple exponential function of dose. No evidence for a "multiple hit" requirement (Pollard *et al.*, 1955) or for targets of two or more different sizes was found. This implies that all exogenous glucose passes through a common structure which is the most radiation-sensitive element in its biochemical pathways. The target analysis of this unit is given in Table I. If it is assumed that the target is a single macromolecular structure, then a calculation of the expected sedimentation constant leads to a value of 20 to 30S.

We can mention briefly the radiation sensitivity found for the "pool." The fact that radiation does have an effect on the pool seems to dispose of the idea that no more is involved than an inert sieve-like membrane. It is of interest that the doses at which an effect on the pool becomes great are also those at which radioactive label begins to leak out of the cell. Whether the action of radiation is on large molecular units within the cell, or on large units comprising the protoplast membrane itself, we cannot say.

We wish to thank Dr. R. B. Roberts and Dr. E. T. Bolton of the Carnegie Institution of Washington for helpful advice with the technical problem of cell filtration and uptake studies, and Mr. J. Lowry and Miss N. Barrett for help in running the cyclotron.

This work is part of a dissertation presented to the faculty of Yale University in candidacy for the degree of Doctor of Philosophy.

# Radiation from wireless technology affects the blood, the heart, and the autonomic nervous system<sup>1)</sup>

**Abstract:** Exposure to electrosmog generated by electric, electronic, and wireless technology is accelerating to the point that a portion of the population is experiencing adverse reactions when they are exposed. The symptoms of electrohypersensitivity (EHS), best described as rapid aging syndrome, experienced by adults and children resemble symptoms experienced by radar operators in the 1940s to the 1960s and are well described in the literature. An increasingly common response includes clumping (rouleau formation) of the red blood cells, heart palpitations, pain or pressure in the chest accompanied by anxiety, and an upregulation of the sympathetic nervous system coincident with a downregulation of the parasympathetic nervous system typical of the “fight-or-flight” response. Provocation studies presented in this article demonstrate that the response to electrosmog is physiologic and not psychosomatic. Those who experience prolonged and severe EHS may develop psychologic problems as a consequence of their inability to work, their limited ability to travel in our highly technologic environment, and the social stigma that their symptoms are imagined rather than real.

**Keywords:** electrosmog; radio-frequency radiation; rouleau; tachycardia; WiFi; Wolff-Parkinson-White Syndrome.

## Introduction

Our exposure to devices using electricity and emitting extremely low-frequency and radio-frequency electromagnetic fields has been increasing ever since Edison invented the incandescent light bulb and Tesla and

Marconi discovered that radio-frequency (RF) radiation can be transmitted without wires. Radio, television, computers, cell phones, and their accompanying cell phone antennas, cordless phones, wireless routers (WiFi), wireless baby monitors, wireless games, and smart meters are increasing our exposure to RF radiation and especially to microwave radiation (300 MHz–300 GHz).

As an example of the proliferation of this technology, access to WiFi was limited in 2002 but by 2012 access was virtually ubiquitous in the USA (Figure 1). We have city-wide WiFi in some communities, WiFi at work, at home, in school, universities, and hospitals, in restaurants and coffee shops, on public transit, at airports, and on an increasing number of airplanes. As a society, we seem to be insatiable for wireless technology and the connectivity it affords.

Although the downside to this technology, namely, the potentially harmful effects of nonionizing radiation, has received relatively little attention in North America and remains controversial, it is an area that deserves proper research funding based on the sheer number of users and people exposed worldwide to RF electromagnetic fields.

In this article, the relationship between electrosmog exposure and electrohypersensitivity (EHS), with a focus on the cardiovascular system, is presented, based on provocation studies and on reports of ill health among those living near cell phone base stations or exposed to WiFi in schools.

## Electrohypersensitivity

Just as some people have multiple chemical sensitivity or react to pollen, mold, and certain types of food, a growing population is becoming “sensitive” to electromagnetic radiation.

Khurana et al. (1) reviewed ten epidemiologic studies, three dealing with cancer and seven with neurobehavioral effects, that examined the putative effects of mobile phone base stations. All of the neurobehavioral studies reported more symptoms with proximity to base stations, and only

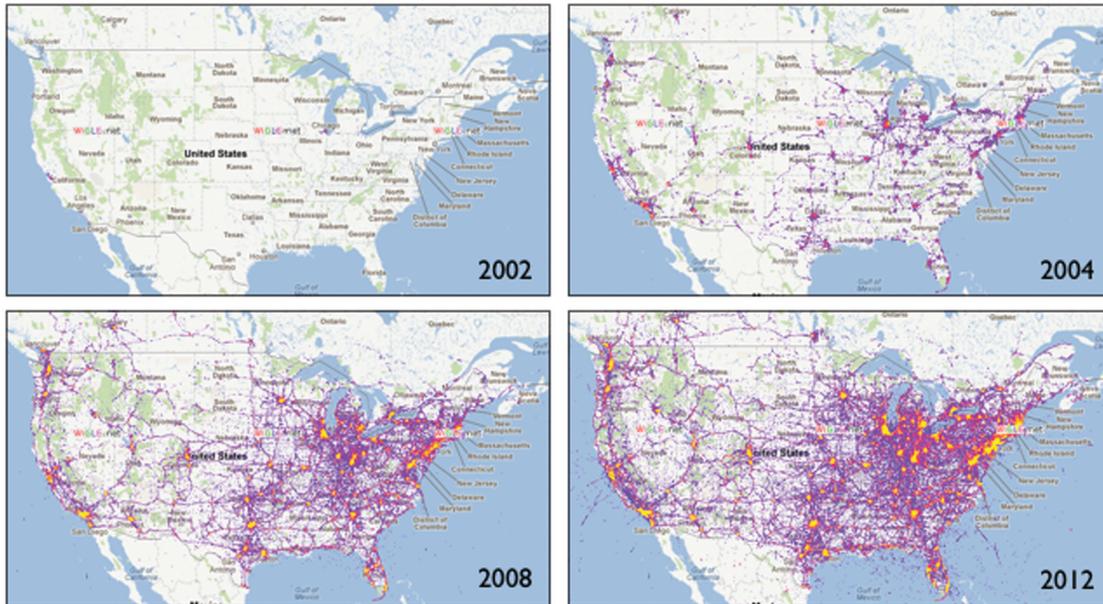

Figure 1 WiFi networks in the USA from 2002 to 2012 (source: wogle.net).

one attributed these health effects to stress rather than RF exposure.

The results from one of these studies are presented in Figure 2 (2). People who lived closest to the antennas experienced the following symptoms more often than those who lived further away: fatigue, sleep disturbance, headaches, feeling of discomfort, difficulty concentrating, depression, memory loss, visual disruptions, irritability,

hearing disruptions, skin problems, cardiovascular problems, dizziness, loss of appetite, movement difficulties, and nausea. Many of these symptoms are more common as we age, thus I prefer to call this rapid aging syndrome (RAS). The difference between real aging and RAS experienced by those who are electrically hypersensitive is that when these people go into an electromagnetically clean environment, many of their symptoms diminish

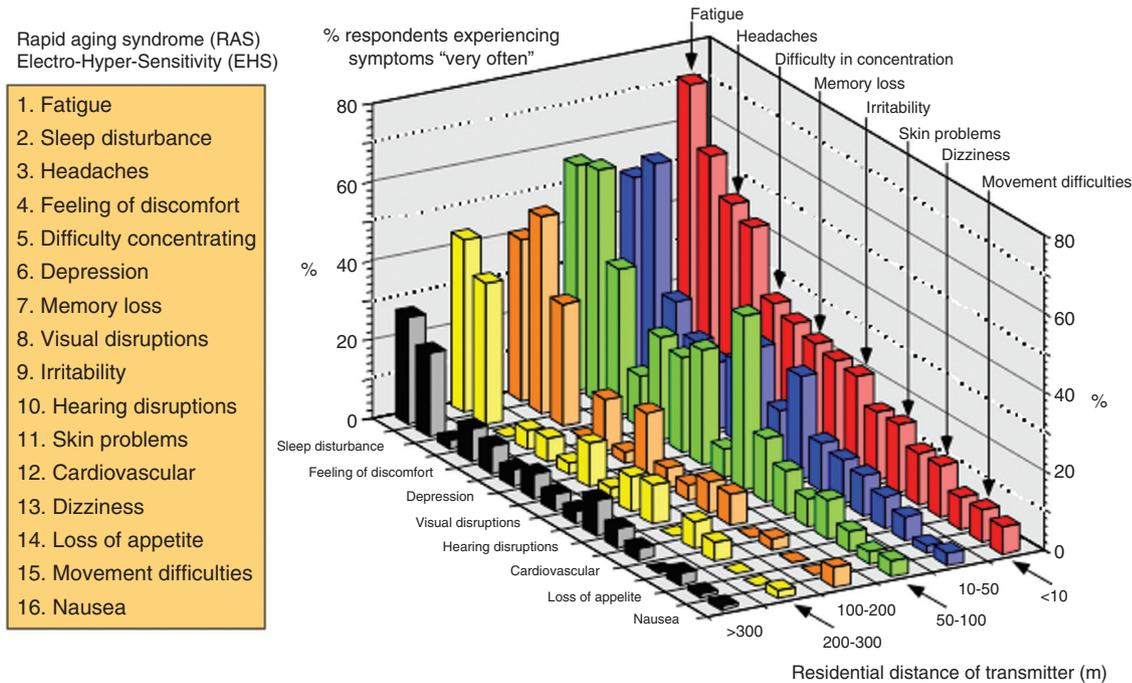

Figure 2 Symptoms experienced by people near cellular phone base stations [based on the work of Santini et al. (2)].

or disappear. Obviously, this does not happen with real aging.

Because cell towers are proliferating and difficult to avoid in both urban and rural communities and if the results of Santini et al. (2) represent what is happening to those who live near cell towers, then it is quite likely that we are going to experience (or are in the midst of experiencing) an emerging health crisis that is contributing to chronic ill health and is promoting the sale of pain medication, sleep medication, antidepressants and anti-anxiety medication, pills to moderate energy level and mood, and drugs for those with attention deficit hyperactivity disorder such as Ritalin® (methylphenidat).

In 2006, Hallberg and Oberfeld (3) documented the increasing prevalence of EHS. Figure 3 clearly shows that self-perceived EHS is on the rise. According to the authors, by 2017, 50% of the population is going to be complaining of this illness. Admittedly, this is a rough calculation but it demonstrates that symptoms of EHS are increasing.

It is difficult to estimate the percentage of the population that has EHS. I use a conservative estimate of 3% of the population for those who have severe symptoms, and this is based on the population in Sweden who have registered as being electrohypersensitive (4). Another 35% population may have mild to moderate symptoms of EHS when exposed to electrosmog (5). Based on these percentages, the cumulative number of people who may be adversely affected in Canada, the USA, and Europe is 25 million, for severe sensitivity (EHS), and another 300 million, for mild to moderate sensitivity (electrosensitivity). People in this latter group can function in an electrosmog environment but may develop headaches or have difficulty sleeping and are living a life compromised by increasingly poor health as a consequence of their exposure (Figure 2).

Historically, environmental contaminants have been presented as contentious issues due, in part, to the media’s need for “balanced reporting” and, in part, to the economic consequences of altering our behavior as consumers. This was certainly the case with asbestos, dichloro-diphenyl-trichloroethane (DDT), lead, mercury, acid rain, and tobacco smoke and is currently the case with climate change and EHS.

EHS may be viewed as a contentious issue, yet a growing number of international experts, scientists, and medical doctors have been asking governments and international agencies for decades to lower existing guidelines for RF radiation because the current guidelines do not protect public health. Table 1 provides a list of some of these resolutions and appeals.

Some governments have heeded the warnings and have exposure guidelines that are a fraction of those recommended by the World Health Organization (WHO) and accepted by the USA, UK, and Canada.

The WHO held an international workshop on electro-sensitivity in Prague in 2004 (6), and they defined EHS as follows:

“... a phenomenon where individuals experience adverse health effects while using or being in the vicinity of devices emanating electric, magnetic, or electromagnetic fields (EMFs).”

“Whatever its cause, EHS is a real and sometimes a debilitating problem for the affected persons.... Their exposures are generally several orders of magnitude under the limits in internationally accepted standards.”

What role should the WHO and other leading health authorities play in helping these sensitive individual? Some would advocate, at the very least, lower exposure

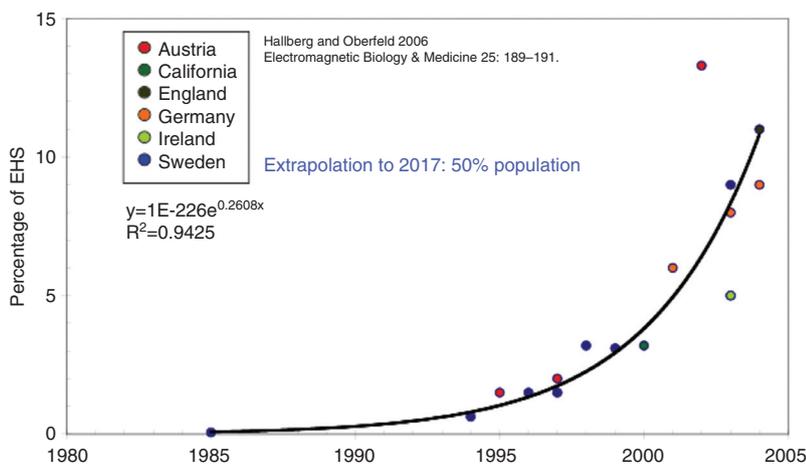

Figure 3 Estimated prevalence of self-proclaimed EHS in various countries [based on the work of Hallberg and Oberfeld (3)].

limits and possibly places where the radiation is not allowed, similar to smoke-free environments. Instead, the WHO recommended that this illness be referred to as “idiopathic illness”, which basically means the cause is unknown. By refusing to acknowledge the cause, the WHO undermines the need for governing agencies to act.

In contrast to the WHO, the Austrian Medical Association (7) came out with guidelines to help doctors diagnose and treat those who experience EHS. In that document, they recognize that there is a rise in stress-related illness and that electrosmog may play a role. They even provide a temporary code (Z58.4, exposure to radiation) under the *International Classification of Diseases, 10th Edition* to be used for EMF syndrome, which is their term for EHS.

A group of psychologists considers EHS to be entirely a psychologic illness rather than a physiologic response to electrosmog (8, 9). A number of the articles reviewed by Rubin et al. are based on flawed assumptions about (1) who is truly experiencing EHS, (2) how people with EHS respond to exposure, (3) what frequencies and intensities they respond to, (3) how quickly they respond and recover following exposure, and (3) how the data should be analyzed. These flawed assumptions lead to flawed conclusions.

For example, not everyone who believes they have EHS actually have EHS. Thus, combing the results for the self-proclaimed “EHS group” is likely to dilute the results, producing no significant effect when analyzed statistically. The question that is being tested by this type of analysis is, “Do those who believe to be electrically sensitive all respond the same way to provocation testing?” and the answer is likely to be “no”.

In the study by Rea et al. (10) of 100 people who believed they were electrically hypersensitive, only 16 responded consistently to real exposure and not to sham exposure. Had the results been statistically analyzed for the entire 100 subjects tested, they would have shown no effect of EMF exposure. Objective testing is required, and people should be assessed as individuals rather than members of a group for analysis. An analogous situation is if there were 16 people with diabetes among a group of 100 people who all thought they were diabetic. Statistical analysis of blood sugar measurements before and after consuming a standard meal for the entire group would likely miss the 16 people with diabetes.

The proper way to test for EHS is to monitor and assess individual responses to electrosmog exposure in a double-blind study, as was done by Rea et al. (10).

However, it is clear that those who experience EHS and are no longer able to live a “normal” life and who are not supported by their family, friends, and physicians also experience stress leading to psychologic problems including depression and anxiety disorders. Where I disagree with Rea et al. (10) about EHS is that I believe the physiologic response precedes the psychologic problem.

In this article, examples of the effects of electrosmog on the blood, heart, and autonomic nervous system (ANS) are provided, indicating that EHS is a physiologic response to electromagnetic pollution. The only legitimate use of the term “idiopathic” (i.e., disease or disorder that has no known cause) is in reference to the trigger that initiated the electromagnetic sensitivity. In some cases, with good medical investigation, this also can be surmised.

## Electrosmog affects the blood

Healthy blood consists of erythrocytes (red blood cells), which are round and which float freely in the plasma. A live blood sample, consisting of a drop of blood from a finger prick, can be viewed under the microscope, as shown in Figure 4. Changes in the size, shape, and clumping of these erythrocytes can indicate impaired health.

Figure 4 shows live blood (blood without any chemicals added to it) in an electromagnetically clean environment (A) and the blood from the same person spoke on a cordless phone for 10 min (B) and after using a wired computer for 70 min (C). The erythrocytes are sticking together and resemble a stack of coins. This is known as rouleau formation and indicates unhealthy blood.

Usually rouleau is caused by an increased fibrinogen concentration or other changes in plasma proteins as in multiple myeloma or macroglobulinemia. An alternative explanation is that the rouleau may be due to a reduction in the electrical potential at the cell membrane, which would weaken the repellent forces between cells. A third possibility is that it is a microscopic artifact, which, in

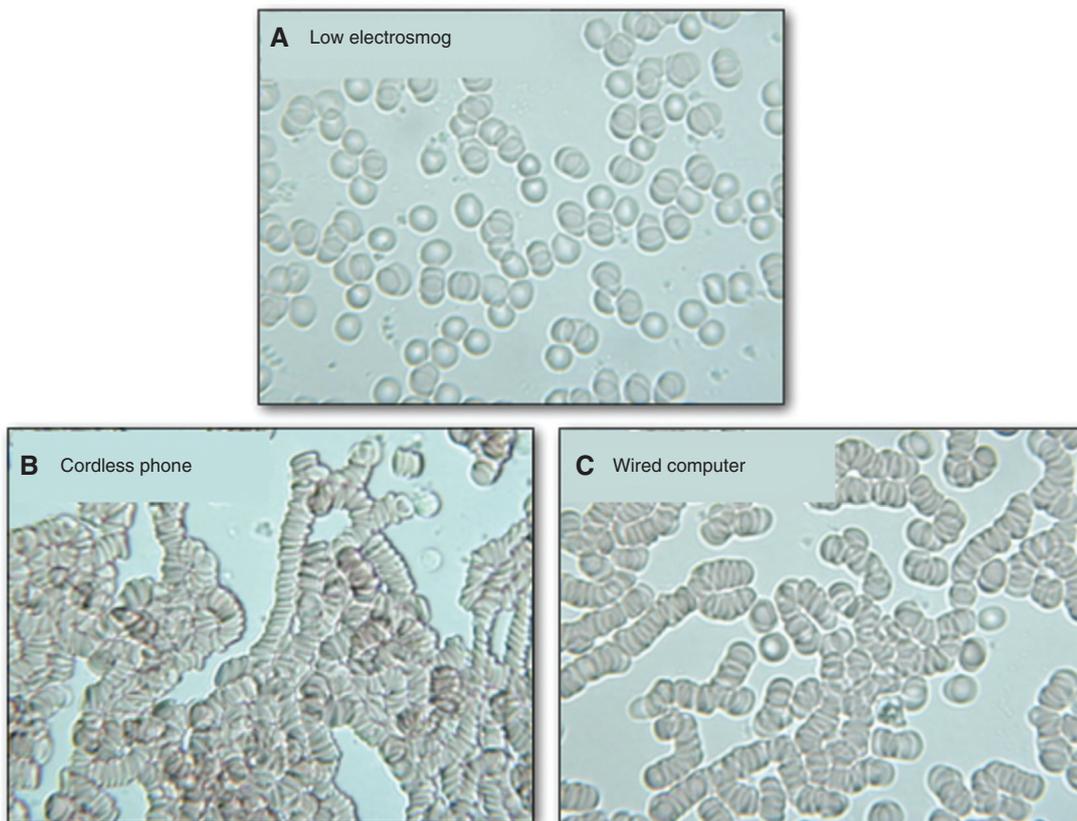

this case, is unlikely because the results are repeatable. Research on the mechanisms involved in the rouleau formation is needed.

With rouleau formation, the surface area of the red blood cells is significantly reduced, and the release of nutrients and the removal of waste products are compromised. Symptoms may include headaches, difficulty concentrating, dizziness, nausea, heart and blood pressure problems as well as cold, numbness, or tingling sensation in the extremities (hands and feet).

The good news is that live blood analysis may be a useful diagnostic for EHS. How quickly the blood clumps and how quickly it recovers following exposure may be a good indicator of the degree of sensitivity.

## Electrosmog affects the heart and the autonomic nervous system

Some people who are electrically hypersensitive complain of pain or pressure in the chest area, heart palpitations,

**Figure 4** Live blood cells in a low-electrosmog environment (A), after using a cordless phone for 10 min (B), and after using a wired computer for 70 min (C).

and/or an irregular heartbeat, accompanied by feelings of anxiety that develop rapidly. The symptoms resemble a heart attack and thus contribute to even more anxiety.

To test the effect of electromog on the heart, Havas et al. (11) designed a simple experiment where subjects were exposed to electromagnetic radiation generated by the base of a cordless phone. This was a double-blind study with randomized real and sham exposure. A cordless phone base station was selected as the source of exposure because the base emits a constant beacon signal when it is plugged into an electrical outlet. The beacon signal in this case was a pulsed frequency of 2.4 GHz, the same frequency used in WiFi.

In the original study (11), 25 subjects from Colorado were tested, and although most subjects did not react adversely to the radiation from the cordless phone base station (see Figure 5, subject A), a few did react with either tachycardia (rapid heart rate) or arrhythmia (irregular heart rate) (Figure 5, subject B). The reaction was often immediate and coincided with exposure to the radiation. When the radiation ceased, the heart returned to normal.

Two examples of responsive subjects are provided. The heart rate of subject B increased from a resting heart rate of 68 beats per minute (bpm) to a rapid 122 bpm during exposure, decreased to 66 bpm as soon as the radiation was stopped, and increased to 129 bpm when it was resumed. This reaction occurred while the subject was resting in a supine position and was unaware of when he or she was or was not exposed.

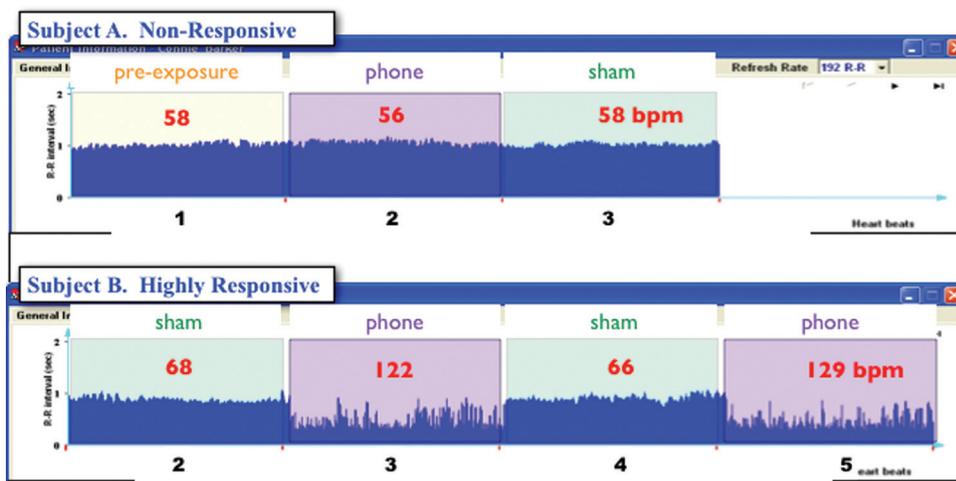

During the exposure to radiation from the cordless phone base station, subject C (Figure 6) experienced a slight increase in heart rate (from 65 to 86 bpm), an irregular heartbeat, and changes in the response of the

sympathetic and parasympathetic nervous system (SNS and PNS, respectively). This upregulation of the SNS and downregulation of the PNS is an example of the “fight-or-flight” response, indicating physiologic stress. During periods of this type of stress, the body redirects most of the blood and energy from the internal organs to the arms and legs to prepare the organism for fighting or fleeing a stressful situation. Intermittent exposure may not cause a problem but if the exposure is continuous and long-term, the immune system of the body will be compromised and the body will not be able to repair itself, resulting in symptoms that are commonly experienced by those who are electrically hypersensitive. This inability to heal is what then accelerates the symptoms of aging (i.e., RAS).

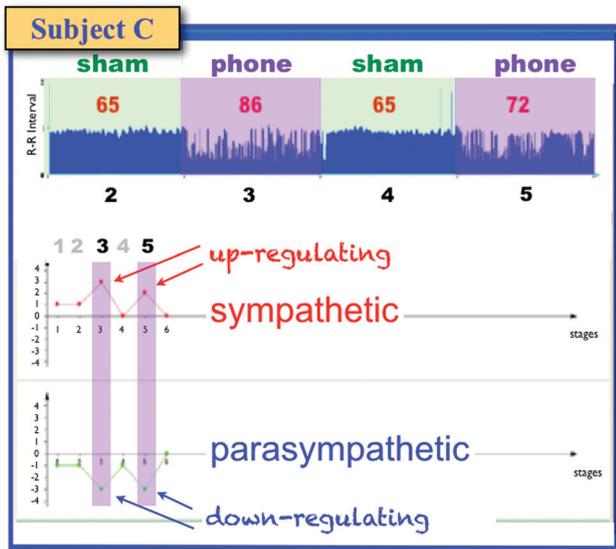

The level of radiation in this experiment was well below international guidelines. Subjects were exposed to  $3 \mu\text{W}/\text{cm}^2$ , or 0.3% of the guidelines recommended by International Centre for Non-Ionizing Radiation Protection (ICNIRP), the Federal Communication Commission (in US) (FCC), and Health Canada for 2.4-GHz frequencies. According to these organizations, harmful biologic effects do not occur below these thermal guidelines. Both blood and heart results from these provocation experiments indicate otherwise, i.e., that biologic effects that can have serious health implications do occur at levels well below current thermal guidelines.

The cordless phone provocation study has since been repeated for a larger group of subjects and shows similar results (12).

Some suggested that the radiation from the cordless phone was interfering with the technology rather than the heart. If this were the case, then 100% of the subjects would have had similar results because the

**Figure 5** Rhythmograph of HRV during provocation with a digital 2.4-GHz cordless phone and sham exposure. The x-axis unit is time, with each stage lasting approximately 3 min. The y-axis is the R-R interval (in seconds).

**Figure 6** Rhythmograph of HRV and functioning of the SNS and PNS during provocation with digital 2.4-GHz cordless phone and sham exposure.

electromagnetic interference (EMI) would have been consistent rather than highly variable and individualistic. Additional testing of higher levels of radiation at the sensor did not affect the heart rate variability (HRV) of a subject who was nonresponsive to the original levels. Had it been EMI, then higher levels of exposure should have had a greater response, but this was not the case (12).

One subject (52-year-old man) told us that he normally experiences a delayed reaction to electrosmog exposure, and thus we monitored him for 30 min postexposure and observed the delayed response during a period of no exposure. The response included periods of short-term and intermittent irregularity in the R-R interval (HRV) as well as episodic downregulation of both the SNS and the PNS, which were both low to begin with (12). The normally low heart rate, 53–55 bpm, began to increase slightly (61 bpm) 25 min postexposure.

## WiFi in schools affects student health

Students in schools with WiFi are complaining of headaches, difficulty concentrating, weakness, and heart palpitations, prompting their parents to take them to their family doctor and to their pediatric cardiologist to determine the nature of their problem.

In one Ontario school district, several students complained of heart problems. A 6-year-old girl had a “musical

heart”, and she experienced headaches and dizziness only at school. A 12-year-old boy had tachycardia (rapid heart rate). A 12-year-old girl experienced nausea, vomiting, no fever, insomnia, blurred vision, and tachycardia only at school. A 13-year-old boy had a pounding heart, insomnia, and headaches. His family moved to a different school district, and his symptoms disappeared.

In the same area, 4 students had sudden cardiac arrests (SCA) during exercise class within a 2-year period. Two of these students were resuscitated. The annual rate for SCA among young people in Canada is approximately 7 per year; hence, 4 in a small community is unusual.

According to Sinatra (13), a cardiologist, Wolff-Parkinson-White (WPW) syndrome, which is a disorder of the conduction system of the heart, is present in 1 out of 700 students. In a school district with 50,000 students, as many as 70 may have this generally undiagnosed condition. According to Sinatra (13), when students with WPW syndrome are exercising and are exposed to microwave radiation, the combined stress on the heart can lead to supraventricular tachycardia, thus creating the “perfect storm”.

Fortunately, due to the Defibrillator Access Act, schools and other public buildings are installing defibrillators. What they should also be doing is trying to determine what is causing SCA and why students are complaining of headaches and heart palpitations at school. A key question that needs to be asked is, “What role does RF radiation from a school’s WiFi system and from nearby cell phone base stations play in these symptoms?”

The effects of microwave radiation on the heart have been known for decades (14). In a 1969 symposium on the biological effects and health implications of microwave radiation, the authors clearly state that, “In the interest of occupational hygiene...researchers have recommended that cardiovascular abnormalities be used as screening criteria to exclude people from occupations involving radio-frequency exposures”. Perhaps students need to be screened at school to ensure that they do not have an underlying heart condition that may be exacerbated with WiFi microwave exposure.

According to Drezner et al. (15), out-of-hospital SCA among young people is on the rise in the USA, although doctors do not know the reason. The increasing exposure to electrosmog may be to blame for at least part of this increase. More research is urgently needed in this area.

Children are much more sensitive to environmental toxins than are adults, and as such, there should be stricter guidelines for exposure. To date, at least nine countries have issued warnings that children should limit their use of cell phones. These countries include the UK (2000), Germany

(2007), France (2008), Russia (2008), India (2008), Belgium (2008), Finland (2009), the USA (2009), and Canada (2012). The same warning should be issued for children exposed to wireless games and WiFi routers, depending on the amount of time students are exposed to these emitters.

WiFi routers emit a beacon signal that is continuous as long as the device is activated. In other words, you do not have to be connected to the Internet to be exposed to the radiation generated by the wireless router. When information is either uploaded or download, the radiation levels increase both at the router and at the computer. The same is true for cordless phones and wireless baby monitors. Voice-activated baby monitors and cordless phones that radiate only when in use are available in Europe but are not currently available in North America.

## Historic research on microwave illness resembles current research on electrohypersensitivity

The information provided in this article is not new. Reviews as far back as 1969 summarized the effects of microwave radiation and identified many of the same symptoms. Dodge (16) reviewed the Soviet and Eastern European literature and reported that microwave radiation affects the central nervous system, ANS (as shown here), neurohumoral systems, endocrine glands and functions, eye and ocular function, blood and hematopoietic system (as shown here), and miscellaneous organs.

Dodge (16) identified general subjective complaints resulting from exposure to electromagnetic radiation (Table 2) that are similar to the symptoms experienced by those who live near cell phone base stations (Figure 2). The major difference is that Dodge was reviewing symptoms for men who were occupationally exposed, whereas Santini et al. (2) was documenting symptoms for those who lived near cell phone antennas and were exposed to radiation in their own homes and as such were unable to avoid exposure.

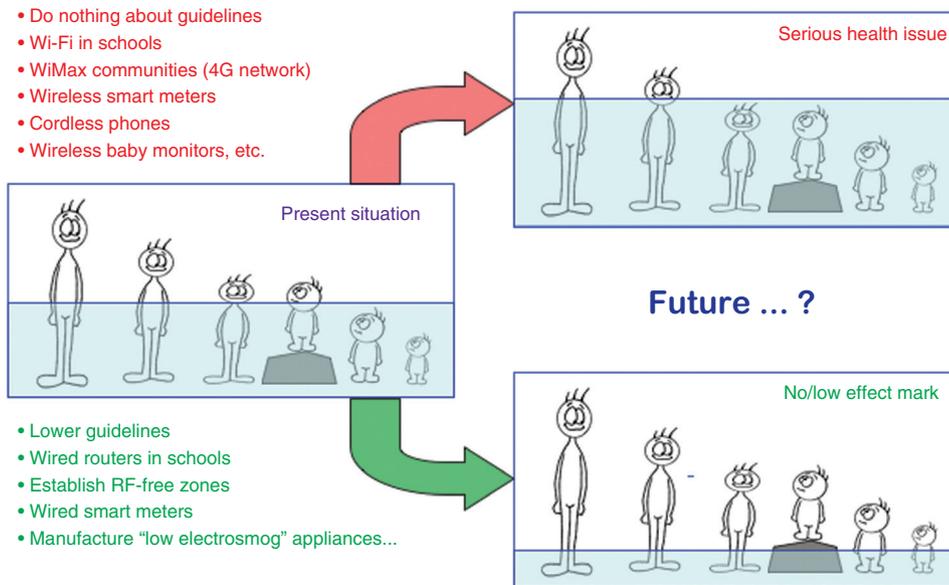

Glaser (17) reviewed the literature on the biologic effects of microwave radiation and provided more than 2000 references in 1972. Although many of these studies were conducted at levels above existing guidelines, we are getting similar results at levels of microwave radiation that are well below these guidelines.

Most revealing are the “psychophysiologic disorders” based on human behavioral studies. These disorders include the following and are similar to those reported by Santini et al. (2): neurasthenia (general “bad” feeling), depression, impotence, anxiety, lack of concentration, hypochondria, dizziness, hallucinations, sleepiness, insomnia, increased irritability, decreased appetite, loss of memory, scalp sensations, increased fatigability, chest pain, and tremor of the hands.

Both Glaser and Dodge worked for the US Navy and had access to information that was later declassified. In one limited-edition (only 15 copies were produced) document, Pollack and Healer (18) recommended that the power density guideline in the USA be reduced from 10,000  $\mu\text{W}/\text{cm}^2$  to the same level used in the Soviet Union (10  $\mu\text{W}/\text{cm}^2$ ), but little attention was paid to this recommendation.

**Table 2** Subjective symptoms associated with RF and microwave radiation.

General subjective complaints resulting from exposure to electromagnetic radiation (16)	Symptoms experienced “very often” by those who live within 300 m of a cell phone base station (2)
Similar symptoms	
Pain in head and eyes	Headaches and visual disruptions
Weakness, weariness, and dizziness	Dizziness and fatigue
Depression, antisocial tendencies, and general irritability	Depression and irritability
Impairment of memory and general mental function	Memory loss
Adenoma and inability to make decisions	Difficulty concentrating
Chest pain and heart palpitation	Cardiovascular
Dyspepsia, epigastric pain, and loss of appetite	Loss of appetite
Sensitivity of mechanical stimulation and dermagraphism	Skin problems
Different symptoms	
Lacrimation	Irritability
Hypochondria, sense of fear, and general tension	Nausea
Inhibition of sex life (male)	Movement difficulties
Scalp sensations and hair loss	Hearing disruption
Trembling of eyelids, tongue, and fingers	Sleep disturbance
Asthma	Feeling of discomfort
Brittle fingernails	

**Figure 7** Two future health scenarios based on the steps we take or fail to take to reduce electromagnetic exposure.

Years later, the power density guideline in the USA was reduced from 10,000 to 1000  $\mu\text{W}/\text{cm}^2$ , although this was still based on thermal effects.

## Where do we go from here?

If we do nothing about guidelines and allow WiFi to be installed in schools, if we allow WiMax to come into neighborhoods as part of the 4G network, if we allow wireless smart meters to be installed on homes, and if we fail to regulate the technology in a way that minimizes microwave exposure, then many more people are likely to become ill and some will die (Figure 7).

If we choose to minimize exposure by establishing biologically based guidelines rather than the current thermal guidelines, by encouraging wired Internet access in schools, universities, hospitals, workplaces, and homes, by installing wired smart meters, and by establishing RF-free zones for those who are highly sensitive, then we can reverse much of the damage that has been inflicted (Figure 7).

The choice is ours, and the real question is, "Do we have the foresight and courage to make the right decision or will we require a health tsunami before we act?"

Received April 23, 2013; accepted July 24, 2013

- Radiation Syndrome

## Subdivisions of Radiation Sickness

- acute radiation sickness
- delayed radiation sickness

## General Discussion

### Summary

Radiation sickness describes the harmful effects--acute, delayed, or chronic--produced by exposure to ionizing radiation. An observable effect due to radiation exposure becomes quite certain after a single dose of several hundred rads. As a rule, large doses of radiation are of concern because of their immediate effects on the body (somatic), while low doses are of concern because of the potential for possible late somatic and long-term genetic effects. The effects of radiation exposure on an individual are cumulative. Although there is currently no treatment to repair cells that have already been damaged by radiation, the FDA has recently approved drugs that are very effective at removing radioactive elements from the body. Because the damage is irreversible, patients exposed to radiation that are experiencing symptoms should seek medical help immediately so that drugs can be administered.

### Introduction

The first observable cases of radiation sickness occurred after the nuclear bombing of Hiroshima and Nagasaki. Japanese doctors described an unknown disease with symptoms that "suddenly appeared in certain patients with no apparent injuries." It is now known that these first patients were suffering delayed effects of radiation exposure. Radiation sickness can result in patients with low exposure levels, such as cancer treatments, and leave them with symptoms similar to a case of the flu. However, in cases of extreme exposure caused from atomic weapons or a power plant meltdown, such as Chernobyl, the effects can be fatal. Total dose and dose rate determine somatic or genetic effects of radiation. The units of measurement commonly used in determining radiation exposure or dose are the roentgen, the rad, and the rem. The roentgen (R) is a measure of quantity of x or gamma ionizing radiation in air. The radiation absorbed dose (rad) is the amount of energy absorbed in any substance from exposure, and applies to all types of radiation. The R and the rad are nearly equivalent in energy for practical purposes. The rem is used to correct for the observation that some types of radiation, such as neutrons, may produce more biological effect for an equivalent amount of absorbed energy; thus the rem is equal to the rad multiplied by a constant called the "quality factor". For x and gamma radiation the rem is equal to the rad. The rad and the rem are currently being replaced in the scientific nomenclature by two units that are compatible with the International System of Units, namely the gray (Gy), equal to 100 rads and the Sievert (Sv), equal to 100 rem.

## Signs & Symptoms

Acute radiation sickness is characterized by nausea, vomiting, diarrhea, anorexia, headache, malaise and rapid heartbeat (tachycardia). With mild ARS, the discomfort subsides within a few hours or days. However, there are three different types of severe ARS, which can develop as a result of high doses (e.g., an atomic explosion) to small doses (e.g., repeated x-rays over a period of days or weeks):

The type of severe ARS depends on dose, dose rate, affected area of the body, and the period of time elapsing after exposure. The severe ARS is due to penetrating radiation to most or all of the body in a short period of time, usually a few minutes. A patient with any type of severe ARS usually goes through three stages: In the prodromal stage, the classic symptoms are nausea, diarrhea and vomiting. This stage can last for a few minutes up to a few days. In the next stage, called the latent stage, a patient seems to improve to the point where they are generally healthy for a few hours or even a few weeks. The last stage, called the overt or manifest illness stage is specific to each type. They are cardiovascular/central nervous system sickness, gastrointestinal sickness, and hematopoietic sickness.

Cardiovascular/central nervous system sickness is the type of ARS produced by extremely high total body doses of radiation (greater than 3000 rads). This type is the most severe and is always fatal. In addition to nausea and vomiting in the prodromal stage, patients with cerebral syndrome will also experience anxiety, confusion, and loss of consciousness within a few hours, the latent period will occur. 5 or 6 hours after the initial radiation exposure, tremors, and convulsions will begin, and eventually coma and death are inevitable within 3 days.

Gastrointestinal sickness is the type of ARS that can occur when the total dose of radiation is lower but still high (400 or more rads). It is characterized by intractable nausea, vomiting, imbalance of electrolytes, and diarrhea that lead to severe dehydration, diminished plasma volume, vascular collapse, infection and life-threatening complications.

Hematopoietic sickness (bone marrow sickness) is the type of ARS occurs at exposure of between 200 to 1000 rads. Initially it is characterized by lack of appetite (anorexia), fever, malaise, nausea and vomiting, which may be maximal within 6 to 12 hours after exposure. Symptoms then subside so that within 24 to 36 hours after exposure. During the latent period for this type, the lymph nodes, spleen and bone marrow begin to atrophy, leading to underproduction of all types of blood cells (pancytopenia). In the peripheral blood, lack of lymph cells (lymphopenia) commences immediately, reaching a peak within 24 to 36 hours. Lack of neutrophils, a type of white blood cell, develops more slowly. Lack of blood platelets (thrombocytopenia) may become prominent within 3 or 4 weeks. Increased susceptibility to infection develops due to a decrease in granulocytes and lymphocytes, impairment of antibody production and granulocyte migration, decreased ability to attack and kill bacteria, diminished resistance to diffusion in subcutaneous tissues, and bleeding (hemorrhagic) areas of the skin and bowel that encourage entrance and growth of bacteria. Hemorrhage occurs mainly due to the lack of blood platelets.

Delayed effects of radiation can lead to intermediate effects and late somatic and genetic effects. Intermediate effects from prolonged or repeated exposure to low radiation doses from a variety of sources may produce absence of menstruation (amenorrhea), decreased fertility in both sexes, decreased libido in the female, anemia, decreased white blood cells (leukopenia), decreased blood platelets (thrombocytopenia), skin redness (erythema), and cataracts. More severe or highly localized exposure causes loss of hair, skin atrophy and ulceration, thickening of the skin (keratosis), and vascular changes in the skin (telangiectasia). Ultimately it may cause a type of skin cancer called squamous cell carcinoma.

Kidney function changes include a decrease in renal plasma flow, glomerular filtration rate (GFR), and tubular function. Following a latent period of six months to one year after extremely high doses of radiation, protein in the urine, kidney insufficiency, anemia and high blood pressure may develop. When cumulative kidney exposure is greater than 2000 rads in less than 5 weeks, kidney failure with diminished urine output may occur in about 37% of cases.

Large accumulated doses of radiation to muscles may result in painful myopathy with atrophy and calcification.

Inflammation of the sac around the heart (pericarditis) and of the heart muscle (myocarditis) have been produced by extensive radiotherapy of the middle region between the lungs (mediastinum).

Myelopathy may develop after a segment of the spinal cord has received cumulative doses of greater than 4000 rads. Following vigorous therapy of abdominal lymph nodes for seminoma, lymphoma, ovarian carcinoma, or chronic ulceration, fibrosis and perforation of the bowel may develop.

Late somatic and genetic effects of radiation can alter the genes in proliferating cells of the body and germ cells. With body cells this may be manifested ultimately as somatic disease such as cancer (leukemia, thyroid, skin, bone), or cataracts. Another type of cancer, osteosarcoma, may appear years after swallowing radioactive bone-seeking nuclides such as radium salts. Injury to exposed organs may occur occasionally after extensive radiation therapy for treatment of cancer.

When cells are exposed to radiation, the number of mutations is increased. If mutations are passed down to children, this can cause genetic defects in the offspring.

## **Causes**

Harmful sources of ionizing radiation are limited primarily to high-energy x-rays used for diagnosis and therapy, and to radium and related radioactive materials. Present sources of potential radiation include nuclear reactors, cyclotrons, linear accelerators, alternating gradient synchrotrons, and sealed cobalt and cesium sources for cancer therapy. Numerous artificial radioactive materials have been produced for use in medicine and industry by neutron activation in reactors.

The accidental escape of moderate to large amounts of radiation from reactors has occurred several times. The radiation from the atomic bombs dropped in Hiroshima and Nagasaki caused hundred of cases of cancer, mutations, and genetic defects years after the explosion. Radiation exposure from reactor accidents like Chernobyl, for example, resulted in 134 illnesses and 28 deaths.

Very low doses of radiation such as unavoidable background radiation (about 0.1 rad/yr), produce no measureable effect. Mild symptoms have been observed with doses as low as 30 rad. The probability of measurable effects increases as the dose rate and/or total dose increases.

The area of the body exposed to radiation is also an important factor. The entire human body can probably absorb up to 200 rads acutely without fatality. However, as the whole-body dose approaches 450 rads the death rate will approximate 50%, and a total whole-body dose of greater than 600 rads received in a very short time will almost certainly be fatal. By contrast, many thousands of rads delivered over a long period of time (e.g. for cancer treatment), can be tolerated by the body when small volumes of tissue are irradiated. Distribution of the dose within the body is also important. For example, protection of bowel or bone marrow by appropriate shielding will permit survival of the exposed individual from what would be an otherwise fatal whole-body dose.

## **Affected Populations**

Radiation sickness can affect males and females in equal numbers.

## **Diagnosis**

Diagnosis is typically made based on a history of significant radiation exposure. The time between exposure and vomiting also can give good estimates of exposure levels in a patient.

## **Clinical Testing and Work-Up**

Monitoring of exposed patients is mandatory, using Geiger counters or sophisticated whole-body counters. Urine should be analyzed for non-gamma-emitting radionuclides if exposure to these agents is suspected. Radon breath analysis can be done in cases of suspected radium ingestion.

## Standard Therapies

### Treatment

Contamination of the skin by radioactive materials should be immediately removed by copious rinsing with water and special solutions containing an agent such as EDTA (ethylenediamine tetraacetic acid), a chelating agent which binds many radioactive isotopes. Small puncture wounds must be cleaned vigorously to remove contamination. Rinsing and removal of contaminated tissue are necessary until the wound is free of radioactivity. Ingested material should be removed promptly by induced vomiting or by washing out the stomach if exposure is recent.

If radioiodine is inhaled or ingested in large quantities, the patient should be given potassium iodide to block thyroid uptake for days to weeks, and diuresis should be promoted.

In 2015, Neupogen (filgrastim) was approved to treat adult and pediatric patients acutely exposed to myelosuppressive doses of radiation (hematopoietic syndrome of acute radiation syndrome, or radiation sickness). Neupogen is manufactured by Amgen, Inc.

Prussian blue is a pigment that has been used in industry for centuries and has also been approved by the FDA for the treatment of radioactive cesium and non-radioactive thallium exposure. Prussian blue traps these elements in the intestine so that they can be passed out of the body as stool instead of being absorbed.

Ca-DTPA and Zn-DTPA are also FDA approved drugs that speed up the excretion of elements such as plutonium, americium, and curium from the body. Ca-DTPA is given as a first dose, as it is more effective, but after the initial 24 hours, both are equally effective and Zn-DTPA becomes preferable because it removes less essential metals, such as zinc.

For the cardiovascular/central nervous system sickness, treatment is symptomatic and supportive. It is aimed at combating shock and lack of oxygen, relieving pain and anxiety and sedation for control of convulsions.

If the gastro-intestinal sickness develops after external whole-body irradiation, the type and degree of therapy will be dictated by the severity of the symptoms. After modest exposure, antiemetics and sedation may suffice. If oral feeding can be started, a bland diet is tolerated best. Fluid, electrolytes, and plasma may be required in huge volumes. The amount and type will be dictated by blood chemical studies (especially electrolytes and proteins), blood pressure, pulse, urine output, and skin turgor.

Management of the hematopoietic sickness, with its obvious potentially lethal factors of infection, hemorrhage and anemia, is similar to treatment of marrow hypoplasia and pancytopenia from any cause. Antibiotics, fresh blood, and platelet transfusions are the main therapeutic aids. However, a side effect of platelet transfusions may be development of an immune response to future platelet transfusions. Rigid germ-free conditions (asepsis) during all skin-puncturing procedures is mandatory as is strict isolation to prevent exposure to disease-causing germs.

Concurrent anticancer chemotherapy or use of other marrow-suppressing drugs, should be avoided.

Radiation ulcers and cancers require surgical removal and plastic repair. Radiation-induced leukemia is treated like any similar spontaneously occurring leukemia. Anemia is corrected by blood transfusion. Bleeding due to lack of platelets (thrombocytopenia) may be reduced by platelet transfusions.

No effective treatment for sterility, or for ovarian and testicular dysfunction (except for hormone supplementation in some cases), is currently available.

## Investigational Therapies

Bone marrow transplants have proven helpful in some cases. If a whole body radiation dose greater than 200 rads is suspected, and if granulocytes and platelets continue to decrease and fall to less than 500 and 20,000/ cu mm, respectively, compatible bone marrow transplantation should be made. With use of cyclosporin to prevent rejection of the graft, a marrow transplant will most likely increase the probability of survival. Thirteen people at Chernobyl who received estimated total body doses of radiation between 5.6 to 13.4, underwent bone marrow transplants after the Chernobyl accident. Two transplant recipients survived. Others died of various causes including burns, graft-vs-host disease, kidney failure, etc. Therefore, the success of bone marrow transplantation for radiation sickness was inconclusive.

Information on current clinical trials is posted on the Internet at [www.clinicaltrials.gov](http://www.clinicaltrials.gov). All studies receiving U.S. government funding, and some supported by private industry, are posted on this government web site.

