Cell phones emit radiofrequency energy, which can be absorbed by tissues closest to where the phone is held, the National Cancer Institute says on its website. "Studies thus far have not shown a consistent link between cell phone use and cancers of the brain, nerves, or other tissues of the head or neck," it says.

Hardell is one of the few researchers who include cordless phones when studying cell phones and cancer risk. He believes emissions from the base stations of cordless phones can be problematic, especially when users sleep next to them.

Children may be most vulnerable to wireless phone emissions, Hardell said. They absorb more radiofrequency electromagnetic fields, he writes, because of their small heads, thinner skulls and higher brain conductivity.

"Girls tend to put the smart phone below the pillow," he said. "It's a bad habit to go to bed with your smart phone."

Zada also believes developing brains may be more susceptible and recommends against sleeping with cell phones.

Nevertheless, he said: "It's hard to make formal recommendations because the data is lacking. It's not smoking and lung cancer because it's not proven."

Has radiation from cell phones and microwaves caused brain tumor cases to double in Denmark?

February 10, 2017

A new report by the Swedish Radiation Protection Foundation, Stralskyddsstiftelsen, has concluded that ever-increasing rates of both brain and central nervous system (CNS) tumors, particularly in Denmark, may be caused by persistent exposure to radiation from mobile phones, microwaves, and other "smart" technology devices that pervade modern society.

Published on January 20, the report shows that such tumors have become increasingly more prevalent since 1990, and especially since 2004 when mobile phones really started to become popular. The data suggests that increasing rates of cancer in the brain, spinal cord cover, CNS spinal cord, and cranial nerves are directly correlated with the increasing use of radioactive devices, including in young people.

Individuals who are more likely to use smart technology devices like Apple iPhones or Wi-Fi enabled tablet devices and laptop computers are much more prone to develop cancer in these areas than those who don't. In fact, such cancers are so prevalent that they are almost on par with rates of melanoma, a type of skin cancer that is much more common.

While there have been claims made by the US National Cancer Institute and the Swedish Radiation Authority that this phenomenon isn't occurring, this just does not align with Stralskyddsstiftelsen's extensive research into the subject over the past several decades, which points to some serious anomalies. It would seem that government authorities are either failing or are refusing to acknowledge the dangers of electromagnetic radiation.

"Case control studies repeatedly show increased risks for CNS tumors from mobile and cordless phone use," the group's latest report emphasizes. "Ever since 2010 all studies investigating risks for brain tumors from mobile phone use over 30 minutes to one hour a day over several years have found increased risks for CNS tumors (glioma, acoustic neuroma and also meningioma)."

"Today 75% of Swedish 16 year old girls use their 'smart phone' over three hours a day and they have been wrongly informed that there are no health risks observed, often with reference to incorrect claims about brain tumor incidence trends."

Thousands of published studies link 'smart' technology use to cancer

Authorities in the US, Sweden, and elsewhere can deny all they want the correlative, and potentially causative, links between the use of smart devices and cancer, but the science speaks for itself. There are hundreds, if not thousands, of published studies and reports that show cancer rates increasing right alongside smart device usage.

For instance, a report by EMFWise Health Effects of Wireless Radiation states that, because microwave radiation can directly penetrate the body, there are serious immune risks associated with the use of these appliances. Some of these risks include alterations of immune cells, changes in lymphocytes, reduced lymphocyte count and hypersensitivity that manifests as autoimmunity.

Non-thermal microwave radiation directly impacts water, it turns out, and the human body is made up of as much as 70 percent water. When interacting with this radiation, the water in the human body is disrupted, which in turn disrupts the complex communications apparatus that exists in the body's cellular network, which uses water to send and receive information.

Similar problems exist for mobile phones, which come into direct contact with the head, hands, and other parts of the body. Electromagnetic pollution ends up interfering with the body wherever the phone is resting, whether via the leg through a pants pocket, the brain as it's pressed against the ear or in the arm as it's held in one's hand.

At this time, industry-funded research on the matter directly conflicts with independent research in most cases. The former presents a cohort of evidence, only 32 percent of which suggests harmful effects, while 70 percent of the latter's research shows harmful effects.

http://newstarget.com/2017-02-10-has-radiation-from-cell-phones-and-microwaves-caused-brain-tumor-cases-to-double-in-denmark.html

Tree damages in the vicinity of mobile phone base stations

Abstract: Since 2005, on the occasion of medical examinations of sick residents living near mobile phone base stations, changes in nearby trees (crown, leaves, trunk, branches, growth) were observed at the same time as clinical symptoms in humans occurred. Both deciduous and coniferous trees as well as shrub species were affected. The assessment of tree diseases is neither impeded by psychological impacts nor by change of location. Impacts of radiofrequency electromagnetic fields (RF-EMF) from radar, radio and TV on plant life have been scientifically demonstrated over the past 80 years. Since 2005, the influence of modulated RF-EMF - that are used in mobile phone telephony - has been investigated in lab experiments. Several research groups reported about the impacts on germination, growth and cell metabolism. Only a few scientific papers have been published to date on research concerning the health conditions of trees in the vicinity of mobile phone base stations. These papers are indicating harmful impacts. For this reason, between 2007 and 2013, the status of trees standing in the neighbourhood of 620 mobile phone base stations was documented. In the radio shadow of buildings or that one of other trees, the trees stayed healthy. However, within the radiation field, damages were observed on exposed trees. Additionally, unilateral crown damage, beginning on the side facing the antenna, strongly indicates a causal relationship with RF-EMF. In the following, examples of crown damages and of premature colouring of leaves are presented. The authors believe, that scientific research is urgently needed to examine these observations.

Conclusion

Observations, that trees are getting damages by radiofrequency electromagnetic fields of mobile phone base stations, accumulate. Often, commonly recognized factors cannot explain the damage patterns. Therefore, the immediate scientific investigation of trees in the radiation field of mobile phone base stations as well as the evaluation of aerial photography is necessary. Synchronously and shortly, exposure tests by using young trees have to be carried out.

In fact this conclusion is well supported by a WHO statement from 1999: that scientific studies on effects of low EMF exposure on animals and plants are urgently needed (MATTHES et al. 2000), a statement which can only be characterized as remarkable.

Study links bee decline to cell phones

A new study has suggested that cell phone radiation may be contributing to declines in bee populations in some areas of the world.

Bee populations dropped 17 percent in the UK last year, according to the British Bee Association, and nearly 30 percent in the United States says the U.S. Department of Agriculture.

Parasitic mites called varroa, agricultural pesticides and the effects of climate change have all been implicated in what has been dubbed "colony collapse disorder" (CCD).

But researchers in India believe cell phones could also be to blame for some of the losses.

In a study at Panjab University in Chandigarh, northern India, researchers fitted cell phones to a hive and powered them up for two fifteen-minute periods each day.

After three months, they found the bees stopped producing honey, egg production by the queen bee halved, and the size of the hive dramatically reduced.

It's not just the honey that will be lost if populations plummet further. Bees are estimated to pollinate 90 commercial crops worldwide. Their economic value in the UK is estimated to be $290 million per year and around $12 billion in the U.S.

Andrew Goldsworthy, a biologist from the UK's Imperial College, London, has studied the biological effects of electromagnetic fields. He thinks it's possible bees could be affected by cell phone radiation.

The reason, Goldsworthy says, could hinge on a pigment in bees called cryptochrome.

"Animals, including insects, use cryptochrome for navigation," Goldsworthy told CNN.

"They use it to sense the direction of the earth's magnetic field and their ability to do this is compromised by radiation from [cell] phones and their base stations. So basically bees do not find their way back to the hive."

Goldsworthy has written to the UK communications regulator OFCOM suggesting a change of phone frequencies would stop the bees being confused.

"It's possible to modify the signal coming from the [cell] phones and the base station in such a way that it doesn't produce the frequencies that disturb the cryptochrome molecules," Goldsworthy said.

"So they could do this without the signal losing its ability to transmit information."

But the UK's Mobile Operators Association -- which represents the UK's five mobile network operators -- told CNN: "Research scientists have already considered possible factors involved in CCD and have identified the areas for research into the causes of CCD which do not include exposure to radio waves."

Norman Carreck, Scientific director of the International Bee research Association at the UK's University of Sussex says it's still not clear how much radio waves affect bees.

"We know they are sensitive to magnetic fields. What we don't know is what use they actually make of them. And no one has yet demonstrated that honey bees use the earth's magnetic field when navigating," Carreck said.

How Your Cell Phone Is Killing Bees And Starving The Planet

Believe it or not, bees are pretty important. They pollinate the food we eat. And their declining population is a major concern for some scientists.

Now a new study says cell phones are to blame.

A Swiss scientist named Daniel Favre conducted the study, and concluded cell phone signals can cause bees to make extra noise, which is a signal to leave the hive. When cell phones are placed near a hive, it acts as a barrier, keeping bees from returning.

When worker bees abandon the hive, the hive as a whole suffers. Thus, the decline in bee population, and a major scare for food scientists.

http://www.businessinsider.com/cell-phones-are-killing-bees-2011-5

It's Official – Cell Phones are Killing Bees

Scientists may have found the cause of the world's sudden dwindling population of bees – and cell phones may be to blame. Research conducted in Lausanne, Switzerland has shown that the signal from cell phones not only confuses bees, but also may lead to their death. Over 83 experiments have yielded the same results. With virtually most of the population of the United States (and the rest of the world) owning cell phones, the impact has been greatly noticeable.

Led by researcher Daniel Favre, the alarming study found that bees reacted significantly to cell phones that were placed near or in hives in call-making mode. The bees sensed the signals transmitted when the phones rang, and emitted heavy buzzing noise during the calls. The calls act as an instinctive warning to leave the hive, but the frequency confuses the bees, causing them to fly erratically. The study found that the bees' buzzing noise increases ten times when a cell phone is ringing or making a call – aka when signals are being transmitted, but remained normal when not in use.

The signals cause the bees to become lost and disoriented. The impact has already been felt the world over, as the population of bees in the U.S. and the U.K. has decreased by almost half in the last thirty years – which coincides with the popularization and acceptance of cell phones as a personal device. Studies as far back as 2008 have found that bees are repelled by cell phone signals.

Bees are an integral and necessary part of our agricultural and ecological systems, producing honey, and more importantly pollinating our crops. As it is unlikely that the world will learn to forgo the convenience of cell phones, it is unclear how much they will contribute to the decline of bees, and their impact on the environment.

http://inhabitat.com/its-official-cell-phones-are-killing-bees/

Cell phone signals really are killing the bees, study shows

If there's one thing people around the world love to do — in fact, need to do — it's eat. Unfortunately, another thing everyone likes to do is talk on their cell phones. And according to a new study, these two activities are completely at odds because of a cell phone signal's confusing effects on one key player: bees.

Researcher Daniel Favre of the Swiss Federal Institute of Technology has found that wireless signals cause honeybees to become so disoriented that they finally just die. Favre's team conducted 83 separate experiments that tested bees' reactions to a nearby cellphone.

The team found that honeybees made 10 times the amount of noise when a cell phone made or received a call than they did when the phone was in off or standby mode. As Fast Company reports, this noise (generally known as "worker piping") usually signals the bees to leave the hive. But when the reaction is triggered by a cellular signal, the bees just became tragically befuddled.

So, what about a cell phone signal makes bees suicidally crazy? As Favre's report explains: "Worker piping in a bee colony is not frequent, and when it occurs in a colony, that is not in a swarming process, no more than two bees are simultaneously active…The induction of honeybee worker piping by the electromagnetic fields of mobile phones might have dramatic consequences in terms of colony losses due to unexpected swarming."

It's the "dramatic…colony losses" part that everyone should be concerned about. Honeybees are responsible for pollinating about 70 percent of the 100 or so crops on the entire planet that humans use for food.

So-called "colony collapse disorder" among the world's bee population has been recorded since 1972. But it wasn't until 2006 that the drop in the bee population took a nosedive, with beekeepers noting a 30 to 90 percent loss of their bee colonies, up from 17 to 20 percent in previous years.

Favre's study corroborates a 2008 report that showed that honeybees would not return to their hive when a cell phone was placed nearby, which sparked the theory that wireless signals are the problem.

There are other reasons scientists believe the world's crucial bee population is plummeting, things like the use of clothiandin, a pesticide used to treat corn seeds. But Favre's study shows that our cell phone habit is playing a major role in the current bee holocaust. New iPhone, anyone?

Report of Possible Impacts of Communication Towers on Wildlife Including Birds and Bees

Executive Summary

India is one of the fastest growing mobile telephony industries in the world. It is estimated that by 2013, 1 billion plus people will be having cell phone connection in India. To support this growth of cell phone subscriber in the country, there has also been a tremendous growth of infrastructure in the form of mobile phone towers. Today, in absence of any policy on infrastructure development and location of cell phone towers, large numbers of mobile phone towers are being installed in a haphazard manner across urban and rural areas including other sparsely populated areas in India. The transmission towers are based on the electromagnetic waves, which over prolonged usage have adverse impacts on humans as well as on other fauna. The adverse effects of electromagnetic radiation from mobile phones and communication towers on health of human beings are well documented today. However, exact correlation between radiation of communication towers and wildlife, are not yet very well established. The Ministry of Environment and Forests usually receives several questions regarding this issue. In view of one such Lok Sabha Starred question regarding 'Ill effects of Mobile Towers on Birds' received on 11th August, 2010, an 'Expert committee to Study the possible Impacts of Communication Towers on Wildlife including Birds and Bees' was constituted on 30th August, 2010 by Ministry of Environment and Forest, Government of India.

Conclusion

The review of existing literature shows that the EMRs are interfering with the biological systems in more ways than one and there had already been some warning bells sounded in the case on bees (Warnke 2007; vanEngelsdorp et al. 2010; Gould 1980; Sharma and Neelima R Kumar 2010) and birds, which probably heralds the seriousness of this issue and indicates the vulnerability of other species as well. Despite a few reassuring reports (Galloni et al. 2005), a vast majority of published literature indicate deleterious effects of EMFs in various species. The window of frequency range and exposure time required to make measurable impacts would vary widely among species and unfortunately we do not have any such data available for most of our free-living floral and faunal species in India. There is an urgent need to focus more scientific attention to this area before it would be too late. Microwave and radiofrequency pollution appears to constitute a potential cause for the decline of animal populations (Balmori 2006; Balmori and Hallberg 2007; Balmori Martínez 2003; Joris and Dirk 2007; Summers-Smith 2003) and deterioration of health of plants and humans living near radiation sources such as phone masts. Studies have indicated the significant non-thermal long-term impacts of EMFs on species, especially at genetic level which can lead to various health complications including brain tumours (glioma), reduction in sperm counts and sperm mobility, congenital deformities, Psychiatric problems (stress, 'ringxity', sleep disorders, memory loss etc.) and endocrine disruptions. However similar aspects are yet to be studied among animal populations. Pollution from EMRs being a relatively new environmental issue, there is a lack of established standard procedures and protocols to study and monitor the EMF impacts especially 22 among wildlife, which often make the comparative evaluations between studies difficult. Moreover, there are no long-term data available on the environmental impacts of EMRs as of now. Well-designed long-term impact assessment studies would be required to monitor the impact of ever-increasing intensities of EMRs on our biological environment. Meanwhile the precautionary principle should prevail and we need to better our standards on EMF to match the best in the world. Studies on impact of Cell phone tower radiation on Birds and wildlife are almost nonexistent from India. There is an urgent need for taking up well designed studies to look into this aspect. Available information from the country on the subject of EMF impacts is restricted to few reports from honey-

bees. However, these studies are not representative of the real life situations or natural levels of EMF exposure. More studies need to be taken up to scientifically establish if any, the link between the observed abnormalities and disorders in bee hives such as Colony Collapse Disorder (CCD).

Impacts of radio-frequency electromagnetic field (RF-EMF) from cell phone towers and wireless devices on biosystem and ecosystem – a review

Abstract: This paper summarizes the effect of radio-frequency electromagnetic field (RF-EMF) from cell towers and wireless devices on the biosphere. Based on current available literature, it is justified to conclude that RF-EMF radiation exposure can change neurotransmitter functions, blood-brain barrier, morphology, electrophysiology, cellular metabolism, calcium efflux, and gene and protein expression in certain types of cells even at lower intensities. The biological consequences of such changes remain unclear. Short-term studies on the impacts of RF-EMF on frogs, honey bees, house sparrows, bats, and even humans are scarce and long-term studies are non-existent in India. Identification of the frequency, intensity, and duration of non-ionizing electromagnetic fields causing damage to the biosystem and ecosystem would evolve strategies for mitigation and would enable the proper use of wireless technologies to enjoy its immense benefits, while ensuring one's health and that of the environment.

Conclusion: The Department of Telecommunication (DoT) in India has set new norms for cell phone towers with effect from September 1, 2012 (The Hindu, 2012). Exposure standards for RF-EMF radiation has been reduced to one-tenth of the existing level and SAR from 2 to 1.6 W/kg. This came after the Ministry of Environment and Forests (MOEF) set up an Inter-Ministerial Committee (IMC) to study the effects of RF-EMF radiations on wildlife (Figure 2) and concluded that out of the 919 research papers collected on birds, bees, plants, other animals, and humans, 593 showed impacts, 180 showed no impacts, and 196 were inconclusive studies. They conclude that there are no long-term data available on the environmental impacts of RF-EMF radiations in India. The population of India is increasing as well as the cell phone subscribers and the cell towers as supporting infrastructure. Hence, there is an urgent need to fill the gaps and do further research in this field with emphasis on the effects of early life and prenatal RF-EMF radiation exposure in animals, dosimetry studies, cellular studies using more sensitive methods, and human epidemiological studies, especially on children and young adults on behavioral and neurological disorders and cancer. Meanwhile, one can take the precautionary principle approach and reduce RF-EMF radiation effects of cell phone towers by relocating towers away from densely populated areas, increasing height of towers or changing the direction of the antenna.

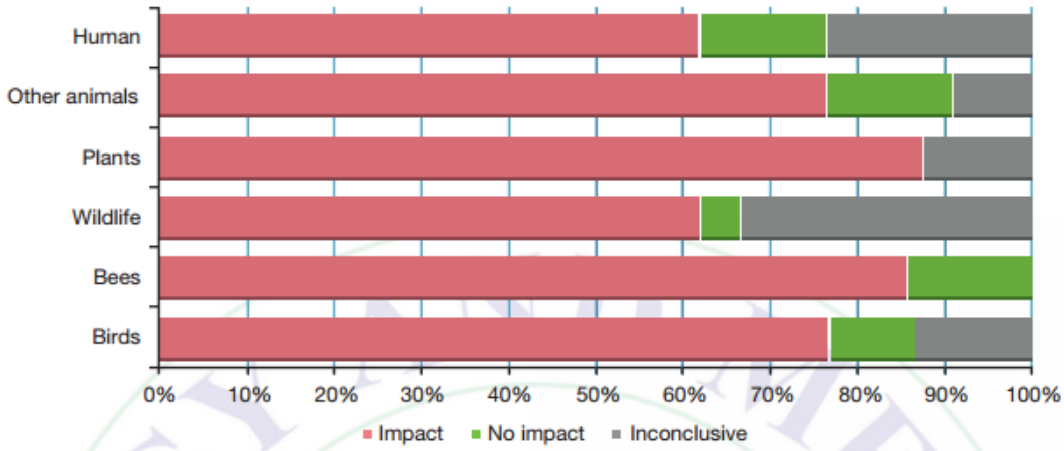

Figure 2: Percentage of studies that reported harmful effect of EMR in various groups of organisms (n = 919), MOEF Report (2010).

http://www.biolmedonline.com/Articles/Vol4_4_2012/Vol4_4_202-216_BM-8.pdf

Cell Phones are the Cigarettes of the 21st Century

A comparison of cell phone use, which continues its meteoric rise and cigarette smoking, is illustrative. Just a few of the similarities between the two habits include:

Manufacturers and industry leaders who either hide or debunk unfavorable study results and continue to promote their products despite awareness of the significant dangers to public health

Government conflict of interest created by lobbies for both industries and revenues collected from use taxes

Expensive, effective marketing campaigns aimed at every segment of society, including children

Massive amounts of scientific data proving beyond a shadow of a doubt the direct link between these products and life-threatening damage to the human body

The addictive nature of both products

The primary distinction between cell phone use and cigarettes is that smoking has been around long enough to confirm it can, indeed, be a fatal habit. According to a 2008 World Health Organization (WHO) report, tobacco use kills 5 million people a year worldwide, and is a risk factor in six of the eight leading causes of death.

These are just a few recent examples of study data linking electromagnetic radiation and cell phone use to a stunning array of serious health concerns:

- At a recent Senate Committee hearing, witnesses testified that cell phone use has been linked to salivary gland tumors
- Wearing a cell phone on your hip – either on your belt or in a pocket – has been linked to decreased bone density in the pelvic region. All the other vital organs located in your pelvic region – your liver, kidney, bladder, colon and reproductive organs – are also susceptible to radiation damage.
- Proximity to cell phone towers causes an increase in the symptoms of electromagnetic hypersensitivity, including fatigue, sleep disturbances, visual and auditory disturbances, and cardiovascular effects, just to name a few.

Thanks to a multimillion-dollar research study funded by none other than the Cellular Telephone Industry Association (CTIA), which certainly didn't set out to uncover these results, we now have proof of:

A significant increase in cell phone users' risk of brain tumors at the brain's outer edge, on whichever side the cell phone was held most often.

A 60 percent greater chance of acoustic neuromas, a tumor affecting the nerve that controls hearing, among people who had used cell phones for six years or more.

A higher rate of brain cancer deaths among handheld mobile phone users than among car phone users (car phones are mounted on the dashboard rather than held next to your head)

In addition to this research, a review of 11 long-term epidemiologic studies published in the journal Surgical Neurology revealed that using a cell phone for 10 or more years approximately doubles the risk of being diagnosed with a brain tumor on the same side of the head where the cell phone is typically held.

Australia has seen an increase in pediatric brain cancers of 21 percent in just one decade. This is consistent with studies showing a 40 percent brain tumor increase across the board in Europe and the U.K. over the last 20 years.

Brain cancer has now surpassed leukemia as the number one cancer killer in children.

In addition to the widespread concern about brain cancer, scientists have found that information-carrying radio waves transmitted by cell phones and other wireless devices can:

- Harm your blood cells and cause cellular changes
- Damage your DNA
- Cause nerve-cell damage
- Possibly accelerate and contribute to onset of autism, and trigger Alzheimer's disease (You may have read the recent spin that cellphone use can cure Alzheimer's, but you should know that study involved exposures that were nothing like a cell phone exposure, even though the publicity suggested otherwise. More on this soon.)
- Damage your eyes
- Cause sleep disruptions, fatigue and headaches

Pediatricians Warn Cell Phone Radiation Poses Cancer Risk to Children

Following a study last May that linked wireless radiation to deadly heart and brain cancers, the American Academy of Pediatrics (AAP) has issued a series of recommendations that warn parents of the dangers cell phones and other wireless devices present to their children. The initial study was carried out by the US National Toxicology Program over a period of two years. It found that rats suffered DNA damage in their brain cells as well as a high probability of developing brain tumors and malignant Schwann cell tumors in the heart. Dr. Ronald L. Melnick, a toxicologist at the National Institutes of Health, said that the cancer risks for children are even greater due to greater penetration and absorption of cell phone radiation as well as a higher susceptibility to tissue-damaging agents. Dr. Jennifer Lowry, chair of the AAP council on Environmental Health Executive Committee, seconded these claims warning that "[cell phones] are not toys. They have radiation that is emitted from them and the more we can keep it off the body and use [phones] in other ways, it will be safer."

The AAP had previously expressed concern about the dangers of cell phone radiation. 5 years ago, an Egyptian study showed that living in proximity to mobile phone base stations increases the risk for developing various problems such as headaches, memory problems, dizziness, depression, and insomnia. Though this study focused on short-term effects, the AAP had previously warned that it was important to consider the possible cumulative damage from the electromagnetic radiation emitted by cell phones and supported further research. The US National Toxicology Program study only confirmed the AAP's suspicions that cumulative exposure to cell phone radiation has damaging effects on human health, especially children whose bodies are still developing.

Pediatricians also expressed their concern over the legal limits of cell phone radiation established by the Federal Communications Commission (FCC). The FCC's allowable limit is currently 1.6 W/kg, but this standard has not been revised since 1996 despite that fact the cell phone use has increased dramatically and that cell phone technology has grown by leaps and bounds. In addition, the FCC's limit is based on the devices' potential effect on fully-grown adults based on 20-year-old, outdated science. The limit does not consider the effect of cell phone radiation on children even though children's skulls are thinner and more readily absorb radiation. These facts also led the AAP to recommend a government review of cell phone radiation standards that "protect children's health, reflect current cell phone use patterns, and provide meaningful consumer disclosure." However, it appears doubtful that the FCC will make changes anytime soon as cell phone manufacturers are likely to fight against any new regulations that would further reduce the radiation limit.

EEG Changes Due to Experimentally Induced 3G Mobile Phone Radiation

Abstract

The aim of this study was to investigate whether a 15-minute placement of a 3G dialing mobile phone causes direct changes in EEG activity compared to the placement of a sham phone. Furthermore, it was investigated whether placement of the mobile phone on the ear or the heart would result in different outcomes. Thirty-one healthy females participated. All subjects were measured twice: on one of the two days the mobile phone was attached to the ear, the other day to the chest. In this single-blind, cross-over design, assessments in the sham phone condition were conducted directly preceding and following the mobile phone exposure. During each assessment, EEG activity and radiofrequency radiation were recorded jointly. Delta, theta, alpha, slowbeta, fastbeta, and gamma activity was computed. The association between radiation exposure and the EEG was tested using multilevel random regression analyses with radiation as predictor of main interest. Significant radiation effects were found for the alpha, slowbeta, fastbeta, and gamma bands. When analyzed separately, ear location of the phone was associated with significant results, while chest placement was not. The results support the notion that EEG alterations are associated with mobile phone usage and that the effect is dependent on site of placement. Further studies are required to demonstrate the physiological relevance of these findings.

Introduction

Mobile phone usage has become an integrated part of modern society. In recent years, number and level of usage of mobile phones has increased rapidly. In 2013, 6.8 billion mobile phone subscriptions were registered [1]. In recent years, new technology of 3rd generation (3G) or universal mobile telecommunication system (UMTS), using the 1.9–2.1 GHz frequency band has been introduced, followed by the 4th generation. Although there are some worries [2] about the potential negative effects of RF-EMF on health, large sections of the population are avid customers. The number of studies investigating whether or not RF-EMF has adverse health effects has increased rapidly. The research field is broad since several areas are explored, ranging from carcinogenesis and infertility to basic effects on physiological parameters. In general, results are conflicting and inconclusive [3–6]. While a number of studies demonstrate influence of radiation on health, others cannot replicate these findings. Nevertheless, the International Agency for Research on Cancer concluded that there is “limited evidence in humans” and in 2011 it was decided to classify mobile phone radiation in group 2B—possibly carcinogenic [2]. In contrast, the 2012 overview report of the Mobile Telecommunications and Health Research (MTHR) Programme concluded that there is no evidence of carcinogenic effects due to exposure to mobile phone signals [7]. However, examining possible effects due to long-term exposure and the effects on other outcomes were suggested as priority research areas. Also in the WHO Research Agenda for Radiofrequency Fields of 2011, “provocation studies to identify neurobiological mechanisms underlying possible effects of RF on brain function, including sleep and resting EEG” are considered to have a high priority [8].

The effects of mobile phone radiation on electroencephalography (EEG) have been studied since the mid-nineties [9]. There are a number of studies which have investigated the effects of mobile phone radiation on resting EEG, on sleep EEG, on the performance of cognitive tasks, and on event related potentials (ERP) of conscious sensory stimuli. Apart from a relative consistent finding [9–15] of an increased power in the alpha band, no consistent results have been reported. A possible contributing factor to these varying results may be found in the diversity of designs and in the statistical analyses.

Some examples are: type of exposure (network 2G/3G and a real mobile phone versus a radiating module), duration of exposure (ranging from minutes to several hours), and statistical tests (parametric versus non-parametric tests). Apart from these methodological aspects, it has been suggested that source of funding might influence the results [16]. It has been shown that 87% of brain activity studies are sponsored by the mobile phone industry [4]. Although this does not necessarily imply that the results of these articles are biased, the issue of conflict of interest cannot be neglected.

To shed further light on this topic, it was decided to set up a basic experiment to investigate whether EEG is influenced by mobile phone radiation. The focus on EEG as the dependent variable was deliberate since functioning of brain tissue is based on electrochemical processes [17] and interference by an electromagnetic device (mobile phone) placed directly against the head is, from a physical point of view, very likely to occur. Despite this plausible physical interference mechanism, adverse effects are rarely reported.

Before setting up the experiment, several methodological issues were considered. First, in most studies a control session was included on a separate day [12–15,18]. It is known, however, that resting EEGs can differ across days, even without any intervention [19]. Therefore, it was decided to compare an exposure condition with two control measurements, directly preceding and following the exposure condition. In addition, a control-exposure-control session was conducted on two different days in order to test whether the location of placement of the mobile phone might be of influence. Apart from the obvious placement of the mobile phone on the ear, it was decided to also place the phone on the chest. Any differences in outcome between placement locations may be informative about a working mechanism. Third, an actual mobile phone was used instead of a GSM module or other method to simulate mobile phone radiation. This decision was made to represent reality as accurately as possible. In order to ensure that the radiation did not have a direct effect on the measurement equipment, shielded EEG electrodes were used. Finally, multilevel random regression analysis was used instead of ANOVA techniques. The main reason is that EEG data show hierarchical clustering in at least four levels: subjects, sessions, conditions and EEG segments. Multilevel regression analysis also allows modulation of random effects (regression coefficients may vary between subjects) as well as the incorporation of an autoregressive covariance structure (since consecutive EEG segments are highly correlated).

Two a priori hypotheses were tested. Based on existing literature, an increase in alpha activity during exposure was expected. Second, because of the smaller distance to the brain, the influence on the EEG of radiation was expected to be larger with ear placement as compared to chest placement.

Discussion

In this placebo-controlled, single-blind, cross-over study, we investigated whether a 15 minute RF-EMF exposure by a 3G mobile phone impacts EEG activity. It was demonstrated that the results (and conclusions) strongly depend on the method of analysis. Analysed in the traditional fashion, that is, not controlling for the nested structure of the data, no significant differences could be demonstrated (see Table 2), a finding which is in accordance with several other studies [18,25–28]. However, when the data were analysed with an appropriate multilevel statistical model, 'radiation' proved to be a significant predictor of the alpha, slow beta, fast beta, and gamma frequency bands over almost all brain regions (Figs (Figs11 and and2).2). There is a trend for the radiation effect to be stronger on the ipsilateral side. The positive significant time effect (segment) within conditions, observed in all regions and frequency bands, was unexpected and an explanation is lacking at this moment. Guided by the significant

placement*radiation interactions, separate analyses for the ear and heart placements made clear that the radiation effect was mainly present in sessions where the mobile phone was placed on the ear (Figs (Figs33 and and4).4). To our knowledge, this ear-heart contrast has not been studied before. The present data suggest that a greater distance to the brain in case of the chest placement results in less EEG effects.

Although there are some studies which found an increase in the alpha frequency band due to RF-EMF [9–15], the extent to which the different EEG bands are affected in the present study has not been reported in literature to date. This discrepancy needs clarification and probably has to be sought in methodological differences with other studies. As mentioned above, the type of statistical approach is an important factor in this issue. The multilevel approach is the preferred approach given the present study design. As stated in the introduction, this approach allows for modelling clustered data, to correct for autocorrelation, and for modelling random effects. In addition, in this study radiation was used as the predictor of primary interest instead of a general condition (exposed vs. non-exposed conditions) effect. This was made possible by connecting the radiation detector to the amplifier. Another methodological difference may lie in the usage of shielded electrodes (most articles do not describe this specific information) which prevents a direct influence of RF-EMF on the wires. Yet another difference is that in the present study an actual mobile phone was used functioning within the UMTS bandwidth (instead of 2G). The studies which also used UMTS do not find EEG effects [18,27,29]. A final difference pertains to the control measurement. Whereas most studies had the control session on a separate day, the present study used a crossover moment in the same session, directly preceding and following the exposure session.

Some limitations have to be considered. First, the study was performed with adult female subjects only. The generalizability of the results to, for example, male subjects, children, and the elderly has to be demonstrated in future research. Second, a sample size of thirty-one is relatively small. Future studies with larger sample sizes are required. Two other critical points are exposure time and follow up measurements. In this study, only one exposure condition (15 minutes) was used and a (long term) follow up measurement was not included. It would be interesting to investigate what the effects are of other (shorter or longer) exposure periods to mobile phone radiation, as well as to find out what the effects are of frequent experimental exposure to radiation in the long term. Fifth, no inner ear temperature was measured. As there is evidence that mobile phones cause a thermal, heating effect [30], it could be argued that inner ear temperature fluctuations between the conditions may have confounded the findings. On the other hand, it has also been reported that any changes in cerebral blood flow due to mobile phone radiation, assessed by positron emission tomography, are unlikely to be temperature-related [31,32]. This issue needs further investigation. Sixth, the experiment was performed in a non-shielded room, thus including environmental background radiation. It would be ideal to carry out such experiments in a radiation-free environment. As a seventh point of concern, in retrospect it would have been preferable to not enter the experimenting room in-between conditions to change phones. Ideally the phone should be programmed from outside the room. Furthermore, a note should be made with respect to the number of tests performed. For example, Fig 1 contains eighteen test results. When corrected with the Bonferroni procedure, only two p-values (slow-beta left and midline) would remain significant. However, at least some of the findings would hold up under such a correction and it should be noted that the Bonferroni method is actually overly conservative for multiple correlated tests. [33] Instead, the ‘False discovery rate’ (FDR) was used to correct for multiple testing.

Most results were still significant after correction. Finally, information on other (psycho)physiological and biological measures may be included in future work.

The question is whether the (temporary) EEG changes, induced by mobile phone radiation, have clinical/adverse consequences. Answering this question is complex and beyond the scope of the present manuscript. First, it is unknown whether mobile phones change EEG activity in the long term. Second, EEG is a reflection of very complex cerebral processes. It is thought that the activity in the different frequency bands represents underlying cortical functions. An example is the thalamocortical network, which plays an important role in the generation of alpha activity [34]. Beta activity, however, only plays a role in the cortex and can, for example, be related to active concentration [35]. Since the functional role of the different frequency bands is still not fully understood, it is also hard to draw conclusions on the (clinical) implications of EEG changes.

In future studies other indicators of brain activity may be included. For example, transcranial magnetic stimulation is a method to test brain excitability. There are several indications that brain excitability is modified due to mobile phone radiation [36–38].

This study attempted to approach the question whether or not mobile phones cause (short-term) changes in EEG activity. There was evidence that mobile phone radiation is associated with increased activity of the alpha, beta, and gamma frequency bands in nearly every brain region. The distance of the mobile phone to the brain was relevant, a larger distance resulting in less or no EEG interference. Replication of the present findings and investigation of possible long term (clinically relevant) effects is urgently required.

Effects of radiofrequency electromagnetic fields on the human nervous system

Abstract

The effects of exposure to radiofrequency electromagnetic fields (EMF), specifically related to the use of mobile telephones, on the nervous system in humans have been the subject of a large number of experimental studies in recent years. There is some evidence of an effect of exposure to a Global System for Mobile Telecommunication (GSM)-type signal on the spontaneous electroencephalogram (EEG). This is not corroborated, however, by the results from studies on evoked potentials. Although there is some evidence emerging that there may be an effect of exposure to a GSM-type signal on sleep EEG, results are still variable. In summary, exposure to a GSM-type signal may result in minor effects on brain activity, but such changes have never been found to relate to any adverse health effects. No consistent significant effects on cognitive performance in adults have been observed. If anything, any effect is small and exposure seems to improve performance. Effects in children did not differ from those in healthy adults. Studies on auditory and vestibular function are more unequivocal: neither hearing nor the sense of balance is influenced by short-term exposure to mobile phone signals. Subjective symptoms over a wide range, including headaches and migraine, fatigue, and skin itch, have been attributed to various radiofrequency sources both at home and at work. However, in provocation studies a causal relation between EMF exposure and symptoms has never been demonstrated. There are clear indications, however, that psychological factors such as the conscious expectation of effect may play an important role in this condition.

Evaluation of Mobile Phone and Cordless Phone Use and Glioma Risk Using the Bradford Hill Viewpoints from 1965 on Association or Causation

Abstract

Objective. Bradford Hill's viewpoints from 1965 on association or causation were used on glioma risk and use of mobile or cordless phones. Methods. All nine viewpoints were evaluated based on epidemiology and laboratory studies. Results. Strength: meta-analysis of case-control studies gave odds ratio (OR) = 1.90, 95% confidence interval (CI) = 1.31-2.76 with highest cumulative exposure. Consistency: the risk increased with latency, meta-analysis gave in the 10+ years' latency group OR = 1.62, 95% CI = 1.20-2.19. Specificity: increased risk for glioma was in the temporal lobe. Using meningioma cases as comparison group still increased the risk. Temporality: highest risk was in the 20+ years' latency group, OR = 2.01, 95% CI =1.41-2.88, for wireless phones. Biological gradient: cumulative use of wireless phones increased the risk. Plausibility: animal studies showed an increased incidence of glioma and malignant schwannoma in rats exposed to radiofrequency (RF) radiation. There is increased production of reactive oxygen species (ROS) from RF radiation. Coherence: there is a change in the natural history of glioma and increasing incidence. Experiment: antioxidants reduced ROS production from RF radiation. Analogy: there is an increased risk in subjects exposed to extremely low-frequency electromagnetic fields. Conclusion. RF radiation should be regarded as a human carcinogen causing glioma.

Fetal radiofrequency radiation exposure from 800-1900 mhz-rated cellular telephones affects neurodevelopment and behavior in mice

Abstract

Neurobehavioral disorders are increasingly prevalent in children, however their etiology is not well understood. An association between prenatal cellular telephone use and hyperactivity in children has been postulated, yet the direct effects of radiofrequency radiation exposure on neurodevelopment remain unknown. Here we used a mouse model to demonstrate that in-utero radiofrequency exposure from cellular telephones does affect adult behavior. Mice exposed in-utero were hyperactive and had impaired memory as determined using the object recognition, light/dark box and step-down assays. Whole cell patch clamp recordings of miniature excitatory postsynaptic currents (mEPSCs) revealed that these behavioral changes were due to altered neuronal developmental programming. Exposed mice had dose-responsive impaired glutamatergic synaptic transmission onto layer V pyramidal neurons of the prefrontal cortex. We present the first experimental evidence of neuropathology due to in-utero cellular telephone radiation. Further experiments are needed in humans or non-human primates to determine the risk of exposure during pregnancy.

Prenatal and Postnatal Cell Phone Exposures and Headaches in Children

Abstract

OBJECTIVE:
Children today are exposed to cell phones early in life, and may be at the greatest risk if exposure is harmful to health. We investigated associations between cell phone exposures and headaches in children.

STUDY DESIGN:
The Danish National Birth Cohort enrolled pregnant women between 1996 and 2002. When their children reached age seven years, mothers completed a questionnaire regarding the child's health, behaviors, and exposures. We used multivariable adjusted models to relate prenatal only, postnatal only, or both prenatal and postnatal cell phone exposure to whether the child had migraines and headache-related symptoms.

RESULTS:
Our analyses included data from 52,680 children. Children with cell phone exposure had higher odds of migraines and headache-related symptoms than children with no exposure. The odds ratio for migraines was 1.30 (95% confidence interval: 1.01-1.68) and for headache-related symptoms was 1.32 (95% confidence interval: 1.23-1.40) for children with both prenatal and postnatal exposure.

CONCLUSIONS:
In this study, cell phone exposures were associated with headaches in children, but the associations may not be causal given the potential for uncontrolled confounding and misclassification in observational studies such as this. However, given the widespread use of cell phones, if a causal effect exists it would have great public health impact.

Reduction of Phosphorylated Synapsin I (Ser-553) Leads to Spatial Memory Impairment by Attenuating GABA Release after Microwave Exposure in Wistar Rats

Abstract

Background

Abnormal release of neurotransmitters after microwave exposure can cause learning and memory deficits. This study investigated the mechanism of this effect by exploring the potential role of phosphorylated synapsin I (p-Syn I).

Methods

Wistar rats, rat hippocampal synaptosomes, and differentiated (neuronal) PC12 cells were exposed to microwave radiation for 5 min at a mean power density of 30 mW/cm^2. Sham group rats, synaptosomes, and cells were otherwise identically treated and acted as controls for all of the following post-exposure analyses. Spatial learning and memory in rats was assessed using the Morris Water Maze (MWM) navigation task. The protein expression and presynaptic distribution of p-Syn I and neurotransmitter transporters were examined via western blotting and immunoelectron microscopy, respectively. Levels amino acid neurotransmitter release from rat hippocampal synaptosomes and PC12 cells were measured using high performance liquid chromatograph (HPLC) at 6 hours after exposure, with or without synapsin I silencing via shRNA transfection.

Results

In the rat experiments, there was a decrease in spatial memory performance after microwave exposure. The expression of p-Syn I (ser-553) was decreased at 3 days post-exposure and elevated at later time points. Vesicular GABA transporter (VGAT) was significantly elevated after exposure. The GABA release from synaptosomes was attenuated and p-Syn I (ser-553) and VGAT were both enriched in small clear synaptic vesicles, which abnormally assembled in the presynaptic terminal after exposure. In the PC12 cell experiments, the expression of p-Syn I (ser-553) and GABA release were both attenuated at 6 hours after exposure. Both microwave exposure and p-Syn I silencing reduced GABA release and maximal reduction was found for the combination of the two, indicating a synergetic effect.

Conclusion

p-Syn I (ser-553) was found to play a key role in the impaired GABA release and cognitive dysfunction that was induced by microwave exposure.

Purkinje cell number decreases in the adult female rat cerebellum following exposure to 900 MHz electromagnetic field

Abstract

The biological effects of electromagnetic field (EMF) exposure from mobile phones have growing concern among scientists since there are some reports showing increased risk for human health, especially in the use of mobile phones for a long duration. In the presented study, the effects on the number of Purkinje cells in the cerebellum of 16-week (16 weeks) old female rats were investigated following exposure to 900 MHz EMF. Three groups of rats, a control group (CG), sham exposed group (SG) and an electromagnetic field exposed group (EMFG) were used in this study. While EMFG group rats were exposed to 900 MHz EMF (1h/day for 28 days) in an exposure tube, SG was placed in the exposure tube but not exposed to EMF (1h/day for 28 days). The specific energy absorption rate (SAR) varied between 0.016 (whole body) and 2 W/kg (locally in the head). The CG was not placed into the exposure tube nor was it exposed to EMF during the study period. At the end of the experiment, all of the female rats were sacrificed and the number of Purkinje cells was estimated using a stereological counting technique. Histopathological evaluations were also done on sections of the cerebellum. Results showed that the total number of Purkinje cells in the cerebellum of the EMFG was significantly lower than those of CG ($p<0.004$) and SG ($p<0.002$). In addition, there was no significant difference at the 0.05 level between the rats' body and brain weights in the EMFG and CG or SG. Therefore, it is suggested that long duration exposure to 900 MHz EMF leads to decreases of Purkinje cell numbers in the female rat cerebellum.

The 2100MHz radiofrequency radiation of a 3G-mobile phone and the DNA oxidative damage in brain

Abstract

We aimed to evaluate the effect of 2100MHz radiofrequency radiation emitted by a generator, simulating a 3G-mobile phone on the brain of rats during 10 and 40 days of exposure. The female rats were randomly divided into four groups. Group I; exposed to 3G modulated 2100MHz RFR signal for 6h/day, 5 consecutive days/wk for 2 weeks, group II; control 10 days, were kept in an inactive exposure set-up for 6h/day, 5 consecutive days/wk for 2 weeks, group III; exposed to 3G modulated 2100MHz RFR signal for 6h/day, 5 consecutive days/wk for 8 weeks and group IV; control 40 days, were kept in an inactive exposure set-up for 6h/day, 5 consecutive days/wk for 8 weeks. After the genomic DNA content of brain was extracted, oxidative DNA damage (8-hydroxy-2'deoxyguanosine, pg/mL) and malondialdehyde (MDA, nmoL/g tissue) levels were determined. Our main finding was the increased oxidative DNA damage to brain after 10 days of exposure with the decreased oxidative DNA damage following 40 days of exposure compared to their control groups. Besides decreased lipid peroxidation end product, MDA, was observed after 40 days of exposure. The measured decreased quantities of damage during the 40 days of exposure could be the means of adapted and increased DNA repair mechanisms.

Association between number of cell phone contracts and brain tumor incidence in nineteen U.S. States

Abstract

Some concern has arisen about adverse health effects of cell phones, especially the possibility that the low power microwave-frequency signal transmitted by the antennas on handsets might cause brain tumors or accelerate the growth of subclinical tumors. We analyzed data from the Statistical Report: Primary Brain Tumors in the United States, 2000–2004 and 2007 cell phone subscription data from the Governing State and Local Sourcebook. There was a significant correlation between number of cell phone subscriptions and brain tumors in nineteen US states ($r = 0.950$, $P < 0.001$). Because increased numbers of both cell phone subscriptions and brain tumors could be due solely to the fact that some states, such as New York, have much larger populations than other states, such as North Dakota, multiple linear regression was performed with number of brain tumors as the dependent variable, cell phone subscriptions, population, mean family income and mean age as independent variables. The effect of cell phone subscriptions was significant ($P = 0.017$), and independent of the effect of mean family income ($P = 0.894$), population ($P = 0.003$) and age (0.499). The very linear relationship between cell phone usage and brain tumor incidence is disturbing and certainly needs further epidemiological evaluation. In the meantime, it would be prudent to limit exposure to all sources of electro-magnetic radiation.

Effects of mobile phone radiation (900 MHz radiofrequency) on structure and functions of rat brain

Abstract

OBJECTIVES:
The goals of this study were: (1) to obtain basic information about the effects of long-term use of mobile phones on cytological makeup of the hippocampus in rat brains (2) to evaluate the effects on antioxidant status, and (3) to evaluate the effects on cognitive behavior particularly on learning and memory.

METHODS:
Rats (age 30 days, 120 ± 5 g) were exposed to 900 MHz radio waves by means of a mobile hand set for 4 hours per day for 15 days. Effects on anxiety, spatial learning, and memory were studied using the open field test, the elevated plus maze, the Morris water maze (MWM), and the classic maze test. Effects on brain antioxidant status were also studied. Cresyl violet staining was done to assess the neuronal damage.

RESULT:
A significant change in behavior, i.e., more anxiety and poor learning was shown by test animals as compared to controls and sham group. A significant change in the level of antioxidant enzymes and non-enzymatic antioxidants, and an increase in lipid peroxidation were observed in the test rats. Histological examination showed neurodegenerative cells in hippocampal sub regions and the cerebral cortex.

DISCUSSION:
Thus our findings indicate extensive neurodegeneration on exposure to radio waves. Increased production of reactive oxygen species due to exhaustion of enzymatic and non-enzymatic antioxidants and increased lipid peroxidation indicate extensive neurodegeneration in selective areas of CA1, CA3, DG, and the cerebral cortex. This extensive neuronal damage results in alterations in behavior related to memory and learning.

A Challenging Issue in the Etiology of Speech Problems: The Effect of Maternal Exposure to Electromagnetic Fields on Speech Problems in the Offspring

Abstract

Background

Nowadays, mothers are continuously exposed to different sources of electromagnetic fields before and even during pregnancy. It has recently been shown that exposure to mobile phone radiation during pregnancy may lead to adverse effects on the brain development in offspring and cause hyperactivity. Researchers have shown that behavioral problems in laboratory animals which have a similar appearance to ADHD are caused by intrauterine exposure to mobile phones.

Objective

The purpose of this study was to investigate whether the maternal exposure to different sources of electromagnetic fields affect on the rate and severity of speech problems in their offspring.

Methods

In this study, mothers of 35 healthy 3-5 year old children (control group) and 77 children and diagnosed with speech problems who had been referred to a speech treatment center in Shiraz, Iran were interviewed. These mothers were asked whether they had exposure to different sources of electromagnetic fields such as mobile phones, mobile base stations, Wi-Fi, cordless phones, laptops and power lines.

Results

We found a significant association between either the call time (P=0.002) or history of mobile phone use (months used) and speech problems in the offspring (P=0.003). However, other exposures had no effect on the occurrence of speech problems. To the best of our knowledge, this is the first study to investigate a possible association between maternal exposure to electromagnetic field and speech problems in the offspring. Although a major limitation in our study is the relatively small sample size, this study indicates that the maternal exposure to common sources of electromagnetic fields such as mobile phones can affect the occurrence of speech problems in the offspring.

Effects of Cell Phone Radiofrequency Signal Exposure on Brain Glucose Metabolism

Abstract

Context

The dramatic increase in use of cellular telephones has generated concern about possible negative effects of radiofrequency signals delivered to the brain. However, whether acute cell phone exposure affects the human brain is unclear.

Objective

To evaluate if acute cell phone exposure affects brain glucose metabolism, a marker of brain activity.

Design, Setting, and Participants

Randomized crossover study conducted between January 1 and December 31, 2009, at a single US laboratory among 47 healthy participants recruited from the community. Cell phones were placed on the left and right ears and positron emission tomography with (18F)fluorodeoxyglucose injection was used to measure brain glucose metabolism twice, once with the right cell phone activated (sound muted) for 50 minutes ("on" condition) and once with both cell phones deactivated ("off" condition). Statistical parametric mapping was used to compare metabolism between on and off conditions using paired t tests, and Pearson linear correlations were used to verify the association of metabolism and estimated amplitude of radiofrequency-modulated electromagnetic waves emitted by the cell phone. Clusters with at least 1000 voxels (volume >8 cm3) and $P < .05$ (corrected for multiple comparisons) were considered significant.

Main Outcome Measure

Brain glucose metabolism computed as absolute metabolism (µmol/100 g per minute) and as normalized metabolism (region/whole brain).

Results

Whole-brain metabolism did not differ between on and off conditions. In contrast, metabolism in the region closest to the antenna (orbitofrontal cortex and temporal pole) was significantly higher for on than off conditions (35.7 vs 33.3 µmol/100 g per minute; mean difference, 2.4 [95% confidence interval, 0.67–4.2]; $P = .004$). The increases were significantly correlated with the estimated electromagnetic field amplitudes both for absolute metabolism ($R = 0.95$, $P < .001$) and normalized metabolism ($R = 0.89$; $P < .001$).

Conclusions

In healthy participants and compared with no exposure, 50-minute cell phone exposure was associated with increased brain glucose metabolism in the region closest to the antenna. This finding is of unknown clinical significance.

https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3184892/

900 MHz electromagnetic field exposure affects qualitative and quantitative features of hippocampal pyramidal cells in the adult female rat

Abstract

The effects of electromagnetic fields (EMFs) emitted by mobile phones on humans hold special interest due to their use in close proximity to the brain. The current study investigated the number of pyramidal cells in the cornu ammonis (CA) of the 16-week-old female rat hippocampus following postnatal exposure to a 900 megahertz (MHz) EMF. In this study were three groups of 6 rats: control (Cont), sham exposed (Sham), and EMF exposed (EMF). EMF group rats were exposed to 900 MHz EMF (1 h/day for 28 days) in an exposure tube. Sham group was placed in the exposure tube but not exposed to EMF (1 h/day for 28 days). Cont group was not placed into the exposure tube nor were they exposed to EMF during the study period. In EMF group rats, the specific energy absorption rate (SAR) varied between 0.016 (whole body) and 2 W/kg (locally in the head). All of the rats were sacrificed at the end of the experiment and the number of pyramidal cells in the CA was estimated using the optical fractionator technique. Histopathological evaluations were made on sections of the CA region of the hippocampus. Results showed that postnatal EMF exposure caused a significant decrease of the pyramidal cell number in the CA of the EMF group ($P<0.05$). Additionally, cell loss can be seen in the CA region of EMF group even at qualitative observation. These results may encourage researchers to evaluate the chronic effects of 900 MHz EMF on teenagers' brains.

https://www.ncbi.nlm.nih.gov/pubmed/19230827

Chronic prenatal exposure to the 900 megahertz electromagnetic field induces pyramidal cell loss in the hippocampus of newborn rats

Abstract

Widespread use of mobile phones which are a major source of electromagnetic fields might affect living organisms. However, there has been no investigation concerning prenatal exposure to electromagnetic fields or their roles in the development of the pyramidal cells of the cornu ammonis in postnatal life. Two groups of pregnant rats, a control group and an experimental group, that were exposed to an electromagnetic field were used. For obtaining electromagnetic field offspring, the pregnant rats were exposed to 900 megahertz electromagnetic fields during the 1-19th gestation days. There were no actions performed on the control group during the same period. The offspring rats were spontaneously delivered--control group (n = 6) and electromagnetic field group (n = 6). Offspring were sacrificed for stereological analyses at the end of the 4th week. Pyramidal cell number in rat cornu ammonis was estimated using the optical fractionator technique. It was found that 900 megahertz of electromagnetic field significantly reduced the total pyramidal cell number in the cornu ammonis of the electromagnetic field group ($P < 0.001$). Therefore, although its exact mechanism is not clear, it is suggested that pyramidal cell loss in the cornu ammonis could be due to the 900 megahertz electromagnetic field exposure in the prenatal period.

https://www.ncbi.nlm.nih.gov/pubmed/19671630

Mobile Phone Use, Blood Lead Levels, and Attention Deficit Hyperactivity Symptoms in Children: A Longitudinal Study

Abstract

Background

Concerns have developed for the possible negative health effects of radiofrequency electromagnetic field (RF-EMF) exposure to children's brains. The purpose of this longitudinal study was to investigate the association between mobile phone use and symptoms of Attention Deficit Hyperactivity Disorder (ADHD) considering the modifying effect of lead exposure.

Methods

A total of 2,422 children at 27 elementary schools in 10 Korean cities were examined and followed up 2 years later. Parents or guardians were administered a questionnaire including the Korean version of the ADHD rating scale and questions about mobile phone use, as well as socio-demographic factors. The ADHD symptom risk for mobile phone use was estimated at two time points using logistic regression and combined over 2 years using the generalized estimating equation model with repeatedly measured variables of mobile phone use, blood lead, and ADHD symptoms, adjusted for covariates.

Results

The ADHD symptom risk associated with mobile phone use for voice calls but the association was limited to children exposed to relatively high lead.

Conclusions

The results suggest that simultaneous exposure to lead and RF from mobile phone use was associated with increased ADHD symptom risk, although possible reverse causality could not be ruled out.

Effect of low level microwave radiation exposure on cognitive function and oxidative stress in rats

Abstract

Use of wireless communicating devices is increasing at an exponential rate in present time and is raising serious concerns about possible adverse effects of microwave (MW) radiation emitted from these devices on human health. The present study aimed to evaluate the effects of 900 MHz MW radiation exposure on cognitive function and oxidative stress in blood of Fischer rats. Animals were divided into two groups (6 animals/group): Group I (MW-exposed) and Group II (Sham-exposed). Animals were subjected to MW exposure (Frequency 900 MHz; specific absorption rate 8.4738 x 10(-5) W/kg) in Gigahertz transverse electromagnetic cell (GTEM) for 30 days (2 h/day, 5 days/week). Subsequently, cognitive function and oxidative stress parameters were examined for each group. Results showed significant impairment in cognitive function and increase in oxidative stress, as evidenced by the increase in levels of MDA (a marker of lipid peroxidation) and protein carbonyl (a marker of protein oxidation) and unaltered GSH content in blood. Thus, the study demonstrated that low level MW radiation had significant effect on cognitive function and was also capable of leading to oxidative stress.

https://www.ncbi.nlm.nih.gov/pubmed/23720885

Cognitive impairment and neurogenotoxic effects in rats exposed to low-intensity microwave radiation

Abstract

The health hazard of microwave radiation (MWR) has become a recent subject of interest as a result of the enormous increase in mobile phone usage. The present study aimed to investigate the effects of chronic low-intensity microwave exposure on cognitive function, heat shock protein 70 (HSP70), and DNA damage in rat brain. Experiments were performed on male Fischer rats exposed to MWR for 180 days at 3 different frequencies, namely, 900, 1800 MHz, and 2450 MHz. Animals were divided into 4 groups: group I: sham exposed; group II: exposed to MWR at 900 MHz, specific absorption rate (SAR) 5.953 × 10(-4) W/kg; group III: exposed to 1800 MHz, SAR 5.835 × 10(-4) W/kg; and group IV: exposed to 2450 MHz, SAR 6.672 × 10(-4) W/kg. All the rats were tested for cognitive function at the end of the exposure period and were subsequently sacrificed to collect brain. Level of HSP70 was estimated by enzyme-linked immunotarget assay and DNA damage was assessed using alkaline comet assay in all the groups. The results showed declined cognitive function, elevated HSP70 level, and DNA damage in the brain of microwave-exposed animals. The results indicated that, chronic low-intensity microwave exposure in the frequency range of 900 to 2450 MHz may cause hazardous effects on the brain.

Maternal mobile phone exposure alters intrinsic electrophysiological properties of CA1 pyramidal neurons in rat offspring

Abstract

Some studies have shown that exposure to electromagnetic field (EMF) may result in structural damage to neurons. In this study, we have elucidated the alteration in the hippocampal function of offspring Wistar rats (n = 8 rats in each group) that were chronically exposed to mobile phones during their gestational period by applying behavioral, histological, and electrophysiological tests. Rats in the EMF group were exposed to 900 MHz pulsed-EMF irradiation for 6 h/day. Whole cell recordings in hippocampal pyramidal cells in the mobile phone groups did show a decrease in neuronal excitability. Mobile phone exposure was mostly associated with a decrease in the number of action potentials fired in spontaneous activity and in response to current injection in both male and female groups. There was an increase in the amplitude of the afterhyperpolarization (AHP) in mobile phone rats compared with the control. The results of the passive avoidance and Morris water maze assessment of learning and memory performance showed that phone exposure significantly altered learning acquisition and memory retention in male and female rats compared with the control rats. Light microscopy study of brain sections of the control and mobile phone-exposed rats showed normal morphology.Our results suggest that exposure to mobile phones adversely affects the cognitive performance of both female and male offspring rats using behavioral and electrophysiological techniques.

Neurodegenerative changes and apoptosis induced by intrauterine and extrauterine exposure of radiofrequency radiation

Abstract

Adverse health effects of radiofrequency radiation (RFR) on the ongoing developmental stages of children from conception to childhood are scientifically anticipated subject. This study was performed to identify the effects of global system for mobile communications (GSM) modulated mobile phone like RFR in 1800MHz frequency on oxidative DNA damage and lipid peroxidation beside the apoptotic cell formation, using histopathological and immunohistochemical methods in the brain tissue of 1-month-old male and female New Zealand White rabbits that were exposed to these fields at their mother's womb and after the birth. Oxidative DNA damage and lipid peroxidation levels were investigated by measuring the 8-hydroxy-2'-deoxyguanosine (8-OHdG) and malondialdehyde (MDA) levels, respectively. Histopathological changes were observed using by hematoxylin and eosin (HE) staining. Apoptotic cells were detected in the examined organs by terminal deoxynucleotidyl transferase-mediated dUTP nick end-labeling (TUNEL) staining. For both male and female infants; 8-OHdG levels increased in the group exposed to RFR in both intrauterine and extrauterine periods compared to the infants that were never exposed to RFR and the ones were exposed when they reached one month of age ($p<0.05$). MDA results were different for male and female rabbits. There was no difference between all female infant groups ($p>0.05$), while only intrauterine exposure significantly causes MDA level increase for the male infants. HE staining revealed mild lessions in neuronal necrobiosis in brain tissues of female rabbits that had only intaruterine exposure and male rabbits had only extrauterine exposure. Gliosis were mildly positive in brain tissues of rabbits that are exposed only intrauterine period, also the group exposed both intrauterine and extrauterine periods. However, there was no apoptotic change detected by TUNEL staining in the brain tissues of all groups.

Effects of radiofrequency radiation exposure on blood-brain barrier permeability in male and female rats

Abstract

During the last several decades, numerous studies have been performed aiming at the question of whether or not exposure to radiofrequency radiation (RFR) influences the permeability of the blood-brain barrier (BBB). The objective of this study was to investigate the effect of RFR on the permeability of BBB in male and female Wistar albino rats. Right brain, left brain, cerebellum, and total brain were analyzed separately in the study. Rats were exposed to 0.9 and 1.8 GHz continuous-wave (CW) RFR for 20 min (at SARs of 4.26 mW/kg and 1.46 mW/kg, respectively) while under anesthesia. Control rats were sham-exposed. Disruption of BBB integrity was detected spectrophotometrically using the Evans-blue dye, which has been used as a BBB tracer and is known to be bound to serum albumin. Right brain, left brain, cerebellum, and total brain were evaluated for BBB permeability. In female rats, no albumin extravasation was found in in the brain after RFR exposure. A significant increase in albumin was found in the brains of the RF-exposed male rats when compared to sham-exposed male brains. These results suggest that exposure to 0.9 and 1.8 GHz CW RFR at levels below the international limits can affect the vascular permeability in the brain of male rats. The possible risk of RFR exposure in humans is a major concern for the society. Thus, this topic should be investigated more thoroughly in the future.

Effects of prenatal exposure to a 900 MHz electromagnetic field on the dentate gyrus of rats: a stereological and histopathological study

Abstract

Electromagnetic fields (EMFs) inhibit the formation and differentiation of neural stem cells during embryonic development. In this study, the effects of prenatal exposure to EMF on the number of granule cells in the dentate gyrus of 4-week-old rats were investigated. This experiment used a control (Cont) group and an EMF exposed (EMF) group (three pregnant rats each group). The EMF group consisted of six offspring (n=6) of pregnant rats that were exposed to an EMF of up to 900 megahertz (MHz) for 60 min/day between the first and last days of gestation. The control group consisted of five offspring (n=5) of pregnant rats that were not treated at all. The offspring were sacrificed when they were 4 weeks old. The numbers of granule cells in the dentate gyrus were analyzed using the optical fractionator technique. The results showed that prenatal EMF exposure caused a decrease in the number of granule cells in the dentate gyrus of the rats ($P<0.01$). This suggests that prenatal exposure to a 900 MHz EMF affects the development of the dentate gyrus granule cells in the rat hippocampus. Cell loss might be caused by an inhibition of granule cell neurogenesis in the dentate gyrus.