# MICROWAVE RADIATION FREQUENCY AND W/FI SYMPTOMS

- Confusion
- Short term memory loss
- Inability to focus
- Brain fog/sluggish thinking
- Difficulty concentrating
- Headaches
- Migraines
- Vision disruption or eye problems
- Eye pain
- Cataracts
- Head or chest pressure
- Allergies
- Difficulty breathing
- Respiratory problems
- Slow reaction time
- Sleep disruption
- Insomnia
- Night sweats
- Nightmares
- Dizziness
- Disorientation
- Balance Problems
- Agitation
- Anxiety
- Depression
- Suicide
- Tension
- Irritability
- Tremors
- Nervousness
- Seizures
- Vertigo
- Nausea or vomiting
- Flu-like symptoms
- Digestive difficulty
- Nose bleeds
- Hair Loss
- Rapid Aging/oxidative damage
- Skin problems including rashes
- Skin irritation/dryness
- White Noise 24/7
- Ringing or buzzing in ears
- Ear pain
- Tinnitus
- Bed wetting
- Urinary problems

- Behavioral problems in children
- Pets get jumpy
- Mood disorders
- Lethargy
- Exhaustion
- Chronic fatigue
- Lost productivity/sick days
- Loss of employment
- Unusual family conflicts
- Disintegrating relationships

- organ and brain damage
- Psoriasis
- Autoimmune disease
- Lupus
- Damages mitochondria
- Free radical damage and aging
- Worsening existing poor health
- Demineralization of cells/tissue
- Impotence
- Infertility
- Birth defects
- Life span decreases by +/-8 years
- Heart Attack
- Pacemaker defibrillation
- Circulation problems
- Joint difficulty
- Muscle pain
- Fibromyalgia
- Dementia
- Personality changes
- Alzheimer's, Parkinson's, ALS  
Amyotrophic Lateral Sclerosis
- Childhood cancers increase
- Brain tumors
- Rare Deadly Brain Gliomas
- Leukemia
- Cancer
- Diabetes
- Heating beamed on humans that mimics a high fever
- Rhinitis (inflammation nasal membranes)
- Asthma
- Allergies such as hay fever
- Food allergy
- Atopic dermatitis (inflammation of the skin)
- Itching and chapped skin on the trunk
- Rheumatism (painful condition of the joints and muscles characterized pain and stiffness)
- Benign uterine fibroid tumors
- Bone loss/osteoporosis
- Dehydration
- Kidney damage

- Electronic Harassment-Stalking-Mind Control
  - Violent behavior
  - Autism
  - ADHD
  - Weakened immune system
  - Physical weakness or pain
  - High blood pressure
  - Leg cramps
  - Stiff neck or back
  - Shuts down the cells-cell death
  - Changes in genetic makeup
  - DNA breakage
  - EMF causes mercury dental filling vapor to leak causing

## INTRODUCTION

With respect to my fellow scientists I shall be writing this report in non-scientific speak for all of those readers who have not had the benefit of a scientific education.

## WHAT IS ALL THIS REALLY ABOUT?

Imagine the field around a magnet and imagine ordinary everyday static electricity. If you put the force field from the magnet with the force field from the static electricity you make a wave. This wave is called an electromagnetic wave. There are lots of different types of electromagnetic waves but they are all made of the same two things – magnetic and static. The only difference between the waves is their wavelength or the length of the wave and the number of waves that can be produced a second, i.e. the frequency. All of these waves are put into a table called the electromagnetic spectrum.

At one end of this electromagnetic spectrum you have the very short waves, namely gamma rays and x-rays and at the other end of the spectrum you have the very long waves, namely radio, TV and waves from overhead power cables. All of these waves have the same properties; that is to say they all behave the same. They can all be reflected, refracted, and they all travel at the same speed, which is the speed of light. For interest, if you were one wave of light you would be able to travel around the world nearly seven times every second; that is the speed of light. The electromagnetic spectrum is ordered so that at the short wave end you have the gamma rays, x-rays, ultra-violet, visible light, infra red, microwaves, radar, TV and radio in that order. The ultra-violet and above are known as ionising waves and there is no argument as to the damage they can cause when entering the body. Below ultraviolet is said to be non-ionising and this is where arguments occur between scientists as to whether damage can occur inside the human body through exposure to these waves. The microwaves

used in the TETRA system are in the non-ionising section of the electromagnetic spectrum and I will be discussing the arguments concerning microwaves and health in this report.

## SAFETY LEVELS

In this country, when somebody asks about whether a certain level of electromagnetic radiation is safe they are usually quoted a safety limit. This safety limit is laid down by the NRPB (National Radiological Protection Board). Usually when you ask about a dose of radiation you find that the amount that you were asking about is thousands of times below the safety limit and thereby reportedly safe. A safety limit is really a personal opinion. This personal opinion may be based on many factors by an individual or individuals from whatever data they have in their possession. To give you an example of some safety limits around the world, for one particular type of microwave transmitter, these read as follows:

Toronto Health Board	:	6 units
Italy	:	10 units
Russia	:	10 units
Poland	:	100 units
US Research Base	:	100 units
International Commission	:	450 units
The NRPB for Britain	:	3,300 units

There are other values for other transmitters but there is no need to list those in this document.

To look at this another way, supposing you took your car to a garage and one mechanic estimated a price of £6 and another mechanic estimated a price of £3,300 for the same job, you would feel justified about questioning the decisions. The reason that our safety limit is much higher than the rest of the world is that in other countries they base their safety limits on possible effects from the electric field, the magnetic field and the heat produced in the body. Our NRPB will only base the safety limit for this country on the heat produced in the body. I will comment on heat further in this report (Appendix 1, Reference 1).

## WHAT IS BELIEVED TO HAPPEN AS THESE WAVES ENTER OUR BODIES?

I will try to summarise the thousand or so research papers written over the last 20 or so years and explain or summarise what happens when the electric and magnetic part of the wave goes into our bodies.

We being water based animals act like aerials to these waves. As the waves go into our bodies an electric current is generated inside our bodies which is how aerials work; waves come in and electricity is generated. The electricity generated in our bodies like all electric currents goes to ground through our bodies and like all electric currents it takes the path of least resistance. Unfortunately the path of least resistance through our bodies, although only representing 10% of our pathways, carries 90% of our traffic rather like the M1 motorway. The traffic in our bodies, namely hormones, antibodies, neurotransmitters know where they are going because they also carry an electric charge. The hormones, antibodies and neurotransmitters know where to "get off" because there is a corresponding opposite charge at the site of delivery rather like the positive and negative ends of a battery. The problem is if you have an electric current passing through the body it can change this charge, either on the hormones, antibodies or neurotransmitters or the site of delivery.

An analogy to that would be - if you were in Paris on the Underground system and you could not speak a word of French, but you had a map with the station name of where to get off and somebody tippexed out one or two of the letters, you may get off or you may

not, and this can happen in the body. The hormones, antibodies or neurotransmitters may get off where they are meant to get off or they may carry on and miss their target. As a one-off this probably would not be very important but continuous interference over many years it is argued can lead to many illnesses.

A similar effect is that the destination for some of these hormones, neurotransmitters, antibodies is a surface of a cell where chemicals will pass through a membrane into a cell. If you think of a cell in our body, be it a brain cell, bone cell etc, as having a positive and negative charge on the outside and the inside similar to a battery the difference in these charges will draw the chemical into the cell or draw poisonous substances out of the cell. If the charge is changed on the outside of the cell, then necessary chemicals may not go in or poisonous chemicals may not go out. An analogy to that would be – think of your house as a cell in your body. Essential things like food, water and fuel come into the house and poisonous things like waste and gases leave the house. In fact a house is very similar in many ways to a cell in our body. Now, if we had a blockage and waste could not leave the house or sometimes food or electricity did not come into the house, over a short period of time we would survive this, but continual disruption over many years will probably have a knock-on effect on the health of the inhabitants particularly if they are young or frail. This is my explanation of how electromagnetic waves affect our cells.

A final description is possibly the accumulative effect of all the particles going through the body each second. Each particle and for TETRA we are talking about 400,000,000

particles a second carries a small amount of momentum with it. As an analogy, imagine you are driving down the M1 in the largest lorry you could possibly imagine and you are hit by the smallest dust particle you could ever imagine. Obviously the dust particle will not effect the speed or momentum of your lorry but if you have 400,000,000 dust particles a second for many years they could if something else was going wrong with your lorry exacerbate the effect and slow your lorry, and that is the crucial point. All of these effects I have described are believed to have one final conclusion. They all in their own way suppress the immune system. When you suppress the immune system as I will show in research papers, you tend to have more colds, more coughs, longer colds, longer coughs, longer illnesses, depression, anxiety leading to suicide or taken to its ultimate – leukaemia.

I will summarise just four of what I consider to be extremely well written research papers by arguably the worlds leading scientists in this field. There are other leading scientists of course but I cannot list them all in this report. I am using these as specimen papers.

When I refer to research papers I am not referring to something that somebody has sat down one Sunday afternoon and just written. These research papers have sometimes hundreds of references in the back and each reference on its own is usually 5-10 years work by a group of scientists where their work would have been peer reviewed, and in a lot of cases published. So for arguments sake, if a paper has say 100 references in the back that could well constitute 500-1,000 years accumulative work.

The first paper (Appendix 2, Reference 2) by Dr Neil Cherry was presented in May 2000 to the New Zealand Parliament, to Italy, Austria, Ireland and the European Parliament in Brussels. This paper has 122 references. I have photocopied the references to show that as well as being peer reviewed, many are published. I will do this with the other three papers (Appendix 3).

From this research paper some illnesses caused by long-term low level electromagnetic radiation are:

Heart problems;

Blood problems;

Interference with bone marrow;

Tumours;

Calcium interference;

46% reduction in night-time melatonin;

It is believed that during the daytime light going through our eyes passes a message to the pineal glands in the brain which slows down the production of melatonin. At night when no light goes through our eyes the production of melatonin is speeded up. Melatonin is believed to scavenge cancer cells and impurities in our bodies and boost the immune system. If an officer is sleeping in quarters within range of the TETRA transmitter, the microwave radiation is believed to act on the pineal gland and suppress the night-time melatonin to daytime levels; hence the good work of the melatonin at night will be restricted leading to suppression of the immune system.

Increased arthritis;

Skin problems;

Ear problems;

Risk to leukaemia;

Childhood cancer;

Sleep problems;

Depression;

Memory loss;

Difficulty in concentrating;

Mental conditions;

A very recent discovery shows that microwave radiation changes the permeability of the blood brain barrier. Our brain has its own immune system as does our body. The blood brain barrier keeps everything that is designed to be kept within the brain inside it and protects the brain from any unwanted diseases or chemicals which could harm it. Similarly it allows out of the brain anything dangerous to the brain. The blood brain barrier is rather like a sieve where only particles of a certain size may go through. Professor Salford at Lund University in Sweden has shown that such pulsing as from mobile phones can alter the permeability of the blood brain barrier (Appendix 4, Reference 3). I will argue as TETRA pulses, which is arguably more powerful than the average mobile phone, this situation could be worse with TETRA.

Also, it is shown that the electromagnetic radiation going into the body can change the size of the particles moving around the body (Reference 4). This is rather like an ice skater spinning on her skates. With her arms out she spins slowly, but if she pulls her arms in she spins faster. Microwaves can affect the particles in our body by changing their spin; hence their size. They can be made smaller or larger. With the changing of the permeability of the blood brain barrier and the changing in size of particles unwanted particles may enter the brain or necessary particles may leave the brain. The connection here with mental conditions is that Dr Hyland of Warwick

University has written that the uptake of drugs; in particular neurological drugs is inhibited because of changes in the blood brain barrier.

Neurological illnesses;

Headaches;

Dizziness;

Fatigue;

Miscarriage; and

Infertility.

I have listed all of the references on this particular research paper because all of these researches correspond to the above list.

The second paper I would like to comment on (Appendix 5, Reference 5) has 80 references and as well as a lot of the illnesses written in Dr Cherry's paper goes on to mention that with regard to mobile phone handsets you should avoid keeping the handset when switched on adjacent to the body, in particular in the vicinity of the waist or heart. There have been deaths due to colon cancer from the Royal Ulster Constabulary who wore radio or microwave transmitters in the small of their backs for extended periods of time. Dr Hyland recommends keeping the duration of calls to an absolute minimum and on his back page relating to pulse mobile phone radiation on alive humans and animals, the following may occur:

Epileptic activity;

Effects on human EEG;  
Effects on blood pressure;  
Depression of immune systems;  
Increased permeability of the blood brain barrier;  
Effects on brain electro-chemistry;  
DNA damage in rodent brain;  
Cancers in mice; and  
Synergistic effects with certain drugs.

Dr Hyland, in my opinion, is one of the world's leading authorities in this area and his advice is not to be dismissed lightly. Similarly, another very highly respected scientist is Dr Coghill. I would add that both Dr Hyland and Dr Coghill are members of the Stewart Committee.

Dr Coghill's paper which has 218 references (Appendix 6, Reference 6) agrees largely with the work by Dr Hyland and Dr Cherry. In this paper, Section 1.16, Dr Coghill writes "the ultimate question must be whether chronic exposure to say 1 V/m electric fields at the envisaged frequencies is likely to produce adverse health effects in the long term. At present the NRPB guidelines recommend an investigation level of 192 V/m while ICNIRP now offers much lower levels. However these are based on thermal effects: if non thermal evidence is accepted than 1 V/m is demonstrably able to induce biological effects, some of which may be adverse". I will show in a later paper that TETRA delivers a lot more than the 1 V/m recommended as a maximum by Dr Coghill.

Dr Coghill also, in his summary in the back, lists symptoms caused by mobile phone use. Again, I will argue that as TETRA is pulsed and pulsed radiation is arguably more aggressive than the continuous analogue wave and TETRA uses more power than the ordinary mobile the symptoms will be enhanced rather than be reduced for TETRA.

The symptoms listed by Dr Coghill are:

Fatigue;

Headache;

Warmth behind the ear;

Warmth on the ear; and

Burning skin.

My final paper by a very highly respected New Zealand doctor, Dr Eklund (Appendix 7, Reference 7) which has 37 references shows leukaemia clusters in and around ordinary radio and TV transmitters around the world. She says on page 13 that adult leukaemia within 2 kilometres of a transmitter is 83% above expected and significantly declines within increasing distance from the transmitter. Similarly skin and bladder cancers follow a similar pattern. As a scientist I could argue that if leukaemia's and cancers are known to exist from ordinary radio and TV transmitters which take many years to form and radio and TV waves are at the long end of the electromagnetic spectrum, and it is known that exposure to gamma rays or x-rays can cause death within a matter of weeks, a hypothetical line could be drawn from the long waves to the short waves to determine the length of time or exposure doses needed to cause such illnesses. Fitting

into this pattern would be several years exposure to sunlight causing skin cancer. There are obvious anomalies with this; namely personal health, hygiene and all sorts of other factors, but as a crude estimate I would argue that the further up the electromagnetic spectrum you go, the shorter the time for the serious illnesses to occur. The microwaves used by TETRA are above radio and television waves. Being water-based animals we are particularly sensitive to microwaves; this is why microwave ovens work. Microwave ovens resonate the water molecules in food and when molecules resonate they re-emit the energy they absorb as heat. This is why the food warms up and the plate does not, because it does not contain water.

The warmth on and behind the ear felt by users of mobile phones is one type of heat. Another type of heat unknown to the user, therefore not reported are hotspots within the body from microwaves. These hotspots are tiny areas in the body which warm up considerably when exposed to microwave radiation. The problem with warming up areas inside the body is that a very recent research paper has shown that heat shock proteins are produced to protect the cells in the body from damage. Heat shock proteins act rather like scaffolding around a building; they go around the cell and protect the DNA from damage from the heat. Heat shock proteins have been known to work when the temperature rises by just 2 degrees. Now the problem with heat shock proteins is as well as protecting the good cells they can also protect and save from destruction cancer cells. So, if you have a cell in your body which is turning cancerous and would normally be destroyed by the body's immune system, the heat shock proteins

will protect it and it will continue to grow. This work was carried out by Dr David de Pomerai, of Nottingham University (Appendix 8, Reference 8).

A report on mobile telephones and their transmitters by the French Health General Directorate, dated January 2001, states in its conclusion of the group of experts that "a variety of biological effects occur at energy levels that do not cause any rise in local temperature". The group ask "is it possible to state that there are no health risks?" and they reply "No". They go on to say "minimise the use of mobile telephones when reception is poor, use an earpiece kit and avoid carrying mobile phones close to potentially sensitive tissue, i.e. a pregnant woman's abdomen or adolescent gonads". They recommend hospitals, day-care centres and schools should not be directly in the path of the transmission beam. Also and very important, they say "the cumulative exposure over their lifetime will be higher ...". The word cumulative is also mentioned by Professor Sosskind and Dr Prausnitz in their paper (Reference 9) where they say "an accumulated cellular level damage mechanism is not necessarily related to the intensity but can relate to total dose ... Hence the averaging of weekly exposure is a meaningful adverse effect related level".

This accumulative factor puts a very different slant on doses of microwave radiation. In particular an accumulative level of radiation can build up very quickly when you receive 400,000,000 waves every single second. This is why scientists are concerned and warnings have been issued for people with pacemakers, hearing aids, insulin pumps in relation to interference of their apparatus from electromagnetic waves. Warnings are

also given to persons with metal implants in their bodies. These implants can a) warm up; and b) absorb the microwave radiation and re-emit it at a different wavelength. I have been around the world talking to scientists and we agree, although it cannot be proved, that the recent incidents in breast cancers in ladies could be due to the metal underwiring in bras absorbing microwave radiation and re-emitting it at a different wavelength into the mammary glands of the breast. The mammary glands are known to be particularly sensitive to radiation and they are known to be easily changed into cancer cells.

Following this line of thought, I would argue scientifically that using a TETRA handset, remembering that if you are using a TETRA handset you must also be receiving radiation from the main transmitter, i.e. you do not just have the radiation from the phone you would have the radiation from the transmitter as well, or the phone would not work, could enhance breast cancer in the lady police officers. A similar argument follows with the argument that the eyes receive 29% extra radiation because of their moist make-up. Metal-rimmed spectacles will absorb the microwave radiation and re-emit it onto the surface of the eye. Again, unproven, but I can follow the arguments that support the two recent research papers which have found increases in eye cancers in two separate areas of the eye. One cancer has been found in the side of the eye, one cancer has been found in the front of the eye (Appendix 9, Reference 10) (Appendix 10, Reference 11).

As a result of using pulsed mobile phones, again I will argue that as TETRA is more powerful than the average mobile there could be long-term damage to the eyes of the officers using TETRA.

A union document (Reference 12) printed 4 December 1979 for microwave transmitters up to 100,000 MHz warns its members of the following illnesses which may occur from accumulative exposure:

Menstrual problems;

Miscarriage; and

Problems of the eye, heart, central nervous system, reproductive organs.

They say "a false sense of safety may exist and non-thermal effects are much lower than have been recognised". The TETRA system of 380-400 MHz is within this range of this union paper. I emphasise that these effects are not new; they were being reported on as far back as 1979 and further on in this paper I will show documents that relate to exposure effects going way back to the early 1960s. A very important sentence in this research paper states "non-ionising radiation increases molecular vibration and rotational energies". I will refer to this further on in this document.

## INSURANCE

Two of the worlds largest insurance companies, Lloyds and Swiss Re, have recommended to other insurance companies on the advice of Dr Theodore Litivitz, Professor Emeritus of Physics at the Catholic University of America, to write in exclusion clauses against paying compensation for illnesses caused by continuous long-term low level radiation. My concern for the police force, although adequately insured, is that if in future years officers start claiming for spine or brain tumours the insurance company will terminate its contract with the police force and leave it uninsured.

## SURVEYS

Two recent surveys printed in Electromagnetic Hazard & Therapy 1998, Volume 9 and 2000, Volume 11; the first of a study of 11,000 mobile phone users, the second a study of 17,000 mobile users showed the symptoms already mentioned of fatigue, headache, warmth behind the ear, warmth on the ear and burning skin in various degrees, depending on the use and type of person. From the 17,000 persons studied, these symptoms varied from 31% to 78% of the users. If I take the lowest number of 31% as a purely hypothetical exercise which is easily dismissed as rubbish, but does give us a look at some of the numbers that could be involved; if we take 100,000 police officers then 31,000 of these officers could experience one symptom. Playing the numbers game, if these 31,000 that experienced one symptom were to progress to a more complicated level, let's argue 10% of them may develop a migraine or a headache or require one day's sick we would have 3,100 officers taking a day's sick. If 10% of those developed something more serious that required further sickness we would have 310 officers off sick. If we take 10% of those and suggest that something more serious may occur then we could be looking at 31 officers, or I would argue 31 families, per hundred thousand involved in something which may develop into a serious medical condition. I stress that this is hypothetical because it is very difficult to predict the future for a device that has not been tested and there are no long-term studies available.

As an aside it was noted last year that the Public & Commercial Services Union recommended to its 266,000 Civil Service members that they should not be forced to carry mobile phones.

## GROUND CURRENTS

A very little understood phenomena and reported by Dr D Dahlberg (Reference 13) is ground currents from living in the proximity of transmitters on animals. I mention this with a view to the police dogs and the police horses in their kennels or stables at a constabulary base which is bound to have a transmitter. All transmitters pass an electric current to the ground beneath them. If the ground is particularly wet this has an adverse static effect on the animals concerned and in farm animals can effect milk productions or food production. Huge static charges are built up in the animals and everytime they come across a metal object the charge is discharged through the head; the nose being wet. It has been shown that if animals are taken away from this environment they recover very quickly, yet in the environment of ground currents they also become very sick very quickly. I am particularly concerned for the acutely sensitive brains and organs of the highly trained police dogs.

Three years ago when a lot of research papers individually were being dismissed I decided to look at several of the main papers and show that there was a knock-on effect in the body. I drew two flow diagrams showing the knock-on effects from approximately 25 research papers to show that even if one symptom is dismissed there can be an accumulative effect throughout the body. The two flow charts - Appendix 11 relates to the body and Appendix 12 relates to the brain, show clearly that our body systems are very closely interlinked.

Taking TETRA's lowest operating power level of 2W I wrote a hypothetical equation, and being hypothetical it is very easily dismissed, which shows that at the 2W cell activity may be accelerated by a factor of 6 or slows down by a factor of 7.5.

There are experimental papers which do in fact show that mobile phones may speed up thought processes or may slow down cellular activity. I have tried to explain this using theoretical physics. I based my paper on the already previously mentioned accumulative doses and increased molecular vibration (please see previous references). I am fully prepared to be told that I am wrong or mistaken but I believe I can explain the process by which energy once inside the body affects the cell potential (charge on the outside of the cell), the signal transduction (movement from the outside to the inside of the cell) and the cell cycle timing (the process by which our cells operate). I have placed this calculation in Appendix 13.

Often overlooked are the electromagnetic waves from the cables and transformers of all electrical transmitters. These are usually in cabinets near the transmitters, hence near offices or sleeping quarters on constabulary bases or near kennels or stables. A research paper published in the Journal of Biological Chemistry in 1998 (Reference 14) describes the 50 cycles a second waves emitted by transformers and power cables, and how they may induce leukaemia. Although the NRPB and the National Grid have denied that these waves are dangerous both this paper and an article in the New Scientist dated 10 March 2001, page 7 which reads "Guilty as Charged. Powerful fields

from pylons and cables are linked to childhood cancer", demonstrates to me scientifically that these transformers and power cables should not be overlooked.

## THE CONCLUSIVE PROOF ARGUMENT

The Government's scientists will often ask for conclusive proof when they are challenged. It is a word often used when you wish to win your side of the argument. Scientifically conclusive proof is impossible to obtain – let me explain.

I was at a legal hearing in Torquay representing a community and the barrister representing the communications industry said "there is no conclusive proof that these microwaves will cause damage". I argued: if somebody stood up and shot me in this courtroom there would be three levels of proof. You would have everybody as a witness and that would be accepted in a Court of Law. A pathologist could perform a post mortem, decide that the bullet killed me and that would be a second level of proof. If, however you wanted conclusive proof that the bullet killed me, you would have to argue that at the split second the bullet went into my body every system in my body was working perfectly because there are thousands of reasons why I could drop dead on the spot before the bullet went in and you would have to prove conclusively that all of these systems were working perfectly before the bullet went in. Clearly, this is scientifically impossible; there is no such thing as conclusive proof, yet it is what is demanded by government scientists when challenging their decisions.

Conclusive proof has been demanded by scientists defending their decisions after they have said the following are safe:

Thalidomide;

Asbestos;

BSE;

Smoking;

Sheep dip;

Gulf War Syndrome;

GM Foods; and

Vitamin B6.

With the above list it will be recognised that evidence of damage from these comes only from counting the people who are injured. I am arguing scientifically that there is a blanket denial by some scientists and the only way to show them wrong is to present them with a certain number of bodies. When commercial interests are at stake there seems to be a denial of relevant scientific data. The problem with the microwave communications industry is that they do not have to prove it is safe; you have to prove it is not, and that is an entirely different ball game. As a scientist, if I develop a new pill I have to run a 5 or 10 year clinical trial and convince a Board of my peers that it is safe before I have permission to release the pill onto the market. With the telecommunications industry the tables are completely turned around. They do not have to show these instruments are safe; you have to show they are not.

## UNDERSTANDING RADIATION (MICROWAVE AS IN TETRA)

There are unknown phenomena concerning low level radiation that is not generally understood by the users of communication instruments. Following the Chernobyl incident it was found that long-term continuous low level radiation of all types was as dangerous as high level doses of radiation. With high level doses of radiation the anti-oxidants in the body (Vitamins A, C, E etc) rush to defend and repair the area of the body being damaged. However with low level radiation the anti-oxidants are not activated and because the dose is accumulative the problems can build up and are usually present before the body realises that there is trouble. So, low level does not necessarily mean safer. Also the smaller you are the more you tend to absorb. Wavelengths for TETRA and mobile phones are relatively short and the nearer the part of the body or the infant to the wavelength the more similarity they have to an aerial and the more they absorb. With ordinary mobiles the wavelength is around the size of a foetus and with TETRA you are looking at a 3-6 year old child. I mention this because TETRA may be used in areas where children are running around and there are very well known and documented cases of pulse radiation affecting epileptic children.

Pulse radiation from TETRA at 17.6 Hz (waves per second) is known to interfere with our natural brains rhythm. Our brains generate their own waves within our head. One of these waves, called beta waves is on a very similar frequency to the TETRA handsets. What happens is: If you could imagine yourself jumping on a trampoline and somebody larger and heavier jumps on and dances at a slightly different speed you will

bounce at their pace rather than yours. When they jump off you will still bounce at their speed. The jumping on of the person onto the trampoline is known as entrainment and this occurs when the TETRA is used in close proximity to an officer's brain. Because TETRA affects the beta rhythm of the brain it will affect what the beta rhythm is responsible for; namely sounds judgement in emergency situations. Entrainment is always followed by a phenomena called long-term potentiation. This is an analogous to the person getting off the trampoline leaving you dancing. Long-term potentiation has been known to last several weeks after the initial source has died down. The implications for this are that the officers' brain waves would continue to suffer entrainment even after the sets have been switched off, which would be reinforced everytime the sets are switched on again.

The first paper written on this subject was by a scientist called Ptolomy who was a Greek living in Egypt in 64BC. Ptolomy found that when he spun a wheel with holes in up against the sun at different rotational speeds he could induce different effects on the brains of his subjects. To get an idea of the complexity of the brain, if you imagine every single person in every single city in the world picking up their telephone and dialling everybody in their phonebooks, that is roughly how many connections we have in the brain. I will show later that even the Stewart Committee advised against using any communication instruments that pulsed above 16 waves per second. TETRA is of course 17.6 waves per second.

## MY SCIENTIFIC CONCERNS ABOUT THE NRPB

From a court case towards the end of 1998 Dr McKinlay was questioned in court about the use of mobile phones. Dr McKinlay is a senior scientist in the NRPB. It is known that roughly half of the NRPB's funding comes from the industries it represents, the other half of its funding comes from the Government. In court Dr McKinlay explained that data on tissue conductivity was supplied to the NRPB by Dr Camelia Gabriel of Microwave Consultants Limited. It transpired that virtually none of the NRPB documents on non-ionising radiation are peer reviewed and that Dr McKinlay himself had not authored any experimental studies. Dr McKinlay admitted he had no biological expertise. Dr Camelia Gabriel is Director of Microwave Consultants Limited and she reports to the Home Office and the Health & Safety Executive. She is also Chairman of the European Standardisation Body.

To summarise, the NRPB subcontract research on microwave radiation to Microwave Consultants Limited; namely Dr Camelia Gabriel. Dr Camelia Gabriel is also a senior consultant for Orange plc and has authored jointly with others the Orange Base Stations Health & Safety Manual (please see Appendices 14 and 15). Dr Gabriel's son, also of Microwave Consultants Limited, confirms the safety of transmitters for Orange plc in school playgrounds (Appendix 16). This dual interest between Dr Camelia Gabriel as representing the NRPB and Orange plc was picked up and reported on, on 19 April 1999, by The Observer where Sarah Ryle writes "concerns are increasing about industry's involvement in research. Some of the NRPB's conclusions have been based

on research by Dr Camelia Gabriel, a technical advisor to network operator Orange and Head of Private Consultancy, Microwave (Appendix 17).

The problem as I see it is that when it comes to asking about safety concerning TETRA or any other communication instrument there is not one single independent person to give an answer. Every single person who has a word to say about the safety of police officers is somehow in the "food chain" going back to the communications industry. The communications industry fund the NRPB and the Government who fund Microwave Consultants Limited so every single person has a financial interest in recommending the product.

## THE ABSOLUTE PARADOX

Since the early 1960s this country, America and Russia have had what is called the non-lethal weapons programme or synthetic telepathy programme. It is very well documented now that in the early 1960s in Moscow the Russians beamed continuous low level radiation (microwaves) down onto the American Embassy causing miscarriages, leukaemia's and other illnesses to the Embassy staff. Since then the non-lethal weapons programme has become very sophisticated indeed. It is used a) as a long-term low level radiation weapon to cause populations illness and b) at higher intensities to cause blindness, heart attacks or confusion. Details of all of the intensities are unknown to me but knowing that microwave radiation is accumulative, any effect can only be a matter of time. In quoting this research I refer to documents listed under Reference 15. So sophisticated is this research, and I refer to Operation Pandora Joint CIA/MI6 Operation since the 1960s, Operation Woodpecker USSR 1976, Operation HAARP still running in USA; they are able to define specific pulse frequencies to cause specific brain malfunctions or illnesses. For instance:

<u>Frequency</u>	<u>Illness Caused</u>
4.5	Paranoia
6.6	Depression/Suicide
11	Manic behaviour/Anger
25	Blindness if aimed at the head/Heart attack if aimed at the chest

Other consequences of frequencies used but not listed here are hysteria, trauma, lust, murder and cancer, and may all be induced.

The TETRA frequency is 17.6 Hz (waves per second) so as a scientist looking at this data which is well publicised I ask myself, if the illnesses moving up the frequency range are progressive and TETRA is between the frequency of 11 and 25 on this table, what will be the effect of TETRA's 17.6 waves per second on the brains of the police force? This phenomena cannot be denied by the NRPB; it is listed in their own document which I will refer to later in this paper, where on page 26 they have described how at 8 waves per second animals can be made to fall asleep and at different frequencies behave differently in various parts of their brains.

As this phenomena is written about by the NRPB for 8 waves per second I would like to know what other research they have for other frequencies in and around the TETRA range.

HAARP, which is being researched by a nun, Dr Rosalie Bertell, who is concerned about what it represents along with other scientists knows that HAARP is capable of bouncing low level continuous microwave radiation pulsed off the ionosphere to any community in the world and may cause cataracts, leukaemia, changes in blood brain chemistry, changes in blood sugar levels, blood pressure and heart rates.

The paradox of course is how can one system of pulsed microwaved radiation be used as a weapon to cause illness or death and at the same frequency and unless close range, a similar low intensity be used as a safe communications instrument. Following this research I fail to see how TETRA can possibly be safe for the officers which use it.

This argument is further reinforced by a Channel Four document (Reference 16) and I quote: "The telecoms industry has known about American research suggesting there may be brain effects from TETRA for at least a year". "The research suggests that TETRA radios may have a direct effect on the brain's bio chemistry". "The researchers found that balance changed when brain cells were exposed to pulsed radio signals".

On page 4 it is quoted "the Government was warned about the issue last year. The Stewart Report into mobile phones recommended research into pulsed signals and suggested the technology be avoided ... As a precautionary measure amplitude modulation (pulses) around 16 Hz should be avoided if possible". He continues "what the frequency of 17.6 Hz is doing is duplicating microwave weapons which you buy at arms fairs. So by holding one of these devices to their heads they are putting a small microwave weapon to their head everytime they use it". He finishes "but there is enough to warrant asking why the system is being rolled out before the proper research has been conducted into an effect which not only falls outside all the existing regulations but which the Government advises on mobile phones believes it important enough they recommend the technology not to be used and which the military authorities apparently

believe is so powerful that they can design non-lethal weapons to disrupt the minds of their targets".

In *Electromagnetic Hazard & Therapy* 2001, Volume 11, Numbers 2-4, Page 9, Simon Best says when writing about microwave crowd control weapons "after 20 years of rumours and speculation the Pentagon has finally confirmed that it has developed a device as part of its joint non-lethal weapons programme ..." He continues "in the UK many of the women protestors at Greenham Common in the 1980s experienced symptoms that they attributed to being zapped by microwave weapons from the US base".

Reported in *The Guardian*, Tuesday 8 May 2001 (Appendix 18) Stuart Millar and Stuart MacWilliam write "two independent experts on the biological effects of electromagnetic radiation have accused Ministers of using the police as guinea pigs by pressing on with the launch of the BT Airwave System in the absence of detailed research into potential health risks". They continue "last year Sir William Stewart's report on mobile phone safety concluded that systems modulating at frequencies around 16 Hz should be avoided if possible in future developments of signal coding". They conclude "low frequency electromagnetic radiation was identified as far back as the 1960s as a potential anti-personnel weapon when the superpowers began conducting experiments into non-lethal mind control devices".

Low level pulsed signals have even been tried in the oceans. It was reported (Reference 17) by Gibby Zobel that the whales and dolphins beached themselves because their delicate navigation systems were damaged by the low level pulses. This is not surprising as like us they are mammals. The comment from the Minister at the time was "it's their fault for being in that part of the ocean when they could have moved away".

Reporting in The Sunday Express, 4 February 2001, Nick Fleming writes "BT advise officers to turn off the handsets when they are near sensitive hospital, breathalyser and speed camera equipment ... Officers are also being advised to mount speed traps or breath tests only if the equipment is 35 ft from their handsets or 11 ft from radio sets in their cars". He concludes "someone using a TETRA handset will be receiving between 2 and 4 times as much power or energy as if they were using a mobile phone. The low frequency also means about double the penetration into the head".

Another document (Reference 18), Mr Stevens quoting from a US Defence document writes "if the more advanced nations of the West are strict in the enforcement of stringent exposure standards there could be unfavourable effects on industrial output and military functions". Listed in this document are all of the symptoms we now come to expect with long-term low level microwave radiation; for example "personnel exposed to microwave radiation below thermal levels experience more neurological cardio-vascular and haemodynamic disturbances than do their unexposed counterparts". Further down the document other symptoms include hypertension, changes in blood, headache,

fatigue, menstrual disorders, depression, anxiety and many of the other ailments previously listed.

## ADDING UP ALL OF THE WAVES THAT YOU ARE EXPOSED TO

An officer on duty may be exposed to his or her own handset, plus the handsets of officers around, plus the transmitter, plus anything else that happens to be on around them, i.e. vehicles. It may seem fairly easy for people to think that all you have to do is add up the radiation from each source, but in fact it can be very complicated and I would argue so complicated that scientists have yet to agree on a standard formula.

For example when measuring the magnetic part of the wave in Norwich it is known by some scientists that the maximum dose would be 0.4 units. When the arithmetic average was taken it came out at 0.46 above the danger level for the child. When the interested parties came and did their measurements they got the reading to be 0.26 units below the safety level; they calculated the geometric average. Clearly there is a difference between 0.26 and 0.46. When measurements are taken and quoted to you, you should always ask how the answer has been calculated and check the figures. Other ways of measuring waves may be time weighed average, constructive or destructive interference, the polarisation, the nearfield, the farfield, the root mean square, the peak to peak, the electric or the magnetic vectors; all of these are legitimate calculations and in my opinion could be used to make a reading look more acceptable if it was desired.

In Appendix 19 I enclose an e-mail conversation by three eminent scientists who are trying to agree on the best way to calculate multiple waves. The multiple wave

phenomena is of concern to me with regards the health of the police officers, simply because I have yet to find anybody who can say for sure the dose that each officer will be receiving. Arguably if the dose cannot be calculated therefore the health of the patients cannot be calculated.

Reporting in Engineering, February 2001 Matt Youson writes about the case where a man had a heart attack and in his journey to the hospital in an ambulance the ambulance crew using their TETRA sets, affected his heart monitoring devices which sadly resulted in the man's death. In an exclusive report in the Manchester News 11 May 2001 Dianne Bourne quoting the Head of Brain Surgery at NASA writes "the Head of Brain Surgery at NASA has even said he would not consider holding one of these to his head (with regards to TETRA). He said the net result is that the police are guinea pigs". Writing in Issue 51 of Caduceus magazine, in an article entitled 'Mobile Phones: The Pressure & Evidence Continues to Mount' by Simon Best, he writes "certainly if mobile phones had been a new drug they would never have got out of the laboratory". He continues commenting on TETRA "a 420 MHz signal producing a waveform that maximises radiation absorption for 3-6 year olds but also a pulse at 17 Hz right in the brains' beta rhythm – 17Hz is close to the peak frequency that triggers calcium e-flux in the brain which in turn affects apoptosis (programmed cell death) which can initiate cancer development. Despite this there is a complete lack of research on TETRA's possible health effects". He concludes "consider that you are talking about cumulative pulsed microwave radiation into your head, eyes and other organs possibly everyday for the rest of your life".

A Powerwatch comment dated 2 June 2001 reports in the first paragraph "as far as we can find out virtually no meaningful biological research on the effects of TETRA signals has been carried out. None of this is on humans nor is any on brain functions". In a late study published this month by The Independent entitled 'Mobile Phone Use Can Treble Risk of Brain Tumour', Charles Arthur writes that a research paper studying 1,600 people by a cancer specialist at the University of Sweden will be publishing his research paper on this data when it is finished.

In 1997 the Health Council of The Netherlands Radio Frequency Radiation Committee published their paper entitled 'Radio Frequency Electromagnetic Fields (300 Hz to 300 GHz) (this is within the TETRA range). They warn of interference to embryo development, hotspots inside the body, damage to eyes specifically infants, elderly and the sick. They also comment on interference to metallic implants and pacemakers. In Section 261 they write "the effects of electromagnetic fields occur at lower powered entities when the object is exposed to pulsed electromagnetic fields". I write this because TETRA is pulsed and most of the research which has been done has been done on continuous waves. The inference from these new research papers can only suggest that the symptoms will become more serious as pulsed radiation is arguably more aggressive.

In a recent paper (Reference 19) Dr Hyland who is also a member of the Stewart Committee and of the International Institute of Biophysics in Germany writes in Section

3 "the introduction of TETRA on the other hand gives rise to an increased level of both thermal and non-thermal concern". On page 14 Dr Hyland comments on the expression of calcium ions from brain cells and on page 15 writes a chapter on the magnetic field associated with current surges from the battery of the phone. Many people do not appreciate that batteries can produce magnetic fields that go into the body.

## THE NRPB DOCUMENT ON TETRA (Appendix 20)

The Governments' NRPB produced their own document (Reference 20) which is a report of an advisory group on non-ionising radiation and TETRA. Each page I quote from I will photocopy and place in the Appendix so that the reader may read the NRPB's research and the reader may compare my answer to that research.

On page 3 (Appendix 21) the picture shows the microwave signals labelled radio signals as a continuous not-pulsed signal. I would argue that this has been measured by the Cambridge researcher Alisdair Philips and has been shown to be pulsed leaving the transmitter going to the officer.

Page 4 (Appendix 22), Section 21 states "some radiation is also emitted from the case". It does not say which type of radiation – electric or magnetic or when the radiation is emitted, or the strength of the radiation or what part of the body will receive most of the exposure. In Section 22 "the main exposure to the body should be from the antenna and case of the hand portable". The question arises where is the rest of the exposure coming from and how much will there be? Section 24 refers to the earphone. If an earpiece is used and the smallest possible imaginable crack occurs in the earpiece radiation will have a direct path straight through the auditory canal to the brain. The officer will not even have the protection of the skull. In the rough and tumble world of a police officer where earpieces may be frequently knocked, what protection is there for the officer in checking that the earpieces do not leak?

I would recommend that earpieces should be checked with very accurate equipment for leaks at least on a weekly basis. The earpieces should be of the highest quality possible and definitely leakproof.

Page 5, Section 25 (Appendix 23) "the terminal is mounted inside the vehicle and connected to an antenna mounted on the outside". My concern is what sort of insulation is there inside the vehicle to protect the officers from the terminal inside the vehicle. If the terminal inside the vehicle is not sufficiently insulated from the officers they are effectively sitting inside a microwave oven, except for the windows.

Page 6, Section 26 (Appendix 24) shows that the useful range of a mobile terminal (car) to a transmitter is 56 km. 56 km is a fairly powerful transmitter and again I question if an officer is standing outside the vehicle or inside the vehicle, how much research has been done on the radiation levels being received by this officer?

Page 7, Section 28 (Appendix 25); this diagram shows a vehicle being used as a transmitting station to relay a message 56 km from a transmitter to 56 km to an officer. Again, I question how much insulation there is to protect the officers from the radiation if they are to be used as mobile transmitting stations?

Page 8, Section 37 (Appendix 26); this confirms that the pulses are 17.6 Hz and 35.2 Hz or waves per second. I emphasise that the Stewart Committee warned about using frequencies close to the brain above 16 Hz.

Page 9, Sections 39/40 (Appendix 27) refer to a top output in the table of 30 W and for hand terminals 3 W or 10 W for a vehicle mounted transmitter. My concern is that with ordinary mobile phone transmitters no sooner are they up when an engineer comes along and adds another section, then another section and within a few years the original transmitter is unrecognisable because of additional instruments. With TETRA when it expands to cover all of the emergency services; possibly traffic wardens, the new reserve police force, maybe even park keepers and security officers, I am wondering whether these outputs may be exceeded. In my own mind I find 3 W and 10 W outputs particularly high when in proximity to a living being. If we look at Professor Cherry's table (Appendix 27), it can be seen that in millionths of watts, the long-term exposure can lead to various ailments. On this graph I have drawn a line below which the TETRA power level applies. This is obviously an estimate because when the handset is switched on, there is a surge of power. If you are a long distance from a transmitter the power increases, or on standby the power drops down. Due to the lack of research in measuring TETRA in and around vehicles it is very difficult to place an accurate estimate on this graph at present. Suffice to say that the power on this table is in millionths of watts and Sections 39 and 40 are in watts. For the reader I have enclosed a three page guide of reported biological effects from low level radiation.

Page 10, Section 44 (Appendix 28); the table shows that the TETRA handsets are slightly more powerful than the ordinary GSM mobile phone systems. This is the basis of one of my arguments that if TETRA is pulsed, which is arguably more aggressive and

powerful than the ordinary mobile phone, the medical symptoms could arguably be more severe.

Page 14, Section 61 (Appendix 29) reads "hence with TETRA the energy is absorbed in a larger volume of tissue and so is less concentrated". Scientifically I cannot decide whether it is better to have the energy spread over a larger area or concentrated on a smaller area; I will have to discuss this with colleagues. Also in Section 61 the NRPB write "however, since the radiation from TETRA penetrates further into the head ...", that I am particularly concerned about because the most delicate parts of our brain are in its centre for maximum protection and if this is where TETRA is going to reach then I have grave concerns.

Page 15, Section 63 (Appendix 30) reads "VERY LITTLE INFORMATION EXISTS ON THE SAR'S PRODUCED BY TETRA AND PORTABLES. NO NUMERICAL MODELLING APPEARS TO HAVE BEEN CARRIED OUT". SAR means Specific Absorption Rate and refers to the heat generated inside that part of the body exposed to microwave radiation. I mentioned heat earlier with regard to heat shock proteins protecting cancer cells and to prevent damage to the DNA. I find it absolutely beyond belief that the NRPB can admit they have very little information on a system that is already being used and to say that no numerical modelling appears to have been carried out suggests to me as a scientist that no measurements have been taken to assess any medical damage which may occur to the officers. What experimentation has been done (Gabriel 2000), appears to have been carried out by Mr Gabriel of

Microwave Consultants Limited. As this research could possibly affect what may turn out to be brain tumours or spine cancers for the lady or gentlemen officers I would feel justified as a Police Federation in asking which totally independent scientists not connected in any way to the Government or communications industry peer reviewed this research paper and what were there comments?

Page 15, Section 65 (Appendix 30); this section explains that SARs could be up to 4 times larger than those in table 6 above. If the reader looks at the unit at the top of the table after SAR ( $Wkg^{-1}$ ), the reader can go to Appendix 27 'Reported Biological Effects', and the reader will observe one of the pages lists the medical symptoms expected from SAR doses. The reader will notice that for an SAR of 2 or 3 W/kg, cancer acceleration in the skin and breast tumours may be found. Coming back to the table it shows for the left ear an SAR of 2.88 but in the document below it explains that the SAR could be 4 times larger than this, i.e. you could be receiving an SAR above 8.

Page 11, Section 51 (Appendix 31) (NB: the NRPB bound document has pages 11-13 out of order and I cannot change this, and I apologise to the reader). This table shows that the power output may reach 40 W from a TETRA transmitter. My concern is that the officer will be receiving the radiation from the transmitter as well as the radiation from the handset.

Page 16, Section 66 (Appendix 32); "the main exposure to the body is expected to be at waist level from the antenna and base of the hand portable". My concern with this is the

reported cases of cancer of the spine from officers who have carried their hand portables on their belts. To my knowledge 4 deaths have occurred because of this.

"Although there could be some exposure from the earphone if RF current is induced in the cable ...". When the signal goes from the handset to the earpiece, electromagnetic waves are emitted from the cable, i.e. the cable actually becomes its own transmitter. These waves would obviously go through the neck and my concern is that they could affect the sensitive glands within the neck. Another concern, but unproven, came from a dentist who was concerned about the metal in peoples' fillings absorbing radiation and re-emitting it up into the centre of the brain where there is no protection from the skull. This is obviously a very complex research area to go into but nevertheless I feel that this dentist has a justifiable argument and one which should not be dismissed without thought.

Page 16, Section 67; "the situation is complicated by the metal body of the vehicle. It is not evident that this could be relied upon to provide shielding, since the non-conducting parts, e.g. windows of the vehicle are comparable to the wavelength of the radiation". Scientifically what this means to me is that there could be a considerable risk of electromagnetic radiation for the persons either inside or just outside of the vehicle. I find this incredible in so far as the risk is obviously appreciated by the NRPB and yet, as they stated earlier, no numerical modelling has been carried out. To me it appears that the risk in and around vehicles has been overlooked.

Page 16, Section 68; "the data in table 6 suggest that for both 3 W and 10 W vehicle mounted terminals the ICNIRP basic restrictions for the general public could be exceeded if a persons' head were within a few centimetres of a vehicle mounted transmission antenna for several minutes". The question I ask is what if the call is some big disaster emergency and the call may last longer than several minutes, or once the system is upgraded you are waiting for pictures to come through? Have calculations been done for say an accumulative 10 minute call?

NB: The Police Federation may wish to ask whether the dose levels in these tables are calculated as a geometric average or arithmetic average.

Page 16, Section 69; "at these power levels there will be regions in the immediate vicinity of the base station antenna where guidelines could be exceeded". My argument here is similar to the argument above. What if an officer has to remain through duty in the vicinity of a base station or transmitter where even the NRPB's high guidelines are exceeded or the International Commission's guidelines are exceeded? These guidelines, as shown in Appendix 1, are way above what the rest of the world recommends.

Page 18, Section 76 (Appendix 33); "no measurements appear to have been made of the exposures received inside or outside vehicles with externally mounted antennas". My simple question is, if officers are using what could be potentially dangerous

instruments, why have no measurements been taken to assess their risk? I find this beyond belief.

Page 26, Section 111 and 112 (Appendix 34). Here the NRPB agree that the phenomena of non-lethal weapons exists because they say that with a frequency of 8 waves per second into the brain, animals can be made to go to sleep, or be stimulated at higher frequencies. To me this simple statement by the NRPB verifies the non-lethal weapons programme as sound.

Page 29, Section 128 (Appendix 35); "HOWEVER THERE ARE LIMITATIONS TO THE REASSURANCE THAT THEY CAN PROVIDE. IN PARTICULAR THEY DO NOT EXCLUDE THE POSSIBILITY THAT RF RADIATION FROM CELLULAR PHONES MIGHT CARRY A RISK OF CANCER THAT BECOMES MANIFEST MANY YEARS AFTER FIRST EXPOSURE OR THAT RELATES TO INTENSE EXPOSURE OVER MANY YEARS. NOR DO THEY RULE OUT A HAZARD FROM RF RADIATION MODULATED SPECIFICALLY AT AROUND 16 Hz". Here, the NRPB are not ruling out that there may be a risk of cancer to the officers in several years time. Also there could be a risk because of TETRA's unique pulsing to the officers' brains.