Effects of prenatal and postnatal exposure to GSM-like radiofrequency on blood chemistry and oxidative stress in infant rabbits, an experimental study

Abstract

We aimed to investigate the potential hazardous effects of prenatal and/or postnatal exposure to 1800 MHz GSM-like radiofrequency radiation (RFR) on the blood chemistry and lipid peroxidation levels of infant rabbits. A total of 72 New Zealand female and male white rabbits aged 1-month were used. Thirty-six female and 36 male were divided into four groups which were composed of nine infants: (i) Group 1 were the sham exposure (control), (ii) Group 2 were exposed to RFR, 15 min daily for 7 days in the prenatal period (between 15th and 22nd days of the gestational period) (prenatal exposure group). (iii) Group 3 were exposed to RFR 15 min/day (14 days for male, whereas 7 days for female) after they reached 1-month of age (postnatal exposure group). (iv) Group 4 were exposed to RFR for 15 min daily during 7 days in the prenatal period (between 15th and 22nd days of the gestational period) and 15 min/day (14 days for male, whereas 7 days for female) after they reached 1-month of age (prenatal and postnatal exposure group). Results showed that serum lipid peroxidation level in both female and male rabbits changed due to the RFR exposure. However, different parameters of the blood biochemistry were affected by exposure in male and female infants. Consequently, the whole-body 1800 MHz GSM-like RFR exposure may lead to oxidative stress and changes on some blood chemistry parameters. Studies on RFR exposure during prenatal and postnatal periods will help to establish international standards for the protection of pregnants and newborns from environmental RFR.

Mobile phone use and risk for intracranial tumors and salivary gland tumors - A meta-analysis

Abstract

Results of epidemiological studies on the association between use of mobile phone and brain cancer are ambiguous, as well as the results of 5 meta-analysis studies published to date. Since the last meta-analysis (2009), new case-control studies have been published, which theoretically could affect the conclusions on this relationship. Therefore, we decided to perform a new meta-analysis. We conducted a systematic review of multiple electronic data bases for relevant publications. The inclusion criteria were: original papers, case-control studies, published till the end of March 2014, measures of association (point estimates as odds ratio and confidence interval of the effect measured), data on individual exposure. Twenty four studies (26 846 cases, 50 013 controls) were included into the meta-analysis. A significantly higher risk of an intracranial tumor (all types) was noted for the period of mobile phone use over 10 years (odds ratio (OR) = 1.324, 95% confidence interval (CI): 1.028-1.704), and for the ipsilateral location (OR = 1.249, 95% CI: 1.022-1.526). The results support the hypothesis that long-term use of mobile phone increases risk of intracranial tumors, especially in the case of ipsilateral exposure. Further studies are needed to confirm this relationship. Int J Occup Med Environ Health 2017;30(1)27-43.

Cell phone use and behavioral problems in young children

Abstract

BACKGROUND:
Potential health effects of cell phone use in children have not been adequately examined. As children are using cell phones at earlier ages, research among this group has been identified as the highest priority by both national and international organizations. The authors previously reported results from the Danish National Birth Cohort (DNBC), which looked at prenatal and postnatal exposure to cell phone use and behavioral problems at age 7 years. Exposure to cell phones prenatally, and to a lesser degree postnatally, was associated with more behavioral difficulties. The original analysis included nearly 13 000 children who reached age 7 years by November 2006.

METHODS:
To see if a larger, separate group of DNBC children would produce similar results after considering additional confounders, children of mothers who might better represent current users of cell phones were analyzed. This 'new' dataset consisted of 28 745 children with completed Age-7 Questionnaires to December 2008.

RESULTS:
The highest OR for behavioral problems were for children who had both prenatal and postnatal exposure to cell phones compared with children not exposed during either time period. The adjusted effect estimate was 1.5 (95% CI 1.4 to 1.7).

CONCLUSIONS:
The findings of the previous publication were replicated in this separate group of participants demonstrating that cell phone use was associated with behavioral problems at age 7 years in children, and this association was not limited to early users of the technology. Although weaker in the new dataset, even with further control for an extended set of potential confounders, the associations remained.

https://www.ncbi.nlm.nih.gov/pubmed/21138897

Prenatal and postnatal exposure to cell phone use and behavioral problems in children

Abstract

BACKGROUND:
The World Health Organization has emphasized the need for research into the possible effects of radiofrequency fields in children. We examined the association between prenatal and postnatal exposure to cell phones and behavioral problems in young children.

METHODS:
Mothers were recruited to the Danish National Birth Cohort early in pregnancy. When the children of those pregnancies reached 7 years of age in 2005 and 2006, mothers were asked to complete a questionnaire regarding the current health and behavioral status of children, as well as past exposure to cell phone use. Mothers evaluated the child's behavior problems using the Strength and Difficulties Questionnaire.

RESULTS:
Mothers of 13,159 children completed the follow-up questionnaire reporting their use of cell phones during pregnancy as well as current cell phone use by the child. Greater odds ratios for behavioral problems were observed for children who had possible prenatal or postnatal exposure to cell phone use. After adjustment for potential confounders, the odds ratio for a higher overall behavioral problems score was 1.80 (95% confidence interval = 1.45-2.23) in children with both prenatal and postnatal exposure to cell phones.

CONCLUSIONS:
Exposure to cell phones prenatally-and, to a lesser degree, postnatally-was associated with behavioral difficulties such as emotional and hyperactivity problems around the age of school entry. These associations may be noncausal and may be due to unmeasured confounding. If real, they would be of public health concern given the widespread use of this technology.

The influence of microwave radiation from cellular phone on fetal rat brain

Abstract

The increasing use of cellular phones in our society has brought focus on the potential detrimental effects to human health by microwave radiation. The aim of our study was to evaluate the intensity of oxidative stress and the level of neurotransmitters in the brains of fetal rats chronically exposed to cellular phones. The experiment was performed on pregnant rats exposed to different intensities of microwave radiation from cellular phones. Thirty-two pregnant rats were randomly divided into four groups: CG, GL, GM, and GH. CG accepted no microwave radiation, GL group radiated 10 min each time, GM group radiated 30 min, and GH group radiated 60 min. The 3 experimental groups were radiated 3 times a day from the first pregnant day for consecutively 20 days, and on the 21st day, the fetal rats were taken and then the contents of superoxide dismutase (SOD), glutathione peroxidase (GSH-Px), malondialdehyde (MDA), noradrenaline (NE), dopamine (DA), and 5-hydroxyindole acetic acid (5-HT) in the brain were assayed. Compared with CG, there were significant differences ($P<0.05$) found in the contents of SOD, GSH-Px, and MDA in GM and GH; the contents of SOD and GSH-Px decreased and the content of MDA increased. The significant content differences of NE and DA were found in fetal rat brains in GL and GH groups, with the GL group increased and the GH group decreased. Through this study, we concluded that receiving a certain period of microwave radiation from cellular phones during pregnancy has certain harm on fetal rat brains.

Possible cause for altered spatial cognition of prepubescent rats exposed to chronic radiofrequency electromagnetic radiation

Abstract

The effects of chronic and repeated radiofrequency electromagnetic radiation (RFEMR) exposure on spatial cognition and hippocampal architecture were investigated in prepubescent rats. Four weeks old male Wistar rats were exposed to RF-EMR (900 MHz; SAR-1.15 W/kg with peak power density of 146.60 µW/cm(2)) for 1 h/day, for 28 days. Followed by this, spatial cognition was evaluated by Morris water maze test. To evaluate the hippocampal morphology; H&E staining, cresyl violet staining, and Golgi-Cox staining were performed on hippocampal sections. CA3 pyramidal neuron morphology and surviving neuron count (in CA3 region) were studied using H&E and cresyl violet stained sections. Dendritic arborization pattern of CA3 pyramidal neuron was investigated by concentric circle method. Progressive learning abilities were found to be decreased in RF-EMR exposed rats. Memory retention test performed 24 h after the last training revealed minor spatial memory deficit in RF-EMR exposed group. However, RF-EMR exposed rats exhibited poor spatial memory retention when tested 48 h after the final trial. Hirano bodies and Granulovacuolar bodies were absent in the CA3 pyramidal neurons of different groups studied. Nevertheless, RF-EMR exposure affected the viable cell count in dorsal hippocampal CA3 region. RF-EMR exposure influenced dendritic arborization pattern of both apical and basal dendritic trees in RF-EMR exposed rats. Structural changes found in the hippocampus of RF-EMR exposed rats could be one of the possible reasons for altered cognition.

Maternal exposure to a continuous 900-MHz electromagnetic field provokes neuronal loss and pathological changes in cerebellum of 32-day-old female rat offspring

Abstract

Large numbers of people are unknowingly exposed to electromagnetic fields (EMF) from wireless devices. Evidence exists for altered cerebellar development in association with prenatal exposure to EMF. However, insufficient information is still available regarding the effects of exposure to 900 megahertz (MHz) EMF during the prenatal period on subsequent postnatal cerebellar development. This study was planned to investigate the 32-day-old female rat pup cerebellum following exposure to 900MHz EMF during the prenatal period using stereological and histopathological evaluation methods. Pregnant rats were divided into control, sham and EMF groups. Pregnant EMF group (PEMFG) rats were exposed to 900MHz EMF for 1h inside an EMF cage during days 13-21 of pregnancy. Pregnant sham group (PSG) rats were also placed inside the EMF cage during days 13-21 of pregnancy for 1h, but were not exposed to any EMF. No procedure was performed on the pregnant control group (PCG) rats. Newborn control group (CG) rats were obtained from the PCG mothers, newborn sham group (SG) rats from the PSG and newborn EMF group (EMFG) rats from the PEMFG rats. The cerebellums of the newborn female rats were extracted on postnatal day 32. The number of Purkinje cells was estimated stereologically, and histopathological evaluations were also performed on cerebellar sections. Total Purkinje cell numbers calculated using stereological analysis were significantly lower in EMFG compared to CG ($p<0.05$) and SG ($p<0.05$). Additionally, some pathological changes such as pyknotic neurons with dark cytoplasm were observed in EMFG sections under light microscopy. In conclusion, our study results show that prenatal exposure to EMF affects the development of Purkinje cells in the female rat cerebellum and that the consequences of this pathological effect persist after the postnatal period.

Microwave radiation induced oxidative stress, cognitive impairment and inflammation in brain of Fischer rats

Abstract

Public concerns over possible adverse effects of microwave radiation emitted by mobile phones on health are increasing. To evaluate the intensity of oxidative stress, cognitive impairment and inflammation in brain of Fischer rats exposed to microwave radiation, male Fischer-344 rats were exposed to 900 MHz microwave radiation (SAR = 5.953 x 10(-4) W/kg) and 1800 MHz microwave radiation (SAR = 5.835 x 10(-4) W/kg) for 30 days (2 h/day). Significant impairment in cognitive function and induction of oxidative stress in brain tissues of microwave exposed rats were observed in comparison with sham exposed groups. Further, significant increase in level of cytokines (IL-6 and TNF-alpha) was also observed following microwave exposure. Results of the present study indicated that increased oxidative stress due to microwave exposure may contribute to cognitive impairment and inflammation in brain.

Wi-Fi

Wi-Fi Radiation: An Invisible Threat to Your Health?

We have long been told that the form of radio frequency radiation that Wi-Fi devices utilize is non-ionizing. That is to say it doesn't have sufficient energy to break the bonds that hold molecules together, and that there is no heating effect… so therefore it is harmless. Or at least that's what we're told.

But thousands of peer reviewed studies now tell a different story. Wi-Fi radiation may not cause a thermal heating effect, and it might be non-ionizing – but it is far from harmless.

Independent research dating back some 80 years links Wi-Fi radiation to a long list of adverse biological effects, including:

- DNA chain breaks
- Increased blood-brain-barrier permeability
- Disruption to brain glucose metabolism
- Creation of stress proteins
- Disruption of cell metabolism

Studies also associate Wi-Fi radiation exposure with such symptoms as fatigue, irritability, headaches, and digestive disorders. Long-term exposure to Wi-Fi radiation has been linked with many serious diseases – including cancer.

Numerous studies link Wi-Fi radiation exposure with cancer. Notably, the German telecommunications company T-Mobile carried out a major independent study. It found that *"on the cellular level, a multitude of studies found the type of damage from high frequency electromagnetic fields which is important for cancer initiation and cancer promotion."*

In 2011, the World Health Organization classified radio frequency radiation of the type used by Wi-Fi devices as a Group 2B possible carcinogen. A study conducted by the University of Vienna have found Wi-Fi exposures to cause genotoxicity as they break single and double strand DNAs in our body. This indicates that there are effects that may potentially surface with our future generations.

Safety standards do exist for radio frequency radiation emissions, but these standards are only based on thermal heating effects. That is to say they only consider these exposures to be harmful if they heat tissue. But these safety standards do not protect us from adverse biological effects which are thought to be the precursor to serious diseases. Scientists have already raised the alarm regarding this issue.

In 2015, scientists from around the world united for the *International EMF Scientist Appeal* based on the results of over 2,000 research papers. The appeal is the collective voice of 190 scientists from 39 different countries. They are calling for tighter regulations and more security measures when dealing with electromagnetic field exposures generally, and Wi-Fi in particular.

Last year, 15-year-old English schoolgirl Jenny Fry was found hanged in woodland near her home. According to her parents she suffered from electrical sensitivity, making it impossible for her to sit in Wi-Fi classrooms and have Wi-Fi at home. The school refused to remove the Wi-Fi. Speaking at the inquest her mother said, "I believe that Wi-Fi killed my daughter."

10 Shocking Facts about the Health Dangers of Wi-Fi

Wi-Fi is convenient but many have raised doubts concerning the safety of unseen forces that permeate everything around us. Since the introduction of Wi-Fi in 1997, researchers have performed dozens of studies to explore the subject. The results are clear and shocking — Wi-Fi can negatively affect overall health and brain health, especially in children.

Perhaps most shocking is that this information is not new or even that controversial. In fact, in 2008 the well-renowned publication Scientific American ran a piece called "Mind Control by Cell Phone" which explained the danger Wi-Fi has on the human brain. [1] Let's further explore the potential dangers of Wi-Fi with these 10 facts.

1. **Contributes to the development of insomnia**
   Have you ever felt more awake after using Wi-Fi or even struggled to sleep through the night? Reports of these phenomena have been frequent and even prompted a study in 2007 that evaluated low-frequency modulation from cell phones and its impact on sleep. Participants were exposed to the electromagnetic signals from real phones or no signal from fake phones. Those exposed to the electromagnetic radiation had a significantly more difficult time falling asleep and changes in brainwave patterns were observed. [2]

   It's been suggested that sleeping near a phone, in a home with Wi-Fi, or in an apartment building with many Wi-Fi signals can create chronic sleep problems as the constant bombardment of Wi-Fi pollution interferes with falling asleep and sleep patterns. For many, sleep deprivation is just the start for larger problems. The development of depression and hypertension have also been linked to inadequate sleep. [3]
2. **Damaging to Childhood Development**
   Exposure to non-thermal radio frequency radiation from Wi-Fi and cellular phones can disrupt normal cellular development, especially fetal development. A 2004 animal study linked exposure to delayed kidney development. [4] These findings were supported by a 2009 Austrian study. In fact, the disruption of protein synthesis is so severe that authors specifically noted, "This cell property is especially pronounced in growing tissues, that is, in children and youth. Consequently, these population groups would be more susceptible than average to the described effects." [5] In short, bathing the developmentally young in Wi-Fi increases their risk of developmental issues.
3. **Affects Cell Growth**
   When a group of Danish ninth graders experienced difficulty concentrating after sleeping with their cell phones by their head, they performed an experiment to test the effect of wireless Wi-Fi routers on garden cress. One set of plants was grown in a room free of wireless radiation; the other group grew next to two routers that released the same amount of radiation as a cell phone. The results? The plants nearest the radiation didn't grow. [6]
4. **Derails Brain Function**
   Just as the Danish high schoolers noticed problems with concentration, scientists have begun to look at the impact of 4G radiation on brain function. Using MRI technology, research performed just last year found that persons exposed to 4G radiation had several areas of reduced brain activity. [7]
5. **Reduces Brain Activity in Females**

A group of 30 healthy volunteers, 15 men and 15 women, were given a simple memory test. First, the entire group was tested without any exposure to Wi-Fi radiation — no problem. Then, they were exposed to 2.4 GHz Wi-Fi from a wireless access point for about 45 minutes. During that portion of the testing, brain activity was measured and the women had a noticeable change in brain activity and energy levels. [8] Sorry ladies! But guys, don't get too comfortable…

6. **Neutralizes Sperm**
   …Because we've known for a long time that the heat generated by laptops kills sperm. Well, now it turns out that heat isn't the only threat to a man's virility. Research has found exposure to Wi-Fi frequencies reduce sperm movement and cause DNA fragmentation. [9] Both human and animal testing has confirmed that exposure negatively affects sperm. [10] [11]
7. **May Impact Fertility**
   And, it's not just sperm. The results of an animal study suggest that some wireless frequencies may prevent egg implantation. During the study, mice exposed 2 hours a day for 45 days had significantly increased oxidative stress levels. The cellular damage and impact on DNA structure from exposure suggest a strong possibility of abnormal pregnancy or failure of the egg to implant. [12]

   The Karolinska Institute in Sweden released a warning in 2011, stating:
   - "Pregnant women are cautioned to avoid using wireless devices themselves and distance themselves from other users,"
   - "Current US [and Canada]…standards for radio frequency and microwave radiation from wireless technology are entirely inadequate," and
   - "Safety standards also ignore the developing fetus…" [13]
8. **Provokes Cardiac Stress**
   If you think your heart races when surrounded by wireless networks or 3G or LTE cell phones, it may not be in your head. A study involving 69 subjects reported that many of them experienced a real physical response to electromagnetic frequencies. Exactly what was the physical response? Increased heart rate — similar to the heart rate of an individual under stress. [14]
9. **Linked to Cancer?**
   This is extremely controversial but we can't ignore that plenty of animal models indicate that exposure to electromagnetic radiation increases the risk of tumor development. While human studies are rare, reports and case studies abound. One such case involves a young 21-year-old woman who developed breast cancer. What makes this case unique was that her family did not have a predisposition to breast cancer… and she developed the tumor right on the spot she carried her cell phone in her bra. [15]

http://www.globalhealingcenter.com/natural-health/10-shocking-facts-health-dangers-Wi-Fi/

Can Wi-Fi Signals Stunt Plant Growth?

A Danish science experiment by a group of 9th-graders has gained worldwide interest and may have us rethinking the proliferation of wireless devices in our homes.

Five girls from Hjallerup Skole, a primary education school in Denmark, began the experiment after noticing that when they slept with their cellphones near their heads overnight, they had trouble focusing the next day, according to Danish News site DR.

The resources weren't available to conduct an experiment around wireless signals affecting brain activity, so instead the girls decided to monitor the growth of plants near Wi-Fi routers - and the results were a bit shocking.

Six trays containing the seeds of a garden cress herb were placed in a room without a Wi-Fi router, and six trays were placed in a different room and next to two Wi-Fi routers which, according to the girls' calculations, emitted about the same type of radiation as an ordinary cellphone, reports DR.

During the 12 days of the experiment, the seeds in the six trays away from the Wi-Fi routers grew normally, while the seeds next to the routers did not. In fact, the project photos show that many of the seeds placed near the routers turned brown and died.

"This has sparked quite a lively debate in Denmark regarding the potential adverse health-effects from mobile phones and Wi-Fi-equipment," Kim Horsevad, biology teacher at Hjallerup Skole told ABC News.

Horsevad said that some of the local debate over the experiment has been over whether the negative effects were due to the cress seeds drying from the heat emitted by the computer/Wi-Fi routers used in the experiment. But she explained that the students kept the cress seeds in both groups sufficiently moist during the whole experiment, and the temperatures were controlled thermostatically.

A similar study was conducted about three years ago in the Netherlands when researchers noticed that some trees in urban areas were showing "bark lumps," according to Popular Science. The experiment, conducted by Wageningen University, involved exposing 20 ash trees to various kinds of radiation for three months. The trees chosen to test tolerance to heavy Wi-Fi signals began to show typical signs of radiation sickness, including a "lead-like shine" on their leaves.

As for the attention the girl's science fair project is getting, Horsevad said neuroscience professor Olle Johanssen with the Karolinska Institute in Sweden has expressed great interest.

"[Johanssen] will probably be repeating the experiment in controlled, professional, scientific environments," said Horsevad. "One would therefore generally be advised to await the results of his experiments before basing any important decisions on the outcome of the girls' experiment."

http://abcnews.go.com/blogs/technology/2013/05/can-Wi-Fi-signals-stunt-plant-growth/

Oh my...what's in Wi-Fi?

Second grader patterns science fair project after Danish experiment

When the school district rolled out the Ipads this year, Aiden Fitchett noticed something new; as he did when seated near the wireless projector any time a teacher used one for a presentation: headaches. Bad ones. Bad enough that the 8-year-old second grader would come home crying from the pain.

His mom, biologist Rachel Fitchett, made a correlation between Aiden's headaches and the circumstances: wireless fidelity waves or Wi-Fi, which has been associated with causing physical effects in a small percentage of the population.

"I knew the health risks associated with Wi-Fi and asked the teacher to relocate him and the headaches stopped," Rachel says.

While that was great, the situation still puzzled Aiden's inquisitive mind. So when Science Fair time rolled around he knew exactly what he wanted to delve into.

"I want to know why I get headaches when I'm around wireless devices but not the wires," Aiden says. "We use a laptop at home, and we have a television set, and it's only around wireless that I get the headaches."

So Aiden set about to answer his question. Patterning his experiment after a Danish experiment by a group of 9th grade students, Aiden and his mom bought some garden cress seeds, growing trays and napkins and got to work.

Aiden placed an equal amount of garden cress seeds atop two napkins, which he placed inside two growing trays. Each was watered until damp. One tray was placed six inches from a wired laptop which was kept on the whole time.

The other tray was placed six inches from a Wi-Fi router in a neighbor's home which was turned on the whole time as well.

Both trays received sunlight from west windows, and both rooms were kept at 69 degrees. The trays were watered daily with the same amount of water.

After six days, the results—similar to those in the Danish experiment—were stunning.

"At first Aiden was excited as the seeds started to grow, but by the second to the last day one of his notations on the Wi-Fi sprouts was 'strange,'" Rachel says.

In the Danish experiment, the cress seeds placed near the Wi-Fi device did not sprout at all. While Aiden's Wi-Fi seeds sprouted, they did not look anything like the robust sprouts growing in the wired room.

The sprouts tasted different as well. Garden cress is a fast-growing herb with a peppery, tangy flavor and smell. The wired seeds tasted strong and peppery—so much so that Aiden had to run for a glass of water. The Wi-Fi seeds had little taste at all. In fact, Aiden said they tasted "like water."
Aiden's conclusion?

"The garden cress are living and growing just like me," he says. "The ones by the Wi-Fi were not healthy and looked crazy. Wireless devices must send things through the air that are not good for my body."

Aiden's mom tends to agree—although in more scientific terms.

"Results clearly showed reduced DNA repair capacity and cell proliferation , hence mimicking the growth of cancerous cells," she says. "The Garden Cress seeds exposed to wireless signals were in fact mutated and unhealthy."

Rachel believes when the wireless signals are intensified by use of multiple devices, so is the negative effect.

"The more that are together, the more concentrated the ill effects are," she says.

Aiden's headaches continued during computer class, so he has since been pulled.

"He's a very bright kid who excels in all subjects, Rachel says. "He doesn't need to get whatever it is they're getting in there."

Checkout 5 Ways Your Wi-Fi Could be Causing You Harm

Wi-Fi is a technology that allows electronic devices to connect to a wireless LAN (WLAN) network, mainly using the 2.4 gigahertz (12 cm) UHF and 5 gigahertz (6 cm) SHF ISM radio bands. A WLAN is usually password protected, but may be open, which allows any device within its range to access the resources of the WLAN network.

The Wi-Fi Alliance defines Wi-Fi as any "wireless local area network" (WLAN) product based on the Institute of Electrical and Electronics Engineers' (IEEE) 802.11 standards. However, the term "Wi-Fi" is used in general English as a synonym for "WLAN" since most modern WLANs are based on these standards. "Wi-Fi" is a trademark of the Wi-Fi Alliance. The "Wi-Fi Certified" trademark can only be used by Wi-Fi products that successfully complete Wi-Fi Alliance interoperability certification testing.

Devices which can use Wi-Fi technology include personal computers, video-game consoles, smartphones, digital cameras, tablet computers, digital audio players and modern printers. Wi-Fi compatible devices can connect to the Internet via a WLAN network and a wireless access point. Such an access point (or hotspot) has a range of about 20 meters (66 feet) indoors and a greater range outdoors. Hotspot coverage can be as small as a single room with walls that block radio waves, or as large as many square kilometers achieved by using multiple overlapping access points.

Depiction of a device sending information wirelessly to another device, both connected to the local network, in order to print a document.
Wi-Fi is less secure than wired connections, such as Ethernet, precisely because an intruder does not need a physical connection. Web pages that use TLS are secure, but unencrypted Internet access can easily be detected by intruders. Because of this, Wi-Fi has adopted various encryption technologies. The early encryption WEP proved easy to break. Higher quality protocols (WPA, WPA2) were added later. An optional feature added in 2007, called Wi-Fi Protected Setup (WPS), had a serious flaw that allowed an attacker to recover the router's password. The Wi-Fi Alliance has since updated its test plan and certification program to ensure all newly certified devices resist attacks.

Many are on edge because they can't imagine a world without the internet. But every good thing has it's bad side and it's better to educated yourself to be safe.
Insomnia

When exposed to electromagnetic radiation, you will have more difficulty falling asleep. So when you can't sleep maybe you should just turn off your phone.

Affects cell growth
Sleeping with your phone next to your head can affect your ability to concentrate.
Experiment: One set of plants was grown in a room free of wireless radiation; the other group grew next to two routers that released the same amount of radiation as a cell phone.
Result: The plants closest to the radiation didn't grow.

Reduces brain activity in females

Experiment: A group of 30 healthy volunteers, 15 men and 15 women, were given a simple memory test. First, the entire group was tested without any exposure to Wi-Fi radiation and the results were fine.

Then, they were exposed to 2.4 GHz Wi-Fi from a wireless access point for about 45 minutes.

Result: During that portion of the testing, brain activity was measured and the women had a noticeable change in brain activity and energy levels.

Effects on fertility

Results of experiments on animals show that some specific wireless frequencies can prevent egg implantation. According to the Global Healing Center, during the study, mice exposed 2 hours a day for 45 days had significantly increased oxidative stress levels.

Cardiac stress

Your heart reacts when surrounded by wireless networks including 3G and LTE phones. Your heart rate increases as if you are under stress. You may have not noticed this because you weren't aware of the dangers.

http://nigeriana.org/technology/checkout-5-ways-Wi-Fi-causing-harm/

Wi-Fi Radiation Is Killing Trees, New Study Finds

Studies on the impact of wireless radiation on humans are endlessly inconclusive, but a recent study on the effects of Wi-Fi radiation on trees--yes, trees--indicates that our woody friends may be much more vulnerable than we are. And trees can't even enjoy the benefits of Wi-Fi. It's all very unjust.

The study, conducted by Wageningen University, investigated findings that trees in areas with high Wi-Fi activity (urban areas, especially) were suffering from symptoms that couldn't be tied to typical bacterial or viral causes. The symptoms included bleeding (!), fissures in the bark, the death of parts of leaves, and abnormal growth.

To test the hypothesis that the mystery illness was caused by radiation poisoning, the researchers took 20 ash trees and exposed them to various kinds of radiation for three months. Sure enough, the ash trees exposed to Wi-Fi signals showed telltale signs of radiation sickness, including a "lead-like shine" on their leaves, indicating the oncoming death of those leaves. In the Netherlands, a whopping 70% of urban trees are suffering from radiation poisoning, up from only 10% five years ago--understandable, considering the explosion in Wi-Fi use in the past five years.

Of course, trees in rural or even simply non-urban environments are pretty much unaffected, but theoretically, all deciduous trees in the Western world could be affected.

The researchers are planning several more studies to figure out the precise effects of radiation on plant life. In the meantime, they don't really offer any preliminary solutions, but I'm sure they'd approve of wrapping every urban tree you see in tin foil, root to leaf. *(Note: Wrapping public trees in tin foil may be illegal in your city, state, arrondissement, or prefecture. PopSci cannot be held responsible if you are arrested for such activities.)*

Wi-Fi radiation from laptops, smartphones is damaging your sperm

The latest in a long line of radiation vs. sperm studies has shown, yet again, that you really ought to take your laptop off your lap. The report, published in the Fertility and Sterility journal by some Argentinian scientists, details how semen samples from 29 healthy, potent men suffered significant damage when placed underneath a Wi-Fi-connected laptop.

In a control test — with the sperm kept away from Wi-Fi emissions, but at the same under-laptop temperature — 14% of the sperm died within four hours, and 3% showed DNA damage. When placed underneath a laptop for four hours, 25% of the sperm died and 9% showed DNA damage. The important finding here is that Wi-Fi electromagnetic (EM) radiation damaged the sperm — almost every other study has focused on increased temperature (which also damages sperm, incidentally).

Before you go out and buy a lead jockstrap, though, bear in mind that this is ex vivo — the sperm were outside the testes — and the scientific study does not go as far as to say that that EM radiation actually affects your chance of getting a girl pregnant. Basically, it's entirely possible that the (thin) skin of your testicles is enough to stop Wi-Fi signals from cooking your little men — and furthermore, you constantly produce sperm throughout the day, so unless you preface every conception attempt by having a laptop on your lap for four hours, you should be OK (though I fear I probably just described the standard evening setup for most households…)

Perhaps more importantly, though, this study does show that very weak, low-frequency radiation does have an effect on sperm. We might know the extent of that effect, but this is proof that we at least ought to be careful. If anything, it reaffirms that we shouldn't keep a notebook on our lap for a significant amount of time — and the same should be said of an iPad, Kindle Fire, or your choice of Wi-Fi-enabled gizmo. You probably shouldn't keep Wi-Fi permanently enabled on your smartphone, either.

http://www.extremetech.com/extreme/106977-Wi-Fi-radiation-from-laptops-smartphones-is-damaging-your-sperm

Use of laptop computers connected to internet through Wi-Fi decreases human sperm motility and increases sperm DNA fragmentation

In recent years, the use of portable computers (laptops, connected to local area networks wirelessly, also known as Wi-Fi) has increased dramatically. Laptops have become indispensable devices in our daily life, offering flexibility and mobility to users. People using Wi-Fi may be exposed to radio signals absorbing some of the transmitted energy in their bodies. Portable computers are commonly used on the lap (1, 2, 3), therefore exposing the genital area to radio frequency electromagnetic waves (RF-EMW) as well as high temperatures (3, 4).

Infertility is a common worldwide condition that affects more than 70 million couples of reproductive age (5). It has been suggested that male fertility has declined during the past several decades (6). Such decline has been attributed to the direct or indirect exposure to certain environmental factors such as RF-EMW (7).

Extremely low frequency magnetic fields can initiate a number of biochemical and physiological alterations in biological systems of different species (8, 9, 10, 11, 12). Many of these effects have been associated with free-radical production (13, 14). Free radicals are causative factors of oxidative damage of cellular structures and molecules such as lipids, proteins, and nucleic acids. Free radicals react with polyunsaturated fatty acids in cell membranes promoting a process called lipid peroxidation. In human spermatozoa the presence of unesterified polyunsaturated fatty acids is causally associated with the induction of reactive oxygen species (ROS) generation and lipid peroxidation (15). Damage may occur at the membrane level, leading to immotility and cell death, or at the DNA level. DNA integrity is essential to normal conception. Sperm DNA fragmentation has been associated with impaired fertilization, poor embryonic development, high rates of miscarriage, and increased incidence of morbidity in the offspring, including childhood cancer (16, 17). It has been proposed that genetic and environmental factors would be involved in the etiology of sperm DNA damage (18).

The RF-EMW from mobile phones may cause DNA damage (19), in addition to decreased motility and viability (20, 21). Increased levels of intracellular ROS (22) would be the cause of these deleterious effects.

Portable computers using Wi-Fi emit RF-EMW and are typically positioned close the male reproductive organs. Their potential negative effects on male germ cells have not been elucidated. To assess this potential association we used an in vitro model incubating human sperm in the presence of an active portable computer connected to the internet by Wi-Fi. Sperm viability, motility, and DNA fragmentation were the main study end points.

To our knowledge, this is the first study to evaluate the direct impact of laptop use on human spermatozoa. Ex vivo exposure of human spermatozoa to a wireless internet-connected laptop decreased motility and induced DNA fragmentation by a nonthermal effect. We speculate that keeping a laptop connected wirelessly to the internet on the lap near the testes may result in decreased male fertility. Further in vitro and in vivo studies are needed to prove this contention.

How Does The iPad Influence Your Health: What You Are Not Being Told is This…

Aside from the wide misconception that iPad or other tablets don't emit much radiation, there's growing evidence that links wireless radiation to leukemia, autism, ADHD, cancer, and Alzheimer's.

And according to the World Health Organization, wireless radiation has been classified as a potential carcinogen, being ranged in the same class with DDT, lead, and tailpipe exhaust in terms of ability to cause cancer.

On the other hand, non-ionizing or microwave radiation not only damages the brain, but also the sperm of lab animals. For one thing, tablets are microwave transmitters, which means every few seconds they send out short but strong bursts of pulsed radiation. And this radiation can pose serious risks on children's rapidly-developing nervous and immune systems, resulting in brain maturation and reproductive damage. What this microwave radiation does is disturb DNA, deteriorate the brain's protecting barrier, and discharge highly reactive and damaging free radicals. Sadly, the bone marrow of a child's head absorbs 10 times more radiation than an adult, whereas those of infants and toddlers even more.

According to research, adults who have consistently used wireless gadgets for at least ten years are at a greater risk of brain cancer (glioma and acoustic neuroma), salivary gland cancer, and even rare eye cancers on that side of the head where the cell phone was most held (Davis, 2010). Moreover, a number of men diagnosed with testicular cancer had the cancer appear in the testicle closest to the pant pocket where they usually kept their cell phone (Davis, 2013).

Ways to reduce your EMF exposure when using an iPad or other Tablets:

- Try to use your iPad tablet on airplane mode and Wi-Fi to Off as this will stop the connection radiation.
- Avoid using your iPad on your lap. Hold it further away from the body as every inch decreases the power of radiation exposure to a greater extent.
- Reduce the time spent using wireless devices.

STEALTH CANADA—deep-sixing the science on wireless radiation

Health Canada is inspiring activism in even the most passive Canadians (especially those harmed by wireless microwave radiation from Wi-Fi, cell phones etc)—motivating them to protect their own health, ensure their own survival, stand up for their rights, and tap into their compassion and humanity—since Health Canada seems incapable of doing any of these things for them.

Teachers, too, are being challenged to become empowered. If they dare to test the levels of radiation coming from Wi-Fi routers in their school, to protect their own health as well as the health of the schoolchildren, or if they turn the router off when not in use, they can lose their job. One teacher in BC—Maria Plant—who has been teaching for 30 years, was forced to retire because the Wi-Fi in her school became intolerable, and she now has such severe electro-sensitivity, as a result, that she can no longer lead a normal life. "It's been emotionally and physically devastating to slowly succumb to this disorder of EHS [electromagnetic hypersensitivity]," she says, "as it forced me to give up the two loves of my life: teaching and physical outdoor activity, because my inner ear and balance are most severely affected by radiofrequency signals."

Yet fighting for your rights can be hard to do when you're ill, and Plant says that EHS has resulted in depression and a crippling sense of defeat. "Sometimes, it feels as if it would be easier to just quit living," she says. "My personal life and relationships have fallen apart and I can no longer engage in social activism or contribute as a teacher and Union Rep. It has torn me from my close-knit community and the life-long friends who were my source of joy and support."

Paying for alternative medicines, therapies and specialists can be tough for a single adult, but the financial burden of selling her home and moving several times, working part-time for five years, and losing her last five years of pension contributions has been overwhelming for Plant.

Worst of all, she says, is the ridicule and humiliation from uninformed doctors, specialists, colleagues and parent groups, friends, associates and family members who mocked her symptoms. "They did not believe me when I told them that wireless radiation was the cause of my illness, or the cause of the anxiety and the flu-like symptoms (vomiting, dizziness, head pain, eye pain etc.) that my vulnerable seven-year-old students reported while working near the Wi-Fi routers at school."

If adults can be so severely affected, imagine what these high levels of non-stop microwave radiation are doing to young schoolchildren. One of them—12-year-old Tyler from Victoria, BC (pictured below)—can no longer go to school as the Wi-Fi radiation causes severe headaches, vomiting, insomnia, night terrors and fatigue. Three school districts in BC have refused to accommodate him by turning off the Wi-Fi routers or hard-wiring the computers—which could so easily be done. Instead, Tyler is being denied his right to an education, not to mention being able to socialize with his friends, build important life skills such as communication and team-building, take part in sports, build his self-esteem or do any of the things that teenagers normally do as part of their healthy development.

What kind of government refuses to allow children such as Tyler to go to school without being harmed—and knowingly harms all the other children who may not yet be feeling the radiation's effects? Why should any child—or adult—be denied this fundamental right, and instead be excluded and forced to function in isolation as if *they* were the problem rather than the toxic environment?

http://olgasheean.com/stealth-canada-deep-sixing-the-science-on-wireless-radiation/

Effects of 2.4 GHz radiofrequency radiation emitted from Wi-Fi equipment on microRNA expression in brain tissue.

Abstract

PURPOSE:
MicroRNAs (miRNA) play a paramount role in growth, differentiation, proliferation and cell death by suppressing one or more target genes. However, their interaction with radiofrequencies is still unknown. The aim of this study was to investigate the long-term effects of radiofrequency radiation emitted from a Wireless Fidelity (Wi-Fi) system on some of the miRNA in brain tissue.

MATERIALS AND METHODS:
The study was carried out on 16 Wistar Albino adult male rats by dividing them into two groups such as sham (n = 8) and exposure (n = 8). Rats in the exposure group were exposed to 2.4 GHz radiofrequency (RF) radiation for 24 hours a day for 12 months (one year). The same procedure was applied to the rats in the sham group except the Wi-Fi system was turned off. Immediately after the last exposure, rats were sacrificed and their brains were removed. miR-9-5p, miR-29a-3p, miR-106b-5p, miR-107, miR-125a-3p in brain were investigated in detail.

RESULTS:
The results revealed that long-term exposure of 2.4 GHz Wi-Fi radiation can alter expression of some of the miRNAs such as miR-106b-5p (adj p* = 0.010) and miR-107 (adj p* = 0.005). We observed that mir 107 expression is 3.3 times and miR- 106b-5p expression is 3.65 times lower in the exposure group than in the control group. However, miR-9-5p, miR-29a-3p and miR-125a-3p levels in brain were not altered.

CONCLUSION:
Long-term exposure of 2.4 GHz RF may lead to adverse effects such as neurodegenerative diseases originated from the alteration of some miRNA expression and more studies should be devoted to the effects of RF radiation on miRNA expression levels.

Schools

Inviting Discussion about Safer Tech Use in Schools – Katie Singer

2/7/2017

In one generation, use of electronic technologies has exploded, creating dramatic environmental and cultural changes, including in classrooms. As we read, write, research, meet and express ourselves, electronics offer extraordinary possibilities. Meanwhile, to develop self-respect, empathy, humor, awareness of themselves and others and social skills, children still depend on human contact in a real (not virtual) world.

Electronics are tools, not substitutes for human teachers or peers. Every community still needs children who are familiar with the real world around them; who learn (from other people) to think critically and ethically; who are well versed in biology, chemistry, physics, literature, music and art. Students need to create and imagine from their own minds, not to follow a computer programmer's choices or direction. For healthy development, children need time without electronics, in nature, socializing with each other and contributing to their communities. Youth need purpose. They need to participate in person-to-person conversation about real world problems and solutions.

Prudent integration of technology use in classrooms requires that school board members work with administrators, teachers and parents to clarify educational priorities, identify problems and determine best practices. Basing purchasing decisions solely on an IT director's recommendations may lead to technology dominating a classroom–rather than serving as a tool that enhances learning.

Indeed, most schools implement wide use of technology even though its effects (including among children) are largely unknown. Because no federal agency regulates children's use of electronics, schools must create their own guidelines.

This paper aims to encourage discussion about safer, more responsible use of technology in educational settings. It presents critical issues and options for consideration:

Screen-time contact is no substitute for in-person relating. For healthy neurological, social and emotional development, infants, children and teenagers need to relate with adults, each other and the natural world. Because technology use can contribute to aggressive behavior, depression and neurological problems including autism, ADHD and addiction, users need to learn limits.
Common educational software tracks students' preferences, interests, social contacts and locations. Software manufacturers collect this data from each student and can use it for lifelong marketing tools. Students and parents need protection from such tracking. Further, wireless technologies increase vulnerability to hacking. Schools therefore need wired Internet access.
Wireless devices and infrastructure emit man-made electromagnetic radiation (EMR). Scientific studies have shown the high likelihood that EMR exposure causes brain and heart cancer, DNA damage, neurological harm, general malaise, medical implant malfunctioning and more. To reduce students' EMR exposure, schools need to provide wired Internet access.
During a power outage, schools without a corded telephone on a copper legacy landline may be unable to reach first responders.
Because current federal law regarding telecommunications prohibits municipalities from determining cellular antenna placement based on health or environmental concerns, parents, teachers and children

may have little control over their EMR exposure. School communities need to exercise their rights to reduce their exposure within existing legal parameters.
In the event of security breeches or health damages caused by school-issued computers, who is liable? To what extent can a school board ensure that students' data and health are safe? Before authorizing tech purchases, do school boards need to study whether computer use improves learning and/or harms development?
To begin discussion, school administrators, board members, teachers, parents and students might adopt a routine of asking questions such as:
* What are the long-term consequences of using electronic devices–to health (including brain development), social skills and community?
* Could we do this activity without an electronic device?
* Could we balance screen-time with time in nature and with others?
* How can we minimize exposure to man-made electromagnetic radiation?
* What steps might prevent tech addiction?
* What steps minimize hacking risks?
* Online, how/can we maintain privacy? Why/does privacy matter?
* Until what age (or the achievement of what skills) should children not learn computer coding or programming?
* Given federal and municipal mandates, what limits can schools and households reasonably impose to support safer tech use?

Screen-time, addiction and ADHD
The situation: In the 1970s, four-year-olds who could delay eating a marshmallow for fifteen minutes (by singing to themselves, making up a game or napping) became more confident and skilled adults, more able to cope with stress.[1] Now, temptations are electrified. Microwaves (frequencies required for mobile devices to operate) increase activity of brain endorphins or endogenous opioids, the biological base of addiction to opium, alcohol and morphine.[2]

Like all electronics users, children need skills in delaying gratification (i.e. waiting to check messages) and limiting screen time.

Dr. Nicholas Kardaras, author of Glow Kids: How Screen Addiction is Hijacking Our Kids–and How to Break the Trance, has found treating heroin and crystal meth addicts easier than "lost-in-the-matrix video gamers or Facebook-dependent social media addicts." Dr. Kardaras reports that one out of three children now uses a tablet or smartphone before they can talk.[3]

Integrative child psychiatrist Dr. Victoria Dunckley, MD, author of Reset Your Child's Brain, reports that screen time overloads the sensory system, fractures attention and depletes mental reserves. It desensitizes the brain's reward system, can increase suicide risk and reduce physical activity levels.[4] Even 30 minutes of computer use can disturb sleep; and interactive screen-time (playing video games and/or manipulating a screen with a keyboard, mouse or touch) is more detrimental to brain development than non-interactive, passive TV watching.[5]

Pediatric occupational therapist Chris Rowan explains that technology use's
* sedentary nature is causally related to obesity, diabetes, developmental delay, illiteracy and learning difficulties.[6],[7],[8],[9]
* isolating factor can escalate mental illnesses including ADHD, autism and depression and create difficulties in self-regulation.[10],[11]

* overstimulation factors into ADHD, aggression, sleep disturbance and chronic stress.[12],[13],[14],[15]

Screen-time based sedentary behavior can contribute to childhood and adolescent depression.[16]

Using a portable screen device also impacts sleep.[17]

"Distracted" walking and driving injuries and fatalities are on the rise. A Mayo Clinic study finds that text messaging appears to produce a unique brainwave form that can cause epileptic and nonepileptic seizures. This "texting rhythm" was also found in iPad users.[18]

Options:
* Minimize use of electronic devices until reading, writing and math skills are established on paper.
* Do not offer computer time as a reward, a babysitter or pacifier.
* Ban cell phones in classrooms. Some schools ban them during hallway and lunch breaks, confiscate the phone for 1-30 days with the first violation, and, with the second violation, until the school year ends. Bans require school board support and sufficient warning to parents and students. At Monte del Sol (charter high school) in Santa Fe, New Mexico, Principal Dr. Robert Jessen reports that with the ban, students face teachers during class and talk to each other during lunch breaks. A study from the Univ. of Texas and Louisiana State Univ. found that test scores rose by up to 6% in schools with strict cell phone bans.[19]
* Teach parents and students to identify symptoms of excessive screen time: aggressive behavior, disrupted academic or social performance. If use becomes problematic, consider Dr. Dunckley's three-week electronic fast to "detox" and determine the student's healthy tech threshold.[20]
* Encourage movement, hiking, sports, chess, book reading, hand-writing, theatrical productions, painting, pottery-making, conflict resolution skills, research by in-person interviews, playing music, learning a second language, composting kitchen scraps and growing and preparing food.
* According Jocelyn Glei, author of Unsubscribe: How to Kill Email Anxiety, Avoid Distraction and Get Real Work Done, on average, people check email eleven times per hour. Such frequency decreases productivity. To help children develop healthy work habits, teach them to check email in batches–say two or three times per day.
* Provide Wi-Fi-free and tech-free areas for students and staff.
* Encourage teachers and parents to model self-awareness and self-regulation around screen-time limits.

Activities:
* Create "Personal Tech Contracts" and ongoing discussions about responsible tech use.[21],[22]
* Establish "crews" that meet daily over years with the same students and teachers to help children build real relationships.
* Encourage discussion about how tech influences our relationships.
* Recognize the danger of texting while driving. Encourage students and families to pledge to stop texting and driving. Texting takes your eyes off the road for an average of five seconds. At 55 mph, that's like driving the length of a football field–completely blind. Car crashes caused by texting and driving kill an average of eleven teens each day and injure 330,000 people every year.[23]
* Invite discussion: What is addiction? What are signs of tech addiction? What do camps in China do to remedy tech addiction?[24] What steps prevent tech addiction? What screen-time limits are healthy for you?
* Read and discuss Jerry Mander's Four Arguments for the Elimination of Television, Quill, 1978.

* View and discuss "Screenagers," Delaney Ruston, MD's documentary about teen cell phone use. www.screenagersmovie.com

Security and Privacy
The situation: School-issued computers likely collect info about students' Social Security numbers, food preferences, friends' names, grades and discipline records. School-issued computers may contain geo-trackers that provide students' exact locations. Without regulations, manufacturers (i.e. Apple and Pearson) who sell computers and software to schools may collect students' info to create "data-mined profiles" for lifetime marketing tools.

Further, according to applied physicist Dr. Ronald M. Powell, "The second you go wireless, you expose yourself to greater risk of interception. Fiber optic systems (fios) will always be able to carry data faster and more securely than any wireless system." Staff and student data can be hacked.[25],[26] Thirteen percent of educational organizations have been hacked–more than three times the rate of ransomware (payment for releasing data taken "hostage") found in healthcare and more than that of the financial sector.[27]

Computer-based assessments of students and Smarter Balanced Test Scores have led to unfair test administration, security and privacy issues related to test data, violation of students' rights, delivery of tests on faulty networks and technology, and long-term motivational problems that likely result from misdiagnosing students with unfit assessments.[28],[29]

Options:
* Eliminate wireless service and devices. Opt for fiber optics (fios) and wired phones, computers, mice and printers. For affordable fiber connections, see Harvard's Berkman Center for Internet and Society's Maximizing K-12 Fiber Connectivity Through E-Rate.[30]
* Teach users not to use physical addresses or birthdates in email addresses or passwords, not to reply to email from strangers, and to open an attachment only when you know the sender and expect the attachment.
* Teach staff and students that each device (i.e. a tablet, chromebook, or smartphone) has its own security practice.
* Establish email security protocols, monitor key third party vendors, track vendors' security ratings and avoid file sharing.

Activities
* Interview people who've been hacked. What happened? What advice do they have to prevent hacking?

Invite discussion: Do you prefer mobility (which risks hacking) or wired-only communications (which decreases hacking risks)?

2a. Critical thinking and tech design

The situation: According to Tristan Harris, former Design Ethicist at Google, tech product designers limit and even control users' thinking by creating a menu of choices. For example, in response to the question, "Where can we go to talk?" a server might offer a menu of bars–and not include nearby parks or diners.[31]

Activities:
* As they conduct research for school reports, encourage students to ask, What are the menu providers' goals? What's not on the menu? Does the menu serve my real needs or distract me? Does the server provide websites with opinions or well-referenced reports?
* Read and discuss Dr. Kenneth J. Saltman's Scripted Bodies: Corporate Power, Smart Technologies and the Undoing of Public Education, Routledge, 2017.

EMR exposure
The situation: In living creatures, every cell functions by electro-chemical signals.[32] Our physiological functions (i.e. sleep, digestion, decision-making and locating home) ultimately depend on cues from the Earth's electromagnetic fields, the solar wind and other natural sources.

Electronics (including cell phones, tablets, compact fluorescent bulbs, cordless phones) and infrastructure (such as cellular antennas; Wi-Fi routers; "smart" digital, wireless utility meters; powerlines and transformers) emit man-made electromagnetic radiation (EMR). In May, 2011, The World Health Organization classified EMR as a 2B carcinogen.[33] In May, 2016, NIH's National Toxicology Program found that 2G cell phone radiation causes brain and heart tumors and DNA damage.[34] A Feb., 2016 report published by the journal Neuro-Oncology and funded by the American Brain Tumor Association finds that malignant brain tumors are the most common cause of cancer-related deaths in adolescents and young adults aged 15-39, and the most common cancer occurring among 15-19 year olds.[35] (Leukemia used to be the leading cancer among children, but now it is #2, behind brain cancer, signaling an environmental change.) In September, 2016, the American Academy of Pediatrics issued recommendations to reduce exposure to cell phones.[36]

Because children's skulls are thinner and their brains contain more fluid than adult skulls and brains, children absorb proportionately more radiation than adults. The effects of EMR exposure on a child's development may have lifetime impacts,[37] including on their fertility.[38]

Neither wireless devices nor the infrastructure that they require have been proven safe for children, pregnant women, people with medical implants, the general population or wildlife.

Options:
* Get informed about the health and environmental effects of EMR-exposure. Studies are posted at www.saferemr.com (from UC/Berkeley's School of Public Health) and www.bioinitiative.org.
* Recognize that every reduction in EMR-exposure is worthwhile.
* Encourage students and staff to keep mobile devices off when not in use. To ensure that a device is off, test its EMR emissions. Www.magneticsciences.com/ rents meters for reasonable fees.
* Choose wired connections–for phones, web access, mice, printers.[39]
* For affordable fiber connections, see Harvard's Berkman Center's Maximizing K-12 Fiber Connectivity Through E-Rate.[40]
* Avoid or correct equipment that defaults to wireless.
* Teach school nurses, teachers, parents and students to identify common symptoms of EMR exposure, including bloody noses, sleep disturbances, headaches, fatigue, rashes, migraines, dizziness, nausea and aggressive behavior.[41],[42]
* Recognize the short and long-term effects of near, whole body, second-hand, combined and cumulative EMR exposures.[43]
* See "Schools, Unions and PTA Actions," an int'l list of schools that have removed Wi-Fi, posted by the Environmental Health Trust.[44]

* Create Wi-Fi and tech-free zones for children and staff.

Activities:
* Learn which diseases correlate with different kinds of EMR exposure. http://www.bioinitiative.org/rf-color-charts/
* At parent-teacher meetings, encourage family time without electronics and keeping Wi-Fi off for at least 12 hours each night. Read "Calming Behavior in Children with Autism and ADHD."[45]
* Stage contests between classrooms and schools to reduce EMR emissions.

3a. Cell phones and health

The situation in the mid-1990s, to determine cell phone safety, the FCC took the temperature of a 220-pound mannequin's head before and after six minutes of cell phone use. Because this mannequin's temperature did not change by two degrees Celsius, the FCC determined that mobiles are safe.[46] In other words, to determine safety, the FCC considered only the immediate, thermal effects of cell phone use.

The FCC has not tested non-thermal effects of EMR exposure, including for children's or pregnant women's cell phone use, nor for combined, chronic or cumulative exposures.

In 2015, Dr. Om Gandhi, Professor of Electrical Engineering at the University of Utah, co-chair of the Institute of Electrical and Electronics Engineers' (IEEE's) Subcommittee on RF Safety Standards (1988-97), wrote: "it is very hard to understand why" FCC's safety guidelines only consider the head of a mannequin whose size is in the 90th percentile of US military recruits–and do not consider children's head size when creating safety guidelines.[47]

Cell phone radiation contributes to brain and heart tumors and damages DNA.[48] It weakens the blood-brain barrier.[49]

In utero EMR exposure results in an 85% greater risk for behavioral problems by the time children reach school age. [50]

Options:
* Keep devices in airplane mode with Wi-Fi and Bluetooth off, especially in class and around others.
* Do not keep a phone in a bra, pant pockets or shirt pocket. Make the bra a no-phone zone.
* To decrease RF exposure, download images and videos only via a wired (fiber optic, cable or DSL) connection.
* Maintain landlines and corded telephones as long as possible and/or until fiber optics are in place.
* Mitigating EMR emitted by a cell phone or voice over Internet protocol (VOIP) is unique to each situation. Could local electrical engineers help students to measure and reduce emissions?
* Create protected areas to prevent second-hand EMR exposure (received by people and wildlife near cell towers, routers, "smart" meters and/or people using mobile devices).

Activities:
* View "Cell Phones Cause Cancer."[51]
* View "Save the Girls" [52] and "Save the Males."[53]
* View Dr. Devra Davis' talk at the University of Melbourne.[54]

* Read your cell phone manufacturer's warning. For one week, abide by it–i.e. keep your phone at least 7/8" from your head.
* Make your own flier with warnings and solutions about cell phone use.
* Invite discussion: Should cell phones have warning labels at the point of sale, as Berkeley, California requires?[55] How/could pregnant women limit their cell phone use? For ideas see www.babysafeproject.org.

3b. Wi-Fi and health

The situation: No medical organization has deemed that Wi-Fi is safe. No pre-market safety testing (including by FDA or EPA) was conducted on Wi-Fi. Wi-Fi presents whole body EMR-exposure to users and non-users. Faculty and students who work or study near routers may receive more intense exposure.

British biologist Dr. Andrew Goldsworthy, retired lecturer from Imperial College, explains: "Just after birth, a child's brain goes through an intense period of becoming aware of new sensory input. He or she recognizes his or her mother's face, her expressions, and eventually, other people and their relationships. During this process, the neurons in the brain make countless new connections, and the brain stores what the child learns. Connections that are rarely used are pruned. This pruning process is completed by the time of sexual maturation.[56]

"If the child is exposed to radiofrequency fields during this pruning process, the production of too many and often spurious signals will generate frequent random connections. These will not be pruned, even though they may not make sense. Because the pruning process in children exposed to RF fields may be more random, these children–who may have more brain cells than the rest of us–may lack the mindset for normal patterns of social interaction. This may then contribute to various autistic behaviors.

"Like mobile phone signals, Wi-Fi signals can also cause cell membranes to leak and calcium ions to flow through them in a relatively uncontrolled manner.[57] In the classroom, this may result in children's brains losing the ability to concentrate.

"Further, electromagnetic radiation (such as that emitted by Wi-Fi, cell phones, cell towers and 'smart' meters) may affect the body like light does at night–and inhibit melatonin production. Melatonin is a sleep hormone and a powerful antioxidant. It can reverse oxidative stress that results from radiation exposure.[58]

"While scientists explore further how EMR exposure reduces melatonin production and study whether EMR-induced oxidative stress contributes to autism–along with many other questions–we ought to first do no harm to our children. Wi-Fi should therefore be considered an impediment to learning, rather than an aid. Wi-Fi may be particularly hazardous to pregnant teachers, since exposing the brain of a fetus or a very young child to EMR may prevent normal brain development."[59]

In a 2013 letter to the Los Angeles Unified School District, Dr. Martha Herbert, MD, PhD, pediatric neurologist at Harvard Medical School wrote: "EMF/RFR from Wi-Fi and cell towers can exert a disorganizing effect on the ability to learn and remember, and can also be destabilizing to immune and metabolic function." She urged the LAUSD to "opt for wired technologies."[60]

Dr. Hugh Taylor, MD, head of Yale Medical School's Ob/Gyn Department, recommends that pregnant women (including pregnant teachers, students and parents) "avoid prolonged or direct exposure to Wi-Fi routers." (www.babysafeproject.org.)

A recent study from the California Department of Health found that three percent of Californians (770,000 people) experience radio-frequency sickness (headaches, rapid heartbeats, memory problems, insomnia, nausea, fatigue, tinnitus) with EMR exposure.

Www.ehtrust.org has compiled an international list of schools and countries that have banned Wi-Fi.[61]

Options:
* Read applied physicist Dr. Ronald M. Powell's report on school Wi-Fi.[62]
* Read Dr. Joel Moskowitz's report on Wi-Fi in schools.[63]
* Install wired connections. Until Internet access is wired, every router needs an on-off switch. When not in use, keep routers off.
* Encourage students and teachers to keep routers off at night.

Activities:
* Per classroom, have students make signs to encourage keeping Wi-Fi off when not in use.
* Research policies about Wi-Fi in schools and libraries in France, Israel and other countries.[64]
* Invite discussion: What do we win and what do we lose with mobility? With wired connections? Which is better for the short-term: mobility or wired connections? Which is better for the long-term? How/can we orient ourselves for the long-term?

3c. Cellular antennas and health

The situation: Studies find that people living near cellular antennas experience fatigue, headache, sleep disruption, irritability, depression, memory loss, dizziness, nausea, increased risk of cancer, tremors, loss of appetite, rashes, visual disruptions and overall discomfort.[65]

People who live within 350 meters (about 1000 feet) of a cellular antenna for more than a decade experience a four-fold increase in cancer rates. Among women, the increase is tenfold.[66],[67]

People who live within 200 to 500 feet of an antenna report genetic, growth and reproductive effects; increases in the blood-brain barrier's permeability; behavioral, molecular, cellular and metabolic effects; and an increased risk of cancer.[68]

Many schools already have cellular antennas on campus. [69] Do staff and parents deserve to know about antenna sitings? Should staff and students be able to work and study in a building without cellular antennas?

5G will support the Internet of Things (IoT, machine-to-machine communication) at speeds 100-fold faster than 4G.[70] 5G will operate with millimeter wave signals that have been tested only minimally for health and environmental effects. (Skin and eyes may have most significant effects.)[71] What choices will schools have regarding 5G antenna placement?

Options:

* Provide easy access to a map of routers, smart meters, cellular antennas, wireless chargers, electrical/mechanical rooms, solar power inverters and other electrical hot spots on school property.
* Learn diseases associated with exposure to hot spots and transmitters.[72]
* If EMR levels on campus are high, allow students and staff to transfer to a school with lower levels.
* Explore legal options for preventing cellular antennas on campus.
* Read applied physicist Dr. Ronald M. Powell's "Cell Towers and Health."[73]

3d. EMR exposure on school vehicles

The situation: In a moving vehicle, every time a mobile device connects to a new cell tower (approximately every mile), the device goes to maximum power. Much of the EMR gets trapped within the vehicle (a metal box).

Wi-Fi on school buses traps yet more EMR.

Computers used by vehicles including hybrid and electric cars can emit especially high electromagnetic fields.

Options:
* Keep mobile devices off in school vehicles.
* Do not allow Wi-Fi on school buses.
* Test vehicles' EMR emissions. Do not allow children, pregnant women and people with implants to sit in seats with high levels.

3e. Electronic interference with medical implants

The situation: According to NIH, in year 2000, 8-10% of the American population had a medical implant (i.e. an insulin pump, cochlear implant, pacemaker or neurostimulator).[74] Nearness to a metal detector, refrigerator, air conditioner, mobile phone or tablet, Wi-Fi router, wireless recharger, an electric or hybrid car can cause a medical implant to malfunction or shut off.[75] For example, walking through a library's metal detector can shut off a person's deep brain stimulator. The person would have a few seconds to reset–or they'd shake so badly that they could not reset the implant without help.

Option:
* Post signs to alert and protect people with implants, i.e.:

WARNING electromagnetic radiation (EMR) in this area could cause a medical implant to malfunction or shut off

Activities:
* View 2009 talk by Dr. Gary Olhoeft (geophysicist and electrical engineer) about electronic interference with his deep brain stimulator. [76]
* Read Katie Singer's 2015 talk, "Aiming to First Do No Harm: The Education of an Electronics' User," about the FCC's definition of "harmful interference" and the reality of living with an implant. [77]

3f. Grounding and wiring errors and "chopped" current

The situation: Buildings that have no wireless service may still generate dangerous magnetic fields and/or stray voltage from grounding and/or wiring errors. If clean, man-made electricity (which may not exist, inpractice) is a smooth AC wave at 50 or 60 Hz, high frequencies or pulses on the wires can "chop" current, disrupt power quality and harm health. "Chopped" current is also called harmonics or "dirty" power.

"Smart" utility meters, wiring errors and any device with a power supply (including a wired computer) or an electronic ballast (including compact fluorescent bulbs) can chop current, disrupt power quality and harm health. Sitting in or near a room with wired computers or even near one computer can thereby contribute to a child's EMR exposure.