Page 29, Section 129; "further research is needed using modern molecular and cellular biology techniques to assess the reliability of the positive findings and to determine the extent and significance of any effects that do occur". Scientifically to me, what the

NRPB are saying is that they need to do research to find out what effects TETRA will have on the officers.

Page 30, Section 133 (Appendix 36); "HOWEVER THEY DO NOT EXCLUDE THE POSSIBILITY OF A RISK OF CANCER THAT APPEARS ONLY AFTER MANY YEARS OF EXPOSURE, NOR OF A HAZARD FROM RF RADIATION MODULATED SPECIFICALLY AT AROUND 16 Hz". This suggests that cancer and brain damage has not been ruled out as a possibility of using TETRA. As an analogy, this seems to me like a situation where I could go to my GP and ask for some tablets and the GP can say, you can take these but there may be a risk of cancer in several years time, I don't know, or a risk of brain damage.

Page 31, Section 135 (Appendix 37); "A number of recommendations for further research are suggested by the Advisory Group". My observation is why wasn't this research was done before the system was introduced? This puts officers' health at risk unnecessarily.

"Proposals for experimental investigations of the possible biological effects of specific TETRA signals modulated at about 16Hz". Again, I suggest this should have been carried out before it was used on police officers.

"Further studies need to be carried out on effects of amplitude modulation or pulsing on neuronal activity and on signalling within and between nerve cells ... The likelihood of

epileptic seizures could be investigated ...". If the NRPB are suggesting this now, my question stands, why wasn't this research carried out before the officers began their trials with TETRA?

- Page 31, Section 135 - Section 5; "HUMAN VOLUNTEER STUDIES SHOULD BE CARRIED OUT TO MEASURE CHANGES IN COGNITIVE PERFORMANCE ARISING FROM EXPOSURE TO TETRA HANDSETS. THESE SHOULD INCLUDE EXAMINATION OF THE EFFECT OF VARYING PARAMETERS SUCH AS THE DURATION OF CALLS, THE EXTENT OF EXPOSURE, AS WELL AS SIGNAL CHARACTERISTICS".
- Page 31, Section 135 – Section 6; "THE TETRA SYSTEM IS EXPECTED TO BE DEPLOYED WIDELY FOR USE BY STAFF IN EMERGENCY SERVICES. THIS IS A RELATIVELY STABLE WORKFORCE WITH DEFINED PATTERNS OF WORK. IT WOULD BE WORTH CARRYING OUT STUDIES TO EXAMINE WORKING PRACTICES AND CONDITIONS OF EXPOSURE TO RF RADIATION FROM TETRA SYSTEMS. RECORDS OF USE SHOULD BE KEPT WHICH COULD BE OF VALUE IN ANY FUTURE EPIDEMIOLOGICAL STUDIES".  
Clearly this means that the police, although to my knowledge not volunteers, as a regular and stable workforce are absolutely ideal for a scientific study into the long-term effects of electromagnetic radiation from TETRA. The NRPB will use all of this data as an epidemiological study, as recorded in their own document.

- Page 31, Section 135 - Section 8; "ONLY LIMITED INFORMATION IS PRESENTLY AVAILABLE ON EXPOSURES FROM TETRA HAND PORTABLES. FURTHER WORK IS NEEDED TO PROVIDE MORE INFORMATION ON EXPOSURES FROM HAND PORTABLES AND FROM ANY OTHER TRANSMITTING EQUIPMENT DEPLOYED FOR USE". My simple observation to this statement is why? Why is only limited information presently available on exposures if the system is up and running? There has got to be a risk to the officers from unknown exposures.

## CONCLUSION

If you take a complete overview of this entire document, I would suggest that there is a lot of information which could suggest long-term low level exposure to microwave radiation is harmful. However, science is always about argument. I find it a very dangerous time when a scientist insists that he or she is right. Scientists that have insisted they are right (sometimes publicly) and have later to have been shown to be incorrect are those concerning thalidomide, asbestos, BSE, smoking, sheep dip, Gulf War Syndrome, GM foods, Vitamin B6, to mention just a few. So, let us assume that I am wrong and let us assume that every single scientist I have quoted in this report, which may involve thousands of years of work accumulatively, is also wrong, just for arguments sake. My argument is unchanged and my argument is simple. All I am suggesting is that the ladies and gentlemen of the police force have the opportunity to read both sides of this scientific debate with all of the literature at their disposal and they, be allowed to decide whether or not they would like to use the TETRA system. If every officer decides that they love the TETRA system so much they want to take it home to bed with them, I do not have a problem with that. All I ask is that the officers have the choice where their long-term future health could be at risk.

## RECOMMENDATIONS

- I would like to see a totally independent group of scientists, not connected with the communications industry or the NRPB, be able to represent the police force at their request.
- Should TETRA become widespread, a long-term full indemnity insurance policy should be guaranteed for the officers for any possible future long-term risks.
- That all major documents relating to TETRA safety be made available to the officers of the police force along with how the figures were calculated, i.e. which average was taken, which totally independent scientists peer reviewed the papers, the comments of those scientists and if necessary, the relative expertise of the scientist who carried out the experiments and wrote the paper.

I recommend this because when I applied to teach Advance Level Physics at College, all of my degrees are personally checked and when we go camping with College students, our mountain leadership certificates, life-saving certificates, updates to those certificates are all scrutinised by the parents. And I totally agree with this. I believe that if you are making decisions pertaining to persons' safety or health, your qualifications, background, experience should all be available for scrutiny. Also, anything that you write should be checked by totally independent persons, and their comments made available.

- My final recommendation with all of the information I have to hand is that the TETRA system be halted until further research on safety has been carried out. This research be made available to the ladies and gentlemen of the police force and not until they are satisfied with the safety of the system, should it be implemented. In other words, I am suggesting that the police have the final say in whether TETRA is introduced or not to their force. I believe the ladies and gentlemen of the police force should be credited with the intelligence they have to make decisions regarding their own safety. Further, any scientific document written for them to read should have full explanatory notes so that they can understand any complicated scientific terms.

NB: Before my lectures to the Police Federation and writing this report, I submitted my full CV for their scrutiny.

## QUESTIONS

- With all of the research written here showing dangers from electric, magnetic, pulsed microwave electromagnetic fields, why with the officers' safety at risk are we still sticking to our ridiculous safety limit, which only measures heat?
- Can more information be given to the officers on our Government's non-lethal weapons programme concerning pulses into the brain around 17.6 Hz, or stored information from other research papers?
- Can the signals from the transmitter to the officer be rechecked as they are listed in the manual as continuous waves, whereas they have been measured independently to be shown to be pulsed? This is important because pulsed radiation is arguably more aggressive than continuous.

NB: the following questions arise from the NRPB document on TETRA, Volume 12, Number 2, 2001, appended at the back of this document.

- Section 21 – How much radiation, and of which type is emitted from the case?
- Section 24 – What safeguards are in place to guarantee that the earphones are absolutely leakproof and with the rough and tumble world of the police officer, how

often are the earphones going to be checked for leaks? Who will do this, and which type of apparatus will be used?

- Section 25 – What experiments have been done to measure how the officers inside the vehicle are insulated from the transmitting device?
- Section 28 – If a police car is to be used as a relay transmitter, again, what measurements have been taken to ensure the officers are insulated from the electromagnetic waves?
- Section 37 – Why is a pulsed frequency of 17.6 Hz being used when it is known to interfere with the brains' beta rhythm and it was warned against by the Stewart Committee?
- Section 39/40 – If TETRA becomes widespread to all of the emergency services, reserve officers, traffic wardens, security officers, what is the expected output to be from handsets and the main transmitters? Transmitters generally increase their power to cope with additional calls. Will this be the case for TETRA?
- Section 61 – Has a neurosurgeon been consulted to comment on the effect of TETRA penetrating deep into the head?

- Section 63 – Why does very little information exist on the SAR produced by TETRA hand portables, why has no numerical modelling been carried out? Can this be done before TETRA is used nationally?
- Section 63 – Can all of the information relating to the experiments of measuring radiation inside the head (Gabriel 2000) be made available to the Police Federation for scrutiny, along with an independent peer review assessment from scientists, totally unconnected with the NRPB or communications industry?
- Section 65 – If the SAR's could be up to 4 times larger than those in table 6, what risk assessment has been carried out for officers receiving radiation with an SAR of over 8 W/kg? Can this information be made available to the Police Federation?
- Section 66 – With the main exposure expected to be at waist level, what research has been carried out relating this to the known deaths of officers from spine cancer from carrying transmitters on their belts? Could this research be made available to the Police Federation?
- Section 66 – Has an ear, nose and throat specialist been contacted for an opinion concerning radiation from the cable being transmitted into the glands of the neck? If not, could this be done?
- Section 67 – As vehicles cannot be relied upon to provide shielding for the officers, can further improvements to insulate the officers be recommended, then scientific

studies carried out to test this insulation and all data be made available to the Police Federation?

- Section 68 – If international guidelines could be exceeded, what risk assessment has been carried out for the officers and passers by who may be using pacemakers, insulin pumps, have metal plates in their bodies, or be epileptic? Could this risk assessment be made available to the Police Federation?

Similarly, for Section 69, concerning base station transmitters which will also exceed guidelines.

- Section 76 – Why have no measurements of exposures been made inside or outside vehicles? Could these be done and the data made available to the Police Federation along with how averages are calculated?
- Section 128 – As the possibility is not excluded that TETRA might carry a risk of cancer that becomes manifest many years after first exposure, or there may be a hazard from the pulses around 16 Hz, would it be a good idea to allow the ladies and gentlemen of the police force an opinion in the decision making processes which may concern their long-term health? Should these long-term health risks be published for the police force so that, like members of the armed forces, they may volunteer to expose themselves to possible danger?

- Section 129 – As further research is needed, should this not be done before TETRA becomes national, and can the results be made available to the Police Federation for their scrutiny?
- Section 133 – Again, the possibility of a risk of cancer after many years of exposure is commented on along with the hazard of pulsed radiation at 16 Hz. I repeat my observation that this risk assessment ought to be made available with full consultation with the officers concerned who will be using the system and that they should have the final decision concerning their future health risks. Is this a possibility?
- Section 135, Section 2 – Has a neurosurgeon been contacted to assess the risk of pulsing and its effect on the signalling mechanisms between nerve cells? Could this report please be made available to the Police Federation?
- Section 135, Section 5 – Shouldn't the human volunteers study on TETRA be carried out before its use becomes widespread?
- Section 135, Section 6 – As an epidemiological study is recommended to be carried out on the use of TETRA and its effects on "a relatively stable workforce with defined patterns of work", shouldn't the police officers be asked their permission if they are going to take part in what is a long-term medical study which

may result in a number of brain tumours, spine tumours, eye cancers, heart disorders and many other illnesses?

- Section 135, Section 8 – Why is TETRA being used by officers if "only limited information is presently available on exposures from TETRA hand portables and further work is needed to provide more information on exposures from hand portables and from any other transmitting equipment"?

## LEGAL IMPLICATIONS

Although I have legal documents in my possession I do not have the knowledge or confidence to even begin to try and explain legal words. I would recommend the Federation's solicitor contact Mr Alan Meyer who is in my opinion this country's leading authority on matters electromagnetic and all of its relevant implications. I would add I do not have shares in his firm nor do I receive "backhanders", in fact I have never met the gentleman. Mr Meyer will be able to advise on Government responsibilities, the human rights, civil rights and European Law. Mr Meyer may be contacted at:

**Abstract:** Radiation-induced organizing pneumonia (RIOP) is an inflammatory lung disease that is occasionally observed after irradiation to the breast. It is a type of secondary organizing pneumonia that is characterized by infiltrates outside the irradiated volume that are sometimes migratory. Corticosteroids work acutely, but relapse of pneumonia is often experienced. Management of RIOP should simply be symptom-oriented, and the use of corticosteroids should be limited to severe symptoms from the perspective not only of cost-effectiveness but also of cancer treatment. Once steroid therapy is started, it takes a long time to stop it due to frequent relapses. We review RIOP from the perspective of its diagnosis, epidemiology, molecular pathogenesis, and patient management.

**Keywords:** organizing pneumonia; bronchiolitis obliterans organizing pneumonia; breast cancer; corticosteroid treatment; radiation-induced organizing pneumonia

## 1. Introduction

Pneumonia is one of the most common causes of death around the world, but various pathogeneses may be responsible. It is divided into alveolar and interstitial pneumonia, and interstitial pneumonia needs further classification [1]. Organizing pneumonia (OP) is a type of interstitial pneumonia and consists of cryptogenic organizing pneumonia (COP) and secondary organizing pneumonia (SOP) [2]. Radiation-induced organizing pneumonia (RIOP), which also used to be called radiation-induced bronchiolitis obliterans organizing pneumonia (BOOP) syndrome is one type of SOP. It was first reported by Crestani et al. and Bayle et al. in 1995 [3,4]. Since the term “bronchiolitis obliterans” does not reflect the actual pathophysiology, the name BOOP was replaced by organizing pneumonia. According to this, the name radiation-induced organizing pneumonia (RIOP) is considered better [5]. Several reports of RIOP were published, and its incidence was reported to be less than 3% [5–12] (1.7% in an extensive literature review [13]) after radiotherapy involving the breast. Although RIOP is classified as SOP, no actual fatal cases have been reported so far. However, the mortality of OP is estimated to be 5% [14], and SOP is reported to have a higher mortality than COP [15,16], so physicians need to pay attention in the management of RIOP.

## 2. Diagnosis

In the report of Crestani et al., the following four criteria were introduced [17]: (1) radiation therapy to the breast within 12 months; (2) general and/or respiratory symptoms lasting for at least two weeks; (3) lung infiltrates outside the radiation port; and (4) no specific cause. However, subsequent reports contained patients who did not fulfill all of these criteria, and the nature of RIOP was gradually revealed, which requires us to reconsider them.

### 2.1. Partial Irradiation Involving the Lung Occurring Approximately within 12 Months

Since most reports were based on the original criteria, most of the RIOP cases in the literature were diagnosed within 12 months after the completion of radiotherapy. Among them, up to 90% of the reported cases were diagnosed within six months after the completion of radiotherapy [5–9,11,18–20]. However, RIOP cases after more than 12 months were also reported; Arbetter et al. reported one case after 17 months, who was diagnosed by resection of an asymptomatic lung nodule [19]; Kubo reported a case after 23 months whose diagnosis was confirmed by bronchoscopy and whose onset was presumed to be delayed by immunosuppressive agents prescribed for coincident rheumatoid arthritis [9].

RIOP is not specific to irradiation of the breast or to women. Although reports are limited, RIOP has also been reported in lung cancer and thymoma patients, including male patients [21–25]. This fact supports the idea that the pathogenesis of RIOP is not related to breast cancer or sex, but to partial irradiation involving the lung. In addition, not only the conventional irradiation technique, which takes more than one month, but also ablative radiotherapy, which is completed within one or two weeks, can cause RIOP. Murai et al. and Ochiai et al. reported RIOP after stereotactic body radiotherapy (SBRT) for lung tumors [26,27]. Interestingly, the onset is longer after SBRT than after conventional radiotherapy; it has been reported to be at least 6 months after completion of radiotherapy and sometimes more than 12 months, in contrast to the short duration of treatment.

### 2.2. Lung Infiltrates Outside the High Irradiation Dose Area

After the completion of radiotherapy involving the lung, radiographic pulmonary changes on computed tomography (CT) are reported in 78% of cases at 3–9 months after radiotherapy and are thus common [28]. In the management of breast cancer patients, the volume of these changes is usually limited and seldom causes symptoms in this range. RIOP is noticed by the spreading of infiltrate outside the irradiated volume [3,4]. Chest radiographs show air-space opacities or diffuse infiltrative opacities, which are often detectable without CT scans. On CT scan images, peripheral air-space opacities with air bronchograms and ground-glass opacities are common, and multiple alveolar opacities on imaging represent the most frequent and typical imaging features of OP [29]. Migratory infiltrates are another feature of RIOP [4,5] and can be observed until corticosteroid therapy is initiated [17]. Ogo et al. classified the infiltrative pattern into four types: Type A, peripheral area in the radiation field and a continuous opacity that represents consolidation with or without an air-bronchogram, ground-glass attenuation, and/or nodular opacity; Type B, peripheral area in the radiation field and continuous alveolar infiltration in the zone of the middle lung; Type C, peripheral area in the radiation field and isolated consolidation on the back side of the radiation field; and Type D, peripheral area in the radiation field and consolidation or ground-glass attenuation (or both) in the contralateral side [8]. Among these patterns, Type A was the most common (65%), and multiple types were observed in 43% of patients. The clinical course of lung infiltrates was also classified into 3 types: Type 1, the ipsilateral side; Type 2, progressing on the ipsilateral side; and Type 3, moving from the ipsilateral side to the contralateral side [8]. Type 2 (13%) and Type 3 (22%) would correspond to migratory lesions in other reports [4], but their incidence varies from 17% to 100% [5,7,17,19,20].

### 2.3. No Other Specific Cause

Organizing pneumonia is known to occur from several triggers. The most important cause to be distinguished is infection, since subsequent corticosteroid treatment might worsen the condition. Bacterial pneumonia sometimes resembles OP on radiographic examination. Microbial culture of sputum or bronchoalveolar lavage (BAL) fluid would be helpful in ruling out bacterial infection. When BAL fluid is available, it shows an increase in lymphocytes, mast cells, CD3 cells, and CD8 cells, and a decrease in CD4 cells and the CD4/CD8 ratio [30], and this would support the diagnosis of RIOP.

Cottin et al. reported that chronic eosinophilic pneumonia (CEP) occurred after radiotherapy to the breast [31]. Interestingly, the clinical features of CEP after radiotherapy were almost the same as those of RIOP: CEP was observed 1–10 months after completion of radiotherapy; the migratory lung infiltrate was also similar to that of RIOP; and corticosteroids worked well. Considering these similarities, patients with CEP after radiotherapy might have been diagnosed as RIOP. Since all patients had a history of asthma or atopy [31], patients with allergy seemed to be predisposed to CEP. Eosinophilia may be a key finding to discriminate it from RIOP, and an increased number of eosinophils in the BAL fluid may support the diagnosis. However, considering that corticosteroid works effectively, as in RIOP, as mentioned above, definite discrimination of these two would not be critical in managing patients.

General and/or respiratory symptoms lasting for at least two weeks were another diagnostic criterion. Clinical manifestations include fever, nonproductive cough, dyspnea, malaise, fatigue, chest pain, and weight loss [8,13,17]. However, several reports included asymptomatic patients [5,10,19] who manifested similar radiographic features or histopathologic observations. RIOP has gradually gained attention, and the diagnosis of RIOP can often be made within two weeks. Despite the impressive lung imaging findings, symptoms are not always serious and can be relieved by antitussives or non-steroidal anti-inflammatory drugs within two weeks. Indeed, the symptoms are important when considering the management of RIOP, but the diagnosis of the massive lung infiltrates does not require the presence of symptoms.

Although these criteria describe the features of RIOP, RIOP is ultimately COP with a history of irradiation. In the current criteria, RIOP includes genuine COP after radiotherapy by chance. It is not very important to discriminate them because their general management is similar [14], but we should carefully diagnose RIOP as much as COP if the patient's general condition is unfavorable. If the treatment response is poor, or the clinical course or chest imaging findings are not typical for RIOP, a video-assisted thoracoscopic lung biopsy should be considered to confirm a definitive diagnosis of OP [13].

### 3. Pathogenesis and Epidemiology

OP is known as an inflammatory response to acute lung injuries. Development of OP has been reported to go through three stages [32]. The first stage is the injury phase: local epithelial injury induces the death of pneumocytes and the formation of gaps in the basal lamina [29,33]. The second stage is the proliferating phase: fibroblasts and inflammatory cells, such as lymphocytes, neutrophils, and eosinophils, infiltrate the alveolar interstitium and form fibroinflammatory buds. Activated fibroblasts proliferate, differentiate into myofibroblasts, and form cell clusters within the distal airspaces. The third phase is the mature phase: mature fibrotic buds occupy the lumens of bronchioles, alveolar ducts, and adjacent peribronchiolar alveoli [29,33,34]. Recently, transgenic mice overexpressing human C-C motif chemokine ligand 2 (hCCL2) under control of the surfactant protein C promoter in type II alveolar epithelial cells were reported to work as an animal model for OP [35]. This animal model showed pathogenomic, molecular, and morphological features of human OP and exhibited a similar inflammatory profile, which is a key feature in interpreting human OP. In this model, the generation of OP was completed in 7 days. As for RIOP, the epithelial injury would be irradiation-induced. The most lethal effect in the irradiated cells is DNA double-strand breaks, and the cells in the thorax develop apoptosis if they fail to recover from the DNA damage. Interestingly,

cell death after irradiation can start within 10 h [36], but the onset of RIOP is delayed by about 6 months after the completion of radiotherapy. Furthermore, RIOP after SBRT, which delivers a higher dose to the cancer and circumscribed lung tissue than does conventional radiotherapy to the breast, is delayed even more [26,27]. In COP cases, the time to onset is known to be less than three months [32]. Additional insights are necessary to understand what is going on during this long gap. When we look into other secondary OPs, drug-related OP can occur months to years after drug administration [14]. The first step to treating drug-related OP is to discontinue the suspected agents. In contrast, most cases of RIOP occur after completion of radiotherapy. The trigger had already been disseminated and already finished several months before the onset of RIOP.

As another explanation of the pathogenesis of RIOP, mutations in the ATM (ataxia telangiectasia mutated) gene were proposed [37]. The ATM gene is a key molecule to repair DNA double-strand breaks whose mutation brings hypersensitivity to irradiation [38] and predisposes to cancer [39]. A patient with RIOP who was also diagnosed to have monoallelic germline ATM mutation was reported [37]. Interestingly, the frequency of ATM mutation carriers among women affected with breast cancer has been estimated to be 2.04% [40], similar to that with RIOP. This might be the explanation of the long time between radiotherapy and RIOP. Further epidemiologic evidence and analysis of causal molecular background are expected.

Several risk factors have been identified for RIOP: age [11,41], irradiated lung volume [9], concurrent endocrinology [11], and smoking [13,41]. Kubo et al. reported that a central lung distance of more than 1.8 cm, which means the extent of irradiated lung volume is a risk for RIOP [9]. Considering the pathogenesis, it is reasonable that some extent of irradiated lung volume is required to prime the consequent immune-responses that lead to RIOP. However, a central lung distance of below 1.8 cm is too strict a limit to require for every breast-irradiation treatment. Since the incidence of RIOP is below 3.0% [13] and its prognosis is generally good, the radiation field should not be minimized too much for fear of RIOP.

As another risk factor for RIOP, concurrent endocrine therapy is controversial. Katayama et al. reported that endocrine therapy, including both tamoxifen and anastrozole, was a risk factor [11], but Kubo did not find it to be significant [9]. Tamoxifen is known to induce transforming growth factor- $\beta$  (TGF- $\beta$ ) secretion, which causes lung fibrosis [42,43]. Epidemiologic observations reported that tamoxifen was a risk for lung fibrosis on multivariate analysis [44]. However, epidemiologic data showed that concurrent usage of tamoxifen does not increase the incidence of pneumonitis compared to the sequential usage of tamoxifen [45,46]. Today, the concurrent usage of tamoxifen is considered tolerable. As for aromatase inhibitors, a randomized controlled trial showed that the incidence of lung fibrosis was similar between concurrent and sequential administration of aromatase inhibitors [47]. Although these data did not refer to RIOP as a specific disorder, concurrent endocrine treatment is considered tolerable. Because of the rarity of RIOP, it is difficult to assess the actual risk of concurrent endocrine therapy, but it seems that endocrine therapy need not be interrupted at the initiation of radiotherapy.

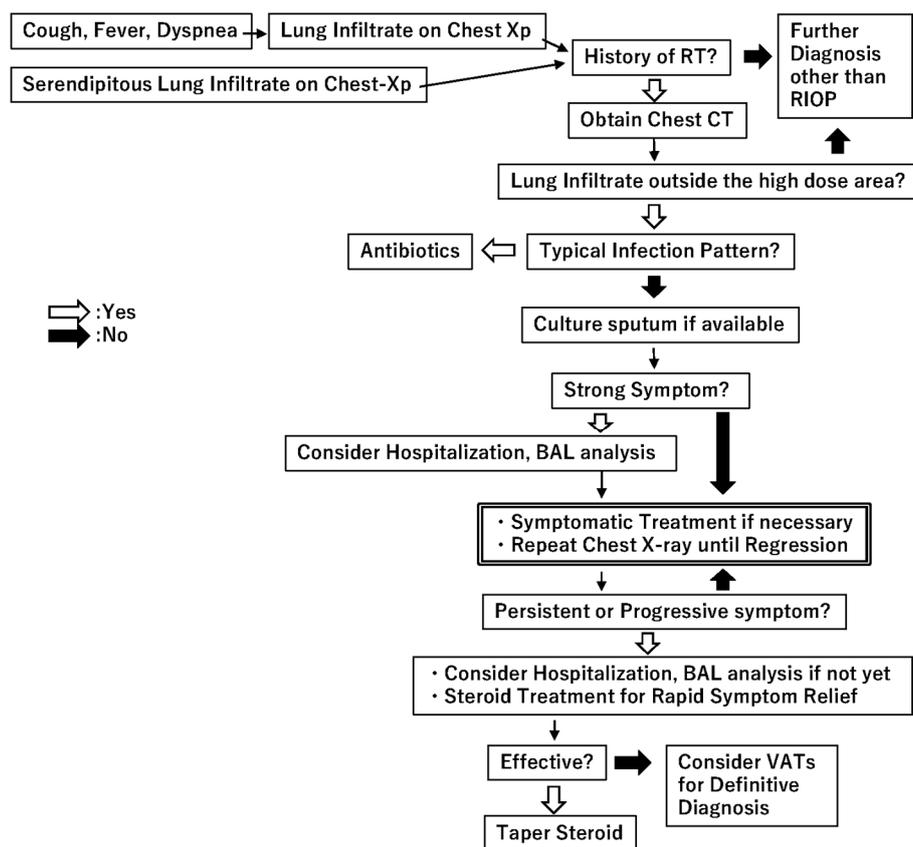

#### 4. Patient Management

RIOP is generally a complication with a good prognosis due to the acute effectiveness of corticosteroids [17]. However, relapse of RIOP is common when steroids are administered [13,17]. Okada et al. reported that relapse after steroid therapy was associated with higher C-reactive protein levels at RIOP diagnosis [12]. We previously reported that steroid-treated patients relapsed at a significantly higher rate [5]. Since no new lesion was recognized during steroid administration, we assumed that steroid therapy effectively suppresses the development of new lesions (migratory infiltrate). However, this suppressive effect seemed to decline with steroid tapering; therefore, new lesions (relapses) appeared particularly in patients in the steroid group. We hypothesized two reasons: steroids can postpone the development of new lesions by suppressing tissue responses to inflammation; and they can cause the relapse of tissue-damaging responses.

We also showed that patients in the steroid group took less than half a month to achieve symptom relief after the administration of steroids. Other reports also indicate that steroid therapy has a strong role in the rapid relief of initial RIOP symptoms [6,17]. In contrast, some patients in the nonsteroid group experienced persistent symptoms for up to three months [5]. Since nonsteroidal treatment of RIOP was reported to result in almost normal lung function without severe sequelae [5,10], steroids can be saved as a last resort in managing RIOP. If RIOP is relieved without steroid therapy, the overall time to become free of symptoms, steroids, and other medications would be shorter than with steroid treatment [5]. Adverse effects of systemic steroid therapy include infection, adrenal insufficiency, osteoporosis, peptic ulcer disease, cataract formation, dermal thinning, hypertension, diabetes, psychosis, and hyperadrenocorticism [48], and additional management is necessary once steroid is initiated. Steroid is routinely used in several situations during cancer treatment, such as controlling nausea and vomiting and improving symptoms caused by advanced disease [49]. However, patients who undergo chemotherapy are predisposed to lung infections [50], and steroid therapy shares this risk. In addition, use of corticosteroids in patients with solid tumors could induce resistance to treatment in cancer cells in some patients [49,51,52]. Thus, nonsteroidal treatment is favored in terms not only of short treatment time, requiring less care and medicine, and therefore cost-effectiveness, but also of treatment effectiveness for cancer.

RIOP is often noticed during the follow-up after completion of radiotherapy. RIOP patients may come to clinics with flu-like symptoms or massive lung infiltrates. For the physicians who are not engaged in their cancer treatment, getting the history of radiotherapy is the first step to diagnosing RIOP. The next step is to evaluate the chest X-ray. As for breast cancer patients, lung infiltrates of RIOP are obvious, in contrast to radiation pneumonitis. If the chest X-ray is abnormal, CT is necessary. These steps are similar to common pneumonias. If there is a history of radiotherapy within one year or more, and infiltrates outside the high-dose irradiated area are confirmed, the diagnosis of RIOP takes just one more step, but it is the most difficult one. On the radiographic appearance, if typical imaging features of OP are seen, most experienced clinicians may make the diagnosis [29]. COP had the highest rate of correct diagnosis among the interstitial pneumonias, in 79% of cases [53], suggesting that the CT imaging features are characteristic. However, it is not always easy to rule out infection. Sputum culture is recommended if available. Empiric antibiotic therapy is permitted for ambiguous cases because it does no harm to RIOP, but it makes the diagnosis unclear. BAL is indicated in all cases where COP is suspected [29]. Since RIOP includes various general conditions, patients with no or mild symptoms should undergo repeated chest imaging instead of BAL [13]. Patients with severe symptoms and/or considerable steroid therapy will benefit from BAL fluid analysis.

Treatment of RIOP should simply be symptom-oriented (Figure 1); no medication is necessary for asymptomatic patients, and antitussives and non-steroidal anti-inflammatory drugs can be prescribed for patients with cough and/or fever. If the patient develops shortness of breath, evaluation of hypoxemia is necessary, and hospitalization should be considered depending on the degree. Steroid treatment can be used whenever rapid symptom relief is required, but it should be restricted to patients who have already undergone BAL fluid analysis and the diagnosis of RIOP is supported. If steroid treatment response is poor, or the clinical course or chest imaging findings are not typical for RIOP, a video-assisted thoracoscopic lung biopsy should be considered to confirm a definitive diagnosis of OP [13]. Relapse of RIOP is common once tapering of steroid therapy begins. The optimal tapering schedule to avoid RIOP relapse is not yet known.

**Figure 1.** Diagnostic and treatment decision tree of radiation-induced organizing pneumonia. Abbreviations: RT: Radiotherapy; RIOP: radiation-induced organizing pneumonia; CT: computed tomography; BAL: bronchoalveolar lavage; VATs: video-assisted thoracoscopic lung biopsy.

### 5. Conclusions

In summary, RIOP is an OP observed after radiotherapy involving a limited volume of lung. It is relatively rare, but its prognosis is good. Steroid treatment works well, but is related to relapses. Patient management should be symptom-oriented, and use of steroid should be limited to those who require rapid symptom relief.

**Conflicts of Interest:** The authors declare no conflict of interest.

### Abbreviations

RIOP	Radiation-induced organizing pneumonia
OP	Organizing pneumonia
COP	Cryptogenic organizing pneumonia
SOP	Secondary organizing pneumonia
BOOP	Bronchiolitis obliterans organizing pneumonia
SBRT	Stereotactic body radiotherapy
CT	Computed tomography
BAL	Bronchoalveolar lavage
CEP	Chronic eosinophilic pneumonia
ATM	Ataxia telangiectasia mutated
TGF-β	Transforming growth factor-β

# Radio Frequency Technology damages Plant DNA in 48hrs and is carcinogenic, new research reveals

By [Sara Vincent](#)

2017-02-21 03:29

Scientists revealed in a new [study](#), the damaging effects of [Radio Frequency](#) exposure through the use of cell phones and laptops. In this experiment, researchers exposed 150 healthy dry seeds of chickpea, which were distributed in two petri plates, and each plate was placed at distances of 1 inch to cell phone and laptop for 24 and 48 h. This simple experiment revealed that all radio frequency exposure inhibits seed germination percentage.

A decrease was observed in [mitotic index \(M.I\)](#) and increase in [abnormality index \(A.I\)](#) with the increase in exposure duration and frequency in (Hz).

Cell phone Radio frequency at 900MHz had less inhibitory effect in the germination process, than the laptop at 3.31 GHz. Nevertheless, the damage to the germination process of the chickpea seed was evident, with a negative effect of 17% germination only. The researchers suggested that in order to avoid reported DNA damages, cell phones should always be used either for short duration or with hands free for long duration and they should not be kept in pockets or near body. Laptops should not be used unnecessarily for enjoyment purpose. It must be placed on desk top rather lap to minimize their exposure to the human body.

Another revealing finding was the damage that Radio Frequency does on the DNA of the plant, as cell membrane degradation was observed. There was also maximum nuclear membrane damage and [ghost cells](#), which is a clear indication that such Radio Frequency induces the formation of cancerigenous cells.

The effects of Radio Frequency in humans and animals are well documented. Recently an [in vitro study](#), evaluated the induction of DNA and chromosomal damage in human blood leukocytes and lymphocytes by cells phone signals of 837 MHz and 1909.8 MHz. This research demonstrates that, under extended exposure conditions, Radio Frequency signals at an average Specific [Absorption Rate](#) of at least 5.0 W/kg are capable of inducing chromosomal damage in human lymphocytes.

[An analysis](#) of 100 peer-reviewed studies about the oxidative effects of low-intensity (RFR) Radio Frequency Radiation, revealed that 93 studies confirmed that RFR induces oxidative effects in biological systems. The conclusion was low- intensity RFR is in fact expressive oxidative agent for living cells.

According to the American Cancer Society "If RF radiation is absorbed in large enough amounts by materials containing water, such as food, fluids, and body tissues, it can produce heat. This can lead to burns and tissue damage."

**What are the technologies that emit Radio Frequency?**

There are many ways you can be exposed to man made radiation. The most common are through: microwaving food, television and radio signals, wi - fi and blue tooth, cordless phones, cell-phones and cell phone towers, laptops, satellite phones, 2-way radios, Radar, Millimeter wave scanners, microchip implants and more.

### **The recent applications of RFID technology and moving forward**

At the fast pace technology is developing, and the way in which society's infra - structure seems to be leaning towards a dependence in technology to operate. There are many ideas being put forward by the scientific community. Some of these ideas are bellow:

- 1) implantable RFID device to track the elderly or [brain implant device for patients with Alzheimers](#)
- 2) [implantable drug to deliver medicine](#)
- 3) Some are using to [buy and sell](#) and identify themselves

## KEYWORDS

Radio frequency radiation;  
Genotoxicity;  
Carcinogenicity;  
Chromosomal aberrations

**Abstract** Present study was under taken to predict the possible DNA damages (genotoxicity) and carcinogenicity caused by radiofrequency radiations (RF) to living tissue. Dry seeds of chickpea were treated with GSM cell phone (900 MHz) and laptop (3.31 GHz) as RF source for 24 and 48 h. Untreated seeds were used as (0 h) negative control and Gamma rays (250 Gray) as positive control. Plant chromosomal aberration assay was used as genotoxicity marker. All the treatment of RF inhibits seed germination percentage. 48 h laptop treatment has the most negative effect as compared to untreated control. A decrease was observed in mitotic index (M.I) and increase in abnormality index (A.I) with the increase in exposure duration and frequency in (Hz). Cell membrane damages were also observed only in 48 h exposure of cell phone and laptop (RF). Maximum nuclear membrane damages and ghost cells were again recorded in 48 h exposure of cell phone and laptop. The radiofrequency radiations (900 MHz and 3.31 GHz) are only genotoxic as they induce micronuclei, bi-nuclei, multi-nuclei and scattered nuclei but could be carcinogenic as 48 h incubation of RF induced fragmentation and ghost cells. Therefore cell phones and laptop should not be used unnecessarily to avoid possible genotoxic and carcinogenic effects.

## 1. Introduction

Electromagnetic radiation (EMR) can be classified into two types: Ionizing radiation and Non-ionizing radiation. Non-ionizing radiation refers to any type of electromagnetic radiation that doesn't carry enough energy per quantum to ionize atoms or molecules. ([www.wikipedia.com](http://www.wikipedia.com)). Non-ionizing radiation includes Ultra Violet (UV), Microwave and

radiofrequency radiation. Probably the most important use of radiofrequency (RF) energy is in providing telecommunication services. Radio and television broadcasting, cellular telephones, laptops, radio communication for police and fire departments, amateur radio, microwave point-to-point links, and satellite communication. Besides being so useful these radiofrequency radiations have many biological effects on living tissues. Recent studies link exposure to health problem that includes lower sperm counts (Avendano et al., 2012), memory loss (Koivisto et al., 2000; Cech et al., 2008), sleep disruption (Loughran et al., 2005), decreased immune function, dizziness, headaches, higher blood pressure and reduced DNA repair capacity (Braune et al., 1998; Trimmel and Bachmann, 2004; James, 2008; Tyagi et al., 2011).

Genotoxicity is the property possessed by some substances that make them harmful to the genetic information contained in organism. Physical and chemical agents having ability to damage deoxyribonucleic acid (DNA) are called genotoxic (Galloway, 1994). Segment breaks in DNA molecule are called chromosomal aberrations. These are only visible in cell divisions. Mitosis is widely used for the study of genotoxic compounds using chromosomal aberration assay.

The damage of DNA or genotoxicity is an important consideration, because it has a potential to cause irreversible changes to genes and even cancer (M-boh, 2003). Mainly *Allium cepa* chromosomal aberration assay was used as bioassay plant since 1938 (Levan, 1938) for investigating environmental pollution factors, toxicity of chemical compounds, and evaluating potential anticancer properties (Bakare et al., 2000; Majewska et al., 2003; Babatunde and Bakare, 2006; Kuraš et al., 2007) but now researchers are also using *Vicia Faba*, *Vigna mungo* and *Cicer arietinum* L. (Rank and Nielsen, 1993; Unyaya et al., 2006; Chahal et al., 2012; Siddiqui, 2012; Arain and Maqbool, 2011).

Non-thermal level of radiofrequency exposure has genotoxic effects in the form of chromosomal instability, altered gene expression, gene mutation, DNA fragmentation and DNA structure break. Some other genotoxic effects are documented to occur on neurons, blood lymphocytes, sperms, Red Blood Cell (RBC), epithelial cells, hematopoietic tissues, lung cells and bone marrow (Mashevich et al., 2003). Microwave frequencies ranging between 375 and 36.64 GHz can increase cell membrane permeability to staining dye used to study cytological aspects in living human buccal epithelium cells (Shckorbatov et al., 2002, 2011). EMFs can change secondary structure of cell membrane proteins by causing reversible changes to peptide linkage (Ikehara et al., 2003). EMFs have

ability to influence usual oxidation and reduction inside a cell (Kovacic and Somanath, 2010) and their long time exposure can alter cellular balance resulting in oxidative stress (Scaiano et al., 1994; Repacholi and Greenebaum, 1999; Jajte et al., 2002; Akdag et al., 2007; Simkó, 2007).

Chromosomal aberrations have been used as a measure of reproductive success in plants for many years but now they are also used as measure of co-relation between reduction in fertility, mutagenesis and carcinogenesis (Kostoff, 1934). Cytogenetic abnormalities are a characteristic attribute of cancer cells. To date, chromosome aberrations have been found in all major tumor types of cancer. Translocations and double stranded breaks (deletions) are more commonly found chromosomal aberration in tumor cells (Hindus and Weinberg, 1994; Knudson, 2001; Keen-Kim et al., 2008; Stratton et al., 2009).

Chromosomal aberrations in plants serve as excellent monitoring system for the detection of environmental chemicals that may pose a genetic hazard. The plant systems have proven most useful for this purpose (Nilan and Vig, 1976; Gustavino et al., 2015). Use of *C. arietinum* L. as assay plant is reported by many workers (Arain and Maqbool, 2011; Qureshi et al., 2014; Parihar and Mawal, 2015).

The usage of GSM cell phone and laptop has increased many folds over the last few years. It is therefore a matter of great concern. Prolonged use of GSM cell phones due to free call packages and use of laptops on our laps during travel and leisure expose humans to more intense radiation. More portable devices with RF are to be expected in future that may be operated near the body. This will further increase the exposure of people to high frequency electromagnetic fields. Many researchers worked on effects of far field RF on plants but no study is carried out on near field effects. Therefore present study is first attempt to predict possible radiofrequency radiation induced genotoxic and carcinogenic effects.

## 2. Material and methods

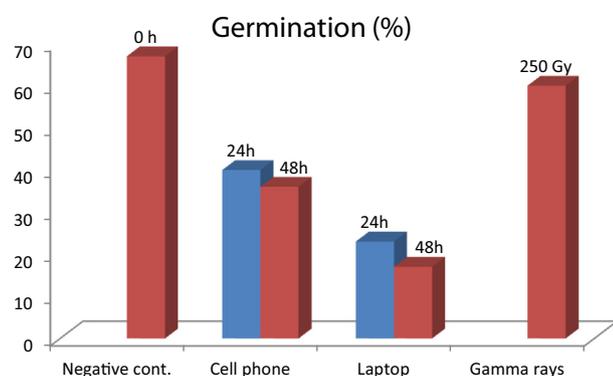

Plant chromosomal aberration assay was used as genotoxicity marker as suggested by (Grant, 1978). Kabuli chickpea genotype NCS 0530 was obtained from National Agriculture Research Center, Islamabad (NARC) was used in assay.

### 2.1. RF source and treatment plan

In order to predict possible cytotoxic and genotoxic effects by near field RF, Nokia GSM set, model N0# X2-00 (900 MHz)

Figure 1 RF treatment of chickpea seeds.

**Figure 2** Effect of radiofrequency radiations on germination of chickpea (h = hours; Gy = Gray).

and HP laptop, model N0# 430 core i5 (3.31 GHz) were used as RF sources. 150 healthy dry seeds of chickpea were distributed in two petri plates. Each petri plate was placed at distances of 1 inch to cell phone and laptop for 24 and 48 h (Fig. 1). Untreated seeds were used as (0 h) negative control and Gamma rays 250 (Gray) as positive control.

## 2.2. Seed germination

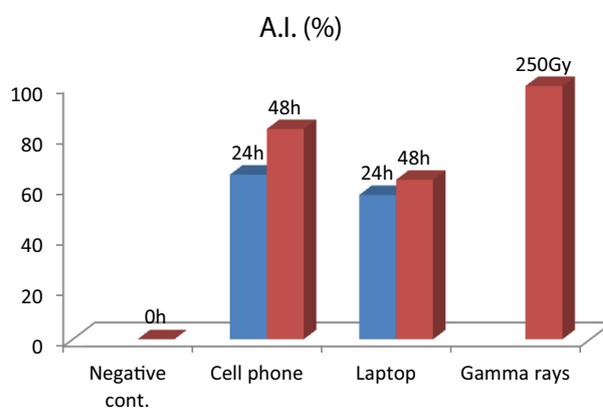

Seeds were soaked in distilled water for 2 h before sowing in the sand pots. The number of roots recovered was expressed in percentage.

## 2.3. Root fixation and slide preparation

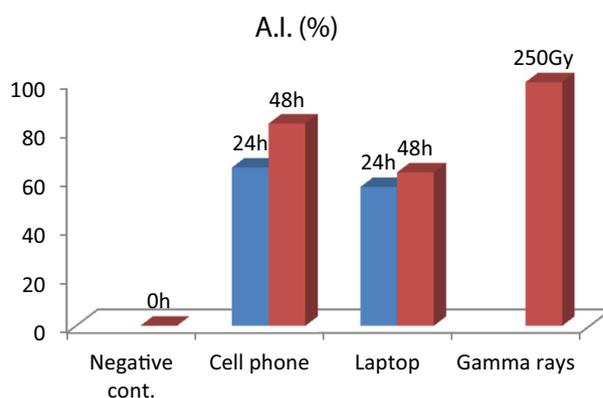

2 cm root samples were collected and fixed in Carnoy solution (3:1 alcohol and glaciated acetic acid) for 24 h. Roots were then transferred to 70% alcohol until used. Root tips were spread using the squash technique (Dille and King, 1983; Dille et al., 1986) and stained with 2% Acetocarmine (2% in 45% glacial acetic acid).

## 2.4. Microscopy of mitotic slide

Slides were studied and photographed with Olympus 1X51 Microscope at 100 × magnification. Five slides per treatment were used to score number of cells for each chromosomal aberration (DNA damages).

**Figure 3** Effect of radiofrequency radiations on abnormality index (%) (h = hours; Gy = Gray).

**Figure 4** Effect of radiofrequency radiations on mitotic index (%) (h = hours; Gy = Gray).

## 2.5. Data analysis

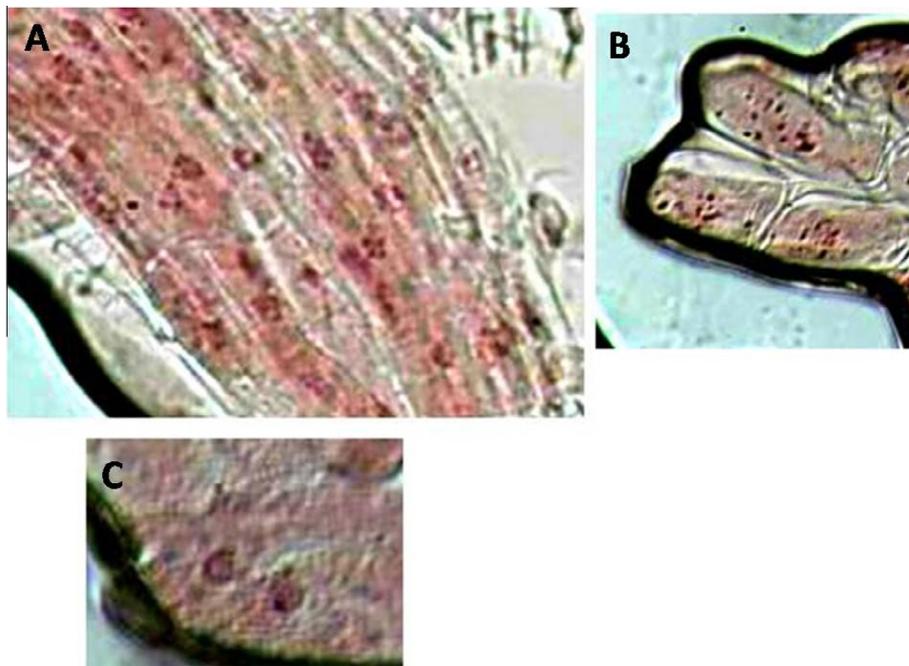

### 2.5.1. Mitotic Index (M.I.)

Mitotic index was calculated as described by Racuciu (2009). It was calculated by the following formula:

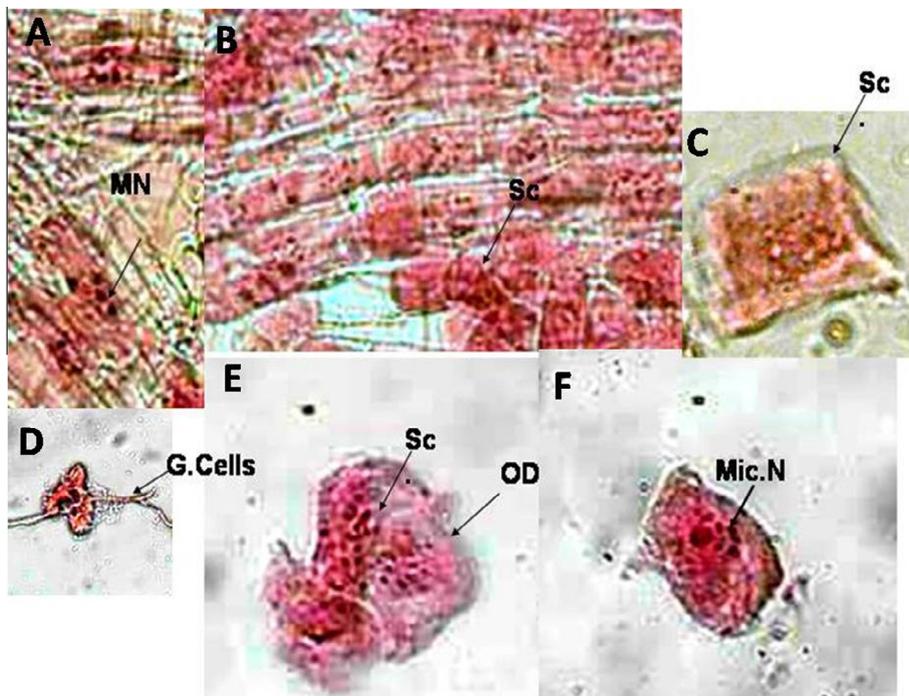

$$\text{M.I.} = \frac{\text{Total dividing cells}}{\text{Total cells analyzed}} \times 100$$

**Table 1** Effect of radiofrequency on abnormality index (A.I.) and mitotic index (M.I.) in chickpea root tip cells.

Treatments	Hours	Number of cells				No. of abnormal cells in stages of mitosis			A.I. (%)	M.I. (%)
		Dividing	Abnormal	Normal	Non-dividing	Metaphase	Anaphase	Telophase		
Negative control	0	500	0	500	0	75	0	141	0	100
Cell phone (900 MHz)	24	419	276	143	81	42	143	92	65	84
	48	316	263	56	184	27	117	116	83	63
Laptop (3.31 GHz)	24	450	260	140	50	169	76	0	57	90
	48	397	318	78	103	243	75	0	63	79
Positive control	250	211	211	0	189	128	37	0	100	52
Gamma ray (Gy)										

**Figure 5** Negative control showing normal mitotic cells (A and B = pro-metaphase; C = prophase).

**Figure 6** Positive control Gamma rays (250 Gy) induced chromosomal aberrations (A) Multinuclei (MN); (B, C and E) sticky metaphase (Sc) and oxidative cell membrane damage (OD); (D) ghost cell with pilus; (F) micro-nuclei (Mic. N).

### 2.5.2. Abnormal index (A.I.)

Abnormal index was calculated by the method of (Racuciu, 2009) according to the following formula.

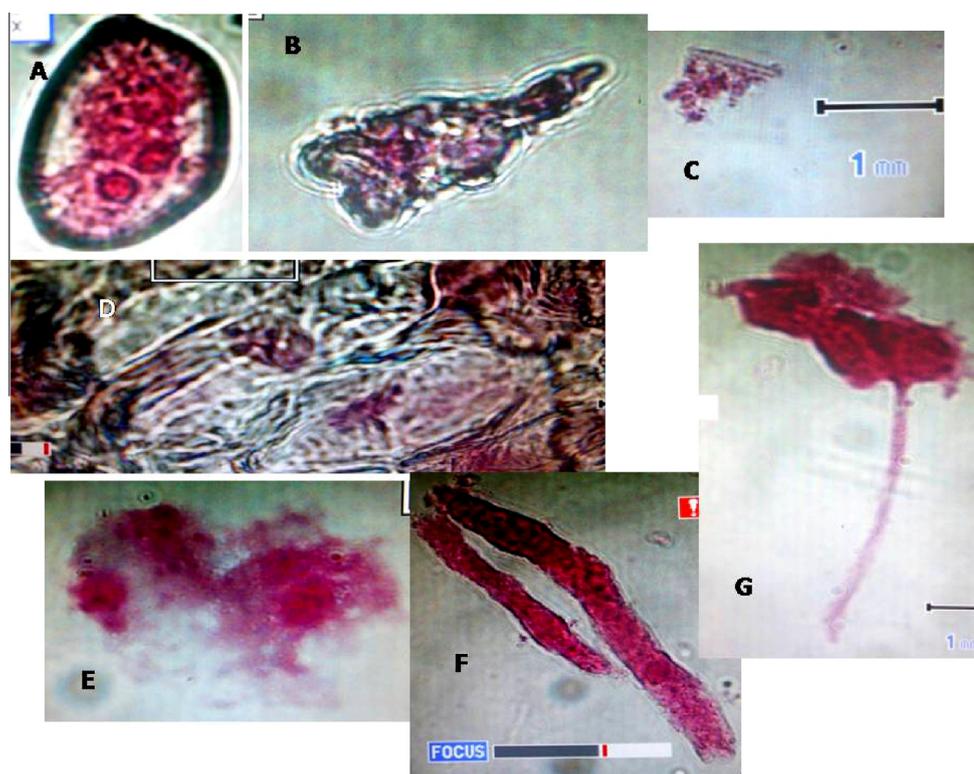

$$A.I. = \frac{\text{Total abnormal dividing cells}}{\text{Total dividing cells}} \times 100$$

### 3. Results

The effect of radiofrequency radiations on the germination percentage of chickpea is presented in (Fig. 2). All the treatment of RF inhibits seed germination percentage. Cell phone RF (900 MHz) has less inhibitory effect than laptop

**Table 2** Types of chromosomal aberrations induced by radiofrequency radiations.

Mitosis stage	S. No	Abnormalities	Control (%)		Cell phone (900 MHz)		Laptop (3.31 GHz)	
			Negative control (0 H)	Positive control Gamma rays (250 Gy)	24 (H)	48 (H)	24 (H)	48 (H)
Metaphase	1	Sticky metaphase	0	31	0	27	33	0
	2	Translocations	0	0	42	0	0	0
	3	Distributed metaphase	0	15	0	0	0	0
Anaphase	4	Scattered nuclei	0	34	118	0	130	60
	5	Laggard	0	43	0	2	0	0
Interphase	6	Fragmentation	0	36	25	117	39	183
	7	Micronuclei	0	0	25	43	16	25
	8	Multinuclei	0	37	0	0	33	0
	9	Dinuclei	0	0	67	73	27	50

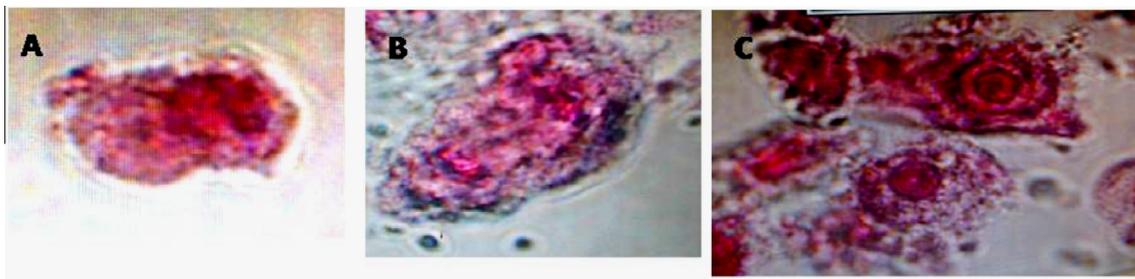

**Figure 7** Cell phone 24 h treatment induced chromosomal aberrations (Showing (A and E) Di-nuclei; (D) sticky metaphase; (B and C) ghost cells; (G) ghost cell with proliferation pilus); (F) fragmentation.

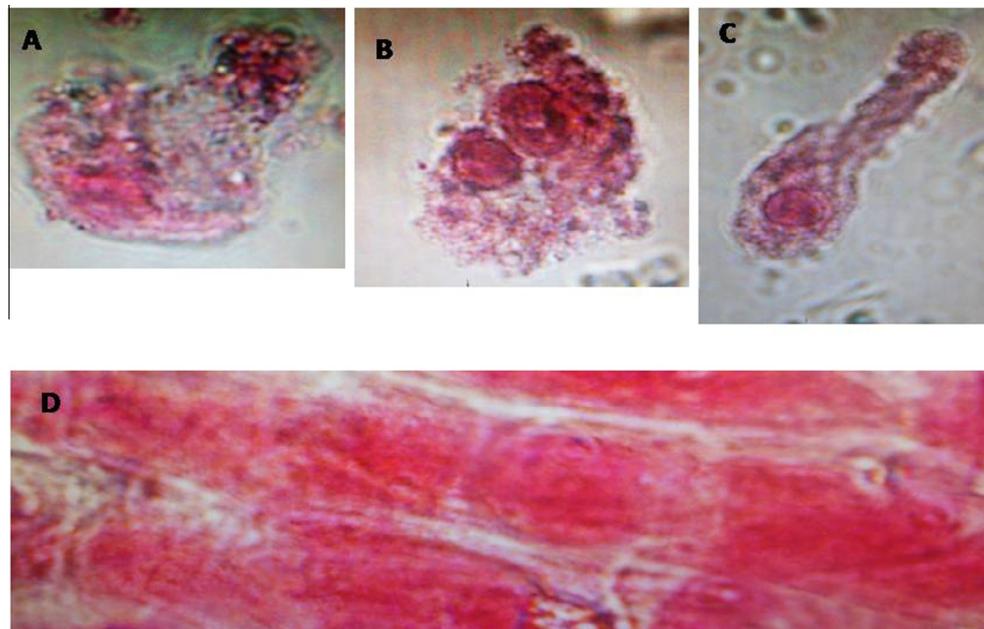

(3.31 GHz). 48 h laptop exposure has the most negative effect with 17% germination as compared to negative control with 67% germination. Present results are consistent with Racuciu et al. (2015) and Kumar et al. (2015) who reported electromagnetic radiation of mobile phone induced root and coleoptiles growth inhibition in *Zea mays* and Cammaerts and Johansson (2015) in *Lepidium sativum*. Possible reasons for reduced growth observed by these researchers were retarded in chlorophyll pigments and nucleic acid content, interference in starch and sucrose metabolism and lack of imbibitions by germinal cells. Parihar and Mawal (2015) working with

radiations emitted by 2G and 3G mobile phones also observed growth retardation and diminished fresh and dry weight of roots in pulses. On the contrary Brozouei et al. (2010) reported that only high dose of ionization radiation can depress germination percentage.

The results indicate negative association between radiation exposure duration and germination percentage except 24 h cell phone exposure (40%). This may be due to random mutation induced by RF. A slight mutation in genes responsible for cell division may cause germination inhibition. The possible reason behind decline in germination, growth and survival are

**Figure 8** Cell phone 48 h treatment induced chromosomal aberrations (A and B) Laggard; (C) micronuclei.

**Figure 9** Laptop 24 h treatment induced chromosomal aberrations (A and C) abnormal telophase with nuclear membrane damage (B) Di-nuclei with cell membrane damage and (D) chromosomal fragmentation.

generally metabolic disorders of which cytokinin breakdown or lack of synthesis is most common (Gandhi et al., 2014; Gustavino et al., 2014).

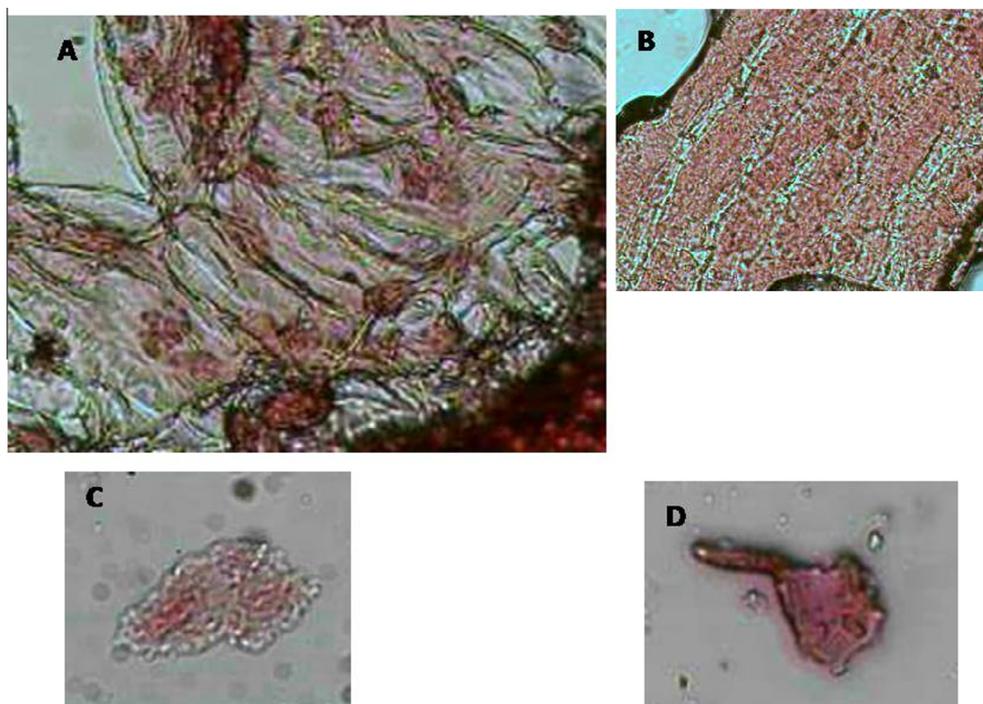

The results of effect of radiofrequency on abnormality index and mitotic index on chickpea root tip cells are compiled in Table 1. The abnormality index showed a linear increase with exposure and frequency in Hz (Fig. 3). Whereas mitotic index (%) exhibited a linear decrease with increased RF exposure (Fig. 4). Similar trends were observed by Lamsal et al. (2010) in *Allium cepa* root tip cells treated with agricultural insecticide. Results showed that mitotic index decreases as abnormality index increased. The altered mitotic rate of the plant subjected to EMR is mostly attributed to interference in normal steps of mitosis and spindle formation (Moisescu et al., 2008; Tkalec et al., 2009), failure of DNA replication and proteins synthesis (Lia and Singh, 2004), enzyme production, function and regulation and low level of ATP generation due to decreased oxidative photophosphorylation (Hao et al., 2015) (see Figs. 5 and 6).

The types of chromosomal aberrations induced by radiofrequency are compiled in (Table 2). During 24 h with cell phone treatment most frequent abnormality was scattered nuclei (118

cells) while least frequent abnormality was micronuclei (25 cells) (Fig. 7).

In 48 h cell phone treatment fragmentation (117 cells) was the most frequent abnormality, while least frequent abnormality was sticky metaphase (27 cells) (Fig. 8). In 24 h laptop exposure most frequent abnormality was scattered nuclei (130 cells) while the least frequent abnormality was micronuclei (16 cells) (Fig. 9). In 48 h laptop exposure, the most frequent abnormality was fragmentation (183 cells) while the least frequent abnormality was micronuclei (25 cells) (Fig. 10).

Present research reveals increased DNA damages with increasing duration of RF exposure. Chavdoula et al. (2010) reported mobile phone radiations (900 MHz–1800 MHz) induced DNA fragmentation in the egg chamber cells resulting in decreased fertility and apoptosis in *Drosophila melanogaster*. Gustavino et al. (2015) evaluated mutagenic potential of radiofrequency radiation of 915 MHz continuous wave radiation for 72 h on secondary root tips of *Vicia faba* and recorded dose dependent increase in micronucleus frequency. Similarly Zotti-Martelli et al. (2005) assess the micronucleus (MN) induction capability of microwaves (1800 MHz), on peripheral blood lymphocytes of humans and found statistically

**Figure 10** Laptop 48 h treatment induced chromosomal aberrations (A and C) normal prophase (B) fragmentation (C) scattered nuclei and (D) ghost cells with pilus.

**Table 3** Oxidative damages induced by radiofrequency radiations in chickpea root tip cells.

Treatments	Hours	Type of oxidative damage (No. of cells)		
		C.M. damage	N. M. damage	Ghost cells
Negative control	0	0	0	0
Cell phone (900 MHz)	24	0	164	60
	48	100	342	132
Laptop (3.31 GHz)	24	0	200	200
	48	20	254	250
Gamma ray 250 Gy		17	32	255
Grand mean		137	992	897

(C.M. = Cell membrane; N.M. = Nuclear membrane).

significant increase of MN, in exposure time and applied power density dependent manner. Presence of pilus like tube in some cells treated with cell phone 24 and laptop 48 h is evidence of cellular connection that may lead to proliferation of apoptotic cells and nuclear aggregation commonly found in cancerous cells. This may be due to error of repair machinery and high level of fragmentation that leads to defected chimeric gene (Shaffer and Pandolfi, 2006; Meyerson, 2007) expressing pilus like tubular out growth. Therefore it is suggested to carry out PCR amplifications with all type of pilin promoters in such cells (see Fig. 8).

The results of oxidative damages induced by radiofrequency are presented in Table 3. Maximum cell membrane damages were observed in 48 h exposure with cell phone (100 cells) and laptop (20 cells). Maximum nuclear membrane damages were again recorded in 48 h exposure with cell phone (342 cells) and laptop (254 cells).

Maximum numbers of ghost cells were found in 48 h cell phone (432 cells) and laptop (255 cells) RF. It can be inferred from the results that increase in exposure duration and frequency (Hz) of RF increased the number of cells with oxidative damages. Overall cell membrane damage (137 cells) was the least frequent oxidative damage while nuclear membrane damage (992 cells) was most frequent. All the treatments with RF induced more oxidative stress than positive control (250 Gy). The disruption of membrane integrity may be due to interference of RF with membrane permeability or membrane proteins leading to oxidative stress (Livingstone, 2003). Afzal and Mansoor (2012) reported mobile phone emitted radiofrequency radiation induced oxidative stress in mung bean and wheat crops. Burlaka et al. (2013) observed significant overproduction of free radicals/reactive oxygen species and oxidative damage of DNA in quail embryo cells exposed to GSM 900 MHz for one hundred and fifty-eight

hours. They relate oxidative changes to health effects up to oncogenesis.

Similar findings are reported by Xu et al. (2010) working with cultured neurons irradiated with 1800 MHz RF radiation. They reported that RF is capable of causing oxidative damage to mtDNA that leads to the neurotoxicity of RF radiation in the brain. In another study with 1.8 GHz Global system for mobile communication (GSM) Avci et al. (2012) concluded that RF exposure can enhance protein oxidation in rat brain cells as compared to control group ( $p < 0.001$ ).

#### 4. Conclusion

It is concluded that radiofrequency radiations are genotoxic as they induced chromosomal aberrations in chickpea mitotic cells and the presence of ghost cells is clear indication of their carcinogenic potential. To avoid reported DNA damages in this work cell phones should always be used either for short duration or with handsfree for long duration and they should not be kept in pockets or near body. Laptops should not be used unnecessarily for enjoyment purpose. It must be placed on desk top rather lap to minimize their exposure to human body. Further assay of carcinogenicity are recommended on mouse and human cell lines.

# Power-Frequency EMFs Promote Cancer in Massive Animal Study

## Italians Call for a “Reevaluation of the Safety of Non-Ionizing Radiation”

February 27, 2016

Last updated

May 24, 2016

Once again, power-frequency magnetic fields have been found to act as a cancer promoter.

Eighteen months ago an international team led by [Elisabeth Cardis](#) in Spain showed cancer promotion in workers exposed to chemicals and extremely low frequency (ELF) EMFs. Now an Italian team has found essentially the same promotional effect in animals exposed to ionizing radiation and ELF EMFs.

Rats, which received a single low-dose of gamma radiation early in life and were exposed to magnetic fields for their entire lifetime, developed higher than expected rates of three different types of cancer: Breast cancer and leukemia/lymphoma, as well as an extremely rare and obscure tumor, called malignant schwannoma of the heart.

The [new study](#), which was carried out at the [Ramazzini Institute](#) in Bologna, Italy, is part of the most ambitious EMF–animal project ever attempted. Future reports from the same group will describe the action of EMFs combined with a number of other cancer agents, specifically formaldehyde and aflatoxin, in addition to EMFs alone. Together, all these experiments involve more than 10,000 rats at a cost in excess of 5 million euros (\$5-6 million). The EMF–gamma radiation study had more than 650 exposed rats and 1,001 controls.

“We have confirmed the old epidemiological observations of Milham, Wertheimer and Matanoski regarding the increased risk of lymphoma/leukemia and mammary cancers, as well as the more recent study by Cardis,” said [Morando Soffritti](#), the director of the project, in an interview with *Microwave News*. Soffritti was referring to the pioneering work of [Sam Milham](#), [Nancy Wertheimer](#) and [Geneveive Matanoski](#) from 1979 through the 1990’s.

Magnetic fields can “enhance the effects of a well-known carcinogen,” said [Fiorella Belpoggi](#), the scientific director of the Institute, in an e-mail exchange. Soffritti, the former scientific director, is now the honorary president of the Institute and continues to work on this and other projects. [Their paper](#) will appear in an upcoming issue of the *International Journal of Radiation Biology* and is now posted on the journal’s Web site.

The Ramazzini researchers did not mince words about the implications of the new findings. In the “Conclusions” section of their abstract, they wrote just one sentence: “These results call for a reevaluation of the safety of non-ionizing radiation.”

The new animal results “lend support to [our recent findings](#) on ELF and brain tumor risk,” said Cardis of the Center for Research in Environmental Epidemiology ([CREAL](#)) in Barcelona. Her project, known as the [INTEROCC study](#), investigated brain cancer among workers exposed to chemicals and EMFs (see our report: [“EMF Cancer Promotion: An Old Idea Makes a Strong Comeback”](#)).

Soffritti declined to describe the findings of the EMF–formaldehyde animal experiment, saying only that they have found some “very interesting results regarding public health” and that a paper has been submitted to a peer-reviewed journal. A number of other publications, including a commentary, are also in the pipeline. [May 24, 2016 update: The formaldehyde paper has been published. [Details here.](#)]

### **The Ramazzini Experiment**

The Ramazzini team followed what is commonly known as an [initiation-promotion protocol](#). Male and female Sprague-Dawley rats were exposed in their mothers’ wombs and then for the rest of their lives to 50 Hz magnetic fields at an intensity of either 20 $\mu$ T or 1,000 $\mu$ T (200 mG or 10 G). At the age of six weeks, they each received a single 0.1Gy dose of gamma radiation, a known cancer agent. (They say that such a human exposure to ionizing radiation, from a set of CT scans for example, “cannot be called unusual.”)

Here are the key findings in the researchers’ own words:

- (a) A significant dose-related increased incidence of mammary adenocarcinomas [breast cancer] in males and females in particular in males exposed to 20 $\mu$ T plus 0.1Gy and in females exposed to 1,000 $\mu$ T plus 0.1 Gy;
- (b) In males a significant dose-related increased incidence of heart malignant schwannomas with a significant increase among males exposed to 20 $\mu$ T plus 0.1Gy [statistically significant] and to 1,000 $\mu$ T plus 0.1 Gy; and
- (c) A significant increased incidence of hematopoietic neoplasias [leukemia and lymphoma] in males treated at 1,000 $\mu$ T plus 0.1 Gy.

The Italian team expressed surprise at the observed excess of breast tumors in male rats. “In our historical controls, mammary cancer in male rats is a very rare tumor,” they wrote.

The link between EMFs and breast cancer in men was [first described](#) by Matanoski of Johns Hopkins University more than 25 years ago. Others later reported similar findings (see [MWN, J/A90](#), p.1 and [MWN, M/A91](#), p.5). A recent [meta-analysis](#) of ten studies of male breast cancer and EMFs found support for the association.

Yet, members of the EMF establishment have contested the hypothesis that there may be a link between EMFs and breast cancer, male or female. One notable critic is [Maria Feychting](#) of the Karolinska Institute who serves as the vice chair of [ICNIRP](#). She has called for an end of all such studies (see our [“The Shrill Cry To Stop EMF Research”](#)). ICNIRP has never accepted the possibility that there may be any type of cancer risk—to the breast, brain or blood—from EMFs or RF radiation.

### **Some Sordid History on EMFs and the NIEHS**

The new support for the hypothesis that EMFs can promote breast cancer in animals is the latest chapter in a long-running drama that pitted the National Institute of Environmental Health Sciences ([NIEHS](#)) against a research group at the School of Veterinary Medicine in Hannover, Germany. The German team, led by [Wolfgang Löscher](#) and [Meike Mevissen](#), ran a series of animal experiments in the 1990’s which showed that EMFs could promote breast cancer in animals that had been initiated by [DMBA](#), a chemical carcinogen (see, for instance, “Löscher Again Finds EMFs can Promote Breast Cancer,” [MWN, S/O99](#), p.4). When an NIEHS-funded team was unable to replicate that work, a senior NIEHS official, Gary Boorman, waged a dirty tricks campaign to discredit the German researchers. Boorman was later disciplined and the NIEHS offered Löscher a formal apology (for more on this fiasco, see our [“It’s Genetics, Stupid”](#)). Nevertheless, NIEHS, like ICNIRP, has declined to acknowledge an EMF–cancer risk.

After reviewing the Ramazzini results, we contacted Mevissen, who is now a professor of veterinary pharmacology and toxicology at the University of Bern in Switzerland, for a comment. “The new study indicates that ELF EMFs can promote breast cancer,” she told us. “This and the leukemia findings contribute new pieces of the puzzle supporting the IARC decision of 2001 that ELF EMFs is a possible carcinogen.” Mevissen was a member of the [IARC](#) panel that designated [power-frequency magnetic fields as a 2B \(possible\) carcinogen](#) (see [MWN, J/A01](#), p.1). Soffritti attended the meeting in Lyon as an observer.

### **No Cancer Seen with EMFs Alone**

In an interview, Belpoggi said that they are planning to publish the results of a concurrent experiment in which rats were exposed to power-frequency EMFs, without any other treatment. “In our preliminary data, ELF EMFs alone didn’t appear to show an increase of cancer in experimental animals so far,” she disclosed. “The main result of our experiment,” she said, is that “ELF EMFs have a synergistic effect: They are able to enhance the effects of a well-known carcinogen at low doses that was negative at those doses in the same experimental model.”

Belpoggi said that, for the present, she prefers the term “enhancement” to “promotion” because, “we don’t know the mechanism of action.” She added that, “We are open to give our frozen material and paraffin blocks to qualified laboratories for studies of these synergistic effects.”

### **Lifetime vs. Two-Year Exposures**

We asked Belpoggi why the Ramazzini animal studies had found an EMF effect on cancer development while a similar effort that had been coordinated by NIEHS’ Boorman during the 1990’s had not. “A basic difference,” she replied is that the Ramazzini team had used lifetime exposures while NIEHS had limited them to two years. (Note that the Boorman [EMF–DMBA experiments](#) were even shorter, lasting only 13 or 26 weeks.)

“We forgot something very simple,” Belpoggi explained, and continued:

“When we started in the 1970s, experimental carcinogenesis was the main tool to study *occupational exposures*, and exposures started in adulthood and lasted until two-thirds of the natural life, about 60 years in humans, corresponding to 104 weeks in animals. The rationale for industrial carcinogenesis in laboratory animals is very different from ‘environmental carcinogenesis,’ which often means low doses for the whole lifespan, starting from gestation. This is crucial and this is the reason we used long-lasting exposures.”

We posed the same question to Sam Milham: He too favors extended exposure durations. “Due to the long latencies for most cancers, lifetime animal and human EMF exposure studies show most of their mortality and morbidity after midlife. This makes lifetime studies superior to short-term, follow-up studies,” he said.

Back in 1998 when the first results of the Boorman–NTP EMF animal study emerged, Soffritti and his mentor, [Cesar Maltoni](#), wrote to the NTP arguing that its experiment had ended too early and questioned whether the study had been misdesigned. “It is our belief,” they said, “that the NTP bioassay was planned and conducted with a protocol that could only allow negative conclusions on 60 Hz [EMF] carcinogenesis.” (See [MWN, M/A98](#), p.4.)

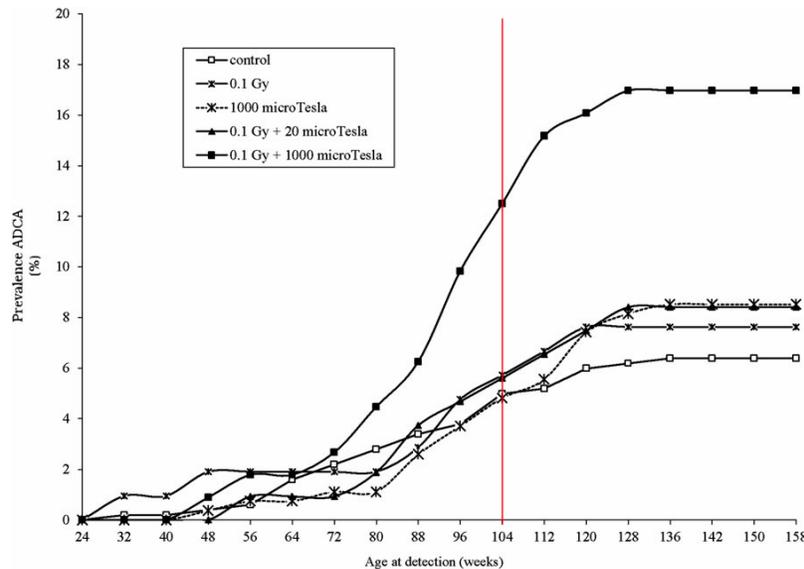

### **Should NTP’s \$25 million RF–Animal Studies Have Used Lifetime Exposures?**

The Ramazzini group is running a similar project with RF radiation. Here again, these are lifetime exposure studies. Soffritti said the exposures have been completed and the experimental data are under analysis. The results should be available sometime next year. The Ramazzini studies are using far-field RF signals to mimic exposures from cell towers rather than from phones.

The National Toxicology Program (NTP) has its own ongoing, and long delayed, project on cell phone radiation — with a \$25 million price tag. Here again, the NTP ended exposures after two years, even though Ron Melnick, who designed the protocol, had wanted to run lifetime exposures. He was overruled at the last minute.

We turned to Chris Portier, who made the initial decision to stop the RF exposures after two years: Do you have any regrets after reading the new Ramazzini paper, we asked. “No misgivings,” he replied. “This study actually supports that decision, it does not refute it.” (Portier noted that [John Bucher](#), who replaced him at the helm of NTP, had made the final decision to limit the RF study to two years.)

We pointed to a graph in the Ramazzini paper showing that the prevalence of breast cancer in female rats continues to increase after two years (104 weeks, marked by our vertical red line, see below).

Cumulative incidence of breast tumors among female rats over time (in weeks); Figure 7 from the [Ramazzini paper](#) with our addition of the red line at 104 weeks

Portier countered that those later tumors would likely have been found had the study ended at two years and the animals been sacrificed and their organs examined.

### History Repeats at NTP/NIEHS

There is another, disquieting parallel between the NTP’s EMF and RF animal projects. In 1995, when the NTP EMF animal studies had only just got underway and no results were yet on the horizon, Boorman gave a press interview in which he stated that it had become “obvious” to him that “there’s really nothing there,” that is, EMFs have no effects on the development of cancer (see [MWN, J/A95](#), p.6).

In 2010, when the NTP RF animal studies were still in their very early stages, Bucher, the NIEHS senior manager in charge, told a local newspaper that he did not believe that cell phones can cause cancer —the very question his agency was spending \$25 million to answer (see [“Will NIEHS Ever ‘Get’ EMFs?”](#)).

For more on the NTP RF study and NIEHS’ peculiar modus operandi, see our [recent report](#).

# Peer-reviewed scientific studies on EMF related subjects

Science index » [Overview](#) | [Article library](#) | List of studies | [Basic guide to EMFs](#) | [International guidance levels](#) | [Unit conversion](#) | [Frequently asked questions](#) | [Other resources](#)

---

When it comes to EMF issues, one of the most frequently heard phrases is "There is no evidence to support EMFs having health effects" or simply "There is no conclusive evidence".

This is completely wrong; there is an enormous body of evidence out there, but public and even academic awareness seems to be very poor. Therefore, we will be presenting a list of papers and odds ratios which either show serious effects or are considered important papers on the subject which we have collected over the years. This page will be updated regularly.

P This study has found effects from the exposure or radiation category

N This study has found no effects from the exposure or radiation category

- This study has offered important insights or findings but is neither a positive or null finding

---

Evan Rachlin, MD

Michael Watson, MB ChB, MRCP, AFPM

## INTRODUCTION

Vaccines to prevent infectious diseases are the greatest medical innovation of all time. The CDC estimates that U.S. childhood vaccinations given in the past two decades will prevent Americans from 322 million illnesses, 21 million hospitalizations, 732,000 deaths, \$295 billion of direct costs, and \$1.3 trillion in social costs. For example, before the advent of the measles vaccine in 1963, the virus infected 500,000 Americans annually, causing 480,000 hospitalizations. Today, we see only 60 measles cases a year, primarily from foreign travelers. Smallpox, polio, diphtheria, pertussis, measles, mumps, and many other vaccines have also had an enormous impact on public health. (Figure 1)

However, despite these remarkable successes, there is significant room for innovation in vaccine research, development, manufacturing and delivery.

## EXISTING VACCINE PARADIGM

Immunization against disease has been practiced for a thousand years, from variolation (deliberately exposing a healthy person to small amounts of infected material) to vaccination in all of its forms today. The goal of vaccination is to safely pre-expose our immune system to a small, harmless dose of all or a piece of a pathogen (called an antigen) so that, if and/or when we encounter the actual pathogen in the future, our immune system is already prepared to fight it and prevent disease.

Today we have vaccines against more than 25 different diseases<sup>1</sup>, using at least half a dozen different approaches. These include weakened or killed versions of pathogens, inactivated toxins, partial subunits of the pathogen, and conjugates (combinations of strong and weak antigens). All of these traditional approaches involve long, complex, and costly development and production.

Traditional vaccines face a number of challenges (Figure 2):

1. The target pathogens/antigens are grown in dedicated cell-culture and/or fermentation-based production before being extracted, killed, separated and purified. This involves a long, complex and costly process.
2. They often demonstrate efficacy empirically (i.e., without knowing why they work). The exact mechanism of protection may only be fully elucidated after the vaccine has been licensed and used and in some cases, such as pertussis (whooping cough), we still do not understand the mechanism of efficacy.
3. They require bespoke vaccine-specific production processes, production facilities and operators. Moreover, these capital investments must be made years in advance of vaccine approval, with all of the attendant risks that the vaccine could ultimately fail and waste this capital. This, in turn, limits the vaccine targets that developers are able or willing to sustainably pursue.
4. Existing vaccines are only just learning to adjust the kind of immune response they induce, using adjuvants.

## NUCLEIC ACID VACCINES

Nucleic acid vaccines, DNA and messenger RNA (mRNA), deliver the nucleotide sequence (eg, "AAAGGCC...") that codes for the proteins that pathogens use to cause disease. The idea is that those proteins will act as antigens that the immune system will recognize. In other words, these vaccines enable the body to innately mimic a native infection to elicit an immune response, but without the ability to cause disease or spread.

<sup>1</sup><https://www.fda.gov/BiologicsBloodVaccines/Vaccines/ApprovedProducts/UCM093833>

This approach has three main advantages over traditional vaccines (Figure 3):

1. The discovery stage can be exceedingly rapid because many of these antigens are already identified. Discovery also benefits from significant *in silico* (computer-based) antigen design and rapid testing of vaccines in small animal models.
2. Production is standardized. It does not involve either pathogens or the development of target specific cell culture or fermentation. There is no need to grow the vaccine. As a result, a single facility can produce *all* mRNA vaccines, with efficient utilization of a single set of processes, capital equipment, and labor.
3. The vaccine mimics natural viral infections in a way that the immune system recognizes. It's delivered to the muscle and immune cells, which process the nucleotide sequence just as they would do during an infection using viral DNA/mRNA inside the body's own cells (but safely).

Moreover, because the vaccine is DNA or mRNA, it can be sequenced and produced in a standardized process with fewer, more precisely controlled steps. This renders production faster, cheaper, and less vulnerable to unnecessary batch losses due to batch-to-batch variability. mRNA and DNA vaccines offer extraordinary improvements over traditional vaccines in both modularity and standardization.

In addition, nucleic acid vaccines offer the potential to adjust the balance between humoral protection and cellular protection based on the ability to precisely adjust the antigens being delivered. Because of this, nucleic acid vaccines can be designed to address pathogens that are exceptionally difficult to address using traditional vaccines approaches. (Figure 4)

## DNA VACCINES

DNA vaccine work began thirty years ago, but as yet there are no licensed DNA vaccines and most remain in Phase 1 testing. (Figure 5)

The key challenge associated with DNA vaccines is that they must penetrate the cell nucleus (crossing two membranes; the cytoplasm and the nucleus). The DNA must then be transcribed in the nucleus into mRNA before moving to the cytoplasm to stimulate antigen production. This core complex pathway often requires both larger doses and special, often painful delivery devices using electric shocks or gold microspheres into person's skin to deliver the DNA vaccine. Once inside the nucleus, DNA vaccines have a risk of permanently changing a person's DNA.

## mRNA VACCINES

There are now six prophylactic mRNA vaccines in clinical trials, four of which are being conducted by Moderna Therapeutics. These vaccines combine the advantages of DNA vaccines (natural antigen expression and production that is faster and standardized) while addressing many of the disadvantages. Unlike DNA vaccines, mRNA vaccines do not need to enter the nucleus, nor do they risk being integrated into our DNA, and they are directly translated into protein antigens. As a result, mRNA vaccines require only 1/1000 the dose of DNA vaccines and do not need special delivery devices. (Figure 6)

The first-ever published data demonstrating a prophylactic mRNA vaccine's ability to elicit robust immunity in humans was published in *Molecular Therapy* in April 2017. (Bahl *et al.*, 2017)<sup>2</sup> As with all new vaccines, time is needed to establish the level and duration of immunogenicity and the safety profile of mRNA vaccines in larger, more diverse populations. However, the innovation of mRNA vaccines offers the opportunity to improve upon DNA vaccines. These vaccines work seamlessly with the body to mimic the natural sequence of exposure and protection, without the dangers of a real infection. The precision and standardization of the antigen design and delivery offer public health and commercial advantages in terms of the speed and cost of discovery, the speed of development, the probability of success for many targets and the speed, cost and adaptability of production. mRNA offers us a new paradigm in vaccinations' hundred-year history.

	DNA Vaccine	mRNA Vaccine
Risk of DNA Integration	Yes	No
Dose	mg	µg (1000x lower)
Special Delivery Device	Yes	No
Factory Size	Large	Small
Membrane Penetration	Cytoplasm & Nucleus	Cytoplasm

## *America's Next Defense Against Zika and Other Foreign Invaders; Experimental DNA vaccines could shield against infectious-disease outbreaks that now spread around the world with alarming speed*

By Betsy McKay and Peter Loftus

**PHILADELPHIA**—Dr. Keith Hamilton took his turn in the patient chair and braced for the sting of an experimental Zika vaccine.

The injection was the easy part. Next, a nurse jabbed three tiny needles in his upper arm with a device that delivered two electrical jolts strong enough to flex muscle. He said it felt like a needle piercing his arm, again and again.

Dr. Hamilton, an infectious-diseases doctor, was on a break from his rounds to volunteer in a landmark trial of a next-generation vaccine at the University of Pennsylvania's medical school.

The Zika epidemic is accelerating work on this and other experimental DNA vaccines, which could turn out to be America's best defense against infectious-disease outbreaks that now spread around the world with alarming speed, fueled by rising populations and global travel. These vaccines, made with synthetic DNA, can be developed and manufactured quickly.

Researchers in the U.S. and Canada have injected dozens of volunteers in the past few months with two competing DNA vaccines intended to provide immunity to the Zika virus. The mosquito-borne virus has caused hundreds of birth defects, including brain damage, and fetal deaths, mostly in Brazil.

Inovio Pharmaceuticals Inc., which makes the vaccine in the trial here, is in a race to market its vaccine and accompanying "electroporation device," a tool the size of an electric toothbrush that uses a jolt of electricity to help usher the firm's DNA vaccine

into human cells.

One of the National Institutes of Health is pursuing its own DNA vaccine for Zika in a trial that began this summer.

While there are significant hurdles, some researchers believe DNA vaccines could provide faster, more effective ways to combat Zika, as well as Ebola, Middle East respiratory syndrome and other deadly viruses and bacteria that have sickened millions.

Scientists can develop DNA vaccines in weeks and begin human trials within months. DNA vaccines also may provide longer-lasting immunity compared with conventional vaccines and, in some cases, even cure the malady they are intended to protect against.

Conventional vaccines take years to develop and test. They often cost more than pharmaceutical companies are likely to recoup from sales in the mostly poor tropical countries where the diseases originate. The economics discourage many firms from producing them for new, emerging diseases.

Yet the stakes are high, concluded a report this year from health experts convened by the U.S. National Academy of Medicine: "A pandemic could kill as many people as a devastating war."

Preparedness against most of the emerging infectious diseases that threaten the world is hobbled by a lack of vaccines and drugs, experts say.

More than 41 million people have died around the world over the past decade from AIDS, malaria, tuberculosis, Ebola and other tropical diseases, according to a tally by the Institute for Health Metrics and Evaluation at the University of Washington.

The World Health Organization

declared last month that Zika was no longer a global public health emergency, but public-health leaders said it would remain a long-term crisis until a vaccine is developed to prevent its spread.

Zika has infected more than 170,000 people in the Americas, according to the Pan American Health Organization, with hundreds of thousands more suspected cases. Brazil is girding for a resurgence of the virus as summer arrives in the southern hemisphere.

DNA vaccines are made with so-called platform technologies, building blocks that shave years off development time. Ideally, they could deliver protection while an epidemic was still spreading instead of years later. Ebola, which struck West Africa in 2014, still has no licensed vaccine.

Traditional vaccines are developed by growing batches of viruses and bacteria, a slow, labor-intensive process. DNA vaccines are made by inserting a gene related to a particular virus or bacterium into pieces of synthetic DNA called DNA plasmids, an all-purpose platform.

Last fall, as it became apparent that Zika was taking a toll, researchers at the National Institute of Allergy and Infectious Diseases, or NIAID, retrieved an experimental DNA vaccine the agency had developed about a decade ago for West Nile virus. The vaccine had shown promise in human tests, but no company agreed to finish development and produce it.

The health agency retooled the shelved West Nile vaccine by substituting a gene for Zika in the platform DNA, providing "a big head start on Zika," said Anthony Fauci, the NIAID director. "That's where the field of vaccinology is going—having a series of readily interchangeable platforms."

D | DOW JONES

NIAID took less than four months from the time it settled on a vaccine design to begin a human trial, said Barney Graham, deputy director of the agency's Vaccine Research Center. The trial to assess its safety, and see if it generates an immune response, began in August. Initial results are expected by year's end. A second DNA vaccine is also being tested.

The DNA vaccines by Inovio and NIAID were the first two administered to human volunteers among nearly 30 Zika vaccines in development, according to the World Health Organization.

Even if Inovio's and NIAID's vaccines work in human trials, they aren't likely to be on the market for a couple of years, the approximate time needed to satisfy regulatory requirements for effectiveness and safety.

From a business perspective, the market may be small if public-health authorities determine that a Zika vaccine need only be stockpiled for emergencies rather than administered routinely to the general population.

Companies pursuing Zika vaccines are hoping public demand for widespread immunization will create a commercial market similar to the vaccine for rubella, another disease that causes birth defects. Any Zika vaccine wouldn't likely be aimed at pregnant women because of potential risks, but instead administered more broadly to young people.

Hundreds of millions of people are at risk, said Thomas Monath, chief operations officer of the infectious-disease division at NewLink Genetics Corp., which is developing two Zika vaccines.

Zika, he said, "is the biggest opportunity for a new vaccine that's come along in my career, and I've been in vaccines for 40 years."

#### Electric shocks

Scientists have been working on DNA vaccines for a quarter-century, including ones for the flu and severe acute respiratory syndrome, known as SARS, an infectious virus that sprang from China in 2002 and killed 774 people out of more than 8,000 infected on several continents. None of the DNA vaccines have made it to market for human use. The main problem has been that human cells don't easily absorb them.

Inovio's electroporation device is

intended to be a solution. After the vaccine shot, the device delivers a mild electrical current to the same spot on the arm, temporarily opening cell membranes to allow the DNA inside. "That's the fire that cooks the meal," said J. Joseph Kim, Inovio's chief executive.

In late summer 2015, Dr. Kim read about the spread of Zika in South America and began work on a DNA vaccine to fight the virus. It only took about two weeks to design the DNA sequences on a computer and make a small batch of the vaccine. By December 2015, it was being tested on mice.

In June, the Food and Drug Administration approved a human study, based on animal tests that showed the vaccine triggered immunity to the Zika virus.

Inovio and GeneOne Life Science Inc., which are codeveloping the vaccine with academic collaborators at the University of Pennsylvania and the nearby Wistar Institute, a medical-research center, began their trial in July, around the same time as NIAID.

Dr. Hamilton, one of about 40 people who have volunteered to receive the experimental vaccine, said electroporation "felt more like putting a needle in multiple times rather than an electrical shock."

Helping science was worth the discomfort, he said: "This is a small piece in a larger puzzle to come up with an effective vaccine for the people who need it the most."

The Inovio trial is expected to be completed this month. Researchers are monitoring the volunteers for any side effects, as well as taking blood tests to see if the vaccine induces the expected immune response.

Inovio, based in Plymouth Meeting, Pa., also began a 10-month trial this summer with 160 participants in Puerto Rico, where Zika spread rapidly.

Dr. Kim, the company's 47-year-old chief executive, got his Ph.D. in biochemical engineering at the University of Pennsylvania, where he met David Weiner, a biologist and now a director at Inovio.

After working in vaccine manufacturing and research at Merck & Co., Dr. Kim co-founded a company called Viral Genomix in 2000. The company later acquired a San Diego-based company called Inovio and took

its name.

Inovio explored experimental DNA vaccines for HIV, among other technologies. At the time, the vaccines showed promise in animal studies, but failed in humans when given via standard vaccine injections.

Drs. Kim and Weiner turned to electroporation—first tried in the 1980s to boost the effectiveness of chemotherapy. In 2006, they tested an electroporation device, developed by a Texas company called Advisys, to immunize monkeys against a form of HIV.

One evening, close to midnight, Dr. Kim's home phone rang. It was Dr. Weiner calling to say the HIV vaccine, assisted by the electroporation device, had kick-started an immune response in the monkeys.

"That really triggered the path we're on now," Dr. Kim said. His company acquired Advisys in 2007.

The company reported positive results for its DNA vaccine against Ebola; 64 of 69 subjects mounted a strong antibody response after three doses. Inovio's vaccine for Middle East respiratory syndrome—a virus that can cause fatal respiratory illness—was developed with GeneOne in partnership with the Walter Reed Army Institute of Research. It is in an early clinical trial.

Inovio has had to delay a new trial of its vaccine against human papillomavirus vaccine until next year after the FDA in October asked the company for more information about the stability and sterility of the disposable parts in its electroporation device, which is used to both inject vaccine and deliver an electrical jolt. Its device in the Zika trial delivers only the shock.

Not everyone has embraced DNA vaccines. Merck & Co. explored a DNA vaccine for HIV several years ago, but dropped it after a study in 2007 found it didn't work.

Merck is now exploring synthetic RNA-based vaccines, a spokeswoman said. In theory, the approach is easier because RNA needs only to get into a cell's cytoplasm—the material between its outer surface and the core nucleus. DNA vaccines must penetrate the nucleus to work, said W. Ripley Ballou, head of Glaxo's U.S. vaccine research center in Rockville, Md.

GlaxoSmithKline also is exploring an RNA-based vaccine for

Zika, in collaboration with NIAID. It is being tested in animals and could move to human studies next year, Dr. Ballou said.

Using the method for different vaccines is a relatively simple process, he said, "once you figure out how to do it."

#### Health frontier

NIAID has pioneered DNA vaccines over the past several years for HIV, Ebola and other diseases.

Dr. Graham at the agency's Vaccine Research Center began thinking about a Zika vaccine after learning about the spread of the virus from a Brazilian researcher who approached him at a conference in July 2015.

NIAID researchers started work on the vaccine in November and accelerated their efforts after the World Health Organization declared in February that the complications of Zika posed a global public health emergency. By June, the agency had an experimental vaccine for the human trial.

NIAID's Zika vaccine doesn't use an electroporation device and it may not be necessary, according to Julie Ledgerwood, chief of the clinical trials program for the Vaccine Research Center.

Data from NIAID's trials of the DNA Zika vaccine in monkeys, and evidence from its progenitor West Nile vaccine in humans, "makes us think this vaccine is highly immunogenic and it should work well even delivered by traditional needle," Dr. Ledgerwood said.

A few studies conducted by other scientists have found little difference in the immune response generated by experimental DNA vaccines for HIV and the H5N1 flu that were given with and without electroporation.

NIAID has used electroporation in animal tests. "In our opinion, the device development probably still has a way to go," Dr. Graham said. "But the technology itself, I think, is promising."