Options:
* To correct grounding and wiring errors, refer to Karl Riley's Tracing EMFs in Building Wiring and Grounding, 2nd ed. www.magneticsciences.com
* To locate and correct electric, magnetic and RF fields and "dirty" power on school property, hire independent engineers to conduct an annual survey. Follow up corrections with another survey. Encourage students to participate in the surveys and the corrections. Shut down rooms with dangerous levels of exposure. Note that finding a reliable surveyor may not be easy. (See applied physicist Dr. Ronald M. Powell's review of a survey of RF levels in Montgomery County, Maryland Schools.[78])
* Read the American Medical Association's 2016 paper about LEDs' human and environmental effects.[79] Do not use mercury vapor lights, compact fluorescents or LEDs with electronic ballasts. These produce "dirty" power that radiates out from electrical wires. Prefer incandescent bulbs. (They do not generate chopped current.)

Activities:
* Read "Is Dirty Electricity Making You Sick?" by Michael Segell, Prevention, Nov. 3, 2011.
* Learn to install battery and/or solar-powered DC lights.
* Invite discussion: Should wiring and grounding errors be determined and cleaned up before deploying new technologies?

Emergency preparedness
The situation: In the event of a power outage, only hard-wired, corded telephones on copper legacy landlines will work. Cell phones and voice over Internet protocols (VOIPs, i.e. Magic Jack and Skype) require electricity and therefore will not work in a power outage.

Note: the FCC and 13 states have passed legislation that will "sunset" copper legacy landlines by 2020. Only cell phones and VOIPs will be available.

Options:
* Maintain copper legacy landlines and corded landline telephones as long as possible.
* Maintain industrial strength battery backup for phone systems that require electricity.

4a. Lithium ion batteries

The situation: Lithium ion batteries are used in laptops, smart phones, e-cigarettes, "smart" meters and many other electronic devices. They are light and store lots of energy per weight. They can also explode; they are also flammable. [80]

Option:
* In the event of an explosion or fire caused by a device with a lithium ion battery, keep a fire extinguisher nearby.

Rules, regulations and liability re cell towers and phones
The situation: Section 704 of the 1996 Telecommunications Act prohibits municipalities from denying a permit to install a cellular antenna based on health or environmental effects of exposure to radiofrequency emissions. Underwriters like Lloyds of London will not insure for health or property damages caused by wireless radiation.[81]

Activities:
* Teach staff and students to measure electric, magnetic and radiofrequency fields and "dirty" power emitted by their own devices. Www.magneticsciences.com rents meters for reasonable fees.
* When introducing students to an electronic device, encourage them to read and abide by the manufacturer's warnings in the product's manual.
* View "Broadcast Blues," a documentary about the Golden, Colorado area's health and legal battles in the late 90s around radio and TV broadcasting antennas placed on Lookout Mountain.[82]
* View "Blood in the Mobile," a Danish documentary about coltan, a mineral mined primarily in Congo that holds charge in every mobile device. More people have been murdered over coltan than were murdered in any other event since WWII.[83]
* View "We the People 2.0," Matthew Schmid's documentary about municipalities like Pittsburgh enacting ordinances that effectively prevent fracking or toxic sludge in their areas.[84] Could such a community rights ordinance work with cellular antenna placement?
* Invite discussion: Given that federal and manufacturers' guidelines regarding EMR emissions do not recognize non-thermal, biological harm, and some people want to reduce exposure, what regulations can individuals, households, schools and/or businesses reasonably create? What regulations should they create? Could you create model guidelines for a household or school?

Message to Schools and Colleges about Wireless Devices and Health

March 11, 2017
Ronald M. Powell, Ph.D

If wireless devices, such as Wi-Fi, are used in your schools and colleges, then the health of your students, your faculty, and your staff can be at risk. This is a difficult problem but an addressable one if you act.

Background: Wireless devices transmit information using radiofrequency/microwave radiation. The international biomedical research community has been studying the biological impact of such radiation for decades, but more intensely in recent years. Thousands of peer-reviewed studies published in biomedical research journals have contributed to our understanding of this impact. So many serious biological effects have been found that immediate responsive action is warranted. Further, these biological effects are occurring at levels of radiation far lower than earlier understood. Simply stated, a worldwide health crisis is emerging and is becoming a hallmark of the 21st Century. The international biomedical research community is trying to warn us; but we, in the USA, are not yet listening. I hope this message will help to change that.

As a scientist, I urge you to look into the **health impact of the radiofrequency/microwave radiation** produced by wireless devices. Examples of wireless devices of concern in our environment are Wi-Fi in all of its forms; cell phones and cell towers (especially those located on school grounds); cordless phones; wireless computers, whether desktop, laptop, or tablet versions; wireless baby monitors; wireless smart electricity meters; emerging wireless smart appliances; and microwave ovens (because they always leak radiation).

This crisis is the consequence of many factors. Here are some of them:

- All living things are bioelectrical in nature. That is why electrocardiograms and electroencephalograms work. They, of course, measure the tiny electrical signals that operate the heart and the brain. The critical tasks performed by these tiny electrical signals, and so many other electrical signals in all living things, can be disrupted by man-made radiofrequency/microwave radiation.
- The levels of man-made radiofrequency/microwave radiation in our environment are increasing exponentially and already exceed, by many orders of magnitude, the levels at which all life on Earth evolved. Simply stated, we are drowning in a rising sea of radiofrequency/microwave radiation.
- The invisible nature of radiofrequency/microwave radiation leaves the public and the decision-makers unaware of the rising levels of radiation around them.
- The genuine usefulness of wireless devices promotes denial of the risks.
- The intense advertising, the economic power, and the political power of profitable wireless industries enable them to dominate the public dialogue and to hold sway over government regulators and legislators.
- Current Federal standards for limiting the exposure of the public to radiofrequency/microwave radiation are outdated and overly permissive. Those standards are based on thermal heating alone. In effect, the Government claims that if you are not cooked too much by the radiation, then you are fine. Those Federal standards ignore the many biological effects that occur at much lower levels of radiation, leaving the public unprotected.

- Federal and state governments are advocating unlimited expansion of wireless technology, and are even co-funding such expansion and mandating the acceptance of wireless technology by the public. Such actions reflect a widespread lack of understanding of, or willful blindness to, the underlying science and its consequences for public health.
- Some of the more serious consequences of exposure to radiofrequency/microwave radiation (such as DNA damage, cancer, and infertility) are especially nefarious because they give no early warning signs.
-
- Other consequences of exposure do give early warning signs (such as sleep disruption, headaches, fatigue, ringing in the ears, memory loss, dizziness, heart arrhythmia, and many others); but those signs are too often dismissed because they can have other causes as well, complicating identification of the true cause.
- The absence of routine training of physicians in the biological effects of radiofrequency/microwave radiation makes it difficult for physicians to identify the causes and to provide responsive guidance.
- Even aware individuals cannot control their exposure in any environment shared with others, because the radiation around them, much like second-hand smoke, is forced on them by unaware individuals. Only governments can fully solve this problem, but they are currently part of the problem. For now the public will have to protect itself, and that will require public education and action.

Fortunately, many of the services that wireless devices offer can be realized with much safer wired devices. The wired devices achieve connectivity with fiber-optic, coaxial, or Ethernet cables. The wired devices are faster, more reliable, and more cyber secure. They are, however, less mobile, often less convenient, and somewhat more expensive to install. But those drawbacks pale in comparison to the benefits of good health.

Simply stated, schools and colleges can protect their students, staff, and faculty from the health risks posed by wireless devices, including Wi-Fi, by converting to safe wired connectivity. If your institution lacks the resources to convert now, do consider shutting down your wireless devices anyway and converting as soon as you can. You can advance learning without leaving a trail of illness behind you, some of which can be lifelong.

Regards,
Ronald M. Powell, Ph.D.

My background
I am a retired U.S. Government scientist (Ph.D., Applied Physics, Harvard University, 1975). During my Government career, I worked for the Executive Office of the President, the National Science Foundation, and the National Institute of Standards and Technology. For those organizations, respectively, I addressed Federal research and development program evaluation, energy policy research, and measurement development in support of the electronics and electrical-equipment

industries and the biomedical research community. I currently interact with other scientists and with physicians around the world on the impact of the environment – including the radiofrequency/microwave environment – on human health.

School officials may be personally liable for exposing children to wireless radiation

School districts, school boards and school medical health officers in Canada have been notified that Lloyd's of London has now excluded any liability coverage for injuries, "directly or indirectly arising out of, resulting from or contributed to by electromagnetic fields, electromagnetic radiation, electromagnetism, radio waves or noise." This includes the radio frequency radiation emitting from Wi-Fi and other wireless devices in schools.

On February 18, 2015, the UK agent for Lloyd's stated, "the Electromagnetic Fields Exclusion (Exclusion 32) is a General Insurance Exclusion and is applied across the market as standard. The purpose of the exclusion is to exclude cover for illnesses caused by continuous long-term non-ionizing radiation exposure i.e. through mobile phone usage."

This decision is important because Lloyd's of London, one of the largest insurance companies in the world, often leads the way in protection by taking on risks that no one else will. But, the decision is not surprising because Lloyd's refused to cover mobile phone manufacturers against risks to users' health more than a decade ago in 1999.

What (exactly) are the risks associated with Wi-Fi radiation?

In 2011, the World Health Organization designated radio frequency radiation of the type emitted by Wi-Fi devices to be a 'class 2B possible human carcinogen.' Many independent experts now think this classification downplays the significant dangers posed by wireless technology – especially when you consider the thousands of peer-reviewed, non-industry funded studies by scientists and medical experts that show that Wi-Fi radiation is harmful, especially to children.

According to Associate Professor Olle Johansson from the Department of Neuroscience at the Karolinska Institute in Stockholm "the debate is over". He says, "the spectrum of possible health problems arising is extraordinarily wide – from brain tumors and leukemia to exhaustion, decreased memory and concentration and just feeling uncomfortable."

Professor Johansson goes on to say, "The allowed radiation limits throughout the world are insane, to say the least. We are talking about values up to 1,000,000,000,000,000,000 (10 to the 18th) times higher than nature's background radiation, to which the human body has adapted through many 100,000 of years, and within a couple of decades, we have all been surrounded by biblical levels of artificial radio-waves, well knowing that they have major impacts on both human and animal health."

Princeton University recently removed its position statement on wireless safety from their website after parents raised concerns that Princeton's information was "outdated and inaccurate." Earlier, this year, France banned Wi-Fi in nursery schools. In addition, schools in Germany, Austria, Israel and Australia have pulled the plug on Wi-Fi altogether.

Reykjavik Appeal on wireless technology in schools

We, the signers, are concerned about our children's health and development in schools with wireless technology for teaching. A vast amount of scientific studies have shown considerable medical risks with long-term exposure to Radiofrequency Radiation (RFR) from wireless devices and networks well below the recommended reference levels from the International Commission on Non-Ionizing Radiation Protection (ICNIRP). We ask the authorities to take their responsibility for our children's future health and wellbeing.

In May 2011 the International Agency for Research on Cancer (IARC) at WHO classified RFR as a Group 2B carcinogen, i.e., 'possibly' carcinogenic to humans. Since then more scientific studies on exposure to RFR in humans, animals and biological material have strengthened the association of an increased risk for cancer, especially brain tumors. Several laboratory studies have shown mechanistic effects in carcinogenesis such as oxidative stress, down regulation of mRNA and DNA damage with single strand breaks. The IARC cancer classification includes all sources of RFR. The exposure from mobile phone base stations, Wi-Fi access points, smart phones, laptops and tablets can be long-term, sometimes around the clock, both at home and at school. For children this risk may be accentuated because of a cumulative effect during a long lifetime use. Developing and immature cells can also be more sensitive to exposure to RFR. Based on scientific studies no safe level of this radiation has been established and therefore we have no safety assurances.

Besides the cancer risk, RFR may also affect the blood-brain barrier to open and let toxic molecules into the brain, hurt neurons in hippocampus (the brain center for memory), down or up regulate essential proteins in the brain engaged in the brain's metabolism, stress response and neuro-protection and affect neurotransmitters. Sperms exposed to Wi-Fi have been seen with more head defects and DNA damage. RFR can increase oxidative stress in cells and lead to increase of pro-inflammatory cytokines and lower capacity to repair DNA single and double strand breaks.

Cognitive impairments in learning and memory have also been shown. Results from the OECD's PISA performance surveys in reading and mathematics show decreasing results in countries that have invested most in introducing computers in school. Multitasking, too many hours in front of a screen, less time for social contacts and physical activities with risk for aches in neck and back, overweight, sleep problems, and information technology (IT)- addiction are some of the known risks and side effects of IT. They stand in marked contrast to the often claimed, but largely unproven possible benefits.

We ask the school authorities in all countries to acquire knowledge about the potential risks of RFR for growing and developing children. Supporting wired educational technologies is a safer solution than potentially hazardous exposures from wireless radiation. We ask you to follow the ALARA (As Low As Reasonably Achievable) principle and Council of Europe Resolution 1815 to take all reasonable measures to reduce exposure to RFR.

Practical rules for schools concerning children and wireless technology.

- No wireless networks in preschool, kindergarten and schools.
- A hard wired direct cable connection is recommended to each classroom for the teacher to use during lessons.
- Prefer wired telephones for personnel in preschool, kindergarten and schools.

- Prefer cabled connection to Internet and printers in schools and turn off Wi-Fi settings in all equipment.
- Prefer laptops and tablets that can be connected by cable to Internet.
- Students should not be allowed to use cell phones in schools. They can either leave them at home or the teacher collects them in turned off mode before first lesson in the morning.

Children, Screen time and Wireless Radiation – International Conference Reykjavik February 24, 2017

Maryland State Advisory Council Recommends Reducing School Wireless to Protect Children

03/03/2017

Children's environmental health experts respond to new US study linking wireless radiofrequency radiation to cancer after the American Academy of Pediatrics recommends reducing radiofrequency exposures.

After reviewing new and growing evidence on health risks of wireless radiation, the Maryland State Children's Environmental Health and Protection Advisory Council (CEHPAC) issued a Report advising the Department of Education to recommend local school districts reduce classroom wireless radiation exposures by providing wired-rather than wireless-internet connections. CEHPAC's health experts include Governor appointed pediatricians, Maryland State House/Senate appointees and representatives of the Department of Education and Department of Health. Theodora Scarato, MSW, of the Environmental Health Trust, first brought the issue to the Council's attention three years ago, in February of 2014. The Council cited the recent US National Toxicology Program (NTP) findings of increased rates of rare malignant cancers in animals, as well as children's unique vulnerability to the radiation in their recommendations to minimize exposure.

Several countries, such as France, Israel and Cyprus, already have protective measures minimizing school wireless radiation exposures as national policy. However, CEHPAC's action to issue recommendations to reduce classroom wireless exposures is the first of its kind by an expert state body in the United States.

The Children's Environmental Health and Protection Advisory Council recommends:

1. "The Maryland State Department of Education should recommend that local school systems consider using wired devices" "Wi-Fi can be turned off" and instead "a wired local area network (LAN) can provide a reliable and secure form of networking...without any microwave electromagnetic field exposure."

2. New construction and renovations: "If a new classroom is to be built, or electrical work is to be carried out in an existing classroom, network cables can be added at the same time, providing wired (not wireless) network access with minimal extra cost and time."

3. The Maryland State Department of Education should recommend that local school systems use strategies to minimize exposures: "Have children place devices on desks to serve as barrier between the device and children's bodies; Locate laptops in the classroom in a way that keeps pupil heads as far away from the laptop screens (where the antennas are) as practicable; Consider using screens designed to reduce eyestrain; Consider using a switch to shut down the router when it is not in use."

4. "The Maryland Department of Health and Mental Hygiene should provide suggestions to the public on ways to reduce exposure: Sit away from Wi-Fi routers, especially when people are using it to access the internet. Turn off the wireless on your laptop when you are not using it. Turn off Wi-Fi on smartphones and tablets when not surfing the web. Switch tablets to airplane mode to play games or watch videos stored on the device."

5. "The General Assembly should consider funding education and research on electromagnetic radiation and health as schools add Wi-Fi to classrooms."

6. The Maryland Department of Health and Mental Hygiene should "ask the United States Department of Health and Human Services to formally petition the FCC to revisit the exposure limit to ensure it is protective of children's health and that it relies on current science."

7. The Report should be shared with the United States Department of Health and Human Services, Federal Communications Commission, Maryland State Department of Education and Maryland General Assembly.

"While this report focused on Wi-Fi radiation in schools, there are additional concerns about mobile phones and cell phone towers. CEHPAC plans to look at these broader issues over the next year," the CEHPAC Council Report states.

"Our children's healthy future rests on the responsible actions of today," stated Scarato. "21st century learning should include 21st century science," Scarato pointed to research that found wireless alters brain development in addition to increasing cancer. "Corded non-wireless connections in school are an important part of a safe and healthy school environment, respecting not only our children but also the teachers and staff."

Referring to the fact that US wireless public exposure limits were set in 1996, without testing for long term safety, the CEHPAC Council Report also stated that, "decades-old standards need updating in light of new science." Such statements are in line with the American Academy of Pediatrics, which has also called for a regulatory review and states that children's brains are less mature and can absorb proportionately twice the wireless radiation as an adult because of children's thinner skulls that contain more fluid.

"If you plan to watch a movie on your device, first download it, then switch to airplane mode while you watch in order to avoid unnecessary radiation exposure," recommends the American Academy of Pediatrics as part of its "Ten Tips on Cell Phone Radiation."

In response to the 2016 NTP study findings of a cancer link, the American Academy of Pediatrics, Consumer Reports, Obstetricians and several Medical Associations issued recommendations to reduce cell phone and wireless exposures to children. The American Academy of Pediatrics has also repeatedly called on the United States government to strengthen wireless exposure regulations to protect children and pregnant women.

The Council heard testimony from health organizations and from parents who reside in multiple counties in the State of Maryland, including Montgomery County, Prince Georges County, Anne Arundel County, Baltimore County and Howard County. The Council also received hundreds of pages of expert scientific material and comments prior to the final Report, which the Council has posted on their website.

"Parents have a right to know if there is an environmental hazard in the classroom and actions that can be taken to reduce exposure. The stakes are so high for our children, yet we are way behind what has been happening around the world. Over 20 countries have taken steps and in some cases passed legislation to protect their youngest and most vulnerable citizens and it is time we do the same for

ours," stated Montgomery County parent Laura Simon, pointing to countries like France, Cyprus and Israel.

"I was shocked to learn no government health agency had reviewed the issue from a health and safety standpoint considering how fast Wi-Fi was being installed in schools across the State." Scarato described the process of how she brought the health issue of children's exposures to wireless in schools to Maryland State agencies almost three years ago, by first writing letters of concern about the school radiation exposures.

Dr. Sharfstein, then Secretary of the Maryland Department of Health, initially responded to Scarato's concern by stating, "It is fair to say there are legitimate questions about the long-term health implications of microwave radiation" and that the Department of Health "would be interested in the advice and counsel of groups such as the Children's Environmental Health and Protection Advisory Council."

Scarato pointed out that the Education Department representative on the Council voted in favor of the CEHPAC recommendations to reduce wireless exposures. The Maryland State Department of Education (MSDE) also had responded to Scarato's initial concerns by referring her to CEHPAC, which "exists for the purpose of identifying environmental hazards that may affect children's health and recommending solutions to those hazards."

Medical researchers are pointing to an array of psychological, emotional and physiological health issues screens pose to children at the same time that schools are integrating wireless networks and one to one device initiatives into classrooms.

In 2017, Maryland lawmakers heard testimony on Bill HB866, a first in the nation bill to create uniform screen safety guidelines for screen use in public schools "to protect children from the documented health hazards posed by daily use of digital devices." In response to wireless radiation health concerns, many schools worldwide are replacing wireless systems with wired systems, and limiting time children spend on screens.

Cyprus Removes Wi-Fi from Kindergartens and Halts Wireless Deployment Into Public Elementary Schools

03/06/2017

The Cyprus Minister of Education and Culture issued a Decree on January 31, 2017, marked „urgent" to all Directors of Kindergartens and Primary Schools, with specific measures to eliminate and minimize wireless radiation exposure to children in schools. „We have taken the decision to have the wireless network Wi-Fi disabled in all Public kindergartens in Cyprus," reads the Decree. Wireless is to be removed from all Cyprus kindergartens, and wireless installations have been halted in elementary schools and limited to administrative offices.

"The Ministry of Education does not intend to proceed with the installation of wireless points and Wi-Fi access classrooms in elementary schools."

The Decree reminds teachers that wired internet is already available in all classrooms if the internet is needed for educational purposes. Wireless is only to be used, if needed, in the administrative areas of elementary schools, and wireless is not to be used in the classrooms.

However, if the use of Wi-Fi is deemed necessary for a specific educational program, the Decree stipulates that, „necessary measures to protect children should be taken, and wireless access points should remain inactive when not in use for teaching purposes." Furthermore, „the consent of parents should be ensured in advance." The Decree instructs the School Directors to assure parental consent and send a letter to the parents of children who will participate in programs involving wireless technology – informing the parents of the reason and duration of Wi-Fi usage.

Alongside their other campaigns about tobacco smoke and toxic chemicals, The Cyprus National Committee on Environment and Child Health initiated a nationwide campaign several years ago to raise awareness about cell phone and wireless radiation exposures to children. The multimedia public awareness campaign was lauded at an international conference on Wireless and Health held at the Israel Institute for Advanced Studies at Hebrew University in January of 2017, and organized in cooperation with the U.S. National Institute of Environmental Health Sciences (NIEHS) and Environmental Health Trust (EHT).

Dr. Stella Michaelidou, President of the National Committee on Environment and Child Health shared public service video announcements and brochures about children and pregnancy at the conference. „This Committee has developed tools that are a model for other countries to follow," stated Devra Davis, PhD, MPH, of the Environmental Health Trust at the conference.

Several countries already have health policies in place to reduce school children's exposure to wireless. Cypress now joins France, Brazil, Ghent in Belgium, and Israel in banning wireless in kindergarten classrooms and enacting strong measures to minimize wireless exposures in elementary schools. France passed comprehensive new legislation in 2015 and has developed tools to inform the public about how to reduce exposure, similar to the efforts underway in Cyprus. Canada's Standing Committee on Health of the House of Commons also issued a report recommending a public education campaign.

In the United States, the Maryland State Children's Environmental Health and Protection Advisory Council recently issued a Report advising the Department of Education to recommend all school districts in the State of Maryland install wired—rather than wireless—internet connections for classrooms. This

action represents the first action of a state advisory body to issue guidance on wireless exposures. In Massachusetts and Oregon, several Bills have been proposed to address the health issues posed by electromagnetic radiation in schools and raised by consumers, researchers and medical professionals as concerns about school wireless exposures gains momentum in the United States.

Radiofrequency Radiation in Communities and Schools Actions by Governments, Health Authorities and Schools Worldwide

See source for document.

http://ehtrust.org/wp-content/uploads/International-Policy-Precautionary-Actions-on-Wireless-Radiation.pdf

Wi-Fi banned from pre-school childcare facilities in a bold move by French government

The French National Assembly has adopted a bill to limit exposure to electromagnetic fields (EMFs) generated by wireless technologies - cell phones, tablets, Wi-Fi etc. This bill will mean the following:

- A ban on Wi-Fi in all childcare facilities for children under the age of 3.
- Cell phone manufacturers will have to recommend the use of hand-free kits.
- A ban on all advertising targeting children under 14.

Children's EMF exposures are a particular cause for concern. Studies show that children's brains can absorb up to three times as much radiation compared to adults.

A recent International Agency for Research on Cancer (IARC) report suggested that EMF exposures can be more devastating in children because their:

- Brain tissue is more conductive.
- Skull is thinner.
- Smaller brains and softer brain tissue allows radiation to penetrate more effectively.
- Potentially longer period of exposure due to use beginning at an earlier age.

This new French bill seems to have taken these concerns into account.

EMFs are widespread in our daily environment. Anything electrical creates an electromagnetic field. According to the French national Agency for Food, Environmental and Occupational Safety (ANSES):

- The biggest source of EMF exposure by far is cell phones.
- Cell towers exposures are developing very rapidly with the deployment of 4G, but average exposure is well below that of phones.
- Electrical power lines, transformers and railway lines are also sources of EMFs.

•Wireless devices in our personal environment expose us to radiofrequency EMFs: computers and tablets, Wi-Fi, Bluetooth and electronic chips, as well as fluorescent lights, microwave ovens, induction hotplates and washing machines.

ANSES now urges "limiting exposure of the population", particularly to cell phones. It also encourages the use of an earpiece.

ANSES already rang the alarm bell in October 2013. After evaluating more than 300 international studies, the agency published a report highlighting the biological effects of EMFs on humans and animals concerning sleep, male fertility and cognitive performance.

A spokesperson for ANSES stated that "the massive development of technologies relying on radiofrequencies, leading to intensive exposure of the population, specifically more sensitive persons, which cannot be avoided". They went on to say that the deployment of 4G "will be accompanied by increased exposure of the public".

French exposure limits are based on a 2002 decree. They are set at 61 volts per meter (V/m) for 3G and 4G, the same as in the USA. The Council of Europe recommends an exposure limit of 0.6 V/m, some 100 times lower.

Switzerland and Liechtenstein and eight Member States of the European Union (Belgium, Bulgaria, Greece, Italy, Lithuania, Luxembourg, Poland, Slovenia) have adopted more restrictive limits than those of France.

In Europe there is a growing recognition of the plight of persons suffering ill health from exposure to electromagnetic fields, a condition known as electrical hypersensitivity or electrical sensitivity. This new bill requires that the French government provides Parliament with a report detailing "the opportunity to create areas of limited electromagnetic radiation, notably in the urban environment". It also requires that the conditions of electrosensitives by taken into account in the workplace.

Though this bill has to be adopted by the French Senate for it to be made into law, clearly this bill reflects the buildup of public opinion in France and other European countries that EMF exposures are dangerous and the public needs protecting. How long before US public opinion is successful in introducing similar protective legislation?

http://www.naturalnews.com/043695_electrosensitivity_Wi-Fi_French_government.html

Could Wi-Fi in schools be harming our kids?

Students in Lindsay Freedman's split Grade 3/4 class at Red Willow Public School are working away on tablets, laptops and iPods. It's Bring Your Own Device day, a regular occurrence here, and supplementing the devices brought from home are 20 school-owned iPads. Freedman walks around the classroom, marveling at her students' instant embrace of the online presentation app she's just introduced. "They're an instant motivator," she says, referring to the tools in their hands.

Red Willow belongs to the Peel District School Board (near Toronto), one of several across Canada that have adopted Wi-Fi throughout its schools, an embrace of 21st-century technologies designed to "ensure that our students can thrive in a future that can't be predicted," as Peel's promotional brochure puts it.

Though most parents and educators celebrate the move, some are raising concerns about the possible health impacts of the radio-frequency (RF) radiation on which wireless technologies operate. Exposure levels to this kind of radiation, which fall in the same frequency bandwidth on the electro-magnetic spectrum as radios, televisions and mobile phones, continue to rise as wireless technologies become more prevalent.

Canada's current guidelines on RF exposure are in line with those of the International Commission on Non-Ionizing Radiation Protection – the largest regulatory body in this field. But many other jurisdictions have adopted considerably lower limits, either as a precautionary measure or because they view the science differently.

How is it that health agencies reach such different conclusions when faced with the same scientific evidence? Why are some Canadian schools installing Wi-Fi while France is limiting exposure? Switzerland heavily favors wired Internet connections in schools, yet Israel is pulling it out of its lower grades altogether.

While most Western bodies have deemed the scientific evidence on health effects inconclusive, many European jurisdictions are choosing to err on the side of caution until more is known. In a resolution in 2011, the Council of Europe recommended that the As Low As Reasonably Achievable (ALARA) principle be applied to electromagnetic radiation, fearing "there could be extremely high human and economic costs if early warnings are neglected." It also condemned the "lack of reaction to known or emerging environmental or health risks and virtually systematic delays in adopting or implementing effective preventive measures."

Lichtenstein, Italy and Belgium responded by drastically lowering their exposure guidelines. In France, a bill currently before the Senate insists on a principle of moderation where RF radiation is concerned. If passed, Wi-Fi will be banned from maternity wards and child-care facilities, communities would have to be consulted before any installations in schools, and if installed, all routers would have to be accessible to teachers who could turn them off when not in use. Laurence Abeille, the Green MP behind the bill, had originally proposed a ban in all schools around students up to the age of six. She had to water it down to gain broad support in the National Assembly, but feels public concern in France is rising. This spring, a 32-year-old man received medical benefits from the local health authority in Essonne, south of Paris, for his electro-hypersensitivity – a first in France.

Switzerland prides itself on having among the most stringent regulations on electromagnetic radiation in the world. As of 2000, it has supplemented its exposure limits (which are in keeping with Canada's) with much more restrictive limits for installations of power lines, television and radio transmitters, and mobile phone base-stations in well-frequented locations. The new regulations were accompanied by an aggressive public awareness campaign about the health risks of RF radiation. Swisscom, the national telecom company, promotes its line of low-radiation "Ecomode" phones and routers as "safer" – openly acknowledging the risks inherent in these devices. And for 10 years, Swisscom has been installing wired Internet connections in Swiss schools for free. Why not wireless? As company spokesman Carsten Roetz wrote in an e-mail, "because there's no reason to put a radiation source that isn't absolutely necessary in schools." Of Switzerland's 6,800 schools, Roetz estimates that fewer than 100 have opted for wireless connections.

In March of this year, the Jerusalem Post reported that the Israeli Education Ministry had ordered radiation testing in all Israeli schools, banned Wi-Fi from pre-schools and kindergartens, and restricted its use to one hour a day for students up to Grade 3. The move came in response to persistent complaints from parents whose children suffer from some form of electromagnetic hypersensitivity.

Russia's exposure limits for RF radiation are 100 times lower than Canada's. While Russian schools can choose to install Wi-Fi, they are the exceptions, says Oleg Grigoriev, chairman of the Russian National Committee on Non-Ionizing Radiation Protection (an expert group that reports to the Russian parliament). He says damage to children's cognitive function caused by long-term exposure to low-strength electromagnetic fields has long since been demonstrated by Russian researchers. Russia, he explains, began experimenting with the impacts of electromagnetic fields on the nervous system a century ago, and, as a result, does not consider its approach precautionary, but rather "science-based."

While faced with the same scientific evidence, these countries have adopted very different rules on exposure. It's all about managing risk. Marc Saner, a professor at the Institute for Science, Society and Policy at the University of Ottawa, affirms that scientific evidence is just one element in the multi-factorial nature of risk management in public policy. "The focus on risk reflects many things – a country's history of science, its trade interests, the pet causes of its movie stars … Policy decisions are always a few steps away from data, there's always an emotional component."

Most Canadian school boards are introducing Wi-Fi, but at a slower rate than Peel – slower not because of concern about exposure, but because installation is more complicated in older schools with thicker walls. Toronto's school board aims to have at least partial Wi-Fi in all its schools by 2016, and is adding zones regularly. Because Wi-Fi exposure has been deemed safe in Canada, the expansion proceeds without notification.

Paradoxically, outside the schools' walls, Toronto's Board of Health insists on a "prudent avoidance policy" with respect to cell tower locations, keeping RF radiation levels in areas of the city "where people normally spend time" 100 times lower than what federal guidelines insist on – much like in Switzerland. The Board argues that as long as radiation sources in the urban environment continue to increase, the cumulative effect is unknown and caution is warranted. The policy has been in place since 1999.

In Canada, the lack of public concern about Wi-Fi exposure in schools seems at odds with a culture of parenting that's often called hyper-cautious. Here, public awareness on the issue of exposure has been

mainly focused on cellphones. The science at play is beyond the reach of most citizens, and many would rather not entertain the possibility that these incredibly useful technologies may pose a risk.

"We're not just talking about Wi-Fi in schools," Saner says. "We're asking much bigger questions, like what is education? Are these devices good for society generally? Is this speed of innovation a good thing? The stakes here are huge."

http://www.theglobeandmail.com/life/health-and-fitness/health/is-there-such-a-thing-as-too-much-Wi-Fi/article18592972/

Teen Allergic to Wi-Fi Commits Suicide, Parents Say

The mother of a teen who committed suicide after suffering from what she calls a rare allergy to Wi-Fi is accusing her daughter's school of failing to protect her.

Jenny Fry, 15, was found hanging from a tree near her home in the U.K. last June. Her story is now coming to light because of a legal investigation into the cause of Jenny's death.

Her mother, Debra Fry, told the Mirror that Jenny suffered from blinding headaches, fatigue, concentration problems, and bladder issues that she says were caused by electro-hypersensitivity syndrome (EHS), a condition in which electromagnetic radiation emitted from wireless technology, including Wi-Fi, cellphones, and cell towers, causes debilitating physical symptoms.

Although Jenny's parents had removed Wi-Fi from their home, which helped, it was still present at her school. "Both Jenny and I were fine at home, but Jenny continued to be ill at school in certain areas," said Fry.

Jenny received several detentions in school, not for being disruptive in class, but because she'd often have to leave the classroom to find an area away from Wi-Fi where she could concentrate.

Fry had shared information about Wi-Fi's potential problems with the head teacher of Jenny's school, Simon Duffy, but according to Fry, Duffy told her there was an equal amount of information that shows Wi-Fi is harmless.

"I also had a heated exchange with teachers telling them Jenny was allergic to Wi-Fi, and that it made no sense making her take detentions in rooms that were making her ill," said Fry. "The least they could do was allow her to take them in rooms where she felt able to concentrate, but they wouldn't listen."

Fry believes Jenny's suicide attempt was meant to be a cry for help. A police statement said that on the day Jenny died, she had texted a friend twice, telling the friend about her intentions to commit suicide and stating where she was, according to the Mirror. But her friend didn't have her phone with her to see the texts in time.

"Jenny left letters for us where she said she couldn't cope with her allergies from Wi-Fi anymore," Fry told the Telegraph. "She left them for us in case things went too far, but I don't believe she wanted to die."

Arthur Firstenberg, a leading anti-electromagnetic health activist, admits that EHS is not a simple subject, but that it's not taken seriously enough by the medical community. Firstenberg believes there are genuine health issues stemming from the escalation of wireless technology, and that schools have a responsibility to keep children safe. "Imagine if this was a toxic chemical, and the school suddenly decided to spray the chemical throughout the school just because other schools were doing it," Firstenberg told Yahoo Parenting. "Don't people have a responsibility for what they do, regardless of whether others are doing it too?"

"Just because Wi-Fi is new and all around us doesn't mean it is safe," Fry told the Telegraph. "Wi-Fi and children do not mix. Much more research needs to be done into this because I believe that Wi-Fi killed my daughter."

Jenny's parents are now trying to raise awareness about the dangers of Wi-Fi. Fry added, "I am not against a bit of technology, but I do feel schools should be aware that some children are going to be sensitive to it and reduce its use."

Cell Phone Usage Inside Schools

My kids have been educated on the dangers of electromagnetic radiation (EMR) from cell phones, cordless phones and Wi-Fi networks, so they were aware enough to come home and tell me how they're unwillingly getting exposed to EMR at their school – via other kids' cell phones and the wireless computers in the computer room.

My children have told me that many children in their classes own cell phones, which are allowed to remain turned on, whilst in the classroom. Whether these phones are set to ring or just vibrate is not the issue. If they are turned on, then they are transmitting (and receiving) to the nearest cell phone tower continually and emitting electromagnetic radiation (EMR) throughout the classroom.

My son has also told me that all the computers in the computer room are wireless. Again, as computers on a Wi-Fi network are in the "ultra-high frequency range" and nearly up to the "super high frequency" range (see info below on radiation frequencies from NASA), this likewise is transmitting very high EMR to the children (and teachers) in that classroom.

When we were in Singapore in 2001, there was huge coverage in all the newspapers because 20-year-olds throughout the city were having heart attacks and they couldn't figure out why. Then, someone figured out it was because it was the fashion at that time for young people to wear their cell phones on decorative cords around their necks. This meant that their cell phones were hanging right next to – you guessed it – their heart. So a warning went out in all the local newspapers, telling kids not to wear their cell phones on these cords. But funnily enough, no one I've spoken to in Canada (or the U.S.) ever heard about that. And no one thought about warning people not to wear their cell phones clipped to their belt, or in their pocket.

Of course there are huge revenues at stake with wireless technology and until recently, not much long-term hard data on the risks or effects. But as you can see from the first reference listed below (from the head of a cancer research institute), that has now changed, and there IS enough data in place for respected scientists and doctors to conclude that cell phone and other ultra-high frequency wireless devices are not safe for long-term, or cumulative human use – *especially* for children.

I have also listed my own research below – including hard data from NASA's website, that has led me to completely avoid cell phone, cordless phone and wireless computer usage in my family and my house.

Many people are comparing cell phones and Wi-Fi network usage to cigarettes – which were also once thought to be a "private" choice, but later acknowledged as a public health issue – where your choice affects my health.

I encourage you to review the research and sources below – of the thousands of references available (over 2,000 scientific, peer-reviewed studies), I have included only a few of the most pertinent.

And if you would like a set of "action tools" that you can download and hand out to neighbours, schools, other parents, etc. to help get Wi-Fi removed from your school, they're all available at my kids' site: www.RadiationEducation.com

****

Associated Press

Thurs., July 24, 2008

PITTSBURGH – The head of a prominent cancer research institute issued an unprecedented warning to his faculty and staff Wednesday: Limit cell phone use because of the possible risk of cancer.

The warning from Dr. Ronald B. Herberman, director of the University of Pittsburgh Cancer Institute, is contrary to numerous studies that don't find a link between cancer and cell phone use, and a public lack of worry by the U.S. Food and Drug Administration.

Herberman is basing his alarm on early unpublished data. He says it takes too long to get answers from science and he believes people should take action now — especially when it comes to children.

In the memo he sent to about 3,000 faculty and staff Wednesday, he says children should use cell phones only for emergencies because their brains are still developing.

Adults should keep the phone away from the head and use the speakerphone or a wireless headset, he says. He even warns against using cell phones in public places like a bus because it exposes others to the phone's electromagnetic fields.

"Although the evidence is still controversial, I am convinced that there are sufficient data to warrant issuing an advisory to share some precautionary advice on cell phone use," he wrote in his memo.

****

CBC News

Saturday, July 12, 2008

"Toronto's department of public health is advising teenagers and young children to limit their use of cellphones to avoid potential health risks."

****

Dr. Robert Becker, M.D., one of the first medical pioneers to study natural electrical currents in the human body and to caution about electropollution, answers the question, "Can EMR exposure cause harm?" in this interview. Dr. Becker was twice nominated for the Nobel Prize in Medicine.

****

Good summation article on CELL PHONE RISKS TO CHILDREN by Dr. Joseph Mercola:

Children today will experience previously unimaginable exposure to information-carrying radio waves from mobile phones because they start out using them at a very early age.

I am absolutely convinced that the explosion of cell phone usage around the world is a health disaster in waiting, and contributing to the rapid rise in several neurological epidemics, such as autism and early-onset of Alzheimer's.

One reason for this is that the information-carrying radio waves from cell phone base stations and cell phones make children's exposure to vaccines and heavy metals much more dangerous than they typically are. EMR can actually trap heavy metals inside your cells, causing cellular damage and

hindering your body from detoxifying. For this reason — while I realize that most people will not get rid of their cell phones because of their convenience — I would still urge you to not let your kids use them.

I am so convinced this danger is real, on par with the dangers of tobacco, which all the "experts" claimed was safe, that I'm writing an entire book on the subject, due out in 2009.

And, I'm not alone in trying to educate the public. In fact, some European countries are already working on public health campaigns designed to warn school-age children of the dangers, by putting up posters in schools and community halls.

Will Europe Ban Cell Phones for "Under-age" Use?

The Vienna Medical Association is demanding the removal of zero tariffs and the banning of mobile phone advertising targeting children and adolescents. Says Erik Huber, environment advisor for the association: "Children under the age of 16 should never use a mobile phone."

Many scientists and government agencies in Europe have already accepted that EMF from cell phones does pose health risks, reflected in Huber's statement, "Scientists do not argue anymore whether mobile phones are harmful, but how harmful they are."

Don't be Deceived – SAR is Not an Indication of Safety

Although the National Research Council's report states that Specific Absorption Rates (SAR) for children are likely to be higher than for adults, let's not get confused.

Because the danger from most land-based portable phones, cell phones and Wi-Fi routers is NOT from the magnetic radiation or the microwave carrier wave for which typical SAR ratings are given on phones. Unless you have massive exposures like you might expect in a microwave oven, these thermal effects are insignificant.

So simply lowering the allowable SAR will NOT make cell phones safer.

Instead, nearly all the biological damage comes from the modulated signals that are carried ON the carrier microwave. These modulated information carrying radio waves resonate in biological frequencies of a few to a few hundred cycles per second, and can stimulate your cellular receptors causing a whole cascade of pathological consequences that can culminate in fatigue, anxiety, neurological decline, and ultimately cancers.

The density of your child's skull is also far less than yours, and therefore their brain is far more susceptible to these information-carrying radio waves.

This Deserves Your SERIOUS Attention

The studies showing the long-term risks of cell phone use are just beginning to come in because cell phone use didn't become widespread until the late 1990s. It typically takes at least 10 to 20 years for cancers to show up, so now is the time when these risks will become apparent.

It is almost as if NO ONE was smoking and then all of a sudden nearly 90 percent of the planet started. Of course, we would not see any spectacular increase in major damage for more than 10 years. It takes time for this damage to accumulate and be noticed.

Unfortunately, most people fail to correlate common symptoms and health problems to their exposure to cell phones and other radio frequencies, perhaps because these conditions can so easily be attributed to other causes (including so-called "unknown" causes) as well.

Take a look at these common illnesses and ailments, which have all been scientifically linked to cell phone information carrying radio waves:

* Alzheimer's, senility and dementia
* Parkinson's
* Autism
* Fatigue
* Headaches
* Sleep disruptions
* Altered memory function, poor concentration and spatial awareness

Although cancer and brain tumors are most often cited as the potential health risks from cell phone radiation, as you can see, cancer is not the only, or most common danger that you and your children face.

Protecting Yourself and Your Children From Dangerous RF

The best way to protect yourself would be to simply not use a cell phone and revert back to a corded phone. At the very least I would urge you to not let your kids use them or severely limit their use. Their developing nervous systems and thinner skulls are simply too vulnerable to cell phone damage.

If you choose to keep your cell phone, make sure you use a non-Blue Tooth headset. Also remember, even when you're not using your phone, keep it as far away from your body as possible. Do not keep it on your belt or in your pocket as the radiation WILL penetrate your body wherever the phone is attached. According to a scientific study published in Fertility and Sterility in May 2007, statistically significant changes were found in men's sperm count and health of the sperm, based on cell phone use.

Their conclusion?

"Use of cell phones decreases the semen quality in men by decreasing the sperm count, motility, viability and normal morphology. The decrease in sperm parameters was dependent on the duration of daily exposure to cell phones, and independent of the initial semen quality."

So, make sure you stow your cell phone in a bag, briefcase, or your car's glove compartment.

****

Dr. Carolyn Dean MD ND recently shared this information:

Last September Dr. Devra Lee Davis, an epidemiology professor from the University of Pittsburgh testified before the U.S. Senate…

"Dr. Davis," asked Senator Tom Harkin, chairman for Health & Human Services, "you said that a cell phone should not be kept any closer than an inch to your body?"

Dr. Davis nodded.

"Where does that come from?" asked Senator Harkin.

"That actually comes from the BlackBerry manual," replied Dr. Davis, "as well as from the iPhone manual. If you read the manual– which almost none of us does — that is what they say."

Seeing is believing… so I found a PDF copy of iPhone's "Important Product Information Guide" online which states: "iPhone's SAR measurement may exceed the FCC exposure guidelines for body-worn operation if positioned less than 15 mm (5/8 inch) from the body…"

The BlackBerry manual takes it 10mm further by advising: "…keep the device at least 0.98 inches (25mm) away from your body…"

So if you can't avoid cell and cordless phones entirely — at least do what the industry's own manuals suggest: Avoid any direct physical contact while they are activated.

****

An article in the Los Angeles Times reported:

"Belgium, France, Finland, Germany, Russia and Israel have publicly discouraged use of cellphones by children. (Independent research in Sweden last year concluded there was an astonishing 420% increased chance of getting brain cancer for cellphone users who were teenagers or younger when they first started using their phones.) France has gone so far as to issue a generalized national cellphone health warning, banned cellphones in elementary schools and considered outlawing marketing the phones to children."

****

WI-FI RESEARCH

You can go here to NASA's site to get an easily understood definition of exactly what electromagnetic radiation is, and the distinction between the different types of waves.

This article tells you what wavelength/frequency wireless computer devices work with (frequency and wavelength are inter-related as explained in the NASA article):

Once we know the frequency wireless (Wi-Fi) technology uses, we can then compare that to Radios and TVs.

FM Radio is in the 88 – 110MHz range

Analogue TV (what most people have in their homes) is at 400 – 600MHz

Digital TV is at 600 – 1000MHz.

Here's a great definition of radio frequency and then an excellent chart showing the strength of the various frequencies:

Radio frequency is also abbreviated as rf or r.f. – any frequency within the electromagnetic spectrum associated with radio wave propagation. When an RF current is supplied to an antenna, an electromagnetic field is created that then is able to propagate through space. Many wireless technologies are based on RF field propagation.

These frequencies make up part of the electromagnetic radiation spectrum:

- Ultra-low frequency (ULF) — 0-3 Hz
- Extremely low frequency (ELF) — 3 Hz – 3 kHz
- Very low frequency (VLF) — 3kHz – 30 kHz
- Low frequency (LF) — 30 kHz – 300 kHz
- Medium frequency (MF) — 300 kHz – 3 MHz
- High frequency (HF) — 3MHz – 30 MHz
- Very high frequency (VHF) — 30 MHz – 300 MHz
- Ultra-high frequency (UHF)– 300MHz – 3 GHz
- Super high frequency (SHF) — 3GHz – 30 GHz
- Extremely high frequency (EHF) — 30GHz – 300 GHz

CONCLUSION: WI-FI IS NOT SAFE FOR FREQUENT, ONGOING USAGE

So, based on the information gathered above, here's where each item (cell phones, radio, TV, wireless computers) lies in terms of intensity of electromagnetic radiation:

FM Radio is 88-110 MHz –> Low frequency electromagnetic radiation

Cell phones are 824-869 MHz –> Ultra-high frequency electromagnetic radiation.

Wireless computers/internet are 2.4 GHz –> Ultra-high frequency electromagnetic radiation (but nearly up into Super High frequency range).

Therefore, surprise-surprise, wireless computers and their networks are NOT SAFE for frequent, ongoing human use! And when salespeople, politicians and presidents of wireless companies tell you that "there's no problem, it's the same as FM Radio" – you will know they are lying, or misinformed.

Worrying also is current TV transmission at 400-600 MHz (Ultra-high frequency) and Digital TV in the 600-1000MHz range (also Ultra-high frequency). But at least one tends to sit a good distance away from a TV!

Landlines

Saving Your Landline May Save Your Life

See source for publication.

https://wirelessaction.files.wordpress.com/2016/09/saving-your-landline-may-save-your-life-sccma-bulletin_may-2016.pdf

Mauk said her landline was the only thing working in her house after the 2015 windstorm

Lee Ann Mauk spent nine days without power after Spokane's 2015 windstorm. She couldn't turn lights on, take a hot shower or keep food frozen. But through it all, her landline phone kept working.

"We didn't have stoves. We didn't have hot water. We didn't have refrigerators. But we did have our phone," she said.

It's no secret that the number of households with landlines is dwindling across the United States.

As of December 2015, the most recent data available from the Federal Communications Commission, Spokane County had 96,000 active residential landlines. That's about one for every two households. That number is down from the June 2014 FCC count, which showed 106,000 residential landlines in Spokane.

In Kootenai County, the number for both snapshots was 40 percent.

We asked readers to weigh in about whether they had a landline and why on Facebook and got nearly 100 responses.

Those who still have landlines said the ability to reach kids at home, power outages and call quality were all reasons to keep the phone around.

Jenny Louie said she uses her landline to sign up for things that require a phone number, and so she doesn't have to get her 11-year-old a cellphone.

"We need a phone at home that they can use in case of emergency," she wrote. Others pointed out schools still teach young kids to dial 911 on a landline.

Some readers said they felt more secure in an emergency knowing 911 dispatch can read their location off a landline. But it's not quite that simple, said Spokane fire communications dispatch chief Jay Atwood.

Traditional landlines that rely on cables, usually provided by CenturyLink in Spokane County, transmit an address to 911 dispatch. But cellphones often do, too, and in many cases, the location is fairly accurate.

"Sometimes it can be really precise and sometimes it's a quarter-mile off," Atwood said.

Cellphone location pinpointing is a county-by-county technology. Spokane has had it for years, Atwood said, and tends to be ahead of the curve. Smaller or more rural counties may not have that ability.

What can be a problem are landlines that use the internet to transmit calls. Those landlines, called voice over internet protocol, or VOIP, are usually the ones that come bundled with Comcast or other cable TV service.

Atwood said VOIP landlines come up with the subscriber's address, based on whatever information they have in their account. If someone's recently moved and hasn't updated that information, 911 could end up with the wrong address.

Regardless of how a call comes in, 911 dispatchers always ask for a location to avoid confusion.

"We always confirm the address no matter what," Atwood said. "It's never one of those things we take for granted."

Some people said they keep a landline around because of spotty cellphone service at home. Surprisingly, FCC data show little correlation between how rural a county is and the percentage of households with landlines.

Landline coverage is highest by far in Wahkiakum County in southwestern Washington, at 82 percent. But Whitman County saw the lowest coverage in the state, at just 39 percent. Other more rural counties, including Asotin, Adams, Douglas, Kittitas and Walla Walla, are between 40 and 50 percent, while 54 percent of King County households still have a landline.

Among readers who had given up a landline, telemarketers were a big reason. Many said they didn't see the point of paying for an extra service, cheap though it can be. Some said they got rid of it when their children got old enough to have cellphones.

"I got rid of mine when I got comfortable with having just a cellphone, but I have been thinking a lot about getting a landline again. I never missed a call when the house phone rang like I do with my cell," wrote Vicki Denz, who's in her early 50s.

State regulations have shifted over the past three years to reflect the declining number of people using landlines. The state Utilities and Transportation Commission used to regulate the price phone companies could charge for service, since they usually had a monopoly. In 2014, they stopped price regulations on landlines in most areas because of the competition provided by VOIP, Skype, cellphones and other options.

"There wasn't a need to discipline prices under regulation anymore because the assumption, and I think it still holds, is that the marketplace will discipline their prices," said Brian Thomas, the director of policy for the commission. The commission does still regulate consumer safety, including 911 availability.

The Department of Social and Health Services used to require a landline phone for foster parents, but dropped that requirement around 2013. Now, regulations say only that parents must "have access to a working telephone at all times" while children are at home.

Mauk's house has a functioning rotary phone, along with a more modern device upstairs. She still uses the rotary dial to make calls, though it can be tricky if she has to go through an automated menu after reaching her local pharmacy.

A Landline Might Be Your Best Option during a Storm

Think about how much life has changed since Hurricane Andrew, some 24 years ago. We likely had that wall phone in the kitchen with the really, really, really long cord. We got most of our news from television, radio or newspapers. The web was something Spiderman produced as he battled villains.

Imagine if we had today's technology back then. We could text, Snap, Tweet, Facebook-message, Instagram, etc. all of our loved ones instantly how we were dealing with the post storm damage and stress. We could jump on the utilities apps to see all we need to know about when we might get power back. There are probably apps that let us know which gas station has fuel, which stores have bread and milk or the closest emergency center for aid of any kind.

Wait, no, we probably couldn't do all those things because today's technology is dependent on energy and Wi-Fi. And after a storm like Andrew, we would likely be out of both. So, we might have to go into the attic and pull out the old wall unit after all.

Mimi Whitefield of the Miami Herald recently wrote about this strange phenomenon and shared her ideas on how to communicate if another big storm comes through.

WLRN: I use my phone as an alarm, as a radio and my source of news oftentimes. Looking at my checklist, I'm not prepared. Do you think people are ready for another storm?

Whitefield: Well, we may not be prepared. We have all these technological advances. There are all these apps out there that help you deal with natural disasters, weather, lots of information, but you're not necessarily going to be getting those if the power goes out and inevitably it does during a storm.

The telephone companies such as Verizon and AT&T say that their towers and their systems are able to withstand quite a bit of wind damage and storm damage. But are they confident their systems can withstand an Andrew?

I think with each storm and each natural disaster they learn a little bit more. They will move their personnel and their equipment into an area that they think is going to get slammed and they've got these mobile cell phone units. But of course these things can't move into an area until after the debris is cleared. And so they have a lot more capacity, they are a lot more robust than they were 10 years ago when the last major hurricane hit Florida, but it's kind of an unknown about how they will be able to perform it...if a major hurricane hits.

What did you take away from researching and writing this story and has it changed anything in the way you view what you have to do to get ready?

I think I may go out and buy some battery packs and these are relatively inexpensive. You can probably get one for $20-$25 but you can plug your cell phone in there, you could maybe plug your laptop, a fan, some lights, unless you are really able to splurge for a generator, but you want to have power. And even the ability of news organizations dependent on power, dependent on the Internet to get their message out there, could be challenged as well.

I remember specifically with Andrew and we were trying to call our families everywhere else to let them know what was going on. And I know my mom was going days trying to get through trying to get through. Did they [phone companies] learn anything from the experiences after Andrew?

What they recommend, because they really don't want to jam up the phone lines and the cell networks, is well in advance of a storm designate a friend or someone in your family as your central contact point. Try to get in touch with that person and that person try to get in touch with everyone else after a storm, like your information central. So instead of calling 10 friends and family members you're making that one call. I think that obviously could help quite a bit. You cannot go on your cell phone during a storm for entertainment or to play games. It's basically for an emergency, that and you're likely to get denial of service.

One thing that has changed a lot, about 47 percent of American households are cell-phone-only households. I do have a landline at my house and I keep it specifically for this reason, but I have wireless phones. They will not work because they're dependent on electricity, so I keep an old style telephone and I pull it out whenever the weather is bad.

Landlines: The 'Dinosaur Phone Technology' That Could Save You in a Crisis

As cell phone service has grown reliable and more widely available, many households have given up their landline telephones.

Today, about two-thirds of younger Americans use cell phones only, and about 40 percent of households overall have given up landlines.

This, though, can be a problem during an emergency.

Some, but not all, cell towers have backup generators, but during Hurricane Sandy they provided only an additional four to six hours of power. In Long Island, N.Y., every single cell phone tower eventually failed, leaving an entire community holding worthless cells phones.

"There was one woman in particular who passed away, of natural causes, an elderly woman," city manager Jack Schnirman told *NPR*. "And her daughter had to walk literally a mile and a half from her home to police headquarters just to say, 'Listen, my mom has passed, and I thought I should tell somebody."

Said college student Colleen Marron, "It was scary because you don't know what is going on. You feel helpless."

Additionally, cell towers are not designed to handle a mass of people calling all at once.

Landline phones, assuming they are not wireless, generally work during a power outage. This is because power is sent to the phones through the phone line from the power companies. The power companies have battery backup and backup generators so that their operations can continue for well over a week during a power outage.

The lines often are underground, preventing them from being damaged during a storm. That's a selling point for landline companies who are trying to maintain customers.

"When the power's out, a landline phone connection will work more than 99.9 percent of the time," says a TDS Telecom website. "It's required by the FCC. This means you can still reach 911 and friends

and family; they can all reach you, too. Even if a major storm (tornado or hurricane) comes through the area. It might take out the cell tower, but it can't take out the underground phone lines."

In other words, during a power outage, cell phone towers will exhaust their battery power within a matter of hours, while landlines will work for well over a week, maybe more (depending on the ability of the phone company to keep its generators running).

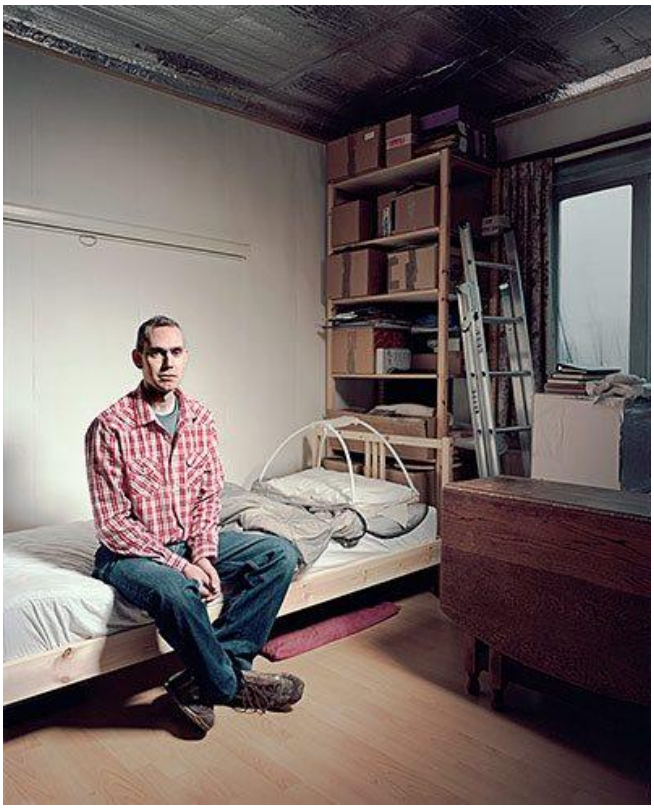
Electromagnetic Hypersensitivity

Electrosensitivity: is technology killing us?

Is modern life making us ill? Yes, say those who suffer from electrosensitivity. Are they cranks, or should we all be throwing away our mobile phones?

Tim Hallam, Leamington Spa

Tim is a science and history of art graduate from Cambridge University. He has insulated his bedroom and has fitted foil on the walls, under the floor and on the ceiling. He sleeps in a custom-made silver-coated sleeping bag every night, which helps block out electromagnetic fields. Tim can't work in an office environment and the condition has severely impacted his career aspirations. He currently drives a supermarket delivery van. 'Where I'm living now, it's not a great situation,' he says. 'I'm lucky that the shielding worked to a large degree. But I would love to live somewhere I didn't have to live in a metal box and sleep in a bag, where I could go to a cafe and see my friends, go to the cinema – all those things that people take for granted.'



Damian May, Reading

Damian is a cabinet maker and runs a property-maintenance business. He discovered he suffered from electrosensitivity after buying a Nintendo Wii for his family for Christmas. It triggered severe headaches and body pains. His electrosensitivity has made it very difficult for him to run his company, because he finds it painful to work in areas with Wi-Fi or mobile phones. He has turned off everything wireless in his home, has insulated his office and is campaigning to have Wi-Fi removed from his son's school.

Eileen O'Connor, Merseyside

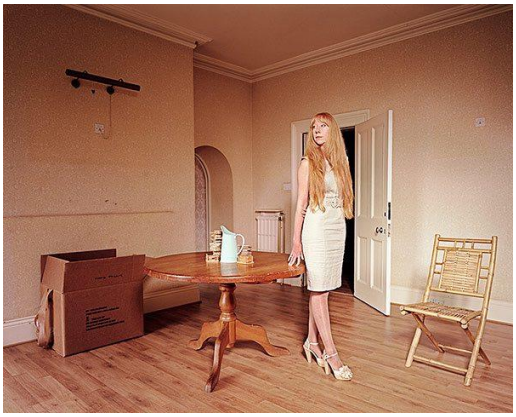
Eileen lived 100m from a mobile phone mast for many years in Wishaw. She experienced many symptoms typical of electrosensitivity, but could not work out the cause. When she was diagnosed with breast cancer aged 38 and discovered that a number of her neighbors had similar symptoms and cancers, she became part of a very public campaign to have the mast removed. She is a director for The Radiation Research Trust charity and works with the International EMF Alliance. 'It's heartbreaking to see people who are not getting support at the family,' she says. 'It's awful. It's a double insult, really – not only are you suffering with this terrible condition, but then you've got people who think you're going crazy at the same time.'

Chris McKenzie, Cumbria

In 2008, when Chris moved into his own flat, he quickly became ill and suffered headaches, body pains and insomnia. He attributed this to exposure to Wi-Fi, which he had never lived with before. His family found it hard to understand the condition, especially when he wore a tin foil hat at home and stopped work as a stone mason. His mother sent him to a psychologist for help, and he was placed on heavy medication and sent to a psychiatric ward against his will. 'There were questions coming everywhere, they were putting words into my mouth. They were saying, "You know this isn't real, don't you?" I got dragged away to a psychiatric ward with people who have serious mental conditions.' He sought help from the charity Electrosensitivity UK and was later released. He now lives on his own and has made various attempts to shield his home from electromagnetic fields with carbon paint and aluminum foil.

Doctor Erica Mallery-Blythe, Lincolnshire

Erica worked as an emergency medical doctor for 12 years in trauma rooms across the UK and abroad. In 2008 she became interested in radiation research and is now a medical advisor for the charity Electrosensitivity UK. She advises EHS sufferers on how to improve their health, and in serious cases has given refuge at her rural home to people needing to escape their home environments. 'It's very uncharted territory in terms of what exactly EHS is, and how many people it's affected. My own personal instinct is just like with so many other things we see in life, it's a bit of a bell-shaped curve. You've got some people who show almost no reaction whatsoever to an EMF challenge, and others you would say have EHS, who are at the other side of that curve, and their life is utterly turned upside down by it, given the modern world. Most people will probably fall somewhere in between.'



Clare Woodward, Devon

Clare worked as a computer programmer for nine years and then retrained as a complementary therapist. When her family moved into a new house in Devon, she began suffering from insomnia and heart palpitations, which she attributed to a mobile phone and Tetra* mast very close by. They have since insulated their home at great expense with carbon paint and specialist windows.

**Tetra - Terrestrial Trunked Radio – is a powerful two-way radio system primarily used by the emergency services*

Hannah Metcalfe, Kent

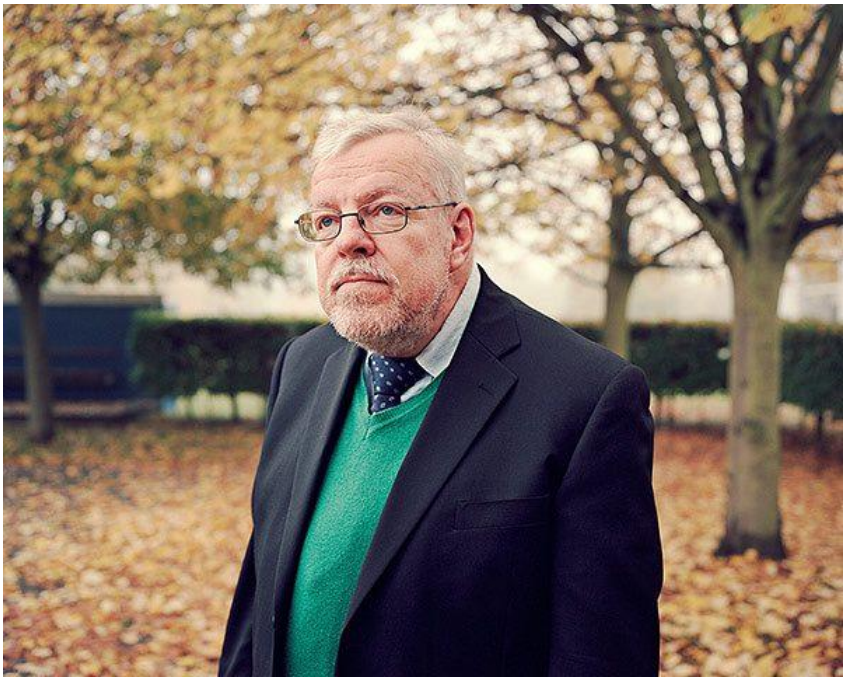
Hannah suffered from psoriasis as a child and started sun bed treatment at the age of nine to help clear up her skin. In her late 20s, she started developing severe migraines and fatigue when working in offices with fluorescent lights. She always felt discomfort when using a mobile phone. The severity of her symptoms got worse when she later discovered a sensitivity to Wi-Fi. She gave up her job as a trainee criminal solicitor in 2010 and now lives with her husband and two children on a farm in Kent. 'When I realized that Wi-Fi was making me ill, I also turned off the digital phone, so [there] was nothing wireless in the house. I went from feeling like this sluggish person to feeling so vibrant and alive, with so much energy. It's just amazing to feel well.'

Freda Thornhill, retired teacher
Freda's first symptoms of electrosensitivity began in 1999 while using computers and CRT monitors at school. The condition became so severe that she had to give up her job. She is now also affected by mobile phones and Wi-Fi, and spends extended periods of time away in her 'lifeboat van' so she can escape the electromagnetic fields at home.

Jenny Layton, Devon
When she developed unexplained headaches, tinnitus, heart palpitations and insomnia, she and her GPs were at a loss as to the cause. After months of research, she finally attributed her symptoms to a new neighbor who had set up Wi-Fi next door.

Michelle Berriedale-Johnson, London
Michelle has run a series of magazines and websites for 20 years, covering issues related to food allergy and intolerance. Her electrosensitivity began after heavy use of mobile phones and CRT computer monitors for work. She is now also affected by Wi-Fi and has insulated much of her home. She is photographed wearing a jacket made from a silver-coated material that reduces the strength of electromagnetic fields.

Professor Olle Johansson, department of neuroscience, Karolinska Institute, Sweden
'From the very beginning, it was said that this was just a post-menopausal problem in women. Then men started to report electro hypersensitivity, and the self-proclaimed experts said it's actually only elderly [people], because they are afraid of new technology. We then started to get children and teenagers and young people, and they rolled out a new explanation, which was that it's actually people with higher education. And it went on like this. But today you can see that any political color, any income class, both sexes, all age groups, are affected.'



Raphael Cuesto, London

In 2004, while working for a telecommunications company in Kuala Lumpur, Raphael noticed that he was developing pains in his arms and hands every time he worked on his laptop. His symptoms got worse and he began getting headaches and heart palpitations when using his mobile for only a few minutes, and this progressed to almost immediate pain when he brought the phone near his head. He decided to stop using his mobile altogether and left his job. He is now a teacher. 'When you spend a minute on the phone and get palpitations, you know you have to do something about it. I remember one day turning [over] a piece of paper and writing in the middle of the page, "Jobs without a mobile phone." I had to change everything.'

Ray Parsons, Weston-Super-Mare, retired joiner

When Ray started developing severe fatigue and body pains in his late 40s, he initially thought he had developed ME. After eight years of analyzing his symptoms, he concluded that he was, in fact, suffering from electrosensitivity. He is photographed in his sitting room, where he has fitted a silver-coated netting over the window that reduces the strength of electromagnetic fields.

Steve Miller, Cornwall

Steve is a successful record producer. His electrosensitivity to Wi-Fi and mobile phones has forced him radically to change his lifestyle and to give up touring almost entirely. 'I went to see a friend in Falmouth and he's surrounded by student flats and Wi-Fi coming in from all directions. I put up with it for a while because I thought, 'I'm being rude, there's something other than this, something's wrong with me'. By the time I actually managed to leave, I staggered out of the building, couldn't drive for an hour – I didn't feel safe to drive – and then felt rotten for next two days. It was at that point I spoke to a GP about it and he said you're probably electrosensitive to pulsed microwave radiation, which is, wireless, phone masts, mobile phones, cordless phones.'

Electromagnetic Hypersensitivity: Evidence For A Novel Neurological Syndrome

ABSTRACT

Objective: We sought direct evidence that acute exposure to environmental-strength electromagnetic fields could induce somatic reactions (EMF hypersensitivity).

Methods: The subject, a female physician self-diagnosed with EMF hypersensitivity, was exposed to an average (over the head) 60-Hz electric field of 300 V/m (comparable to typical environmental-strength EMFs) during controlled provocation and behavioral studies.

Results: In a double-blinded EMF provocation procedure specifically designed to minimize unintentional sensory cues, the subject developed temporal pain, headache, muscle-twitching, and skipped heartbeats within 100 s after initiation of EMF exposure ($P < 0.05$). The symptoms were caused primarily by field transitions (off-on, on-off) rather than the presence of the field, as assessed by comparing the frequency and severity of the effects of pulsed and continuous fields in relation to sham exposure. The subject had no conscious perception of the field as judged by her inability to report its presence more often than in the sham control.

Discussion: The subject demonstrated statistically reliable somatic reactions in response to exposure to subliminal EMFs under conditions that reasonably excluded a causative role for psychological processes.

Conclusion: EMF hypersensitivity can occur as a bona fide environmentally-inducible neurological syndrome.

DISCUSSION

Appropriately controlled provocation studies are required to establish the existence of EMF hypersensitivity and to understand the relative importance of psychological and nonpsychological processes in mediating any observed symptoms. A working laboratory definition of EMF hypersensitivity formulated in symptomological terms is therefore needed to permit recognition of hypersensitivity reactions when they occur. In previous provocation studies the assumption was made that true hypersensitive subjects would exhibit more or less the same symptoms in response to repeated provocations. The assumption led to experimental designs that involved averaging across exposed and control groups, which is an inherently insensitive statistical procedure for detecting real but variable responses [3, 4]. The assumption is particularly inapplicable to EMF hypersensitivity because intra- and inter-subject variability are its salient features [1, 2]. We defined EMF hypersensitivity as the occurrence of any medically recognized symptom in response to provocation using an environmentally relevant EMF; there was no requirement that the same symptom must reoccur when the EMF provocation was repeated. This definition avoided the problem of masking real effects and more appropriately matched the laboratory procedure to the known characteristics of EMF hypersensitivity [1, 2]. We focused on a single self-reported subject and employed a procedure in which she served as her own control. While controlling for artifacts, chance, and somatization, the question whether she reliably exhibited any symptomatic responses to an EMF was addressed; the alternative hypothesis was that she did not exhibit EMF-triggered symptoms. The laboratory conditions were controlled in such a way that a putative role of psychological processes could reasonably be identified. The subject developed symptoms in association with the presentation of a pulsed electric field significantly ($P < 0.05$) more often than could reasonably be explained on the basis of chance (Table 3). Several considerations

suggested that the statistical link was a true causal association with a subliminal EMF. First, the subject's environment was carefully controlled to avoid putative confounding factors. The testing took place in an acoustically quiet environment and the presence of uncontrolled environmental EMFs was nil. The environmental conditions during the field-exposure and shamexposure intervals were identical except that during the sham-exposure intervals, at a point far removed form the subject's field of view, the wires carrying the plate voltage were disconnected. A key aspect of our laboratory procedure was the elimination of sensory cues that could serve as conscious markers of the electric field leading to a somatization reaction. All appropriate precautions were taken to eliminate potential confounders. Second, the occurrence of symptoms was significantly associated with the type of EMF (Table 4). The symptomatic response was associated with the pulsed EMF, which maximized occurrence of the number of transient changes in the EMF (off-on and on-off), not with the presence of the field, as expected on the basis of prior animal studies where the issue of somatization was irrelevant [9]. Finally, in a behavioral study specifically designed to assess awareness of the field, yes response rates were 8.7% and 9.9% in the field and sham conditions, respectively, which provided no evidence for a psychological role in the development of the subject's symptoms. We therefore conclude with a reasonable level of certainty that the causal association we found between the presence of the EMF and the subject's symptoms was mediated by a subconscious neural process. Although chance was an unlikely explanation for the association, that possibility could not be excluded. The existence of the neurological syndrome reported here was previously suspected, but not documented. The mechanism for the subject's symptoms of headache, visual disturbances, and somatic musculoskeletal discomfort following exposure to EMFs is unknown. Based on clinical evaluation, intermittent seizure activity is not a credible explanation, although a deeper epileptic focus with partial seizure activity may have escaped the detection of surface EEG electrodes. The abnormal findings in the subject's medical workup included the abnormal MR image (cortical dysplasia and polygyric changes) and extensive sleep discontinuity and fragmentation manifested in the overnight polysomnogram; the possible association of these findings with the subject's syndrome of EMF hypersensitivity is unknown. Our aim here was to concentrate on the previously unaddressed question whether acute exposure to weak EMF could produce real but not precisely predictable somatic effects mediated by nonpsychological processes. Within the limitations of the study we concluded that we demonstrated the neurological syndrome in the subject we studied. The question of whether EMF hypersensitivity is a significant public-health problem was not addressed here. The EMF we employed was equivalent in strength and pulse structure to EMFs pervasively present in the environment [1, 2], and our results were consistent with the possibility that environmental EMFs can directly trigger clinical symptoms. Nevertheless resolution of the public-health issue depends on a deeper understanding of how internal EMFs caused by environmental EMFs are related to physiological process, and of the role of psychological factors and co-morbidities in the exposed population in exacerbating the processes resulting in disease.

Electromagnetic Field Sensitivity

Abstract

A multiphase study was performed to find an effective method to evaluate electromagnetic field (EMF) sensitivity of patients. The first phase developed criteria for controlled testing using an environment low in chemical, particulate, and EMF pollution. Monitoring devices were used in an effort to ensure that extraneous EMF would not interfere with the tests. A second phase involved a single-blind challenge of 100 patients who complained of EMF sensitivity to a series of fields ranging from 0 to 5 MHz in frequency, plus 5 blank challenges. Twenty-five patients were found who were sensitive to the fields, but did not react to the blanks. These were compared in the third phase to 25 healthy naive volunteer controls. None of the volunteers reacted to any challenge, active or blank, but 16 of the EMF-sensitive patients (64%) had positive signs and symptoms scores, plus autonomic nervous system changes. In the fourth phase, the 16 EMF-sensitive patients wer rechallengd twice to the frequencies to which they were most sensitive during the previous challenge. The active frequency was found to be positive in 100% of the challenges, while all of the placebo tests were negative. We concluded that this study gives strong evidence that electromagnetic field sensitivity exists, and can be elicited under environmentally controlled conditions.

Introduction

Interaction mechanisms that underlie the health and biological effects of electromagnetic fields (EMF) on humans have been studied by many authors.1,2,3,4,5,6 This subject was reviewed recently at the 1990 spring meeting of the American Physical Society .7 Choy et. al.8 investigated individuals with multiple sensitivities who reported reactions to various types of electrical equipment, including power lines, electronic office equipment such as typewriters and computer terminals, video display terminals, household appliances (such as hair dryers), and fluorescent lights.

This paper presents preliminary data on electromagnetic field tests using a square wave generator to evaluate the EMF sensitivity of patients reporting such sensitivities under environmentally controlled and monitored conditions.

Results

Phase I. The EMF measurements were quite reproducible. We found that the lights. and air handling equipment had to be off during the tests because of their electromagnetic field output. Baseline studies on patients were completed without remarkable result.

Phase II. Of the total of 100 patients tested in the single-blind study, 50 reacted to several of the placebos in addition to the active challenges, and were excluded from further study. Twenty-five subjects who did not react to any active challenges were also excluded. A final 25 subjects who did react to active challenges, but not to blanks, were selected for the third phase of the study (Table 1).

Phase III. The 25 subjects selected from phase II were rechallenqed, and 16 (64%) reacted positively to the active challenges. The total number of positive reactions to the 336 active challenges in the 16 patients was 179 (53%), as compared to 6 positive reactions out of 60 blanks (7.5%). There were no reactions to any challenge, active or placebo, in the volunteer group of naive subjects (Table 2).

When evaluating frequency response, 75% of the 16 patients reacted to 1 Hz, 75% to 2.5 Hz, 69% to 5 Hz, 69 % to 10 Hz, 69% to 20 Hz, and 69% to 10 KHz (Table 3). No patient reacted to all 21 of the active frequencies in the challenges. The average was 11 reactive frequencies per patient, with a range of 1 to 19 positive responses.

The principal signs and symptoms produced were neurological (tingling, sleepiness, headache, dizziness, unconsciousness), musculoskeletal (pain, tightness, spasm, fibrillation), cardiovascular (palpitation, flushing, tachycardia, edema), oral/respiratory (pressure in earss tooth pains, tightness in chest, dyspnea), gastrointestinal (nausea, belching), ocular (burning), and dermal (itching, burning5 prickling pain) (Table 4). Most reactions were neurological.

Phase IV. In the 16 patients again rechallenged in a double-blind manner, using only the single frequency to which they were most sensitive, all reported reactions to the active frequencies when challenged. None reacted to the placebos (Table 5). Signs and symptoms in all 16 patients were positive as was the autonomic nervous system dysfunction, as measured by the iriscorder (Table 6, Figure 1). Examples of changes were a 20% decrease in pulmonary function and a 40% increase in heart rate. In the 16 patients with positive reactions to EMF challenges, two had delayed reactions; gradually became depressed and finally became unconscious. Eventually, they awoke without treatment. Symptoms lasted from 5 hours to 3 days.

Discussion

Since it has been found that electromagnetic fields can affect health, researchers have investigated these phenomena in vivo and in vitro, in animals10,11,12 and humans.1,2,3,4,5,6,7 No individual had been specifically challenged in an attempt to reproduce acute symptoms until Smith and Monro5 followed by Choy, Monro, and Smith,8 who used a series of oscillators of varying frequency to trigger symptoms in electrically sensitive patients. We modified this procedure by developing controlled environmental area, where baselines were constantly monitored for particulates, pollutants, and extraneous fields. Here, controlled EMF output was applied so that data would be more reproducible.

Several factors have led us to believe that we have reproducible results. Meticulous construction of environmental rooms made a great difference in the reproducibility of test results. Prior to the use of such facilities and careful monitoring, a variety of factors, such as diet, exposure to chemicals, EMF, or dust gave rise to symptoms which would have been mistaken for placebo reactions. Such effects were minimized here, as evidenced by the sinail number of placebo reactions. A few patients reacted to the tields generated by the monitoring devices (Iriscorder, EKG, and computers) and had to be dropped from the study as too fragile for accurate analysis. Some patients reacted to the fields generated by the fluorescent lights, and others did not present the same signs and symptoms at each challenge, even though the reactions were significant when contrasted with the blank responses. The Iriscorder data were objective, however, and were always reproducible (Figure 1).

We also noted that patients sometimes had delayed or prolonged responses. Therefore, care had to be taken to be certain that the patient had returned to baseline before the next challenge. This carry-over was first noted when evaluating responses to placebo challenges. Such a response could usually be explained and eliminated by use of longer intervals between challenges.

In this study, of the 100 patients who expressed suspicion of EMF sensitivity, 75 actually responded to fields, whereas none of the controls did. Of the 75, 25 had no reactions to blanks, whereas 50 did, and

thus were discarded from the study; even though we felt that some of the reactions to blanks might be evidence of delayed reaction to previous frequencies, or prolonged response to the previous positive challenge, as well as true placebo reactions.

We learned that challenge with 21 frequencies was impossible on many sensitive patients. They were often unwell for several hours or days, which confused the data from repeat challenges on subsequent days. Hence, we selected the one frequency of maximum sensitivity for repeat challenges in the phase IV studies.

When one compares the various groups to controls, it is clear that there is a group of patients who have unstable response systems which appear different from those of the individuals who acted as controls. These studies show that EMF sensitivity could be elicited under environmentally controlled conditions. As a result of the weak field levels and short exposure time, the responses were mild except in two patients whose symptoms were so severe (e.g., drop attack, severe itching) that they received intravenous vitamin C, magnesium, and oxygen as a result of the prolonged and delayed reactions.

Signs and symptoms appeared similar to those seen in food or chemically sensitive patients at the Environmental Health Center-Dallas, and included neurological, musculoskeletal, cardiovascular, respiratory, gastrointestinal, dermal, and ocular changes. The neurological symptoms were most comon. Similar responses have been recorded by others in the literature.5,6,7,6,13,14 In 1972, after the Soviets reported that electrical utility workers were suffering from listlessness, fatigue, and nausea, Subrohmangam and coworkers13 investigated and reported decisive changes in cardiac function and bioamine levels when pulses of 0.01 and 0.1 Hz were used. They found significant changes in the hypothalamus in response to the EMF fields.

In these studies, the preponderance of reactions occurred at one to 10 Hz, which accords well with their observations. However, many reactions also occurred at 50 and 60 Hz, as well as some up to 5 MHz. We conclude that in any given individual susceptibility may develop to any frequency and produce reactions.

Static magnetic fields are known to cause increased blood pressure on some individuals.14 Choy and coworkers8 found that EMF reactions in EMF sensitive patients were not limited to the nervous system, but occurred in the same systems as in these studies, which basically corroborate theirs, though neurological symptoms predominated in our experiments.

Over the past 30 years, numerous investigations with animals and a few epidemiological studies of human populations have been devoted to assessing the relationship of microwave exposure to cataract development. The severity and speed of formation depends not only on intensity, but also on wavelength and duration of exposure.16-21 McCally et al.22 reported damage to corneal epithelium in Cynomolgus monkeys after 2.45 GHz irradiation for 6everal hours at only 20-30 mW/cm^2 (CW) or even 10-15 mW/cm^2 with pulsed fields. Therefore, the results of Paz23 strongly suggests that the potential for eye injury exists in surgery where EMF fields are present.

In our experience, the patients' clinical responses could not always be reproduced completely, but the objective Iriscorder, EKG, and respirometer could be. However, the responses were definitely different from controls or placebo challenges. In our experience over the years, we have found partial reproduction of symptoms on repeat challenge to be as significant as total reproduction. Therefore, significant differences from controls in objective ineasurementa were deemed valid.

There are several explanations for lack of exact reproducibility. These are the following: (a) the patients total body loads were different at different exposure periods. For example, some patients may only respond to EMF when in a reactive hypersensitive state;5,8 (b) tissue resistance could influence the effect of the EMF. Zimerman24 reported that electrical resistance of skin decreased with increasing temperature and increased with progressive drying, as might be expected; (c) injections of antigen neutralizing substances prior to test may have reduced the response to EMF. One patient with asthma was sensitive to high voltage power lines a well as low voltage house wiring. He experienced muscle spasms in head, neck, arms, and legs. This patient was also sensitive to dust, weeds, dust mites, and some foods. He reacted in our tests to 2.5 and 60 Hz and to 5 and 50 KHZ with tightness in the chest. He then received an antigen shot to neutralize his hypersensitivity reactions. Five months later, he was unreactive to EMF; (d) weather changes might affect the results, since we know that the weather can influence the propagation of EMF, as may alterations in the geomagnetic fields. Since humidity, pollution, temperature, etc. can affect resistance and total body load, weather should perhaps affect the results. Adverse weather (inversions, for example) may increase pollution load, while good weather lessens it. There is some evidence of resonance between geomagnetic fields and an applied ac magnetic field,25 which implies that the results may depend in part at least upon the strength and orientation of the geomagnetic field in the test area; and (e) different wave forms might cause different responses. In these experiments, we used only square wave inputs to the coils. Consequently, we do not know whether other wave forms (sine, sawtooth, triangular, etc.) might induce different types or intensities of reactions.

Thus far, definitive information has not been sufficient to identify a plausible mechanism for EMF interactions with biological tissue. Interactions appear to take place at the cell surface, perhaps acting on receptor sites and altering ion and molecular transport across the membranes.25 Further work remains to be done in the field.

It is clear that EMF sensitivity is a real phenomenon in some environmentally sensitive patients, because some had consistent reactions while none of the controls did. This study must be considered as only preliminary, but the evidence clearly points to sensitivity in some people.

In conclusion, it is evident that EMF testing is at a rudimentary stage; but clearly EMF sensitivity exists and can be elicited under environmentally controlled conditions. Further studies are needed to investigate the effects of EMF fields on human health.

Science: Plant and Animal Electromagnetic Sensitivity

Introduction

- **Animal Electromagnetic Sensitivity long known:**
  Animal sensitivity to electromagnetic exposure has been known as long as human electromagnetic sensitivity. The biological effects of the electric eel were known in ancient times. From the 17th century scientists studied how electricity and magnetism affected both animals and humans. Many modern studies depend on animal or plant research to establish biological pathways before moving on to human studies to verify low-level effects of electromagnetic exposure.
- **Animal and plants do not experience Electrophobia:**
  One great advantage of animal and plant studies is that there is no likelihood of confusion between real Electromagnetic Sensitivity and psychological Electrophobia, since animals and plants cannot be conditioned by a cognitive, as opposed to a behaviorally conditioned fear, and cannot therefore suffer from a 'Nocebo' effect, although anyway studies show that the 'Nocebo' effect is not part of real human Electromagnetic Sensitivity.

Plant Electromagnetic Sensitivity

The electromagnetic sensitivity of plants is now well established. It is used in many aspects of horticulture and agriculture. Since many biological electromagnetic effects have 'windows' or bands of effects, and these effects can be opposite to those of other 'windows', care is needed to apply the appropriate frequency.

A school experiment on the growth of cress under Wi-Fi and non-Wi-Fi conditions became international news.

- Daniel Bean: "Can Wi-Fi Signals Stunt Plant Growth?" (ANC News, 2013)

The increase in fungus and viral attacks on different species of trees has been linked with reduced immune systems because of man-made electromagnetic pollution, as has reduced anthocyanin production.

- Katie Haggerty (2010) "Adverse Influence of Radio Frequency Background on Trembling Aspen Seedlings: Preliminary Observations" (Int J Forestry Res. 2010)
- Dan Nosowitz: "Wi-Fi Radiation is killing trees, new study finds" (Popular Science, 2010)
- René Schoemaker: "Study finds Wi-Fi makes trees sick" (Macworld, 2010)

Trees near cellphone towers show increased disease, starting on the side closest to the tower. Experts say that cellphone towers should be banned because of the damage they are causing to nearby trees.

- Waldmann-Selsam C et al: "Tree damage in the vicinity of mobile phone base stations" (Umwelt-medizin-gesellschaft. 2013; trans.)

- Waldmann-Selsam C et al: "Radiofrequency radiation injures trees around mobile phone base stations" (Sci Total Environ., 2016)
- Waldmann-Selsam C et al: "Trees in Bamberg and Hallstadt in the radiation field of 65 mobile phone base stations: Examples from a documentation about 700 trees (2006-2016)" (Sci Total Environ. 2016)

The effects are specific to types of plants, parts of plants, and exposures. Wi-Fi may be particularly harmful to some plants.

- Grémiaux A et al: "Low-amplitude, high-frequency electromagnetic field exposure causes delayed and reduced growth in Rosa hybrid" (J Plant Physiol., 2016)
- Soran ML et al: "Influence of microwave frequency electromagnetic radiation on terpene emission and content in aromatic plants" (J Plant Physiol., 2014)
- Stefi AL et al: "The effect of the non ionizing radiation on cultivated plants ofArabidopsis thaliana (Col.)" (Flora, 2016)

About 90% of studies on cellphone radiation on plants show physiological changes:

- Halgamuge MN: "Review: Weak radiofrequency radiation exposure from mobile phone radiation on plants" (Electromagn Biol Med., 2016)

Plants' environmental sensitivity, memory and cognitive control:

Plants show the ability to learn behaviors from sensitivity to electromagnetic and other environment factors, even though they lack an animal's nervous system, suggesting that pathways like calcium-based regulation can include memory and drive cognitive processes based on a variety of stress sensitivities. As with humans, not all plants display this learnt behavior by association, with about 60% responding and 40% not responding. The metabolic state of the plant and electromagnetic cues from visible light are also significant, with learnt behavior occurring according to the internal circadian rhythm mainly in subjective day. Epigenetic mechanisms help with transcriptional regulation to build systemic acquired resistance at distant sites.

- Sharma VP et al.: "Changes in honey bee behaviour and biology under the influence of cell phone radiations" (2010)

Animal Electromagnetic Sensitivity

This is now well established for a wide range of biological conditions.

- Geomagnetic effects

bird and animal migration (Kishkinev DA e al, 2014)

nest-building (Malkemper EP et al, (2015)

animal orientation and location in:
bats (Tian LX et al, 2015)
cattle and deer (Begall S et al, 2008)

dogs (Hart V et al, 2013)

fish (Takebe A et al, 2012)

lizards (Diego-Rasilla FJ et al, 2017)

- Pre-Seismic Eelectromagnetic Sensitivity:

  Sensitivity to pre-seismic changes in the electromagnetic environment, especially if transmitted through water, either sea water or water on land, appears to correlate with established effect before earthquakes on a variety of animals.

  In 373 BCE, animals including rats, weasels and snakes left the Greek city of Helice before an earthquake and tsunami:
  "For five days before Helike disappeared, all the mice and martens and snakes and centipedes and beetles and every other creature of that kind in the city left in a body by the road that leads to Keryneia." [quinque enim diebus priusquam pessum iret Helice, omnes in ea mures, mustelae, serpentes, scolopendrae verticilli, et alia hujusmodi animalia, magnis copiis exibat per viam, quae ducit Coriam] (Claudius Aelianus, *De Natura Animalium*, XI.19)

  Before the February 4 1975 earthquake at Haicheng, China, there were reports of anomalous animal behaviour, including among animals such as rats, snakes appearing frozen on roads, cows and horses becoming restless and agitated, rats appearing drunk, chickens refusing to enter their coops and geese frequently taking flight (Adams RD, 1976; Anon., 1977)

  Since 2000 many studies have suggested that animals are sensitive to the electromagnetic changes before earthquakes.

  In 2003 Dr Kiyoshi Shimamura in Japan reported a jump in dog bites and other dog-related complaints before and after earthquakes. He examined records of complaints from public health centres affected by the 1995 earthquake in Kobe and found that accounts of dogs barking "excessively" went up by 18% on average in the months before the earthquake. Above the epicentre on Awaji Island, there was a 60% increase in complaints compared with a year earlier. (Alok Jha: "Can dogs really predict earthquakes?" Guardian, October 2 2003)

  Another study concerned toads at L'Aquila, Italy, in 2009. Since then studies have included anomalous behaviors in many other animals, including ants, cows, pets such as cats and dogs, and milk yields in cows 340 km from the subsequent epicenter.

  Ceteceans, such as whales and dolphins, show, through mass beachings, sensitivity to changes in electromagnetic energy, probably including geomagnetic changes before earthquakes:
  Klinowska M: "Cetacean live stranding sites relate to geomagnetic topography" 1985

  "It is my observation, confirmed over the years, that mass suicides of whales and dolphins that occur sporadically all over the world, are in someway related to change and disturbances in the electromagnetic field coordinates and possible realignments of geotectonic plates thereof."
  Dr Arunachalam Kumar, professor of anatomy, Kasturba Medical College, Mangalore,

Karnataka, India,
December 4 2004 (Michael McCarthy: "Did whale beaching foretell disaster?" February 2 2005)

Toads may show sensitivity to changes in electromagnetic energy through changes in breeding patterns before earthquakes:

"Our study is one of the first to document animal behaviour before, during and after an earthquake, It was a serendipitous thing that happened. One day there were no toads. I was actually very annoyed. I thought my research was all going down the drain. And the earthquake happened, and then they all started coming back the day after."
Rachel Grant, Open University, Milton Keynes, England, 2011

Common toads (Bufo bufo) showed a dramatic change in behaviour five days before an earthquake shook L'Aquila, Italy in April 2009. Grant and her colleague found the toads abandoning spawning days before the shaking started. She has been studying frog reproduction during the lunar cycle for four years, and was at a site 74 km from the epicentre of the quake with her assistant between the new moons of March and April. This meant they were watching the 'seismic toads' before, during, and after the magnitude 6.3 event. Male toads usually stay at the breeding sites until spawning is complete, but 96% them abandoned the pool five days before the quake and numbers remained low until 10 days afterwards. The number of amplexed pairs—where males grasp females tightly with their arms—declined to zero just three days before the earthquake and stayed low until the last aftershock.
(Janet Fang: "Toads 'predict earthquakes'" Nature.com, March 31 2010)

One suggested mechanism is ionization of the air at the ground-to-air interface where positive airborne ions cause changes in stress hormone levels in animals and humans. Another mechanism is the electric field and current induced in the animal as it passes through the magnetic field, or where a change in the magnetic field induces an electric field in the organism. It has been shown that magnetic fields of below 10 nT, well below the Earth's background magnetic field, can induce these currents and thus cause biological effects in sensitive animals. Some relevant studies:
Kirschvink JL, 1982; Klinowska M, 1985; Kirschvink JL, 2000; Grant RA et al, 2011; Berberich G et al, 2013; Freund FT et al, 2013; Fidani C et al, 2014; Yamauchi H et al, 2014

- Disturbance of natural electromagnetic environment:

ants' foraging and avoidance nest location (Cammaerts MC et al, 2012) (Cammaerts MC et al, 2014)m

bee foraging and failure to return to hive, perhaps related to colony collapse disorder (Liang CH et al, 2016).

birds unable to adapt to RF fields (Wiltschko R et al, 2015).

mice nesting show clockwise shift (Malkemper EP et al, 2015).

.

- Biological Mechanisms:

Most of the mechanisms and pathways established for human Electromagnetic Sensitivity were first shown for animals such as rats and mice (see: Science - Mechanisms)

Bees detect electric fields using mechanosensory hairs (Sutton GP et al, 2016)

Two different magneto-reception systems have been proposed for bird and fish navigation:

- bio-magnetite

- cryptochromes

- or possibly MagR, a protein combining both (Cyranoski D, 2015)

Marine sensitivity

The latest studies indicate that much marine life is sensitive to man-made electrical and sonar pollution.

1. There are three main sources:

(a) Cathodic currents used to slow marine corrosion on metal hulls of ships, pipe-lines, oil platform rigs, marine wind turbine installations, floating platforms.
(b) Microwave pulsed microwave radiation from ship and shore radar and communications.
(c) Sonar detection from military and fishing ships.

2. The effects on marine life include the following.

(a) Coral reef corrosion or oxidation, where calcium (a mineral or metal) carbonate structures are especially affected.
(b) Fish and cetaceans, which can be overheated by, for instance, lock-on radar systems.
(c) Fish and cetaceans, which can be adversely and cumulatively affected by low-level electrical currents induced by radar and radio frequency transmissions,
(d) Divers if not wearing dry suits, where approaching within 3,000 feet of a ship can cause cardiac arrest.

Animal sensitivity

1. Animals best suited to formulate EM exposure limits

Because animals are more easily studied objectively than humans, it has been suggested that their sensitivity could be used for formulating biological safety limits. This could be true for the Fruit Fly (Margaritis LH et al, 2014).

2. Animal Electromagnetic Hyper-Sensitivity

A growing number of anecdotal reports show that the there are variations in the degree of sensitivity to electromagnetic exposure displayed by animals, just as there are among humans. This is an inevitable consequence of biological diversity even with a single species, including genetic variants and differences in diet, habitat and behavior. People with Electromagnetic Sensitivity often report that their pet cat or dog, if the animal is particularly sensitive to electromagnetic exposure, prefers to find an area of the house or yard for sleep which the use of an electronic meter shows is the area with the lowest level of electromagnetic pollution. Similarly, an especially sensitive pet avoids typically avoids areas with especially high electrosmog.

Need for new radiation limits to protect wildlife

Since wildlife is affected as much as humans by the high levels of man-made radiation on Earth, new biological non-thermal safety limits are needed to protect wildlife as well as humans.

- Albert M. Manville: "A Briefing Memorandum: What We Know, Can Infer, and Don't Yet Know about Impacts from Thermal and Non-thermal Non-ionizing Radiation to Birds and Other Wildlife" (2016)

Solar Biological Effects

For hundreds of years it has been known that plants in particular show responses to solar electromagnetic events, such as the sunspot cycle. These effects are more difficult to detect in humans, but attempts through chronobiology often show similar patterns (Hrushesky WJM et al, 2011).

Lunar Biological Effects

A potentially important theory has recently been proposed (Bevington, 2015), that some lunar biological effects, which have been established since ancient times for most plants, some animals and some humans, may relate to variations in electromagnetic exposure at the phases of the lunar Full Moon at night, or at New Moon's lunar wake in daytime. If confirmed, this would explain many plant and animal observations, in addition to human behavioral and medical changes among those especially sensitive to electromagnetic exposure.

http://www.electrosensitivity.co/science--plant-and-animal-electromagnetic-sensitivity.html

Will We All Become Electrosensitive?

Each year an increasing number of people claim to suffer from electrosensitivity (see, e.g., compilation of references given in Table 1), also known as being electrically hypersensitive (EHS). There are also other diseases, such as fibromyalgia and burn-out syndrome, that have symptoms similar to those exhibited by people suffering from electrosensitivity. In Sweden, electrosensitivity is recognized as a handicap, but there is still controversy surrounding the diagnosis of the disease. The mainstream view by governmental and medical authorities is that this handicap is a psychological phenomenon with no basis in physical or medical mechanisms (Swedish National Board of Health and Welfare, SNBHW, 1995), whereby perpetuating the misconception that only a small fraction of the population is concerned about electrosensitivity or the proximity of new radio transmission masts. The number of reported cases of electrosensitivity has been steadily increasing since it was first documented in 1991. Data presented here are estimates and are based on large sample inquiries where different sets of questions have been used. To determine whether the statistics indicate a sub-population of electrosensitivity or if the total population is at stake, we plotted reported prevalence estimates over time in a normal distribution diagram (Table 1 and Figure 1). Contrary to the views of mainstream medical authorities, Figure 1 shows that the group of electrosensitive people around the world, including Sweden, is not just a small fraction that deviates from the rest of the healthy population. Instead, it points at the possibility that electrosensitivity will be more widespread in the near future. The extrapolated trend indicates that 50% of the population can be expected to become electrosensitive by the year 2017.

http://www.next-up.org/pdf/EHS2006_HallbergOberfeld.pdf

Corded or cordless: have you made the connection?

This weekend, I'm going out to dinner. Hardly cause for a blog, you might say—or even a Facebook status update, given that most people go out for dinner several times a month or week. For me, though, it's a rare event. In fact, I haven't had dinner at a restaurant or a friend's place for over two years. It's not because I can't eat. (Boy, can I eat!) It's not because I haven't been invited out, either. (I do have friends.) And it's not because I'm broke or have BO. No. The reason I haven't been out is because there's Wi-Fi everywhere, generating harmful radiation that affects me so badly I can barely function. And it's not worth the risk of getting another brain tumor, no matter how good the food is.

This time, we're going to a friend's place—a friend who has shown himself to be exceptionally caring and considerate. He has offered to switch off his Wi-Fi when we arrive and even asked his neighbor if he'd be willing to do the same, if necessary. The neighbor agreed, and I love them both already. To be sure that our friend's home was radiation-free, however, my man Lewis took my gauss meter and went to check the place out. (I love my man, too …and it seems to me that a lot more loving happens when Wi-Fi is turned off.) He was surprised to find that the levels of radiation were sky-high. Yet the Wi-Fi had been switched off, so where was it coming from? It wasn't from a Smart meter and it wasn't coming from the neighbors' place.

It turned out that it was coming from a cordless phone system. Our friend has three cordless phones in his house, and they were emitting shockingly high levels of radiation—*500 times higher* than the radiation from a Samsung cell phone (known for its particularly strong signals). When the base unit was unplugged and the handsets disabled, the meter readings dropped down to minimal levels.

If you have a digital enhanced cordless technology (DECT) phone in your house, you're almost certainly being exposed to far more radiation than your system can tolerate, over time—and you may be unaware of how it's affecting you. Some people are concerned about the radiation from their cell phone, but few ever think about cordless phones, which are far more harmful. These phones emit the same type of pulsed microwave radiation as cell phones, but they never 'power down'. They are always transmitting and the pulses they emit are far more aggressive than those used in cell phones. With long-term use, cordless phones have been found to increase the risk of brain tumors, including acoustic neuromas—previously considered to be rare. (My hubby tells me I'm one in a million, but even I got one of these growths, which are rapidly becoming common.) Several studies of analogue cell phone, digital cell phone and cordless phone use have revealed that all three types of phones were linked with increased tumor rates. Research by Swedish scientists confirms that the risk of cancer is greater for those who use either DECT cordless phones or cell phones—and even greater for those who use both.

A German medical physicist and researcher at the University of Luebeck, Dr. Leberecht von Klitzing, has researched the biological effects of DECT systems. He took blood samples from children who had cordless phones in their homes and found that the red blood corpuscles did not mature properly, resulting in listlessness and/or aggression, pallor, sleeplessness and many other symptoms—all of which could be reversed when the phones were removed.

According to Lloyd Burrell of electricsense.com, we'd do well to follow the advice of respected Harley Street physician, Dr. David Dowson, who says: "Having a cordless phone is like having a mobile [cell phone] mast in your house. I'd recommend anyone who has one to switch to a plug-in phone."

Yes, it's inconvenient. If you use a corded phone, you won't be able to walk around the house while you're on a call. You might actually have to sit down and focus on the conversation, rather than doing the laundry or making dinner as you talk. But I can tell you from personal experience that it's far, far less inconvenient than having brain surgery, which can cramp your style in unimaginable ways.

According to Dr. Magda Havas, an expert in electromagnetic radiation who petitioned for first-generation DECT phones to be banned in Canada, serious health effects occur near DECT phone base units. "[A]t a distance of just beyond 3 meters from my DECT phone base unit (according to studies of RF radiation)," she says, "EEG brain waves are altered. At 2.8 meters, motor function, memory and attention of children are affected. At 1.7 meters, sleep is disturbed. At 30cm, memory is impaired and, at closer distances, the immune system is affected, REM sleep is reduced, insulin levels drop, and there are pathological changes in the blood–brain barrier. Studies also show that there is a 100% increase in adult leukemia between 45 and 130cm from the phone and a similar increase in childhood leukemia between 35 and 260cm."

Havas also reports that studies of 356 people, exposed long term to high-frequency pulsed electromagnetic fields associated with DECT phones and/or cell phone base stations, revealed a disturbingly long list of effects.

The following symptoms increased with greater proximity to the phone base:

- sleep disturbance, fatigue, depression
- headaches, restlessness, irritability
- mental confusion, difficulty concentrating, forgetfulness
- learning difficulties, trouble finding words
- frequent infections, sinusitis, lymph node swellings, allergies
- joint and limb pains, nerve and soft tissue pains
- numbness or tingling
- tinnitus, hearing loss
- giddiness, impaired balance
- visual disturbances, eye inflammation, dry eyes
- tachycardia, episodic hypertension, collapse
- hormonal disturbances, thyroid disease
- night sweats, frequent urge to urinate
- weight increase, nausea, loss of appetite
- nose bleeds, skin complaints
- tumors and diabetes.

Many of these symptoms are now associated with the rapidly growing phenomenon of electromagnetic hypersensitivity (EHS), and they're a healthy, normal reaction to an invisible threat.

Because DECT phones are so powerful and because the radiation instantly passes through walls, you can be exposed to this radiation even if you don't own a DECT phone …but your neighbors do.

http://olgasheean.com/corded-or-cordless-have-you-made-the-connection/

Electromagnetic Hypersensitivity, It is real!

Wikipedia continues to categorize Electromagnetic Hypersensitivity as "pseudoscience." Ask these people if this is all in their head. Especially, the children's stories that are posted on this page. There is nothing that is "pseudoscience" about this! Plus a medical code, though it is not billable, exists in the ICD10 as **W90.0 Exposure to radiofrequency** which is under **W90 Exposure to other nonionizing radiation** and here is a camera photo of the ICD10 Manual.

Cell Phone Victim Testimonials

1. **Tiffany Frantz** - At the age of 21, developed breast cancer in the exact location of where she kept her cell phone. In fact the images of her cancer outline the exact size of her phone on her chest and how it laid upon her. Watch her story at: https://youtu.be/ZWN838VCUv4.
2. **Attorney Jimmy Gonzalez** - Please do not forget Attorney Jimmy Gonzalez from Florida who died of three cancers all related to where his cell phone was. Here is his testimony at https://youtu.be/lzOjK6PHUas.
3. **Matt Huck** - You can read the 20 page story at http://truthandfactsneverlie.info/blog/my-full-story which is downloadable at the bottom in PDF format.
4. **Donna Jaynes** - At the age of 38, she developed breast cancer exactly where she kept her cell phone. Watch her story here: https://youtu.be/BJib5GHxOsE.
5. **Alan Marks** - He won a lawsuit that enabled the city of Berkeley to warn cell phone users from his experiences of having a cell phone for over 20 years. A brain tumor specialist in Sweden remarked how Alan was "the poster boy" for people about the increased risk of one developing cancer due to their prolonged cell phone activities. His story available at http://www.jweekly.com/article/full/58831/cancer-calling-east-bay-couple-on-a-mission-to-warn-of-cell-phone-risks/
6. **Paul Prischman** - He died at the age of 42 due to a cell phone induced cancer. Listen to his widow at https://youtu.be/aBwk4WbM6CA

Cell Phone Tower Victim Testimonials

1. **Eileen O'Connor -** One of the victims of the Wishaw mobile phone mast and the cancer cluster tower. Here is a copy of her presentation: http://www.radiationresearch.org/pdfs/eileen_my_story.pdf. Her information is available on cell phone masts; http://www.radiationresearch.org/campaigns/mobile-phone-masts
2. **Fairfax County, Virginia Children -** These children ask to stop a cell tower from being put up in their playground. Video link is: https://youtu.be/dEDxOBZhZwY
3. **A woman's story about rooftop antennas –** She shares her daughter's and her story at: https://youtu.be/-G3CWrgDS5E

Smart Meter Victim Testimonials

1. **Connie -** Watch her story about smart meters at: https://youtu.be/3TIRwrR0llE
2. **Sandy Aiders -** Her husband and she suffer from being harmed by smart meters. Watch Sandy tell their story at: https://youtu.be/1zzRP_J7P-c?t=3m32s

Wi-Fi Victim Testimonials

1. **Teenagers and Childrens testimonies to Wi-Fi –** Watch that here: https://youtu.be/jvkxO8xLqMQ
2. **Jenny Fry -** At the age of 15, she committed suicide because no one would support her with her realization that Wi-Fi at her school was the cause of her problem. Did the medical field help or investigate, NO! Her story is at http://www.dailymail.co.uk/news/article-3339511/Schoolgirl-15-hanged-developing-allergic-reaction-Wi-Fi-school.html
3. **Sixth Grader -** This girl's comments can be watched at: https://youtu.be/E7oj-ZXBAF4?list=PL2TxgdaZ0lgDyO6MdGnBQrNG7pfs8fKOW
4. **Student at Onteora School District -** This student talks about their health at: https://youtu.be/6Z3d8FxFhQk
5. **Student Story -** Here is a video of a female student: https://youtu.be/tNpKShvxar0?t=45s

Electromagnetic Hypersensitive Testimonials - Microwave Sickness Testimonials

You can call it what you want, but these people below suffer just like the ones above. They give it a name, it's "Electromagnetic Hypersensitivites" however the German's in the early 20th Century called it "Microwave Sickness." Once your life has been destroyed by man-made radiation, there is no "cure all" fix to make things the way they were before. You can do things to ease the pain, even put a Band-Aid fix on it. However, this does not cure it but will only help make you feel that you are almost whole once again. Please respect the "canaries in the coal mine."

1. **Candy -** Her comments can be seen at: http://time.com/golden-cage/
2. **Reverend Carsten Häublein -** He committed suicide after suffering from wireless radiation and after ten years of suffering took his own life. His story is at http://ehsfighback.blogspot.com/2014/02/when-priests-commit-suicide.html
3. **Sarah Riley -** Her story is available at: https://youtu.be/1zzRP_J7P-c?t=9m40s
4. Andrew McAfee – His story is available by watching "Search for a Golden Cage:" http://time.com/golden-cage/
5. **Dafna Tachover -** Take part in her journey to find a place of residency due to being harmed by technology. Watch at: http://time.com/golden-cage/
6. **David Wientjes –** David's wife and David started having symptoms to wireless radiation from antennas put up near them. Watch his comments at: https://youtu.be/1zzRP_J7P-c?t=57s.
7. **Silvia Wilson -** She moved across the Atlantic Ocean to find relief. Her story is available at; http://www.bbc.com/news/uk-england-lincolnshire-21386477
8. **Jennifer Wood -** Hear her story at: http://time.com/golden-cage/

Supporter Testimonials

1. **Virginia Farver –** She lost her son Rich Farver at the age of 29 to glioblastoma multiforme (GBM) brain cancer on October 11, 2008 which was a direct consequence of having a cell phone. This cancer was in direct location of where Mr. Farver held his cell phone. Story can be found at We Are The Evidence.
2. **Traci Frantz -** She is the mother of Tiffany Frantz, who at the age of 21, developed breast cancer in the exact location where she kept her cell phone. In fact the images of her cancer outline the exact size of her phone on her chest and how it laid upon her. Watch Tiffany's story at: https://youtu.be/ZWN838VCUv4

Direct Testimony of Joshua Hart

BEFORE THE NEW MEXICO PUBLIC REGULATION COMMISSION

***Case No. 15-00312-UT**, 7/11/2016*

IN THE MATTER OF THE APPLICATION OF PUBLIC SERVICE COMPANY OF NEW MEXICO FOR PRIOR APPROVAL OF THE ADVANCED METERING INFRASTRUCTURE PROJECT, DETERMINATION OF RATEMAKING Case No. 15-00312-UT PRINCIPLES AND TREATMENT, AND ISSUANCE OF RELATED ACCOUNTING ORDERS

PUBLIC SERVICE COMPANY OF NEW MEXICO,

Q. Please state your name and address.

A. Joshua Hart, Post Office Box 682 Portola, CA 96122

Q. Briefly state your occupation, educational background and current employment.

A. Currently I am Director of Stop Smart Meters!, an organization fighting the forced deployment of utility meters that harm health, violate civil liberties and endanger public safety. I have worked in the energy industry, as an urban and transportation planner, environmental advocate, and freelance journalist. I obtained my MSc in Transport Planning in the UK at University of West England, Bristol in 2008, and completed research entitled *Driven to Excess*, presenting the social and quality of life impacts of car traffic on local residents. The research was covered in over 100 international media outlets including the *BBC*, the *Guardian*, *Tehran Times*, and the *Daily Mail*. Part of this work included the creation and implementation of a series of surveys and questionnaires. I have been interviewed by PBS Newshour, as well as hundreds of other local and national news outlets. My writing has appeared in *the Wall Street Journal, Surveyor Magazine*, *Walk Magazine*, *Make Magazine*, and Lonely Planet's anthology *Flightless: Incredible Journeys without Leaving the Ground*. Attached as Exhibit A is a copy of my CV.

Q. Briefly describe your professional experience.

A. I have worked for a number of professional health and environmental advocacy organizations, including the Rails-to-Trails Conservancy, San Francisco Bicycle Coalition and a UK-based pedestrian advocacy organization called Living Streets. Since 2010, I have been director of California-based Stop Smart Meters! I have studied the relevant literature regarding aspects of the current "smart grid" deployment including studies on RF health and environmental impacts.

Q. Have you authored any papers or journal articles?

A. I carried out a master's dissertation between 2007-2008 at the University of the West of England entitled *Driven to Excess: Impacts of Motor Vehicles on the Quality of Life of Residents of Three Streets in Bristol UK.* A journal article based on the research results was published in June 2011 in Volume 17.2 of *World Transport, Policy and Practice.*

Q. Briefly describe your work and experience related to the study of electromagnetic fields and radio frequency ("RF") waves in the 30 MHz to 300 GHz range, as related to smart meters.

A. As a grassroots journalist and advocate, I have investigated hundreds of cases of reported health and environmental impacts of smart meters. I have also read hundreds of scientific reports on the subject and attended multiple workshops, public forums, and conferences regarding RF, electromagnetic fields, and health.

Q. In your role as Director of Stop Smart Meters! have you obtained information confirming that utility customers have been injured by smart meters?

A. Yes. I have personally interviewed, read first person accounts and listened to first and second hand accounts of smart meter victims suffering from a wide range of health effects from mild to severely debilitating. I am familiar with well over twelve hundred such accounts that have been documented. Many of these victims became sick before they knew a smart meter had been installed either on their home or in their neighborhood. Many didn't even know what a smart meter was before they were injured. Some of these people have become so sensitized to RF that they have been forced from their homes

because of proximity to area meters and other wireless infrastructure or have been forced to leave their jobs because of RF in the workplace. For many people who have become sensitized to RF, they have remained so even after the removal of the smart meter. It is astoundingly clear that smart meters can cause illness and that lasting sensitivity to RF can result from instantaneous exposure and/or chronic exposure over time.

Q. Have you obtained information about smart meters being implicated in house fires and appliance failures and fires?

A. Yes. Thousands of such fires, explosions, and electrical problems have been reported over the past 6-7 years. We have reported on a number of such fires and electrical faults on StopSmartMeters.org. A series of 26 smart meter fires forced Peco Energy in Pennsylvania to halt their smart meter deployment in August 2012. Hundreds of thousands of smart meters have been recalled, across several US states and Canadian provinces due to fire safety problems.

Q. Have you gathered accounts of illness from smart meters and if so please describe how?

A. Yes, Stop Smart Meters! has collected complaints about smart meters related to RF health impacts, fires, overcharging, and other issues since October 2011. We worked with a web professional who volunteered to design and manage the website http://smartmeterhelp.com. Results of online surveys came in from all over the country, were entered into a SQL database, and complaints from California periodically forwarded to Governor Jerry Brown, the customer's utility company, the California Public Utilities Commission, and the California Department of Public Health, who set up a special e-mail address to receive smart meter health complaints. More than 1400 written complaints in total were received. A significant percentage were health complaints. The attached declarations (Exhibits B) were received in response to an email request to those complainants who entered an electronic complaint at smartmeterhelp.com.

Q. Are the attached Exhibits B true and accurate copies of the declarations received by Stop Smart Meters! from people who had responded to your online survey?

A. Yes. I have reviewed each of the attached declarations. They are all true and accurate copies of the declarations received by Stop Smart Meters!

Q. Is there anything else you would like the Commission to know?

A. Given the strong peer-reviewed science now linking wireless radiation to disease, and given my own firsthand experience, a policy decision to blanket entire New Mexican communities with smart meters and associated infrastructure poses a serious threat to public health and safety. Particularly relevant are the results of a recent study from the National Toxicology Program which found significant 3 levels of DNA damage, and brain and heart cancer in rodents exposed to ambient RF— of a similar type to that emitted by wireless utility smart meters. This is consistent with the smart meter health complaints we have received. In areas of RF safety, privacy, fair and transparent billing practices, national security, efficiency and fire safety, basic electromechanical analog meters remain superior.

EDUCATION

MSc Transport Planning
June 2008
University of the West of England, Bristol

Bachelor of Arts in Psychology
Minor in History, June 1998
University of California at Santa Cruz

EMPLOYMENT

Director, Stop Smart Meters! StopSmartMeters.Org July 2010- present

• Educated the public about the health, safety, and privacy impacts of digital "smart" meters, through broadcast, print, and online media
• Provided technical assistance to dozens of groups and individuals opposing the smart grid and organizing locally
• Interpreted the science on biological effects of wireless for the public benefit

Consultant, San Francisco County Transportation Authority May 2006 to August 2007
• Researched environmental impacts of automobiles to inform a proposed shift from auto level of service (LOS) to auto trips generated (ATG) as an environmental review threshold
• Collaborated with colleagues to identify strategies to bring San Francisco's environmental review processes into line with latest knowledge on environmental impact of automobiles
Program Director, San Francisco Bicycle Coalition January 2003 to April 2005
• Initiated and ran SFBC's BikeEd Program, based on the League of American Bicyclists BikeEd curriculum, teaching safe cycling skills to thousands of adults citywide.
• Organized members and allied community groups to support improvements in the City's bicycle route network, as well as changes in policies to support greater levels of cycling, testifying at dozens of City Hall hearings and meetings.
• Ran publicity campaigns to educate motorists and cyclists on safe roadway sharing
CA Project Coordinator, Rails-to-Trails Conservancy January 2000-June 2002
• Provided in-depth technical assistance to a variety of local advocacy organizations and public agencies around California working on rail-trail conversions
• Gave presentations to elected officials and community groups about the benefits, proper design, and management of public trails and on-road bicycle and pedestrian facilities
• Organized statewide legislative trail advocacy day in Sacramento to support the efforts of dozens of organizations engaged in trail policy development
• Researched and authored Tunnels on Trails, a study of 78 bike/ pedestrian tunnels in the United States (2001) as well as The Mission Creek Bikeway Concept Plan (2002)
Energy Sales Coordinator, Green Mountain Energy June 1999- December 1999
• Negotiated partnerships with retail outlets in San Francisco, Oakland, San Diego, and Santa Cruz as part of the California storefront tabling program
• Trained/ managed Field Consultants in sales strategy, environmental policy, and data concerning climate destabilization, energy use, and transport
League Cycling Instructor, League of American Bicyclists June 1998-June 2006
• Underwent intensive teacher's training program (both on and off road) and became accustomed with strategies for teaching the leading US cycling curriculum
• Organized, planned, and taught BikeEd classes to community groups and businesses with an emphasis on the environmental benefits of decreased auto dependence
ADDITIONAL SKILLS
• Attended Spin Project media training course, which advised on media strategy for charitable organizations San Francisco April 2004
• Extensive experience dealing with television, radio, and print media concerning a range of cycling, environmental, and climate messages

Another testimonial provided by Joshua Hart, MSc can also be found here:

Collateral Damage: Speaking Out Against Wireless Harm

The following is an anonymous testimonial from a sufferer of electromagnetic hypersensitivity:

For those of you obsessed with your wireless technology, I need to ask–why are my children and I considered acceptable collateral damage so you can have your wireless convenience? Have you utterly lost your sense of humanity? Maybe you don't feel any health effects (yet) from this technology, but many of us do–millions of us–and we are suffering. Do you not care? I want to know why you don't care. I want to know why your wireless gadgets are worth more to you than my children's health or my health or our lives. What in God's name is so important about your texting that we have become inconsequential?

You wouldn't force a child who is allergic to peanuts to live in a home filled with peanuts, would you? Would you force a peanut-allergic child to endure such a potentially deadly assault on their immune system? But Super Wi-Fi, smart meters, Wi-Fi, etc. are essentially doing just that to people like us who are sensitive. Perhaps you don't acknowledge the problem because the radiation is invisible (you can at least SEE peanuts). Yet we are being bombarded by toxic radiation everywhere we go, whether we like it or not–and we have become inconsequential because you want what you want: your wireless convenience. I want to know why–even if you are seemingly unaffected by this technology–I want to know why you don't care about those of us who ARE affected.

I want to know why you think it is okay for me to get severe migraines every time I have to go into a public place that uses Wi-Fi. Nowadays, that means a debilitating migraine nearly every single day. I want to know why you think it is okay for my child to be drowning in his own mucus and struggling to breathe because his immune system goes berserk when he's exposed to this radiation. I want to know why you think it is okay that my other child has profound memory loss, insomnia, and can't think straight due to these frequencies. Or didn't you know that pulsed microwave radiation (now classified as a Class 2B carcinogen) causes these symptoms??? Well now you know, and according to experts nearly 35% of the population (50% by 2017) is in the same boat as us with these or other symptoms (although most don't even know what's making them sick). I want to know why you are not speaking out on our behalf. Because now that you know, there is no excuse. You are, by your silence, saying it is okay for us to suffer. Please tell me how to explain to my children that you having wireless convenience is more important than their health or their lives. Please tell me as a mother how to cope with watching my children needlessly suffer. Try to put yourself in my shoes.

I don't care if this technology is "popular" or if "everyone is using it"; this is not okay. It is not okay to say "well it's not going away so you'll just have to live with it." Many of us who are sick from this radiation are now too ill to speak out. Many of us struggle just to find a safe place to live, shop, or go to school. We can't even safely go to a doctor or a hospital without getting seriously ill because of Wi-Fi exposure. There are electrosensitive people living in tents in the mountains and the deserts of our country because they can't live anywhere else due to the amount of radiation in our communities.

I post info on this subject all the time. Some of you read it (thank you if you do), but I'm sure many of you don't bother because you're not affected (yet) or you haven't figured out that your health problems are being caused by it. Or maybe you just don't want to hear it because you love your wireless gadgets so much. But what about those of us who are fully aware this technology is making us sick? Do we not

matter to you? Maybe it's just easier for you to think we are imagining it. Well if you think you're not affected, think again.

I don't know about you, but I'm sick and tired of kids dying from leukemia, cancer, and brain tumors (are they perhaps sitting underneath a wireless access point at school? using a cell phone themselves? or just frying in Mom or Dad's car while the parents use their cell phone?) Now, appallingly, I see parents giving their toddlers smartphones to keep them busy and help them "get through the day." I am sick of cell towers going up outside schools and residential neighborhoods. I'm sick of Distributed Antenna System (DAS) units (the equivalent of a cell antenna) being installed on the telephone wires right outside people's bedroom windows–and they don't even know because the radiation is invisible.

I'm disgusted by the number of children being drugged for "ADHD" and "behavior problems" (how can they think or behave properly when bombarded by whole-body radiation from Wi-Fi at school???) I'm sick of getting yet another phone call that my sister, my cousin, or my friend has breast cancer (oh that's right, they have a wireless digital utility meter on their house, Wi-Fi in their home/office, and/or they use a cell phone). I'm tired of hearing about my friends' husbands dying from kidney and bladder cancer (can you say laptop???)

I want to know where all the bees have gone (they used to be EVERYWHERE when we were kids). I want to know how the hell we're going to grow food if all the pollinators are dead! I'm tired of flocks of birds dropping dead out of the sky, and millions of bats (also pollinators) dying of mysterious fungal diseases (the immune system cannot function properly in the presence of these frequencies). If you think you're not affected by all this, please think again.

Please care enough to acknowledge that this technology is essentially free license to commit genocide in slow motion against those of us who cannot tolerate these frequencies. And you or your child may be next if/when your body can't tolerate it anymore either. So please have the moral fortitude and common human decency to do something about it, because those of us who are getting sick from it can't do it alone anymore. We need your help. The problem has gotten too big and soon there will be no escaping it (Super Wi-Fi is on its way). If you are truly a human being, start acting like one. Please don't accept what is happening to your fellow human beings. Please care about me and my kids and others like us. Please care about those who are being affected and don't even realize it yet. Please do something about this.

It is not okay to essentially cripple and/or kill off an entire segment of the population for the sake of wireless convenience. We, as a species, should be better than that.

http://stopsmartmeters.org/2012/02/29/collateral-damage-speaking-out-against-wireless-harm/

On the run …from the silent, invisible foe

I'm on the run—a fugitive, darting furtively from one safe house to another. When I dare to go out, I cover my face and as much of my body as I possibly can. I've become invisible, silent and stealthy. I haven't been seen out in public for a long time. Think about it: when was the last time you saw me out there, in person, openly socializing? Exactly. See what I mean?

I'm trying not to let it get to me, trying not to get paranoid and start imagining things that aren't really there, on top of what I know is there. Who am I fleeing? No one. What crime have I committed? None. Yet I'm on the run from the biggest, stealthiest, most insidious take-over of all time. And I'm all alone. The corporate giants hold all the cards and the government won't help. They know I've figured out what's really going on, but they don't want anyone else to know. There is nowhere safe for me to go and no safe way for me to get there.

Sometimes, when I'm dehydrated and desperate for some human contact, I slink into a café for a drink. But then my heart starts to pound, my whole body breaks into a sweat, my head throbs, I feel dizzy and I get the shakes—not milk shakes, just plain old body shakes. People are looking at me and reaching for their phones …and suddenly everyone feels like a threat. It's as if they've all become part of some unspoken conspiracy and there's no one I can trust. I've barely drunk my fizzy water but I have to leave.

This has been going on for a while—over two years—and I'm running out of stamina and safe places to hide. It's taken a toll on my health, aging and debilitating me. My nervous system is in perpetual 'fight or flight' mode, and I'm unable to relax, rest or be at peace. I've hardly any friends left, and I can't remember the last time I went to a restaurant, the movies or a dinner party. I'm a recluse and a social pariah, and I doubt that more than a handful of people will miss me if I disappear.

I've tried fighting back, but the enemy is slippery, skillful and beyond my reach. It's protected and sanctioned by the powers that be, and I'm just a little person—someone they can easily quash. I'm taking legal action, but even the courts are in the pockets of these predators, and their legal 'experts' have been won over with misinformation and political spin.

There are others like me, but we're widely dispersed, so it's hard to muster a force strong enough to make an impact. Plus, like me, they're tired of fighting for what's right. I can see why some of them decided to take their own lives. I've considered it—not because I feel suicidal, but because it feels as if there's nowhere left for me to go. I feel cornered, surrounded, stuck in a cycle of diminishing returns.

Yet I refuse to be a victim and I won't go down without a darn good fight. In fact, I'll fight and not go down. I know I'm being challenged to find a powerful solution. I'm smart, creative and good with words, and I've done some interesting stuff in my life—for WWF International and the United Nations in Switzerland. I've published books, been on TV and radio, been featured in local and national newspapers, and have helped others find their own powerful voice. I've written about the deeper truth of what it means to be human. But the truth is not enough, it seems, and I'm running out of time.

If anyone reads this, what will they think? That I've lost my marbles? That I'm some kind of conspiracy nut with an axe to grind against the establishment?