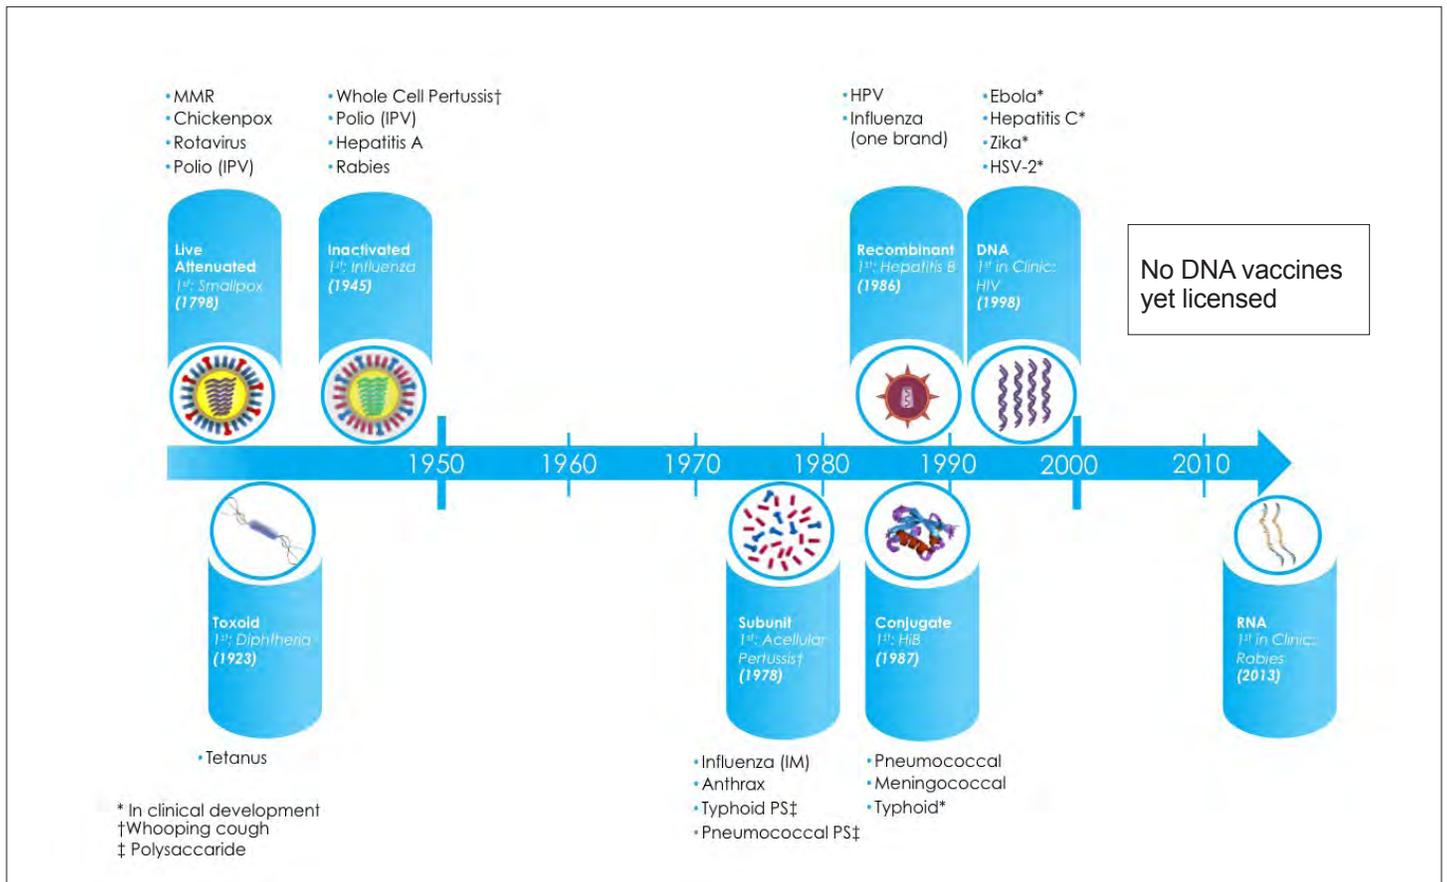

Whether with or without an electrical shock, a successful DNA vaccine would accelerate the exploration of new technologies against Zika and other outbreaks, said Kayvon Modjarrad, associate director for emerging infectious disease threats at the Walter Reed Army Institute of Research.

Dr. Modjarrad is the principal investigator of the DNA vaccine trial for Middle East respiratory syndrome that uses electroporation.

"The way we make vaccines now and what's on the horizon," he said, "is very, very different from the way we've been making vaccines for the past 100 years."

About the Authors

**Evan Rachlin, M.D.**

*Senior Director of Strategic Planning*

Dr. Rachlin leads Strategy across Moderna’s portfolio of mRNA medicines. Prior to joining Moderna, Dr. Rachlin was a principal at Bain Capital Ventures, an engagement manager at McKinsey & Company, and an associate in the Portfolio and Decision Analysis Group at Pfizer. He received his M.D./M.B.A. from Harvard University.

**Michael Watson, MB ChB, MRCP, AFPM**

*President, Valera, a Moderna venture*

Dr. Watson is a UK-trained physician in internal medicine and infectious disease, bringing his twenty-year career in vaccine work to his role as President of Valera, Moderna’s infectious disease-focused venture. Previously, Dr. Watson was Global Head of Vaccination Policy and Advocacy at Sanofi Pasteur. He has also held positions including Head of R&D for Acambis, UK Medical Director of Aventis Pasteur MSD, as well as Head of Clinical and Epidemiology for SPMSD in France.

# Scientific evidence contradicts findings and assumptions of Canadian Safety Panel 6: microwaves act through voltage-gated calcium channel activation to induce biological impacts at non-thermal levels, supporting a paradigm shift for microwave/lower frequency electromagnetic field action

**Abstract:** This review considers a paradigm shift on microwave electromagnetic field (EMF) action from only thermal effects to action via voltage-gated calcium channel (VGCC) activation. Microwave/lower frequency EMFs were shown in two dozen studies to act via VGCC activation because all effects studied were blocked by calcium channel blockers. This mode of action was further supported by hundreds of studies showing microwave changes in calcium fluxes and intracellular calcium  $[Ca^{2+}]_i$  signaling. The biophysical properties of VGCCs/similar channels make them particularly sensitive to low intensity, non-thermal EMF exposures. Non-thermal studies have shown that in most cases pulsed fields are more active than are non-pulsed fields and that exposures within certain intensity windows have much larger biological effects than do either lower or higher intensity exposures; these are both consistent with a VGCC role but inconsistent with only a heating/thermal role. Downstream effects of VGCC activation include calcium signaling, elevated nitric oxide (NO), NO signaling, peroxynitrite, free radical formation, and oxidative stress. Downstream effects explain repeatedly reported biological responses to non-thermal exposures: oxidative stress; single and double strand breaks in cellular DNA; cancer; male and female infertility; lowered melatonin/sleep disruption; cardiac changes including tachycardia, arrhythmia, and sudden cardiac death; diverse neuropsychiatric effects including depression; and therapeutic effects. Non-VGCC non-thermal mechanisms may occur,

but none have been shown to have effects in mammals. Biologically relevant safety standards can be developed through studies of cell lines/cell cultures with high levels of different VGCCs, measuring their responses to different EMF exposures. The 2014 Canadian Report by a panel of experts only recognizes thermal effects regarding safety standards for non-ionizing radiation exposures. Its position is therefore contradicted by each of the observations above. The Report is assessed here in several ways including through Karl Popper's assessment of strength of evidence. Popper argues that the strongest type of evidence is evidence that falsifies a theory; second strongest is a test of "risky prediction"; the weakest confirms a prediction that the theory could be correct but in no way rules out alternative theories. All of the evidence supporting the Report's conclusion that only thermal effects need be considered are of the weakest type, confirming prediction but not ruling out alternatives. In contrast, there are thousands of studies apparently falsifying their position. The Report argues that there are no biophysically viable mechanisms for non-thermal effects (shown to be false, see above). It claims that there are many "inconsistencies" in the literature causing them to throw out large numbers of studies; however, the one area where it apparently documents this claim, that of genotoxicity, shows no inconsistencies; rather it shows that various cell types, fields and end points produce different responses, as should be expected. The Report claims that cataract formation is produced by thermal effects but ignores studies falsifying this claim and also studies showing  $[Ca^{2+}]_i$  and VGCC roles. It is time for a paradigm shift away from only thermal effects toward VGCC activation and consequent downstream effects.

## Introduction

There has been a literature reporting various non-thermal effects of microwave/radiofrequency radiation exposures starting with the Soviet literature in the 1950s. Subsequently, there have been thousands of international published studies reporting non-thermal or what are sometimes called micro-thermal effects producing therapeutic responses, changes in calcium fluxes and signaling, increased oxidative stress, and a wide variety other health-related responses in humans and animal models.

Nevertheless, there has been a series of medical reports, arguing that only thermal effects need be considered when setting guidelines or safety standards for microwave electromagnetic field (EMF) exposures. These have been based mainly on two types of arguments:

- That there cannot be any biophysically viable mechanism for any such non-thermal effects and therefore that reports of such effects should be viewed with great skepticism.
- That there are many “conflicts” or “inconsistencies” in the literature which according to these reports, justify rejection of the various thousands of publications showing apparent non-thermal effects.

The focus of this review is to consider whether it is time for a “paradigm shift” away from strictly thermal effects toward non-thermal effects. Specifically, it is focused on the recent finding that most, possibly all non-thermal effects can be produced by microwave activation of voltage-gated calcium channels (VGCCs). It is also focused on the 2014 Report of the Canadian Panel of Experts on Safety Code 6 as the most recent and therefore up-to-date summary of the evidence supporting the strictly thermal point of view.

## EMFs act via stimulation of voltage-gated calcium channels (VGCCs)

Calcium provides an essential role in cell function, being normally maintained at very low, circa  $10^{-7}$  M

intracellular levels, but also with transient intracellular calcium ( $[Ca^{2+}]_i$ ) increases being used for widespread and important regulatory signaling. A recent review (1), noted that in two dozen studies, calcium channel blocking drugs block a wide range of electromagnetic field (EMF) effects on cells and organisms by blocking voltage-gated calcium channels (VGCCs which are also known as voltage-operated, voltage-dependent or voltage-regulated calcium channels). In most but not all cases, L-type VGCCs were studied, but T-type, N-type and P/Q-type channels can also have roles, as shown by channel blockers specific for these other channels (1). In each of these studies, calcium channel blockers blocked or greatly lowered each of the responses studied, showing that VGCC activation is required for low intensity fields to produce a wide range of responses (1). Each of these channel blockers is thought to be highly specific, such that with two different types of L-type blockers being used that act at different sites on the L-type VGCCs and also one each of the T-type, N-type and P/Q type blockers being used, with each showing activity in blocking or greatly lowering EMF responses, it is highly unlikely that a non-VGCC mechanism is involved here.

VGCC activation is thought to act mainly by increasing  $[Ca^{2+}]_i$ . Other considerations also support VGCCs as a major EMF target, accounting for numerous biological impacts of microwave exposures (1–3) at levels not producing substantial changes in temperature.

Pilla published a very important paper, suggesting in retrospect that these low-level fields directly activate the VGCCs (4, see also 1–3). He showed that cells in culture when exposed to a low intensity pulsed microwave field, produce an almost instantaneous  $Ca^{2+}$ /calmodulin-dependent increase in nitric oxide (NO), occurring in  $<5$  s. The NO increase is produced by the  $[Ca^{2+}]_i$  activating the two  $Ca^{2+}$ /calmodulin-dependent NO synthases, which can occur almost instantaneously. These results show that the  $[Ca^{2+}]_i$  increases must also occur almost instantaneously, providing strong evidence that the VGCCs are directly activated by the low intensity field in this study. The known properties of the VGCCs are discussed below, properties that are expected to make them particularly susceptible to activation by such low intensity fields.

In addition to calcium channel blocker studies, the important role of VGCC activation for the biological effects of microwave radiation at levels that do not produce measured changes in temperature is also supported by a large number of studies, some of which were reviewed earlier (5, 6), showing that low level microwave EMF exposures lead to measured changes in calcium signaling and/or calcium fluxes consistent with VGCC activation. There are

also hundreds of studies of oxidative stress responses to low intensity field exposures, which can also be produced by downstream effects of increased  $[Ca^{2+}]_i$  (1–3). The mode of microwave action via VGCC activation also confirms earlier predictions of Panagopoulos et al. (7, 8) that EMFs may act via voltage-gated ion channel activation. The whole issue of the biophysics of VGCCs and other voltage-gated ion channels is discussed in some detail below.

Various frequencies, intensities and pulse patterns of EMFs act via VGCC activation (1), including extremely low frequency fields of 50 or 60 Hz electrical wiring, microwave frequency EMFs also referred to as radiofrequency (RF), very short “nanosecond” pulses, and even static electric or magnetic fields. Given recent global increases in exposures to microwave/RF EMFs, the findings for microwave EMFs create the most concerns for both human and environmental health.

We are therefore in a situation where the paradigm of EMF action focused solely on heating (9–13), should be replaced by one based on VGCC activation of microwave and other EMFs (1–3).

In addition to impacts of EMFs directly involving VGCCs, there are a number of other related mechanisms which should be explored. For instance, Pilla reviewed 2 studies in which microwave EMFs increased apparent calmodulin activation (14). Calmodulin is regulated by  $[Ca^{2+}]_i$  such that calmodulin activation may act along with VGCC activation in two related pathways of action discussed below.

## Three other types of observations that contradict the assumptions of current safety standards

Current safety standards are based on the assumption that all important biological effects of microwave and lower frequency EMFs are due to tissue heating (thermal effects) and that specific absorption rates (SARs) of EMFs are therefore a measure of their ability to produce all important biological effects. While the VGCC studies, discussed above clearly invalidate that assumption, there are three other distinct types of observations that also contradict that assumption. As discussed below, an extensive scientific literature reports biological microwave EMF effects at exposure levels well within safety standards and that therefore should not occur according to current safety standards. Two other types of falsifying evidence are the findings that pulsed fields are often much more biologically active than non-pulsed fields and that certain intensity windows of exposure are more biologically active than

are exposures of both lower and higher intensities. These two are each discussed in some detail immediately below.

It has been known for well over 30 years that pulsed microwave fields are often much more biologically active than are continuous non-pulsed fields. This was shown, for example, by Seaman and Wachtel in studies of microwave exposures of *Aplysia* pacemaker cells (15). Pacemaker cells have a very high density of VGCCs, suggesting that the pulsed microwave exposures may in this study act via VGCC activation. This was shown by Bassett et al. (16) and by Pilla (17) both in 1974 studies of augmentation of bone repair, that pulsed field microwaves were much more active than continuous field microwave exposures. Both Baranski (18) and Czerski (19) showed that microwave pulsed field exposures were more active than non-pulsed fields in terms of their impact on blood forming cells. Micro pulsed field exposures were also more effective than non-pulsed continuous wave (CW) fields in producing a breakdown of the blood-brain barrier (20). Adey’s review (21) stated that “There is evidence of interactions with radio and microwave fields pulse-modulated at higher frequencies from 500 to 1500 Hz and an absence of similar effects with CW fields of the same average power density at the same carrier frequency.” Several other studies are cited in the Adey (21) review documenting higher biological activity of pulsed fields than non-pulsed CW fields at identical power levels. A recent study showing that pulsed microwave EMFs acted via activation of L-type VGCCs (22) suggests that all these inconsistencies of the pulsed field findings with any heating mechanism may be due to their action in VGCC activation.

More than four decades ago, the biological impact of non-thermal levels of pulsed fields was sufficiently well documented that it became the basis for a number of therapeutic applications of microwave pulses. Therapies currently employed include a wide range of bone growth and orthopedic rehabilitation regimens as well as some applications to enhance the uptake of chemotherapeutic agents (14). These numerous therapeutic effects are well established to be non-thermal and operate through increased levels of  $[Ca^{2+}]_i$  and nitric oxide (NO) signaling (2, 14). The medical use of these pulsed fields provides therefore prima facie evidence that such fields are often more active in VGCC activation than are non-pulsed fields.

The greater biological activity of pulsed field exposures were sufficiently well documented 30–48 years ago, such that it influenced safety standards of the 1960s and 1970s. For example, the Canadian Standards Association 48 years ago in 1966, adopted lower standards [see Table 2 in ref. (23)] for occupational exposure to pulsed field exposures (1 mWhr/cm<sup>2</sup>, limited to 6 min exposure) in contrast to those for continuous, that is non-pulsed exposures

(10 mW/cm<sup>2</sup>, for which there was no time limitation). In 1974, in the United States, the American National Standards Institute (ANSI) adopted essentially identical standards as had Canada for occupational pulsed field and non-pulsed field exposure (23). In 1970, the Czechoslovakian government adopted more stringent occupational and general public standards for pulsed field exposures vs non-pulsed field exposures (23). Pulsed fields are, of course, produced by any type of wireless communication device since it is the pattern of pulsations that conveys the information. Different devices often use different types of pulsation patterns. However, we do not know how biologically active the different pulsation patterns are, because this has not been systematically studied. As a result, we cannot rationally compare the dangers of one device vs another.

Furthermore, Barrie Trower, a retired military intelligence expert from the United Kingdom, has stated that classified research indicates that different wavelengths vary in their biological activities as well. He reports that the specific details about the biological impacts of variations in pulsed electromagnetic fields are classified by multiple countries because of “national security”. Thus much of what research appears to have been done in this field remains unavailable to decision makers charged with setting standards on such devices that emit pulsed electromagnetic fields.

It has been shown that there can be intensity “windows” where biological activity is greater than at intensities both higher and lower than the window intensity (24–32). This again argues against a heating mechanism as there are no known thermal dose-response curves with similar windows. In addition, these window effects are also found at levels where there is extremely low heating. For example, Blackman et al. (28) state that “Because of the extremely small increments of temperature associated with positive findings [less than  $4 \times 10^{-4}$  degrees C], and the existence of more than one productive absorption rate (“window”), a solely thermal explanation appears extremely unlikely”. It is (31) stated that “Since there was no detectable temperature increase during exposures, the recorded effects are considered non-thermal”. The suggested mechanism (31) may involve a role of voltage-gated ion channels such that “the action of external EMF on cells is dependent on irregular gating of membrane electro-sensitive ion channels whenever a force on the channel sensors exceeds the force exerted on them by a change in the membrane potential of about 30 mV which is necessary to gate the channel normally. If in some kind of cells there is an upper limit for this value of membrane potential change, then the channel would be gated

whenever the force exerted on its sensors is within this ‘window’”. Five of these studies show effects on [Ca<sup>2+</sup>]<sub>i</sub> fluxes (24–28), consistent with possible roles of VGCCs. These studies provide strong evidence that these window effects occur at levels where there is either no measured change in temperature or extremely low heating.

Perhaps the strongest evidence for non-thermal effects of EMFs comes from studies on animal female and human male reproduction. This literature indicates that sperm exposed to microwave radiation emitted by approved mobile phones die three times faster and develop significantly more damage to their mitochondrial DNA (33). Studies of pregnant mice, rats and rabbits report that prenatally exposed offspring develop significantly more damage to their eyes, skin and liver (33) with hippocampus and pyramidal cell formation are impaired as well.

In summary, four distinct types of evidence provide contradictory information about the basic assumption underlying current US, Canadian and International Commission on Non-Ionizing Radiation Protection (ICNIRP) safety standards that non-thermal effects do not exist: Microwave and other lower frequency EMFs act via VGCC activation rather than by heating; there are numerous papers in the scientific literature reporting biological effects with exposures well within safety standards where substantial heating cannot occur. Moreover, pulsed fields are, in most cases, more biologically active than non-pulsed fields that produce equal heating; windows of exposure intensities occur which are more active than both higher and lower exposures of the same fields. While, in general, lower intensities are safer than higher intensities, this “window” effect shows that there are some major, biologically and medically important exceptions to this pattern. The pulsed field effects and the window effects make it impossible to currently predict biological activity without doing actual measurements of biological activity of specific devices at specific exposure intensities. The question of how to best approach and evaluate such biological effects is discussed below.

## **The properties of VGCCs and other voltage-gated ion channels may make them uniquely susceptible to low intensity MF activation**

There has been an argument repeatedly put forth that there cannot be a biophysically viable mechanism for low intensity, apparently non-thermal effects. This claim

is argued as follows [see Sheppard et al., ref. (34)]: While they acknowledge that EMFs can exert forces on charged groups, they argue that weak EMFs produce only weak forces that are less than are exerted by thermal motion produced at normal body temperature. They argue therefore that the only effects that can be produced by weak EMFs would be dwarfed by a high background noise created by random thermal motion. One of the problems with the Sheppard argument comes from a consideration of the structure of the voltage-gated ion channels and how these channels detect electrical changes, which may lead to opening the channel. The structure of the alpha-1 subunit containing the channel has been modeled and discussed (35–38).

What can be seen is that there are four similar domains in this protein, with each domain containing six transmembrane alpha helices in it. These four domains are thought to have been produced evolutionarily by two tandem duplications, starting with a gene encoding a protein with one such domain. The fourth helix in each domain contains five positively charged amino acid side chains which collectively make up the voltage sensor (37, 38). It is thought that 20 (4×5) charges make up the voltage sensor, each of which must be pushed in approximately the same direction (and the right direction) at the same time in order for the channel to open. Changes in the membrane potential across the plasma membrane can do this, as can EMFs, because the fields will produce forces on these different charged groups in the same direction at a particular time. Random thermal motion, in contrast, is random in three dimensions and will only extraordinarily rarely produce forces on 20 groups in approximately the same direction at the same time. So you can see the thermal motion argument is clearly at best highly questionable when it is applied to voltage-gated ion channels including VGCCs.

There are other issues that come into play, both influencing the effects of fields on the VGCC voltage sensor. One is that the plasma membrane has high electrical resistance whereas both the aqueous extracellular fluid and the aqueous cytoplasm, with their dissolved salts are good electrical conductors. EMFs only traverse plasma membranes with great difficulty (39, 40). Therefore, fields will produce rapid movement of charges in the intracellular and extracellular aqueous phases which will be blocked by the plasma membrane such that voltage sensor will be influenced by greatly amplified electrical forces, in a direction perpendicular to the plane of the plasma membrane. That circa 3000-fold amplification is recognized by Sheppard et al. (34) immediately before their Conclusion section. The only example of an integral membrane that may be influenced in this way, that they give (34) is that

of bacteriorhodopsin, where light exposure leads to the pumping of a proton across the plasma membrane. They attempt to estimate the effects of voltages on the proton pumping, by looking at the effects of voltages on the absorption changes that occur in bacteriorhodopsin (34); however, the cycling of bacteriorhodopsin is a complex process (41) where the proton pumping is not rate-limiting and therefore these studies give little insight into the actual effects on proton pumping.

Bacteriorhodopsin differs from the voltage-sensor in the VGCCs in several important ways:

- The voltage sensor has evolved to respond to voltage changes across the plasma membrane, whereas bacteriorhodopsin has evolved to respond to light exposure.
- There are 20 charged groups in the VGCC voltage sensor (37, 38), whereas there is one charge involved in the bacteriorhodopsin mechanism.
- Whereas the bacteriorhodopsin has considerable water in the center of its structure, water seems to be excluded near the helix 4 structures that constitute the voltage sensor.

The third way, above, is important because the force on charged groups, as shown by Coulomb's law, is inversely proportional to the dielectric constant of the surrounding material. The charged groups of the voltage sensor are found in the lipid region of the plasma membrane. The dielectric constant of the lipid section of the membrane is similar to the dielectric constant of hydrocarbon solvents (41), whereas the water dielectric constant is about 40 times higher than that of hydrocarbon solvents (41). The dielectric constant of the extracellular fluid is 2.5–3.5 times that of water, because of the dissolved salts (42, 43) and the measured dielectric constant of cytoplasm is quite similar to the dielectric constant of extracellular fluid. It follows from this that the aqueous phase where most charges exist in cells has about 120 times the dielectric constant of the membrane where the voltage sensor resides. Therefore, the forces on the voltage sensor charges are on the order of 120 times higher than the forces on most charges in the cell.

It follows from this that if one wants to compare the forces on the voltage sensor with that produced by EMFs on most other charged groups in the cell, the voltage sensor forces are approximately  $3000 \times 120 \times 20 = 7.2$  million times greater. [Please note again that the 3000 figure is recognized by Sheppard et al. (34); 120 is the effect of the dielectric constant and 20, the number of charges in the voltage sensor.]

The above considerations in this section, clearly show that Sheppard et al. (34) provide no evidence arguing for biophysical implausibility of the VGCC voltage sensor as

a target of low-intensity EMFs, such that when we have compelling empirical evidence that it is the main target, that evidence should be taken at face value. Furthermore, the VGCC voltage sensor is likely to be many orders of magnitude more sensitive to EMF effects than are any non-plasma membrane localized target. Because heating is produced by the joggling of charged/partially charged groups almost all of which are outside the plasma membrane, the much greater forces on the VGCC voltage sensors show that fields 6–7 orders of magnitude lower than produce heating may activate the VGCC voltage sensors.

Have others been influenced by somewhat similar considerations? I believe it is likely that W.R. Adey was influenced by the plasma membrane properties when in the 1980s he proposed that a plasma membrane protein was the likely target of weak EMFs. Panagopoulos et al. (7, 8) may have been influenced by these plasma membrane and voltage sensor considerations when they decided to do biophysical modeling on voltage gated ion channels. The two reviewers of this paper each had some criticisms of the Panagopoulos et al. (7, 8) modeling, and some of the things in their papers go beyond my biophysics understanding, so I am unable to judge. What I would say is that the modeling studies came to three important predictions: That voltage-gated ion channels may be targets of low-intensity EMFs, that the VGCCs may be particularly activated because of the mechanism of the actual calcium flux through the channel and that pulsed fields may be more active than non-pulsed fields. Biophysical modeling of such complex membrane proteins as the voltage-gated ion channels is, at best a work in progress, given their complexity.

At this point, there is much evidence implicating VGCC activation but no apparent evidence implicating other voltage-gated ion channels in low intensity EMF responses (1–3). Possible reasons for this should be assessed elsewhere.

What is most needed at this point is not more biophysical modeling, although that would be useful, but extensive detailed information on the effects of various fields on VGCC activation. Such information can be obtained via the types of studies advocated below for biologically-based safety standards.

## Canadian Royal Society Expert Panel Report on radiofrequency fields

This Royal Society Expert Panel was charged with reviewing Safety Code 6 (2013) safety limits for exposure to radiofrequency (primarily microwave frequency) fields,

following the charge to “advance knowledge, encourage integrated interdisciplinary understanding and address issues that are critical to Canadians”. The Expert Panel Report (44) can be judged based on these charges and also the requirements that apply to authors of all purportedly scientific documents:

- The need to provide documentation that it has given as objective an assessment of the science as possible;
- The need for clarity of thought and clarity of expression, such that it will be clear to the reader what the Report is trying to say;
- The need to provide the reader of the Report with sufficient information in the Report and in the citations provided in the Report such that the reader can make an independent assessment of the quality of the science;
- And perhaps most importantly, the need to follow widely accepted principles for assessing scientific evidence.

This paper considers both the charges to the panel and these more generally applicable scientific principles to judge the scientific merit of the Report.

## What is in the report?

The Report is, in the author’s view, stronger on opinion than on evidence (44). Let us consider some specifics.

The Report states that “The Panel considered an ‘established adverse health effect’ as an adverse effect that is observed consistently in several studies with strong methodology. With this definition in mind, the Panel reviewed the evidence for a wide variety of negative health impacts from exposure to RF energy, including cancer, cognitive and neurologic effects, male and female reproductive effects, developmental effects, cardiac function and heart rate variability, electromagnetic hypersensitivity, and adverse health effects in susceptible regions of the eye.” Despite this claim to have reviewed a broad array of biological impacts, in fact the Report does not provide a comprehensive review. Rather it engages, as documented below, in what can be referred to as “cherry-picking” – selecting studies consistent with its assumptions. Moreover, it often ignores studies that are not consistent with its assumption that there are no biological effects excepting those that, in their view, may be tied to heating. Thus the Report completely excludes many different studies on prenatally exposed animals and those on spermatogenesis, on oxidative stress, changes of calcium fluxes and

thousands of studies on therapeutic effects, all at non-thermal levels of exposure.

The Report uses the existence of what it calls “inconsistent,” and others have called “conflicting” studies to argue that conflict *per se* indicates a lack of established health impact. This paper considers below whether there are any genuine “inconsistencies” in this literature. Henry Lai and Devra Davis have documented that “conflicting” scientific evidence in the field of bioelectromagnetics relating to mobile phones has been carefully cultivated (45), an inference that may also explain the data of Huss et al. (46). Huss et al. stated “We found that the studies funded exclusively by industry were indeed substantially less likely to report statistically significant effects on a range of end points that may be relevant to health. Our findings add to the existing evidence that single-source sponsorship is associated with outcomes that favor sponsors’ products.” The panel ignores these findings and considers that conflicting evidence about effects of exposure to RF energy on cancer or other end points means that effects are possible but are not ‘established’ in accordance with its definition of ‘established health effects’. Similarly, while the Report notes that effects of exposure to RF energy on aspects of male reproductive function have been found, it concludes that “the evidence has not been established to indicate that these translate into fertility or health effects” even when such aspects are used clinically to assess male fertility.

The Panel reviewed “inconsistent” evidence about effects of exposure to RF energy on cancer, concluding that effects are possible but are not ‘established in accordance with its definition of ‘established health effects’. The Report states that the Panel’s conclusion on cancer is in agreement with a recent report from the International Agency for Research on Cancer (47). In fact, the Report’s characterization of the IARC (47) position does not agree with the IARC actual position. IARC states that “In the text, the Working Group provides comments on those findings that are of greatest relevance to the evaluation, e.g., risk in the overall exposed group, patterns of change in risk with increasing exposure (such as a monotonic increase in risk with increasing exposure), and changes in risk with duration of exposure or latency.” Furthermore, the Report ignores the fact that WHO considers microwave radiation to be a Class 2B carcinogen, and the Report also ignores the fact that four prominent reviews on this topic (48–51) all come to the conclusion that microwave exposures can cause cancer. It is apparent therefore that the Panel of Experts on Safety Code 6 has allowed its assumptions to greatly influence its assessment here, rather than providing an objective assessment of the literature.

There are complexities here that the Expert Panel fails to consider. For example, oxidative stress produced by microwave EMF exposure is likely to have a role in causation of cancer. For decades, it has been established that low level oxidative stress can lower oxidative stress markers below initial, pre-stress levels and protect the body from subsequent higher level oxidative stress, a phenomenon known as hormesis that has been recently shown to act by raising the activity of a transcriptional regulator, Nrf2; it has been suggested that this may explain some observations that low level cell phone use may lower cancer incidence via this mechanism, whereas higher level, long-term cell phone use may produce major elevation of cancer incidence. However, the Expert Panel apparently considers these studies to be conflicting, when to the contrary, these studies may raise the issue of biological complexity and a possible U- or J-shaped dose-response curve.

Another even clearer example where inferences of “inconsistencies” or “conflicts” in the literature have been misconstrued regarding the induction of single strand breaks in cellular DNA, measured by what are known as alkaline comet assays, a well-documented method for such studies (1). This literature was reviewed by the author (1), who found 19 different studies where greatly elevated levels of such single strand breaks were found following exposure as well as eight studies where they were not found. However, in examining these studies in detail, it is clear that the differences can be easily explained. For instance, regarding *in vitro* studies of DNA damage, some of the studies have used different cell types and studied different microwave source EMFs. Thus adult lymphocytes appear relatively resistant to EMF, while neural stem cells are much more susceptible. Different cell types differ from one another in how many and what types of VGCCs may be present and they may differ as well in how the VGCCs are regulated and so may be expected to differ widely in terms of response. All of these studies were done using exposures that were well within current safety standards. Consequently, each of these 19 positive findings contradict the assumptions behind the current safety standards, assumptions that are being defended by the Expert Panel Report, but the Report ignores all of these studies. Moreover, in two of the 19 positive studies, results were positive in some cell types but not others (1), clearly showing that in measurements using identical methodologies, the properties of the cells being studied are critical in determining the biological response found.

Thus the Panel has failed to take into account important nuances regarding scientific research in this field. It has limited considerations to what the Panel calls

“established health effects” defined in terms of consistent responses of various cell and tissue types (44). Where apparent conflict exists, the Panel uses its existence as proof that an effect is not established. In doing so, the Panel fails to take into account scientific details that account for many “inconsistent” results. Such details are likely to include, in addition to the factors discussed above in this section, such factors as the role of different pulsation patterns in different types of exposures, the presence of “window effects” providing very complex dose-response relationships and the role of field frequencies in determining biological response. In effect, the panel dismisses science that does not comport with their underlying assumptions that only thermal effects are relevant.

## Genotoxicity of non-thermal microwave exposures: examples of inconsistency?

This inconsistency issue is central to the Report’s consideration of genotoxicity of non-thermal microwave exposures. This is one of the two areas (pp. 80–82) where the Report cites substantial numbers of primary citations (22 in this case). It lists 13 citations where studies found genotoxicity following exposure levels, well within safety standards. It also lists nine citations where the Report states that no genotoxic effect was found. The Report only cites a small fraction of the overall literature on genotoxicity. For example, it only cites one of the 19 studies reviewed earlier by the author (1) on induction of single strand DNA breaks in microwave frequency exposed cells [that of Kesari et al. (52)]. In overall outline, the literature cited in the Report on this topic reflects fairly well this overall much larger literature. There are, however, a number of ways in which the Report is problematic in dealing with this subject. The author has looked up all 22 of these studies to determine from the original papers what the original authors stated.

Scientists often look at genotoxicity because of its importance in carcinogenesis and this section of the Report is part of a larger section on carcinogenesis. However, the Panel of Experts nowhere considers that many of the authors of these studies discuss their own work as strengthening the case that such fields are carcinogenic. A second connection, to male infertility, is also hidden in the report. Two of the positive studies (53, 54) are falsely stated in the Report as being on blood formation but what was actually being studied

in both of these studies was testicular sperm formation. The positive study Liu et al. (55) which shows genotoxicity in a spermatocyte cell line may also have implications regarding male infertility, because of the cell type being studied. There is also a connection with male infertility of one of the negative studies (56). This study of effects of mobile phones, found no genotoxic effects on human sperm, but the same group published two earlier studies showing that other EMFs had substantial effects that suggested lowered fertility as a consequence of exposure. The Report cited the Falzone et al. (56) study but not the two earlier studies. Perhaps this is an overreaction, but the Report seems to be hiding studies providing substantial support for the view that these EMFs can substantially impact male fertility and also hiding the implications of many of these studies on carcinogenesis.

There are other aspects of this section that are problematic. The Report listed the Franzellitti et al. (57) study as a negative one but it is not; it reports increased single strand DNA breaks as measured by alkaline comet assays following exposure. The Report accurately lists the Bourthoumieu et al. (58) study as being negative, but that study cites other studies by the same research group using other cell types as being positive; these positive studies are not cited or discussed in the Report. Similarly, the Report correctly lists two studies by Zeni, Sannino and their colleagues as being negative for apparent genotoxicity; however, this same research group published 6 additional studies, with three showing positive effects, depending on the cell type being studied. The Xu et al. (59) study found genotoxicity in two cell types but not in four other cell types. These studies clearly show that different types of cells respond differently to low level microwave exposures, but for some reason, the Panel of Experts seems unable to draw this very important conclusion. The cell type differences are discussed above in relation to the role of VGCCs in producing single strand breaks in cellular DNA (1). Another problematic aspect of this part of the Report, is that it lists seven of the 13 positive studies as studies providing evidence for “genotoxic or epigenetic” changes but none of those seven have anything to do with epigenetics.

We have here 13 (14 actually when the Franzellitti study is added) studies each of which provide clear evidence for genotoxic activity of non-thermal microwave fields and each of which therefore falsify the heating/thermal hypothesis underlying the Report and also falsify current safety standards. Therefore, based on widely accepted scientific standards, the heating/thermal hypothesis and the safety standards should be rejected.

What conclusion does the Panel draw? It concludes that “Extensive in vitro studies have generated inconsistent evidence that RF energy has genotoxic or epigenetic potential”. There is, however, no inconsistent evidence whatsoever. When one studies different cell types, different fields with different pulsation patterns, and different end points, even an elementary understanding of biology argues that different results are likely to be obtained. This section of the Report makes very clear on what basis the Panel is inferring “inconsistency”. The authors of the Report are simply looking at superficial similarities of studies and falsely inferring that differences should be interpreted as “inconsistencies” or “conflicts”, when they are not inconsistent or conflicting at all. The only type of studies that can produce clear evidence of inconsistency are identical studies that produce different results. Neither the Report nor, to my knowledge, its predecessors have provided any examples of such identical studies. Because this inconsistency argument underlies so much of the Report, one can see that this argument and the Report and also the current safety standards are each deeply flawed.

## Karl popper and how to assess scientific evidence

What is the responsibility of the Expert Panel as a group of scientists attempting to produce a scientifically defensible Report? Probably the most influential work on this topic comes from the famous philosopher of science Karl Popper. In his work, *Conjectures and refutations*, Popper argues that scientific hypotheses cannot be proven, but they can be falsified (60). Thus science is to be regarded as tentative information that can always be advanced through further research. Falsifying information, information that apparently falsifies a theory, is the most important type of scientific information and needs therefore to be considered very carefully. The next more important type of evidence is what he calls “risky predictions” where one makes a prediction based on a hypothesis, a prediction that is not likely to be made based on any other unrelated hypothesis. Confirmation of such a risky prediction provides substantial support whereas lack of confirmation can again lead to falsifying the hypothesis. Finally, there are confirmatory evidence studies where multiple hypotheses may explain any confirmation and consequently such confirmation is of low scientific significance.

When considered against the Popperian framework, all of the evidence supporting the heating/thermal

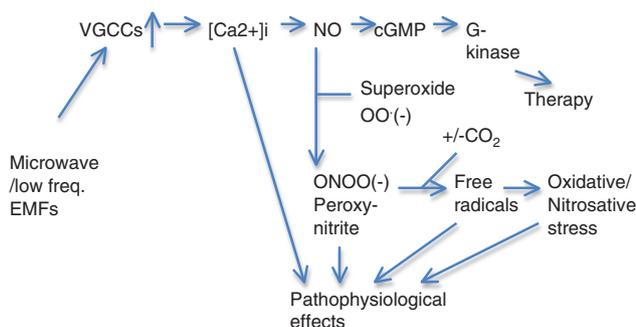

hypothesis, favored by the Expert Panel (44) is of the third type. It is widely established therefore that a scientific assessment of this area needs to consider in detail each apparently falsifying study and unless each of them can clearly be shown to be deeply flawed, the inference that should be drawn is that the heating hypothesis should be rejected. This rejection is the one aspect of this that may need to be modified in biology, given the inherent complexity of biology. It is possible that rather than rejection, the hypothesis needs instead to be modified in such a way that the information no longer falsifies the new hypothesis. However, in this situation where perhaps thousands of such modifications may be needed because of thousands of apparent falsifying studies, the difference in practice from outright falsification by each study may be trivial. It is clear, in any case that the Expert Panel has completely avoided doing its scientific duty here, failing to assess each of the thousands of apparent falsifying studies, and opting instead, as seen above, to make specious arguments. That is tragic, in my view, failing to protect the health of many Canadians, and indeed others around the world.

## Some other aspects

Most of the Report is focused on their heating/thermal interpretation of microwave radiofrequency effects (44). That is, perhaps, not surprising. What is however very surprising, is that having made such a fetish out of the “inconsistencies” in dealing with various topics, nowhere does the Expert Panel consider in this very large section of the Report, the thousands of findings that clearly conflict with their own favorite hypothesis. What sections of data should be thrown out that may be relevant to this section? The Panel of Experts seem to be completely oblivious that if in its view “inconsistencies” are sufficient to throw out many studies in one area, it should have at least a little consistency in dealing with “inconsistencies” in the heart of their own Report.

In the first paragraph in the conclusion section, the Panel of Experts state that (44) “No viable biophysical mechanism has been proposed for carcinogenic effects for exposure below the levels of SC6 that are supported by results in experimental systems,” citing three earlier studies but neglecting to consider the VGCC mechanism of microwave EMF action. The VGCC mechanism is clearly a viable biophysical mechanism, because of the properties of the voltage sensor located in the plasma membrane. VGCC activation produces downstream effects including [Ca<sup>2+</sup>]<sub>i</sub> elevation, NO elevation and peroxynitrite/oxidative stress/

free radical elevation (1–3), see Figure 1. It has been shown that NO and peroxynitrite/oxidative stress/free radical elevation are central to the mechanism of inflammatory carcinogenesis (61–64), the type of carcinogenesis that occurs in chronically inflamed tissues and therefore causes cancer in such tissues. It follows that it is biophysically and physiologically plausible, that microwave caused VGCC activation may cause cancer via the same mechanisms shown to cause cancer in inflammatory carcinogenesis. It has also been shown that free radicals formed through Compton scattering by ionizing radiation have essential roles in ionizing radiation carcinogenesis (65–67), providing probable mechanistic similarities between microwave EMF carcinogenesis and ionizing radiation carcinogenesis, as well. There have been many arguments made by the advocates of the heating/thermal mechanism of action, emphasizing the correct fact that the individual microwave photons have insufficient energy to perturb the chemistry of our bodies and they infer from this that these photons cannot cause cancer or many other pathophysiological responses. But what the Panel of Experts and others fail to realize is that the microwave fields as a whole, acting through downstream effects of VGCC activation, lead to high densities of intracellular free radicals (Figure 1) and can produce therefore similar effects on the body to those produced by ionizing radiation exposure. In any case, it follows from this paragraph, that the statement, in the Report, that there is

**Figure 1:** Mechanisms of action for microwave EMFs leading to diverse pathophysiological responses and therapeutic responses. Microwave/lower frequency electromagnetic fields (EMFs) act to stimulate voltage-gated calcium channels (VGCCs), increasing levels of intracellular calcium  $[Ca^{2+}]_i$ . Elevated  $[Ca^{2+}]_i$  increases nitric oxide (NO) synthesis which can act along two pathways. The NO signaling pathway, raises cyclic GMP (cGMP) levels and G-kinase activity, producing therapeutic effects. In the other pathway of action of NO reacts with superoxide to form peroxynitrite  $[ONOO(O)]$ , which either before or after reaction with carbon dioxide ( $CO_2$ ) can break down to form free radicals, producing oxidative/nitrosative stress. The excessive calcium signaling produced by  $[Ca^{2+}]_i$  and the peroxynitrite/free radical/oxidative stress pathway each contribute to pathophysiological responses.

no viable biophysical mechanism for low level microwave exposure to cause cancer or other diseases is false, with that falsehood apparently based on the failure of the Panel of Experts to consider the information provided to the panel by the author (Refs. 1 and 3).

This issue of biophysical plausibility of a mechanism for such low intensity exposures is a terribly important one. In the Report, there is a quote from a 2009 Health Canada document, which authors of the Report essentially adopt as their own [p. 78, ref. (44)]; “At present, there is no scientific basis for the occurrence of acute, chronic and/or cumulative adverse health risks from RF field exposure at levels below the limits outlined in Safety Code 6. The hypothesis of other proposed health effects occurring at levels below the exposure limits in Safety Code 6 suffer from lack of evidence of causality, biological plausibility and reproducibility and do not provide a credible foundation for making science-based recommendations for limiting human exposures to lower-intensity RF fields (Safety Code 6).” Whether or not this was a defensible position in 2009, it clearly is not defensible in 2014. This issue of biological/biophysical plausibility is a key one in considering various types of epidemiological evidence, such as were considered in the Report, whenever the role of such stressors in initiating disease is being considered based on studies of groups of people. Hennekens and Buring (68), on p. 40 in their textbook *Epidemiology in Medicine* state “The belief in the existence of a cause and effect relationship is enhanced if there is a known or postulated biologic mechanism by which the exposure might reasonably alter risk of developing disease.” Consequently, all of the epidemiological evidence considered in the Report and elsewhere needs to be reconsidered in the light of the biophysical and physiological plausibility of the VGCC mechanism and downstream effects produced by VGCC activation.

## Cataract formation as claimed effects of microwave-caused heating

The Report presents a fairly extensive specific case, arguing that microwave exposure produced cataract formation is produced by their heating/thermal mechanism (44). Unlike most other areas of the Report, the Panel considers substantial amounts of the primary literature on this topic. The studies discussed, provide evidence for the third and weakest test, according to Karl Popper’s analysis

(60), namely that the exposures studied are mostly within the range that produce substantial tissue heating and may therefore produce both cataracts and lens opacification via heating. This type of evidence is considered to be the weakest of the three types of evidence in Popper's schema, because alternative mechanisms are not in any way ruled out.

What is interesting is that there are three published studies which argue strongly against a heating mechanism for cataract formation by microwave exposures. One of these, a study by Cleary and Mills (69), showed that in comparison with other treatments raising lens temperatures, microwave radiation "appears to exert a unique component of thermal stress in the induction of opacification in the mammalian lens," arguing against a strictly thermal mechanism. Two studies have been published testing in effect the "risky prediction" that microwave-induced cataracts are produced by heating. One of these showed that neither eye-localized or whole-body hyperthermia to 42° produced any cataract-like opacity in the rabbit (70). The other showed that localized eye heating in the rabbit, producing the same temperature for the same duration as cataractogenic microwave exposures, produced no opacity in the rabbit eye (71). Both of these "risky predictions" failed to confirm the prediction and strongly suggest falsification of the hypothesis that microwave-induced cataracts are produced through heating. What is particularly disturbing about the Report is that it fails to cite any of these three studies (44) despite the fact that each of them has been cited by others in this context, according to the Google Scholar database. Clearly, the literature the Expert Panel cites regarding cataract formation, which includes the second most extensive primary literature in the Report, does not provide an objective assessment of the scientific literature in this area.

In contrast to studies discussed in the previous paragraph, the equally "risky prediction" that VGCCs and excessive  $[Ca^{2+}]_i$  have roles in such cataract formation have produced validation of the hypothesis that microwave-induced VGCC activation causes cataracts. Walsh and Patterson (72) demonstrated that elevated  $[Ca^{2+}]_i$  in the lens of the frog eye has a central role in cataract formation and that calcium channel blockers, which of course block VGCC activation, can block cataract formation. In a recent review, it was shown that excessive  $[Ca^{2+}]_i$  in the lens of the human and mammalian eye plays a major role in the opacification process producing cataracts and that VGCCs can have a substantial role in this process (73). While these studies do not directly relate to microwave exposures, they clearly show that excessive  $[Ca^{2+}]_i$  in the lens of the eye has essential roles in cataract formation

and that excessive VGCC activity causes cataract formation in experimental animals. Much of the action of  $[Ca^{2+}]_i$  in cataract formation has been shown to occur through the action of several calcium receptors that act independently of NO. However, there is also an established role of oxidative stress in cataract formation, and it is thought that peroxynitrite also has a role because of the elevation of a marker for peroxynitrite, 3-nitrotyrosine in cataracts (74). It is likely therefore that microwaves act to produce cataracts via calcium signaling as well as via downstream effects involving peroxynitrite and oxidative stress (see Figure 1). The difference in confirmation of these "risky predictions" clearly shows that the VGCC/ $[Ca^{2+}]_i$  role in producing cataracts is far better documented than any possible heating role.

It can be seen from the above, that although the Canadian Panel of Experts seems to argue that cataract formation is the strongest example of a strictly thermal EMF response (44), the case for such a thermal mechanism is to the contrary extremely weak. Their case is totally dependent on ignoring both evidence that falsifies their view and also evidence that confirms "risky predictions" of the VGCC mechanism that is ignoring the two strongest types of evidence. Thus the claimed role for heating being the cause of cataract formation following microwave exposure, advocated by the Expert Panel, has now been apparently debunked.

## Summary of the report

In summary, then each of the following failures in the Report can be seen to be important in our rejecting its conclusions:

- It fails to individually assess the thousands of studies that provide evidence apparently falsifying their heating/thermal paradigm. By failing to assess studies containing this most important type of evidence, as shown by Popper (60), this failure provides more than sufficient reason to reject the conclusions of the Report.
- The Report fails to provide any "risky prediction" type evidence (the second most important type of evidence) in favor of the heating/thermal hypothesis, but such risky predictions are available supporting the VGCC mechanism of action.
- The Report bases its conclusion on the weakest type of evidence, evidence that some responses could be generated by heating but does not rule out other types of mechanisms. A close examination of what the Expert Panel considers to be the strongest case for heating,

- that of cataract formation, shows that this is another example of a probable VGCC mechanism, not heating.
- The Report repeatedly fails to provide an objective assessment of the scientific literature. Because omitted citations consistently have the effect of weakening their position, it seems unlikely that these omissions are just coincidental.
  - The Report claims that there is no biophysically viable alternative to the heating/thermal paradigm, a claim clearly shown here to be false.
  - The Report claims extensive inconsistencies (what others have called conflicts) occur in the literature, where what it considers “similar” studies produced different results and it uses these claims of “inconsistencies” to throw out large amounts of the literature. However, these “similar” studies are in fact, dissimilar, differing in cell type being studied, the properties of the fields being studied and/or the end point being studied, with each of these having demonstrated roles in determining outcome. It follows that the Report provides no evidence for any such “inconsistencies.” Any claims of such “inconsistencies” are at best undocumented.
  - The Report fails to use its own inconsistency argument (6 above) in the heart of the report, the part that argues for a heating/thermal mechanism, thus failing to be consistent in its own treatment of this issue.
  - The Report fails to give the reader enough information in the Report itself or in the citations provided to allow the reader to assess its scientific merit.

The author is aware that similar flaws to those described immediately above occur in earlier studies arguing for the heating/thermal/SARs mechanism (9–13). But that only emphasizes the fact that this whole point of view has been on extraordinarily weak ground all along. That makes it crucially important that safety standards on which the health of most Canadians and indeed, most people around the world are dependent, be examined in scientifically defensible ways.

It is perhaps surprising that the case developed by the Panel of Experts is so weak. That is especially so because industry-funded research has been skewed in support of the heating/thermal interpretation (45, 46), so one would think that with a lot of industry-supported research, the Expert Panel would have come up with some stronger evidence.

Let me say that it is my opinion that the Panel of Experts may not have been corrupted by industry influence, but rather it may have fallen victim to a common affliction, that of groupthink. Groups of people each

carrying misconceptions in common, act to encourage their common misconceptions in other members of the group. What was apparently lacking in the Panel of Experts was someone who could challenge those misconceptions, rather than encourage them. However the “logic” presented in the Report provides industry with a strategy to indefinitely prevent any true scientific standards from being used to assess safety. Industry need only fund research that ends up making “inconsistent” conclusions, thus allowing all independently funded studies to be thrown out because of these “inconsistencies” and thus indefinitely preventing adoption of safety standards based on genuine, independent science. It is my hope and expectation that this was not the goal of the Expert Panel, but it is nevertheless an apparent consequence of their Report, if it is viewed as being scientific.