You can look me up, if you're curious. It's so wonderfully easy to do that, these days. Just touch-and-type and all the information in the universe is at your fingertips. But when you reach for your iPhone, think of me. When you're in the elevator with half a dozen other people with their heads down, when

you're pressed against other intently texting bodies on the bus, or when you're e-mailing while walking down the street—think of me being on the run …from the 20-foot aura of radiation coming from your phone, extending all around you, instantly penetrating cement, metal, plastic, clothing, cars, skin, muscles, tissue and bone, damaging red blood cells within minutes, causing cellular leakage of calcium, killing neurons, inhibiting your brain, reducing your libido, affecting your memory, disrupting your sleep cycles, and slowly chipping away at your health without you ever feeling a thing.

And you probably won't feel a thing, until the damage is done (and even then you'll blame it on everything but your phone). I was just like you—loving my electronic gadgets and blissfully oblivious to their effects …until I got a brain tumor. But I sure am feeling it now.

So, think of me when you're on your phone, and remember that you're just like me—with the same red blood cells, the same nervous system and all the other bodily bits that react exactly as they're meant to, when exposed to electromagnetic radiation. If I can get a brain tumor, so can you. It may be hard to accept, but death doesn't just happen to other people, while you're busy texting.

I'm leaving, now—heading off to a teepee in the forest so my body can reconnect with the earth and (hopefully) bounce back. Like so many others reacting to all this radiation, I'm being forced to disconnect. But if you're committed to non-stop wireless living, you're already disconnected—from the deeper truth about the damaging effects, from your body's subtle messages, and from the changes already taking place inside you, masquerading as fatigue, stress, ADD, insomnia or other seemingly 'normal' ailments—as well as the far more disturbing neurological conditions, autism, dementia and infertility that are now affecting so many people. You simply haven't yet connected the dots.

I have special radiation-shielding fabrics to protect me when I go out. But the only reason I need to cover up is because of the corporate cover-up. You're not getting the facts. And the cell phone companies and Internet service-providers are not your buddies. Intent on keeping you addicted to your gadgets (and too engrossed to connect any of those dots), they will happily collude with you in your denial of the dangers.

But the body—that delicate electrical system that can't be upgraded or replaced with the latest technology? The body never lies.

http://olgasheean.com/on-the-run-from-the-silent-invisible-foe/

My Life Living 6 Feet Under Cell Phone Towers

If you told me three months ago not to hold a cell phone to my head or body, and that if I did, to at least have the battery pack facing outwards, I would have listened but it would not have changed my mind. If you told me to exchange my cordless phones for good old-fashioned corded phones, I would have listened, but it would not have changed my mind, I liked my cordless phones thank you very much. If you told me three months ago to use an Ethernet cable with my laptop and keep Airport mode turned off, or to move the Wi-Fi antennae from my bedroom and to turn it off at night or when not in use, or to get rid of all Wi-Fi all together, I would have listened, while thinking to myself "that's a lot of work, why would I want to do all of that?" If you told me thee months ago that baby monitors should not be placed near babies or to ask my 14yr. old daughter to text more than talk, and not sleep with her phone or computer on the pillow beside her, I would have listened but still it might not have changed a thing. If you told me three months ago that the microwave radiation emitted by cell phones, cordless phones, Wi-Fi antennas, cell towers and masts, WLAN and other wireless technology was an invisible culprit causing thousands of people to experience all manner of symptoms from insomnia to high blood pressure, and should be avoided completely or at least whenever possible, I would have listened, but still I might not have changed a thing. After all, the government was there to protect our health and they were approving these things, and the mass media told all of us these devices are safe to our health. But before three months ago I hadn't spent more than a month living 6 feet under as well as in front of cell towers that were placed on my balcony roof. Before three months ago I was healthy, vital and slept like a baby. I didn't wake up with numb hands and feet, my body feeling prickly all night and tingling or vibrating almost all day. I didn't spend night after night in a hyper active state, as though electricity was running through me. Before three months ago I lived in a beautiful home that I loved, it was my sanctuary. I didn't have a hissing or buzzing or high-pitched ring in my ear, known as tinnitus or microwave hearing, mostly when in that home. I didn't get tension headaches ever, or feel like there is an invisible band around my head creating pressure. I didn't feel bouts of nausea on a regular basis, sometimes accompanied by a metallic taste in my mouth, and I didn't get dizzy spells. I wasn't afraid I might have a heart attack as I slept on a makeshift floor mattress in my apt and felt my heart race all night while my body from top to toe became increasingly numb and tingly. I wasn't without focus and direction and unable to concentrate. I'd never gotten shocks touching my bed mattress, home light switches, pots on my stove, and with every stroke of my cats. Before three months ago my daughter didn't have more than one unexplainable rash that hurt 'in' the skin as she described it, she didn't have headaches or feel nauseous and dizzy in our home, or experience the blood in her hand going cold. She never had sleepless nights. Before three months ago I hadn't abandoned my home at the advice of someone who could have sold me thousands of dollars worth of products and equipment by convincing me they would alleviate this situation. Instead I was told, "you have to get out of there, if you care about you and your daughters health you're going to have to move". I had never couch surfed with my 14yr old in tow while tying to maintain some semblance of a normal life or schedule for her. Before three months ago I hadn't researched everything I could find to educate myself about the real dangers of exposure to microwave radiation, or electromagnetic frequencies. I wasn't fully aware of cell towers and this invisible Wireless web that continues to be woven above all of our heads. I couldn't tell the difference between a Bell cell tower, a Rogers cell tower, a Globealive or Wind cell tower or a Telus cell tower. I'd never heard of Industry Canada or Spectrum, Canada Safety Code 6, or the Bioinitiative report. I hadn't spoken to Health Canada, Industry Canada, Canadian Environmental Legal Association, Environmental Health Clinic, Environmental Health Association, The Environmental Protection Office,

The Toronto Environmental Alliance, Public Health office, Canadian Association of Physicians for the Environment, my City Counselors office, trying to find some-any answers as to how safe it is to live in such close proximity to a cell tower. So far none of them have told me it's not safe, but thankfully I have better judgment, a body that is telling me the truth, and Liala, Kevin and Magda to confirm what I already knew. Before three months ago I hadn't spent 15 days getting 2 hours sleep a night because my body was still vibrating all the time, and the rest of the night in tears while feeling like I was losing my mind from sleep deprivation combined with the physical stress of feeling fight or flight 24 hours a day. I didn't have a clear and unpleasant physical reactions to my cell phone, the usage of cell phones by people in close proximity to me, the touch of my computer keyboard, or the experience of sitting close to the monitor for too long. I didn't feel my legs tingling-and going cold and slightly numb if I spent too much time in the same room as a Wi-Fi station. I didn't feel nauseous and have sharp pains go through my hand and up my arm if I held a cordless phone or a cell phone while in use. I didn't feel nauseous if I sat for too long or too close to a television. I do now. Before three months ago I couldn't tell you when I was standing within two to four blocks from a cell tower installation. I never thought twice about leaning on walls or in close proximity to the electrical wiring in a building, or lying on the floor above a basement for the same reasons. I never had to consider the effects of my neighbors Wi-Fi antennas and cordless phone base station broadcasting through any wall that stood between us. Before three months ago I hadn't heard the words Electro Sensitive or Electro Hypersensitive. I hadn't spent hours and hours on the phone trying to find a good doctor, preferably one who knew what a cell tower was and the possible effects of living 6 feet under or in front of one, only to find that it is nearly impossible to find any doctor at all taking new patients. Unfortunately for me, the ones that were, who offered the kinds of analysis or treatment I needed, cost an arm and or a leg or a plane ticket which I didn't have to spare at that time. Before three months ago I hadn't slept in six locations over a period of nine days in the middle of a three week period, while trying to find a place where I could get a good nights sleep because even after friends and family pulled the plug on the Wi-Fi, cordless phones, and everything but the fridge, my body was reacting to the wireless technology from the neighbors, emitting through the walls to where I slept. Before three months ago I hadn't heard of EMF Solutions, Earthcalm, Magda Havas, Jim Vella, the Weep Initiative, the Electro-sensitive Society, a Qlink, a gauss meter or an Electro smog meter. I hadn't read stories from hundreds of people around the world whose lives have been profoundly impacted by something we can't see or hear (for the most part) but can most definitely feel… by microwave radiation, and electromagnetic frequencies emitting at levels not meant for human consumption, by something we are led to believe is harmless and benefits us in more ways than it bombards us, in favor of convenience and especially someone's bottom line, over our continued health and longevity. Three months ago my life got turned upside down by exposure to microwave radiation while living 6 feet under and in front of 10 Cell towers. I am now preparing to move to a home yet to be found, and challenged by the fact that I have to consider my recently acquired sensitivities more than the location, size, and cost. There is no doubt in my mind or my body as to when and where this all began. There is no doubt in me at all, that human beings are affected on a biological level by exposure to microwave radiation well below the levels considered safe by Health Canada's Safety Code 6. A lot can happen in three months, and like anyone else, I don't like being blindsided. I share this with you not because I expect you to listen, but because I do want you to pay attention. Pay attention to the choices that are yours to make, and especially to the ones that are made for you. Because even if I had listened to every piece of advice in terms of precaution, I still would have had no choice about whether or not I

wanted to live in a neighborhood rife with cell towers... or should I say live and sleep 6 feet under and in front of 10 of them. Pay attention now, before you have to pay dearly.

Sincerely Veronica C.

Paul's EMF Refugee Story

Paul Doyon, Building Biology Certified Electromagnetic Radiation Specialist (EMRS), speaking to you from a "normal" wired pay phone in Upper Lake, CA

A New Job at Kyushu University

In August of 2004, I received word that I would be hired as an Associate Professor at Kyushu University, one of Japan's top universities. I was 42 years old and my future was bright. I had at the time been living in Japan for approximately 15 years and had earned MA's in Teaching (TESOL) and Advanced Japanese Studies, not to mention my BA in Psychology before coming to Japan 15 years earlier. I was fluent in Japanese and had numerous publications under my belt. My future looked bright and if I had continued on that trajectory I would have certainly earned my Ph.D. or Ed.D. in Applied Linguistics and would be now a tenured professor at one of Japan's numerous universities. Things did not, however, work out that way.

Starting to Get Sick

In and around March of 2005 I started to develop a host of symptoms and I was extremely sick for six months before I was even aware — let alone even imagined — that the two cell towers within about 200 meters (and another about 500 meters away) from my apartment and perhaps the Wi-Fi from my neighbors' apartments bleeding into mine might have had something to do with the host of symptoms — insomnia, anxiety attacks, loss of appetite, rapid weight loss, excessive thirst, swollen lymph nodes, intestinal disturbances, increased sensitivities, weakened immune system, dry and irritated eyes, etc. — I was experiencing at the time. I had been eating a healthy diet consisting of mainly organic fruits and vegetables, brown rice, tofu, healthy meats, lots of Japanese tea, and was doing yoga every morning, and going to the gym three or four times a week. I was doing everything one is supposed to do to stay healthy and was quite perplexed as to why I was getting sick.

Six months earlier, in November of 2004, I had started my new job as an Associate Professor at Kyushu University in Fukuoka, Japan and had moved into their staff housing also in the city of Fukuoka with my wife and son (both who also experienced health complaints, though not as severe as mine).

I started to wake up earlier and earlier until I got to the point where I could not sleep anymore. I developed extreme thirst: I remember that I would go to the vending machine at the university during breaks and between classes to guzzle several bottles of water or oolong tea. I developed very bad skin allergies. My eyes became extremely red and irritated. My lymph nodes started to become swollen and painful. I was experiencing extreme fatigue. Most of the time I felt nauseated. I was getting heart pain and palpitations. I would wake up in the middle of the night dripping in sweat. I had intestinal disturbances. I needed to go to the bathroom several times a night. I started to develop brain fog and forgetfulness. I also started to experience anxiety attacks with things that never bothered me before like getting on the elevator, being left alone, driving through a tunnel, etc. Furthermore, I lost my appetite and I dropped about 20 kilograms (about 44 pounds) in a month.

Chronic Fatigue Syndrome

I started googling my symptoms and finally concluded that I had been experiencing what was being described in the literature as "Chronic Fatigue Syndrome" (CFS) and started reading everything I could on the subject. I read Martin Pall's work about free radicals, Garth Nicolson's work about mycoplasma infections, Andrew Cutler's work on heavy metal toxicity, and Michael Goldberg's work on Neurological Immune Endocrine Dysfunction and how autism, ADHD, CFS, and Alzheimer's were all connected. To be honest, there are probably at least 100 theories about this condition and I joined every Yahoo group addressing one or more of these. I eventually went to Kyushu University Hospital to talk with their CFS expert. (While the literal translation for CFS is 慢性疲労症候群 [manseihiroushoukougun] , they actually call it 自律神経失調症" [jiritushinkeishcchoushou] or "autonomic nervous system disorder.") He did some tests on me for a number of viral infections, toxoplasmosis, and (at my request) mycoplasama and told me basically that there was pretty nothing he could do for me and that my situation would worsen until I was pretty much just bedridden all the time.

He wanted to give me anti-depressants/anti-anxiety medication and I had him prescribe me antibiotics instead, as I had been by that point reading Dr. Garth Nicolson's theories on mycoplasma infections and believed that that might have been the major cause of my problems — though I later came to a different conclusion — as I was later to learn that the same symptoms described a disease identified by the Russians in the early 70s as "Microwave Sickness.".

Another interesting fact I discovered was that people in the USA started experiencing these same symptoms in 1984, the same year the first commercial cellphone network was set up across the country. CFS was initially dubbed by the media as Yuppie Flu. Well, if you think about it, yuppies were indeed the first people to start using computers and cellphones. In fact, the first Apple Macintosh made its debut the same year, along with commercial usage of the first MMR machines.

It's the Electropollution, Stupid

I eventually had to stop working I was so sick. I was frantically searching for the cause and a cure reading whatever I could find on the web. I was following the blog of a guy in Europe who was suffering from both CFS and Crohn's Disease and who had lots of interesting scientific theories about what was causing his problem when one day he wrote (to paraphrase him):

"It is the electropollution. I went to my parents' house in the French countryside and all my symptoms disappeared. I went back and measured the EMFs in my Amsterdam apartment and the EMFs were through the roof."

That really made me start thinking. I did feel better at night when people were not using their cell phones (in spite of the fact that I could not sleep without sleeping pills at the time). I also felt better out in the country away from all the cell towers in the city — though it was not 100%. I was also able to correlate my anxiety attacks with peak cell-phone usage times in Japan as I had a technician (really a PR man) from Nippon Telephone and Telegraph (NTT) come to my apartment and do measurements. The technician looked sicker than I was and was sweating like a pig. However, he did reveal to me the peak usage times which I was able to correlate with times I would experience extreme feelings of un-wellness.

Dr. Yayama

Before moving into this log house and while we were still living in the Kyushu University's staff housing, my wife was calling around Japan trying to find a doctor who did chelation therapy. She had called a doctor in Tokyo who said that we should just go and see a Dr. Yayama in the city of Yamato, Saga Prefecture, as he was the best alternative doctor around. When we finally went to see him, I read the following in his pamphlet: That modern diseases were caused by the following: 1. Heavy Metal Toxicity, 2. Electromagnetic Pollution & Geopathic Stress, 3. Pathogens (viruses, bacteria, fungi, and parasites), 4. Chemical Toxicity, and 5. the Body's Internal State (e.g. including psychological stress) and then noticed all the cell towers along the road on the drive back to Fukuoka.

A Log House in the Saga Mountains

When we started to realize that we were being bombarded by wireless exposures and that this might be behind our decline in health, we quickly started searching for and found a log house in a white zone — an area devoid of wireless signals — in the mountains of Saga Prefecture, (about 30 minutes outside of Fukuoka). We called the owners and asked if we could rent it out for just about three days. They told us that there was no cell phone signal there: Exactly what we wanted. After like the first 24 hours, I experienced a disappearance in I would say 50% of my symptoms. I then knew that this was it. I ended up staying in that log house for four months and I would say recovered during that time about 85-90% of my previous health.

Miraculously, also, Dr. Toshihiko Yayama's Clinic, was conveniently located about 20 to 30 minutes away from this log house.

And via multiple chelation treatment modalities (homeopathy, Chinese Medicine, and IV EDTA, etc.) of chelating the metals out of my body, having all the metal removed from my mouth, and by taking lots of antioxidants, Transfer Factor, and doing Qigong, I was able to recover much of my health and became much better able "tolerate" the EMFs.

Electrosensitivity

However, at the time, whenever I would get into range of a cell phone tower or around people with cell phones, many of these symptoms would start to come back. I could feel an intense pressure in my head, I felt nauseous, I would feel pain in the lymph nodes under my right arm and in my right testicle and groin area. Fortunately, gradually, over the years, these symptoms have diminished with many of them disappearing — though, at the time, it pretty much freaked me out.

The Zero Search Machine

Dr. Yayama, probably the most famous alternative medical doctor in Japan, is quite the amazing person. I would say he is a great genius. He invented a diagnostic tool he calls "Zero Search" which he connects

with a German Rayometer to check frequencies, as they have found that everything has its own signature frequency.

Hence, when I initially went to see him, he was able to pretty much tell me in less than 10 minutes that I had 1. systemic candida, 2. mycoplasma, 3. toxoplasmosis, 4. Epstein Barr Virus, 5. Cytomegalovirus, 6. mercury toxicity, 7. aluminum toxicity, and 8. lead toxicity. Unbeknownst to him at the time, the mycoplasma, Epstein Barr, and Cytomegalovirus had been confirmed by blood tests earlier at Kyushu University Hospital.

My wife (who is Japanese), at the time, wrote to all the Japanese media outlets to get some coverage for our newly discovered problem that those seemingly innocuous waves of wireless radiation were damaging to our health. She received zero replies; they seeming — for (what are now for me) obvious reasons — did not want to touch our story.

EMF Refugee & "Denjiha Nanmin" (電磁波難民)

After four months of living in this log house, we started running out of our savings. I was probably feeling from between 85-90% better but would still start to feel sick when exposed to EMFs. We moved back into our apartment and bought a canopy to sleep under and shielded the windows with special material to block out the EMFs. In early 2006, I started a Japanese Yahoo group in Japanese called "Denjiha Nanmin" (電磁波難民） and its equivalent Yahoo group in English called "EMF Refugee." (We now have almost 1000 members.) I started having people contact me from all over Japan who were having the same problems. We had a meeting at my apartment in Fukuoka. People flew from all over Japan.

Ad Hoc Publications

Around about the same time, I also wrote several papers that were published ad hoc on the Internet: One was called, "Do You Have Microwave Sickness?" (originally published in Feb. 2006) where I wrote, for example

"19. Exposure to microwave radiation has also been shown to effect an abnormal increase in nitric oxide (NO). One theory holds that an abnormal increase in cellular calcium will also lead to an abnormal increase in cellular NO, which in excess produces a damage-producing free radical or oxidant called peroxynitrite."

and the other one "Are Microwaves a Major Causal Factor in Chronic Fatigue Syndrome (CFS) and Myalgic Encephalomyelitis (ME)? (originally published in July 2006). These got quite a bit of fanfare given the fact that I was an associate professor at one of Japan's top universities. Next-up (France) took up the story and there was an article published in the Belgium newspaper LeLibre entitled "Les micro-ondes liées à la fatigue chronique?" or "Are Microwaves Related to Chronic Fatigue?" The Townsend Letter Group even published an article about me in their newsletter in 2009 entitled "Microwaves Role Examined."

Looking for a Place to Live: Kunming, China

At any rate, after going back and forth with a Japanese president of an IT firm who himself developed ES about starting an eco-village for ES people, I eventually decided that the levels of EMF were just too high for me in Japan. I decided to search for another place to live and took a trip around Southeast Asia — Thailand, Myanmar, India, Southwest China, and Laos — looking for a suitable place to live. Upon

traveling to Thailand, I realized that I felt better there EMF-wise than in Japan, and then felt better China than I did in Thailand. I attributed it to the fact that at the time, Japan (if my memory serves me right) was moving into 3G, Thailand was still working on 2G, and China had stricter regulations regarding ambient levels of EMF. I eventually severed my ties with Kyushu University and ended up in the city of Kunming, Yunnan Province in 2006.

It was a fascinating place to live and I started studying Mandarin, worked at a language school and eventually secured a teaching position at Yunnan Normal University, where I worked for a year.

After living there alone for six months, my wife and son joined me.

We had a very interesting time living in Kunming together for a year. Our weekends and breaks were often spent taking trips to other parts of Yunnan Province. Interestingly, a person named Peter Monaghan had contacted me in response to an ad I put on GoKunming (the local community website) selling some stuff who said that his mother was a Doyon and that he was coming to Kunming to teach English at one of its universities. It ended up that his mother was my father's cousin, had grown up in the same town as my father in Quebec (St. Benoit), and that Peter was my second cousin. Small world, eh! We often spent our weekends together either taking trips around the city or to other cities in the vicinity.

Auroville

However, after a year of living in Kunming together, we decided to leave and go live in the intentional community of Auroville, India, which was very progressive with alternative forms of medicine, agriculture, building, education, health, and electromagnetic policy (i.e. there was a rule in place that no cell towers could be built within the city's limits of 20 square kilometers). They do not use pesticides or chemicals on their land, food is organic vegetarian, medicine is mainly Ayurvedic, Chinese, Naturopathic, and Homeopathic, and buildings are Building Biology standard: i.e. a very healthy place to live.

But before doing that we had a nice trip together through Thailand, which I love except for all the chemicals there to which my body reacts. Ah!

Back to Thailand: ITM

Auroville was wonderful, but at the time, we did not have the funds to sustain ourselves in this sustainable community. I needed to go to China to do training with the British Council to become qualified as an IELTS examiner and got stuck in Chiang Mai, Thailand because China would not give me a visa. I ended up doing a Thai Massage Workshop at a school called ITM in Chiang Mai.

Mae Fah Luang University: Chiang Rai

Later I got a job teaching English as a Foreign Language (EFL) at Mae Fah Luang in Chiang Rai, Thailand, about two hours northeast of Chiang Mai.

Allergies Gone Crazy

After living in Thailand for awhile, I started to gradually experience a worsening condition of skin allergies: I think it was a combination of dust, pollen, mold, smoke (from the burning of the fields), pesticides, formaldehyde, and food chemicals. My skin was extremely itchy, red, and irritated. I needed to take sleeping pills to sleep and when I woke up my sheets would be covered with blood from the unconscious scratching that had occurred while I was sleeping.

Escape to Chiang Mai
I had to eventually leave my teaching position and seek help in Chiang Mai. After a month of seeking treatment from all the alternative health practitioners (acupuncturists, chiropractors, naturopaths, and so on) and not getting better, we decided to return to Japan.

Back to Japan: Dr. Sei Takahashi: An Amazing Acupuncturist
However, after a month of daily acupuncture treatments with an amazing acupuncturist,and medical qigong practitioner, Dr. Takahashi Sei, at his clinic Ishindo, not to mention daily far infrared saunas, and the drinking of lots of alkaline water, I was thankfully pretty much back to normal.

Utsunomiya University
Within a month, I had applied for teaching positions at a number of Japanese universities and had several interviews lined up. I applied at Utsunomiya University and received a phone call from the directly after getting home. She wanted to hire me. I accepted and moved to the city of Utsunomiya in March of 2010.

I worked there until March of 2011 when Fukushima happened and we were approximately 100 miles away — too close for comfort.

The International Institute for Building Biology and Ecology: Electromagnetic Radiation Specialist (EMRS)

Out of Sight and Out of Mind
When something is out of sight, it is also out of mind — and microwaves from cellphones, cellphone towers, and other wireless-radiation emitting devices are invisible, tasteless, odorless, and cannot be sensed with touch. Naturally, it has been difficult for many — even most doctors — to fathom them as being a culprit in the disease process. However, increasingly, people worldwide are starting to wake up to the fact of what is indeed the cause of their previously mysterious symptoms. An increasing number of these people become noticeably ill when exposed to this invisible source of pollution and they are starting to connect the dots. Also, it is becoming known that people with an inordinate amount of metal toxicity seem to be particularly sensitive. When people realize the problem, and come together to find solutions, progress can be made.

Connecting the Dots
After having had this experience, and in line with the growing quantities of ambient electromagnetic pollution in our environments, I began to suspect that the large number of people around me becoming sick with some kind of illness may also have been unwittingly affected by this health-damaging ambient electromagnetic radiation. Just as cellphones were starting to become popular, I remember a student of mine's three-year-old daughter dying of influenza. This was the first time I had ever heard of a little girl

dying of influenza, though apparently it is increasing more common and one has to seriously consider the fact that all this electromagnetic radiation we are being exposed to 24/7 might in fact be weakening our immune systems. It seems that when people catch colds nowadays that it takes them longer to recover — whereas instead of the normal 3-4 days we are now seeing people sick for up to two weeks or longer. We are being fed with the idea that the bugs are becoming stronger and not rather that our immune systems might be becoming weaker.

Since that time, I had the unfortunate fate to have known a number of people who have committed suicide, developed or died of cancer, had their children diagnosed with Autism Spectrum Disorders (ADS) or ADHD, developed brain tumors, been diagnosed with intestinal disorders (Crohn's Disease, Irritable Bowel Syndrome, Colitis), developed vision problems, strokes, and were diagnosed with epilepsy. I have also known women who have had miscarriages due to deformity of the fetus. This has become the norm — but it is not normal. Also, every year, in Japan, the news programs report about an increasing number of people suffering (or dying) from heat stroke in the summer. Something I had never heard when I first went there in 1988. When one looks at the research on how EMFs negatively affect the immune system, the endocrine system, the autonomic nervous system, alter the brain's neurotransmitters, open up the blood-brain-barrier, damage DNA, and create a deluge of free radicals in the body, one can view the causal factors of many of these disease states in a new light.

Public Brainwashed by the Wireless Industry

While the Wireless Industry has had the money to lobby politicians to get the laws they wanted passed, to fund the researchers to get the research results they wanted, and to promote their desired narrative through their media arms, in the past five-or-six-or-seven-or-so years, I have started to notice not only a shift in how the media is starting to change the way it covers this problem, but also in the public's acceptance and acknowledgement that this may in fact be a serious problem, whereas before the media was pumping out — and the public regurgitating — a narrative in which anyone questioning the health and environmental effects of wireless radiation was nothing but a tinfoil-hat-wearing conspiracy-theorist Luddite. There is now an increasing acknowledgement that this wireless might indeed be an actual serious health and environmental quagmire; that it might in fact even be behind unexplained increases in a plethora of health and environmental problems — autism, ADHD, chronic fatigue syndrome, MS, diabetes, Parkinson's, Alzheimer's, epilepsy, not to mention the skyrocketing rates of cancer, plus the disappearance of insects, frogs, other amphibians, and birds —and that we might have to seriously do something about it.

The Simple Truth

Dr. Robert O. Becker's statement 30 years ago in his book The Body Electric, may very well be accepted as the truth by the majority of people alive in my lifetime:

The dangers of electropollution are real and well documented. It changes, often pathologically, every biological system. What we don't know is exactly how serious these changes are, for how many people. The longer we as a society, put off a search for that knowledge, the greater the damage is likely to be and the harder it will be to correct. p. 304

Lastly, Major insurance firm, Swiss Re, warns of large losses from "unforeseen consequences" of electromagnetic frequencies:

http://media.swissre.com/documents/SONAR_+Emerging_risk_insights_from_Swiss_Re.pdf

The insurance companies are starting to grasp what the stakes are here; do you?

Conclusion

We don't want to believe that our new toys to which we are so attached and which bring enormous profits could also cause our demise or that of our children. But science is not about belief. Government's responsibility to their citizens should not be either.

— Devra Davis, PhD

If governments did their job correctly and were the responsible entities they were meant to be, electrosmog might never have become a problem. Cell phones would never have made it past the drawing boards, and we'd all be talking during power outages because cordless phones would never have made it off the shelf either. Rather than experiencing the slow connectivity wireless networking offers, every computer in the world could be connected with Ethernet and Fiber Optic cables.

This dream of a safe, hospitable world is still possible. But nobody else is going to make it happen for you. It will require each of us to stand up for our human rights. It took 50 years for the curtain to fall on tobacco; who knows how many decades of lies and millions of causalities will be required before the truth becomes apparent to the mainstream?

Despite the large body of emerging science confirming the negative health implications of pulsed radiofrequency radiation and the existence of electromagnetic hypersensitivity, the majority of the world's population remains in the dark, ignorant or unreceptive of the truth. In a world dominated by science and research, it is quite unfortunate that even well-regarded scientists remain opposed to the truth. Many governments themselves are compromised, lobbied by the very industries they are there to presumably 'regulate'.

Until there is a critical shift in the way technology is used in this world, both wired and wireless, it will be up to the individual to become empowered to make a difference. What little progress has been made so far towards a healthier, safer, more sustainable future, has been made by like-minded activists working towards a healthier future for ourselves and our offspring. In the face of critics, skeptics, tin-foil hat paranoids, and the ever-growing influence of industry, facts will ultimately prevail. If it is when, not if, a critical reorganization of our technological infrastructure occurs that we can pursue its own betterment instead of resenting the ailments that have befallen us.

Regardless of industry pseudoscientific claims, the jury is no longer out. There are tens of thousands of peer-reviewed studies out there confirming the negative health implications of radiofrequency radiation; some of them are contained in this publication. It is not a valid decision to choose to "believe" the science or not. The truth does not go away simply because it is ignored.

If you are still unreceptive of the truth, however forbidding it may be, take some time to look at some more research. Anyone who isn't yet concerned about the perils of wireless technologies hasn't looked at the research carefully enough yet.

If you are receptive and acknowledge the truth, pass it on. Ditch your cell phone and cordless phones and replace them with corded phones. Apart from the physiological impacts of wireless technology, the social and physiological implications of wireless technology are more

visible. An increasing social disconnect among one another is being experienced, namely due to the rise in usage of mobile devices. Those who remain unconvinced of the health implications of mobile devices may appreciate the humanity of the era predating cellular technologies.

Wireless technologies are often likened to tobacco. Their impacts on biological life, after all, are varying but very similar. Despite the ubiquity of tobacco in society even five decades ago, the usage of cigarettes has declined dramatically and constantly since the collapse of industry claims of tobacco's safety in the late twentieth century.

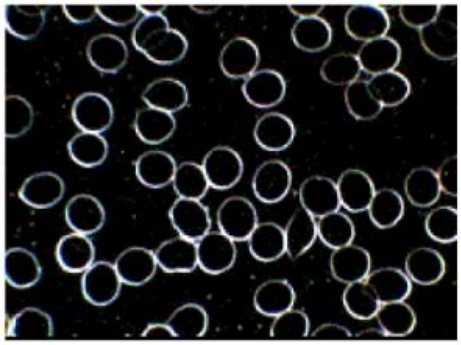
A growing number of scientists agree that wireless proliferation is, and will continue to be, the biggest public health crisis of the twenty-first century, perhaps the biggest health crisis humanity as ever faced. However long it may take for our world to return to a safer state, there is no need to wait for government approval of industry acknowledgement. The technology that will keep us safe is already here; in the form of corded landlines, hardwired Ethernet cables, and fiber-optics. Truly, a return to the dominant technologies of yesteryear is what will pave the way forward in the future.

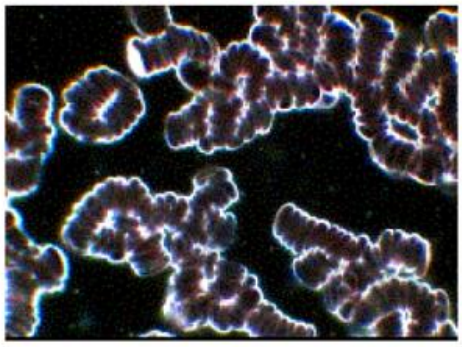
Appendix A: Measuring Radiation

Detecting and measuring radiation is beyond the scope of this text. To measure levels of RF radiation in your home:

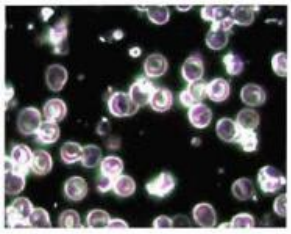
- Purchase an Electrosmog meter. You can buy meters of varying sensitivities at http://stopsmartmeters.org/store
- Aluminum foil shielding is a last resort and can possibly make levels worse. However, because radiofrequency fields do not penetrate metal well, if done right and levels are confirmed with a meter, shielding can significantly reduce your exposure to radiofrequency fields.
- Want to find out if there are any cell towers or antennas radiating near you? Look no farther than Antenna Search and TowerKill!
- You can use Xfinity's Wi-Fi search portal to find out if there are any radiating Wi-Fi hotspots near you.

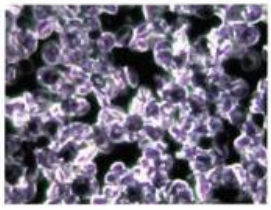
Appendix B: Pictures & Diagrams





Red Blood Cells Before and After a 90-Second Cell Phone Call

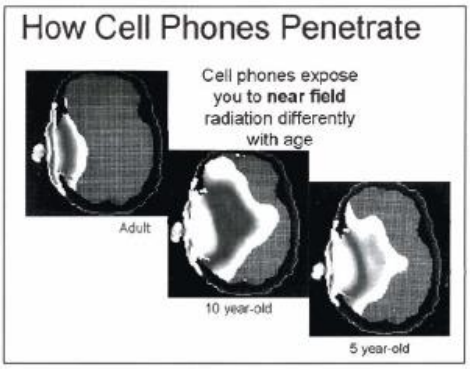


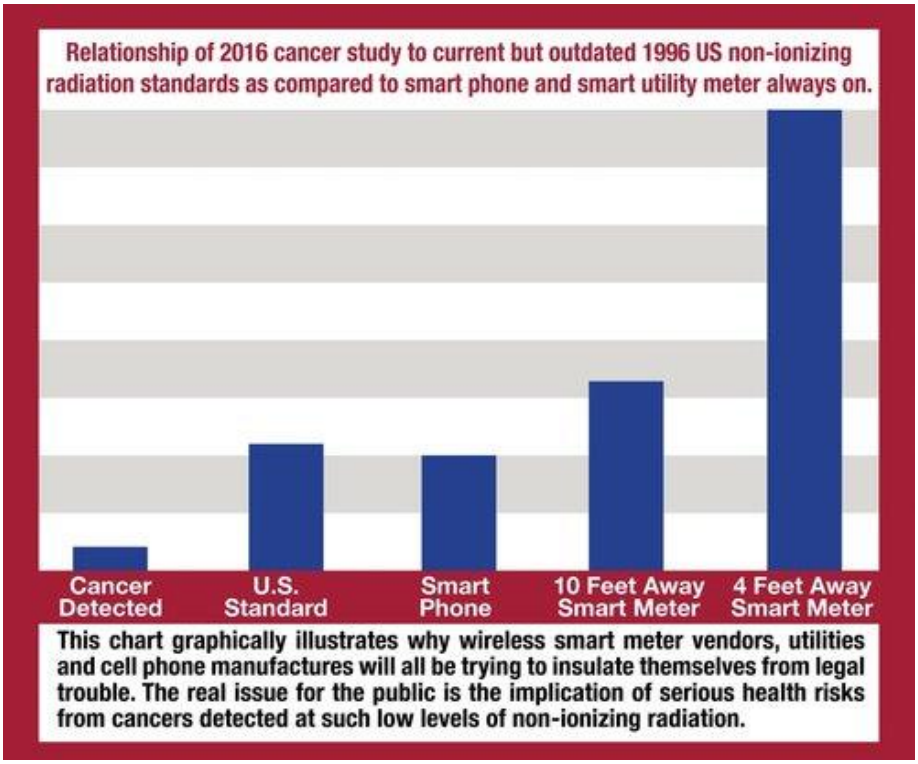


Disrupted red blood cell intercellular communication occurs within minutes of exposure to information carrying radio waves. Red blood cells must be able to sense the location of other blood cells to avoid clumping. Slide at left: prior to cell phone exposure – red cells are functional. Slide at right: after five minutes on a cell phone red cells are clumped and non-functional.

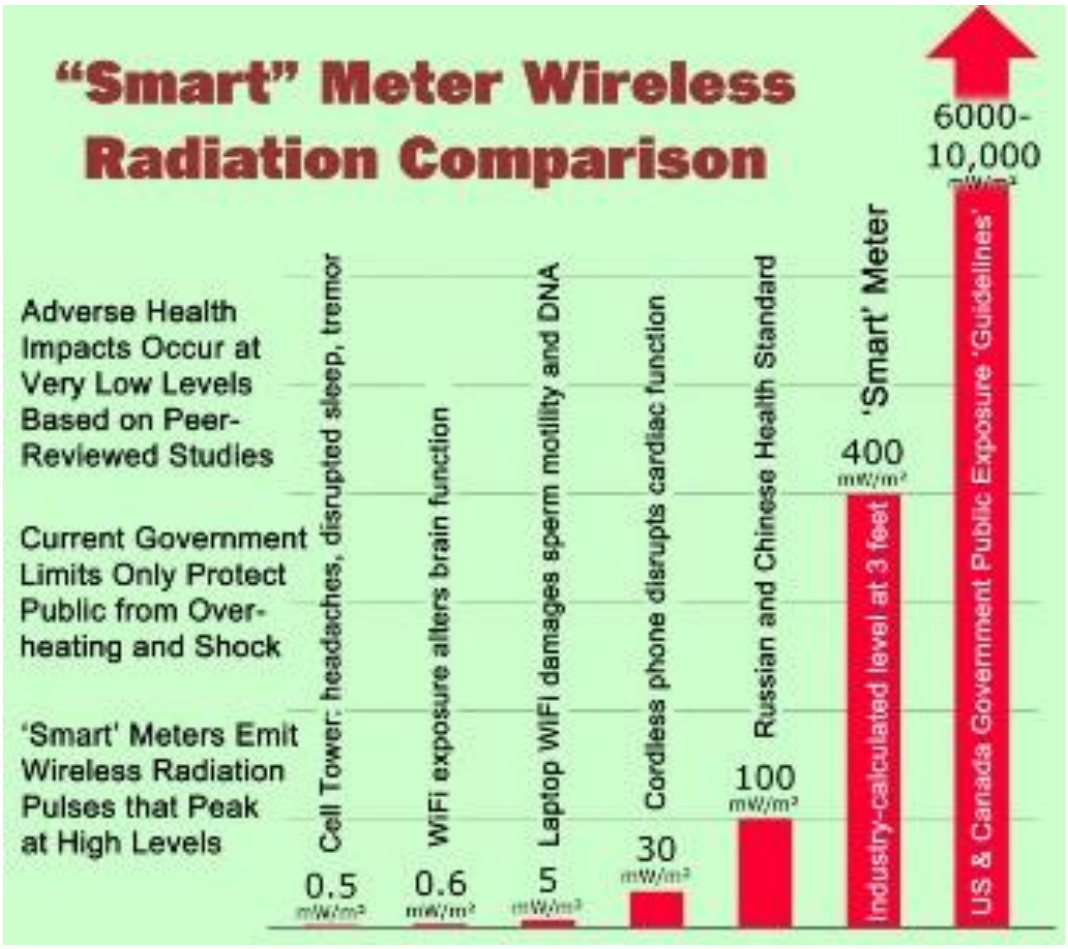
Deformed cows near cell phone towers in Germany are just one example among many animal deformities appearing around the world. Research has also connected the worldwide disappearance of frogs, birds, and insects [most recently bees] with the dramatic increase of electrosmog permeating our planet.

The amount of radiation penetration of a skull for an adult, a 10-year-old child, and a five-year-old child.





Relationship of 2016 cancer study to current but outdated 1996 US non-ionizing radiation standards as compared to smart phone and smart utility meter always on.
Cancer Detected
U.S. Standard
Smart Phone
10 Feet Away Smart Meter
4 Feet Away Smart Meter
This chart graphically illustrates why wireless smart meter vendors, utilities and cell phone manufactures will all be trying to insulate themselves from legal trouble. The real issue for the public is the implication of serious health risks from cancers detected at such low levels of non-ionizing radiation.



"Smart" Meter Wireless Radiation Comparison
Adverse Health Impacts Occur at Very Low Levels Based on Peer-Reviewed Studies
Current Government Limits Only Protect Public from Over-heating and Shock
'Smart' Meters Emit Wireless Radiation Pulses that Peak at High Levels
Cell Tower: headaches, disrupted sleep, tremor
0.5 mW/m²
WiFi exposure alters brain function
0.6 mW/m²
Laptop WiFi damages sperm motility and DNA
5 mW/m²
Cordless phone disrupts cardiac function
30 mW/m²
Russian and Chinese Health Standard
100 mW/m²
'Smart' Meter
400 mW/m²
Industry-calculated level at 3 feet
6000-10,000 mW/m²
US & Canada Government Public Exposure 'Guidelines'

Appendix C: Listservs & Support Groups

The number of refugee camps for electrohypersensitive individuals in the United States and around the world is growing exponentially. You can join the discussion today if you are interested in either planning or joining an EMF free retreat.

You can follow Stop Smart Meters! and Save Landlines on Twitter and subscribe to Stop Smart Meters! Newsletters. You can also find local groups in your area to join in the fight against smart-meters and forced wireless proliferation.

WHO – Setting the standard for a wireless world of harm – 30 January 2017
https://olgasheean.com/wp-content/uploads/2017/02/WHO-setting-the-standard-for-a-wireless-world-of-harm.pdf

DOCUMENTARIES

Take Back Your Power – This documentary highlights the negative impacts of smart-meters to our health and the environment. *While* Take Back Your Power *documents smart-meter problems well, many of the solutions proposed are dubious ones, and Josh del Sol believes climate change is not caused by humans, a viewpoint we believe is dangerous and ignorant.*
Public Exposure: DNA, Democracy and the Wireless Revolution – When do we draw the line?
Offline is the New Luxury – Where are the "white spots" on the map? Are there any sanctuaries left in a world full of wireless?

Resonance: Beings of Frequency – This sensational documentary reveals the harm of existing in a world of man-made wireless frequencies.
Full Signal – With over 3.5 billion cell phone users and thousands of cell towers popping up across the globe, people are starting to feel the effects.
"Wi-fried" on ABC 2016 – 2016, 30 mins.
Generation Zapped – We are getting ZAPPED by wireless technology.
Mobilize: A Film on Cell Phone Radiation – The long term effects from cell phone radiation are investigated.
Is Your Cell Phone Killing You? – 2011, 45 mins.
Beyond Coincidence – The Perils of Electrical Pollution, Part 1 – 2011, 11 mins.
Beyond Coincidence – The Perils of Electrical Pollution, Part 2 – 2011, 8 mins.
Grounded: Could It Happen to You? – 2013, 74 mins.
Microwaves, Science, and Lies – 2014, 92 mins.
Lo and Behold: Reveries of the Connected World – 2016, 98 mins.
Invisible Danger – 2016, 172 mins.

Frankfort, Kentucky 40602-0615

Re: Case files 2012-00428, 2016-00370, 2016-00187, 2016-00152 and all other Utility Company Case Files regarding Wireless Utility Meters (ie., AMI, AMR, AMS, ERT, Wireless, Smart Meters, etc.)

Dear Kentucky Public Service Commission, All Electric, Gas and Water Utility Companies, President, Agents, Officers, Employees, Contractors and Interested Parties:

We, the undersigned, are scientists and health professionals who together have co-authored many peer-reviewed studies on the health effects of radiofrequency radiation (RFR). We are aware that the Kentucky Public Service Commission is considering a proposed smart meter opt-out fee from Duke Energy. Smart meters, along with other wireless devices, have created significant public health problems caused by the radiofrequency radiation (RFR) they produce, and awareness and reported problems continue to grow. With Duke Energy being America's largest utility provider and, consequently, having the largest potential smart meter implementation reach, it is imperative that the Kentucky Public Service Commission be fully aware of the harm that RFR can cause and allow utility customers to opt out of smart meter installation with no penalty.

The majority of the scientific literature related to RFR stems from cell phone studies. There is strong evidence that people who use a cell phone held directly to their ear for more than ten years are at significantly increased risk of developing gliomas of the brain and acoustic neuromas of the auditory nerve. There is also evidence that the risk of developing these cancers is greater in younger than older people. The May 2016 report from the US National Toxicology Program showing that rats exposed to cell phone radiation for nine hours per day over their life-span develop gliomas of the brain and Schwannoma of the heart (the same kind of cancer as acoustic neuroma) adds proof to the conclusions from the human health studies that radiofrequency radiation increases risk of cancer.

East Campus, 5 University Place, Room A217, Rensselaer, NY 12144-3429

www.albany.edu/ihe

Smart meters and cell phones occupy similar frequency bands of the electromagnetic spectrum, meaning that cell phone research directly applies to smart meter RFR. Smart meter RFR consists of frequent, very intense but very brief pulses throughout the day. Because smart meter exposure over a 24 hour period can be very prolonged (pulses can average 9,600 times a day), and because there is building evidence that the sharp, high intensity pulses are particularly harmful, the cell phone study findings are applicable when discussing adverse health impacts from smart meters.

While the strongest evidence for hazards coming from RFR is for cancer, there is a growing body of evidence that some people develop a condition called electro-hypersensitivity (EHS). These individuals respond to being in the presence of RFR with a variety of symptoms, including headache, fatigue, memory loss, ringing in the ears, “brain fog” and burning, tingling and itchy skin. Some reports indicate that up to three percent of the population may develop these symptoms, and that exposure to smart meters is a trigger for development of EHS.

In short:

- Smart meters operate with much more frequent pulses than do cell phones, increasing the potential for adverse health impacts.
- Smart meter pulses can average 9,600 times a day, and up to 190,000 signals a day. Cell phones only pulse when they are on.
- Cell phone RFR is concentrated, affecting the head or the area where the phone stored, whereas smart meter RFR affects the entire body.
- An individual can choose whether or not to use a cell phone and for what period of time. When smart meters are placed on a home the occupants have no option but to be continuously exposed to RFR.

The Public Service Commission should not be relying on industry representatives for assistance, due to their obvious conflict of interest. Too often they rely on biased research and hold opinions that are not consistent with medical evidence. The symptoms and illnesses experienced from wireless utility meters are related to length and accumulation of exposure and therefore not everyone will exhibit symptoms immediately. In addition, as with many other diseases, not everyone is equally susceptible. There are a number of double-blind studies which clearly show that some people with EHS will develop symptoms when exposure to RFR is studied in a double blinded experimental protocol, in which the subject do not know whether or not the RFR is being applied. These individual are not suffering from a psychosomatic disease, but rather one that is induced by the exposure to RFR. Public health agencies that label these symptoms as being only psychosomatic are ignoring this evidence and are not working to ensure fair treatment of and protection of the public.

The adverse health impacts of low intensity RFR are real, significant and for some people debilitating. We want to stress three fundamentals as your agency proceeds to consider a smart meter opt-out:

- The Federal Communication Commission’s safety standards do not apply to low intensity RFR.
- There is no safe level of exposure established for RFR.
- People around the world are suffering from low intensity RFR exposure, being at increased risk of developing both cancer and EHS.

Citizens rely on their government agencies for protection from harm. Accordingly, we urge the Kentucky Public Service Commission to reject any fees or tariffs associated with smart meter opt-out and allow citizens to opt out without penalty.

Thank you for your attention and consideration. What you do in this instance affects the lives of many in Kentucky and beyond.

Yours sincerely,

FOXe report: Smart meter concerns

- Posted: Apr 16, 2014 4:32 PM EDT Updated: Apr 17, 2014 10:53 AM EDT

By Robin Schwartz, Fox 2 News - email

Smart meters have been installed in 1.5 million homes across Michigan.
About 1,900 people have chosen to get an opt-out meter, in which the radio is turned off.
An engineer tests the radio frequences coming from a smart meter.
(WJBK) - DTE Energy crews have installed smart meters at 1.5 million homes across Michigan. The new meters are an advancement in technology and can be read remotely by radio signals, but some homeowners say the meters are intrusive and dangerous.

For example, a fire in Pennsylvania is believed to have started when a smart meter exploded. Some homeowners fear the technology will be used for spying by tracking your energy use, even being able to pinpoint when you're not home. National news reports have indicated that is possible.

Others say the meters also cause health problems.

Jeanette Wagner says a smart meter on her previous house in Kentucky left her temporarily paralyzed. She's since moved to Michigan and lives in a hotel.

"I cannot find a house that doesn't have a smart meter on it, so I don't feel safe," she tells FOX 2's Robin Schwartz.

Leslie Panzica-Glapa says her son, Drew, got sick from the smart meter. He has diabetes and she says his blood sugar levels spiked when the meter went in. She says she also experienced insomnia and terrible headaches.

Schwartz took all the concerns to the General Manager of DTE's Advanced Meter Program, Bob Sitkauskas.

"We've got 10,000 employees, two million customers. We're not going to install something that we feel is unsafe," he says. He adds that he uses a smart meter in his own home.

DTE adds it would never sell the homeowner's readings, which could lead to the aforementioned spying.

An engineer came to Schwartz's home to test the radio frequencies coming from her smart meter. She was told the amount is less than 1 percent of the maximum exposure allowed by federal guidelines. DTE says research proves the smart meters are not a health concern.

Still, others choose to do their own research.

"The research being handed to us by utility companies is going to be skewed. They can get away with telling you their research shows no health dangers, but it's called "interpretive difference," says Wagner.

Panzica-Glapa chose to remove the meter from her home after her and her son experienced those various ailments. DTE has since threatened a lawsuit.

DTE does, however, have a program that gives customers an option.

Homeowners who don't want a smart meter can opt out, and so far about 1,900 people have. For a fee they can get an opt-out meter, which is the same meter with the radio turned off.

Participating in the opt-out program costs about 70 dollars, plus another $9.80 a month.

Some say the opt-out meter is just as bad, though, because it creates so-called "dirty electricity."

An appeal is pending for DTE to allow people with health problems to keep old analog meters, instead of the opt-out meters. Some are still fighting to get smart meters banned altogether.

If you are interested in the opt-out program, call 1-800-477-4747.

Leukemia and Exposure to Ionizing Radiation

Summary: Strong evidence has been recorded of a possible connection between forms of leukemia and exposure to ionizing radiation. This evidence is based upon studies conducted at Los Alamos National Laboratory, studies of nuclear workers at other sites, and others exposed to ionizing radiation. These findings are consistent with the National Research Council's determination that radiation can cause acute leukemia and chronic myeloid leukemia. Leukemia (except chronic lymphocytic leukemia) is designated as a "specified" cancer under the Energy Employees Occupational Illness Compensation Program Act. Historically, incidence of leukemia has been very high for Los Alamos County while mortality has been in the lowest third of New Mexico counties. Incidence and mortality due to leukemia in Rio Arriba County has been roughly comparable to other NM counties. Incidence means new cases of cancer, while mortality means deaths due to cancer.

What is Leukemia?

When leukemia develops, the body produces large numbers of abnormal blood cells. In most types of leukemia, the abnormal cells are white blood cells. There are several types of leukemia. They are grouped in two ways. One way is by how quickly the disease develops and gets worse. The other way is by the type of blood cell that is affected. Leukemia is either acute or chronic. In acute leukemia, the abnormal blood cells remain very immature and cannot carry out their normal functions. In chronic leukemia, some immature cells are present, but in general, these cells are more mature and can carry out some of their normal functions. Leukemia can arise in either of the two main types of white blood cells. When leukemia affects lymphoid cells, it is called lymphocytic leukemia. When myeloid cells are affected, the disease is called myeloid or myelogenous leukemia.

These are the most common types of leukemia:

- **Acute lymphocytic leukemia** (ALL) is the most common type of leukemia in young children. This disease also affects adults, especially those age 65 and older.
- **Acute myeloid leukemia** (AML) occurs in both adults and children. This type of leukemia is sometimes called acute nonlymphocytic leukemia (ANLL).
- **Chronic lymphocytic leukemia** (CLL) most often affects adults over the age of 55. It sometimes occurs in younger adults, but it almost never affects children.
- **Chronic myeloid leukemia** (CML) occurs mainly in adults. A very small number of children also develop this disease.

There are also other less common type of chronic leukemia. (National Cancer Institute)

---

* *Findings were statistically significant (strong evidence)*

\+ *Evidence of a dose-response relationship (strongest evidence)*

Findings of Human Health Research Studies

Human health research studies compare the patterns of disease among groups of people with different amounts of exposure to a suspected risk factor. Below are results reported from such studies of leukemia among people exposed to ionizing radiation.

These studies found increases and possible increases in leukemia among certain groups of exposed individuals, in some cases followed over time. Statistically significant is a term used to mean that the connection between the health outcome and the exposure was strong enough that it was unlikely to be due to chance. An asterisk (*) was placed by statistically significant findings. The research included incidence studies, which look at new cases of cancer. Incidence studies can track health more quickly and accurately than mortality studies of deaths due to cancer. Adding to the strength of the findings is that increasing rates of leukemia were observed with higher doses in some studies.

Studies of Los Alamos National Laboratory (LANL) Workers

Research conducted of LANL workers provides the most direct evidence about possible relationships between a health problem and workplace exposures at LANL.

- **Mortality Study up to 1991:** Increasing rates of death due to lymphocytic leukemia were found with increasing doses of external radiation, assuming a latent period of two years. *+ However, all four of the cases were chronic lymphocytic leukemia (CLL) which is not thought to be caused by ionizing radiation. [21]

- **Survivors of Accidents:** Two of the security guards who were present at early criticality accidents in 1945 and 1946 developed fatal acute lymphocytic leukemia 20 to 30 years later.[55]

Studies of Other Nuclear Workers in the United States

The next most relevant evidence comes from studies of workers in similar occupations with the same types of exposures. Listed below are studies that looked at leukemia and workplace exposures among nuclear workers in other parts of the United States.

- **Fernald, Ohio:** Possible increase in deaths due to leukemia (and all blood and lymph cancers) were observed in a study of 4,014 uranium processing workers employed between 1951 and 1989, followed through 1989. [1]

- **Hanford, Washington:** A possible increase in deaths due to all blood and lymph cancers were observed in a study of 44,100 workers who were employed between 1944 and 1978. [52] A possible increase in deaths due to myeloid leukemia was observed in 35,000 men employed at Hanford between 1944 and 1972. [51]

---

* *Findings were statistically significant (strong evidence)*

+ *Evidence of a dose-response relationship (strongest evidence)*

- **Mallinckrodt, St. Louis, Missouri:** A possible increase in leukemia deaths was observed in a study of 2,514 males who were employed between 1942 and 1966, and then followed through 1993. [2]

- **Mound, Ohio:** Increase in leukemia deaths (and blood and lymph cancers) was found in a study of 3,229 males who were monitored for external radiation between 1947 and 1949, assuming a 10-year latent period (time after exposure for the disease to develop). [56 *+]

- **Oak Ridge:** A possible increase in leukemia deaths was observed in a study of 8,375 males employed at least 30 days between 1943 and 1972, and then followed through 1977. Possible increasing rates of death were seen with increasing doses of external radiation, assuming a latent period of 10 years. [50 +] For each rem (a measure of radiation dose) of exposure to external radiation, there was a 6-9% increase in the risk of leukemia. When the follow up period was extended through 1984, there was an increase in leukemia deaths in workers monitored for internal contamination. [57 *]

- **Pantex:** A possible increase in deaths due to all blood and lymph cancers was observed in a study of 3,564 males who were employed between 1951 and 1978, and then followed through 1978. [58]

- **Pooled Analysis of Nuclear Worker Studies:** For all blood and lymph cancers combined, a 20% increased risk at 1-5 rem (a measure of radiation dose) of exposure and a doubling of risk at more than 5 rem of external radiation was found across studies. [59]

- **Rocketdyne/Atomics International:** Increasing rates of death due to all blood and lymph cancers with increasing doses of external and internal radiation were found in a study of workers who were employed between 1950 and 1993, and then followed through 1995. [*+] The largest effect was seen with a latent period of 15 to 20 years. The researchers who performed the study were "somewhat surprised" because the levels of internal radiation were low. [25] A possible increase in leukemia deaths was observed in workers monitored for external and internal radiation. [27]

- **Rocky Flats:** An increase in deaths due to all blood and lymph cancers was found in a study of 5,412 males who were employed for at least two years between 1952 and 1979 who had plutonium body burdens of at least 2 nanocuries (a measure of radiation exposure). The analysis assumed a latency period of five years following exposure for the disease to develop. [*] Possible increasing rates of death due to blood and lymph cancers were observed with increasing body burdens of plutonium or external radiation dose, assuming a latent period of two years. [+] The authors considered this "suggestive" of dose-response trends. [28]

- **Savannah River Site**: An increase in deaths to leukemia (and all blood and lymph cancers) was found in hourly workers hired before 1955, and employed for 5 to 15 years. [*]

---

* *Findings were statistically significant (strong evidence)*

+ *Evidence of a dose-response relationship (strongest evidence)*

All blood and lymph cancers were also increased in white males employed before 1955. * Possible increases were observed in other groups. [44, 60]

- **West Chicago (Kerr-McGee) Thorium Plant:** Possible increase in deaths due to leukemia and aleukemia were observed in a study of 1,352 men who were employed between 1940 and 1954, and then followed through 1975. [45]

- **Women at 10 DOE Sites**: An increase in deaths due to leukemia (excluding CLL) was found in a study of 65,984 women employed between start-up and 1980 at 10 DOE facilities. [37 *]

Studies of Other Nuclear Workers World-Wide

Below are studies of nuclear workers outside of the United States that looked at leukemia in connection with radiation exposures.

- **Canadian Radiation Workers:** A 5.9% increase in the incidence of leukemia was found per 100 rem (a measure of radiation dose) in a study of 191,300 workers employed between 1951 and 1988. [47 *+]

- **Nuclear Workers in 3 Countries:** An increase in rates of death due to all leukemias (except CLL) was found in a study of 95,673 workers employed for at least six months and monitored for radiation. [40 *+]

- **3 Nuclear Workforces in the U.K.:** Increasing rates of death due to all blood and lymph cancers was found with increasing time since first monitored for plutonium in a study of 12,498 workers.[*+] Increasing rates of leukemia deaths was found with increasing whole body dose in a study of 75,211 workers who were employed between 1946 and 1986, and then followed through 1988. An increase in leukemia deaths (except CLL) was found in workers monitored for any radionuclide (This study assumed a latency period of 0 or 10 years). [29 *+]

- **Registry of Nuclear Workers in the U.K.:** Increasing rates of leukemia deaths (except CLL) were found with increasing doses of external radiation in a study of 95,217 workers, who were followed through 1988. [5]

- **Sellafield, England:** Increasing rates of leukemia deaths were found with increasing doses of external radiation in a study of 10,382 workers who were employed between 1947 and 1975, and then followed through 1992, assuming a latent period (time following exposure for disease to develop) of 2 years.[*+] Increasing incidence of leukemia was found with increasing combined dose of plutonium and external radiation in a study of 5,203 workers. [3 *+]

---

* *Findings were statistically significant (strong evidence)*

+ *Evidence of a dose-response relationship (strongest evidence)*

Studies of Other Ionizing Radiation Exposures

Studies among other groups of people who were not nuclear workers can also be significant as evidence of possible increases in leukemia among those who have been exposed to ionizing radiation. Most other research has been conducted of people exposed to atomic bombs.

- **Atomic Bomb Survivors:** Increasing leukemia deaths were observed with increasing doses of radiation in a study of 86,572 A-bomb survivors.*+ Most of the deaths occurred within the first 15 years following exposure.[8] Children under age 15 are more susceptible.[38]

Is Leukemia Radiation-Sensitive?

- **Yes.** The National Research Council's BEIR V committee performed a detailed analysis of the risks of leukemia from radiation exposures. Among their conclusions are that radiation causes acute leukemia and chronic myeloid leukemia.[9]

The National Research Council advises the U.S. government on scientific matters. Their Committee on Biological Effects of Exposure to Ionizing Radiations (BEIR) V reviewed sensitivity of parts of the body to radiation. Their findings are based mostly on studies of cancer among atomic bomb survivors, as well as on some of the available information on the biology of the body, animal studies, and other evidence. The greatest risk is at high exposure levels.

Is Leukemia a "Specified" Cancer Under the Energy Employees Occupational Illness Compensation Program Act (EEOICPA)?

- **Yes.** Leukemia is a "specified" cancer under the EEOIC Act consideration of Special Exposure Cohorts, except for CLL.

Policy makers have identified certain types of cancer among energy employees at nuclear facilities, including those employed at Los Alamos National Laboratory, as being potentially related to occupational exposures under the EEOICPA.

---

* *Findings were statistically significant (strong evidence)*

\+ *Evidence of a dose-response relationship (strongest evidence)*

What Are Other Risk Factors Associated with Leukemia?

In considering the cancer risk from exposure to ionizing radiation at work, it is important to understand other risk factors. Below is a list of other possible risk factors for leukemia.

- **Electromagnetic fields.** Some research suggests that exposure to electromagnetic fields is a possible risk factor for leukemia. (Electromagnetic fields are a type of low-energy radiation that comes from power lines and electric appliances.)
- **Genetics.** Certain genetic conditions can increase the risk for leukemia. One such condition is Down's syndrome; children born with this syndrome are more likely to get leukemia than other children.
- **Certain Chemical exposure.** Workers exposed to certain chemicals over a long period of time are at higher risk for leukemia. Benzene is one of these chemicals.
- **Certain cancer drugs.** Some of the drugs used to treat other types of cancer may increase a person's risk of getting leukemia. However, this risk is very small when compared with the benefits of chemotherapy.
- **Viruses.** Scientists have identified a virus that seems to increase the risk for one very uncommon type of leukemia. However, this virus has no known connection with common forms of leukemia. (National Cancer Institute)
- A "weak relationship" has been observed between myeloid leukemia and smoking in men. But not for women or for other types of leukemia. [41]

These factors may add to any risk due to workplace exposure to ionizing radiation. Leukemia occurs in males more often than in females and in white people more often than in black people.

Rates of Leukemia in Exposed Counties

Los Alamos County

There have been very high rates of leukemia incidence reported in Los Alamos County; yet relatively low rates of cancer mortality. In the 1950's and 1960's, all blood and lymph cancers may have been increased in males in the county, due to occupational exposures during the early years of the nuclear complex. [61] In recent years, about two to three case have occurred annually. [13, 14] Los Alamos County ranked:

- Ranked second highest in incidence of leukemia and
- 21st in mortality among the 33 counties in New Mexico from 1970 to 1996. [33]

Rio Arriba County

There have been moderate rates of leukemia reported in Rio Arriba County for both cancer incidence and mortality. Rio Arriba County:

- Ranked 16th in incidence and
- 12th in mortality among the 33 counties in New Mexico from 1970 to 1996. [33]

---

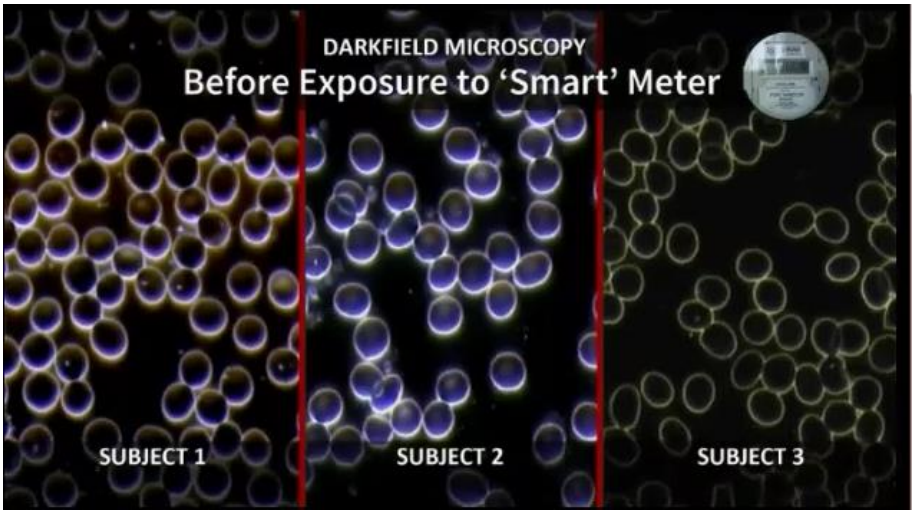
* *Findings were statistically significant (strong evidence)*

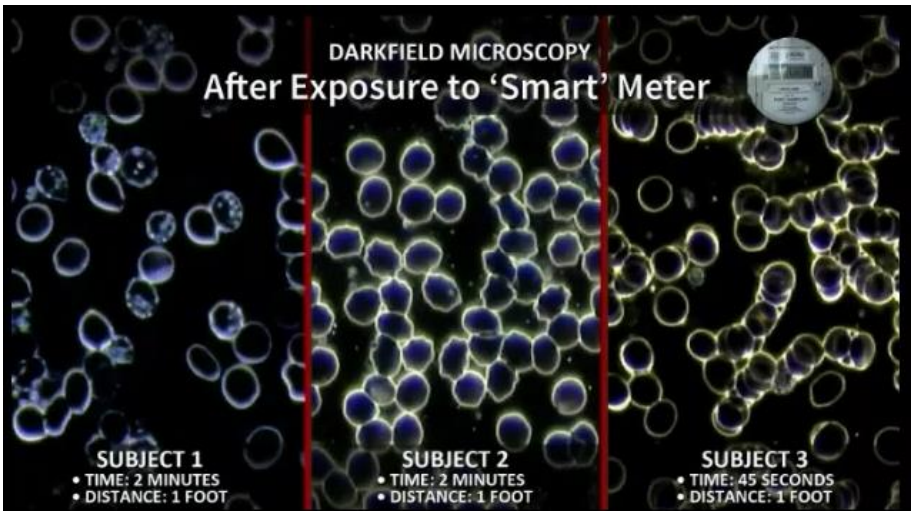
\+ *Evidence of a dose-response relationship (strongest evidence)*

Live Blood Analysis – Observable Effects of Radiofrequency Radiation from Smart Meters

From StopSmartMeters.org.uk

This clip from the film Take Back Your Power shows observable effects of the RF/MW radiation from a Smart Meter on human blood cells using dark-field microscopy.





More than 5,000 studies now show RF/MW radiation to be harmful to human biology, animals and plants. Acute and chronic exposure to RF (radio-frequency) and MW (microwave) radiation can, even at very low power-densities, lead to not only the negative health effects shown in this picture, but calcium ion damage in cells, endothelial cell dysfunction, nitric oxide depletion, oxidative stress, melatonin disruption, blood-brain-barrier leakage, DNA damage, sperm damage and more.

Glucose metabolism changes within the brain are observable after just minutes of cell phone use.

The mechanisms for damage from non-thermal, non-ionizing radiation exposure are now becoming clear.

Unfortunately, so-called "safety" thresholds maintained in the UK are woefully out of date and obsolete, permitting a deluge of highly-profitable, RF-emitting technologies to be introduced into our lives. Whilst

attempts by campaigners in every country are being made to stem and reverse the tide of these environmental toxins, you can take positive action to protect yourself and your family by limiting your own exposure to RF and MW-emitting devices, such as Smart Meters, cell phones, WiFi routers and devices, wireless baby monitors, wireless alarm systems, wireless games consoles, etc.

Long-term exposure to microwave radiation provokes cancer growth: evidences from radars and mobile communication systems.

Yakymenko I[1], Sidorik E, Kyrylenko S, Chekhun V.

Author information

Abstract

In this review we discuss alarming epidemiological and experimental data on possible carcinogenic effects of long term exposure to low intensity microwave (MW) radiation. Recently, a number of reports revealed that under certain conditions the irradiation by low intensity MW can substantially induce cancer progression in humans and in animal models. The carcinogenic effect of MW irradiation is typically manifested after long term (up to 10 years and more) exposure. Nevertheless, even a year of operation of a powerful base transmitting station for mobile communication reportedly resulted in a dramatic increase of cancer incidence among population living nearby. In addition, model studies in rodents unveiled a significant increase in carcinogenesis after 17-24 months of MW exposure both in tumor-prone and intact animals. To that, such metabolic changes, as overproduction of reactive oxygen species, 8-hydroxi-2-deoxyguanosine formation, or ornithine decarboxylase activation under exposure to low intensity MW confirm a stress impact of this factor on living cells. We also address the issue of standards for assessment of biological effects of irradiation. It is now becoming increasingly evident that assessment of biological effects of non-ionizing radiation based on physical (thermal) approach used in recommendations of current regulatory bodies, including the International Commission on Non-Ionizing Radiation Protection (ICNIRP) Guidelines, requires urgent reevaluation. We conclude that recent data strongly point to the need for re-elaboration of the current safety limits for non-ionizing radiation using recently obtained knowledge. We also emphasize that the everyday exposure of both occupational and general public to MW radiation should be regulated based on a precautionary principles which imply maximum restriction of excessive exposure.

Summary. In this review we discuss alarming epidemiological and experimental data on possible carcinogenic effects of long term exposure to low intensity microwave (MW) radiation. Recently, a number of reports revealed that under certain conditions the irradiation by low intensity MW can substantially induce cancer progression in humans and in animal models. The carcinogenic effect of MW irradiation is typically manifested after long term (up to 10 years and more) exposure. Nevertheless, even a year of operation of a powerful base transmitting station for mobile communication reportedly resulted in a dramatic increase of cancer incidence among population living nearby. In addition, model studies in rodents unveiled a significant increase in carcinogenesis after 17-24 months of MW exposure both in tumor-prone and intact animals. To that, such metabolic changes, as overproduction of reactive oxygen species, 8-hydroxi-2-deoxyguanosine formation, or ornithine decarboxylase activation under exposure to low intensity MW confirm a stress impact of this factor on living cells. We also address the issue of standards for assessment of biological effects of irradiation. It is now becoming increasingly evident that assessment of biological effects of non-ionizing radiation based on physical (thermal) approach used in recommendations of current regulatory bodies, including the International Commission on Non-Ionizing Radiation Protection (ICNIRP) Guidelines, requires urgent reevaluation. We conclude that recent data strongly point to the need for re-elaboration of the current safety limits for non-ionizing radiation using recently obtained knowledge. We also emphasize that the everyday exposure of both occupational and general public to MW radiation should be regulated based on a precautionary principles which imply maximum restriction of excessive exposure.

INTRODUCTION

Electromagnetic radiation (EMR) became one of the most significant and fastest growing environmental factors due to intensive development of communication technologies during the last decades. Currently, according to expert estimations, the level of electromagnetic radiation from artificial sources exceeds the level of natural electromagnetic fields by thousand folds. The active development of mobile communication technologies over the world will only raise this level further. In this connection the problem of possible adverse effects of anthropogenic EMR on human health and particularly strictest assessment of possible carcinogenic effects of EMR is extremely important.

In August 2007 an international working group of renowned scientists and public health experts released a report on electromagnetic fields (EMF) and human health [1]. It raised a serious concern about safety limits for public electromagnetic irradiation from power lines, cell phones, radars, and other sources of EMF exposure in daily life. The authors concluded that the existing public safety limits were inadequate to protect public health. Moreover, very recently a vast number of new extremely important studies in this field have been published. Importantly, nowadays the problem is discussed on highest political level over the world. It appears that the most sound political document in Europe is a European Parliament Resolution from April 2, 2009 (*http://www.europarl.europa.eu*), where the direct appeals to activate the research and business strategy for effective solving of the problem over the member states were indicated.

In this review we would like to analyze the results of studies on specific biological effects of microwaves (MW), both epidemiological and experimental that deal with cancer promotion by long term low intensity microwave irradiation of human/animal beings. We will concentrate on unequivocal studies and will not analyze ambiguous data. For additional analysis of microwave risks we can recommend recently published reviews [2—10].

MICROWAVES OF RADARS AND MOBILE COMMUNICATION SYSTEMS

Microwaves are non-ionizing electromagnetic radiation. That means MW is a type of electromagnetic radiation which does not carry enough energy for ionization of atoms and molecules under normal conditions and unlike the ionizing radiation this kind of radiation generally has not enough energy for breaking the intermolecular bonds or for breakaway of electrons from atoms or molecules. MW comprise a part of radiofrequency range. Radiofrequency radiation (RF) refers to electromagnetic waves with a rate of oscillation of electromagnetic fields in the range from 30 kHz to 300 GHz. As any other electromagnetic waves, the radio waves are pulses of electric and magnetic fields. These fields regenerate each other as they move through the space at the speed of light. MW have frequencies from 300 MHz to 300 GHz. As MW have the highest frequency among other RF, it carries the highest energy and produce most thermal effect upon interaction with the matter.

The main sources of radiofrequency radiation during a long period in previous century were broadcasting systems. In some cases, for example, in military and aviation the most powerful local sources of radiofrequency radiation were and still are radars (RAdio Detection And Ranging). However, the situation changed dramatically for general population during recent decades; and currently the most prevailing sources of RF in nearest human environment are mobile communication systems. It is important that both radars and systems for mobile communication use the same microwave part of radiofrequency spectrum.

Radar systems are type of powerful sources of pulsed MW which generally effect only certain groups of military or service staff or population living nearby. Radars are detection systems which use MW to determine both moving and fixed objects like aircraft, ships, missiles, etc. Depending on the tasks they use different frequencies of MW, from 1GHz to 12 GHz.

Mobile communication systems are undoubtedly the most source of MW in human environment over the world nowadays. Starting from the first commercial mobile phone networks in Japan, Europe and USA since 1979—1983 the number of active users of mobile telephony increased globally to over five billion. In developed countries the number of cellular phone users today is over the point of saturation. It means that many people use more than one cell phone. The initial age of youngest users of cell phone is estimated as three years old [5].

Mobile communication technology utilizes MW for connection of cell phones and base transmitting stations. Phone refers to as mobile because it is free from wire connection and it refers to as cellular/cell because technology utilizes cellular network principle. All area is covered by many base transmitting stations, each station operates in one cell (part of area) and cell phone automatically changes the station when moves from one cell to another. In GSM (Global System for Mobile communication) standard, which covers about 80% of all services over the world the frequencies of electromagnetic waves used are about 850; 900; 1850; or 1900 MHz, which belongs to the microwave range. The useful information (sounds or images) is transferred by modulation of electromagnetic wave frequency. In GSM standard TDMA (Time Division Multiple Access) principle is realized. This means a part-time access of each consumer to the logical channel with frequency of channel rotation about 217 Hz. Thus, both base transmitting stations and cell phones emit MW modulated according to the digital standard.

SAFETY LIMITS FOR MICROWAVE RADIATION

The main international recommendations on safety levels of non-ionizing electromagnetic radiation is *Guidelines for Limiting Exposure to Time-Varying Electric, Magnetic, and Electromagnetic Fields (up to 300 GHz)* of International Commission on Non-Ionizing Radiation Protection [11]. The document gives recommended safety limits in all ranges of EMR both for occupational and general public exposure. “Basis for limitation exposure” is dramatically important for understanding the imperfection of this document. Accordingly, the document directly states that “Induction of cancer from long-term EMF exposure was not considered to be established, and so these guidelines are based on short-term, immediate health effects such as stimulation of peripheral nerves and muscles, shocks and burns caused by touching conducting objects, and elevated tissue temperatures resulting from absorption of energy during exposure to EMF.” However, the basic assumption of that is questioned nowadays by numerous data sources.

According to that document a few parameters of EMR energy are recommended to be restricted. Among them the two parameters are used the most often: 1) Specific Absorption Rate (SAR) in W/kg, which indicates the EMR energy absorbed per mass unit of human tissue per second; and 2) power density or intensity of incident radiation in W/m2 (or μW/ cm2) which indicates the amount of electromagnetic energy which falls on a unit of surface (under the right angle) per second. SAR safety limit for general public exposure indicated in Guidelines as 2 W/kg (for head and trunk) for the microwave range. To that, this limit is accepted by industry as mandatory for every commercial cell phone over the world, and real value of SAR of each cell phone model must be indicated in technical specification of the model. Unfortunately, SAR is rather sophisticated index for measurement. Moreover, only models of adult human head are currently used by industry for calculation of SAR, while real SAR values depend on a geometry and structure of tissues and, for example, was shown to be much higher for a child head than for the adult one [12—14].

Power density, or intensity of radiation, is much more direct and simple index as compared to SAR, although it does not estimate the specificity of interaction of EMR and the matter. Occupational exposure limits in microwave range according to ICNIRP are 10–50 W/ m2. Public exposure limits for microwaves according to ICNIRP recommendation were set to 2–10 W/m2 (or 200—1000 μW/cm2) depending on frequency. For example, for GSM—900 MHz standard ICNIRP safety limit will be calculated as 450 μW/cm2 [11].

It is important to note that ICNIRP recommendations have no legal validity, as it is only a recommendation. Each country has their own national legislation in the field of electromagnetic safety, and national limits are rather different in different countries. **Some countries such as the USA and Germany conformed national EMR limits to ICNIRP recommendation. Other countries have much tougher national limits as compared with ICNIRP guidelines.** For example, for GSM-900 MHz standard MW safety limits are: in Italy, Russia and China — 10 μW/cm2, in Switzerland — 4 μW/cm2, in Ukraine — 2.5 μW/cm2 [1]. As we can see, some countries, including Ukraine, have extremely strict national safety limits. Such national positions are explained first of all by long-term national research traditions in a field of electromagnetic biology, and on experience in studying the non-thermal biological effects of this kind of radiation. On the other hand, some countries like Switzerland follow a strict precautionary principle (Better protect than sorry).

RADAR RADIATION AND CANCER PROMOTION

Substantial military and occupational data indicate a significant effect of pulse microwaves on cancer development and other pathological conditions in human. Accordingly, a statistically significant increase in immature red blood cells among workers exposed to a radar was reported [15]. In addition, radar-exposed workers had significantly lower levels of leukocytes and thrombocytes than workers distant from MW sources.

Among Polish soldiers (128 thousand personnel subjects aged from 20 to 59 years), soldiers of 20—29 years old exposed to radar microwaves during 1970—1979 had cancer incidence rates 5.5 folds higher than non-exposed soldiers [16]. The greatest rise of cancer cases was detected in blood-forming organs and lymphatic tissues: by 13.9 folds for chronic myelocytic leukemia and 8.6 folds for myeloblastic leukemia. The level of mortality among all exposed personnel was significantly higher than in unexposed: for colorectal cancer (observed-expected ratio, OER 3.2; 95 %), for cancer of esophagus and stomach (OER 3.2; 95 %), cancer of blood-forming system and lymphatic tissues (OER 6.3; 95 %) [17].

Almost two times more cases of cancer were indicated in the high-exposed American naval personnel served during the Korean War (1950—1954) as compared with the low-exposed subjects among 40 thousands of personnel [18]. Death rates for aviation electronic technicians, the group with the highest exposure rate, were significantly higher than those for the other personnel during the following years up to 1974 [15].

A very substantial increase in cancer incidence was also detected in commercial airline pilots. Thus, the standardized incidence ratio (SIR) for malignant melanoma cases was 10.2; 95.5 % for pilots of commercial airlines in Iceland [19]. Significantly increased risks of acute myeloid leukemia (SIR 5.1), skin cancer, excluding melanoma (SIR 3.0) and total cancer (SIR 1.2) were observed also among Danish male jet pilots [20]. These data have been explained as a result of excess cosmic ionizing radiation or even excessive sun radiation during a leisure time. However, analysis of brain cancers among US Air Force personnel has revealed that non-ionizing radiation and particularly MW had significant effect on cancer development (odds ratio, OR 1.38; 95%), whereas ionizing radiation had negative association with cancer cases (OR 0.58; 95 %) [21]. To that, standardizing mortality ratio (SMR) for brain tumors was 2.1; 95 % among German male cockpit crew members (6,017 people) [22]. Cancer risk was significantly raised (risk ratio 2.2; 95%) among cockpit crew members employed for 30 years as compared to those employed for less than 10 years. In addition, Non-Hodgkin's lymphoma (NHL) was also increased (SMR 4.2; 95%) among male cabin crew members (20,757 people). Importantly, any increase in cancers associated with ionizing (cosmic) radiation was not detected in this cohort study.

In another report, six incident cases of testicular cancer occurred within a cohort of 340 police officers between 1979 and 1991 in Seattle, Washington, observed/expected ratio was 6.9; $p<0.001$ [23]. Occupational use of hand-held radar was the only shared risk factor among all six officers, and all had a routine habit of keeping the radar

gun directly in close proximity to their testicles. Similarly, in Ontario, Canada risk assessment among police officers exposed to radar devices for speed measurement (1,596 females and 20,601 males) revealed an increased risk among men for testicular cancer (SIR 1.3) and for melanoma (SIR 1.45; 95 %) [24].

In another study, eighty seven persons working with radars (and 150 matched control) were divided into risk groups according to frequencies of MW (200 KHz to 26 GHz) and power density (8 μW/cm2 to 300 μW/cm2) [15]. Three specific radiation cataracts in persons working with extremely high MW exposure were identified. Lens changes were associated with level of exposure in different risk groups.

Other occupational studies revealed the highest risk ratio (2.6) for acute myelogenous leukemia in radio and radar operators among all occupational groups studied [25]. In addition, excessive risk for breast cancer was detected (SIR 1.5) among Norwegian female radio and telegraph operators (2,619 women) with potential exposure to radio frequency (405 kHz — 25 MHz) [26].

RADIATION FROM MOBILE COMMUNICATION SYSTEMS AND CANCER PROMOTION

Cell phones. A significant increase of risk of particular brain tumors in long-term (10 years or more) users of cell phones and cordless phones has been detected in series of epidemiological studies of Swedish oncologist Prof. L. Hardell with colleagues [27–33]. It is important that for a short-term use of cell phones similar effects were absent or less evident [4].

The risk of development of high-grade glioma has increased in more than 3 times (OR 3.1; 95 %) for bilateral users of cell phones and in more than 5 times (OR 5.4; 95%) for ipsilateral users after 10 years of using [34].

The risk of development of acoustic neuroma for bilateral users of cell phones was OR 2.9; 95% and OR 3.5; 95 % for ipsilateral users after 10 years of using [29].

Notably, the highest risk of brain tumors has been detected in the youngest users of cell phones (20—29-yr) among all analyzed age groups (20—80 years old), with OR 5.91; 95% for ipsilateral use of cell phones. The highest risk was associated with more than 5-year using period in the 20—29-yr age group for analog cell phones (OR 8.17; 95%) [28].

International multiyear Interphone project conducted under the management of the World Health Organization and substantially supported by industry, was an interview-based case-control study with 2708 glioma and 2409 meningioma cases and matched controls, conducted in 13 countries using a common protocol [35]. The results of study were rather controversial. For example, **authors were forced to declare "a reduced odds ratio related to ever having been a regular mobile phone users was seen for glioma (OR 0.81; 95 %) and meningioma (OR 0.79; 95 %), possibly reflecting participation bias or other methodological limitations."** However, significantly increased risks of tumors development in "heavy" users of cell phones (with more than 1640 hours of using during less than four years) have been revealed in this study: for meningioma OR 4.8; 95 %, for glioma OR 3.77; 95% as compared with the matched controls [35]. One thousand and six hundred forty hours per four years means about one hour per day of a cell phone use. In this connection we can point to our data [36] that indicates amount of time which Ukrainian students (like students in other countries?) spend talking via cell phones every day. Our findings indicated that more than a half of them spend over one hour per day, and more than a quarter of them spend over two hours per day talking via cell phones every day.

Parotid gland, like a human brain, is another potential target for cell phone MW radiation during cell phone talks without hands-free devices. Thus, a study done by an Israeli team has indicated an association between a cell phone use and parotid gland tumors [37]. This study comprised 402 benign and 58 malignant cases of parotid gland tumors diagnosed in Israelis at age over 18 years in 2001—2003. The risk of parotid malignant tumors in intensive users of cell phones (for users with more than 5,479 hours of a use during less than five years) were OR 2.26; 95%. Recently new data have been published that totally a 4-fold increase of parotid malignant tumors in Israel during 1970—2006 took place, whereas other salivary glands tumors had been almost on a stable level during that period of time [38]. Previously, a Finnish study has revealed the OR 5.0; 95% for salivary gland cancer among all Finland digital cell phone subscribers compared with control population after one-two years of a cell phone use [39].

The odds ratio for Non-Hodgkin's lymphoma of T-cell, cutaneous and leukemia types has been found for analogue-cell-phone users as 3.4; 95%; for digital-phone users 6.1; 95 %; and for cordless-phone users 5.5; 95% by L. Hardell group [40]. An American study indicated OR 1.6; 95 % for NHL in users of cell phones with a period of use over eight years [41].

Uveal melanoma (in analysis of 118 cases with uveal melanoma and 475 controls in Germany) has been indicated to have odds ratio 4.2; 95% for people probable/certain exposed to cell phone radiation [42].

Testicular cancer (seminoma) risk had odds ratio 1.8; 95% for men keeping a cell phone during "stand by" in ipsilateral trousers pocket [43]. The results have been based on 542 cases of seminoma in Sweden.

Base transmitting stations. During the last decades more than one and half million base transmitting stations for mobile communication have been installed over the world. However, the World Health Organization suggested a priority to study effects mainly of cell phones, while discouraging studies on the effects of transmitting stations (with an exception of years 2003—2006 when WHO recommended studies of possible effects of radiation of transmitting stations as well) [44]. This is probably the main reason why only a few publications on this particular problem can be found to date [45—49].

The comparison of cancer cases among people living up to 400 m from base transmitting station and people living further than 400 m from station during 1994—2004 was carried out in Germany [48]. A total increase of cancer cases among people living nearby to transmitting station over the control population was 1.26 times during the first five-year period (1994—1998), and 3.11 times during the second five-year period (1999—2004) of operation of the station. Particularly, in the second period the increase of cancer cases was statistically significant both as compared with the population from more distant area and with the expected background incidence.

Population (n=622) living in the area nearby (up to 350 m) the cell phone base transmitting station (850 MHz, 1500 watt of full power) during one year of operation and matched individuals (n=1222) from other area have been compared In Israel [47]. There were 4.15 times more cases of cancer in transmitted station area than in the rest of a city. Relative cancer rates for females were 10.5 for close to station area, 0.6 for control area and 1 for the whole town. Cancer incidence of women in close to base station area was significantly higher ($p<0.0001$) as compared with the control area and the whole city. Keeping in mind that very significant increase in a number of cancer cases took place during only one year period, the authors of the study suggested that MW could provoke latent cases of cancer in inhabitants of the area nearby transmitting station.

French and Spanish researchers also revealed that inhabitants living near base station for mobile communication (up to 300 m) developed significantly higher rates of many subjective symptoms of health

like headache, fatigue, sleep disorder, depression as compared with the matched control from distant area [49, 50].

RODENT MODEL Of CANCER PROMOTION BY MICROWAVES

A highly representative research has been carried out at the University of Washington, Seattle commissioned by US Air Force [51]. The experimental rats (100 animals) were exposed during 24 months at 21.5 hours per day to 2,450-MHz http://canadapharmacy-drugnorx.com/ pulsed microwaves at 800 pps with a 10 μs pulse width. The pulsed microwaves were square-wave modulated at 8 Hz. An average SAR was 0.4 W/kg for a 200-g rat. It was a model of long-term irradiation of Air Force pilots to pulsed microwaves of radar systems. Totally 155 indexes of metabolisms were checked out during the study. As a result, the most expressive effect of long-term MW irradiation of animals was a dramatic increase in a level of cancer cases. In total, 3.6 folds more cancer cases were detected in irradiated animals than in matched control. Lymphoma cases were diagnosed in the irradiated animals 4.5 times more often than in the control group. In addition, benign tumors of adrenal were detected seven folds more often in the irradiated animals than in the control.

In the next study under US Air Force contract, 200 female C3H/HeJ mice were exposed for 21 months (22 h/day, 7 days/week) to a horizontally polarized 435 MHz pulse-wave (1.0 ps pulse width, 1.0 kHz pulse rate) RF radiation environment with an incident power density of 1.0 mW/cm2 (SAR 0.32 W/kg), while 200 mice were sham-exposed [52]. Although under the conditions of this study, an exposure of mice prone to mammary tumors did not affect the incidence of mammary tumors, when compared with the controls, some other tumor cases increased markedly. For example, bilateral cases of ovary epithelial stromal tumor raised by five folds; multiple cases of hepatocellular carcinoma, raised 3 folds, and adrenal gland tumor cases (total) raised 1.63 folds.

In the third published study of this series [53] the same prone-mammary tumor mice were irradiated during 20 months to continuous wave 2450 MHz MW radiation with SAR from 0.3 to 1 W/kg (20 h/day, 7 days/week). A hundred mice were exposed, while 100 mice were used as sham-exposed. As a result, the exposed mice had higher level of mammary tumors (1.27 folds), and higher total level of all types of tumor (1.38 folds) as compared with sham-exposed; the difference between groups was statistically insignificant. Meanwhile, multiple mammary tumor cases occurred in exposed mice twice more frequently than in sham exposed.

In other study mice with high incidence of spontaneous breast cancer and mice treated with 3,4-benzopyrene (BP) were irradiated to continuous wave 2,450 MHz microwaves in an anechoic chamber at 5 or 15 mW/cm2 (2 hours daily, 6 sessions per week, 3 months) [54]. Irradiation with MW at either 5 or 15 mW/cm2 resulted in acceleration of development of BP-induced skin cancer. Microwaves-exposed mice with high incidence of spontaneous breast cancer developed breast tumors earlier than control. Authors indicated that the promotion of cancer development and lowering of natural antineoplastic resistance was similar in mice exposed to MW at 5 mW/cm2 and chronically stressed by confinement, but level of cancer cases in animals exposed to 15 mW/cm2 was significantly higher as compared to chronically stressed by confinement control.

And in well-known study of M. Ripacholi *et al.* (1997)transgenic mice moderately predisposed to develop lymphoma spontaneously have been used for exposure to MW of 900 MHz, with pulse repetition frequency of 217 Hz, incident power densities of 2.6—13 W/m2, and average SAR of 0.13—1.4 W/kg [55]. One group of mice (101 females) has been exposed for two 30-min periods per day during 18 months. Another group of mice (100 females) has been a sham-exposed control. Lymphoma risk was significantly higher, more than twice, in the exposed mice than in the matched control (OR 2.4; 95 %). In particular, follicular lymphoma was the major contributor to the increased tumor incidence.

MICROWAVES AND CELL METABOLISM

Free radical species, including reactive oxygen species (ROS), is an intrinsic feature of cell metabolism [56–58]. But disturbance of redox balance, uncontrolled activation of free radical processes, overproduction of ROS and/or suppression of antioxidant defense in cell often are the important signals of some hazardous changes in cell metabolism [59, 60]. That is why data indicated oxidative effect of some factor is extremely important in risk-assessment research.

A significant increase of ROS and nitrogen oxide generation in cells under non-thermal intensities of MW has been detected both *in vivo* [61—67] and *in vitro* [68—72]. Possibilities of mitochondrial and membrane NADH oxidase dependent ways of ROS generation in exposed cells have been suggested [71, 72]. Accordingly, it was found that the first step in MW (875 MHz, 0.07 mW/cm2) interaction with model cells (Rat1 and HeLa) was mediated in the plasma membrane by NADH oxidase, which can rapidly (during the minutes) generate ROS [72]. ROS directly stimulate matrix metalloproteinases and allow them to cleave and release heparin-binding epidermal growth factor (EGF). This secreted factor activates the EGF receptor, which in turn activates the extracellular-signal-regulated kinase (ERK) cascade and thereby induces transcription and other cellular pathways. On the other hand, on the model of purified human spermatozoa exposed to MW (1.8 GHz, SAR from 0.4 W/kg to 27.5 W/kg) a significant overproduction of ROS in mitochondria was detected, along with a significant reduction in motility and vitality of spermatozoa [71]. All observed effects were significantly correlated with SAR levels, suggesting that significant effects of MW exposure occurred under non-thermal levels of MW.

Therefore, MW can induce cellular oxidative stress, which in turn can cause cancer stimulation [57, 59]. To that, it is known nowadays that in addition to damage via oxidative stress, ROS in cells can play a role of a secondary messenger for certain intracellular signaling cascades which can induce oncogenic transformation [60].

DNA damage in cells exposed to low-intensive microwaves both *in vivo* and *in vitro* was demonstrated during the last years in more than 50 independent studies [73]. The most often method used for detection of DNA damage after the MW exposure was alkaline Comet Assay. A statistically significant increase of both single strand and/or double strand breaks of DNA has been detected in humans [74, 75], animal models [76—79] and cell cultures [76, 80—83] exposed to low intensity microwaves.

Recently, an oxygen damage of DNA in human spermatozoa through formation of 8-hydroxi-2-deoxyguanosine (8-OH-dG) under non-thermal microwaves irradiation *in vitro* has been demonstrated [71].

Consequently, as DNA mutation is a critical step in carcinogenesis and increased level of 8-OH-dG takes place in many tumors [60], the possibility of MW to initiate oxidative damage of DNA is extremely dangerous signal for risk-assessment studies.

Ornithine decarboxylase (ODC) significantly changes its activity under conditions of non-thermal microwave exposure [84—88]. It was one of the first markers of carcinogenesis revealed to be activated under the low intensity microwaves exposure. ODC is involved in processes of cell growth and differentiation, and its activity is raised in tumor cells. Although overexpression of ODC is not sufficient for transformation of normal cells into tumorigenic ones, an increased activity of the enzyme was shown to promote the development of tumors from pre-tumor cells [89].

DISCUSSION AND CONCLUSIONS

In this review we presented evidences for carcinogenic effects of low intensity microwaves. Both epidemiological and experimental data led us to a conclusion that at least under certain conditions the exposure to long term low intensity MW can lead to tumorigenesis. Supporting evidences come from statistically significant epidemiological data based either on long-term analysis, e.g., on mortality of US Navy personnel in 20 years after expose during the Korean War [15], or on relatively short, one year exposure, e.g., by base transmitting station for mobile communication in Israel [47]. In the latter case we fully agree with the authors that MW exposure most likely results in acceleration of pre-existed cancer development. It is of note here that the same conclusion was drawn in epidemiological research on fast increase cancer incidence among adult population in Colorado exposed to extremely low frequency radiation [90].

The main shortcoming of the most epidemiological data, both in military studies and in mobile communication risk assessment, is a lack of a strict dose measurement of exposure. We strongly suggest that in the forthcoming epidemiological studies the correct measurement of intensity and dosage of exposure should be obligatory. The example of a large-scale epidemiological research employing personal MW dosimeters can be found in recent studies in Germany [91—94]. On the other hand, we also realize that the levels of the MW exposure in contemporary epidemiological studies, at least in those which deal with mobile communication systems, were within the official “safety limits” set by appropriate national standards and ICNIRP recommendations. Therefore, taking into account the reviewed data, we conclude that the relatively long-term (e.g., 10 years) exposure to microwaves emitted from mobile communication devices operating within “safety limits” set by current regulating bodies can be considered as a potential factor for promotion of cancer growth. Indeed, in the most studies on rodents the intensity of MW exposure was appropriately measured, and in majority of them the MW intensity was below ICNIRP safety limits. Nevertheless, majority of these studies to a greater or lesser extent demonstrated obvious carcinogenic effects after long term exposure (up to 24 months). This further emphasizes that at least under certain conditions the exposure to both pulsed and continuous MW with intensities below the current official “safety limits” can indeed promote cancer development.

In addition, experimental evidences of involvement of typical markers of carcinogenesis like overproduction of reactive oxygen species or formation of 8-OH-dG under conditions of MW exposure further indicate potential danger of this type of radiation for human health. It is important to emphasize here that experimental data, especially obtained in studies *in vitro* often reveal significant biological effects even after short-term (e.g., only a few minutes) [72] and/or extremely weak intensity of exposure to MW (by several orders of magnitude lower than in ICNIRP recommendations) [95]. Taking these data into account we strongly suggest that currently used “thermal” assessment of potential hazards of MW exposure is far from being appropriate and safe.

Taken together, we state here that nowadays there is enough convincing data to appropriately assert that the long-term exposure to low intensity electromagnetic microwaves can indeed promote cancer development. To that, the official recommendations by ICNIRP and safety limits set by many national regulatory bodies for technical devices emitting microwave radiation, first of all for mobile communication systems, must be re-assessed according to the recent alarming data; and additional studies for unprejudiced risk assessment must be carried out. At present, we strongly suggest for a wide implementation of precautionary principle for everyday microwave exposure that implies maximum restriction of excessive exposure.

CONFLICT OF INTEREST

The authors declare no conflict of interest.

Low doses of radiation used in medical imaging lead to mutations in cell cultures

Discovery that radiation creates breaks that allow in foreign DNA must be confirmed in animal studies

Date: January 16, 2020
Source: PLOS
Summary: Common medical imaging procedures use low doses of radiation that are believed to be safe. A new study, however, finds that in human cell cultures, these doses create breaks that allow extra bits of DNA to integrate into the chromosome.

Common medical imaging procedures use low doses of radiation that are believed to be safe. A new study, however, finds that in human cell cultures, these doses create breaks that allow extra bits of DNA to integrate into the chromosome. Roland Kanaar and Alex Zelensky of Erasmus University Medical Center and Oncode Institute and colleagues report these new findings in a study published 16th January in *PLOS Genetics*.

Scientists have long known that exposing cells to high doses of ionizing radiation generates mutations by creating double-strand breaks that let in external segments of DNA. These extraneous fragments of DNA can occur in the nucleus, left over from natural processes, such as genomic DNA repair and viral infections. In the new study, researchers investigated whether low doses of ionizing radiation have damaging side effects by irradiating human and mouse cells grown in the lab. When they counted the cells that had taken up foreign DNA, they found that low doses of radiation, in the upper range of common diagnostic procedures, create mutations through inserted DNA even more efficiently than the much larger doses studied previously.

While the new results in cell cultures are potentially concerning, the study's authors stress that translating radiation's effects on lab-grown cell cultures to effects in the body is premature. Future experiments using animal models will be necessary to determine the full effects of low-dose radiation, and whether its use in medical imaging has an impact on patient health. If the same phenomenon does occur inside the body, then doctors may need to take into account levels of extraneous DNA, such those resulting from a long-term viral infection, when assessing a patient's risk from a procedure that requires radiation.

"Most molecular radiobiological research is focused on high doses of ionizing radiation relevant to cancer treatment, while effects of physiologically relevant doses of radiation on the cell are notoriously difficult to study at the molecular level," said author Roland Kanaar. "Our discovery that mutagenic insertion of foreign DNA into cell's genome is remarkably responsive to doses encountered during diagnostic, rather than therapeutic, procedures provides a new simple and sensitive tool to study their consequences and revealed surprising molecular genetic details of how cells cope with natural amounts of DNA damage."

Electromagnetic Hypersensitivity: Biological Effects of Dirty Electricity with Emphasis on Diabetes and Multiple Sclerosis

MAGDA HAVAS

Environmental and Resource Studies, Trent University, Peterborough, Ontario, Canada

Dirty electricity is a ubiquitous pollutant. It flows along wires and radiates from them and involves both extremely low frequency electromagnetic fields and radio frequency radiation. Until recently, dirty electricity has been largely ignored by the scientific community. Recent inventions of metering and filter equipment provide scientists with the tools to measure and reduce dirty electricity on electrical wires. Several case studies and anecdotal reports are presented. Graham/Stetzer (GS) filters have been installed in schools with sick building syndrome and both staff and students reported improved health and more energy. The number of students needing inhalers for asthma was reduced in one school and student behavior associated with ADD/ADHD improved in another school. Blood sugar levels for some diabetics respond to the amount of dirty electricity in their environment. Type 1 diabetics require less insulin and Type 2 diabetics have lower blood sugar levels in an electromagnetically clean environment. Individuals diagnosed with multiple sclerosis have better balance and fewer tremors. Those requiring a cane walked unassisted within a few days to weeks after GS filters were installed in their home. Several disorders, including asthma, ADD/ADHD, diabetes, multiple sclerosis, chronic fatigue, fibromyalgia, are increasing at an alarming rate, as is electromagnetic pollution in the form of dirty electricity, ground current, and radio frequency radiation from wireless devices. The connection between electromagnetic pollution and these disorders needs to be investigated and the percentage of people sensitive to this form of energy needs to be determined.

Keywords Diabetes; Dirty electricity; Electromagnetic hypersensitivity; Multiple sclerosis; Power quality; Radio frequency.

Introduction

Most of the research on the biological effects of nonionizing radiation is done at one of two frequency ranges: extremely low frequency (ELF) associated with electricity (50/60 Hz) and radio frequency (RF) associated with wireless telecommunication

Address correspondence to Magda Havas, Environmental and Resource Studies, Trent University, 1600 West Band Drive, Peterborough, ON K9J 7B8, Canada; E-mail: mhavas@trentu.ca

devices (800 MHz to 2.5 GHz range). An intermediate frequency range, at the low end of the RF spectrum (kHz), flows along and radiates from wires (dirty electricity) and thus has characteristics of the two major types of electromagnetic pollution mentioned above. Scientists doing research on the biological effects of power line frequencies seldom measure this frequency range and thus ignore the effects it might have on health.

Recent advances in filtering technology (Graham/Stetzer or GS filters) and measuring equipment (microsurge meter) enable scientists to test for dirty electricity and to reduce it on indoor wires. In this article, case studies are presented of individuals who have benefited after the dirty electricity in their environment was reduced. This technology provides scientists with the tools to monitor, reduce, and experiment with a frequency range that, until now, has been largely ignored and it may help those who suffer from symptoms of electromagnetic hypersensitivity (EHS).

Dirty Electricity

Poor power quality, also known as dirty electricity, has been a concern for the electric utility for decades. Dirty electricity refers to electromagnetic energy that flows along a conductor and deviates from a pure 60-Hz sine wave (Figure 1). It has both harmonic and non harmonic (transient) components and emerged as a problem in the late 1970s with the increasing use of electronic devices that produce nonlinear loads. Karl Stahlkopf, a vice president of the Electric Power Research Institute (EPRI), estimates that dirty power costs U.S. industry between $4 and $6 billion a year, and that it is likely to get worse before it can be mitigated. EPRI expects that 70% of all electricity produced within the U.S. will flow through electronic devices by 2002, compared with 30% in 1999 (Fortune, 1999).

Dirty electricity is ubiquitous. It is generated by electronic equipment such as computers, plasma televisions, energy efficient appliances, dimmer switches, as

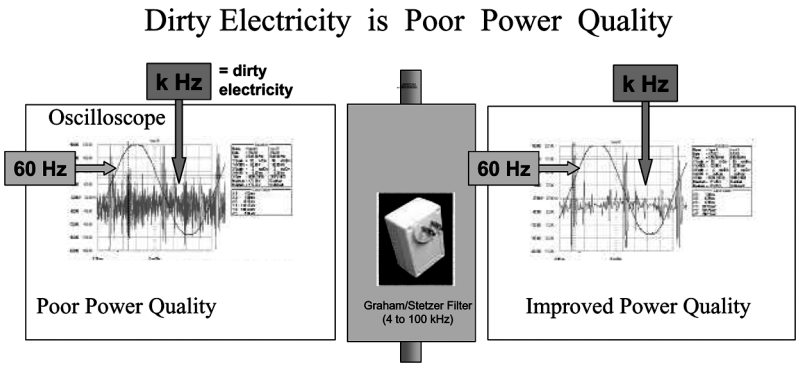

Figure 1. Visual display of dirty electricity (kHz range) and 60 Hz power frequency without (left) and with (right) Graham/Stetzer filters. A 2-channel Fluke 199 Scopemeter was attached to a ubiquitous filter to separate the 60 Hz frequency from the dirty electricity (Graham, 2000). The improved power quality has fewer spikes and smaller amplitude for the high frequency transients. The GS filters have no effect on the 60 Hz sine wave.

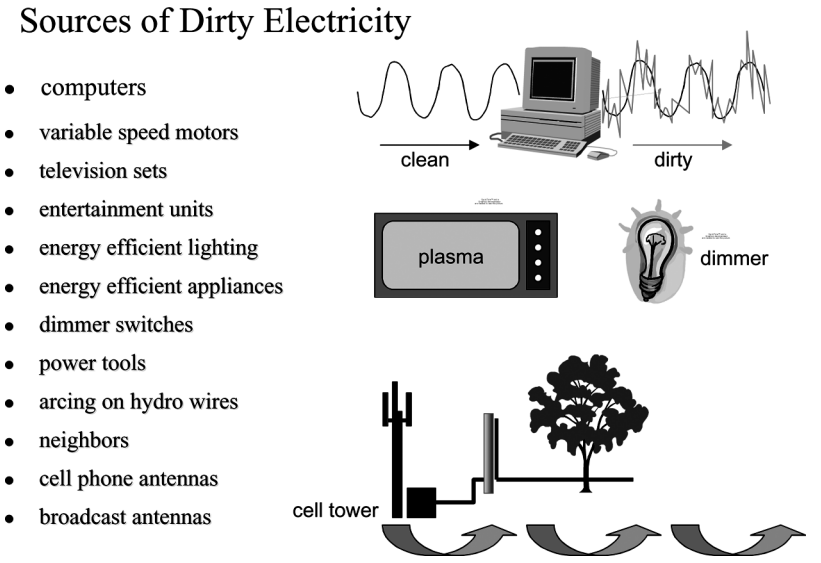

Figure 2. Sources of dirty electricity include electronic equipment and appliances, arcing on wires, and unfiltered cell phone and broadcast frequencies from nearby antennas.

well as arcing on electrical conductors caused by loose wires or contact with trees (Figure 2). Dirty electricity is thus produced within buildings but can also enter buildings from neighbors who share the same transformer. Mobile or broadcast antennas, if not properly filtered, can also contribute to high frequencies on electrical wires in nearby buildings.

The IEEE 519-1992 recommends installing filters to control harmonic distortions on power lines. With 5 kV and higher voltage distribution lines the IEEE identifies voltage notching, which produces both harmonic and nonharmonic frequencies in the radio frequency (RF) range and, as such, can introduce harmful effects associated with spurious RF. Industry uses large capacitors to protect sensitive equipment from power surges, especially in production line work, where malfunctions and down time are costly. Until now filters have not been available for in home use.

Professor Martin Graham from UC Berkeley and power quality expert, Dave Stetzer, President of Stetzer Electric in Wisconsin, have designed a filter that can be used inside buildings to clean the power that enters the building as well as the dirty electricity generated within the building. The Graham/Stetzer (GS) filter is a compact unit that plugs into an electrical outlet (Figure 3). It contains an electrical capacitor that shorts-out the high frequency transients on the circuit and is most effective when placed close to the appliance generating the dirty electricity. The GS filter has optimum filtering capacity between 4 and 100 kHz (Graham, 2000, 2002).

In Russia, the safety guidelines for electric and magnetic field exposure are frequency specific. For frequencies between 5 Hz and 2 kHz, the guideline is 25 V/m for electric fields and 0.25 μT (2.5 mG) for magnetic fields. For frequencies between 2 and 400 kHz, the guidelines are lower by a factor of 10. Since energy is proportional to frequency, the energy is 1,000 times higher at 60 kHz than it is at 60 Hz.

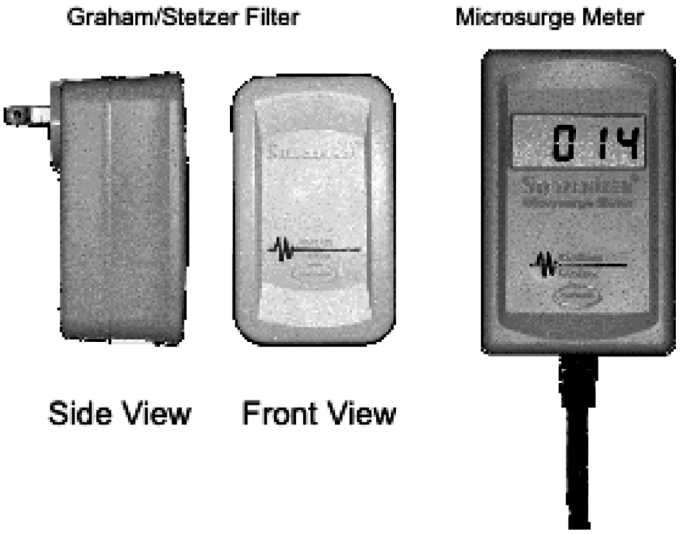

Figure 3. Equipment used to reduce and monitor dirty electricity inside buildings: the Graham/Stetzer filter and the microsurge meter.

The microsurge meter (Figure 3), also designed by Graham and Stetzer, measures the energy associated with dirty electricity in GS units with a range from 1 to 1999 and an accuracy of ±5% (Graham, 2003). The Health Department of the Republic of Kazakhstan (2003) has stated that any reading on the microsurge meter exceeding 50 is unacceptable and steps must be taken to lower such readings. Experience with this meter suggests that values below 30 GS units are undesirable and that extremely sensitive individuals may not see any benefits until the values are at or below 20 GS units. In some extremely dirty environments it is not possible to achieve such low values.

In the following, a number of case studies are presented.

Case Studies

GS filters have been placed in homes, offices, and schools. People report having better sleep, more energy, and less pain. They document cognitive improvements in memory and concentration. Symptoms of radio wave sickness or electrical hypersensitivity (Table 1) are often reduced or eliminated in the filtered environment.

GS filters placed in one Wisconsin school that had sick building syndrome, significantly improved power quality. Shortly after the filters were installed, the health and energy level of staff and students began to improve. According to the District Nurse, of the 37 students in the school who used inhalers on a daily basis, only 3 required inhalers and only for exercise-induced asthma after the filters were in place (Sbraggia, 2002).

GS filters were placed in a Toronto school and approximately 50% of the teachers documented improvements in energy, performance, mood, and/or health in a single blind study (Havas et al., 2004). Student behavior, especially at the elementary level, also improved. The symptoms that changed were ones we associate

Table 1
Symptoms of radio wave sickness first documented among radar workers during the Second World War resemble those now associated with electromagnetic hypersensitivity

Symptoms of radio wave sickness* (Firstenberg, 2001)
Neurological: Headaches, dizziness, nausea, difficulty concentrating, memory loss, irritability, depression, anxiety, insomnia, fatigue, weakness, tremors, muscle spasms, numbness, tingling, altered reflexes, muscle and joint paint, leg/foot pain, "flu-like" symptoms, fever. More severe reactions can include seizures, paralysis, psychosis, and stroke.
Cardiac: Palpitations, arrhythmias, pain or pressure in the chest, low or high blood pressure, slow or fast heart rate, shortness of breath.
Respiratory: Sinusitis, bronchitis, pneumonia, asthma.
Dermatological: Skin rash, itching, burning, facial flushing.
Ophthalmologic: Pain or burning in the eyes, pressure in/behind the eyes, deteriorating vision, floaters, cataracts.
Others: Digestive problems, abdominal pain, enlarged thyroid, testicular/ovarian pain, dryness of lips, tongue, mouth, eyes, great thirst, dehydration, nosebleeds, internal bleeding, altered sugar metabolism, immune abnormalities, redistribution of metals within the body, hair loss, pain in the teeth, deteriorating fillings, impaired sense of smell, ringing in the ears.

**Note:* These symptoms resemble symptoms associated with electrical hypersensitivity.

with attention deficit disorder (ADD) and attention deficit hyperactivity disorder (ADHD). This begs the question, "How much of the increase in ADD/ADHD among young people is due to electromagnetic pollution and poor electromagnetic hygiene?"

People with situational tinnitus (ringing in the ears that is present only in certain environments, often where RF is present) have documented improvements as well after the filters were installed in their home, as have those individuals who are otherwise healthy (Havas and Stetzer, 2004). Two diseases we seldom associate with electromagnetic hypersensitivity are diabetes and multiple sclerosis (MS). What follows are case studies that document the response to dirty electricity of diabetics and those with MS.

Diabetes

Two case studies are presented. (1) A 51-year old male with Type 2 diabetes who does not take medication and (2) an 80-year old female with Type 1 diabetes who takes insulin twice a day. A 51-year old male with Type 2 diabetes monitored dirty electricity in his environment and his blood sugar levels randomly throughout the day for approximately one month in 2003. The microsurge meter was not yet available to measure dirty electricity so he used a Protek 506 Digital Multimeter and measured the peak-to-peak voltage. His blood sugar levels were positively correlated with the amount of dirty electricity in his environment (Figure 4). One day he was

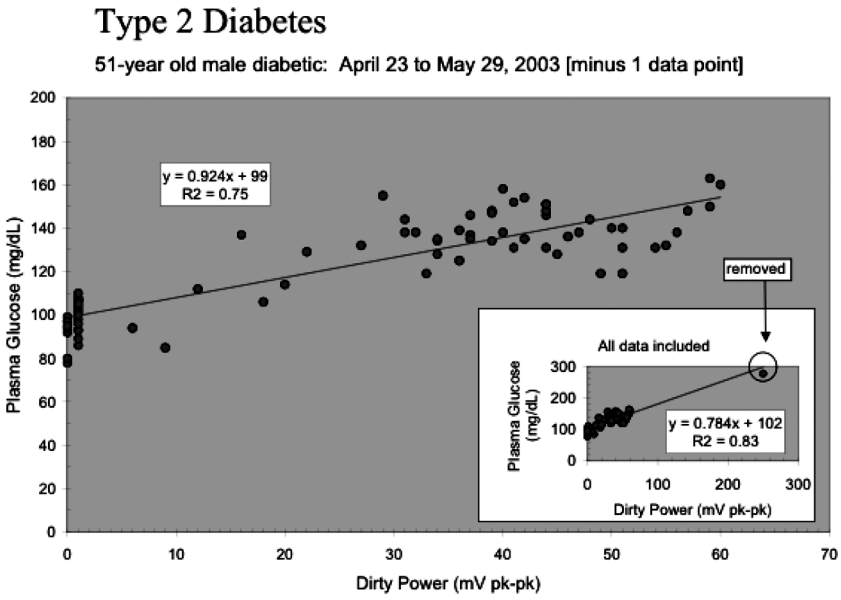

Figure 4. Fifty-one year old male with Type 2 diabetes. His plasma glucose levels correlate with the dirty electricity in his environment. Insert shows exposure on one day to a very high level of dirty electricity and this is reflected in elevated blood sugar.

exposed to very high levels of dirty electricity and this was reflected in exceptionally high levels of blood sugar. He noticed that his blood sugar levels remained low when he was in his truck away from power lines and antennas and when he was in a wilderness setting. In an electromagnetically dirty environment his blood sugar levels would increase within minutes.

An 80-year old female with Type 1 diabetes, who monitors her blood sugar twice daily—once in the morning upon awakening (fasting plasma glucose) and once in the evening before supper—had her home in Arizona filtered by an electrician. He was able to reduce the dirty electricity in her home from an average of 800 GS units to 13 GS units. As soon as the dirty electricity in her home was reduced, her blood sugar began to drop. Her average fasting plasma glucose levels without the filters was 171 mg/dL and this dropped to an average of 119 with the filters (Figure 5). During this period her insulin injections were reduced from a daily average of 36 units to 9 units.

Her evening plasma glucose did not change after the filters were installed in her home but they did change on days she spent away from home. Levels were particularly high after spending time in a casino. Casinos are likely to have high levels of dirty electricity but stress may also have contributed to higher levels of blood sugar (Hinkle and Wolf, 1950).

Multiple Sclerosis

One teacher in the Wisconsin school that was filtered had been diagnosed with multiple sclerosis (MS). She was extremely tired, had double vision, had cognitive

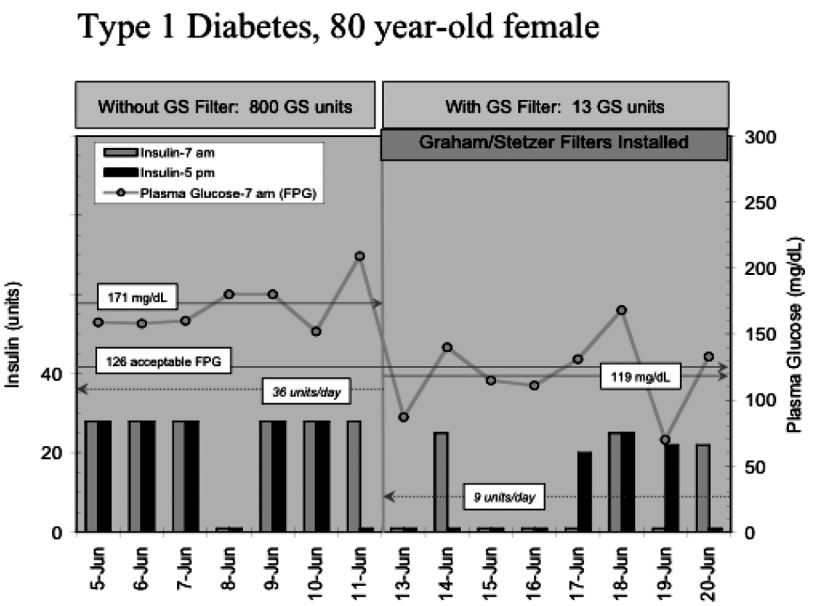

Figure 5. Eighty-year old female with Type 1 diabetes, who takes insulin twice daily. Fasting plasma glucose levels and insulin injections with and without Graham/Stetzer filters are shown.

difficulties and could not remember the names of the students in her 4th grade class. Her health would improve during the summer but her symptoms returned in September. She assumed her problems were mold-related but her symptoms did not improve after the mold was removed from the school. Once the school was filtered her symptoms disappeared. Similar stories prompted studies with people who had MS.

Havas began to work with people diagnosed with MS, who had difficulty walking and who used canes or walkers. The first person she worked with noticed improvements within 24 h. At that stage Havas assumed this was a powerful placebo effect but the subject's symptoms continued to improve weekly and regressed only during wet weather, which had always been a problem for this subject. Several other people with MS were able to walk unassisted after a few days to weeks with the GS filters and Havas began to videotape those who gave her permission to do so.

One of those individuals is a 27-year old male who had been diagnosed with primary progressive MS two years earlier. He walked with a cane or did "wall walking" at home (holding onto the wall or furniture for balance). He had tremors, was exceptionally tired, and was beginning to have difficulty swallowing. Three days after 16 GS filters were placed in his home his symptoms began to disappear. The dirty electricity in his home was reduced from 135–410 GS units to 32–38 GS units. He assumed his body was recovering spontaneously but he had been diagnosed with progressive MS and not relapsing/remitting MS, so spontaneous recovery was unlikely in his case.

A week after the filters were installed in his home he had enough energy to go shopping with his father. He did not take his cane because he had not needed it, but

Figure 6. Video-clip of 27-year old male with primary progressive multiple sclerosis, diagnosed two years earlier. In the video on left (without Graham/Stetzer filters), he walks slowly and is hesitant. In the video on the right (two weeks after Graham/Stetzer filters were installed in his home), he walks with confidence and is well coordinated.

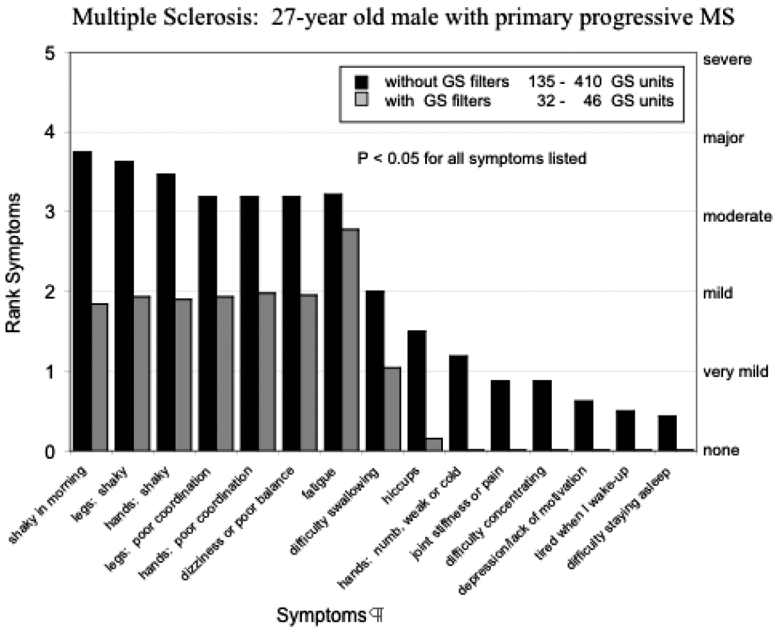

Figure 7. Symptoms of 27-year old male with primary progressive multiple sclerosis with and without Graham/Stetzer filters in his home.

after a couple of hours in the store his symptoms reappeared and he had difficulty walking to the car. His tremors began to subside three hours after arriving home. This experience has been repeated on several occasions and he now knows that if he goes into an environment with dirty electricity his MS symptoms reappear.

Figure 6 is taken from a video before the filters were installed in his home and two weeks later. Prior to the filters his walk was stilted and slow. He staggered and resembled the gait of someone who was intoxicated. Two weeks after the filters were installed his walk was normal with no signs of MS. During this period he began to put on weight, was sleeping better, and had fewer tremors and more energy (Figure 7).

Some other observations that are notable is that his mother had been suffering from hot flashes at night associated with menopause and these came to an end after the filters were installed and his father experienced several episodes of vertigo weekly and these became less frequent.

Conclusions

These case studies and anecdotal reports suggest that dirty electricity is biologically active. Once dirty electricity is reduced, people's health improves. For some it is reflected in more normal blood sugar levels, for others symptoms of MS are reduced, and for still others tinnitus disappears and behavior resembling ADD/ADHD improves. Since dirty electricity is becoming ubiquitous large fractions of the population are being exposed to this pollutant and some are being adversely affected.

Diabetes, multiple sclerosis, ADD/ADHD, asthma chronic fatigue, and fibromyalgia are all increasing in the population and the reasons for this increase are poorly understood. Dirty electricity may be one of the contributors to these illnesses.

According to Philips and Philips (2006) 3% of the population has electromagnetic hypersensitivity (EHS) and 35% have symptoms of EHS. If these percentages apply to diabetics then as many as 5–60 million diabetics worldwide may be responding to the poor power quality in their environment (Wild et al., 2004). Evidence from laboratory studies documents that insulin release and insulin-binding capacity to receptors cells is reduced by electromagnetic fields (Li et al., 2005; Sakurai et al., 2004). It is further known that stress increases blood sugar levels in diabetics and that exposure to electromagnetic energy induces stress proteins at various frequencies (Blank and Goodman, 2004; Hinkle and Wolf, 1950).

Dirty electricity can now be monitored with meters and reduced with filters, providing scientists with the tools needed for research. What is presented here is a handful of studies, many preliminary, with dramatic results. This area warrants further investigation to determine the mechanisms involved and the percentage of the population affected.

Conflict of Interest

Please note that the author has no vested interest, financial or otherwise, in the commercial devices discussed in this article.

Mainstream media admits smart meters are spying devices

By JGVibes -
02.24.2014 @2:28 AM EST

Mainstream media finally recognizes the smart meter dangers that "conspiracy theorists" have warned of for years

By John Vibes

(INTELLIHUB) — For years researchers and activists have been warning about the health and privacy dangers involved with smart meters. As usual, the mainstream media ridiculed these warnings and insisted that smart meters were harmless. However, now it is becoming common knowledge that these smart meters can be used to spy on innocent people, and even the mainstream media is starting to catching on.

Shockingly, news organizations like NBC are even picking this story up, in a recent article for NBC News, Matt Liebowitz writes:

Researchers examining the privacy implications of smart-meter technology found that one German provider's devices contained vulnerabilities that allowed them to snoop on unencrypted data to determine whether or not the homeowners were home.

After signing up with the German smart-meter firm Discovergy, the researchers detected that the company's devices transmitted unencrypted data from the home devices back to the company's servers over an insecure link. The researchers, Dario Carluccio and Stephan Brinkhaus, intercepted the supposedly confidential and sensitive information, and, based on the fingerprint of power usage, were able to tell not only whether or not the homeowners were home, away or even sleeping, but also what movie they were watching on TV.

Smart meters are just one piece of the national surveillance puzzle that has been growing in recent decades.

"Over the last several years, traffic-centric surveillance applications were the most prolific," said Eric Ackermann, sales manager for enterprise solutions and services at Siemens Industry in California's Orange County. *"In the last two years, a vast majority of the demand has come from city water/utility, parks/recreation, police and public works."*

Just last week we reported that many researchers who were labeled as "conspiracy theorists" were vindicated by the mainstream media in regards to weather control, when a mainstream scientist discussed the deep history of government weather modification on nationwide television. As the truth of our reality becomes more undeniable, the mainstream will continue to admit things that they once ridiculed.