Still, it can be argued, that the Panel of Experts has perhaps unwittingly fulfilled a very valuable function. By clearly showing how weak their case is in 2014, the Panel has shown that none of the more recent evidence has substantially strengthened their case. It is still based on a false premise (biophysical implausibility of alternative mechanisms) and circular reasoning, it is still based on the failure to consider large numbers of apparent falsifying studies, it is still based on ignoring large amounts of the relevant literature and it is still based on the failure to provide the most well supported types of evidence needed to establish biological mechanisms in medicine, just as was true earlier (9–13). Of course, the weakness of the Panel’s case means that the current safety standards are based on quicksand.

## How VGCC activation by microwave/ RF exposure can produce a variety of important biological responses

Table 1 summarizes how VGCC activation may plausibly produce a wide range of reported responses to microwave and, in some cases, lower frequency EMF exposures. It can be seen that a wide range of reported responses to low level microwave exposures can apparently all be understood as being a consequence of VGCC activation and downstream effects of such activation that were outlined in Figure 1. These can all be seen as “risky predictions” of the VGCC activation mechanism produced by EMF exposures. While these mechanisms support the inference that all of these effects seem to be produced by VGCC activation, that inference must be viewed as being surprising. After all,

**Table 1:** Apparent mechanisms of action for microwave exposures producing diverse biological effects (see Figure 1).

Reported biologic response	Apparent mechanism(s)	Citation(s)/Comments
Oxidative stress	Peroxynitrite and consequent free radical formation	(1–3); detected via a large number of oxidative stress markers
Single strand breaks in cellular DNA	Free radical attack on DNA	(1, 3)
Double strand breaks in cellular DNA	Same as above	Same as above; detected from micronuclei and other chromosomal changes
Cancer	Single and double strand breaks, 8-nitroguanine and other pro-mutagenic changes in cellular DNA; produced by elevated NO, peroxynitrite	This paper and (3)
Breakdown of blood-brain barrier	Peroxynitrite activation of matrix metalloproteinases leading to proteolysis of tight junction proteins	(3)
Male and female infertility	Induction of double strand DNA breaks; other oxidative stress mechanisms; [Ca <sup>2+</sup> ] <sub>i</sub> mitochondrial effects causing apoptosis; in males, breakdown of blood-testis barrier	(3)
Therapeutic effects	Increases in [Ca] <sub>i</sub> and NO/NO signaling	(1–3; 13)
Depression; diverse neuropsychiatric symptoms	VGCC activation of neurotransmitter release; other effects? possible role of excess epinephrine/norepinephrine (75)	These were reported in occupational exposures (22); also reported in people living near cell phone towers
Melatonin depletion; sleep disruption	VGCCs, elevated [Ca] <sub>i</sub> leading to disruption of circadian rhythm entrainment as well as melatonin synthesis	(3)
Cataract formation	VGCC activation and [Ca] <sub>i</sub> elevation; calcium signaling and also peroxynitrite/oxidative stress	This paper
Tachycardia, arrhythmia, sometimes leading to sudden cardiac death	Very high VGCC activities found in cardiac (sinoatrial node) pacemaker cells; excessive VGCC activity and [Ca <sup>2+</sup> ] <sub>i</sub> levels produces these electrical changes in the heart	(3)

although low level EMF activation of VGCCs is now well-documented, other possible direct targets of EMFs cannot be ruled out, targets that may produce changes that cannot be easily explained as being caused by VGCC activation and downstream effects of such activation. When the apparent mechanisms summarized in Table 1 are put together with the calcium channel blocker studies and other studies on widespread changes in calcium fluxes and calcium signaling following microwave EMF exposures, we are left without any alternative, non-VGCC target of EMF action that currently can be studied for its role in producing biological effects in humans.

## Biologically-based EMF safety standards

Hardell and Sage (76), the Scientific Panel on Electromagnetic Health Risks (77) and the author (3) have called for biologically-based EMF safety standards that are based on genuine biologically relevant responses to low-level microwave and other EMFs, rather than SARs. The only approaches we have available for this based on a known

biological end point, as shown in the previous section, are approaches based on VGCC activation. There are experimental whole animal approaches based on VGCC activation (3), but my feeling is that initial studies should focus on using cells in culture, cells that have high levels of some VGCCs. Some such studies would use cell lines with such high VGCC levels, such as neuroblastoma cell lines or perhaps cell lines derived from endocrine cells with relatively high VGCC levels. Among these cell lines should be the neuroblastoma cell lines previously studied by Dutta et al. (78) and shown to produce changes in calcium fluxes in response to very low level EMF exposures. PC12 cells, a commonly used chromaffin cell line should also be considered for such studies. In addition, it may useful to use cardiac pacemaker cells which have very high activities of VGCCs (35) and can be derived from stem cells (79).

Two approaches suggest themselves for measuring responses of such cells to EMF exposure: Cells in culture could be monitored for NO production using an NO electrode in the gas phase over the culture, both before and following EMF exposure. This approach was used by Pilla in studying effects of pulsed microwave fields (4) in trying to understand the mechanism of microwave therapy. Pilla found that the NO increase in such cultures on EMF field

exposure was almost instantaneous, using a NO electrode in the gas phase (4). With this sort of approach, many different fields can be quickly and easily studied for their ability to produce NO increases, including different frequencies, pulsation patterns and possibly intensities, with the last of these needed to analyze window effects. Different cordless communication devices can be compared for activity using several cell types. Continuous measurements from an NO electrode can be recorded and easily quantified, allowing accumulation of very large amounts of data in very short time periods. Therefore, issues such as reproducibility should be quickly resolved. One might even be able to determine whether previous exposures produce increased sensitivity to exposure, possibly developing a cell culture model of electromagnetic hypersensitivity.

Another approach to such studies involves using calcium-sensitive fluorescent probes that concentrate into the cytoplasm of cells, allowing assessments of [Ca]<sub>i</sub> levels with a fluorescence microscope. This may allow one to obtain information of different types than described in the previous paragraph. One can get information on heterogeneity of responses at the cellular level and also how raised [Ca]<sub>i</sub> levels may propagate over time from one part of the cell to another. However, a limitation to this approach may occur if the fields generated by the microscope perturb the [Ca]<sub>i</sub> levels and cannot be well shielded using a small Faraday cage that does not cage exposures that are to be studied. It is also true that the NO electrode studies are easier to quantify than such fluorescent probe studies. So these two approaches are distinct from one another and whether they will complement each other as they develop is uncertain. It is my view that both of these should be investigated if only to explore their strong points and weak points but that the NO electrode approach may be a very good place to start because it has already been used to assess EMF effects (4) and because it allows easy quantification.

## Brief overview

Havas' recent review (80) discusses 14 different documents prepared by international scientists (dated 2002 through 2012) expressing deep concern about various non-thermal effects of microwave radiation exposures and other studies have expressed similar views. W.R. Adey's papers (6, 21) reviewed much of the then current evidence for many non-thermal effects of microwave radiation. But his prescience is most clearly shown by his statement that

“Collective evidence points to cell membrane receptors as the probable site of first tissue interactions with both extremely low frequency and microwave fields for many neurotransmitters, hormones, growth-regulating enzyme expression, and cancer-promoting chemicals. *In none of these studies does tissue heating appear to be involved causally in the responses*” [italics added, from a talk at the Royal Society of Physicians, London May 16–17, 2002, quoted in ref. (81)]. The recent Herbert and Sage review (81) discusses “the emergence of ever larger bodies of evidence supporting a large array of non-thermal but profound pathophysiological impacts of EMF/RFR in transforming our understanding of the nature of EMF/RFR impacts on the organism.” In a second paper (82), Herbert and Sage state that “Our EMF/RFR standards are also based on an outdated assumption that it is only heating (thermal injury) which can do harm. These thermal safety limits do not address low-intensity (non-thermal) effects. The evidence is now overwhelming that limiting exposure to those causing thermal injury alone does not address the much broader array of risks and harm now clearly evident with chronic exposure to low-intensity (non-thermal) effects.” The Khurana et al. review (83) states: “The authors reviewed more than 2000 scientific studies and reviews, and have concluded that: (1) the existing public safety limits are inadequate to protect public health; (2) from a public health policy standpoint, new public safety limits on further deployment of risky technologies are warranted based on the total weight of evidence. A precautionary limit of 1 mW/m<sup>2</sup> was suggested ...” The Scientific Panel on Electromagnetic Field Health Risks listed four well-documented central conclusions at the beginning of their publication (77):

- Low-intensity (non-thermal) bioeffects and adverse health effects are demonstrated at levels significantly below existing exposure standards.
- ICNIRP and IEEE/FCC public safety limits are inadequate and obsolete with respect to prolonged, low-intensity exposures.
- New biologically-based public exposure standards are urgently needed to protect public health worldwide.
- It is not in the public interest to wait.

Canadian Panel of Experts do not cite these papers or others providing clear and focused views that contradict the views advocated in the Report, showing again that the Report fails to provide an objective assessment of the scientific literature. The current paper adds a number of specific considerations to the needed debate:

- VGCC activation produces most, possibly even all microwave and lower frequency EMF health-related

responses. Each of the studies on VGCC activation or on changes in calcium fluxes and signaling following low level exposure clearly falsifies the thermal/heating paradigm.

- This VGCC activation mechanism by low level microwave and lower frequency fields, rather than individual photons, is biophysically plausible based on the special properties of the voltage sensor and its localization to lipid region of the plasma membrane.
- Downstream effects of VGCC activation (Figure 1) can generate each of 13 different health effects repeatedly found to be produced by microwave exposure (Table 1).
- Studies document roles of pulsation in influencing biological responses to microwave exposures, influences that are incompatible with these being produced by heating.
- “Window” effects occur, where specific intensities of microwave EMF exposure produce higher biological effects than those produced by both lower and higher intensities, observations incompatible with heating effects.
- Thousands of studies have reported biological effects at intensities well within safety standards, each of which appear to falsify the heating/thermal paradigm, none of which have been considered in this light by the Panel of Experts, despite the scientific requirement to do so under well-accepted scientific principles.
- The claims in the Report that microwave induction of cataracts is produced by heating has been tested in three studies, each contradicting this claim; two of them produce clear falsification, but none of these three studies are cited in the Report. Because VGCC activation can cause cataracts and elevated  $[Ca^{2+}]_i$  has essential roles in producing cataracts, a VGCC mechanism for microwave-induced cataracts is much more strongly supported than is the claimed heating mechanism.
- The claim in the Report of widespread “inconsistency” in the literature is tested here through examination of the literature cited on genotoxic effects. No inconsistencies were found in this literature despite the Report claiming such. Furthermore, no identical studies are cited anywhere in the Report showing inconsistency of results, these being the only types of studies that can clearly show inconsistency. Claims of widespread “inconsistency” or “conflict” in the literature must be viewed as, at best, undocumented.
- Each of the 8 considerations listed immediately above clearly show that the Report fails to provide anything

resembling an objective assessment of the evidence on biological effects of microwave EMF exposures and provides therefore no scientifically valid support for Safety Code 6, ICNIRP or other current safety standards.

- Development of biologically-based safety standards has been called for and approaches to using cell culture-based tests that may be used to develop such safety standards are discussed.

It has been clear for a long time that the heating paradigm is indefensible and that a new paradigm is much needed. We now have that with VGCC activation, and while VGCC activation may not be the entire story behind the biological actions of such EMFs in humans and other mammals, it clearly is most of the story. It is time therefore for a paradigm shift away from strictly thermal effects and toward a central role for VGCC activation in the cellular response to microwave and lower frequency EMFs.

**Acknowledgments:** I wish to thank Dr. Devra Lee Davis for her many helpful suggestions. Any remaining errors in this are, of course, my own. This paper is dedicated to the memory of W. Ross Adey (1922–2004) whose studies in this area were impressively prescient – someone I regret never meeting.

## **Introduction to the United Nations EMF Appeal Delivered by Martin Blank, PhD, Department of Physiology and Cellular Biophysics, Columbia University**

I'm here with disturbing news about our favorite gadgets: cell phones, tablets, wi-fi, etc. Putting it bluntly, they are damaging the living cells in our bodies and killing many of us prematurely.

I'm Dr. Martin Blank, from the Department of Physiology and Cellular Biophysics at Columbia University.

It is distressing for me, and more than 160 colleagues, who today are petitioning the United Nations requesting that they address this problem.

We are scientists and engineers, and I am here to tell you - we have created something that is harming us, and it is getting out of control!

Before Edison's lightbulb, there was very little electromagnetic radiation in our environment. The levels today are very *many* times higher than natural background levels and are growing rapidly because of all the new devices that emit this radiation.

An example that a lot of us have in our pockets right now is the cell phone. One study shows that as cell phone usage has spread widely, the incidence of fatal brain cancer in younger people has more than tripled.

We are putting cellular antennas on residential buildings, and on top of hospitals, where people are trying to get well.

Wireless utility meters, and cell towers, are blanketing our neighborhoods with radiation.

It's particularly frightening that radiation from our telecommunication and powerline technology is damaging the DNA in our cells. It is clear to many biologists that this can account for the rising cancer rates.

Future generations - OUR CHILDREN - ARE AT RISK.

These biologists and scientists are not being heard on the committees that set safety standards. The BIOLOGICAL facts are being ignored, and as a result, the safety limits are much too high. THEY ARE NOT PROTECTIVE!

More protection will probably result from full disclosure of possible conflicts of interest between regulators and industry.

Rising exposure to electromagnetic radiation is a GLOBAL problem. The World Health Organization and international standard setting bodies are not acting to protect the public's health and well-being.

International exposure guidelines for electromagnetic fields must be strengthened to reflect the reality of their impact on our bodies, and in particular, on our DNA.

Although we are still in the midst of a great technological transformation, the time to deal with the harmful biological and health effects is long overdue.

We are really all part of a large biological experiment, without our informed consent.

To protect our children, ourselves, and our ecosystem, we must reduce exposure by establishing more protective guidelines.

And so, today, scientists from around the world are submitting an Appeal to the United Nations, its member states and the World Health Organization, to provide leadership in dealing with this emerging public health crisis.

Details of The Appeal can be found at **[EMFScientist.org](http://EMFScientist.org)**

[57] **ABSTRACT**

A silent communications system in which nonaural carriers, in the very low or very high audio frequency range or in the adjacent ultrasonic frequency spectrum, are amplitude or frequency modulated with the desired intelligence and propagated acoustically or vibrationally, for inducement into the brain, typically through the use of loudspeakers, earphones or piezoelectric transducers. The modulated carriers may be transmitted directly in real time or may be conveniently recorded and stored on mechanical, magnetic or optical media for delayed or repeated transmission to the listener.

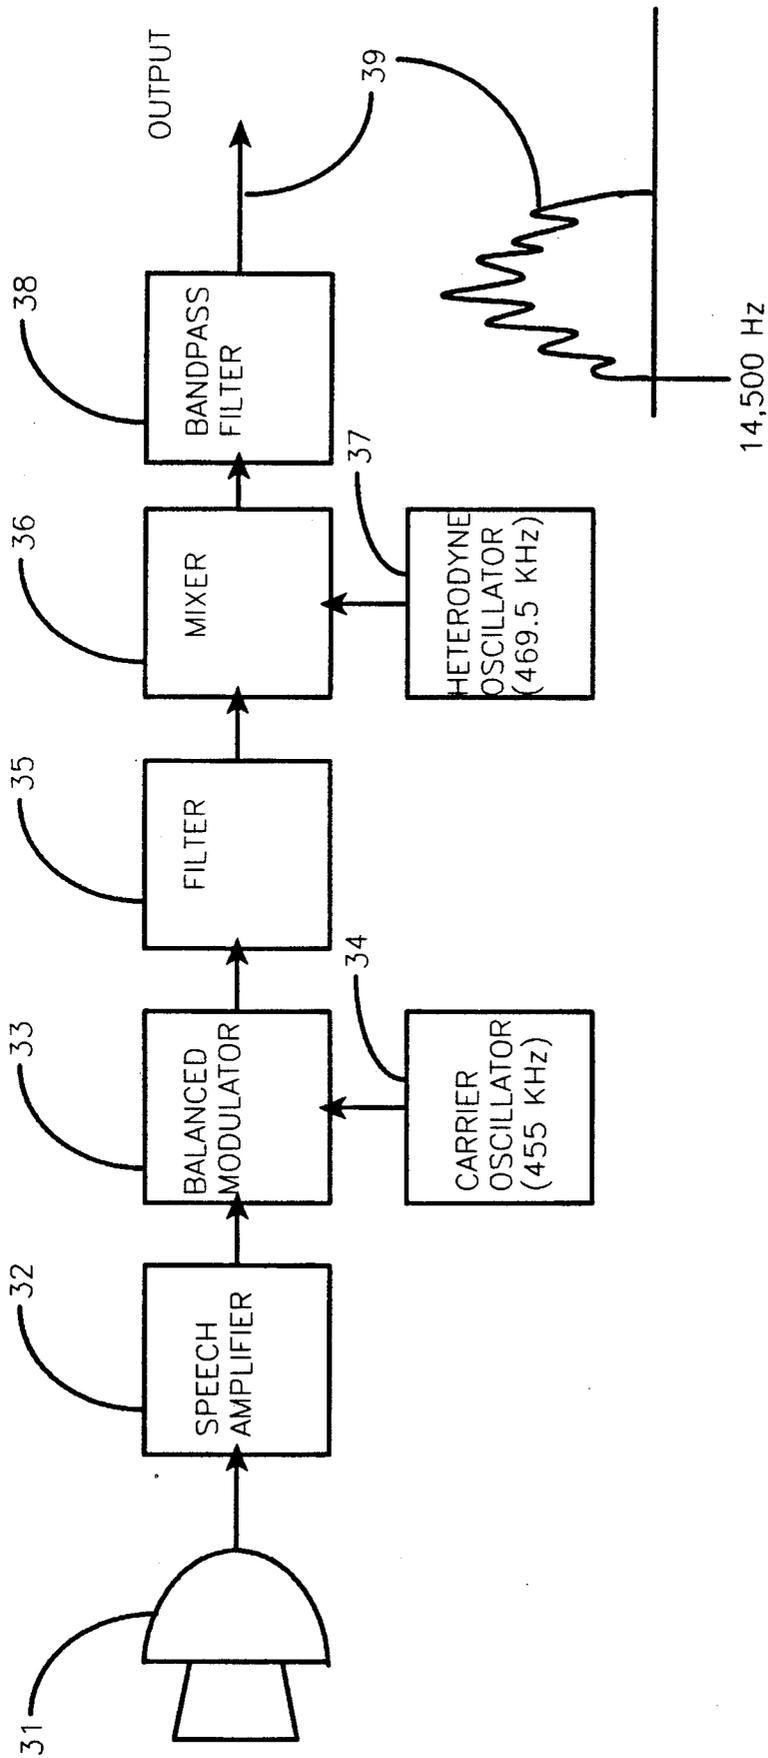

FIG. 3

## SILENT SUBLIMINAL PRESENTATION SYSTEM

### BACKGROUND—FIELD OF THE INVENTION

This invention relates in general to electronic audio signal processing and, in particular, to subliminal presentation techniques.

### BACKGROUND—DESCRIPTION OF PRIOR ART

Subliminal learning enjoys wide use today and subliminal tapes are being manufactured by a number of companies in the United States alone. Several decades of scientific study indicate that subliminal messages can influence a human's attitudes and behavior. Subliminal, in these discussions, can be defined as "below the threshold of audibility to the conscious mind." To be effective however, the subliminally transmitted information (called affirmations by those in the profession) must be presented to the listener's ear in such a fashion that they can be perceived and "decoded" by the listener's subconscious mind. We are referring to audio information in this discussion, however, information could be inputted into the subject's subconscious mind through any of the body's sensors, such as touch, smell, sight or hearing. As an example, early development work in the subliminal field utilized motion pictures and slide projections as the medium. Early research into visual and auditory subliminal stimulation effects is exemplified by U.S. Pat. Nos. 3,060,795 of Corrigan, et al. and 3,278,676 of Becker. U.S. Pat. No. 4,395,600 of Lundy and Tyler is representative of later developments in today's subliminal message techniques.

The majority of the audio subliminal tapes available today are prepared using one basic technique. That is, the verbal affirmations are mixed with, and recorded at a lower level than, a "foreground" of music or sounds of ocean surf or a bubbling mountain brook or other similar "masking" sounds. The affirmations are generally recorded 5 decibels (db) or so below the "foreground" programming and regenerative automatic gain control is usually applied to permit the affirmations to change their recorded amplitude in direct proportion to the short term averaged amplitude of the continually varying "foreground" material. In other words, the volume of the affirmations will follow or track the volume changes of the "foreground" programming, but at a lower volume level. Circuit provisions are also usually included to "gate" the affirmations off when the music amplitude is low or zero. This insures that the affirmations cannot be heard during quiet program periods. Thus, today's subliminal affirmations can be characterized as being "masked" by music or other sounds, of constantly changing amplitude and of being reduced or cut off entirely during periods of low or quiet "foreground" programming.

One of the principal, and most widely objected to, deficiencies in available subliminal tape presentation techniques is that the presence of the "foreground" material is intrusive to both the listener and to anyone else in the immediate area. No matter what "foreground" material is chosen, the fact remains that this material can be heard by anyone within its range and presents a definite distraction to other activities such as conversation, thought, desire to listen to other programming such as radio or television, need to concentrate, etc. Additionally, and because the tapes are used repeatedly by the same listener, any "foreground"

music or material eventually becomes monotonously tiring to that listener.

It is the purpose of the following described invention to eliminate or greatly reduce all of the above deficiencies. Although its application to the magnetic tape medium is described in the following discussion, the technique is equally applicable to most other desired transmission mediums, such as Compact Disc, videocassettes, digital tape recorders, Public Address (PA) systems, background music installations, computer software programs, random access memory (RAM), read only memory (ROM), "live", real time applications and other mediums now in existence or to be developed in the future.

Implemented on tape cassettes, for example, the subliminal presentation described here is inaudible i.e., high audio or ultrasonic frequencies, the affirmations are presented at a constant, high amplitude level, and they occupy their own "clear channel", non-masked frequency allocations. If desired, the previously described "foreground" music or other material can be added to the tape through use of an audio mixer. The "silent" recordings are inaudible to the user or by others present and are therefore very effective for use during periods of sleep or when in the presence of others. Additionally, the basic requirements of subliminal stimulation are met. That is, the affirmations are efficiently transmitted to the ear and, while undetected by the conscious mind, are perceived by and efficiently decoded by the subconscious mind.

### OBJECTS OF THE INVENTION

Accordingly, several objects and advantages of my invention are:

(a) to provide a technique for producing a subliminal presentation which is inaudible to the listener(s), yet is perceived and demodulated (decoded) by the ear for use by the subconscious mind.

(b) to provide a technique for transmitting inaudible subliminal information to the listener(s) at a constant, high level of signal strength and on a clear band of frequencies.

(c) to provide a technique for producing inaudible subliminal presentations to which music or other "foreground" programming may be added, if desired.

Still further objects and advantages will become apparent from a consideration of the ensuing description and drawings.

### BRIEF DESCRIPTION OF THE DRAWINGS

In the drawings, the first digit of each component number also refers to the figure number where that component can be located.

FIG. 1 represents the block diagram of a suitable system which will generate a frequency modulated (FM) signal at 14,500 Hz.

FIG. 2 represents an approximation of the frequency response curve of the human ear and the signal decoding process.

FIG. 3 represents the block diagram of a suitable system which will generate a single sideband, suppressed carrier, amplitude modulated (AM) signal at 14,500 Hz.

### REFERENCE NUMERALS IN DRAWINGS

## REFERENCE NUMERALS IN DRAWINGS

audio input signal	audio oscillator
12 audio preamplifier if required	15 high pass or band pass audio filter
13 frequency modulation circuit	16 output to tape recorder or other device
21 point on low freq end response curve	25 midpoint on curve between points 23 and 24
22 point on low freq end of ear response curve	26 speaker output of FIG. 1 to ear
23 point on high freq end of ear response curve	27 demodulated subliminal audio inputted to ear
24 point on high freq end of ear response curve	31 microphone
32 speech amplifier	33 balanced modulator
34 carrier oscillator (455 KHz)	35 filter
36 mixer	37 heterodyne oscillator (469.5 KHz)
38 bandpass filter	39 output signal

## DETAILED DESCRIPTION OF A PREFERRED EMBODIMENT

Please refer now to FIG. 1 and FIG. 2, which are drawings of a preferred implementation of the invention.

The principle of operation of the silent subliminal presentation system is as follows:

An audio signal in the upper frequency region of the audio spectrum (for example, 14,500 Hz) is modulated with the desired information. The type of modulation may be any type suitable for subliminal applications; frequency modulation (FM), phase modulation (PM), upper single sideband with suppressed carrier, amplitude modulation (AM), tone modulation, etc.

For broadest application, the high audio frequency selected as the carrier frequency must meet two basic criteria:

(1) be high enough in the audio spectrum that its presence to the human ear is essentially unnoticed or undetectable (without the listener being informed that the signal is actually present) and,

(2) be low enough in the audio spectrum that it (and its modulation content) can produce a useful output power from home entertainment type cassette or reel-to-reel magnetic recorders.

This would also include, of course, small portable and automobile tape decks.

Alternatively, the output of the system can be fed directly into an audio amplifier and its speaker/earphone system, Public Address system, etc.

FIG. 1 provides the block diagram of an example of a system capable of generating the desired silent frequency modulated carrier.

The modulation information is inputted into the microphone 11. Other suitable input devices may be substituted for microphone 11, such as a tape recorder or a radio. The microphone 11 is connected to the preamplifier 12 and should have provisions for adjusting its gain in order that the optimum modulation index can be set in the frequency modulator 13. The frequency modulator 13 modulates the frequency of oscillator 14 which has been adjusted for an output of 14,500 Hz as described above. The output of oscillator 14 is fed through a suitable bandpass filter 15 into the tape recorder or directly into a suitable amplifier/speaker system. It is the purpose of the bandpass filter to remove or attenu-

ate audible products of the modulation process in order to maintain as audibly silent an output as practical.

On the receiving end, FIG. 2 represents an approximate and idealized frequency response curve of the human ear. The frequency modulated carrier (centered at 14,500 Hz), as generated above and played through a tape recorder or amplifier/speaker system, is shown on FIG. 2 as speaker output 26, impinging upon the upper slope of the ear's response curve at point 25. The frequency modulated excursions of the speaker output 26 swing between points 23 and 24 on the ear's upper response curve. Because the response curve between points 23 and 25 is relatively linear, this action results in a relatively linear demodulation of the original modulation intelligence, which is passed on subliminally to the inner ear. The amplitude of the demodulated output is not high enough to be detected by the conscious mind but is sufficient in amplitude to be detected by the sub-conscious mind. In the field of communications engineering design, the above demodulation process in known as slope detection and was used in early FM receiver design. In those receivers, the response curve was formed by the action of a tuned (inductive/capacitance) circuit. In our case, the response curve is formed by the natural response curve of the human ear. The same slope detection technique can be performed at the low frequency end of the human ear response curve. This region is indicated on FIG. 2 as between points 21 and 22. This region, however, has a much smaller available bandwidth and is therefore more restricted as to the amount of information that can be transmitted in an inaudible manner.

In practice, the listener adjusts the volume control of the tape recorder or amplifier to a level just below that at which the listener hears an audible sound or noise from the speaker of the tape recorder. If the recording process is properly done, a spectrum analyzer or a calibrated sound level meter will reveal a strong signal emanating from the tape recorder speaker. A calibrated sound level meter, at a distance of 1 meter (with C weighting and referenced to the standard of 0.0002 micro bar) will typically indicate a silent power output of from 60 to 70 decibels. This is equivalent to the audio power of a loud conversation, yet, in the described system, is inaudible or unnoticed by the listener.

FIG. 3 illustrates a system which generates a suitable amplitude modulated (AM) signal, instead of the frequency modulated (FM) system described above. The output is a modulated, single sideband (SSB), suppressed carrier (AM) signal at 14,500 Hz.

The block diagram represents a common scheme for generating an SSB signal and will be briefly described.

The desired subliminal information is spoken into microphone 31. This signal is amplified by speech amplifier 32 and injected into one port of balanced modulator 33. A continuous wave signal of 455 KHz is generated by carrier oscillator 34 and is injected into the second port of balanced modulator 33. The output of balanced modulator 33 is a double sideband, suppressed carrier signal at 455 KHz. This signal is fed through filter 35, causing one of the two sidebands to be removed. This signal is fed into one port of mixer 36. A continuous wave signal at a frequency of 469.5 KHz from heterodyne oscillator 37 is fed into the other port of mixer 36, resulting in an output of the original subliminal audio information but translated 14,500 Hz higher in frequency. The bandpass filter 38 attenuates signals and noise outside of the frequencies of interest. The ampli-

tude modulated audio output signal is shown as output 39.

Thus, as stated earlier, my invention provides a new system for subliminal presentations which is:

- (a) silent,
- (b) outputs a constant, high level modulated signal and,
- (c) occupies a band of clear channel frequencies.

The foregoing description of the preferred embodiment of the invention has been presented for the purposes of illustration and description. It is not intended to be exhaustive or to limit the invention to the precise form disclosed. Many modifications and variations are possible in light of the above discussions. It is intended that the scope of the invention be limited not only by this detailed description, but rather by the claims appended hereto.

What is claimed:

1. A silent communications system, comprising:

- (a) amplitude modulated carrier means for generating signals located in non-aural portions of the audio and in the lower portion of the ultrasonic frequency spectrum said signals modulated with information to be perceived by a listener's brain and,
- (b) acoustic and ultrasonic transducer means for propagating said signals, for inducement into the brain, of the listener, and,

(c) recording means for storing said modulated signals on mechanical, magnetic and optical media for delayed or repeated transmissions to the listener.

2. A silent communications system, comprising:

- (a) frequency modulated carrier means for generating signals located in non-aural portions of the audio and in the lower portion of the ultrasonic frequency spectrum, said signals modulated with information to be perceived by a listener's brain, and;
- (b) acoustic and ultrasonic transducer means for propagating said signals, for inducement into the brain of the listener, and;
- (c) recording means for storing said modulated signals on mechanical, magnetic and optical media for delayed or repeated transmissions to the listener.

3. A silent communications system, comprising:

- (a) a combination of amplitude and frequency modulated carrier means for generating signals located in non-aural portions of the audio and in the lower portion of the ultrasonic frequency spectrum, said signals modulated with information to be perceived by a listener's brain, and
- (b) acoustic and ultrasonic transducer means for propagating said signals, for inducement into the brain of the listener;
- (c) recording means for storing said modulated signals on mechanical, magnetic and optical media for delayed or repeated transmissions to the listener.

This document is the doctrine adopted by the Policy Committee of the Bilderberg Group during its first known meeting in 1954.

The following document, dated May 1979, was found on July 7, 1986, in an IBM copier that had been purchased at a surplus sale.

## Silent Weapons for Quiet Wars

<http://www.lawfulpath.com/ref/sw4qw/index.shtml> - preface

<http://www.lawfulpath.com/ref/sw4qw/>

The following document is taken from two sources. The first, was acquired on a website (of which I can't remember the address) listing as its source the book titled *Behold A Pale Horse* by William Cooper; Light Technology Publishing, 1991. The second source is a crudely copied booklet, which does not contain a copyright notice, or a publisher's name. With the exception of the Forward, the Preface, the main thing that was missing from the first source was the illustrations. As we began comparing the two, we realized that the illustrations, and the accompanying text (also missing from the first) made up a significant part of the document. This has now been restored by The Lawful Path, and so far as I know, is the only internet copy available complete with the illustrations.

We have no first-hand knowledge that this document is genuine, however many of the concepts contained herein are certainly reasonable, important, and bear strong consideration.

If anyone has additional knowledge about the source of this document; has better copies of the illustrations than the ones posted here; has any missing pieces to this document, or has any comments which can improve upon the quality of this document, we will appreciate your comments.

The Lawful Path <http://www.lawfulpath.com/>

Additional information includes confirmation that this policy was adopted by the International "Elites" at the first Bilderberg Meeting in 1954.

## **Forward**

This manuscript was delivered to our offices by an unknown person. We did not steal the document, nor are we involved with any theft from the United States Government, and we did not get the document by way of any dishonest methods. We feel that we are not endangering the "National Security" by reproducing this document, quite the contrary; it has been authenticated and we feel that we are not only within our rights to publish it, but morally bound to do so.

Regarding the training manual, you may have detected that we had to block out the marginal notes made by the selectee at the C.I.A. Training Center, but I can assure you that the manual is authentic, and was printed for the purpose of introducing the selectee to the conspiracy. It has been authenticated by four different technical writers for Military Intelligence, one just recently retired who wants very much to have this manual distributed throughout the world, and one who is still employed as an Electronics Engineer by the Federal Government, and has access to the entire series of Training Manuals. One was stationed in Hawaii, and held the highest security clearance in the Naval Intelligence, and another who is now teaching at a university, and has been working with the Central Intelligence Agency for a number of years, and wants out before the axe falls on the conspirators.

We believed that the entire world should know about this plan, so we distributed internationally one-hundred of these manuscripts, to ask individuals at top level positions their opinions. The consensus opinion was to distribute this to as many people as who wanted it, to the end that they would not only understand that "War" had been declared against them, but would be able to properly identify the true enemy to Humanity.

Delamer Duverus

## **Preface**

Conspiracy theories are nothing new to history. Plots to "kill Caesar" and overthrow Rome abounded, for instance. However, it is seldom that concrete clues to such plots come to light, and are generally known.

Silent Weapons for Quiet Wars, An Introduction Programming Manual was uncovered quite by accident on July 7, 1986 when an employee of Boeing Aircraft Co. purchased a surplus IBM copier for scrap parts at a sale, and discovered inside details of a plan, hatched in the embryonic days of the "Cold War" which called for control of the masses through manipulation of industry, peoples' pastimes, education and political leanings. It called for a quiet revolution, putting brother against brother, and diverting the public's attention from what is really going on.

The document you are about to read is real. It is reprinted in its virgin form, with diagrams, as a touch of reality.

## **Silent weapons for quiet wars**

### **Operations Research Technical Manual TW-SW7905.1**

Welcome Aboard

This publication marks the 25th anniversary of the Third World War, called the "Quiet War", being conducted using subjective biological warfare, fought with "silent weapons".

This book contains an introductory description of this war, its strategies, and its weaponry.

May 1979 #74-1120

## **Security**

It is patently impossible to discuss social engineering or the automation of a society, i.e., the engineering of social automation systems (silent weapons) on a national or worldwide scale without implying extensive objectives of social control and destruction of human life, i.e., slavery and genocide.

This manual is in itself an analog declaration of intent. Such a writing must be secured from public scrutiny. Otherwise, it might be recognized as a technically formal declaration of domestic war. Furthermore, whenever any person or group of persons in a position of great power and without full knowledge and consent of the public, uses such knowledge and methodologies for economic conquest - it must be understood that a state of domestic warfare exists between said person or group of persons and the public.

The solution of today's problems requires an approach which is ruthlessly candid, with no agonizing over religious, moral or cultural values.

You have qualified for this project because of your ability to look at human society with cold objectivity, and yet analyze and discuss your observations and conclusions with others of similar intellectual capacity without the loss of discretion or humility. Such virtues are exercised in your own best interest. Do not deviate from them.

## **Historical Introduction**

Silent weapon technology has evolved from Operations Research (O.R.), a strategic and tactical methodology developed under the Military Management in England during

World War II. The original purpose of Operations Research was to study the strategic and tactical problems of air and land defense with the objective of effective use of limited military resources against foreign enemies (i.e., logistics).

It was soon recognized by those in positions of power that the same methods might be useful for totally controlling a society. But better tools were necessary.

Social engineering (the analysis and automation of a society) requires the correlation of great amounts of constantly changing economic information (data), so a high-speed computerized data-processing system was necessary which could race ahead of the society and predict when society would arrive for capitulation.

Relay computers were too slow, but the electronic computer, invented in 1946 by J. Presper Eckert and John W. Mauchly, filled the bill.

The next breakthrough was the development of the simplex method of linear programming in 1947 by the mathematician George B. Dantzig.

Then in 1948, the transistor, invented by J. Bardeen, W.H. Brattain, and W. Shockley, promised great expansion of the computer field by reducing space and power requirements.

With these three inventions under their direction, those in positions of power strongly suspected that it was possible for them to control the whole world with the push of a button.

Immediately, the Rockefeller Foundation got in on the ground floor by making a four-year grant to Harvard College, funding the Harvard Economic Research Project for the study of the structure of the American Economy.<sup>1</sup> One year later, in 1949, The United States Air Force joined in.

In 1952 the grant period terminated, and a high-level meeting of the Elite was held to determine the next phase of social operations research. The Harvard project had been very fruitful, as is borne out by the publication of some of its results in 1953 suggesting the feasibility of economic (social) engineering.

Engineered in the last half of the decade of the 1940's, the new Quiet War machine stood, so to speak, in sparkling gold-plated hardware on the showroom floor by 1954.

With the creation of the maser in 1954, the promise of unlocking unlimited sources of fusion atomic energy from the heavy hydrogen in sea water and the consequent availability of unlimited social power was a possibility only decades away.

The combination was irresistible.

The Quiet War was quietly declared by the International Elite at a meeting held in 1954.

Although the silent weapons system was nearly exposed 13 years later, the evolution of the new weapon-system has never suffered any major setbacks.

This volume marks the 25th anniversary of the beginning of the Quiet War. Already this domestic war has had many victories on many fronts throughout the world.

## **Political Introduction**

In 1954 it was well recognized by those in positions of authority that it was only a matter of time, only a few decades, before the general public would be able to grasp and upset the cradle of power, for the very elements of the new silent-weapon technology were as accessible for a public utopia as they were for providing a private utopia.

The issue of primary concern that of dominance, revolved around the subject of the energy sciences.

## **Energy**

Energy is recognized as the key to all activity on earth. Natural science is the study of the sources and control of natural energy, and social science, theoretically expressed as economics, is the study of the sources and control of social energy. Both are bookkeeping systems: mathematics. Therefore, mathematics is the primary energy science. And the bookkeeper can be king if the public can be kept ignorant of the methodology of the bookkeeping.

All science is merely a means to an end. The means is knowledge. The end is control. Beyond this remains only one issue: Who will be the beneficiary?

In 1954 this was the issue of primary concern. Although the so-called "moral issues" were raised, in view of the law of natural selection [<sup>1</sup>] it was agreed that a nation or world of people who will not use their intelligence are no better than animals who do not have intelligence. Such people are beasts of burden and steaks on the table by choice and consent.

Consequently, in the interest of future world order, peace, and tranquility, it was decided to privately wage a quiet war against the American public with an ultimate objective of permanently shifting the natural and social energy (wealth) of the undisciplined and irresponsible many into the hands of the self-disciplined, responsible, and worthy few. In order to implement this objective, it was necessary to create, secure, and apply new weapons which, as it turned out, were a class of weapons so subtle and sophisticated in their principle of operation and public appearance as to earn for themselves the name "silent weapons".

---

[<sup>1</sup> This concept was never more than a questionable theory of elitist Charles Darwin]

In conclusion, the objective of economic research, as conducted by the magnates of capital (banking) and the industries of commodities (goods) and services, is the establishment of an economy which is totally predictable and manipulatable.

In order to achieve a totally predictable economy, the low-class elements of society must be brought under total control, i.e., must be housebroken, trained, and assigned a yoke and long-term social duties from a very early age, before they have an opportunity to question the propriety of the matter. In order to achieve such conformity, the lower-class family unit must be disintegrated by a process of increasing preoccupation of the parents and the establishment of government-operated day-care centers for the occupationally orphaned children.

The quality of education given to the lower class must be of the poorest sort, so that the moat of ignorance isolating the inferior class from the superior class is and remains incomprehensible to the inferior class. With such an initial handicap, even bright lower class individuals have little if any hope of extricating themselves from their assigned lot in life. This form of slavery is essential to maintain some measure of social order, peace, and tranquility for the ruling upper class.

## **Descriptive Introduction of the Silent Weapon**

Everything that is expected from an ordinary weapon is expected from a silent weapon by its creators, but only in its own manner of functioning.

It shoots situations, instead of bullets; propelled by data processing, instead of chemical reaction (explosion); originating from bits of data, instead of grains of gunpowder; from a computer, instead of a gun; operated by a computer programmer, instead of a marksman; under the orders of a banking magnate, instead of a military general.

It makes no obvious explosive noises, causes no obvious physical or mental injuries, and does not obviously interfere with anyone's daily social life.

Yet it makes an unmistakable "noise," causes unmistakable physical and mental damage, and unmistakably interferes with the daily social life, i.e., unmistakable to a trained observer, one who knows what to look for.

The public cannot comprehend this weapon, and therefore cannot believe that they are being attacked and subdued by a weapon.

The public might instinctively feel that something is wrong, but that is because of the technical nature of the silent weapon, they cannot express their feeling in a rational way, or handle the problem with intelligence. Therefore, they do not know how to cry for help, and do not know how to associate with others to defend themselves against it.

When a silent weapon is applied gradually, the public adjusts/adapts to its presence and learns to tolerate its encroachment on their lives until the pressure (psychological via economic) becomes too great and they crack up.

Therefore, the silent weapon is a type of biological warfare. It attacks the vitality, options, and mobility of the individuals of a society by knowing, understanding, manipulating, and attacking their sources of natural and social energy, and their physical, mental, and emotional strengths and weaknesses.

## **Theoretical Introduction**

Give me control over a nation's currency, and I care not who makes its laws.

-- Mayer Amshel Rothschild (1743-1812)

Today's silent weapons technology is an outgrowth of a simple idea discovered, succinctly expressed, and effectively applied by the quoted Mr. Mayer Amshel Rothschild. Mr. Rothschild discovered the missing passive component of economic theory known as economic inductance. He, of course, did not think of his discovery in these 20th-century terms, and, to be sure, mathematical analysis had to wait for the Second Industrial Revolution, the rise of the theory of mechanics and electronics, and finally, the invention of the electronic computer before it could be effectively applied in the control of the world economy.

## **General Energy Concepts**

In the study of energy systems, there always appears three elementary concepts. These are potential energy, kinetic energy, and energy dissipation. And corresponding to these concepts, there are three idealized, essentially pure physical counterparts called passive components.

(1) In the science of physical mechanics, the phenomenon of potential energy is associated with a physical property called elasticity or stiffness, and can be represented by a stretched spring. In electronic science, potential energy is stored in a capacitor instead of a spring. This property is called capacitance instead of elasticity or stiffness.

(2) In the science of physical mechanics, the phenomenon of kinetic energy is associated with a physical property called inertia or mass, and can be represented by a mass or a flywheel in motion.

In electronic science, kinetic energy is stored in an inductor (in a magnetic field) instead of a mass. This property is called inductance instead of inertia.

(3) In the science of physical mechanics, the phenomenon of energy dissipation is associated with a physical property called friction or resistance, and can be represented by a dashpot or other device which converts energy into heat. In electronic science, dissipation of energy is performed by an element called either a resistor or a conductor, the term "resistor" being the one generally used to describe a more ideal device (e.g., wire) employed to convey electronic energy efficiently from one location to another. The property of a resistance or conductor is measured as either resistance or conductance reciprocals.

In economics these three energy concepts are associated with:

1. Economic Capacitance - Capital (money, stock/inventory, investments in buildings and durables, etc.)
2. Economic Conductance - Goods (production flow coefficients)
3. Economic Inductance - Services (the influence of the population of industry on output)

All of the mathematical theory developed in the study of one energy system (e.g., mechanics, electronics, etc.) can be immediately applied in the study of any other energy system (e.g., economics).

## **Mr. Rothschild's Energy Discovery**

What Mr. Rothschild had discovered was the basic principle of power, influence, and control over people as applied to economics. That principle is "when you assume the appearance of power, people soon give it to you."

Mr. Rothschild had discovered that currency or deposit loan accounts had the required appearance of power that could be used to induce people (inductance, with people corresponding to a magnetic field) into surrendering their real wealth in exchange for a promise of greater wealth (instead of real compensation). They would put up real collateral in exchange for a loan of promissory notes. Mr. Rothschild found that he could issue more notes than he had backing for, so long as he had someone's stock of gold as a persuader to show his customers.

Mr. Rothschild loaned his promissory notes to individuals and to governments. These would create overconfidence. Then he would make money scarce, tighten control of the system, and collect the collateral through the obligation of contracts. The cycle was then repeated. These pressures could be used to ignite a war. Then he would control the availability of currency to determine who would win the war. That government which agreed to give him control of its economic system got his support.

Collection of debts was guaranteed by economic aid to the enemy of the debtor. The profit derived from this economic methodology made Mr. Rothschild all the more able to expand his wealth. He found that the public greed would allow currency to be printed by

government order beyond the limits (inflation) of backing in precious metal or the production of goods and services.

## **Apparent Capital as "Paper" Inductor**

In this structure, credit, presented as a pure element called "currency," has the appearance of capital, but is in effect negative capital. Hence, it has the appearance of service, but is in fact, indebtedness or debt. It is therefore an economic inductance instead of an economic capacitance, and if balanced in no other way, will be balanced by the negation of population (war, genocide). The total goods and services represent real capital called the gross national product, and currency may be printed up to this level and still represent economic capacitance; but currency printed beyond this level is subtractive, represents the introduction of economic inductance, and constitutes notes of indebtedness.

War is therefore the balancing of the system by killing the true creditors (the public which we have taught to exchange true value for inflated currency) and falling back on whatever is left of the resources of nature and regeneration of those resources.

Mr. Rothschild had discovered that currency gave him the power to rearrange the economic structure to his own advantage, to shift economic inductance to those economic positions, which would encourage the greatest economic instability and oscillation.

The final key to economic control had to wait until there was sufficient data and high-speed computing equipment to keep close watch on the economic oscillations created by price shocking and excess paper energy credits - paper inductance/inflation .

## **Breakthrough**

The aviation field provided the greatest evolution in economic engineering by way of the mathematical theory of shock testing. In this process, a projectile is fired from an airframe on the ground and the impulse of the recoil is monitored by vibration transducers connected to the airframe and wired to chart recorders.

By studying the echoes or reflections of the recoil impulse in the airframe, it is possible to discover critical vibrations in the structure of the airframe which either vibrations of the engine or aeolian vibrations of the wings, or a combination of the two, might reinforce resulting in a resonant self-destruction of the airframe in flight as an aircraft. From the standpoint of engineering, this means that the strengths and weaknesses of the structure of the airframe in terms of vibrational energy can be discovered and manipulated.

## **Application in Economics**

To use this method of airframe shock testing in economic engineering, the prices of commodities are shocked, and the public consumer reaction is monitored. The resulting

echoes of the economic shock are interpreted theoretically by computers and the psycho-economic structure of the economy is thus discovered. It is by this process that partial differential and difference matrices are discovered that define the family household and make possible its evaluation as an economic industry (dissipative consumer structure).

Then the response of the household to future shocks can be predicted and manipulated, and society becomes a well-regulated animal with its reins under the control of a sophisticated computer-regulated social energy bookkeeping system.

Eventually every individual element of the structure comes under computer control through a knowledge of personal preferences, such knowledge guaranteed by computer association of consumer preferences (universal product code, UPC; zebra-striped pricing codes on packages) with identified consumers (identified via association with the use of a credit card and later a permanent "tattooed" body number invisible under normal ambient illumination).

## ***Summary***

Economics is only a social extension of a natural energy system. It, also, has its three passive components. Because of the distribution of wealth and the lack of communication and lack of data, this field has been the last energy field for which a knowledge of these three passive components has been developed.

Since energy is the key to all activity on the face of the earth, it follows that in order to attain a monopoly of energy, raw materials, goods, and services and to establish a world system of slave labor, it is necessary to have a first strike capability in the field of economics. In order to maintain our position, it is necessary that we have absolute first knowledge of the science of control over all economic factors and the first experience at engineering the world economy.

In order to achieve such sovereignty, we must at least achieve this one end: that the public will not make either the logical or mathematical connection between economics and the other energy sciences or learn to apply such knowledge.

This is becoming increasingly difficult to control because more and more businesses are making demands upon their computer programmers to create and apply mathematical models for the management of those businesses.

It is only a matter of time before the new breed of private programmer/economists will catch on to the far-reaching implications of the work begun at Harvard in 1948. The speed with which they can communicate their warning to the public will largely depend upon how effective we have been at controlling the media, subverting education, and keeping the public distracted with matters of no real importance.

## **The Economic Model**

Economics, as a social energy science has as a first objective the description of the complex way in which any given unit of resources is used to satisfy some economic want. (Leontief Matrix). This first objective, when it is extended to get the most product from the least or limited resources, comprises that objective of general military and industrial logistics known as Operations Research. (See simplex method of linear programming.)

The *Harvard Economic Research Project* (1948-) was an extension of World War II *Operations Research*. Its purpose was to discover the science of controlling an economy: at first the American economy, and then the world economy. It was felt that with sufficient mathematical foundation and data, it would be nearly as easy to predict and control the trend of an economy as to predict and control the trajectory of a projectile. Such has proven to be the case. Moreover, the economy has been transformed into a guided missile on target.

The immediate aim of the Harvard project was to discover the economic structure, what forces change that structure, how the behavior of the structure can be predicted, and how it can be manipulated. What was needed was a well-organized knowledge of the mathematical structures and interrelationships of investment, production, distribution, and consumption.