Cutaneous mast cells are altered in normal healthy volunteers sitting in front of ordinary TVs/PCs – results from open-field provocation experiments

Olle Johansson, Shabnam Gangi, Yong Liang, Ken Yoshimura, Chen Jing and Peng-Yue Liu

The Experimental Dermatology Unit, Department of Neuroscience, Karolinska Institute, Stockholm, Sweden

Background: Considerable controversy has surrounded the question of possible biological responses to electromagnetic fields (EMFs) generated from visual display terminals (VDTs), such as personal computers (PCs) and ordinary television sets (TVs). The cellular and molecular mechanisms for such potential harmful health hazards have not yet been understood, although clues from the literature include mast cells and histamine. The aim of this study was therefore to investigate possible biological mast cell responses to TV/PC screens.
Methods: Using the indirect immunofluorescence technique, we studied the presence of histamine-containing mast cells in the dermis of healthy volunteers. Cutaneous biopsies taken before and after exposure to ordinary TV/PC screens for 2 or 4 h were investigated in 13 healthy subjects.
Results: Our present *in vivo* study indicates that normal cutaneous mast cells could be altered by exposure from ordinary TV/PC screens. To our great surprise, we found the number of mast cells in the papillary and reticular dermis to increase, to varying degrees, in 5 out the 13 subjects after such an exposure. A migration of mast cells towards the uppermost dermis appeared as the most important event. Thus, the normally upper "empty zone" of the dermis disappeared, and instead, a higher density of mast cells were found in this zone. These cells also seemed to have a tendency to increase in number towards the epidermal-dermal junctional zone and some of them lost their granular content and the cytoplasm shrunk (=degranulation). These findings could only be seen in the exposed skin. Two of the 13 cases instead showed a decrease in mast cell number, but the shift in mast cells towards the upper dermis was still visible. Twenty-four h after the provocation, the cellular number and location were normalized in all subjects.
Conclusions: By definition, normal healthy volunteers are assumed not to react to a TV/PC screen provocation. To our great surprise, this proved not to be true. The present results might lay a foundation to understand the underlying cause of so-called "screen dermatitis" with special reference to mast cells. However, blind or double-blind experiments using patients ought to be further investigated in order to find out the exact cause for the observed changes. Such causes include the effects of surrounding airborne chemicals, stress factors, etc.

Accepted April 5, 2001

It has previously been assumed that three visual display terminal (VDT)-dependent factors potentially might affect human health: radiation, ergonomics, and stress factors.[1]

The X-ray radiation emitted from the VDT screen was, however, found to be far below accepted risk levels, even under "worst case" conditions, and has not been considered to be associated with any adverse health effects.[1] Considerable controversy has surrounded the question of possible biological responses to low- or high-frequency electromagnetic fields (EMFs). The mechanisms of any harmful health events, such as in so-called "screen dermatitis", have not been understood. Psychological stress factors are believed to be involved in the development of so-called "screen-induced symptoms".[2] Animal experiments have shown disturbances in endogenous opioid systems, with secondary effects on cholinergic systems, after exposure to low-frequency EMFs.[3] Pulsed EMFs imposed on developing chick embryos resulted in an increase in the frequency of abnormal developments.[4] Mammalian cell lines have been shown to respond to extremely low-frequency EMFs with an increase in the activity of a proliferation-regulating enzyme,[5] and stimulation of the calcium influx;[6] furthermore, EMFs could promote peripheral nerve regeneration both *in vivo* and *in vitro*.[7–12] All obtained data thus indicates that EMFs can directly affect biological systems through different, but yet, unclear pathways, including both physiological and biochemical ones.

Most recently, some interesting studies have been published, e.g. Henshaw et al.[13] revealed an enhanced deposition of radon (^{222}Rn) daughter nuclei (^{214}Po; ^{218}Po) in the vicinity of everyday sources of power-frequency EMFs in normal domestic room air. Since countries such as Sweden and the United Kingdom are very rich in ground-based radon as well as radon exposure from building materials, one may ask whether devices like VDTs are true α-emitters?

In this context one has to also mention the findings of Lai & Singh,[14] who investigated the effects of acute (2-h) exposure to pulsed (2 μs pulse width, 500 pulses/s) or continuous-wave 2,450 MHz radiofrequency electromagnetic radiation on DNA strand breaks in the brain cells of rats. An increase in both types of such DNA strand breaks was observed after exposure to either the pulsed or continuous-wave radiation. Again, it is natural to ask what happens with humans using high-frequency devices such as TVs/PCs, mobile telephones, light tubes, etc.?

It has been known for several years that mast cells can be involved in many physiological and pathological reactions in inflammation, allergy, urticaria, psoriasis, itch sensations and pain.[15–17] Cutaneous mast cells are involved in both type I and IV hypersensitivity reactions. In another case-control study (Johansson & Liu, unpublished data), the results in human skin clearly showed that cutaneous mast cells differed both in quantity, quality and distribution pattern in so-called "screen dermatitis" patients as compared to normal healthy volunteers.

Using the same approach in this study, we employed conventional PCs and household TVs as provocation tools to conduct an *in vivo* study on human normal healthy volunteers. The aim of this study was to investigate possible biological mast cell responses to TV/PC screens. By definition, normal healthy volunteers are assumed not to react to such a provocation. To our great surprise, this proved not to be true.

Material and methods

Subjects

Thirteen healthy volunteers (7 male and 6 female, aged 19–34 years old, average 25.7) were selected as the subjects in the study, which was approved by the Committee of Ethics at the Karolinska Hospital. All subjects had no history of dermatoses, allergic diseases or other somatic diseases, and they were all non-smokers.

Test parameters

An ordinary laboratory room without windows was used for the provocation experiment. The room was equipped with 5 conventional PCs (attached to their monitors), 2 ordinary household TVs and 1 portable TV. The temperature in the room was 23–24 °C, and the electric and magnetic fields had a strength of 85 V/m, 35 nA and 310 μT/s in the TVs/PCs "OFF"-position, and a strength of 250–500 V/m, 100 nA and >10,000 μT/s in the TVs/PCs "ON"-position,

as measured at the biopsy spot with a Friman Instrument MF-4 (size of measuring plate: 21.5 mm×65.5 mm; 1 m^2 coil (MF-3) and an RC nT-converting filter (no. 169; Friman Datakonsult AB, Stockholm, Sweden). The subjects were seated at a distance of 40 cm from the TVs/PCs with their backs facing the front of the TVs/PCs. The whole provocation lasted 2 or 4 h. Biopsies from the challenged area were taken in pairs at anatomically symmetric sites right before, immediately after the provocation and at 2, 4 or 24 h after the provocation.

Preparation of tissues

Routine punch (Kai Industries, Japan) biopsies (3 or 4 mm in diameter), including epidermis and dermis, were taken under local anaesthesia (Xylocaine, Astra, Sweden). The biopsies were fixed in 4% carbodiimide (1-ethyl-3–3-dimethylaminopropyl-carbodiimide (Sigma, St. Louis, MO, USA) diluted in phosphate buffer (pH 7.4)) for 2 h at 4 °C.[18] The tissue was then rinsed for at least 24 h in 0.1 M Sörensen's buffer containing 10% sucrose, 0.01% NaN_3 and 0.02% Bacitracin and then sectioned on a Microm cryostat to yield 14-µm-thick sections, thawed onto gelatine-coated slides and processed for indirect immunohistochemistry.

Immunohistochemistry

The indirect immunofluorescence technique was employed.[18,19] The sections were kept in an humid atmosphere, incubated with the primary rabbit histamine antiserum (1:2,000; Milab AB, Malmö, Sweden) overnight at 4 °C, rinsed in phosphate-buffered saline (PBS), incubated for 30 min at 37 °C in rhodamine (TRITC)-conjugated goat anti-rabbit IgG (1:80; Boehringer-Mannheim, Mannheim, Germany), rinsed and mounted. All antisera were diluted in PBS containing 0.3% Triton X-100.

The control of the antiserum specificity was performed by pre-absorption with histamine dihydrochloride (0.1 mM; Sigma). In addition, it has been verified by the manufacturer that the antiserum does not cross-react with norepinephrine, serotonin, vasoactive intestinal polypeptide, glucagon or histidine. To test for any possible non-specific binding of the primary antiserum to Fc receptors in the tissue, a normal rabbit serum (1:100) was used instead of the primary antibody. To control for any possible non-specific reactions of the secondary antiserum, PBS was used on certain sections instead of the primary antibody. Other sections were directly only incubated with the secondary antibody. For observation and photography a Nikon Microphot-FXA fluorescence microscope was used. The results were collected from two independent observers.

Results

First, it should be noted that no cutaneous and/or somatic objective or subjective symptoms at all were induced in or reported by the tested volunteers during and after the provocation. This is fully in accordance with the assumption that normal healthy volunteers should not react to the TV/PC provocation situation at all.

The histamine immunoreactivity was only found in cells of the dermis. The immunoreactive cells observed in this study are considered to be mast cells based on their localization, number and cellular morphology, e.g., size and arrangement of granules according to our previous investigations.[18,19] They were seen around dermal appendages such as hair follicles, sebaceous glands, sweat glands and blood vessels, and they all had a similar morphology. Although mast cells were frequently found close to small capillaries and large blood vessels, they were never actually pres-

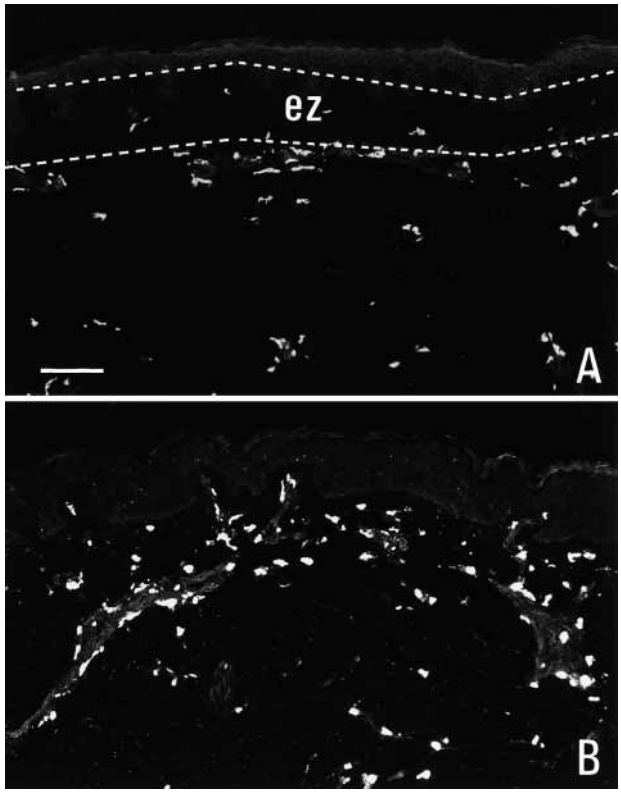

Fig. 1. The distributional alteration of cutaneous mast cells due to the provocation. A) An unexposed biopsy illustrates the relatively empty zone (ez) below the epidermal-dermal junction, where only single cells are seen. Further below this empty zone, mast cells are found in their highest density and gradually decrease towards the deeper dermis. B) In an exposed skin, a cellular migration upwards to the uppermost dermis was induced after exposure, i.e. the normally empty zone disappeared, and, instead, a high density of mast cells is observed in this zone. Bar in A=50 µm. The magnification in A=B.

ent in the vascular wall. The immunolabelling was found exclusively in the cytoplasm of the cells, leaving the ovoid single spherical or oblate spherical nucleus unlabelled, generally displaced to one side of the cells and along the long axis of cell (Fig. 1A). All the positive cells appeared prominently granular and most of them were elongated with cytoplasmic extensions while others were flat or dendritic when examined under high magnification.

In all unexposed biopsies, a relatively empty zone could be seen, which was approximately 100–200 μm wide below the epidermal-dermal junctional zone running parallel to that border (Fig. 1). One could hardly see any mast cells in that zone. This is consistent with our previous results in normal facial skin (Johansson & Liu, unpublished data). Further below the empty zone, mast cells were found in their highest density and gradually decreased towards the deeper dermis.

The main experimental results registered after exposure to the TVs/PCs are shown in Table 1. To our great surprise, the numerical density of mast cells increased in 5 out of the 13 subjects in the papillary dermis and reticular dermis as a response to the provocation; however, the cellular volume seemingly remained unchanged in most cases. Two out of 13 also increased the fluorescence intensity of their histamine granules. Above all, a cellular migration appeared as the most important event in the provocation experiment, i.e. the normally empty zone disappeared, and instead a high density of mast cells was observed in this zone. These cells also seemed to have a tendency to move towards the epidermis and some of them lost their granular content and their cytoplasm shrinked (pointing to a possible degranulation) (Fig. 2).

In contrast to the results mentioned above, two cases showed a numerical mast cell decrease, but the upward movement was still visible. In addition, in one case, the processes of mast cells were found to be

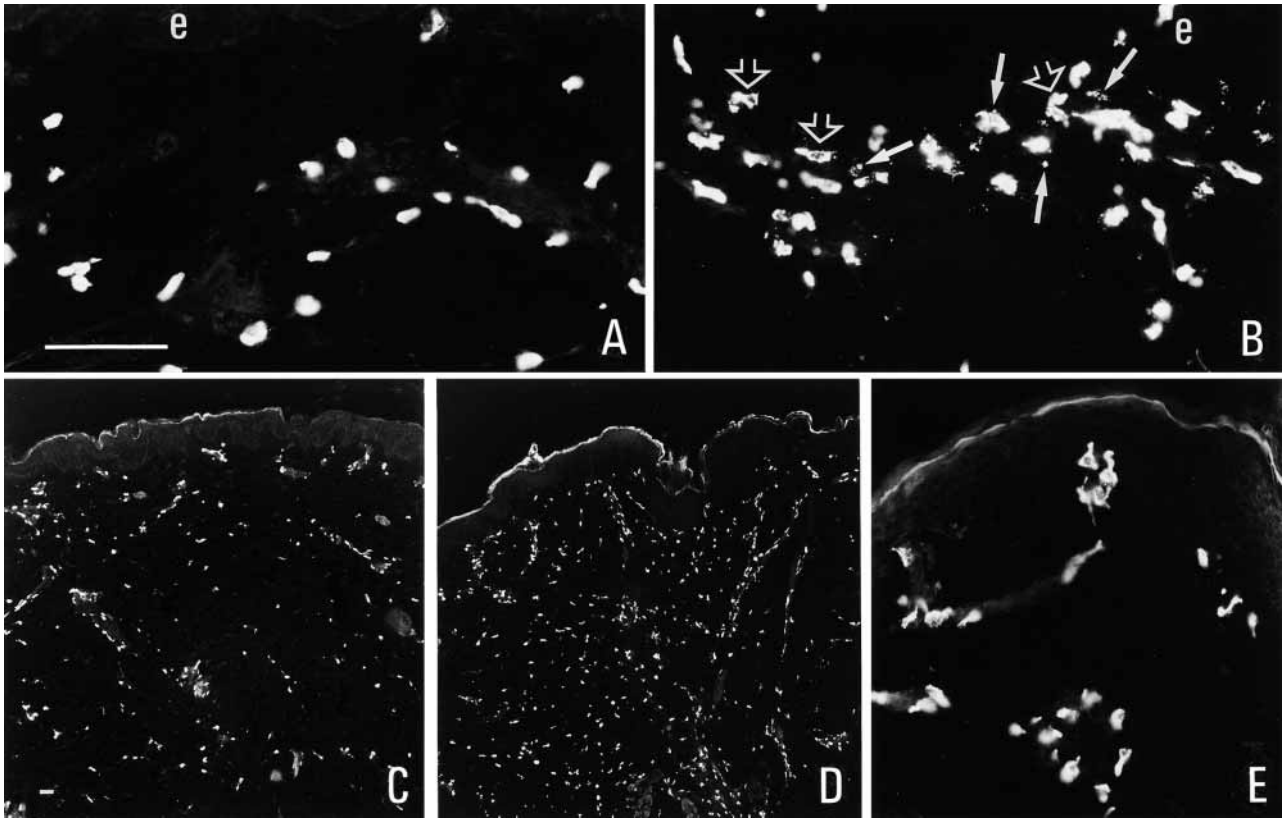

Fig. 2. A typical cutaneous response to TV/PC provocation. Note that biopsies A & C and B & D, respectively, came separately from the same subject. In A, the unexposed biopsy shows the morphology of normal status mast cells. In B, a biopsy from after 4 h of exposure, it is shown that these cells close to the epidermis have degranulated and that their cytoplasm has shrinked. Open arrows point to shrinked mast cells; solid arrows point to discharged histamine granules from mast cells. e=epidermis. C and D are low-power micrographs clearly demonstrating that compared to before (C), after 4-h exposure (D) the number of mast cells has increased and an upward movement of these mast cells has appeared. In E, one case showed an odd morphology of mast cells as a response to the provocation; the processes became more numerous as well as larger, especially in cells that were situated closer to the epidermis. Bars in A and C=50 μm. The magnification in A=B=E, and in C=D.

more numerous as well as larger, especially in cells that were situated closer to the epidermis, as a response to the provocation (Fig. 2E). The morphology of the cutaneous capillaries, sebaceous glands as well as hair follicles always remained unchanged. Finally, it should be noted that 24 h later, all of the subjects with changes reported above revealed a normal pattern.

There was no significant difference between biopsies that were taken instantly after exposure or after 2 or 4 h post-provocation delay. Furthermore, no differences could be seen if the provocation time was 2 or 4 h.

Discussion

Mast cells are effectors of IgE-mediated immune reactions because they have high-affinity receptors for the Fc-portion of IgE.[20] Their ability of rapid response to allergens or poison stimuli may be considered as a first line of defence in protecting the skin from being infiltrated by micro-organisms and other potentially harmful agents. They contain and release, after activation, a wide array of pro-inflammatory mediators affecting structures and cells, and conversely their differentiation and function are affected by their environment.

Histamine is synthesized in mast cells from histidine and is stored within the mast cell secretory granules by forming a complex with the glycosaminoglycan side chains of heparin. In mammalian connective tissue, including the skin, mast cells have generally been regarded as the major source of histamine.[21] It has been found that there were statistically significant correlations between the mast cell number and histamine content.[19,21–24] Therefore, most of the histamine immunoreactivity cells are equal to classical mast cells.

In the present study, we found a special distribution in the papillary dermis, i.e. an empty zone could easily be identified, like in the face (Johansson & Liu, unpublished data), which has not been reported in the back before. This zone may be considered as a 'buffer' zone for immune reactions; once an antigenic substance or stimulus intrude into this area, immunocytes (as well as mast cells) migrate into this zone to participate in the immunological response.

Apart from the fact that mast cells could be provoked to increase their infiltration in the dermis, another prominent finding in this investigation is, of course, the upward migration. It could be induced in most cases (9 out of 13; see Table 1), although two cases showed a decrease of mast cell number. In this context, it may be noted that Donnellan et al.[25] have shown clear-cut effects on a mast cell analogue, RBL-2H3, of EMFs at 835 MHz. The rate of DNA synthesis and cell replication increased, the actin distribution and cell morphology became altered, and the amount of β-hexosaminidase released in response to a calcium ionophore was significantly enhanced, in comparison to unexposed cultures. There were no effects seen on the levels of cytoskeletal protein synthesis or β-actin mRNA. However, the amount of Ras in the membrane fraction of exposed cells increased. The morphological changes persisted following subculture for at least 7 days in the absence of further exposure.[25] This work has now also been extended to yet another mast cell line, namely the HMC-1, and at 864.3 MHz.[26] In their study, the authors reported effects on the localization of the protein kinase C, and expression of 3/588 genes screened. The affected genes included the proto-oncogene c-kit, the transcription factor nucleoside diphosphate kinase B and the apoptosis-associated gene DAD-1. In addition, stress response genes were variably upregulated. No significant effect on cellular morphology or on F-actin distribution was detected. The conclusion of the publication[26] was that the low-power microwave exposure used may act on the HMC-1 cells by altering gene expression via a mechanism involving activation of protein kinase C, and at temperatures (=26.5 °C) well below those known to induce heat-shock responses.

The recent finding that small magnetic particles of magnetite (Fe_3O_4) are present in various biological tissues opens the arena for new speculations on interaction mechanisms.[27] A cluster of cells, denoted magnetocytes or Jurkat cells (a human leukemic T-cell line)[27] and bacteria *Magnetospirillum magnetotacticum* have been reported to contain magnetite, and low-frequency magnetic fields have been shown to increase inositol 1,4,5-triphosphate levels in the Jurkat cell line.[28] Earlier reports from the same group have shown that when a weak 50-Hz magnetic field was applied, the Jurkat cells responded with intracellular

calcium oscillations.[29] The results suggested that the magnetic fields interfered with the signal transduction, although neither target molecules nor molecular mechanisms are at present known. Perhaps some cutaneous mast cells also may contain magnetite and such cells may be involved in possible interactions of environmental EMFs and skin. When there exists an EMF, they might migrate toward the magnetic source, i.e., towards the epidermis, to degranulate their histamine content. Since this effect only happens at the cellular level, it may not be strong enough to immediately cause cutaneous objective/subjective symptoms of long-lasting nature. Support for this idea may be given by the observation that, even if a subject had cellular changes directly after the provocation, 24 hours later they had become normal again (cf. Table 1). But, repeated chronic exposure to magnetic fields may be able to cause symptoms such as itch, smarting, redness, papules, etc.[30] This is correspondent to the fact that mostly when the so-called "screen dermatitis" patients leave their VDT work, the symptoms are relieved or, more or less, disappear.

In conclusion, although the subjects in the present investigation did not report any cutaneous and/or somatic objective or subjective symptoms during as well as after the provocation, 7 out of 13 still had profound cellular changes in their dermal mast cell population. This would mean that normal human skin very well could biologically react to external EMFs generated from TVs/PCs. What this would imply for the whole human being could only, at this stage, be guessed at. Since the subjects did not verbally complain it is not likely that psychological and/or psychosomatic events have taken place, rather the cellular changes point to a UV, microwave, or other high-frequency radiation emitted by the TVs/PCs. The assumption that normal healthy volunteers should not react at all to the TV/PC provocation situation thus proved to be wrong. And, maybe the observed cellular changes are actually just plain radiation damages?

Abstract: Radiation damage to biological systems is determined by the type of radiation, the total dosage of exposure, the dose rate, and the region of the body exposed. Three modes of cell death—necrosis, apoptosis, and autophagy—as well as accelerated senescence have been demonstrated to occur *in vitro* and *in vivo* in response to radiation in cancer cells as well as in normal cells. The basis for cellular selection for each mode depends on various factors including the specific cell type involved, the dose of radiation absorbed by the cell, and whether it is proliferating and/or transformed. Here we review the signaling mechanisms activated by radiation for the induction of toxicity in transformed and normal cells. Understanding the molecular mechanisms of radiation toxicity is critical for the development of radiation countermeasures as well as for the improvement of clinical radiation in cancer treatment.

Keywords: ionizing radiation; apoptosis; necrosis; senescence; autophagy; cancer; primary cell

1. Introduction

In Germany, 1895, Wilhelm Conrad Röntgen observed that invisible rays generated in a vacuum tube induced fluorescence from a barium platinocyanide-coated plate. He found that the rays could differentially penetrate objects of differing densities, and Röntgen generated the first radiographic

images of bones. Later that same year, he reported his discovery in which he called these images X-rays, and later was awarded the Nobel Prize for Physics in 1901 [1,2]. Based on these findings, Antoine Henri Becquerel began investigations to determine whether other forms of naturally occurring phosphorescence were related to X-rays; in 1896 Becquerel discovered spontaneous radioactive properties of uranium ore, for which he too was awarded the Nobel Prize for Physics in 1903 [3]. Investigations conducted by Marie Curie on radioactive substances and their properties led to the discoveries of polonium and radium, which resulted in the receipt of Nobel Prizes in Physics in 1903 (shared with Becquerel and Pierre Curie) and in Chemistry 1911 [4]. The application of radiation has advanced the fields of medicine, biology, physics, astronomy, materials science, engineering. Indeed, the full extent of radiation application is still waiting to be realized.

Despite the many practical uses of ionizing radiation (IR), exposure to high levels of radiation has lethal consequences. The medical effects of radiation exposure have been classified into Acute Radiation Syndrome (ARS) and the Delayed Effects of Acute Radiation Exposure (DEARE). ARS consists in a constellation of health effects ensuing from an exposure of the total body or a significant area of the body to a relatively high dose (>2–5 Gy) delivered at a relatively high dose rate [5]. ARS is usually divided into three types of syndromes, based on the radiosensitivity of the organs/tissues involved: the Hematopoietic Syndrome (occurring after exposure to 0.7–10 Gy), the Gastrointestinal Syndrome (usually greater than 10 Gy), and the Cardiovascular/Central Nervous System Syndrome (>50 Gy) [5,6]. DEARE, on the other hand, consists of syndromes occurring months or years following radiation exposure which include: prolonged gastrointestinal effects, delayed immune reconstitution, delayed skin injury, renal failure, and radiation-induced lung injury [7]. Damage to normal tissue is often a limiting factor for the clinical use of radiation for cancer eradication; all forms of cell death as well as accelerated senescence have been linked to delayed cycles of inflammation, tissue dysfunction, atrophy, and/or fibrotic remodeling [8–12]. While there has been an exponentially growing number of studies attempting to explain the mechanisms of radiation toxicity over the years, there are only a limited number agents approved by the Food and Drug Administration as countermeasures for prevention, mitigation, or treatment of ARS or DEARE [13].

2. Ionizing Radiation-Induced Damage to Biological Molecules

Ionizing radiation (IR) generates both direct and indirect damage to biological molecules. In high linear energy transfer (LET) radiation, such as neutrons and alpha particles, most of the cellular damage results from the direct ionization of cellular macromolecules including DNA, RNA, lipids, and proteins [14]. In contrast, low LET radiation, such as X-rays and gamma rays, indirect damage to biological macromolecules occurs following the generation of reactive oxygen species (ROS) [14]. ROS, especially superoxide and hydroxide radicals from the radiolysis of intracellular H_2O, can have many effects, including the oxidation of biological macromolecules and activation of intracellular signaling pathways [14–18].

A widely accepted dogma in the field of radiation biology is that DNA is the most important molecular target of radiation because of its critical role in cell replication and proliferation [19]. Both single-stranded DNA breaks (SSB) and double-stranded DNA breaks (DSB), along with nucleotide mutations, occur during IR exposure and lead to cell death or mutagenesis if not properly

repaired [20,21]. DSB have more lethal consequences than SSB, as noted in low LET radiation when DSB are induced in a relatively large fraction of cells [20]. Overall, radiation-induced DNA damage is believed to activate a variety of signaling pathways leading to cell death as well as accelerated senescence.

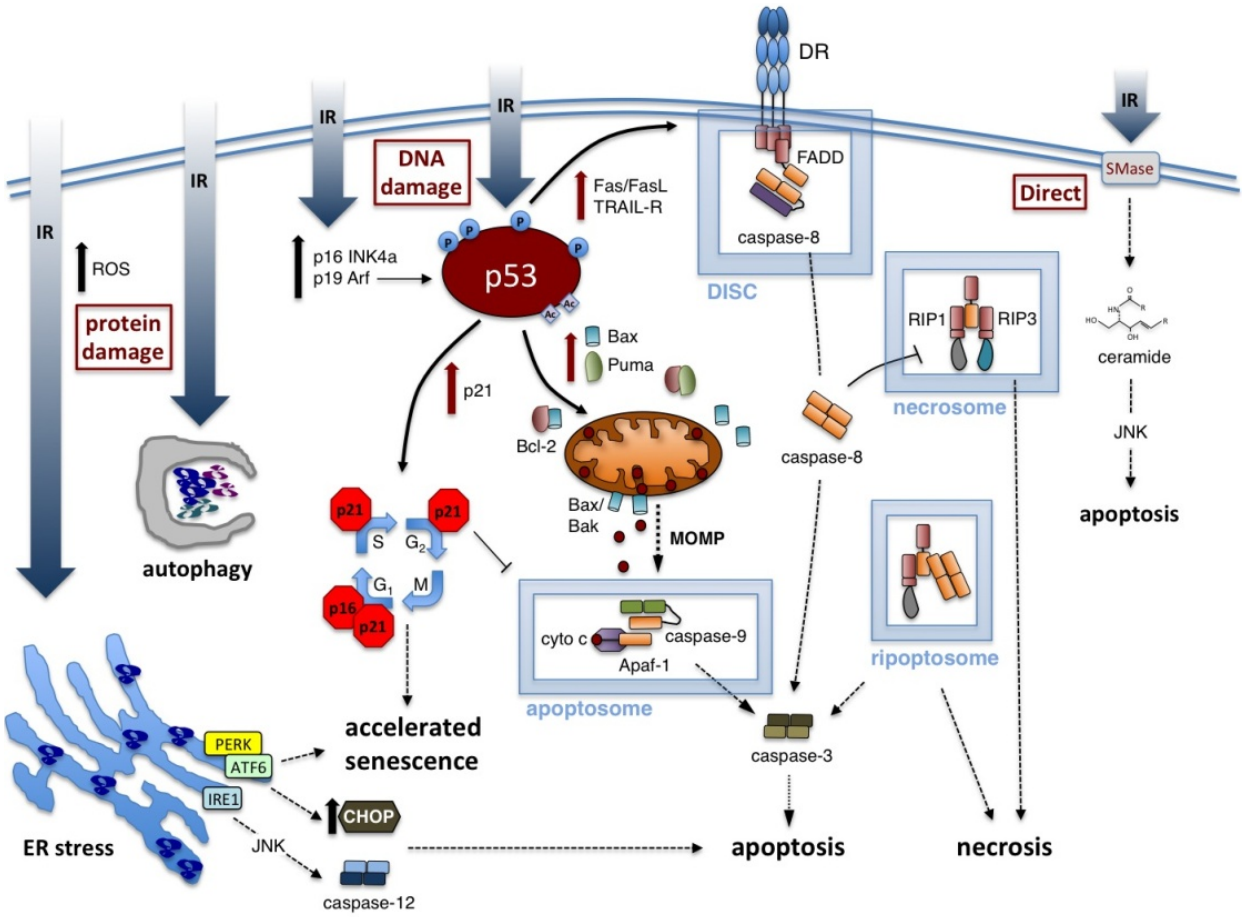
Recent investigations have challenged the classical DNA-centric view of radiation injury by demonstrating that proteins are also critical radiation targets that influence cell death mechanisms. In some cases, radiation-induced death by protein damage is proposed to be a consequence of reduced DNA repair fidelity, indirectly decreasing cell viability [22]. In prokaryotes, Qui *et al.* [23] suggested that protein damage underlies the radiosensitivity of *Shewanella oneidensis* while Daly *et al.* [24] proposed that the extreme radioresistance of *Deinococcus radiodurans* has been attributed to the reduction of protein oxidation by a variety of protective mechanisms. *Bdelloid* rotifers also display resistance to radiation damage due to decreased protein oxidation [25]. Studies using cultured mammalian cells have also provided evidence for protein oxidation in the activation of pro-apoptotic signaling downstream of radiation damage [26,27]. However, a direct comparison has not yet been made for the contribution of protein damage *versus* DNA damage for overall cellular toxicity.

3. Ionizing Radiation-Induced Cell Toxicities

The molecular mechanisms of radiation-induced cellular injury depend on a number of factors including radiation dosage, the cell type, and the transformed status of the cell [21,28,29]. As suggested by the manifestation of acute and delayed radiation syndromes, specific tissues and organ systems have differential radio-sensitivity. In several cases, the vulnerability of tissues to radiation injury is predicted by the Law of Bergonie and Trebondeau which states that radiation is generally more damaging in rapidly dividing cells and in undifferentiated cells [28,30]. For example, untransformed epithelial cells of the gastrointestinal tract and progenitor cells of the hematopoietic system, which have rapid turnover rates, are generally more radiosensitive than the non-dividing neurons of the central nervous system. This differential proliferative capacity corresponds to the induction of Hematopoietic Syndrome at lower radiation exposures (0.7–10 Gy) compared to doses required for inducing Central Nervous System Syndrome (>50 Gy).

Unrepaired DNA damage can lead to mutations, genomic instability, and cell death. Cells have evolved complex systems for the repair of single- and double-stranded DNA breaks [31]. It has been demonstrated that normal (non-transformed, non-immortalized cells) can repair as many as 70 DSB/cell within 24 h of radiation exposure [32]. Different DNA repair mechanisms are thought to be activated during specific phases of the cell cycle [28,33]. DSB can be repaired via a homologous recombination-dependent mechanism during the G2/M phases of the cell cycle, whereas non-homologous end joining mechanisms are believed to be active during G1/G0. In contrast, DNA repair is relatively inefficient during the S phase of the cell cycle [28]. Importantly, the duration for activity of a particular DNA repair mechanism depends upon the time that the cell remains in a particular phase of the cycle [28]. Therefore, cells that move rapidly through the cell cycle have less time to repair their DNA than cells that are paused during a cycle in which a particular DNA repair mechanism is activated.

Figure 1. Molecular responses to ionizing radiation (IR) in exposed cells. Depending on dose and radiosensitivity of the exposed cell, IR may induce cell death (through apoptosis or necrosis) or trigger accelerated senescence. Increased expression of p53, coupled to various post-translational modifications (e.g., phosphorylation (P), acetylation (Ac)), is a critical step in mediating the cellular response to IR-induced DNA damage. Accelerated senescence can result from p53-dependent induction of p21/waf1 or upregulation of other cell cycle inhibitory proteins (e.g., p16 INK4a). p53 activation also triggers *de novo* synthesis of pro-apoptotic molecules that mediate intrinsic (e.g., Bax, Puma) or extrinsic (e.g., Fas) apoptotic cell death (red arrows, p53-dependent). Intrinsic apoptosis is governed by Bcl-2 family proteins that regulate mitochondrial outer membrane permeabilization (MOMP), whereas extrinsic apoptosis is signaled through dedicated death receptors (DRs) such as Fas. Both forms of apoptosis rely on the assembly of large multiprotein platforms, including the apoptosome and death-inducing signaling complex (DISC), which facilitate caspase activation through recruitment, dimerization and autocatalytic cleavage. Separate protein complexes containing RIP-1 and/or RIP-3 (e.g., necrosome) can trigger programmed necrosis under certain conditions (e.g., caspase-8 inhibition). IR can also elicit ER stress and autophagy in response to the accumulation of oxidized or misfolded proteins, which may in turn induce apoptosis. Finally, apoptosis may also be triggered by increased ceramide levels, generated through direct IR-induced activation of sphingomyelinases (SMases) in the plasma membrane.



Our current understanding of the mechanisms of ionizing radiation-induced cell death comes from studies that are mostly conducted on immortalized cancer cell lines that do not represent the biological status of non-immortalized, non-transformed normal cells [29]. Although cancer cells proliferate more quickly than normal cells, leaving their DNA more susceptible to unrepaired damage, these cells often contain multiple mutations resulting in constitutive activation of mechanisms for DNA repair or allowing them to survive following damage that would render normal cells unviable [34].

Radiation exposure to cells has been demonstrated to result in a variety of mechanisms of cell death, including necrosis, apoptosis, or autophagy (see Figure 1) [35]. Additionally, radiation may induce accelerated cellular senescence, a state in which the cell remains viable but with altered functions, and which is no longer competent for proliferation [36]. In some cases, it has been demonstrated that increasing IR dosages shift the cellular response from senescence to apoptosis and/or autophagy, with higher doses leading to necrosis [27]. However, there is no absolute response of all cells to a given dose of radiation exposure. Some cell types rapidly undergo apoptosis in response to the same level of radiation that induces senescence in another cell type (e.g., primary human hematopoietic $CD34^+$ cells undergo apoptosis whereas pulmonary artery endothelial cells primarily undergo accelerated senescence) [27,37]. The selection process resulting in a specific mode of cell death or senescence has not been clearly defined, but research indicates that it is affected by the radiation dose, the dose rate, and multiple aspects of the cellular context [31,32,34,38,39].

3.1. Radiation-Induced Apoptosis

Apoptosis, or programmed cell death, is an evolutionarily conserved and highly regulated form of cell death required for the removal of extraneous, damaged, infected, or transformed cells from normal tissues [40]. Apoptosis is characterized by chromatin condensation, DNA fragmentation, cell shrinkage, and ultimately disintegration of the cell into membrane-bound particles [41,42]. These apoptotic "blebs" are rapidly removed by phagocytic cells *in vivo* to prevent cell death-associated inflammation. Two principal apoptotic pathways are widely recognized—extrinsic apoptosis and intrinsic apoptosis. The extrinsic pathway is activated by extracellular signals transduced by transmembrane "death receptors". In contrast, the intrinsic pathway is initiated by signaling pathways from inside the cell that govern mitochondrial integrity. The use of either of these pathways depends on the nature and origin of the death signal [43,44]. Each apoptotic pathway regulates the activation of specific initiator caspases, a family of cysteine-aspartic proteases required for apoptotic cell death signaling [45]. The two apoptotic pathways eventually converge with the activation of central activator caspases (e.g., caspase-3, -6, and -7) required for proteolytic processing of key cellular proteins as well as DNA fragmentation [45].

Many cancer cells, including lung, prostate, immortalized keratinocytes, and colon cancer cells, commit to apoptotic cell death when exposed to radiation ranging from 1 to 20 Gy [31,46–49]. Low doses of radiation (10–200 cGy) have been demonstrated to induce apoptosis in human skin organotypic culture and murine epidermal cells [50]. In response to low to moderate doses of radiation ($\leq$32 Gy), neurons also undergo apoptosis *in vitro* [11]. In contrast, some non-transformed, non-immortalized cells, such as smooth muscle cells and pulmonary artery endothelial cells, display apoptotic responses only when exposed to higher doses of radiation (>20 Gy) [27,51]. One important

characteristic of apoptosis that it is generally non-inflammatory, with reduced effects on neighboring cells compared to other modes of cell death [52]. However, tumor cell apoptosis has been linked to the induction of increased tumor cell growth in some studies [53]. The mechanisms of apoptotic cell death induced by IR are further described below.

3.1.1. Intrinsic Apoptosis Induced by IR

Because IR is known to cause DNA damage that can initiate a variety of intracellular signaling, the intrinsic pathway has been inferred to be the primary apoptotic mechanism mediating IR-induced apoptosis. Intrinsic apoptosis, also referred to as the mitochondrial pathway, is characterized by mitochondrial outer membrane permeabilization (MOMP) and cytochrome c release [54,55]. Cytosolic cytochrome c interacts with apoptotic protease activating factor 1 (Apaf1) and procaspase-9, forming the apoptosome [43,56]. The primary function of the apoptosome is to activate the initiator caspase-9, which triggers a cascade of caspase activation beginning with the executioner caspase 3 [56,57].

Intrinsic apoptosis is initiated by signaling pathways activated in response to DNA damage [6,31]. DNA breaks are initially sensed by several groups of proteins including: the mediator of DNA damage checkpoint protein 1 (Chk1); p53 binding protein 1 (53BP1); DNA-dependent protein kinase (DNA-PK); the protein complex meiotic recombination 11 homolog 1, Rad50 protein, and nibrin (Mre11/Rad50/NBS1, MRN); and the protein complex Rad9, Rad1, and Hus1 (Rad9/Rad1/Hus1, 9-1-1) [31,33]. Binding of MRN and 9-1-1 to DNA leads to the activation of a number of kinases that amplify the DNA damage response, including the Ataxia telangiectasia mutated protein (ATM) kinase and the ATM and Rad3-related (ATR) kinase [31,35,58]. DNA-PK, ATM and ATR phosphorylate the tumor-suppressor protein p53, the critical mediator of DNA damage-induced intrinsic apoptosis [35,39,57,59–61].

p53 is referred to as the "guardian of the genome" because of its role in maintaining chromosomal stability and determining the fate of the cell following DNA damage: either survival with temporary cell cycle arrest (during which damaged DNA is repaired) or apoptotic cell death [33,44,62]. Expression of p53 protein increases immediately following DNA damage. This increase in p53 protein levels has been shown to be proportional to the extent of DNA damage in a cell, and the kinetics of p53 regulation vary with different types of radiation [63]. Specific posttranslational modifications of p53 (phosphorylation and acetylation) stabilize the protein and activate its functions as a transcription factor as well as modulate its association with other proteins [64]. For example, CREB (cAMP response element-binding) binding protein (CBP)/p300 and the p300-CBP-associated factor (PCAF) acetylate p53, protecting it from ubiquitination and degradation [64]. Acetylation and phosphorylation are also required for p53 transcriptional activity and changes in protein-protein interactions [65,66]. Depending upon the extent and nature of p53 activation, divergent pathways may be activated [63].

p53 dictates apoptosis sensitivity in part through the regulation of levels and functions of pro-apoptotic and anti-apoptotic proteins of the B-cell lymphoma 2 (Bcl-2) protein family [67]. The anti-apoptotic members of the Bcl-2 family protect the mitochondria from MOMP and cytochrome c release, primarily by binding to and neutralizing Bax and Bak (two pro-apoptotic members of the Bcl-2 family), which directly facilitate mitochondrial permeabilization. There are three primary effects of p53 on this system: 1) Increased expression of pro-apoptotic Bcl-2 family proteins; 2) disruption of

the binding between pro- and anti-apoptotic Bcl-2 family proteins; and 3) induction of pro-apoptotic Bcl-2 protein oligomerization. p53 nuclear localization and transcriptional activation leads to increased gene expression of pro-apoptotic Bcl-2 family proteins such as Bax and Puma [68–72]. Furthermore, p53 in the cytoplasm can localize to the mitochondria, where it inhibits the association between anti-apoptotic proteins Bcl-2 and Bcl-x_L with the pro-apoptotic Bax and Bak proteins [35,59,73]. Note that in contrast with its function in the activation of mitochondrial apoptosis, p53 is not localized to the mitochondria during the induction of cell cycle arrest [67]. A combination of release of Bax from Bcl-2-protein binding as well as direct interactions with p53 lead to the oligomerization of Bax and Bak, which then form channels in the mitochondrial membrane inducing MOMP, cytochrome c release, and subsequent apoptosome formation [43,56,74].

The expression level and mutational status of p53 can affect the cellular decision to undergo apoptosis. Studies have indicated that tissues sensitive to radiation-induced apoptosis (spleen, thymus, and testis) display more rapid increases in p53 proteins compared with radioresistant tissues (liver and kidney) [67]. Additionally, cancer cells may evade radiation-induced apoptosis by suppression of p53 expression, or by gaining mutations in p53 that nullify its pro-apoptotic activity [75]. Indeed, over 50% of all human tumors harbor mutations or deletions in the *TP53* gene [76]. Thymocytes lacking p53 were shown to be more resistant to apoptosis induced by DNA DSB than those having wild-type p53 [77,78]. Overexpression of wild-type p53 increases apoptosis in p53-deficient leukemic and colon tumor-derived cell lines [79,80]. A number of agents that increase p53 levels are currently being utilized to increase apoptosis sensitivity of tumor cells to radiation therapy [67].

Independently of p53 function, the sphingomyelin pathway also mediates radiation-induced apoptosis through ceramide generation. Ceramide is an important second messenger molecule for regulating stress responses, including apoptosis induction [81]. For example, IR exposure in endothelial cells has been shown to activate sphingomyelinases (SMases) that hydrolyze sphingomyelin in the plasma membrane to generate ceramide. In fact, mouse embryonic fibroblasts (MEFs) from acid SMase knockout mice are completely resistant to radiation-induced apoptosis [82]. Ceramide appears to engage multiple modes of apoptotic signaling (e.g., JNK activation, PI-3K inactivation, *etc.*) that ultimately require MOMP, even when the death receptor CD95/FAS is implicated [81]. Ceramide can also stimulate BAX integration into the mitochondrial outer membrane to directly facilitate MOMP [83]. Although more studies are needed, pharmacological manipulation of ceramide may represent an attractive and relatively accessible strategy for modulating cellular responses to IR.

3.1.2. Extrinsic Apoptosis Induced by IR

In contrast with the intrinsic apoptotic pathway, the extrinsic pathway of apoptosis is initiated by extracellular activation of transmembrane "death" receptors (DRs)—CD95/Fas, tumor necrosis factor receptor 1 (TNF-R1), and tumor necrosis factor-related apoptosis-inducing ligand (TRAIL) receptors DR4 and DR5—by their corresponding ligands [43,44]. These DRs contain conserved intracellular "death domains" which, upon ligand binding, cluster and nucleate the death-inducing signaling complex DISC containing the adapter protein Fas-associated death domain (FADD) protein and procaspase-8 and -10 [44,62]. Caspase-8 is the main initiator caspase of the extrinsic apoptotic

pathway, equivalent to caspase-9 in the intrinsic pathway. Similar to caspase-9 in the apoptosome, procaspase-8 undergoes autocatalytic cleavage within the DISC, and the active form of caspase-8 directly cleaves and activates the executioner caspases-3 and -7 [84].

In vivo studies have demonstrated that mice deficient in extrinsic apoptosis signaling have reduced apoptosis in response to radiation in a tissue-specific manner. In response to IR, *DR5* knockout mice show reduced apoptosis in the thymus, spleen, Peyer's patches, and the white matter of the brain, with normal levels of apoptosis in the ileum, colon, and stomach [85,86]. IR also causes caspase-8-mediated apoptosis in Jurkat T cells, glioma cells, and some breast cancer and human lymphoma cell lines [87–90]. However, in a number of instances, the activation of both intrinsic and extrinsic apoptosis has been observed simultaneously. Some cancer cells exhibit both extrinsic and intrinsic apoptosis in response to IR [91]. Our laboratory also recently demonstrated that in normal lung endothelial cells caspase-8 is activated by IR concurrent with the activation of caspase-9 [27]. The distinction between intrinsic and extrinsic apoptosis can become blurred, since the effector caspases 3 and 7, which are activated during both intrinsic and extrinsic apoptosis, can feedback to regulate mitochondrial events, such as Bax translocation and cytochrome c release [92].

Several mechanisms have been proposed for the regulation of the extrinsic apoptotic pathway by IR. In some tissues, the regulation of DRs following DNA damage may proceed through the activation of p53 transcriptional activity [31,85]. p53 has been demonstrated to upregulate TRAIL receptors and CD95/Fas, as well as the Fas ligand [85,93]. However, in some tissues, such as the thymus and colon, the regulation of death receptors was shown to be p53-independent [94,95].

Interestingly, the specific inhibition of extrinsic apoptosis is a common mechanism for cancer cell evasion of cell death signals. For example, various isoforms of cellular FLICE inhibitory protein (cFLIP) contribute to DR-induced apoptosis resistance by interfering with caspase-8 activation at the DISC [96]. Therapeutic strategies for targeting cFLIP to lower the threshold for DR-induced apoptosis are generating considerable interest for cancer therapy [97]. Inhibitor of apoptosis proteins (IAPs) also modulate apoptosis and necrosis sensitivity through their ubiquitin ligase activity (e.g., c-IAP1/2) or by directly inhibiting certain caspases (e.g., XIAP) [98]. Apoptosis repressor with caspase recruitment domain (ARC) also functions to suppress both intrinsic and extrinsic apoptosis through multiple mechanisms, including the inhibition of caspase activation, the inhibition of association of DRs with downstream signaling molecules, and through direct inhibition of Bax [99]. Like IAPs, ARC has been found to be overexpressed in a variety of cancer cells, including glioblastoma, melanoma, and lymphoma cells, and in cancers from pancreas, colon, breast, lung, cervix and prostate [100]. Paradoxically, the overexpression of anti-apoptotic Bcl-2 proteins can also protect cancer cells from extrinsic apoptosis, when MOMP and caspase-9 activation are required to amplify the DR-induced caspase cascade [101–103]. Additional mechanisms have been identified for cancer cell evasion of the extrinsic pathway, including downregulation of DRs and the suppression or mutation of proteins required for death receptor signaling [104–107]. Not surprisingly, proteins regulating extrinsic apoptosis have become therapeutic targets for improving the efficacy of both clinical radiation and chemotherapy in resistant cancer cells [102,107–109].

3.1.3. ER Stress and Activation of Apoptosis by IR

DNA damage is a critical target for IR-induced cell toxicity, but increasing evidence indicates that protein damage also contributes significantly to cell death in some organisms [23–25]. In eukaryotic cells, the endoplasmic reticulum (ER) serves as a sensor of cellular homeostasis, being the site for protein folding and maturation for secretory and membrane proteins [110]. Specifically, the ER initiates signaling in response to damaged proteins. An accumulating body of evidence implicates oxidized, damaged proteins as triggers of the ER stress pathway (also known as unfolded protein response, UPR) [111,112]. A critical increase in the level of unfolded proteins is detected by the ER. The ER stress response pathway is designed to transiently halt new protein synthesis and increase the expression of chaperones to promote protein folding as well as to induce the ER-associated degradation (ERAD) system to remove terminally damaged proteins from the ER for proteasome-dependent degradation [110]. Failure to eliminate the damaged/unfolded proteins from the ER can ultimately result in apoptosis or accelerated senescence [110,113,114]. Protein unfolding may typically activate three ER-localized sensors: (1) the RNA-like endoplasmic reticulum kinase (PERK); (2) the activating transcription factor 6 (ATF6); and (3) the inositol-requiring enzyme 1 (IRE1) [112]. PERK, ATF6 and IRE1 are bound in the ER lumen and held in an inactive state by the chaperone glucose-regulated protein 78 (GRP78). Release of these proteins from GRP78 is believed to be the initiating event in UPR [115].

PERK, a transmembrane protein resident of the ER, phosphorylates the eukaryotic initiation factor 2 alpha (eIF2α), leading to the inhibition of protein synthesis to reduce the traffic of newly-synthesized, unfolded polypeptides to the ER [116,117]. Although eIF2α phosphorylation inhibits most protein synthesis, phosphorylated eIF2α specifically enhances some translation, including the translation of the ATF4 transcription factor that can induce the expression of other genes involved in the UPR, such as chaperones, amino acid transporters, and antioxidant proteins [110].

Activation of the ATF6 transcription factor by UPR allows nuclear translocation of the factor to increase the expression of several target genes, including chaperones GRP78 and GRP94, and the transcription factor X-box-binding protein 1 (XBP1). Interestingly, XBP1 mRNA requires further processing by IRE1, suggesting that signaling cross-talk tightly regulates the ER stress pathways (see below) [110]. In some cell types ATF6 also regulates acute inflammatory response genes during ER stress, which can lead to systemic effects [118].

IRE1 is a Ser/Thr protein kinase and endoribonuclease. IRE1 cleaves a number of mRNAs including mRNAs targeted for the ER as well as the 28S ribosomal subunit; both of these events are likely involved in the reduction of protein synthesis [110]. IRE1 also initiates unconventional splicing of XBP1 mRNA in the cytoplasm, allowing XBP1 to be translated in its active form. The active form of XBP1 protein is then translocated to the nucleus where it binds to the ER stress response element (ERSE) found in the promoters of target genes, resulting in the subsequent increased expression of other chaperones, transcription factors, ER associated protein degradation components, and proteins involved in the secretory pathway [119].

In a later stage of ER stress, if protein unfolding is resolved, both eIF2α and ATF6 up-regulate the C/EBP homologous protein transcription factor (CHOP) [112,120]. CHOP targets expression of the growth arrest and DNA damage-inducible protein 34 (GADD34), a phosphatase that dephosphorylates

eIF2α to restore protein translation [112]. However, if the levels of unfolded proteins have not been reduced, the activation of eIF2α by CHOP can induce further ER stress [110]. Data indicate that CHOP, c-Jun NH_2-terminal kinase (JNK), and caspase activation are all involved in ER stress-induced apoptosis [110]. During ER stress, IRE1 can recruit TRAF2 to the plasma membrane, which leads to the activation of the JNK pathway and subsequent cell death via caspase-12 activation [121]. Other studies demonstrated that JNK activation downstream of ER stress leads to Bax activation, MOMP, and activation of caspase 3 [122].

Studies indicate that ROS and ROS-generating substances induce ER stress leading to cell death [113,123–126]. Radiation has also been shown to elicit the induction of ER stress in immortalized cell lines and in normal endothelial cells [27,127]. Our laboratory recently demonstrated that in primary lung endothelial cells IR-induced ER stress contributes to apoptosis but not to accelerated senescence [27]. Inhibition of ER stress by salubrinal reduced levels of caspase-3 activation but not levels of p21/waf upregulation in response to IR. Blockade of ER stress and JNK activation during IR exposure also inhibits MOMP and caspase activation via the intrinsic apoptosis pathway in some transformed cell types [122]. Methodologies for increasing IR-induced ER stress are currently a topic for cancer therapeutic research [128–130].

3.2. Radiation-Induced Necrosis

In contrast to apoptosis, necrosis is traditionally viewed as a passive process, characterized by the early rupture of the plasma membrane, dilatation of cytoplasmic organelles, and uncontrolled release of cytoplasmic contents [131,132]. Necrosis typically results from a higher magnitude of stress relative to either apoptosis or cellular senescence [31,131,133], and radiation-induced necrosis has been demonstrated *in vitro* and *in vivo* [134–137]. For example, high radiation exposures (≥ 32–50 Gy) were demonstrated to induce necrosis in neurons and in p53-deficient human leukemia cells in cell culture [11,138]. However, lower doses of gamma radiation (0.5 Gy) were shown to cause necrosis in the immortalized human keratinocyte cell line HaCaT [137]. In contrast to apoptosis, necrosis (including radiation-induced necrosis) is associated with increased inflammation of the surrounding normal tissue [8,139].

In contrast to necrosis induced by severe physiochemical stress, recent research has focused on programmed necrosis or necroptosis [140]. This dedicated signaling pathway is often triggered by traditional apoptotic stimuli (e.g., TNF, FasL, TRAIL) when caspase-8 activity is inhibited by deletion or binding to cFLIP and/or viral inhibitors such as CrmA or vICA, permitting the formation of "necrosome" protein complexes containing receptor interacting proteins 1 and 3 (RIP1/RIP3). Deubiquitination of RIP1 allows it to interact with the death domain of FADD, promoting recruitment and mutual phosphorylation of RIP1 and RIP3 and downstream necroptotic signaling preferentially through the mitochondrial permeability transition complex [141,142]. In response to genotoxic stress, a similar "ripoptosome" containing FADD, caspase-8 and RIP1 can assemble and mediate either apoptosis or necroptosis, independent of DRs or mitochondrial signaling [143]. In both scenarios, necroptosis is specifically blocked by the RIP1 kinase inhibitor necrostatin-1 [144]. To date, a single study has demonstrated that necroptosis involving RIP1 contributes to IR-induced cell death in irradiated anaplastic thyroid and adrenocortical cancers [145]. IR-induced cell death was blocked in

those tumors by necrostatin-1 treatment, suggesting strategies to promote RIP1 activation may help to radiosensitize certain cells. However, such a strategy must weigh the risks and benefits of promoting the associated release of highly immunogenic molecules known as "danger-associated molecular patterns" (DAMPs) from necrotic cells [140]. Enhanced inflammation triggered by necroptosis may augment anti-tumor immune responses, but ultimately provoke unintended damage to healthy tissues.

3.3. Radiation-Induced Autophagy

Autophagic cell death is a nonapoptotic (caspase-independent), highly evolutionarily conserved mechanism of programmed cell death, characterized by the catabolism of cellular constituents by the cell's own intracellular enzymes [146]. Under normal conditions, microautophagy and chaperone-mediated autophagy allow the limited breakdown of abnormal proteins, cellular debris, or damaged organelles to maintain cellular homeostasis and/or as a means to recycle biological components [146]. Under extreme conditions—including nutrient starvation, oxidative or genotoxic stress, protein aggregation, or extreme organelle damage—autophagy, also called macroautophagy, can result in cell death [147]. Autophagy is recognized as an independent mechanism of programmed cell death, but there is significant cross-talk between pathways activated for autophagy and apoptosis [147].

In mechanistic studies of micro- and macro-autophagy, the nucleation of the double-membraned autophagosome vesicle was demonstrated to require the formation of two key complexes, one comprised of multiple autophagy-related gene (Atg) proteins and the other containing microtubule-associated protein 1 light-chain subunit 3 (LC3) [146,147]. Nucleation of the phagophore can be initiated by the activation of phosphoinositide-3-kinase (PI3K), by mitochondrial activation of the extracellular regulatory kinase (ERK), or by the activation of c-Jun *N*-terminal kinase (JNK) [146]. The phagophore elongates through the incorporation of proteins and lipids to encapsulate the designated cargo. This process is mediated by two ubiquitin-like systems involving a number of Atg proteins and LC3 [147]; although not completely defined, phagophore elongation is hypothesized to involve soluble *N*-ethylmaleimide-sensitive factor attachment protein receptor (SNARE) proteins and endosomal trafficking proteins [146]. Once the autophagosome has matured and is sealed, it fuses with the lysosome to form the autophagolysosome, in which the cargo is degraded. The process of autophagy involves complex regulation by protein sensors of nutrient levels and metabolism, by ER stress pathways, by mitochondrial stress pathways, and by oxidative and nitrative signaling [146].

Because autophagy pathways can function to remove damaged cellular components and serve as a mechanism for programmed cell death, autophagic pathways can paradoxically allow either increased survival or cell death in response to IR depending upon the cellular context [147–149]. IR has been demonstrated to induce microautophagy or macroautophagy in a variety of cancer cells, including breast, colon, lung, esophageal, and prostate cancer cells [129,130,150,151]. Interestingly, key proteins regulating autophagy were shown to be significantly decreased in normal lung tissue *in vivo* 24 h following 6 Gy exposure, suggesting a specific and severe dysregulation of autophagy in this tissue following IR. This effect was not observed in kidney or liver tissue following identical radiation exposures [152].

Several studies have shown that in some cases, agents that increase microautophagy result in improved cellular survival from IR, possibly due to the increased clearance of damaged macromolecules that would otherwise trigger cell death. The PI3K/Akt pathway is a pro-survival pathway in normal and cancer cells, and it was hypothesized that the inhibition of PI3K/Akt in conjunction with IR would increase apoptosis. Paradoxically, the use of inhibitors of the PI3K/Akt pathway (such as Ly294002 and PI-103) actually increased survival in cancer cells exposed to IR through the microautophagy [153]. Chloroquine and bafilomycin A1, both weak bases, raise the pH of the lysosome, and block the fusion of the phagosome with the lysosome, inhibiting late stages of autophagy. In contrast, 3-methyladenine (3-MA) inhibits early autophagy by interfering with the formation of a phagophore initiation complex [146]. Inhibition of autophagy with chloroquine, balfilomycin A1, or 3-MA increased cancer cell death in response to IR, including that of cancer stem cells, via increased apoptosis triggered by the accumulation of autophagosomes [153].

In contrast with these studies, induced autophagy in some cancers results in sensitization to IR. Activation of autophagy abrogated radiation resistance of glioblastoma cells and lung cancer cells to IR [154,155]. Additionally, the zinc ionophore PCI-5002 was demonstrated to radiosensitize lung cancer cells by inducing autophagic cell death [150]. Agents for the sensitization of cancer cells to radiation-induced autophagy are currently being investigated for improving tumor responses to clinical radiation [156,157].

3.4. Radiation-Induced Accelerated Senescence

The concept of cellular senescence was first introduced as early as the 1960s by Hayflick and Moorhead who demonstrated that nontransformed, nonimmortalized cells were capable of a finite number of passages before they lost their ability to replicate *in vitro*; this phenomenon is known as the "Hayflick limit" [158,159]. In contrast with growth-arrested quiescent cells that may resume proliferation in response to physiological stimuli, the growth arrest of senescent cells is essentially irreversible [160]. Various stress stimuli have been shown to induce cellular senescence, including oxidative stress, DNA damaging agents such as IR and chemotherapy, and sustained signaling by certain cytokines such as interferon-alpha and transforming growth factor-β (TGF-β) [161,162]. Senescence can also be induced by oncogenic gene activation, and thus the senescence pathway may provide a mechanism by which cells avoid neoplastic transformation [162,163]. Much of our understanding regarding the activity of senescent cells is derived from cell culture studies, but the importance of senescence *in vivo* is increasingly being recognized. The accumulation of senescent cells in older tissues and in tissues following IR or chemotherapy may account for some age-associated and IR- or chemotherapy-induced pathologies [36,162,164].

Senescent cells display a wide variety of alterations in gene expression, including: (1) aberrant expression of cell cycle regulatory proteins, contributing to the inability to progress through the cell cycle; (2) upregulation of anti-apoptotic proteins; and (3) robust expression of mRNAs for secreted proteins includes inflammatory cytokines, growth factors, and proteases, resulting in a condition termed the "secretory phenotype" [36,164]. In culture, senescent cells have a notably altered morphology, and may assume a "fried egg"-like appearance, with altered cytoskeletal organization and changes in cell-cell contacts. Senescence in many cells has been demonstrated to correlate with

increased expression of a form of β-galactosidase, termed senescence-associated β-galactosidase (SA-β-gal), which has become a recognized marker for senescence [165]. Two primary DNA damage-induced signaling pathways have been demonstrated to lead to cell cycle arrest associated with senescence: the p53/p21waf1 pathway, and the p16 inhibitor of cyclin dependent protein kinase 4(p16INK4a)/retinoblastoma protein (Rb) pathway [166].

Paradoxically, both accelerated senescence and apoptosis can involve stabilization and activation of the p53 protein [163]. Studies indicate that the mechanism of divergent signaling by p53 for differential activation of cell cycle arrest or cell death is not completely understood [167]. Stabilization of p53 in senescence is believed to occur in part by its acetylation as the result of ATM activation and the inactivation of NAD-dependent deacetylase sirtuin-1 (SIRT1), a deacetylase of p53 [168,169]. In contrast with apoptosis, which requires p53 regulation of apoptotic gene proteins, a critical step in p53-induced senescence is the transcriptional activation of p21/waf1. p21/waf1, a cyclin dependent kinase inhibitor 1, inhibits cyclin-dependent kinases (Cdks) including Cdk2 and 4/6; the specific phase of the cell cycle inhibited by p21 may be cell type-dependent, and blockade in G_1, G_2, or S-phase have been reported following DNA damage [161,167,170–173]. p21/waf also protects the cell from undergoing apoptosis following DNA damage [167,174]. The initiation of apoptosis often requires an active cell cycle, which is effectively blocked by expression of p21 [175,176]; additionally p21 can interfere with apoptotic signaling by through direct interactions with pro-apoptotic proteins, thus providing a second mechanism for the generation of cell cycle arrest instead of cell death [174,177,178]. Recently the E2F-associated phosphoprotein (EAPP) was demonstrated to be upregulated in response to DNA damage and to independently increase p21/waf1 transcription; EAPP was also shown to inhibit DNA damage-induced apoptosis in a p21/waf1-dependent manner [174].