To make a short story of it all, it was discovered that an economy obeyed the same laws as electricity and that all of the mathematical theory and practical and computer know-how developed for the electronic field could be directly applied in the study of economics. This discovery was not openly declared, and its more subtle implications were and are kept a closely guarded secret, for example that in an economic model, human life is measured in dollars, and that the electric spark generated when opening a switch connected to an active inductor is mathematically analogous to the initiation of war.

The greatest hurdle which theoretical economists faced was the accurate description of the household as an industry. This is a challenge because consumer purchases are a matter of choice which in turn is influenced by income, price, and other economic factors.

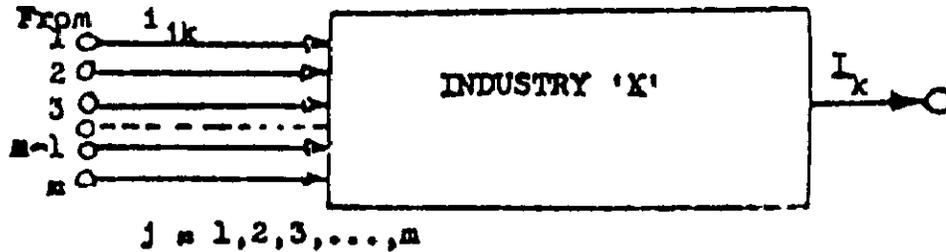

This hurdle was cleared in an indirect and statistically approximate way by an application of shock testing to determine the current characteristics, called current technical coefficients, of a household industry

Finally, because problems in theoretical electronics can be translated very easily into problems of theoretical economics, and the solution translated back again, it follows that only a book of language translation and concept definition needed to be written for economics. The remainder could be gotten from standard works on mathematics and electronics. This makes the publication of books on advanced economics unnecessary, and greatly simplifies project security.

## **Industrial Diagrams**

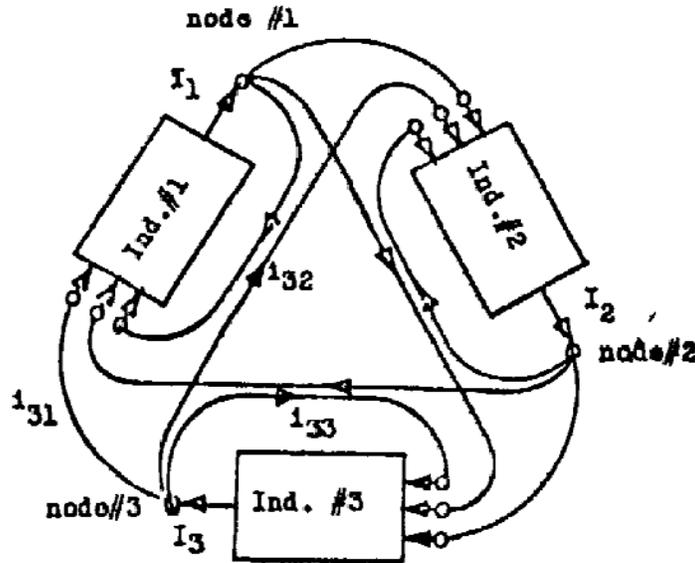

An ideal industry is defined as a device which receives value from other industries in several forms and converts them into one specific product for sales and distribution to other industries. It has several inputs and one output. What the public normally thinks of as one industry is really an industrial complex, where several industries under one roof produce one or more products.

A pure (single output) industry can be represented oversimply by a circuit block as follows:

The flow of product from industry #1 (supply) to industry #2 (demand) is denoted by  $I_{12}$ . The total flow out of industry "K" is denoted by  $I_k$  (sales, etc.).

A three industry network can be diagrammed as follows:

A node is a symbol of collection and distribution of flow. Node #3 receives from industry #3 and distributes to industries #1 and #3. If industry #3 manufactures chairs, then a flow from industry #3 back to industry #3 simply indicates that industry #3 is using part of its own output product, for example, as office furniture. Therefore the flow may be summarized by the equations:

$$\begin{aligned} \text{Node \#1 : } I_1 &= i_{11} + i_{12} + i_{13} = \sum i_{1k} \\ \text{Node \#2 : } I_2 &= i_{21} + i_{22} + i_{23} = \sum i_{2k} \\ \text{Node \#3 : } I_3 &= i_{31} + i_{32} + i_{33} = \sum i_{3k} \\ \text{where } \sum &\text{ denotes } \sum_{k=1}^{k=3} \end{aligned}$$

## Three Industrial Classes

Industries fall into three categories or classes by type of output:

Class #1 - Capital (resources)

Class #2 - Goods (commodities or use - dissipative)

Class #3 - Services (action of population)

**Class #1** industries exist at three levels:

(1) Nature - sources of energy and raw materials.

(2) Government - printing of currency equal to the gross national product (GNP), and extension of currency in excess of GNP.

(3) Banking - loaning of money for interest, and extension (inflation/counterfeiting) of economic value through the deposit loan accounts.

**Class #2** industries exist as producers of tangible or consumer (dissipated) products. This sort of activity is usually recognized and labeled by the public as "industry."

**Class #3** industries are those which have service rather than a tangible product as their output. These industries are called (1) households, and (2) governments. Their output is human activity of a mechanical sort, and their basis is population.

## Aggregation

The whole economic system can be represented by a three-industry model if one allows the names of the outputs to be (1) capital, (2) goods, and (3) services. The problem with this representation is that it would not show the influence, say, the textile industry on the ferrous metal industry. This is because both the textile industry and the ferrous metal industry would be contained within a single classification called the "goods industry" and by this process of combining or aggregating these two industries under one system block they would lose their economic individuality.

## The E-Model

A national economy consists of simultaneous flows of production, distribution, consumption, and investment. If all of these elements including labor and human functions are assigned a numerical value in like units of measure, say, 1939 dollars, then this flow can be further represented by a current flow in an electronic circuit, and its behavior can be predicted and manipulated with useful precision.

The three ideal passive energy components of electronics, the capacitor, the resistor, and the inductor correspond to the three ideal passive energy components of economics called the pure industries of capital, goods, and services, respectively:

- \* Economic capacitance represents the storage of capital in one form or another.
- \* Economic conductance represents the level of conductance of materials for the production of goods.
- \* Economic inductance represents the inertia of economic value in motion. This is a population phenomenon known as services.

## **Economic Inductance**

An electrical inductor (e.g., a coil or wire) has an electric current as its primary phenomenon and a magnetic field as its secondary phenomenon (inertia). Corresponding to this, an economic inductor has a flow of economic value as its primary phenomenon and a population field as its secondary field phenomenon of inertia. When the flow of economic value (e.g., money) diminishes, the human population field collapses in order to keep the economic value (money) flowing (extreme case - war).

This public inertia is a result of consumer buying habits, expected standard of living, etc., and is generally a phenomenon of self-preservation.

## **Inductive Factors to Consider**

- (1) Population
- (2) Magnitude of the economic activities of the government
- (3) The method of financing these government activities (See Peter-Paul Principle - inflation of the currency.)

## **Translation**

(a few examples will be given)

- Charge: Coulombs Dollars (1939)
- Flow/Current: Amperes (coulombs/ second) Dollars of flow per year
- Motivating Force: Volts; Dollars (output) demand
- Conductance: Amperes per volt; Dollars of flow per year per dollar demand
- Capacitance: Coulombs per volt: Dollars of production inventory/ stocks per dollar demand

## **Time Flow Relationships and Self-Destructive Oscillations**

An ideal industry may be symbolized electronically in various ways. The simplest way is to represent a demand by a voltage and a supply by a current. When this is done, the relationship between the two becomes what is called an admittance, which can result from three economic factors: (1) foresight flow, (2) present flow, and (3) hindsight flow.

1. *Foresight flow* is the result of that property of living entities to cause energy (food) to be stored for a period of low energy (e.g., a winter season). It consists of demands made upon an economic system for that period of low energy (winter season).

In a production industry it takes several forms, one of which is known as production stock or inventory. In electronic symbology this specific industry demand (a pure capital industry) is represented by capacitance and the stock or resource is represented by a stored charge. Satisfaction of an industry demand suffers a lag because of the loading effect of inventory priorities.

2. *Present flow* ideally involves no delays. It is, so to speak, input today for output today, a "hand to mouth" flow. In electronic symbology, this specific industry demand (a pure us industry) is represented by a conductance which is then a simple economic valve (a dissipative element).

3. *Hindsight flow* is known as habit or inertia. In electronics this phenomenon is the characteristic of an inductor (economic analog = a pure service industry) in which a current flow (economic analog = flow of money) creates a magnetic field (economic analog = active human population) which, if the current (money flow) begins to diminish, collapse (war) to maintain the current (flow of money - energy).

Other large alternatives to war as economic inductors or economic flywheels are an open-ended social welfare program, or an enormous (but fruitful) open-ended space program.

The problem with stabilizing the economic system is that there is too much demand on account of (1) too much greed and (2) too much population.

This creates excessive economic inductance which can only be balanced with economic capacitance (true resources or value - e.g., in goods or services).

The social welfare program is nothing more than an open-ended credit balance system which creates a false capital industry to give nonproductive people a roof over their heads and food in their stomachs. This can be useful, however, because the recipients become state property in return for the "gift," a standing army for the elite. For he who pays the piper picks the tune.

Those who get hooked on the economic drug must go to the elite for a fix. In this, the method of introducing large amounts of stabilizing capacitance is by borrowing on the future "credit" of the world. This is a fourth law of motion - onset, and consists of performing an action and leaving the system before the reflected reaction returns to the point of action - a delayed reaction.

The means of surviving the reaction is by changing the system before the reaction can return. By this means, politicians become more popular in their own time and the public pays later. In fact, the measure of such a politician is the delay time.

The same thing is achieved by a government by printing money beyond the limit of the gross national product, and economic process called inflation. This puts a large quantity of money into the hands of the public and maintains a balance against their greed, creates a false self-confidence in them and, for awhile, stays the wolf from the door.

They must eventually resort to war to balance the account, because war ultimately is merely the act of destroying the creditor, and the politicians are the publicly hired hit men that justify the act to keep the responsibility and blood off the public conscience. (See section on consent factors and social-economic structuring.)

If the people really cared about their fellow man, they would control their appetites (greed, procreation, etc.) so that they would not have to operate on a credit or welfare social system which steals from the worker to satisfy the bum.

Since most of the general public will not exercise restraint, there are only two alternatives to reduce the economic inductance of the system.

1. Let the populace bludgeon each other to death in war, which will only result in a total destruction of the living earth.
2. Take control of the world by the use of economic "silent weapons" in a form of "quiet warfare" and reduce the economic inductance of the world to a safe level by a process of benevolent slavery and genocide.

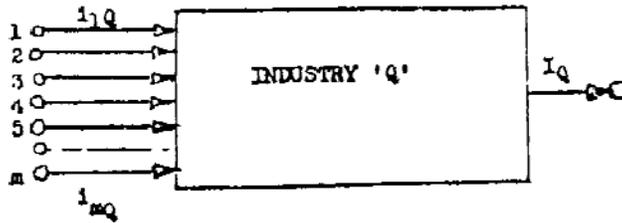

The latter option has been taken as the obviously better option. At this point it should be crystal clear to the reader why absolute secrecy about the silent weapons is necessary. The general public refuses to improve its own mentality and its faith in its fellow man. It has become a herd of proliferating barbarians, and, so to speak, a blight upon the face of the earth.

They do not care enough about economic science to learn why they have not been able to avoid war despite religious morality, and their religious or self-gratifying refusal to deal with earthly problems renders the solution of the earthly problem unreachable to them.

It is left to those few who are truly willing to think and survive as the fittest to survive, to solve the problem for themselves as the few who really care. Otherwise, exposure of the silent weapon would destroy our only hope of preserving the seed of the future true humanity.

## Industry Equivalent Circuits

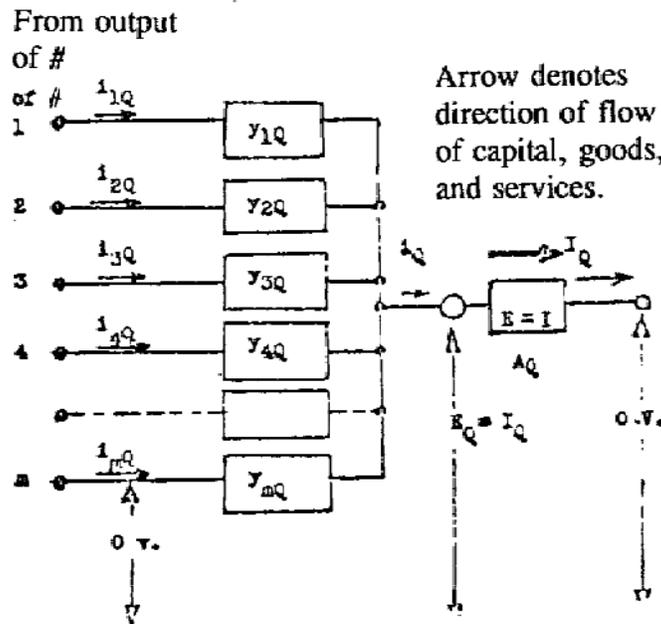

The industry 'Q' can be given a block symbol as follows:

Block Diagram of Industry 'Q'.

Terminals #1 through #m are connected directly to the outputs of industries #1 and #m, respectively.

The equivalent circuit of industry 'Q' is given as follows:

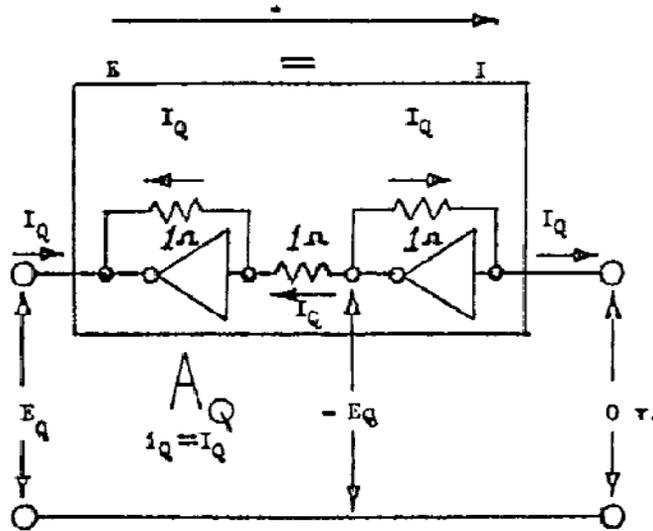

Characteristics:

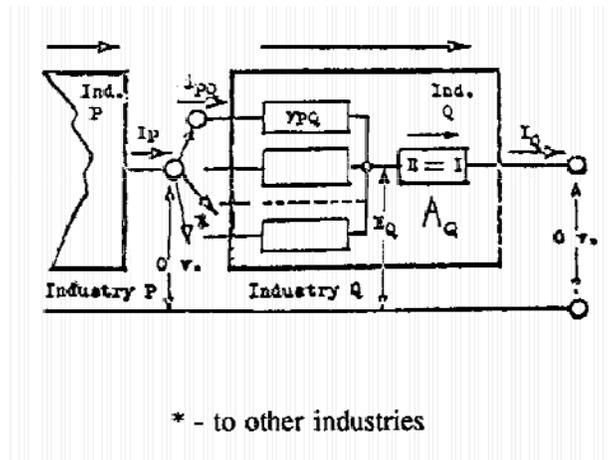

All inputs are at zero volts.

A - Amplifier - causes output current  $I_Q$  to be represented by a voltage  $E_Q$ . Amplifier delivers sufficient current at  $E_Q$  to drive all loads  $Y_{1Q}$  through  $Y_{mQ}$  and sink all currents  $i_{1Q}$  through  $i_{mQ}$ .

The unit transconductance amplifier  $A_Q$  is constructed as follows:

\* Arrow denotes the direction of the flow of capital, goods, and services. The total demand is given as  $E_Q$ , where  $E_Q = I_Q$ .

The coupling network  $Y_{PQ}$  symbolizes the demand which industry Q makes on industry P. the connective admittance  $Y_{PQ}$  is called the 'technical coefficient' of the industry Q stating the demand of industry Q, called the industry of use, for the output in capital, goods, or services of industry P called the industry of origin.

The flow of commodities from industry P to industry Q is given by  $i_{PQ}$  evaluated by the formula:

$$i_{PQ} = Y_{PQ} * E_Q.$$

When the admittance  $Y_{PQ}$  is a simple conductance, this formula takes on the common appearance of Ohm's Law,

$$i_{PQ} = g_{PQ} * I_Q.$$

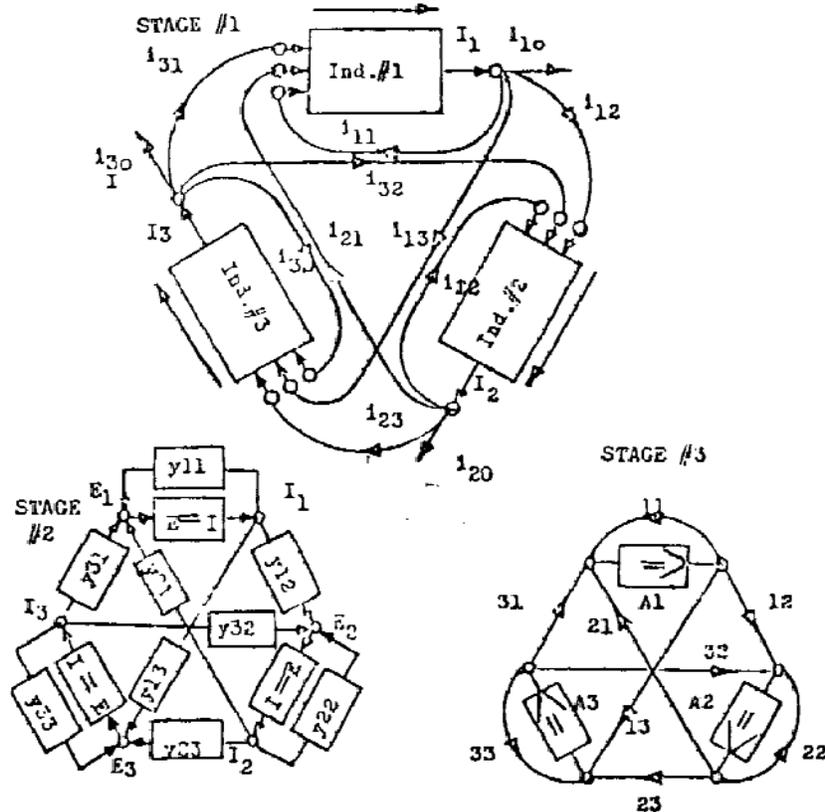

The interconnection of a three industry system can be diagrammed as follows. The blocks of the industry diagram can be opened up revealing the technical coefficients, and a much simpler format. The equations of flow are given as follows:

$$I_1 = i_{11} + i_{12} + i_{13} + i_{10} = \sum i_{1k} + i_{10}$$

$$I_2 = i_{21} + i_{22} + i_{23} + i_{20} = \sum i_{2k} + i_{20}$$

$$I_3 = i_{31} + i_{32} + i_{33} + i_{30} = \sum i_{3k} + i_{30}$$

### Stages of Schematic Simplification

## Generalization

All of this may now be summarized.

Let  $I_j$  represent the output of industry  $j$ , and

- \*  $i_{jk}$ , the amount of the product of industry  $j$  absorbed annually by industry  $k$ , and
- \*  $i_{j0}$ , the amount of the same product  $j$  made available for 'outside' use. Then

$$I_j = i_{j1} + i_{j2} + i_{j3} + \dots + i_{jm} + i_{j0}$$

$$= \sum_{k=1}^{k=m} i_{jk} + i_{j0}$$

Substituting the technical coefficients,  $y_{jk}$

$$i_{jk} = y_{jk} I_k$$

$$I_j = \sum_{k=1}^{k=m} i_{jk} + i_{j0} = \sum_{k=1}^{k=m} y_{jk} I_k + i_{j0}$$

Leontief  
Matrix for  
 $j = 1, 2, 3, \dots, m$

$$\left\{ I_j - \sum_{k=1}^{k=m} y_{jk} I_k = i_{j0} \right.$$

Let  $I_k$  at the output of industry  $k$  be represented by a demand voltage  $E_k$  at its amplifier input, i.e., let  $E_k = I_k$ . Then

$$i_{jk} = y_{jk} E_k$$

which is the general equation of every admittance in the industry circuit.

## Final Bill of Goods

$$\sum_{j=1}^{j=m} i_{j0} = i_{10} + i_{20} + i_{30} + \dots + i_{m0} \text{ is called}$$

is called the final bill of goods or the bill of final demand, and is zero when the system can be closed by the evaluation of the technical coefficients of the 'non-productive'

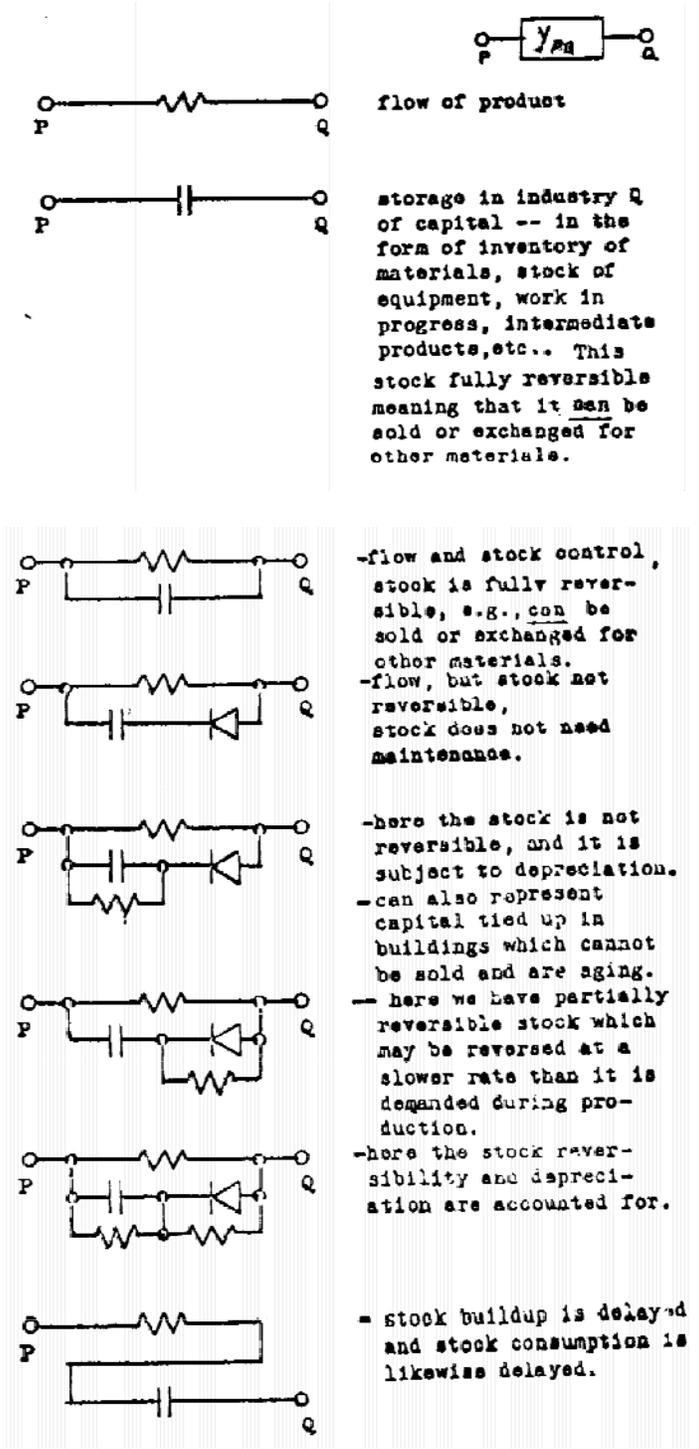

industries, government and households. Households may be regarded as a productive industry with labor as its output product.

## **The Technical Coefficients**

The quantities  $y_{jk}$  are called the technical coefficients of the industrial system. They are admittances and can consist of any combination of three passive parameters, conductance, capacitance, and inductance. Diodes are used to make the flow unidirectional and point against the flow.

- \*  $g_{jk}$  = economic conductance, absorption coefficient
- \*  $y_{jk}$  = economic capacitance, capital coefficient
- \*  $L_{jk}$  = economic inductance, human activity coefficient

## **Types of Admittances**

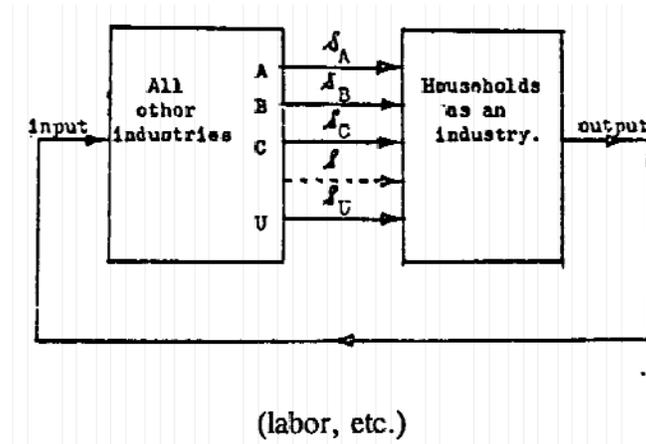

## The Household Industry

The industries of finance (banking), manufacturing, and government, real counterparts of the pure industries of capital, goods, and services, are easily defined because they are

generally logically structured. Because of this their processes can be described mathematically and their technical coefficients can be easily deduced. This, however, is not the case with the service industry known as the household industry.

## Household Models

When the industry flow diagram is represented by a 2-block system of households on the right and all other industries on the left, the following results:

The arrows from left to right labeled A, B, C, etc., denote flow of economic value from the industries in the left hand block to the industry in the right hand block called 'households'. These may be thought of as the monthly consumer flows of the following commodities. A - alcoholic beverages, B - beef, C - coffee, . . . . , U - unknown, etc. . .

The problem which a theoretical economist faces is that the consumer preferences of any household is not easily predictable and the technical coefficients of any one household tend to be a nonlinear, very complex, and variable function of income, prices, etc.

Computer information derived from the use of the universal product code in conjunction with credit-card purchase as an individual household identifier could change this state of affairs, but the U.P.C. method is not yet available on a national or even a significant regional scale. To compensate for this data deficiency, an alternate indirect approach of analysis has been adopted known as economic shock testing. This method, widely used in the aircraft manufacturing industry, develops an aggregate statistical sort of data.

Applied to economics, this means that all of the households in one region or in the whole nation are studied as a group or class rather than individually, and the mass behavior rather than the individual behavior is used to discover useful estimates of

the technical coefficients governing the economic structure of the hypothetical single-household industry...

Notice in the industry flow diagram that the values for the flows A, B, C, etc. are accessible to measurement in terms of selling prices and total sales of commodities.

One method of evaluating the technical coefficients of the household industry depends upon shocking the prices of a commodity and noting the changes in the sales of all of the commodities.

## **Economic Shock Testing**

In recent times, the application of Operations Research to the study of the public economy has been obvious for anyone who understands the principles of shock testing.

In the shock testing of an aircraft airframe, the recoil impulse of firing a gun mounted on that airframe causes shock waves in that structure which tell aviation engineers the conditions under which some parts of the airplane or the whole airplane or its wings will start to vibrate or flutter like a guitar string, a flute reed, or a tuning fork, and disintegrate or fall apart in flight.

Economic engineers achieve the same result in studying the behavior of the economy and the consumer public by carefully selecting a staple commodity such as beef, coffee, gasoline, or sugar, and then causing a sudden change or shock in its price or availability, thus kicking everybody's budget and buying habits out of shape.

They then observe the shock waves which result by monitoring the changes in advertising, prices, and sales of that and other commodities.

The objective of such studies is to acquire the know-how to set the public economy into a predictable state of motion or change, even a controlled self-destructive state of motion which will convince the public that certain "expert" people should take control of the money system and reestablish security (rather than liberty and justice) for all. When the subject citizens are rendered unable to control their financial affairs, they, of course, become totally enslaved, a source of cheap labor.

Not only the prices of commodities, but also the availability of labor can be used as the means of shock testing. Labor strikes deliver excellent tests shocks to an economy, especially in the critical service areas of trucking (transportation), communication, public utilities (energy, water, garbage collection), etc.

By shock testing, it is found that there is a direct relationship between the availability of money flowing in an economy and the real psychological outlook and response of masses of people dependent upon that availability.

For example, there is a measurable quantitative relationship between the price of gasoline and the probability that a person would experience a headache, feel a need to watch a violent movie, smoke a cigarette, or go to a tavern for a mug of beer.

It is most interesting that, by observing and measuring the economic models by which the public tries to run from their problems and escape from reality, and by applying the mathematical theory of Operations Research, it is possible to program computers to predict the most probable combination of created events (shocks) which will bring about a complete control and subjugation of the public through a subversion of the public economy (by shaking the plum tree).

## **Introduction to the Theory of Economic Shock Testing**

Let the prices and total sales of commodities be given and symbolized as follows:

<b>Commodities</b>	<b>Price Function</b>	<b>Total Sales</b>
alcoholic beverages	A	$\mathcal{A}$
beef	B	$\mathcal{B}$
coffee	C	$\mathcal{C}$
gasoline	G	$\mathcal{G}$
sugar	S	$\mathcal{S}$
tobacco	T	$\mathcal{T}$
unknown balance	U	$\mathcal{U}$

Let us assume a simple economic model in which the total number of important (staple) commodities are represented as beef, gasoline, and an aggregate of all other staple commodities which we will call the hypothetical miscellaneous staple commodity 'M' (e.g., M is an aggregate of C, S, T, U, etc.).

## **Example of Shock Testing**

Assume that the total sales,  $P$ , of petroleum products can be described by the linear function of the quantities  $B$ ,  $G$ , and  $M$ , which are functions of the prices of those respective commodities.

$$P = a_{PB} B + a_{PG} G + a_{PM} M$$

Then where  $B$ ,  $G$ , and  $M$  are functions of the prices of beef, gasoline, and miscellaneous, respectively, and  $a_{PB}$ ,  $a_{PG}$ , and  $a_{PM}$  are constant coefficients defining the amount by which each of the functions  $B$ ,  $G$ , and  $M$  affect the sales,  $P$ , of petroleum products. We are assuming that  $B$ ,  $G$ , and  $M$  are variables independent of each other.

If the availability or price of gasoline is suddenly changed, then  $G$  must be replaced by  $G + \Delta G$ . This causes a change in the petroleum sales from  $P$  to  $P + \Delta P$ . Also we will assume that  $B$  and  $M$  remain constant when  $G$  changes to  $G + \Delta G$ .

$$(P + \Delta P) = a_{PB} B + a_{PG} (G + \Delta G) + a_{PM} M.$$

Expanding upon this expression, we get

$$P + \Delta P = a_{PB} B + a_{PG} G + a_{PG} \Delta G + a_{PM} M$$

and subtracting the original value of  $P$  we get for the change in  $P$

$$\text{Change in } P = \Delta P = a_{PG} \Delta G$$

Dividing by  $\Delta G$  we get

$$a_{PG} = \Delta P / \Delta G .$$

This is a rate of change in  $P$  due only to an isolated change in  $G$ ,  $G$ .

In general,  $a_{jk}$  is the partial rate of change in the sales effect  $j$  due to a change in the causal price function of commodity  $k$ . If the interval of time were infinitesimal, this expression would be reduced to the definition of the total differential of a function,  $P$ .

For if  $a_{jk} = \frac{\partial j}{\partial k}$ , and if  $P = a_{PB}B + a_{PG}G + a_{PM}M$  and B, G, and M are independent variables, then

$$a_{PB} = \frac{\partial P}{\partial B} \quad \text{and}$$

$$dP = \frac{\partial P}{\partial B} dB + \frac{\partial P}{\partial G} dG + \frac{\partial P}{\partial M} dM$$

Integrating, we get

$$P = \int \frac{\partial P}{\partial B} dB + \int \frac{\partial P}{\partial G} dG + \int \frac{\partial P}{\partial M} dM.$$

If the  $a_{jk}$  are constant coefficients, then the rates,  $\partial j / \partial k$ , are constant also and can be taken outside of the integrals. Therefore,

$$P = \frac{\partial P}{\partial B} \int dB + \frac{\partial P}{\partial G} \int dG + \frac{\partial P}{\partial M} \int dM \quad \text{or}$$

$$P = \frac{\partial P}{\partial B} B + \frac{\partial P}{\partial G} G + \frac{\partial P}{\partial M} M + K.$$

Furthermore,

$$\begin{aligned} \delta_A &= \frac{\partial \delta_A}{\partial B} B + \frac{\partial \delta_A}{\partial G} G + \frac{\partial \delta_A}{\partial M} M + K_A \\ \delta_B &= \frac{\partial \delta_B}{\partial B} B + \frac{\partial \delta_B}{\partial G} G + \frac{\partial \delta_B}{\partial M} M + K_B \\ \delta_C &= \frac{\partial \delta_C}{\partial B} B + \frac{\partial \delta_C}{\partial G} G + \frac{\partial \delta_C}{\partial M} M + K_C \\ \delta_U &= \frac{\partial \delta_U}{\partial B} B + \frac{\partial \delta_U}{\partial G} G + \frac{\partial \delta_U}{\partial M} M + K_U \end{aligned}$$

When the price of gasoline is shocked, all of the coefficients with round G (2G) in the denominator are evaluated at the same time. If B, G, and M were independent, and sufficient for description of the economy, then three shock tests would be necessary to evaluate the system.

There are other factors which may be represented the same way.

For example, the tendency of a docile sub-nation to withdraw under economic pressure may be given by

$$\phi = \frac{\partial \phi}{\partial G} G + \frac{\partial \phi}{\partial W_P} W_P + \dots$$

where G is the price of gasoline, WP is the dollars spent per unit time (referenced to say 1939) for war production during 'peace' time, etc. These quantities are presented to a computer in matrix format as follows:

$$\begin{array}{cccc|c|c} \frac{\partial F}{\partial G} & \frac{\partial P}{\partial B} & \dots & \frac{\partial P}{\partial U} & G & P - K_P \\ \frac{\partial F}{\partial G} & \frac{\partial F}{\partial B} & \dots & \frac{\partial F}{\partial U} & B & F - K_F \\ \dots & \dots & \dots & \dots & \cdot & \cdot \\ \frac{\partial T}{\partial G} & \frac{\partial T}{\partial B} & \dots & \frac{\partial T}{\partial U} & \cdot & T - K_T \\ \frac{\partial \phi}{\partial G} & \frac{\partial \phi}{\partial B} & \dots & \frac{\partial \phi}{\partial U} & U & \phi - K_\phi \end{array} = \dots$$

$\uparrow \qquad \qquad \uparrow$   
 $X_k \qquad \qquad Y_j$

or  $[a_{jk}] [X_k] = [Y_j]$

where the  $a_{jk}$  are defined by  $a_{jk} = \frac{\partial X_j}{\partial X_k}$

and

$$\begin{array}{ll} X_1 = G & Y_1 = P - K_P \\ X_2 = B & Y_2 = F - K_F \\ X_3 = \text{etc.} & Y_3 = \text{etc.} \end{array}$$

Finally, inverting this matrix, i.e., solving for the  $X_k$  terms of the  $Y_j$ , we get, say,

$$[b_{kj}] [Y_j] = [X_k]$$

This is the result into which we substitute to get that set of conditions of prices of commodities, bad news on TV, etc., which will deliver a collapse of public morale ripe for take over.

Once the economic price and sales coefficients  $a_{jk}$  and  $b_{kj}$  are determined, they may be translated into the technical supply and demand coefficients  $g_{jk}$ ,  $C_{jk}$ , and  $1/L_{jk}$ .

Shock testing of a given commodity is then repeated to get the time rate of change of these technical coefficients.

## **Introduction to Economic Amplifiers**

Economic amplifiers are the active components of economic engineering. The basic characteristic of any amplifier (mechanical, electrical, or economic) is that it receives an input control signal and delivers energy from an independent energy source to a specified output terminal in a predictable relationship to that input control signal.

The simplest form of an economic amplifier is a device called advertising.

If a person is spoken to by a T.V. advertiser as if he were a twelve-year-old, then, due to suggestibility, he will, with a certain probability, respond or react to that suggestion with the uncritical response of a twelve-year-old and will reach in to his economic reservoir and deliver its energy to buy that product on impulse when he passes it in the store.

An economic amplifier may have several inputs and output. Its response might be instantaneous or delayed. Its circuit symbol might be a rotary switch if its options are exclusive, qualitative, "go" or "no-go", or it might have its parametric input/ output relationships specified by a matrix with internal energy sources represented.

Whatever its form might be, its purpose is to govern the flow of energy from a source to an output sink in direct relationship to an input control signal. For this reason, it is called an active circuit element or component.

Economic Amplifiers fall into classes called strategies, and, in comparison with electronic amplifiers, the specific internal functions of an economic amplifier are called logistical instead of electrical.

Therefore, economic amplifiers not only deliver power gain but also, in effect, are used to cause changes in the economic circuitry.

In the design of an economic amplifier we must have some idea of at least five functions, which are:

- (1) the available input signals,
- (2) the desired output-control objectives,
- (3) the strategic objective,
- (4) the available economic power sources,
- (5) the logistical options.

The process of defining and evaluating these factors and incorporating the economic amplifier into an economic system has been popularly called game theory.

The design of an economic amplifier begins with a specification of the power level of the output, which can range from personal to national. The second condition is accuracy of response, i.e., how accurately the output action is a function of the input commands. High gain combined with strong feedback helps to deliver the required precision.

Most of the error will be in the input data signal. Personal input data tends to be specified, while national input data tends to be statistical.

## **Short List of Inputs**

Questions to be answered:

- \* what
- \* where
- \* why
- \* when
- \* how
- \* who

General sources of information:

- \* telephone taps
- \* analysis of garbage
- \* surveillance
- \* behavior of children in school

Standard of living by:

- \* food
- \* shelter
- \* clothing
- \* transportation

Social contacts:

- \* telephone - itemized record of calls
- \* family - marriage certificates, birth certificates, etc.
- \* friends, associates, etc.
- \* memberships in organizations
- \* political affiliation

## **The Personal Paper Trail**

Personal buying habits, i.e., personal consumer preferences:

- \* checking accounts
- \* credit-card purchases
- \* "tagged" credit-card purchases - the credit-card purchase of products bearing the U.P.C. (Universal Product Code)

Assets:

- \* checking accounts
- \* savings accounts
- \* real estate
- \* business
- \* automobile, etc.
- \* safety deposit at bank
- \* stock market

Liabilities:

- \* creditors
- \* enemies (see - legal)
- \* loans

Government sources (ploys)\*:

- \* Welfare
- \* Social Security
- \* U.S.D.A. surplus food
- \* doles
- \* grants
- \* subsidies

\* Principle of this ploy -- the citizen will almost always make the collection of information easy if he can operate on the "free sandwich principle" of "eat now, and pay later."

Government sources (via intimidation):

- \* Internal Revenue Service
- \* OSHA
- \* Census
- \* etc.

Other government sources -- surveillance of U.S. mail.

## **Habit Patterns -- Programming**

Strengths and weaknesses:

- \* activities (sports, hobbies, etc.)
- \* see "legal" (fear, anger, etc. -- crime record)
- \* hospital records (drug sensitivities, reaction to pain, etc.)
- \* psychiatric records (fears, angers, disgusts, adaptability, reactions to stimuli, violence, suggestibility or hypnosis, pain, pleasure, love, and sex)

Methods of coping -- of adaptability -- behavior:

- \* consumption of alcohol
- \* consumption of drugs
- \* entertainment
- \* religious factors influencing behavior
- \* other methods of escaping from reality

Payment modus operandi (MO) -- pay on time, etc.:

- \* payment of telephone bills
- \* energy purchases
- \* water purchases
- \* repayment of loans
- \* house payments
- \* automobile payments
- \* payments on credit cards

Political sensitivity:

- \* beliefs
- \* contacts
- \* position
- \* strengths/weaknesses
- \* projects/activities

Legal inputs -- behavioral control (Excuses for investigation, search, arrest, or employment of force to modify behavior)

- \* court records
- \* police records -- NCIC
- \* driving record
- \* reports made to police
- \* insurance information
- \* anti-establishment acquaintances

### **National Input Information**

Business sources (via I.R.S., etc):

- \* prices of commodities
- \* sales
- \* investments in
  - o stocks/inventory
  - o production tools and machinery
  - o buildings and improvements
  - o the stock market

Banks and credit bureaus:

- \* credit information
- \* payment information

Miscellaneous sources:

- \* polls and surveys
- \* publications
- \* telephone records
- \* energy and utility purchases

### **Short List of Outputs**

Outputs -- create controlled situations -- manipulation of the economy, hence society -- control by control of compensation and income.

Sequence:

1. allocates opportunities
2. destroys opportunities
3. controls the economic environment
4. controls the availability of raw materials
5. controls capital.
6. controls bank rates
7. controls the inflation of the currency
8. controls the possession of property
9. controls industrial capacity

10. controls manufacturing
11. controls the availability of goods (commodities).
12. controls the prices of commodities.
13. controls services, the labor force, etc.
14. controls payments to government officials.
15. controls the legal functions.
16. controls the personal data files -- uncorrectable by the party slandered.
17. controls advertising.
18. controls media contact.
19. controls material available for T.V. viewing
20. disengages attention from real issues.
21. engages emotions.
22. creates disorder, chaos, and insanity.
23. controls design of more probing tax forms.
24. controls surveillance.
25. controls the storage of information.
26. develops psychological analyses and profiles of individuals.
27. controls legal functions [repeat of 15]
28. controls sociological factors.
29. controls health options.
30. preys on weakness.
31. cripples strengths.
32. leaches wealth and substance.

## **Table of Strategies**

<b>Do This</b>	<b>To Get This</b>
Keep the public ignorant	Less public organization
Maintain access to control point for feedback	Required reaction to outputs (prices, sales)
Create preoccupation	Lower defense
Attack the family unit	Control of the education of the young
Give less cash and more credit and doles	More self-indulgence and more data
Attack the privacy of the church	Destroy faith in this sort of government
Social conformity	Computer programming simplicity
Minimize the tax protest	Maximum economic data, minimum enforcement problems

Stabilize the consent	Simplicity coefficients
Tighten control of variables	Simpler computer input data - greater predictability
Establish boundary conditions	Problem simplicity/solutions of differential and difference equations
Proper timing	Less data shift and blurring
Maximize control	Minimum resistance to control
Collapse of currency	Destroy the faith of the American people in each other

## **Diversion, the Primary Strategy**

Experience has prevent that the simplest method of securing a silent weapon and gaining control of the public is to keep the public undisciplined and ignorant of the basic system principles on the one hand, while keeping them confused, disorganized, and distracted with matters of no real importance on the other hand.

This is achieved by:

- \* disengaging their minds; sabotaging their mental activities; providing a low-quality program of public education in mathematics, logic, systems design and economics; and discouraging technical creativity.
- \* engaging their emotions, increasing their self-indulgence and their indulgence in emotional and physical activities, by:
  - o unrelenting emotional affrontations and attacks (mental and emotional rape) by way of constant barrage of sex, violence, and wars in the media - especially the T.V. and the newspapers.
  - o giving them what they desire - in excess - "junk food for thought" - and depriving them of what they really need.
- \* rewriting history and law and subjecting the public to the deviant creation, thus being able to shift their thinking from personal needs to highly fabricated outside priorities.

These preclude their interest in and discovery of the silent weapons of social automation technology.

The general rule is that there is a profit in confusion; the more confusion, the more profit. Therefore, the best approach is to create problems and then offer solutions.

## **Diversion Summary**

Media: Keep the adult public attention diverted away from the real social issues, and captivated by matters of no real importance.

Schools: Keep the young public ignorant of real mathematics, real economics, real law, and real history.

Entertainment: Keep the public entertainment below a sixth-grade level.

Work: Keep the public busy, busy, busy, with no time to think; back on the farm with the other animals.

## **Consent, the Primary Victory**

A silent weapon system operates upon data obtained from a docile public by legal (but not always lawful) force. Much information is made available to silent weapon systems programmers through the Internal Revenue Service. (See *Studies in the Structure of the American Economy* for an I.R.S. source list.)

This information consists of the enforced delivery of well-organized data contained in federal and state tax forms, collected, assembled, and submitted by slave labor provided by taxpayers and employers.

Furthermore, the number of such forms submitted to the I.R.S. is a useful indicator of public consent, an important factor in strategic decision making. Other data sources are given in the Short List of Inputs.

Consent Coefficients - numerical feedback indicating victory status. Psychological basis: When the government is able to collect tax and seize private property without just compensation, it is an indication that the public is ripe for surrender and is consenting to enslavement and legal encroachment. A good and easily quantified indicator of harvest time is the number of public citizens who pay income tax despite an obvious lack of reciprocal or honest service from the government.

## **Amplification Energy Sources**

The next step in the process of designing an economic amplifier is discovering the energy sources. The energy sources which support any primitive economic system are, of course, a supply of raw materials, and the consent of the people to labor and consequently

assume a certain rank, position, level, or class in the social structure, i.e., to provide labor at various levels in the pecking order.

Each class, in guaranteeing its own level of income, controls the class immediately below it, hence preserves the class structure. This provides stability and security, but also government from the top.

As time goes on and communication and education improve, the lower-class elements of the social labor structure become knowledgeable and envious of the good things that the upper-class members have. They also begin to attain a knowledge of energy systems and the ability to enforce their rise through the class structure.

This threatens the sovereignty of the elite.

If this rise of the lower classes can be postponed long enough, the elite can achieve energy dominance, and labor by consent no longer will hold a position of an essential energy source.

Until such energy dominance is absolutely established, the consent of people to labor and let others handle their affairs must be taken into consideration, since failure to do so could cause the people to interfere in the final transfer of energy sources to the control of the elite.

It is essential to recognize that at this time, public consent is still an essential key to the release of energy in the process of economic amplification.

Therefore, consent as an energy release mechanism will now be considered.

## **Logistics**

The successful application of a strategy requires a careful study of inputs, outputs, the strategy connecting the inputs and the outputs, and the available energy sources to fuel the strategy. This study is called logistics.

A logistical problem is studied at the elementary level first, and then levels of greater complexity are studied as a synthesis of elementary factors.

This means that a given system is analyzed, i.e., broken down into its subsystems, and these in turn are analyzed, until by this process, one arrives at the logistical "atom," the individual.

This is where the process of synthesis properly begins, at the time of birth of the individual.

## **The Artificial Womb**

From the time a person leaves its mother's womb, its every effort is directed towards building, maintaining, and withdrawing into artificial wombs, various sorts of substitute protective devices or shells.

The objective of these artificial wombs is to provide a stable environment for both stable and unstable activity; to provide a shelter for the evolutionary processes of growth and maturity - i.e., survival; to provide security for freedom and to provide defensive protection for offensive activity.

This is equally true of both the general public and the elite. However, there is a definite difference in the way each of these classes go about the solution of problems.

## **The Political Structure of a Nation - Dependency**

The primary reason why the individual citizens of a country create a political structure is a subconscious wish or desire to perpetuate their own dependency relationship of childhood. Simply put, they want a human god to eliminate all risk from their life, pat them on the head, kiss their bruises, put a chicken on every dinner table, clothe their bodies, tuck them into bed at night, and tell them that everything will be alright when they wake up in the morning.

This public demand is incredible, so the human god, the politician, meets incredibility with incredibility by promising the world and delivering nothing. So who is the bigger liar? the public? or the "godfather"?

This public behavior is surrender born of fear, laziness, and expediency. It is the basis of the welfare state as a strategic weapon, useful against a disgusting public.

## **Action/Offense**

Most people want to be able to subdue and/or kill other human beings which disturb their daily lives, but they do not want to have to cope with the moral and religious issues which such an overt act on their part might raise. Therefore, they assign the dirty work to others (including their own children) so as to keep the blood off their hands. They rave about the humane treatment of animals and then sit down to a delicious hamburger from a whitewashed slaughterhouse down the street and out of sight. But even more hypocritical, they pay taxes to finance a professional association of hit men collectively called politicians, and then complain about corruption in government.

## **Responsibility**

Again, most people want to be free to do the things (to explore, etc.) but they are afraid to fail.

The fear of failure is manifested in irresponsibility, and especially in delegating those personal responsibilities to others where success is uncertain or carries possible or created liabilities (law), which the person is not prepared to accept. They want authority (root word - "author"), but they will not accept responsibility or liability. So they hire politicians to face reality for them.

## **Summary**

The people hire the politicians so that the people can:

- (1) obtain security without managing it.
- (2) obtain action without thinking about it.
- (3) inflict theft, injury, and death upon others without having to contemplate either life or death.
- (4) avoid responsibility for their own intentions.
- (5) obtain the benefits of reality and science without exerting themselves in the discipline of facing or learning either of these things.

They give the politicians the power to create and manage a war machine:

- (1) provide for the survival of the nation/womb.
- (2) prevent encroachment of anything upon the nation/womb.
- (3) destroy the enemy who threatens the nation/womb.
- (4) destroy those citizens of their own country who do not conform for the sake of stability of the nation/womb.

Politicians hold many quasi-military jobs, the lowest being the police which are soldiers, the attorneys and C.P.A.s next who are spies and saboteurs (licensed), and the judges who shout orders and run the closed union military shop for whatever the market will bear. The generals are industrialists. The "presidential" level of commander-in-chief is shared by the international bankers.

The people know that they have created this farce and financed it with their own taxes (consent), but they would rather knuckle under than be the hypocrite.

Thus, a nation becomes divided into two very distinct parts, a docile sub-nation [great silent majority] and a political sub-nation. The political sub-nation remains attached to the docile sub-nation, tolerates it, and leaches its substance until it grows strong enough to detach itself and then devour its parent.

## **System Analysis**

In order to make meaningful computerized economic decisions about war, the primary economic flywheel, it is necessary to assign concrete logistical values to each element of the war structure - personnel and material alike.

This process begins with a clear and candid description of the subsystems of such a structure.

## **The Draft (As military service)**

Few efforts of human behavior modification are more remarkable or more effective than that of the socio-military institution known as the draft. A primary purpose of a draft or other such institution is to instill, by intimidation, in the young males of a society the uncritical conviction that the government is omnipotent. He is soon taught that a prayer is slow to reverse what a bullet can do in an instant. Thus, a man trained in a religious environment for eighteen years of his life can, by this instrument of the government, be broken down, be purged of his fantasies and delusions in a matter of mere months. Once that conviction is instilled, all else becomes easy to instill.

Even more interesting is the process by which a young man's parents, who purportedly love him, can be induced to send him off to war to his death. Although the scope of this work will not allow this matter to be expanded in full detail, nevertheless, a coarse overview will be possible and can serve to reveal those factors which must be included in some numerical form in a computer analysis of social and war systems.

We begin with a tentative definition of the draft.

The draft (selective service, etc.) is an institution of compulsory collective sacrifice and slavery, devised by the middle-aged and elderly for the purpose of pressing the young into doing the public dirty work. It further serves to make the youth as guilty as the elders, thus making criticism of the elders by the youth less likely (Generational Stabilizer). It is marketed and sold to the public under the label of "patriotic = national" service.

Once a candid economic definition of the draft is achieved, that definition is used to outline the boundaries of a structure called a Human Value System, which in turn is translated into the terms of game theory. The value of such a slave laborer is given in a Table of Human Values, a table broken down into categories by intellect, experience, post-service job demand, etc.

Some of these categories are ordinary and can be tentatively evaluated in terms of the value of certain jobs for which a known fee exists. Some jobs are harder to value because they are unique to the demands of social subversion, for an extreme example: the value of a mother's instruction to her daughter, causing that daughter to put certain behavioral demands upon a future husband ten or fifteen years hence; thus, by suppressing his

resistance to a perversion of a government, making it easier for a banking cartel to buy the State of New York in, say, twenty years.

Such a problem leans heavily upon the observations and data of wartime espionage and many types of psychological testing. But crude mathematical models (algorithms, etc.) can be devised, if not to predict, at least to predetermine these events with maximum certainty. What does not exist by natural cooperation is thus enhanced by calculated compulsion. Human beings are machines, levers which may be grasped and turned, and there is little real difference between automating a society and automating a shoe factory.

These derived values are variable. (It is necessary to use a current Table of Human Values for computer analysis.) These values are given in true measure rather than U.S. dollars, since the latter is unstable, being presently inflated beyond the production of national goods and services so as to give the economy a false kinetic energy ("paper" inductance).

The silver value is stable, it being possible to buy the same amount with a gram of silver today as it could be bought in 1920. Human value measured in silver units changes slightly due to changes in production technology.

## **Enforcement**

### Factor I

As in every social system approach, stability is achieved only by understanding and accounting for human nature (action/reaction patterns). A failure to do so can be, and usually is, disastrous.

As in other human social schemes, one form or another of intimidation (or incentive) is essential to the success of the draft. Physical principles of action and reaction must be applied to both internal and external subsystems.

To secure the draft, individual brainwashing/programming and both the family unit and the peer group must be engaged and brought under control.

### Factor II - Father

The man of the household must be housebroken to ensure that junior will grow up with the right social training and attitudes. The advertising media, etc., are engaged to see to it that father-to-be is pussy-whipped before or by the time he is married. He is taught that he either conforms to the social notch cut out for him or his sex life will be hobbled and his tender companionship will be zero. He is made to see that women demand security more than logical, principled, or honorable behavior.

By the time his son must go to war, father (with jelly for a backbone) will slam a gun into junior's hand before father will risk the censure of his peers, or make a hypocrite of himself by crossing the investment he has in his own personal opinion or self-esteem. Junior will go to war or father will be embarrassed. So junior will go to war, the true purpose notwithstanding.

Factor III - Mother

The female element of human society is ruled by emotion first and logic second. In the battle between logic and imagination, imagination always wins, fantasy prevails, maternal instinct dominates so that the child comes first and the future comes second. A woman with a newborn baby is too starry-eyed to see a wealthy man's cannon fodder or a cheap source of slave labor. A woman must, however, be conditioned to accept the transition to "reality" when it comes, or sooner.

As the transition becomes more difficult to manage, the family unit must be carefully disintegrated, and state-controlled public education and state-operated child-care centers must become more common and legally enforced so as to begin the detachment of the child from the mother and father at an earlier age. Inoculation of behavioral drugs [Ritalin] can speed the transition for the child (mandatory). Caution: A woman's impulsive anger can override her fear. An irate woman's power must never be underestimated, and her power over a pussy-whipped husband must likewise never be underestimated. It got women the vote in 1920.

Factor IV - Junior

The emotional pressure for self-preservation during the time of war and the self-serving attitude of the common herd that have an option to avoid the battlefield - if junior can be persuaded to go - is all of the pressure finally necessary to propel Johnny off to war. Their quiet blackmailings of him are the threats: "No sacrifice, no friends; no glory, no girlfriends."

Factor V - Sister

And what about junior's sister? She is given all the good things of life by her father, and taught to expect the same from her future husband regardless of the price.

Factor VI - Cattle

Those who will not use their brains are no better off than those who have no brains, and so this mindless school of jelly-fish, father, mother, son, and daughter, become useful beasts of burden or trainers of the same.

Re: ET Docket No. 13-84

Dear Federal Communications Commission Commissioners:

The American Academy of Environmental Medicine is writing to request that the FCC review radiofrequency (RF) exposure limits (reference is made to the FCC's NOI sections 48, 51, 52, 53, 56, 60, 65 and 69), recognize non-thermal effects of RF exposure (NOI sections 66 and 69), and lower limits of RF exposure to protect the public from the adverse health effects of radiofrequency emissions (NOI sections 48, 52, 54, 65 and 71).

Founded in 1965 as a non-profit medical association, the AAEM is an international association of physicians and scientists who study and treat the effects of the environment on human health. With an elite membership of highly trained physicians and clinicians, AAEM is committed to education, public awareness and research regarding Environmental Medicine.

It became clear to AAEM physicians that by the mid 1990's patients were experiencing adverse health reactions and disease as a result of exposure to electromagnetic fields. In the last five years with the advent of wireless devices, there has been an exponential increase in the number of patients with radiofrequency induced disease and hypersensitivity.

Numerous peer reviewed, published studies correlate radiofrequency exposure with a wide range of health conditions and diseases. (NOI sections 54, 59, 60 and 65) These include neurological and neurodegenerative diseases such as Parkinson's Disease, ALS, paresthesias, dizziness, headaches and sleep disruption as well as cardiac, gastrointestinal and immune disease, cancer, developmental and reproductive disorders, and electromagnetic sensitivity. The World Health Organization has classified RF emissions as a group 2 B carcinogen. This research is reviewed and cited in the following attached documents: *AAEM Electromagnetic and Radiofrequency Fields Effect on Human Health* and *AAEM Recommendations Regarding Electromagnetic and Radiofrequency Exposure*.

The scientific literature proves that non-thermal adverse effects of RF exposure exist and negatively impact health and physiology. New guidelines based on measurements of non-thermal effects and lowering limits of exposure are needed and critical to protect public health.

In fact, electromagnetic sensitivity and the health effects of low level RF exposure have already been acknowledged by the federal government. In 2002, the Architectural and Transportation Barriers Compliance Board stated:

*“The Board recognizes...electromagnetic sensitivities may be considered disabilities under the ADA if they so severely impair the neurological, respiratory or other functions on an individual that it substantially limits one or more of the individual’s major life activities”*

Additionally, in 2005, the National Institute of Building Sciences, an organization established by the U.S. Congress in 1974, issued an Indoor Environmental Quality Report which concluded:

*“For people who are electromagnetically sensitive, the presence of cell phones and towers, portable telephones, computers,... wireless devices, security and scanning equipment, microwave ovens, electric ranges and numerous other electrical appliances can make a building inaccessible.”*

By recognizing electromagnetic sensitivity, the federal government and affiliated organizations are clearly acknowledging the existence of non-thermal effects. The AAEM urges the FCC to recognize that non-thermal effects of RF exposure exist and cause symptoms and disease. (NOI sections 66 and 69) The AAEM also requests that the FCC base guidelines of RF exposure on measurements of non-thermal effects and lower the limits of RF exposure to protect the health of the public. (NOI sections 48, 52, 54, 65 and 71)

Sincerely ,

A handwritten signature in black ink, appearing to read "Amy L. Dean, DO.", with a stylized flourish at the end.

Amy L. Dean, DO, FAAEM, DABEM, DAOBIM  
President

## Part II

### **Architectural and Transportation Barriers Compliance Board**

---

**36 CFR Parts 1190 and 1191**

**Americans With Disabilities Act (ADA)  
Accessibility Guidelines for Buildings and  
Facilities; Final Rule**

**Americans With Disabilities Act (ADA)  
Accessibility Guidelines for Buildings and  
Facilities; Architectural Barriers Act (ABA)  
Accessibility Guidelines; Recreation  
Facilities; Supplemental Notice of  
Proposed Rulemaking**

**ARCHITECTURAL AND  
TRANSPORTATION BARRIERS  
COMPLIANCE BOARD**

**36 CFR Part 1191**

[Docket No. 98–5]

RIN 3014–AA16

**Americans With Disabilities Act (ADA)  
Accessibility Guidelines for Buildings  
and Facilities; Recreation Facilities**

**AGENCY:** Architectural and  
Transportation Barriers Compliance  
Board.

**ACTION:** Final rule.

**SUMMARY:** The Architectural and Transportation Barriers Compliance Board (Access Board) is issuing final accessibility guidelines to serve as the basis for standards to be adopted by the Department of Justice for new construction and alterations of recreation facilities covered by the Americans with Disabilities Act (ADA). The guidelines include scoping and technical provisions for amusement rides, boating facilities, fishing piers and platforms, golf courses, miniature golf, sports facilities, and swimming pools and spas. The guidelines will ensure that newly constructed and altered recreation facilities meet the requirements of the ADA and are readily accessible to and usable by individuals with disabilities.

**DATES:** The guidelines are effective October 3, 2002. The incorporation by reference of certain publications listed in the guidelines is approved by the Director of the Federal Register as of October 3, 2002.

**FOR FURTHER INFORMATION CONTACT:** Peggy Greenwell, Office of Technical and Information Services, Architectural and Transportation Barriers Compliance Board, 1331 F Street, NW., suite 1000, Washington, DC 20004–1111. Telephone number (202) 272–0017 (Voice); (202) 272–0082 (TTY). E-mail address: [greenwell@access-board.gov](mailto:greenwell@access-board.gov).

**SUPPLEMENTARY INFORMATION:**

**Availability of Copies and Electronic Access**

Single copies of this publication may be obtained at no cost by calling the Access Board's automated publications order line (202) 272–0080, by pressing 2 on the telephone keypad, then 1, and requesting publication S–43 (Recreation Facilities Final Rule). Persons using a TTY should call (202) 272–0082. Please record a name, address, telephone number and request publication S–43. This document is available in alternate formats upon request. Persons who want

a copy in an alternate format should specify the type of format (cassette tape, Braille, large print, or ASCII disk). This document is also available on the Board's Internet site (<http://www.access-board.gov/recreation/final.htm>).

**Background**

The Americans with Disabilities Act recognizes and protects the civil rights of people with disabilities.<sup>1</sup> Titles II and III of the ADA require, among other things, that newly constructed and altered State and local government facilities, places of public accommodation, and commercial facilities be readily accessible to and usable by individuals with disabilities. Recreation facilities are among the types of facilities covered by titles II and III of the ADA.

The ADA designates the Access Board as the agency responsible for developing minimum accessibility guidelines to ensure that new construction and alterations of facilities covered by titles II and III of the ADA are readily accessible to and usable by individuals with disabilities.<sup>2</sup> The Access Board initially issued the Americans with Disabilities Act Accessibility Guidelines (ADAAG) in 1991.<sup>3</sup> Current ADAAG contains general scoping and technical provisions (ADAAG 1 to 4) that apply to all types of facilities, and special application sections (ADAAG 5 to 12) that include additional scoping and technical provisions for certain types of facilities.<sup>4</sup> As discussed in more detail below, this final rule will amend section 4, and create a new section 15 (Recreation Facilities).

The Department of Justice is responsible for issuing regulations to

implement titles II and III of the ADA. The regulations issued by the Department of Justice must include accessibility standards for newly constructed and altered facilities covered by titles II and III of the ADA. The standards must be consistent with the minimum accessibility guidelines issued by the Access Board. The Department of Justice has adopted ADAAG as the Standard for Accessible Design for title III of the ADA.<sup>5</sup>

This final rule amends ADAAG by adding a new special application section for amusement rides, boating facilities, fishing piers and platforms, golf courses, miniature golf, sports facilities, and swimming pools and spas. This rulemaking has had a long history. In 1993, the Access Board established an advisory committee of 27 members to make recommendations on guidelines for recreation facilities. The Recreation Access Advisory Committee met from July 1993 to May 1994 and submitted a report to the Board, "Recommendations for Accessibility Guidelines: Recreational Facilities and Outdoor Developed Areas". After receiving the committee's report, the Board published it as an advance notice of proposed rulemaking (59 FR 48542, September 21, 1994). Over 600 comments were received on the report and questions asked in the advance notice. To obtain additional information for this rulemaking, the Board also sponsored research on access to swimming pools in 1995; held informational meetings and conducted site visits on access to miniature golf facilities in September 1996; and held informational meetings and conducted site visits on accessible amusement rides in December 1999 and March and April 2000.

A notice of proposed rulemaking (NPRM) was published in the **Federal Register** on July 9, 1999. (64 FR 37326, July 9, 1999). The comment period was originally scheduled to close on November 8, 1999, but was extended until December 8, 1999 to allow more time for the public to submit comments. These comments were submitted electronically, in writing, and as oral testimony received during two public hearings held in Dallas, TX (August 26,

<sup>1</sup> See 42 U.S.C. 12101 *et seq.* (<http://www.usdoj.gov/crt/ada/pubs/ada.txt>).

<sup>2</sup> The Access Board is an independent Federal agency established by section 502 of the Rehabilitation Act whose primary mission is to promote accessibility for individuals with disabilities. The Access Board consists of 25 members. Thirteen are appointed by the President from among the public, a majority of whom are required to be individuals with disabilities. The other twelve are heads of the following Federal agencies or their designees whose positions are Executive Level IV or above: The Departments of Health and Human Services, Education, Transportation, Housing and Urban Development, Labor, Interior, Defense, Justice, Veterans Affairs, and Commerce; General Services Administration; and United States Postal Service.

<sup>3</sup> See 36 CFR part 1191, Appendix A (<http://www.access-board.gov/adaag/html/adaag.html>).

<sup>4</sup> The special application sections cover the following facilities: restaurants and cafeterias (ADAAG 5); medical care facilities (ADAAG 6); business, mercantile and civic (ADAAG 7); libraries (ADAAG 8); transient lodging (ADAAG 9); transportation facilities (ADAAG 10); judicial, legislative, and regulatory facilities (ADAAG 11); and detention and correctional facilities (ADAAG 12). ADAAG 13 is reserved for housing and ADAAG 14 is reserved for public rights-of-way.

<sup>5</sup> See 28 CFR part 36, Appendix A (<http://www.usdoj.gov/crt/ada/reg3a.html>). The Department of Justice standards currently include ADAAG 1 to 10. State and local governments currently have the option of using ADAAG or an earlier standard, the Uniform Federal Accessibility Standards (UFAS), when constructing or altering facilities under the Department of Justice regulations for title II of the ADA. See 28 CFR 35.151(c) (<http://www.usdoj.gov/crt/ada/reg2/html>). The Department of Justice has issued a notice of proposed rulemaking to eliminate this option. 59 FR 31808 (June 20, 1994).

1999) and Boston, MA (November 17, 1999). Over 200 people attended these hearings and approximately 54 people provided testimony. The Board received approximately 300 comments during the public comment period.

The Access Board created an ad hoc committee of Board members to review the comments received on the proposed rule. The ad hoc committee discussed significant issues associated with the comments and made recommendations to the full Board for the final rule. In an effort to provide the public with more opportunities for input into the provisions for the final rule, on July 21, 2000 the Board published a summary of the ad hoc committee's recommendations and put the summary in the rulemaking docket for public review (65 FR 4533, July 21, 2000). The comment period on the summary closed on September 19, 2000. Approximately 70 comments were received during the public comment period. Afterwards, the Board held informational meetings on the summary in Washington, DC (August 21–22, 2000) and San Francisco, CA (September 6–7, 2000).

#### General Issues

##### *Incorporating the Final Rule on Recreation Facilities Into Future Revisions to ADAAG*

A complete review of ADAAG has been underway for several years. ADAAG was first published on July 26, 1991. The Board is committed to ensuring that ADAAG continues to reflect technological developments and is improved in terms of usability. Efforts also include coordination with changes in national standards and model code organizations and reconciling differences between ADAAG and national consensus standards, where possible. The Board published a notice of proposed rulemaking on November 16, 1999 with proposed revisions to ADAAG. The Board plans to issue final changes to ADAAG in the near future.

The Board is issuing the final guidelines for recreation facilities prior to the publication of the final ADAAG revision. The Board then plans to incorporate these final guidelines into the final revisions to ADAAG. To effectively incorporate these guidelines into the new format, some minor formatting changes will be made. For instance, the revised ADAAG will include a new format and numbering system. This rule will need to be formatted to fit that system. Some of the provisions will also be modified slightly to avoid redundancy. No substantive changes to the text are planned. Once incorporated, the Board will develop a

guide to assist users with the new ADAAG.

The incorporation of the final recreation guidelines into the revised ADAAG will enhance the usability of the accessibility guidelines for architects, designers, manufacturers, operators and others using ADAAG. For example, accessibility guidelines for accessible parking spaces, toilet rooms, amusement rides, swimming pools, and exercise facilities will be combined into one document. Other improvements in the format of ADAAG will reduce redundancy through the use of basic technical provisions known as "building blocks," which will provide consistent dimensions for clear spaces, turning spaces, and knee and toe clearances for elements. These basic technical provisions will apply unless otherwise modified in the section containing accessibility guidelines for recreation facilities. For example, handrail requirements for sloped entries into swimming pools modify the requirements otherwise required in the ramp provisions (ADAAG 4.8.5).

##### *Multiple Chemical Sensitivities and Electromagnetic Sensitivities*

Individuals with multiple chemical sensitivities and electromagnetic sensitivities submitted a substantial number of written comments and attended the public information meetings on the draft final rule. They reported that chemicals used in recreation facilities, such as chlorine used in swimming pools and spas, and pesticides and synthetic fertilizers used on golf courses, are barriers that deny them access to those facilities. They requested the Board to include provisions in the final rule to make recreation facilities accessible for them.

The Board recognizes that multiple chemical sensitivities and electromagnetic sensitivities may be considered disabilities under the ADA if they so severely impair the neurological, respiratory or other functions of an individual that it substantially limits one or more of the individual's major life activities. The Board plans to closely examine the needs of this population, and undertake activities that address accessibility issues for these individuals.

The Board plans to develop technical assistance materials on best practices for accommodating individuals with multiple chemical sensitivities and electromagnetic sensitivities. The Board also plans to sponsor a project on indoor environmental quality. In this project, the Board will bring together building owners, architects, building product manufacturers, model code and

standard-setting organizations, individuals with multiple chemical sensitivities and electromagnetic sensitivities, and other individuals. This group will examine building design and construction issues that affect the indoor environment, and develop an action plan that can be used to reduce the level of chemicals and electromagnetic fields in the built environment.

Neither the proposed rule nor the draft final rule included provisions for multiple chemical sensitivities or electromagnetic sensitivities. The Board believes these issues require a thorough examination and public review before they are addressed through rulemaking. The Board does not address these issues in the final rule.

##### *Existing Recreation Facilities*

The Board received a significant number of comments related to the impact of these accessibility guidelines on existing facilities. Some commenters interpreted the proposed rule and the draft final rule to require all existing recreation facilities or elements of these facilities to be modified to meet the new accessibility guidelines. They expressed concern that the guidelines would have a significant economic impact on existing recreation facilities.

To clarify, ADAAG and the final accessibility guidelines for recreation facilities apply to newly designed or newly constructed buildings and facilities and to existing facilities when they are altered. ADAAG and the Department of Justice regulations address whether a change to a building or facility is considered an alteration. The publication of this final rule does not require that all existing facilities be modified to meet these guidelines. State and local governments who provide recreation facilities have a separate obligation under title II of the ADA to provide program accessibility which may require the removal of architectural barriers in existing facilities. See 28 CFR 35.150 (<http://www.usdoj.gov/crt/ada/reg2.html>). Private entities who own, lease (or lease to), or operate recreation facilities have a separate obligation under title III of the ADA to remove architectural barriers in existing facilities where it is readily achievable (*i.e.*, easily accomplishable and able to be carried out without much difficulty or expense). See 28 CFR 36.304 (<http://www.usdoj.gov/crt/ada/reg3a.html>).

Federal tax credits and deductions are available to private entities for architectural barrier removal in existing facilities. Federal funds also are available through the Community Development Block Grant Program to

remove architectural barriers in existing facilities. State and local governments may use Community Development Block Grant funds to remove architectural barriers in publicly and privately operated facilities. Entities requesting guidance on their obligations for existing facilities should contact the Department of Justice.

#### *Equivalent Facilitation*

Commenters addressing various sections of the recreation rule indicated the need for flexibility in designing and constructing accessible recreation facilities and elements. Commenters wanted to ensure that alternative designs would be permitted for providing accessibility with some of the unique elements and facilities addressed in this rule. Specific concerns were raised in comments related to accessible amusement rides and miniature golf courses.

The Board recognizes that many of the facilities and elements addressed in this rule are unique and supports the need for flexibility in making them accessible. Section 2.2 of ADAAG currently permits "departures from particular technical and scoping requirements of this guideline by the use of other designs and technologies \* \* \* where the alternative designs and technologies used will provide substantially equivalent or greater access to and usability of the facility." This provision applies to all facilities and elements addressed by ADAAG, including recreation facilities.

#### *Section-by-Section Analysis*

This section of the preamble contains a concise summary of the final rule and an analysis of the comments the Board received on each section. The final rule amends several existing sections of ADAAG and adds a new special application section. Section 4 of ADAAG has been amended to include provisions addressing miscellaneous sports facilities and elements as explained below.

#### *Miscellaneous Sports Facilities and Elements*

The accessibility guidelines for recreation facilities are primarily set forth in Section 15. Several changes, however, were also required within ADAAG section 4 to adequately address some of the unique sports facilities and elements.

#### *Section 3.5 Definitions "Area of Sport Activity"*

An area of sport activity is defined as "that portion of a room or space where the play or practice of a sport occurs."

The term is defined in order to clarify the requirements for connecting an accessible route with this type of space. The term is used broadly to define spaces where the play or practice of a sport occurs. It includes, but is not limited to, field sports such as softball, football, lacrosse, baseball, and soccer; court sports such as tennis, racquetball, and volleyball; and other sports such as gymnastics.

*Comment.* A few commenters suggested that further clarification would be helpful in the use of the term "sport" and "practice" of a sport.

*Response.* Providing an exhaustive list of sports is not practical, since it may inadvertently omit a sport, or fail to recognize an emerging sport of the future. The "area of sport activity" will vary from sport to sport. Exceptions to technical provisions in ADAAG 4.1.2 (3) and (4) and 4.1.3 (2) and (3) clarify that accessibility is not required in the "area of sport activity." This is consistent with the recommendations of the Recreation Access Advisory Committee and supports access to each "area of sport activity," while not affecting the nature of the sport.

#### *Section 4.1.1(5)(b) General Exceptions*

The following recreation facilities or portions of recreation facilities are exempt from accessibility requirements: Raised structures used for refereeing, judging, or scoring a sport; water slides; animal containment areas not for public use; and raised boxing rings and wrestling rings.

*Comment.* The proposed rule exempted structures used solely for refereeing a sport. A commenter questioned whether structures used for "judging" or "scoring" a sport would also be considered exempt.

*Response.* The exception has been modified in the final rule to include the term "judging" and "scoring." The Board considers the structures used for these activities to be consistent with the intent of this exception.

*Comment.* The proposed rule did not include any specific requirements for access to water slides. Question 4 in the proposed rule requested comments on this issue. Most of the commenters did not support providing access to the top of water slides. A few commenters suggested that access be required to the top of smaller water slides with an exemption for larger slides.

*Response.* An exception has been added in the final rule exempting water slides, including the structure supporting the water slide, from the guidelines. Providing access to water slides would require extensive ramping or elevators which would make the

slides cost prohibitive. Designers and operators are encouraged to provide access to smaller water slides, where possible. Recent designs for "leisure pools" have incorporated an accessible route to the top of water slides using the different elevations on a site. These designs provide increased access for individuals with disabilities.

*Comment.* The proposed rule did not specifically address access to "life guard stands." A few commenters recommended that structures such as life guard stands be addressed.

*Response.* ADAAG 4.1.1(5)(b) specifically exempts life guard stands and was added during a rulemaking for State and local government facilities (63 FR 2000, January 13, 1998).

*Comment.* The proposed rule included exceptions to technical provisions for accessible routes in animal containment areas. The International Association of Amusement Parks and Attractions expressed concern about general requirements for accessibility in animal containment areas that are not open to the public and are specifically limited to animal handlers.

*Response.* An exception has been added in the final rule to clarify that accessibility is not required to animal containment areas that are not for "public use." Where animal containment areas are open to public use such as petting farms, the provisions of ADAAG 4.3 apply. Several exceptions to the provisions of ADAAG 4.3 in animal containment areas are also included in the final rule.

*Comment.* The proposed rule exempted raised boxing rings from accessibility. A few commenters suggested that raised wrestling rings be added to this exception.

*Response.* The exception has been modified in the final rule to add wrestling rings to the exemption.

#### *Section 4.1.2(2)(b) and 4.1.3(1)(b) Accessible Routes for Court Sports*

These sections are amended to require an accessible route complying with ADAAG 4.3 to directly connect both sides of the court in court sports.

*Comment.* The proposed rule required an accessible route to connect both sides of the court in court sports. The American Institute of Architects (AIA) was concerned that an accessible route connecting the two sides of a court may not be a direct route and could require one to go around a multitude of courts to get to the other side of the court where a sport requires changing sides. This is especially critical in sports such as tennis, where changing sides of the court is part of the game.

*Response.* The accessible route must be a direct route from one side of the court to the other side. Requiring players on one side of the court to traverse through or around another court to get to the other side is not permitted.

*Section 4.1.2(3) and 4.1.3(2)  
Protruding Objects in Areas of Sport Activity*

Areas of sport activity are exempt from the requirements of ADAAG 4.4 (Protruding Objects).

No substantive comments were received and no changes have been made for the final rule.

*Section 4.1.2 (4) and 4.1.3(3) Ground Surfaces in Areas of Sport Activity and Animal Containment Areas*

Two exceptions are added to these sections which require ground surfaces along accessible routes and in accessible spaces to comply with ADAAG 4.5. ADAAG 4.5 requires ground and floor surfaces along accessible routes to be stable, firm, and slip resistant. ADAAG 4.5 also addresses changes in level (ADAAG 4.5.2), carpet (ADAAG 4.5.3), and gratings ADAAG (4.5.4). Exception 1 exempts areas of sport activity from all requirements of ADAAG 4.5. Exception 2 exempts animal containment areas designed and constructed for public use from the requirements of ADAAG 4.5.2 and from providing a stable, firm, and slip resistant ground or floor surface.

*Comment.* The proposed rule required an accessible route to connect to each area of sport activity. A commenter questioned the feasibility of this requirement when connecting multiple sand volleyball courts on a beach.

*Response.* The final rule requires an accessible route to each area of sport activity in newly constructed facilities. For example, where a new sports field is planned with multiple fields, an accessible route is required to each field.

With respect to sand volleyball courts located at beaches, the Board plans to more specifically address the accessible route requirement in a future rulemaking on outdoor facilities, including trails, picnic and camping facilities, and beaches. It is expected that this future rule will address accessible routes on beaches, including their location to various elements on a beach.

*Comment.* The proposed rule exempted animal containment areas for hooved animals from the requirements of a stable, firm, and slip resistant surface. Commenters questioned why the exception was limited to "hooved" animal containment areas. Others suggested that other provisions such as

ADAAG 4.5.2 (Changes in Level) not apply within these areas.

*Response.* This exception has been amended in the final rule to include all animal containment areas and is not limited to those for "hooved" animals. The Board agrees that there often are areas where many different types of animals are contained and are not limited solely to hooved animals. Exemption from the requirements to ADAAG 4.5.2 (Changes in Level) has also been included since absorbent surfaces used to ensure the care and health of animals may conflict with this provision. As previously discussed, an exception has been added to ADAAG 4.1.1(5)(b) to clarify that accessibility is not required in animal containment areas that are not for public use.

*Section 4.1.3(5) Exception 4(f)  
Platform Lifts for Team or Player Seating Areas*

An exception is added to this section permitting the use of a platform lift in new construction as a means of providing access to team or player seating areas serving areas of sport activity.

*Comment.* The proposed rule did not include an option to use a platform lift in new construction to provide access to team or player seating areas. The AIA and several architects representing a firm that specializes in sports facilities commented that platform lifts should be an option. They were particularly concerned about providing access to dugouts and other recessed team player seating areas in major league stadiums. They believed that providing a ramp parallel to the playing field presents a dangerous tripping and falling hazard for players attempting to field foul balls. Other groups representing persons with disabilities commended the Board for not allowing platform lifts in this environment in new construction. Among other issues, they cited the problems associated with relying on a mechanical device to provide access in newly constructed buildings and facilities.

*Response.* The final rule includes an option to use a platform lift as part of an accessible route connecting team or player seating areas. While the Board includes this as an option in new construction, it is recommended that where possible, ramps be utilized. This will reduce reliance for persons with disabilities on a mechanical device when providing access. Several minor league stadiums have incorporated a ramp into their design in recent years. It is the Board's understanding that there have been no reported incidents of accidents related to the ramps.

Information on major league stadiums is not available since ramps have not been incorporated into their designs.

*Section 4.1.3(12)(c) Lockers*

This section is amended to require that where lockers are provided, at least 5 percent, but not less than one, of each type of locker, must comply with ADAAG 4.25.

No substantive comments were received and no changes have been made for the final rule.

*Section 4.1.3(13) Controls and Operating Mechanisms for Exercise Equipment and Machines*

An exception is added to this section to exempt exercise machines from the requirements of ADAAG 4.27 (Controls and Operating Mechanisms).

No substantive comments were received and no changes have been made for the final rule.

*Section 4.1.3(19)(c) Team or Player Seating Areas*

This section is amended to require that where team or player seating areas contain fixed seats and serve an accessible area of sport activity, the seating area must contain the number of wheelchair spaces required by ADAAG 4.1.3(19)(a), but not less than one space. Wheelchair spaces must comply with ADAAG 4.33.2, 4.33.3, 4.33.4, and 4.33.5.

An accessible route is required to connect to the team player seating areas. An accessible route is also required to connect to the area of sport activity which is defined as "that portion of a room or space where the practice or play of a sport occurs." For the most part, the requirement is intended to provide access to the boundary of where the sport is played. In some cases, this will provide for a "level" entry to the area of sport activity such as a softball field or football field. In other cases, there may be changes in level and non-accessible surfaces. The Board recognizes that the accessible route requirement may, in some cases, not ensure access directly onto the area of sport activity. Where possible, designers are encouraged to provide for a smooth transition to the area of sport activity. This requirement is not intended to change the nature of the sport to provide access.

*Comment.* The AIA questioned how wheelchair spaces in team or player seating areas could meet the requirements of ADAAG 4.33.3. ADAAG 4.33.3 requires, among other things, that the wheelchair spaces provide a choice of admission prices or lines of sight

comparable to those afforded members of the general public.

*Response.* An exception has been added in the final rule exempting the wheelchair spaces in team or player seating areas from requirements related to choice of admission price or lines of sight comparable to those for members of the general public. Section 4.1.3(19)(c) is intended to ensure that at least one wheelchair space is provided in team or player seating areas. This can easily be accomplished through clear space adjacent to a fixed bench, for example. Bench seating will also serve as companion seating. Where designers and operators are planning facilities to serve a variety of wheelchair sports, it is recommended that the minimum be exceeded to more adequately accommodate wheelchair sports team.

Exception 2 is added to clarify that the requirements for accessible team or player seating does not apply to bowling lanes that are not required to be on an accessible route. Section 15.7.3 requires 5 percent, but not less than one, of each type of bowling lane to be served by an accessible route. Only those team or player seating areas that serve the bowling lanes required to be on an accessible route must have accessible team or player seating.

*Comment.* The proposed rule included an exception to ADAAG 4.1.3(19) for assembly seating in amusement facilities. The exception permitted use of a transfer seat complying with 15.1.4 where the motion of the seats is an integral part of the amusement experience. A few commenters questioned why this was permitted and recommended that wheelchair spaces be designed so as to provide the same general experience or effects as other seats.

*Response.* This exception has been deleted in the final rule. The Board is aware of amusement facilities where the various effects provided within the wheelchair space. Many of the effects, such as misting or smoke, may be easy to incorporate into the wheelchair space. Others effects, such as aggressive seat motion, may be extremely difficult to incorporate and may possibly be unsafe. The Board expects that designers will provide the same effects for the wheelchair space as other seats, to the extent possible. An appendix note also recommends that providing companion seats with removable armrests will provide an option for persons using wheelchairs to transfer into the seat in these venues, if desired.

#### *Section 4.1.3(21) Dressing, Fitting, or Locker Rooms*

This section requires that where dressing, fitting, or locker rooms are provided, the rooms must comply with ADAAG 4.35. An exception permits 5 percent, but not less than one, of the rooms to be accessible when they are provided in a cluster.

No substantive comments were received and no changes have been made for the final rule.

#### *Section 4.1.3(22) Saunas and Steam Rooms*

This section requires where saunas and steam rooms are provided, the rooms must comply with ADAAG 4.36. An exception permits 5 percent, but not less than one, of the rooms to be accessible when they are provided in a cluster.

No substantive comments were received and no changes have been made for the final rule.

#### *Section 4.35 Dressing, Fitting, and Locker Rooms*

##### *Section 4.35.1 General*

This section requires dressing, fitting, and locker rooms required to be accessible by ADAAG 4.1 to comply with ADAAG 4.35 and to be on an accessible route.

No substantive comments were received and no changes have been made for the final rule.

##### *Section 4.35.4 Benches in Accessible Dressing Rooms, Fitting Rooms, and Locker Rooms*

This section requires benches complying with ADAAG 4.37 in accessible dressing, fitting, and locker rooms.

No substantive comments were received and no changes have been made for the final rule.

#### *Section 4.36 Saunas and Steam Rooms*

##### *Section 4.36.1 General*

This section requires saunas and steam rooms required to be accessible by ADAAG 4.1 to comply with ADAAG 4.36.

*Comment.* Several commenters questioned whether an operator would be required to provide a heat resistant wheelchair in accessible saunas and steam rooms.

*Response.* The provision of heat resistant chairs is an operational issue and outside the jurisdiction of the Board. Questions regarding the operational issues related to the use of accessible facilities and elements will be addressed by the Department of Justice

when it adopts accessibility standards for recreation facilities.

##### *Section 4.36.2 Wheelchair Turning Space*

This section requires wheelchair turning space complying with ADAAG 4.2.3 to be provided within a sauna or steam room. An exception permits the wheelchair turning space to be obstructed by readily removable seats.

*Comment.* The proposed rule permitted the maneuvering space to be "temporarily" obstructed by readily removable seats. Commenters questioned what would be considered "temporary".

*Response.* The term "temporarily" has been deleted in the final rule. The intent of the provision is to permit a seat or bench to be located within the required maneuvering space within a room, provided that it can be readily removed. The focus of the exception is on the seat being "readily removable" to enable persons using wheelchairs to avail themselves of smaller saunas and steam rooms.

##### *Section 4.36.3 Sauna and Steam Room Bench*

This section requires that where seating is provided in a sauna or steam room, at least one bench complying with ADAAG 4.37 must be provided. An exception permits the clear floor space required by ADAAG 4.37.1 to be obstructed by readily removable seats.

*Comment.* The proposed rule permitted readily removable seats to "temporarily" obstruct the clear floor space and commenters questioned what would be considered "temporary".

*Response.* As discussed above, the term "temporarily" has been deleted in the final rule.

##### *Section 4.36.4 Door Swing*

This section requires that doors shall not swing into any part of the clear floor space required at an accessible bench.

No substantive comments were received and no changes have been made for the final rule.

#### *Section 4.37 Benches*

##### *Section 4.37.1 General*

Benches required to be accessible by 4.1 must comply with 4.37. No substantive comments were received and no changes have been made for the final rule.

##### *Section 4.37.2 Clear Floor or Ground Space*

This section requires clear floor or ground space complying with ADAAG 4.2.4 to be provided and be positioned for a parallel approach to a short end of

a bench seat. An exception permits the clear floor or ground space required by 4.37.2 to be obstructed by readily removable seats in saunas and steam rooms.

No substantive comments were received and no changes have been made to this provision in the final rule.

#### Section 4.37.3 Size

The final rule requires benches to be fixed and have seats that are 20 inches minimum to 24 inches maximum in depth and 42 inches minimum in length.

*Comment.* A few comments questioned whether a portable bench would meet the requirements for accessible benches.

*Response.* This provision has been modified in the final rule to include the term "fixed".

#### Section 4.37.4 Back Support

This section requires benches to have back support that is 42 inches minimum in length and that extends from a point 2 inches maximum above the seat to a point 18 inches minimum above the bench.

*Comment.* The proposed rule included the requirement for back support under ADAAG 4.37.2 (Size). Commenters expressed confusion over the requirements for back support for benches and some questioned whether back support was required.

*Response.* Back support is required for an accessible bench in a sauna or steam room, or a dressing room. To clarify this requirement, the technical provisions that were part of ADAAG 4.37.2 in the proposed rule have been included in a separate provision, ADAAG 4.37.3, in the final rule.

#### Section 4.37.5 Seat Height

This section requires benches to be 17 inches minimum to 19 inches maximum above the floor or ground.

No substantive comments were received and no changes have been made for the final rule.

#### Section 4.37.6 Structural Strength

This section requires that benches be strong enough to withstand a vertical or horizontal force of 250 pounds applied at any point on the seat, fastener, mounting device, or supporting structure.

No substantive comments were received and no changes have been made for the final rule.

#### Section 4.37.7 Wet Locations

This section requires that where installed in wet locations, the surface of benches must be slip-resistant and shall not accumulate water.

No substantive comments were received and no changes have been made for the final rule.

#### Section 10.5 Boat and Ferry Docks

This section is deleted in the final rule.

*Comment.* The proposed rule applied the accessibility guidelines for recreational boating facilities to boat and ferry docks located at transportation facilities, covered by ADAAG Section 10. This section of the proposed rule received little comment.

*Response.* The Board is concerned that those involved in the design and construction of boat and ferry docks may not have been fully aware of the proposed rule and therefore may not have evaluated its impact on such facilities. In addition, through the proposed rule, the Board sought information to establish access provisions for gangways based on the size of vessels using floating piers. Few commenters responded to the question, and none provided the type of information the Board was seeking.

The Board is not addressing commercial boat and ferry docks at transportation facilities at this time. In the future, the Board will consider whether such transportation facilities should be treated differently than recreational boating facilities covered by 15.2. As a result, ADAAG 10.5 has been deleted.

#### Section 15 Recreation Facilities

Section 15 has been added to ADAAG and contains accessibility guidelines for amusement rides, boating facilities, fishing piers and platforms, golf courses, miniature golf courses, exercise equipment and machines, bowling lanes, shooting facilities, and swimming pools and spas. Unless otherwise modified in section 4 or specifically addressed in 15, all other ADAAG provisions apply. For example, special technical provisions have not been included in section 15 for toilet rooms or for accessible parking. In this case, other appropriate provisions in ADAAG 4.22 and ADAAG 4.6 apply. The accessibility guidelines for play areas, which were issued on October 18, 2000 (65 FR 62498) are reprinted in Section 15.

*Comment.* A few commenters suggested that the term "recreation facilities" be defined. They suggested that the lack of definition leaves some doubt about how to apply the provisions in this section. They questioned whether locker rooms for a professional sports team, for example, would be considered a "recreation facility".

*Response.* Recreation facilities is not defined in the final rule. The term is used generally to address the types of elements and facilities covered by this section. The term is inclusive and applies to buildings and facilities designed and constructed for recreation, as well as elements and spaces located in a facility. For example, section 15.7.1 would apply to exercise equipment and machines located in an office building as a part of employee health club. Also, these provisions would apply to locker rooms for professional and other sports teams.

#### Section 15.1 Amusement Rides

Significant comment on amusement ride accessibility was received on the proposed rule. The proposed rule would have required that one wheelchair space and one transfer seat be provided for each 100 seats on new amusement rides and proposed technical provisions for the wheelchair spaces and transfer seats. The majority of comments were from amusement park operators, and amusement ride manufacturers and designers. The Board also received comments from groups representing persons with disabilities.

Overall, commenters did not support the provisions in the proposed rule for access to amusement rides. The commenters stated that the proposed rule lacked flexibility, making it impossible for most rides to comply with the guidelines given the uniqueness of this industry. They also raised concern about the lack of available manufactured rides that would meet the proposed provisions. Most rides are manufactured outside the United States where there is an absence of accessibility requirements. The ride manufacturers in the United States indicated significant hardship on their businesses to retool to meet some of the proposed technical provisions. Amusement park operators interpreted the proposed rule to require operators to modify manufactured rides. Most indicated that they were either unwilling or unable to modify a ride in a way that would differ from the manufacturer's specifications because they were not willing to accept the liability associated with modifying the ride or did not have sufficient engineering expertise to do so.

Additionally, several groups representing persons with disabilities expressed concern that some rides, such as walk through attractions and fun houses, would be exempt along with rides in traveling carnivals. They wanted the accessibility guidelines to encourage ride manufacturers to make all rides accessible. The Eastern

Paralyzed Veterans Association (EPVA) wanted the number of accessible amusement rides to be doubled from the proposed rule.

Because of these comments, the Board held several information meetings with representatives from the amusement industry and others to gather additional information. Site visits were also made to several amusement parks to better understand the issues raised. The information gained from these meetings and site visits have shaped the amusement ride section of the final rule.

Based on this information, the final rule differs significantly from the proposed rule. The final rule makes major changes in the number of accessible spaces per ride and in the options for providing access. It also includes different requirements for wheelchair spaces and for ride seats designed for individuals to transfer from their wheelchair or other mobility device. The final rule provides the flexibility requested by commenters in this unique environment, while still providing a high level of accessibility to persons with disabilities.

Since this is the first time national accessibility guidelines have been established for amusement rides, the Board intends to monitor the implementation of these guidelines. As with other accessibility guidelines developed by the Board, future updates and revisions are planned to ensure that the guidelines reflect new designs and technology.

### Section 3.5 Definitions

Three terms are defined for amusement rides.

An "amusement ride" is a system that moves persons through a fixed course within a defined area for the purpose of amusement. Editorial changes are made in the final rule to be consistent with terms used within the amusement industry.

*Comment.* A few commenters questioned whether this section would apply to a ski lift, tram, or a gondola. Trams and gondolas are provided at some amusement parks.

*Response.* Section 15.1 is not intended to apply to ski lifts, trams, or gondolas. These devices are designed primarily for the purpose of transporting people from one point to another. While a ride on a ski lift or tram may be enjoyable, it is not designed primarily for the "purpose of amusement". Trams and similar vehicles are already addressed in the ADA Accessibility Guidelines for Transportation Vehicles (Vehicle Guidelines). See 36 CFR 1192.179.

An "amusement ride seat" is defined as a seat that is built-in or mechanically fastened to an amusement ride intended to be occupied by one or more passengers. This is a new term which has been added to the final rule.

"Amusement ride seats" are referenced in several of the technical provisions.

*Comment.* The proposed rule did not include the term "amusement ride seat." Several commenters including those representing the International Association of Amusement Parks and Attractions (IAAPA) questioned the differences between the transfer seat and the amusement ride seat in the proposed rule. Questions were also raised about the application of the guidelines to rides without seats or those designed with a variety of riding postures, such as toboggan style.

*Response.* A definition for amusement ride seats is added to the final rule. The Board intends the guidelines to apply to amusement rides with seats. Specific technical provisions included in this section address clear floor or ground space and maneuvering space requirements for amusement ride seats where transfer access is provided. Technical provisions focus on ensuring that people can transfer from their wheelchairs or mobility aids to the ride seats. With respect to the various riding postures, the Board intends these guidelines to apply to those amusement rides with ride seats, including toboggan style, but not to those amusement rides where the rider is expected to be in the prone position or standing. In these cases, however, an accessible route complying with ADAAG 4.3 is required to the load and unload area.

A "transfer device" is defined as equipment designed to facilitate the transfer of a person from a wheelchair or other mobility device to and from an amusement ride seat. Several new scoping and technical provisions included in the final rule specify a "transfer device." An appendix note provides additional information on available transfer devices, including ways to provide equipment that will provide for a safe and independent transfer from a wheelchair or other mobility device.

### Section 15.1.1 General

Newly designed or newly constructed and altered amusement rides are required to comply with 15.1.1. Four exceptions are included in the final rule. Under Exception 1, portable or mobile amusement rides are not covered by the guidelines. Exceptions 2, 3, and 4 clarify that amusement rides that are controlled or operated by the rider; amusement rides designed primarily for

children, where children are assisted on and off the ride by an adult; and amusement rides without amusement ride seats are only required to comply with 15.1.4 and 15.1.5, which requires an accessible route to and maneuvering space in the load and unload areas.

*Comment.* Amusement park operators requested clarification regarding how the guidelines apply to existing rides.

*Response.* As previously mentioned, the final rule is significantly different from the proposed rule. The term "new" is included in 15.1.1 to clarify that this section applies to "new" rides and not to existing rides. The Department of Justice has the rulemaking authority to address existing rides.

A custom manufactured ride is new upon its "first use", which is the first time amusement park patrons take the ride. With respect to amusement rides purchased from other entities, "new" refers to the first permanent installation of a ride, whether the ride is used "off the shelf" or is modified before it is installed. The application of these guidelines to existing amusement rides that are altered is discussed elsewhere in this preamble. The final rule provides operators with the requested flexibility. Providing opportunities for access for persons with disabilities may be accomplished under the final rule without modifying the ride itself.

*Comment.* The preamble of the proposed rule explained that the guidelines applied to permanent amusement rides with fixed seats that are set up for a long duration and are not regularly assembled and disassembled. Amusement rides set up for short periods of time such as rides that are part of traveling carnivals, State and county fairs, festivals, and other special events are not addressed by these guidelines. The majority of amusement ride manufacturers supported this approach and considered it appropriate given the uniqueness of these rides. However, the commenters were concerned that the proposed rule did not specifically exempt temporary rides. Others suggested that a time frame be attached to this concept of "temporary" to clarify specifically what is meant. They suggested a 90 day or less time frame be used to define how long such rides can operate at the same location. Several groups representing persons with disabilities believed that temporary rides should also be accessible. They believed that manufacturers should be encouraged to make temporary rides as accessible as permanent rides.

*Response.* Exception 1 is added to specify that mobile or portable amusement rides are not covered by

15.1. The Department of Justice is authorized to determine the applicable requirement for these rides.

While mobile rides are not specifically addressed by these guidelines, other ADA requirements including general nondiscrimination obligations, program accessibility, and barrier removal provisions of the ADA apply to covered entities operating mobile or portable amusement rides. Mobile amusement rides are subject to a variety of site conditions that affect the load and unload areas. Because the rides are transported over the road, their size and weight is also restricted. This can limit the size available for the load and unload areas along with the accessible route to the ride.

Ride operators and manufacturers are encouraged to apply the provisions of this section to mobile amusement rides, where possible. Mobile rides are available that provide roll-on access and others may be close to providing transfer access with some minor adaptations in the load and unload areas. The Board will, upon request, work with interested manufacturers to provide guidance on providing either roll-on access or transfer access for someone using a wheelchair or mobility device.

#### *Exception 2*

*Comment.* The proposed rule excluded from the definition of amusement rides, those rides which are controlled or operated by the rider such as bumper cars and go-carts. A few commenters suggested that these types of rides also be addressed by this section. Several commenters requested guidance on whether making a ride turn faster or shake faster would be considered "control".