A second pathway for DNA damage-induced cellular senescence involves regulation of p16INK4a and Rb [166,169]. IR was demonstrated to increase cellular levels of p16INK4a and the alternative reading frame protein of INK4a (p19Arf), an inhibitor of the p53 inhibitor mouse double minute 2 homolog (Mdm2) [179,180]. These two proteins act together to stop cell cycle progression. p16 INK4a is a cyclin dependent kinase inhibitor; by inhibiting Cdk kinases p16INK4a prevents the phosphorylation and inactivation of the tumor suppressor protein Rb [181]. The primary cell cycle-inhibitory activity of Rb appears to involve its interaction with the members of E2F family of transcription factors. E2F proteins regulate a number of genes involved in the progression through the cell cycle, and Rb binds to E2F proteins, sequestering them in the cytoplasm and inhibiting their transcriptional activity [181]. As its name indicates, p19Arf is transcribed from an alternative reading frame at the same locus as p16INK4a [181,182]. p19Arf is known to inhibit the cell cycle through several mechanisms, including activation of p53 and binding to and inhibition of the ribosomal chaperone nucleophosmin/B23 (NPM) [182,183].

Recent studies suggest that accelerated senescence is a state of continuous cell proliferative signaling in the presence of a cell cycle blockade [184–187]. At the center of this scheme is the mammalian target of rapamycin (mTOR), which acts as a hub for many of the signaling pathways involved in cell growth, proliferation and homeostasis [188]. mTOR inhibition by rapamycin attenuates the increase in senescence-associated β-galactosidase activity in several models of cellular senescence [184–187]. Indeed, rapapmycin is a well-established inducer of autophagy, which may directly impede accelerated senescence. Furthermore, a recent study by Iglesias-Bartolome

demonstrated that rapamycin blocks radiation-induced epithelial stem cell senescence via p16/ink4a and substantially reduces subsequent mucositis in a murine model of head/neck radiation injury [12]. This study also provides evidence that mTOR activation is critical for IR-induced accelerated senescence.

Exposure to IR has been shown to cause some levels of accelerated senescence in almost all types of cells, whether transformed, immortalized or normal cells [27]. It appears that accelerated senescence is the default response of some cell types to IR where accelerated senescence occurs at lower doses than those required for the induction of apoptosis or necrosis in same cells [27]. A variety of cancer cell types contain mutations to avoid cellular senescence. Mutations in Rb, p53, and p16 have been demonstrated to lead to continued proliferation in the presence of DNA damage or oxidative stress, and ectopic expression of these proteins can induce spontaneous senescence [181,189,190]. Furthermore, the p16INK4a pathway appears to be a back-up mechanism for the p53/p21waf1 pathway as p53-deficient fibroblasts exposed to IR to induce senescence accumulate p16INK4a, but not p21 [190].

3.5. Radiation Effects in Bystander Cells

For many years, a dogma in radiation biology posited that manifestation of biological effects of IR is solely due to direct actions on irradiated cells. This classical target theory asserts that cellular damage is due to the deposition of energy for the ionization of biological macromolecules and/or the interactions of generated reactive oxygen species with biological molecules [191]. However, an accumulating body of evidence has established non-targeted (bystander) effects as a *bona fide* response to IR exposure [191–193]. The radiation bystander effect is broadly defined as the induction of biological effects in cells that do not directly absorb radiation including cells that are in close proximity to irradiated cells or, in the case of partial body irradiation, cells in distant organs [193,194]. The significance of the radiation bystander effect is increasingly appreciated as a long-term side effect of radiation exposure. Research indicates that the bystander effect of radiation can be positive or negative [194]. Similar to findings regarding the direct effects of radiation, the bystander effects of radiation are dependent upon the LET, dose rate, total dose and specific radiosensitivity of the cells [194]. The negative effects of radiation on bystander cells include accelerated senescence, necrosis, and apoptosis, each contributing to decreased clonogenicity [195,196]. In contrast, radiation can induce increased proliferation of tumor cells in some settings [194].

Early evidence for the bystander phenomenon originated from experiments utilizing cell culture medium transfer from irradiated cells to non-irradiated cells or the co-culture of irradiated cells with non-irradiated cells [196,197]. Cell culture studies have demonstrated that bystander cells can accumulate DNA damage following exposure to signals from irradiated cells, as evidenced by the development of micronucleus formation, DSB, and sister chromatid exchanges [195,196,198–201]. DNA effects were demonstrated in non-transformed, non-immortalized bystander cells as well as in some transformed cell types [195,196,201]. Research has revealed potential roles for direct cell-cell communication through gap junctions between irradiated cells and bystander cells, as well as the release of soluble factors from irradiated cells to induce bystander effects. A range of extracellular molecules released from irradiated cells has been implicated in bystander effects, including ROS and a

variety of secreted factors such as transforming growth factor-β1 (TGF-β1), tumor necrosis factor-α, and/or cyclooxygenase-2 [193].

Paradoxically, although radiation often has lethal effects on many types of bystander cells, some cells exhibit increased growth as an indirect effect of radiation [194]. Increased proliferation has been observed in normal liver epithelial cells and non-transformed fibroblasts, as well as in several transformed cells [53,202]. Proliferation in bystander cells has been linked to the release of soluble factors into the medium [53,194]. Nitric oxide and TGF-β1 have been identified as potential agents mediating bystander proliferation in some non-transformed cells [203,204]. Another recent study of the effects of radiation-induced tumor cell apoptosis on overall tumor proliferation identified the release of prostaglandin E2 as a proliferative factor [53]. The phenomenon linking tumor cell apoptosis induction to out-of-field tumor cell proliferation has been termed a "Phoenix Rising" pathway [53]. DNA alterations combined with the proliferative effects in bystander cells may together be responsible for the nonlinear threshold model for radiation-induced carcinogenesis [194].

Studies of animal models have attempted to identify bystander effects and mechanisms *in vivo* [194]. Partial lung irradiation in rats demonstrated that regions of the lung outside of the radiation field exhibited DNA damage, albeit at lower levels than areas of the lung exposed to direct irradiation [10,205]. However, the DNA damage in out-of-field areas of the lung was attributed to the generation of ROS by activated inflammatory cells, and the damage could be suppressed by superoxide dismutase or ROS scavengers [10,197]. In mice exposed to unilateral X-irradiation, DNA damage was demonstrated in skin tissue more than 1 cm outside of the radiation field [206]. However, in radiation skin injury, excessive delayed tissue damage can be attributed to the activation of resident mast cells and other inflammatory cells [207]. Thus, the interpretation of *in vivo* out-of-field radiation effects may be complicated by radiation-induced inflammation that can induce tissue damage independently from bystander mechanisms.

4. Conclusions

Radiation-induced toxicity in mammalian cells involves various modes of cell death including apoptosis, necrosis, and autophagy, as well as accelerated senescence. Complex signaling events are induced in these modes of cell death and the cellular response is likely dependent upon the radiation exposure as well as the myriad aspects of the cellular context. The precise mechanisms for the biological selection of a specific mode of cell death following IR exposure have not been unequivocally established. Additionally, the mechanism(s) by which radiation induces death in cells directly affected by radiation are likely different from the mechanism(s) by which bystander cells undergo cell death. Knowledge of the mechanisms for radiation-induced damage in the context of cell death modes may provide insights into the development of more effective therapeutic countermeasures and interventions for the mitigation of radiation associated pathologies.

Merrymeeting News

Spring 2016 Vol. XXV, No. 2

The Newsletter of Friends of Merrymeeting Bay • PO Box 233 • Richmond Maine 04357 • 207-666-1118 • www.fomb.org

Friends of Merrymeeting Bay (FOMB) is a 501(c)(3) non-profit organization. Our mission is to preserve, protect, and improve the unique ecosystems of the Bay through:

Education

Conservation & Stewardship

Research & Advocacy

Member Events

Support comes from members' tax-deductible donations and gifts.

Merrymeeting News is published seasonally and is sent to FOMB members and other friends of the Bay.

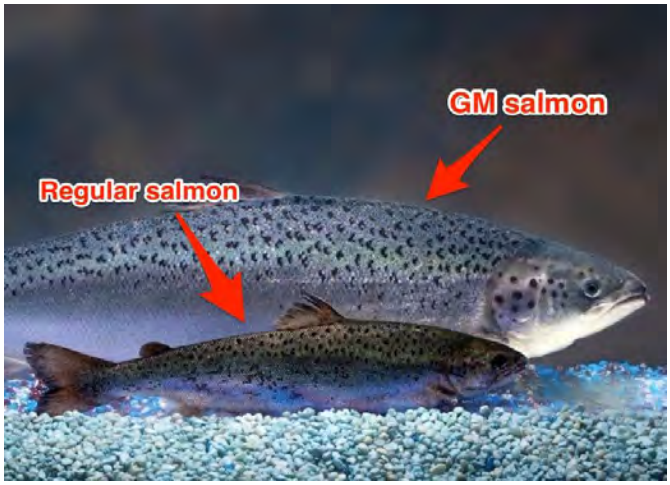
Lawsuit Challenges FDA's Approval of Genetically Engineered Salmon

Coalition of Fishing, Consumer, and Environmental Groups Say First-ever Approval of Laboratory-Created Food Animal Violated Laws and Ignored Risks to Wild Salmon and Fishing Communities

SAN FRANCISCO, CA 3/30/2016 - Friends of Merrymeeting Bay joined with a broad coalition of environmental, consumer, and commercial and recreational fishing organizations in suing the U.S. Food and Drug Administration (FDA for approving the first-ever genetically engineered (GE) food animal, an Atlantic salmon engineered to grow quickly. The man-made salmon was created by AquaBounty Technologies, Inc. with DNA from three fish: Atlantic salmon, Pacific king salmon, and Arctic ocean eelpout. This marks the first time any government in the world has approved a GE animal for commercial sale and consumption.

The plaintiff coalition, jointly represented by legal counsel from Center for Food Safety and Earthjustice, includes Pacific Coast Federation of Fishermen's Associations, Institute for Fisheries Resources, Golden Gate Salmon Association, Kennebec Reborn, Friends of Merrymeeting Bay, Ecology Action Centre, Food & Water Watch, Center for Biological Diversity, Friends of the Earth, Cascadia Wildlands, and Center for Food Safety.

In approving the GE salmon, FDA determined it would not require labeling of the GE fish to let consumers know what they are buying; which led Congress to call for labeling in the 2016 omnibus spending bill. FDA's approval also ignored comments from nearly 2 million people opposed to the approval because the agency failed to analyze and prevent the risks to wild salmon and the environment, as well as fishing communities, including the risk that GE salmon could escape and threaten endangered wild salmon stocks.



AquaBounty's GE salmon will undertake a 5,000-mile journey to reach U.S. supermarkets. The company plans to produce the GE salmon eggs on Prince Edward Island, Canada. The GE salmon will then be grown to market-size in a facility in Panama, processed into fillets, and shipped to the U.S. for sale. That complicated scheme is only for the initial approval, however. AquaBounty has publicly announced plans to ultimately grow its GE fish in the U.S. rather than Panama, and sell it around the world. Despite this, FDA's approval only considered the current plans for the far-flung facilities in Canada and Panama, leaving the risk of escape and contamination of U.S. salmon runs unstudied.

The lawsuit challenges FDA's claim that it has authority to approve and regulate GE animals as "animal drugs" under the 1938 Federal Food, Drug, and Cosmetic Act. Those provisions were meant to ensure the safety of veterinary drugs administered to treat disease in livestock and

Frankenfish (continued)

were not intended to address entirely new GE animals that can pass along their altered genes to the next generation. The approval of GE salmon opens the door to other genetically engineered fish and shellfish, as well as chickens, cows, sheep, goats, rabbits and pigs that are reportedly in development.

"FDA's decision is as unlawful as it is irresponsible," said George Kimbrell, senior attorney for Center for Food Safety and co-counsel for the plaintiffs. "This case is about protecting our fisheries and ocean ecosystems from the foreseeable harms of the first-ever GE fish, harms FDA refused to even consider, let alone prevent. But it's also about the future of our food: FDA should not, and cannot, responsibly regulate this GE animal, nor any future GE animals, by treating them as drugs under a 1938 law."

The lawsuit also highlights FDA's failure to protect the environment and consult wildlife agencies in its review process, as required by federal law. U.S. Atlantic salmon, and many populations of Pacific salmon, are protected by the Endangered Species Act and in danger of extinction. Salmon is a keystone species and unique runs have been treasured by residents for thousands of years. Diverse salmon runs today sustain thousands of American fishing families, and are highly valued in domestic markets as a healthy, domestic, "green" food.

When GE salmon escape or are accidentally released into the environment, the new species could threaten wild populations by mating with endangered salmon species, out-competing them for scarce resources and habitat, and/or introducing new diseases. Studies have shown that there is a high risk for GE organisms to escape into the natural environment, and that GE salmon can crossbreed with native fish. Transgenic contamination has become common in the GE plant context, where contamination episodes have cost U.S. farmers billions of dollars over the past decade. In wild organisms like fish, it could be even more damaging.

"There's never been a farmed salmon that hasn't eventually escaped into the natural environment. Why should we believe that long term, these frankenfish won't be the same?" asked Golden Gate Salmon Association Executive Director John McManus.

The world's preeminent experts on GE fish and risk assessment, as well as biologists at U.S. wildlife agencies charged with protecting fish and wildlife heavily criticized the FDA decision for failing to evaluate these impacts. FDA ignored their concerns in the final approval.

Thoughts from Andrew Kimbrell

Excerpted from an address entitled: Salmon Economics (and other lessons).
23rd ANNUAL E. F. SCHUMACHER LECTURES, October, 2003, Stockbridge, MA

It was early September, and I was standing at the mouth of the Tsiu River on central Alaska's little explored Lost Coast. It was about an hour into the incoming tide, and the water was just above my waist. I was midway in the fifty-foot-wide entrance to the river and could see the waves breaking in front of me with their rhythmic wakes swelling against and around me. The sleek bodies of the silver salmon were everywhere, filling the incoming waves. These beautiful and powerful spawning cohos were rushing en masse into the Tsiu, riding the tide on their last, determined journey.

I stood with legs wide, arms outstretched in the waves, watching and feeling the urgent swell of life coming from the sea to spawn in these chilled waters, which were rushing and tumbling from the melting Bering Glacier eight miles upstream. As the cohos pushed upstream through the narrow inlet, they brushed my thighs and torso, touched my arms and hands. I found myself laughing in surprise and awe.

That day began my multi-year tutelage under the cohos. Over time I have learned many lessons from these beloved wilderness teachers, and just as their return each year keeps a promise, so the promise of ever new lessons is also kept.

Thoughts (continued)

When the Pacific salmon return to the rivers of their birth, they carry in their bodies a number of nutrients, including nitrogen and phosphorous garnered from their ocean sojourn. In fact, isotopic analyses indicate that riverside vegetation near spawning streams receives 22 to 24 percent of its nitrogen—the nutrient that most commonly encourages plant growth—from salmon. As a result, trees on the banks of salmon-stocked rivers grow more than three times faster than their counterparts along a salmon-free river. Alongside spawning streams Sitka spruce (Picea sitchensis) have been found to take eighty-six years instead of the usual three hundred to reach 50 cm. in thickness. Research also shows that at least one-fifth of the nitrogen in the needles of Sitka spruce trees and other plants near spawning sites comes from the ocean via Pacific salmon carcasses. These same trees that have been fertilized by the carcasses enhance the quality of breeding and rearing habitats for the fish by providing shade, sediment and nutrient filtration, and large woody debris.

In more recent years a variety of companies and scientists intensified their efforts to ratchet up the natural salmon growth rates in hopes of maximizing the profitability of aquaculture. With much experimentation it was discovered that salmon size and growth speed could be boosted most efficiently by engineering them with growth genes from other fish species. In 2000 a Massachusetts and Canadian company, Aqua Bounty, was the first to seek permission from the U.S. Food and Drug Administration to grow and sell Atlantic salmon genetically engineered to grow faster and larger.

Subsequently, however, it was discovered during laboratory experiments that the new genes in the salmon were potentially catastrophic to the species. Researchers called them "Trojan" genes, reminiscent of Homer's account of the horse that entered Troy and ultimately caused its destruction. It turned out that the larger, engineered salmon were more attractive to mates during reproduction, but because of unexpected physiological havoc caused by the new genes, there was one-third greater die-off in the offspring of the gene-altered fish. This stood the concept of evolution on its head. It was survival of the unfittest. The engineered fish were triumphant in dominating reproduction, but they were destroying the species as they reproduced. When the researchers looked at the terrible reproductive arithmetic, they calculated that the release of only 60 of these genetically engineered salmon into the environment could result in the extinction of a native species of 60,000 salmon in just 40 generations.

It is important to realize that once the salmon engineered with the Trojan genes escape or are released, they cannot be recalled or eliminated. Chemical pollution most often dilutes over time, but biological pollution such as that caused by these engineered salmon is irreversible. The altered salmon, once in rivers or the ocean, will reproduce, mutate, and disseminate. Their polluting power will only gain with time. Extinction of the wild salmon will be impossible to halt.

Concrete steps such as filing law suits, protecting habitat, and staging protests are critical in protecting salmon, and nature itself, from the onslaught of the demands of capital, technology, and the market. It is becoming ever more evident, however, that these and similar actions will not be sufficient in and of themselves to generate the paradigm shift to a new Earth-centered economics.

The repeated refrains of the silver salmon's cycle and journey vibrate in me still. They have not left me, nor will they. The silvers have become actual and symbolic companions, both comforting and inspiring. Since my first encounter with them many years ago I have often returned to the Tsiu and nearby wilderness streams to be with the cohos for the mystery of their seasonal life-and-death journey (a time that includes my own birthday). Despite the frightening realities our current economic and technological systems have brought us and them, the salmon continue to teach me calmness and courage in my search, no longer for perfection or progress but for completeness and a life-giving return journey. I understand why they have so often attained the highest place in the hierarchy of native Alaskan totems. They have become for me, an often disillusioned child of Christian culture, both a sacrament (something that embodies the sacred) and a lesson about the cyclical journey of giving one's life so others may live.

Andrew Kimbrell is an internationally recognized writer, an activist, and public interest lawyer. He founded and is Executive Director of the Center for Food Safety. As an attorney, Kimbrell has successfully challenged federal agencies in several historic court cases. He initiated the court challenge that resulted in a U.S. Supreme Court victory forcing, for the first time, EPA regulation of greenhouse gases and their impact on climate change. He also pioneered the legal strategy that led to the Supreme Court ruling that DNA is not patentable due to being a "product of nature." Through his leadership at CFS, Kimbrell has been at the forefront of legal challenges to genetically engineered crops and lawsuits forcing FDA to adopt new food safety regulations.

NIH Study Finds Cell Phone/Smart Meter Radiation Causes Brain & Heart Cancers

The National Toxicology Program (NTP) under the National Institutes of Health has completed the largest-ever animal (rats and mice) study on nonionizing radiation and cancer. Partial results released on May 26th confirm whole body exposures to low level radiofrequency radiation (RFR) of the type emitted by cell phones, smart meters and other wireless devices and within currently allowable safety limits, are the "*likely cause*" of brain and heart cancers in these animals, according to Dr. John Bucher, Associate Director of the NTP.

The $25 million dollar study planned since 1999 showed one in twelve (12) male rats (8.3%) developed either malignant cancer (brain and rare heart tumors) or pre-cancerous lesions that can lead to cancer. Tumors called schwannomas were induced in the heart, and in the same kind of brain cells that have led to acoustic neuromas seen in human studies. The NTP says it is important to release these completed findings now given the implications to global health. No cancers occurred in the control group.

Dr. Lennart Hardell, MD, PhD of Sweden's Orebro University and an expert witness in the Maine Smart Meter Health Investigation says "*(T)he animal study confirms our findings in epidemiological studies of an increased risk for glioma and acoustic neuroma among people that use wireless phones, both cell phones and cordless phones (DECT). Acoustic neuroma is a type of Schwannoma, so interestingly this study confirms findings in humans of increased risk for glioma and acoustic neuroma. In 2013 we called for upgrading the risk in humans to Group 1, the agent is carcinogenic to humans. It is now time to re-evaluate both the cancer risk and other potential health effects in humans from radiofrequency radiation and also inform the public," says Hardell. "This NTP evidence is greatly strengthening the evidence of risk, is sufficient to reclassify cell phone radiation as a known cancer-causing agent, and confirms the inadequacy of existing public safety limits.*"

Dr. Christopher Portier, formerly with the NTP commented this is not just an associated finding—but that the relationship between radiation exposure and cancer is clear. *"I would call it a causative study, absolutely. They controlled everything in the study. It's [the cancer] because of the exposure. This is by far—far and away—the most carefully done cell phone bioassay, a biological assessment. This is a classic study that is done for trying to understand cancers in humans".*

We have written in Merrymeeting News since 2011about the dangers of radiofrequency radiation from wireless devices, particularly smart meters which bring exposures to rural Maine. Birds, bees, other insects and mammals all show adverse responses to low-level electromagnetic field exposures. As levels of "electrosmog" grow with wireless proliferation not only from land sources but now also space-based platforms, the harbinger of an "Electronic Silent Spring" should alarm anyone who cares about our wildlife and civilization, much the same as Rachel Carson's alarm did in bringing the effects of pesticide exposure to the public eye.

Dr. Jerry Phillips, PhD, is biochemist and director of the Excel Science Center at the University of Colorado at Colorado Springs. An educator and research scientist, Phillips conducted Motorola-funded research into the potential health impacts of cell phones during the 1990s while he was with the U.S. Department of Veterans Affairs' Pettis VA Medical Center in Loma Linda, California. Phillips and his colleagues looked at the effects of different radiofrequency signals on rats, and on cells in a dish. Phillips also testified for health advocates in Maine's smart meter investigation.

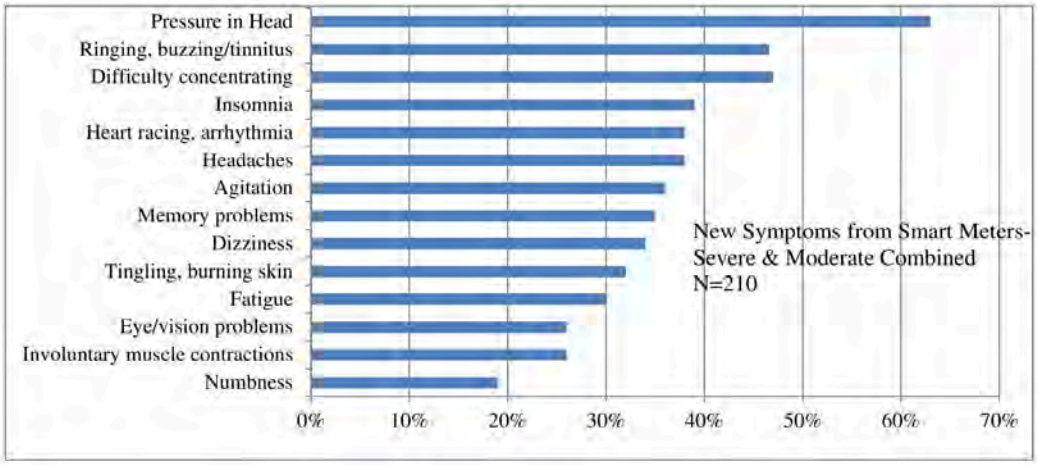
"The most troublesome finding to Motorola at the time is that these radiofrequency signals could interact with living tissues, which is what we saw in the rats," he said in a recent Scientific American interview, adding:

"But you have to realize that this issue opens up a much bigger can of worms than cell phones. If this radiation, this form of energy can interact with biological tissue then it's going to reopen a lot of what were supposedly settled issues regarding the safety of wireless communications. If we're going to be bathed in a whole new electromagnetic environment, how safe is it?"

While cancers from RFR are certainly of great concern, perhaps of greater concern are debilitating non-cancer symptoms disorienting and causing avoidance behavior and other biological and behavioral responses in wildlife and humans. In people,

NTP Study (continued)

relationships have commonly been stressed and destroyed, jobs have been lost and homes of many years sold or abandoned as a result of sensitivities to RFR. Consider if you suffer any or a number of the common RFR symptoms found in an international survey of those affected by smart meters as shown in this chart:



Conrad & Friedman, 2013. Smart Meter Health Effects Survey & Report

Smart meters in particular have sensitized many to any wireless device including routers and cell phones. The inability to use these common tools severely inhibits folks in their personal and economic lives. Their ability to live normal lives in the 21st century has been severely compromised immediately versus 10-30 year latency periods typical in cancer development. This change in ability to use these devices is directly correlated to smart meter exposure.

The suffering and the social and economic effects of chronic debilitating symptoms victims have experienced since smart meter exposure simply cannot be ignored, and provides ample evidence there is something about smart meters (evidence suggests the RF from up to 170,000 transmissions/day is conducted on home wiring) causing extreme harm to at least some, and possibly eventually all persons. While there is obviously only a portion of our population manifesting acute electromagnetic hypersensitivity (EHS) symptoms now (the canaries), and even fewer recognizing their source, we are all being exposed and are all susceptible.

"This is a game changer, there is no question," said Dr. David Carpenter, MD, PhD, director of the Institute for Health and the Environment at the University of Albany and also an expert witness in Maine. *"It confirms what we have been seeing for many years —though now we have evidence in animals as well as in humans."* Quoted in Microwave News, Carpenter went on to add, *"The NTP has the credibility of the federal government. It will be very difficult for the naysayers to deny the association any longer."*

Kennebec and Androscoggin Proposed Critical Habitat for Atlantic Sturgeon

NOAA Fisheries announced June 2, two proposed rules designating critical habitat for five distinct population segments [DPS] of federally listed Atlantic sturgeon. The proposed areas provide important protected river habitats for the threatened Gulf of Maine population segment and the endangered population segments of the New York Bight, Chesapeake Bay, Carolina and South Atlantic. NOAA Fisheries listed the Atlantic sturgeon under the Endangered Species Act in 2012. The two local designations include the Kennebec to Lockwood dam in Waterville and the Androscoggin to the Brunswick-Topsham dam.

The ESA requires NOAA Fisheries [formerly and often still known as the National Marine Fisheries Service or NMFS] designate critical habitat when a species is listed as threatened or endangered. Under the ESA, critical habitat is defined as geographic areas occupied by the species, and containing features essential to the conservation of that species. Critical habitat can also include geographical areas that are not currently occupied by the species, but that are essential to its conservation, historical habitat for example.

Critical habitat does not create preserves or refuges. Instead, when a federal agency is carrying out funding or authorizing an activity that may affect the critical habitat, the federal agency works with NOAA NOAA Fisheries to avoid or minimize

Atlantic Sturgeon (continued)

Photo credit - NOAA Fisheries

potential impacts to the species' habitat. The activity of the federal agency may need to be modified to avoid destroying or adversely modifying the critical habitat.

Shortnose sturgeon, smaller, relative to the threatened Atlantic sturgeon, are listed as endangered but are more abundant in the Merrymeeting Bay estuary. Sturgeon evolved over 200 million years ago. The species has been drastically diminished by over-fishing, toxics, habitat loss and dredging.

Spring Bay Day

May 17th dawned a spectacular Spring Bay Day at Chop Pt. School with blue skies and great temperatures. Students from Pittston, Chop Pt. and for the first time since consolidation of their schools, Brunswick, congregated at this lovely site to have fun learning about "things Bay" while getting their hands and feet dirty. Highlights included Angela Kimberk's Found Art session located right at the Chops being treated to an eagle from the new nest on West Chop Pt. catching a fish in front of them and a seal popping up to check student art works. Although, perhaps it was looking a bit further up the hill to where Lynda Doughty and Dominique Walk from Marine Mammals of Maine taught a session on marine mammal rescue!

Meanwhile over on the east side of the Point students tried their hands at beach seining with Nate Gray and caught a male stickleback in courtship colors while up on the grassy knoll, mud flew in the perennial favorite, watershed modeling taught by Steve Eagles and Kent Cooper. Also on the grass Kathleen McGee, taking a break [not really!] from her awesome job of scheduling students, chaperones and guides with classes for the day, spoke with students about anadromous and catadromous fish using the Bay for spawning and nursery habitat and then coached kids in the ancient practice of gyotaku or fish printing, using our custom school of rubber anadromous species, alewives, blueback herring, American shad, Atlantic salmon, rainbow smelt and striped bass.

Without our volunteers the day couldn't work. Thanks so much to our guides: Betsy Steen, Leslie Anderson, Kathleen McGee, Kent Cooper, Steve Eagles, Steve Musica, Angela Kimberk, Kerry Hardy, Geri Vistein, Jamie Silvestri, Nate Gray, Tom Weddle, Grant Connors, Lynda Doughty, Dominique Walk, Tina and Hannah Goodman, Blaine Carter, Cathy Reynolds, Helen Watts, George Sergeant, Mark Gershman and Amanda Troxell.

Chaperones: Eleanor Wilson, Tom Walling, Bob Fesler, Dana Cary, Jen Jones, Kennon Wilson, Kathie Duncan, David Whittlesey, Judith Clarke, Tina Phillips, Anne Harwood, Bert Singer, Carole Sargent, Tom Foote, David Hammond, Jeff Sebell, Martha Spiess, Joan McDuff, Madelyn Jones-Cressy, Tom Hughes, and Bob Goldman.

Lunch and Critter Wranglers: Joan Llorente and Martin McDonough
And special thanks to out wonderful hosts at Chop Pt. School and to Wild Oats for the fantastic lunch wraps!

We Need You! Please Support Our Important Work

FOMB Leadership

Our accomplishments are due to the hard work of dedicated volunteers, especially those who serve on our committees. If you want to get involved and serve, please contact the committee chair or Kathleen McGee. We always welcome member input and we'd love for you to join us!

Hearing of microwave pulses by humans and animals: effects, mechanism, and thresholds.

Lin JC[1], Wang Z.

Author information

Abstract

The hearing of microwave pulses is a unique exception to the airborne or bone-conducted sound energy normally encountered in human auditory perception. The hearing apparatus commonly responds to airborne or bone-conducted acoustic or sound pressure waves in the audible frequency range. But the hearing of microwave pulses involves electromagnetic waves whose frequency ranges from hundreds of MHz to tens of GHz. Since electromagnetic waves (e.g., light) are seen but not heard, the report of auditory perception of microwave pulses was at once astonishing and intriguing. Moreover, it stood in sharp contrast to the responses associated with continuous-wave microwave radiation. Experimental and theoretical studies have shown that the microwave auditory phenomenon does not arise from an interaction of microwave pulses directly with the auditory nerves or neurons along the auditory neurophysiological pathways of the central nervous system. Instead, the microwave pulse, upon absorption by soft tissues in the head, launches a thermoelastic wave of acoustic pressure that travels by bone conduction to the inner ear. There, it activates the cochlear receptors via the same process involved for normal hearing. Aside from tissue heating, microwave auditory effect is the most widely accepted biological effect of microwave radiation with a known mechanism of interaction: the thermoelastic theory. The phenomenon, mechanism, power requirement, pressure amplitude, and auditory thresholds of microwave hearing are discussed in this paper. A specific emphasis is placed on human exposures to wireless communication fields and magnetic resonance imaging (MRI) coils.

Review

Microwave frequency electromagnetic fields (EMFs) produce widespread neuropsychiatric effects including depression

Martin L. Pall

Professor Emeritus of Biochemistry and Basic Medical Sciences, Washington State University, 638 NE 41st Avenue, Portland, OR 97232-3312, USA

Keywords:
Excessive calcium effects
Oxidative/nitrosative stress
Low-intensity microwave electromagnetic fields

ABSTRACT

Non-thermal microwave/lower frequency electromagnetic fields (EMFs) act via voltage-gated calcium channel (VGCC) activation. Calcium channel blockers block EMF effects and several types of additional evidence confirm this mechanism. Low intensity microwave EMFs have been proposed to produce neuropsychiatric effects, sometimes called microwave syndrome, and the focus of this review is whether these are indeed well documented and consistent with the known mechanism(s) of action of such EMFs. VGCCs occur in very high densities throughout the nervous system and have near universal roles in release of neurotransmitters and neuroendocrine hormones. Soviet and Western literature shows that much of the impact of non-thermal microwave exposures in experimental animals occurs in the brain and peripheral nervous system, such that nervous system histology and function show diverse and substantial changes. These may be generated through roles of VGCC activation, producing excessive neurotransmitter/neuroendocrine release as well as oxidative/nitrosative stress and other responses. Excessive VGCC activity has been shown from genetic polymorphism studies to have roles in producing neuropsychiatric changes in humans. Two U.S. government reports from the 1970s to 1980s provide evidence for many neuropsychiatric effects of non-thermal microwave EMFs, based on occupational exposure studies. 18 more recent epidemiological studies, provide substantial evidence that microwave EMFs from cell/mobile phone base stations, excessive cell/mobile phone usage and from wireless smart meters can each produce similar patterns of neuropsychiatric effects, with several of these studies showing clear dose–response relationships. Lesser evidence from 6 additional studies suggests that short wave, radio station, occupational and digital TV antenna exposures may produce similar neuropsychiatric effects. Among the more commonly reported changes are sleep disturbance/insomnia, headache, depression/depressive symptoms, fatigue/tiredness, dysesthesia, concentration/attention dysfunction, memory changes, dizziness, irritability, loss of appetite/body weight, restlessness/anxiety, nausea, skin burning/tingling/dermographism and EEG changes. In summary, then, the mechanism of action of microwave EMFs, the role of the VGCCs in the brain, the impact of non-thermal EMFs on the brain, extensive epidemiological studies performed over the past 50 years, and five criteria testing for causality, all collectively show that various non-thermal microwave EMF exposures produce diverse neuropsychiatric effects.

Chemicals having roles:

Calcium(2+)
Nitric oxide (NO)
Oxido nitrite (peroxynitrite)

1. Introduction

Microwave syndrome (Hocking, 2001; Johnson Liakouris, 1998), a combination of various neuropsychiatric symptoms originally described in persons with occupational exposures to microwave frequency EMFs, has been disputed largely because of the lack of an apparent mechanism for generating these symptoms. It is reported to often include such symptoms as fatigue, headache, insomnia, dysesthesia (impaired sensation), irritability, lack of concentration and other symptoms (Hocking, 2001; Johnson Liakouris, 1998). Similar but more extensive combinations of symptoms have been reported following occupational exposures in two U.S. government reports from the 1970s/1980s (Naval Medical Research Institute Research Report, 1971; Raines, 1981) and following environmental exposures as described in two more recent reviews (Khurana et al., 2010; Levitt and Lai, 2010).

The goal here is not just to review the epidemiology, however, but more importantly to consider the issue of possible physiological mechanism(s). Hennekens and Buring (1989), on p. 40 in their textbook Epidemiology in Medicine state "The belief in the existence of a cause and effect relationship is enhanced if there is a known or postulated biologic mechanism by which the exposure might reasonably alter risk of developing disease." It is of critical importance therefore to assess possible biological mechanism before considering the epidemiological evidence.

Accordingly, this paper considers the mechanism by which low intensity microwave EMFs impact the cells of our bodies, how that mechanism may be predicted to impact the nervous system, evidence for such impact from experimental animal studies, genetic polymorphism evidence for that mechanism acting in humans to produce neuropsychiatric effects and finally, the epidemiological evidence for such effects in human populations with repeated low level microwave EMF exposure. Consideration of each of these types of evidence influences the overall interpretation presented in this paper.

2. Microwave/lower frequency EMFs act to activate voltage-gated calcium channels

In 24 different studies reviewed earlier (Pall, 2013) and two additional studies (Li et al., 2014; Lisi et al., 2006), microwave and lower frequency low intensity EMF effects were blocked or greatly lowered by calcium channel blockers, agents thought to be specific for blocking voltage-gated calcium channels (VGCCs). In these 26 studies, a total of 5 distinct types of channel blockers were used, with each type having a distinct structure and binding to a distinct site, such that it is essentially certain that these must be acting by blocking VGCCs, which is their only known common property. In each of these 26 studies, each of the responses studied, were blocked or greatly lowered by calcium channel blockers, showing that VGCC activation has roles in producing a wide variety of EMF effects. There is a large literature on changes in calcium fluxes and in calcium signaling following microwave EMF exposure (partially reviewed in Walleczek, 1992; Adey, 1993); each of these, including calcium efflux changes, can be explained as being due to VGCC activation, again suggesting a widespread role of VGCC activation in producing biological responses to EMFs. Pilla (2012) showed that pulsed microwave field exposure, produced an almost instantaneous increase in calcium/calmodulin-dependent nitric oxide (NO) signaling, providing strong evidence that these fields can produce an almost instantaneous VGCC activation. It is likely, that these EMFs act directly on the voltage sensor of the VGCCs to produce VGCC activation (Pall, 2015) with the voltage sensor being exquisitely sensitive to these EMFs because of its physical properties and location in the plasma membrane.

EMFs have been proposed to act to produce a wide variety of responses in the cell, via downstream effects of VGCC activation (Pall, 2013, 2014, 2015), including elevated intracellular calcium [Ca2+]i, excessive calcium and nitric oxide signaling and also excessive peroxynitrite, free radicals and oxidative stress.

VGCC activation has been shown to have a universal or near-universal role in the release of neurotransmitters in the brain and also in the release of hormones by neuroendocrine cells (Berridge, 1998; Dunlap et al., 1995; Wheeler et al., 1994), with such release being produced by calcium signaling. There are high densities of diverse VGCCs occurring in neurons throughout the nervous system. Both the high VGCC density and their function in neurotransmitter and neuroendocrine release throughout the nervous system suggests that the nervous system is likely to be highly sensitive to low intensity EMFs.

3. Genetic polymorphism studies

Genetic polymorphism studies are powerful tools for looking at the roles of specific proteins in human populations. In Table 1, a series of genetic polymorphism studies have been performed that show that an allele producing increased expression of the gene encoding the channel of the main L-type VGCC in the brain, produces diverse neuropsychiatric effects. These studies clearly show that excess L-type VGCC activity can cause neuropsychiatric effects. They also predict, therefore, that increased VGCC activity produced by microwave EMFs may be able to also produce widespread neuropsychiatric effects.

4. Histological and functional changes in central nervous system (CNS) and peripheral nervous system (PNS) in animals exposed to microwave EMFs

The most extensive literature on histological and functional changes in animals is from the Soviet literature from the 1950s/1960s with additional Western literature from the same time period. Both Soviet and non-Soviet literature were reviewed in an English language Publication by Tolgskaya and Gordon (1973). This publication is, therefore, the main focus of this section. That publication was divided into thermal and non-thermal exposure studies, with the non-thermal studies which occupy the majority of the text (pp. 53–137) being of sole interest here.

Table 1
Influence of genetic polymorphism of the CACNA1C in producing diverse neuropsychiatric effects.

Krug et al. (2014)	Polymorphism producing increased expression of CACNA1C L-type VGCC subunit	Influences episodic memory and retrieval
Soeiro-de-Souza et al. (2012)	Polymorphism producing increased expression of CACNA1C L-type VGCC subunit	Produces impaired facial emotion recognition
Tesli et al. (2013)	Polymorphism producing increased expression of CACNA1C L-type VGCC subunit	Produces increased activation of the amygdala during emotional processing
Thimm et al. (2011)	Polymorphism producing increased expression of CACNA1C L-type VGCC subunit	Associated with attention deficits including alerting, orienting and executive control of attention

These were all derived from the Tolgskaya and Gordon (1973) review and page numbers listed are page numbers from that document. All refer to changes produced by non-thermal exposures in the nervous system of experimental animals, with most being in rats.

This discussion scrolls down through Table 2.

The majority of the histological changes seen in these mostly rodent studies, are seen in the nervous system, despite its being less than 2% of the rodent cell mass. There are statements made that the nervous system, both central and peripheral, is the most highly sensitive tissue to these non-thermal microwave and lower frequency EMFs. Following the nervous system in sensitivity are the myocardium and the testis; myocardial cells are known to have very high densities of VGCCs with especially high densities in the pacemaker cells and the testis is known to have high densities specifically of the T-type VGCCs. Pulsed EMFs are more active in producing histological changes in the brain than are non-pulsed fields, in two studies reviewed; there is a much larger literature showing that in most cases pulsed fields are more biologically active (Pall, 2015; Pangopoulos et al., 2013; Belyaev, 2015).

A wide variety of brain and peripheral nervous system tissues show histological changes following non-thermal exposures. Among the important tissues impacted are the hypothalamus and pituitary gland, where both show similar patterns of changes in neuroendocrine activities. There Is an initial increase in neuroendocrine activity (this may be produced directly by VGCC stimulation of secretion), followed over time by "exhaustion" of neuroendocrine activity (this may be produced by tissue damage produced from long term intracellular calcium [Ca2+]i elevation).

There are widespread histological changes produced in neuronal and neuroendocrine tissues. These were repeatedly reported to be largely reversible on cessation of EMF exposure. They become, however, irreversible when exposure is extended in time. There are changes in EEG activity, which may be an easily measurable monitor of neurological damage.

In a summary statement, Tolgskaya and Gordon (1973) state, "This does not confirm the view, so widely held in the past among Soviet investigators and still maintained to a large extent even at the present time in the West, that the action of microwaves is entirely thermal."

While there were many studies of brain impact of non-thermal EMFs performed in the 1950s/60s that make the information content of Tolgskaya and Gordon (1973) quite high, there is also a substantial recent literature on brain effects of non-thermal microwave EMF exposures (see, for example: Ammari et al., 2008a,b; Bas et al., 2009; Brillaud et al., 2007; Carballo-Quintás et al., 2011; Eberhardt et al., 2008; Dasdag et al., 2009, 2012; Grafström et al., 2008; Kumlin et al., 2007; López-Martín et al., 2006; Mausset-Bonnefont et al., 2004; Odaci et al., 2008; Rağbetli et al., 2010; Salford et al., 2003; Sonmez et al., 2010).

5. Older epidemiological reviews and other related studies

Two U.S. Government reports each listed many apparent neuropsychiatric effects of microwave/radiofrequency EMFs and a third recognized the role of non-thermal effects on our bodies, but had only a little consideration of neuropsychiatric effects.

The earliest to these was a Naval Medical Research Institute (NMRI) Research Report (1971) which listed 40 apparent neuropsychiatric changes produced by non-thermal exposures including: 5 central/peripheral nervous system (NS) changes, 9 CNS effects, 4 autonomic system effects, 17 psychological disorders, 4 behavioral changes and 2 misc. effects. This NMRI report also provided a supplementary document listing over 2300 citations documenting these and other effects of microwave exposures in humans and in animals.

The Raines (1981) NASA report reviewed extensive literature based on occupational exposures to non-thermal microwave EMFs, with that literature coming from U.S., Western European and Eastern European studies. There are no obvious differences in the literature coming from these different regions. Based on multiple studies, Raines (1981) reports 19 neuropsychiatric effects to be associated with occupational microwave/radiofrequency EMFs.

The Bolen (1994) report put out by the Rome Laboratory of the U.S. Air Force, acknowledged the role of non-thermal effects of microwave EMFs on humans. This report states in the Conclusion section that "Experimental evidence has shown that exposure to low intensity radiation can have a profound effect on biological processes. The nonthermal effects of RF/MW radiation exposure are becoming important measures of biological interaction of EM fields." Clearly Bolen (1994) rejects the claim that only thermal effects occur. Bolen (1994) discusses a specific non-thermal neuropsychiatric effect, where anesthetized animals are awakened when the head is irradiated with microwave EMFs. This suggests a similar mechanism to that acting in humans where such EMFs produce insomnia (see below).

6. Specific epidemiological studies on neuropsychiatric effects of microwave EMFs

There are 26 different epidemiological studies described in Table 3. Although 4 of these only studied a single neuropsychiatric effect, 22 of these each provide substantial evidence for the pattern described in the earlier U.S. reports, that a wide range of

Table 2
Histological and functional changes in brain function in animals following exposure to non-thermal microwave EMFs.

Observations including page numbers	Comment from Author
The majority of the histological changes seen following non-thermal exposures, occurred in the nervous system, despite its being only about 2% of the tissue mass in rodents; this suggests that the nervous system is highly sensitive to such exposures. Elsewhere (pp. 129, 136), it is suggested that the nervous system is the most sensitive tissue, followed by the heart and the testis, among all of the tissues of the body. The most severe histological changes produced by these non-thermal EMF exposures occur in the nervous system (pp. 136).	High CNS sensitivity to EMFs is predicted by the high density of VGCCs that occur in neurons throughout the nervous system, plus the VGCC role in neurotransmitter and neuroendocrine release.
Pulsed fields were more active than non-pulsed fields in producing histological changes (pp. 71, 97).	Pulsed fields have often been found to be more biologically active than are non-pulsed fields in many different studies from many countries (Pall, 2015; Pangopoulos et al., 2013; Belyaev, 2015).
Nervous system regions impacted by non-thermal microwave and lower frequency fields include: cortex, diencephalon including the hypothalamus and thalamus, hippocampus, autonomic ganglia, sensory fibers, pituitary gland including neurohypophysis.	
Neuroendocrine changes seem to undergo change over increased time of exposure. Neurosecretion in the hypothalamus and in the pituitary each go through a complex sequence over time, where EMF exposure initially produces increased hormone secretion but where over time, the neurosecretory cells become "exhausted", leading to lowered secretion and in some cases cell death (pp. 77–96).	Elevated [Ca2+]i stimulates hormone secretion. However when such elevated [Ca2+]i occurs over extended time periods it is highly damaging to the cell, leading in some cases to apoptosis; thus this time course of action should not be surprising.
Histological changes include boutons/argyrophilia, smaller neurons, vacuole formation in neuroendocrine cells, bead-like thickening along dendrites (pp. 66, 70, 71, 73, 97, 98, 100, 111, 115–117, 121–125). Spines near the ends of dendrites become deformed and with still more sessions of irradiation, disappeared entirely (p. 70). Sensory neurons, following exposures, developed changes characteristic of irritation, with "marked tortuosity of the nerve fibers." Many histological changes are seen in the hypothalamic cells (pp. 87–92) as their neuroendocrine function becomes impacted. Histological changes were found even with exposures that produced no apparent functional changes.	
Many histological and functional changes are reported to initially be reversible, following cessation of exposure, but progressively become irreversible with longer exposure. (pp. 64, 72, 74). Paralleling the development of irreversibility, it is found that "Repeated exposure leads to gradual increase in severity of observed changes." . . . including "increasingly severe disturbance of conditioned reflex activity in the animals, changes in responses of animals particularly sensitive to acoustic stimulation. . .." (p. 104).	If this is also true in humans, then claims that there cannot be non-thermal effects, claims which act to prolong exposures, may be causing irreversible damage to many humans.
EEG changes (pp. 55, 60, 102), including seizure activity following sensory provocation.	Lai (1997) has an extensive review of EEG changes in animals following non-thermal microwave EMF exposures
Neurodegeneration is reported in a number of places in this review (pp. 72, 83, 117).	
Synaptic connections in regions of the brain are disrupted (pp. 65–74, 97, 113, 121, 136), and at the extreme, some neurons are completely asynaptic (p. 73).	Synaptic connections are known to be disrupted in autism; could this suggest that autism may be generated by EMF exposure? No doubt, we need much more evidence on this.
"after prolonged and repeated irradiation with low-intensity centimeter waves, with no elevation of the body temperature and when the animal's condition remained satisfactory, changes were nevertheless found in the sensory fibers of the skin and viscera in the form of irritation phenomena. These findings concur with the view in the literature that the receptor system as a whole and, in particular its preterminal portions are highly sensitive." p. 76. This description is similar to what is reported to occur in electromagnetic hypersensitivity (EHS). Other such studies are described and include cumulative changes over time, that may also explain changes reported in EHS (pp. 75, 99, 100, 104).	One wonders whether almost 60 years ago, the Soviet literature may have already described a possible animal model for EHS. None is known to exist today, and because of that, EHS studies are severely constrained. Clearly one needs to be skeptical about this interpretation, but it is of great importance that this be further studied.

neuropsychiatric effects are produced by exposure to various non-thermal microwave frequency EMFs. Perhaps the most important of these 26 is the Santini et al. (2003) study of people living near cell phone base stations.

There are three recent studies on the generation of headache during or shortly following long mobile phone calls (listed under Chu et al., 2011 in Table 3). The timing of development of these headaches and the finding that they occur on the ipsilateral side of the head, the side receiving much higher EMF exposure during the call, both argue strongly that these headaches are caused by the long mobile phone calls. Such causality was concluded earlier by Frey (1998) based on earlier studies and is now still more strongly documented.

7. Criteria for assessing causality in epidemiological studies

It is important to consider the different criteria that allow one to judge whether a cause and effect relationship is justified by the studies listed in Table 3 and the individual studies cited in Raines (1981). There are five such criteria that should be considered in making that judgment (see pp. 39–43 in Hennekens and Buring, 1989):

Strength of Association: Is there a strong correlation between exposure and the neuropsychiatric symptoms? There clearly is for several studies cited in Raines (1981). One example is the Dwyer and Leeper (1978) study (see Table 3) where there is a large increase in symptoms and where that increase is greater with longer occupational exposure. Another example is the Lerner (1980) study of 1300 microwave workers, where workers with relatively low exposure levels had an approximate doubling of neurological complaints and where those with substantially higher exposure levels had an approximate tripling of neurological complaints over controls. Sadcikova (1974) found that 7 of 8 neuropsychiatric symptoms studied, showed a statistically significant rise in prevalence with longer occupational exposure (see Table 3). Sadcikova (1974), also found that microwave workers had increases of 3 to over 10-fold in: feeling of heaviness in the head; tiredness; irritability; sleepiness; partial loss of memory; and skin sensitivity. There is also a strong association where important new exposures occur – this is clearly the case with all of the studies of people living near cell/mobile phone base

Table 3
Neuropsychiatric symptoms apparently produced by exposure to various electromagnetic fields.

Citation	EMF exposure	Apparent neuropsychiatric symptoms
Abdel-Rassoul et al. (2007)	Living near mobile phone base station	Significant increases in neuropsychiatric complaints included: headache, memory changes, dizziness, tremors, depressive symptoms, sleep disturbance; attributed to effects of EMFs on the human nervous system.
Al-Khlaiwi and Meo (2004)	Mobile phone use	Higher prevalence of fatigue, headache, dizziness, tension and sleep disturbance; the authors conclude that mobile phone use is a risk factor for developing these symptoms.
Altpeter et al. (2000)	Short-wave broadcasting tower, ranging from 6.1 to 21.8 MHz	Sleep disruption shown to occur, correlated with exposures and apparent increase over time; short term suppression of melatonin shown, based on melatonin increases during a 3 day period when the tower was turned off.
Bortkiewicz et al. (2004)	Living near cell phone base station EMFs	Sleep disturbance, irritability, depression, blurred vision, concentration difficulties, nausea, lack of appetite, headache, vertigo.
Bortkiewicz et al. (2012)	Living near mobile phone base stations	Dose response relationships for sleep disturbance, irritability, depression, blurred vision, concentration difficulties, nausea, lack of appetite.
Chu et al. (2011), also Chia et al. (2000), Oftedal et al. (2000)	Mobile phone use	Headache during prolonged mobile phone use or within an hour following such use, with pain occurring on the ipsilateral side of the head; similar observations obtained in each of the 3 studies in column 1; see also Frey (1998).
Conrad (2013)	Smart meter EMF exposure	14 common new symptoms (both severe and moderate) among those exposed and symptomatic, 13 apparent neuropsychiatric: Insomnia, tinnitus, pressure in the head, concentration difficulty, headaches, memory problems, agitation, dizziness, fatigue, skin tingling/burning, involuntary muscle contractions, eye/vision problems, numbness; These ranged in prevalence from 63% to 19% of those experiencing symptoms, such that most symptomatic people experienced multiple symptoms.
Dasdag et al. (1992)	People working in MW broadcasting or at a television transmitter station	These groups suffered from headache, fatigue, irritability, stress, sleepiness, loss of appetite, loss of hearing.
Dwyer and Leeper (1978)	People working in radiofrequency EMFs	Headache, eyestrain, dizziness, disturbed sleep, daytime sleepiness, moodiness, mental depression, memory impairment, muscle and/or cardiac pain, breathing difficulties, increased perspiration, difficulty with sex life.
Eger and Jahn (2010)	Living near mobile phone base station	Neuropsychiatric symptoms, with most showing dose–response relationships: depression; headache; cerebral symptoms; dizziness; disorders of optical and acoustic sensory systems; sleep disturbance; skin changes; with the exception of dizziness, all of these had $p < 0.001$.
Johnson Liakouris (1998)	Study of personnel in U.S. embassy in Moscow exposed to microwave EMFs	Statistically significant increases in neurological (peripheral nerves and ganglia), dermographism (skin responses), irritability, depression, loss of appetite, concentration difficulties, peripheral ganglia and nerve dysfunction.
Khan (2008)	Excessive mobile phone use	Complaints of headache, fatigue, impaired concentration, memory disturbance, sleeplessness, hearing problems.
Kolodynskii and Kolodinska (1996)	Children living near a Radio Location Station, Latvia	Memory dysfunction, attention dysfunction, lowered motor function, slowed reaction time, lowered neuromuscular endurance.
Lamech (2014)	Exposure to wireless smart meter radiation in Victoria, Australia	The most frequent symptoms to develop after smart meter radiation exposure were insomnia, headache, tinnitus, fatigue, cognitive disturbances, dysesthesias (abnormal sensation), dizziness.
Navarro et al. (2003)	Living near cell phone base station	Statistically significant dose response relationships for fatigue, irritability, headache, nausea, loss of appetite, sleep disorder, depressive tendency, feeling of discomfort, difficulty of concentration, loss of memory, visual disorder & dizziness.
Oberfeld et al. (2004)	Living near cell phone base station	Statistically significant dose–response relationships for headache, fatigue, irritability, loss of appetite, visual disorder, nausea, sleeping disorders, dizziness, poor concentration, memory loss.
Oto et al. (1994)	Occupational exposure of 25 workers to either UHF television broadcasting (10) or to 1062 kHz medium wave broadcasting (15)	10 neuropsychiatric changes were assessed, all showing statistically significant changes compared with controls: Somatization*, obsessive compulsivity*, interpersonal sensitivity, depression, anxiety*, hostility*, phobic anxiety*, paranoid ideation, psychoticism*, sleeping disturbance. *$p < 0.001$.
Sadcikova (1974)	Occupational exposure to microwave radiation, including at $<.07$ mW/cm^2	Heaviness in head*, fatigue*, irritability*, sleepiness, memory loss*, cardiac pain*, dermographism (skin sensitivity)*, hyperhidrosis* * significant increase with time of exposure.
Salama and Abou El Naga (2004)	High cell (mobile) phone use	Most common effects were headache, ear ache, sense of fatigue, sleep disturbance, concentration difficulty, face burning sensation. The first three of these had very high statistical significance for correlation with extent of cell phone use.
Santini et al. (2003)	Living near cell phone base stations	Each of the following neuropsychiatric symptoms showed statistical significant dose–response relationships: nausea, loss of appetite, visual disturbance, irritability, depressive tendencies, lowered libido, headache, sleep disturbance, feeling of discomfort, fatigue.
Schüz et al. (2009)	Mobile phone use	Found a small, statistically significant increase in migraine and vertigo. Also found an apparent lowered occurrence of Alzheimer's, other dementia, Parkinson's and epilepsy – these latter were interpreted as being due to perhaps early symptoms of the developing diseases lowering probability of acquiring a mobile phone.
Söderqvist et al. (2008)	Use of mobile phone among adolescents	Increased mobile phone use was associated with increases in tiredness, stress, headache, anxiety, concentration difficulties and sleep disturbances.
Thomée et al. (2011)	High mobile phone use	High mobile phone use was associated with statistically significant rises in stress and sleep disturbance, with somewhat weaker association with depression.
Waldmann-Selsam et al. (2009)	Digital TV signaling	Constant headaches, pressure in head, drowsiness, sleep problems, tightness in chest, shortness of breadth, depressive mood, total apathy, loss of empathy, burning skin, inner burning, leg weakness, pain in limbs, stabbing pain in various organs, weight increase.

stations, listed in Table 3 and also with the two studies of people who become exposed to radiation from smart meters. The studies listed in Table 3 under Chu et al. (2011) (see also Chia et al., 2000; Oftedal et al., 2000) are of a special type. Here people making very long (over 1 h) cell/mobile phone calls develop headaches an hour or more following the initiation of the long call. So these occur within a specific time range following initiation of these long calls, such that headache would only occur very infrequently in that time frame by chance. So here again, there is a strong association. While there is no question that many of these studies show high strength of association, it is also clear that it is becoming progressively more difficult to do these studies. As exposures become almost universal in countries around the world, it is getting difficult if not impossible to find good negative controls. There may be a similar problem in doing animal studies, such that it may be necessary to raise animals in Faraday cages in order to avoid exposures that would otherwise occur as a consequence of our near ubiquitous EMFs.

Biological credibility is extremely strong here, with three aspects of the biology predicting that these low intensity fields cause widespread neuropsychiatric effects. This was discussed above and is reconsidered in the following section.

Consistency within the different epidemiological studies and with other types of studies. The epidemiological studies listed in Table 3 and also those showing neuropsychiatric effects that were cited in Raines (1981) have been performed in many different countries with different cultures. They have been performed in multiple countries in Western Europe, Eastern Europe, the Middle East and in East Asia, as well as in the U.S. and Australia. They are, therefore, not limited to one or two cultural contexts. This is deemed, therefore, an important indicator of causality. We also have a surprising consistency of apparent neuropsychiatric effects of different fields, including various occupational exposures and exposures to cell/mobile phone base stations, exposure to the phones themselves, exposure to smart meter pulses, and other EMFs (see Table 3). Pulsation patterns, frequencies and exact intensities may produce various biological responses (Pall, 2015; Pangopoulos et al., 2013; Belyaev, 2015) so it is a bit surprising that we have as much consistency as we do have across different types of exposures. We also have consistency with the biology discussed in the previous section. Because elevated VGCC activity produced by genetic polymorphism (Table 1) produces diverse neuropsychiatric effects, it is not surprising that elevation of VGCC activity produced by microwave EMF exposure apparently also produces diverse neuropsychiatric effects. Similarly because non-thermal EMF exposures produce widespread changes in brain structure and function in animals (Tolgskaya and Gordon, 1973), it is not surprising that the neuropsychiatric symptoms, which are produced as a consequence of brain dysfunction are produced by such EMFs.

Time sequence: It is clear that the all of these effects follow exposure in the various studies that have been published. In some studies, it is also clear that longer occupational exposure times produce increased symptom prevalence. These include Dwyer and Leeper (1978) and Baranski and Edelwejn (1975). These observations all support a causal relationship between exposure to EMF and the development of neuropsychiatric symptoms.

Dose–response relationship: It is assumed, here, that biological effects have a positive correlation with the intensity of the apparent causal stressor. This is not necessarily true of EMF effects, because it has been shown that there are "window effects" where specific intensities have larger biological effects, than *do either lower or higher intensities* (Pall, 2015; Pangopoulos et al., 2013; Belyaev, 2015). Nevertheless, where different intensities were studied in these epidemiological studies, they do show the dose–response relationship assumed here including Altpeter et al. (2000), Dwyer and Leeper (1978), Eger and Jahn (2010), Lerner (1980), Navarro et al. (2003), Oberfeld et al. (2004), Salama and Abou El Naga (2004), Santini et al. (2003) and Thomée et al. (2011). Thus these data do fit well to the assumed dose–response relationship, found in most causal roles. The Altpeter et al. (2000) study showed a special type of evidence for causality: during a 3-day period when the broadcasting tower was turned off, the melatonin levels recovered to near-normal levels. The studies of headache occurrence on prolonged cell/mobile phone calls (typically well over one hour) listed under Chu et al. (2011) in Table 3 also suggest the assumed dose–response relationship (see also Chia et al., 2000; Oftedal et al., 2000 and earlier citations listed in Frey, 1998). Because such headaches only occur with prolonged cell/mobile phone calls, these studies also provide evidence for a dose–response relationship because low doses are ineffective. Furthermore these same studies provide evidence for such a dose–response relationship from another type of observation. Because the headaches occur predominantly on the ipsilateral side of the head which receives much higher EMF exposure intensity, rather than on the contralateral side of the head, which receives much lower intensities, this provides an additional type of evidence for the predicted dose–response relationship.

While the evidence is convincing that the various neuropsychiatric apparent consequences of microwave EMF exposure are in fact caused by such exposures, there may be somewhat more controversy about another EMF-neuropsychiatric linkage. Havas et al. (2010) have reported a similar list of neuropsychiatric symptoms in electromagnetic hypersensitivity (EHS) patients. They found that each of the following symptoms were common in EHS: poor short term memory; difficulty of concentration; eye problems; sleep disorder; feeling unwell; headache; dizziness; tinnitus; chronic fatigue; tremors; body pain; difficulty speaking; tingling sensation in feet or hands; difficulty writing; difficulty walking; migraine. The similarity of these symptoms to the most commonly found symptoms following non-thermal microwave EMF exposures (Table 3), suggests that EHS is a genuine sensitivity to EMFs. In the bottom row in Table 2, sensitivities were found in rodent studies following non-thermal exposure that suggest a possible animal model for the study of EHS. Each of these EHS-related issues needs to be followed up experimentally.

8. Discussion and conclusions

In the previous section, each of the five criteria for assessing whether an epidemiological association is causal, were considered. Those five are (Hennekens and Buring, 1989): (1) strength of association; (2) biological credibility; (3) consistency; (4) time sequence; (5) dose–response relationship. Each of these five provide strong support for causality such that the combination of all five provides compelling evidence for causality. Low-intensity microwave frequency EMFs do cause diverse neuropsychiatric symptoms. While each of these five is important here, the one that is most important is the criterion of biological credibility.

Three related sets of biological observations each predict that low-intensity microwave EMFs produce widespread neuropsychiatric effects:

1. Such EMFs act via activation of VGCCs, acting through the VGCC voltage sensor which is predicted to be exquisitely sensitive to these EMFs (Pall, 2015). VGCCs occur in high densities throughout the nervous system and have essential roles throughout the nervous system in releasing neurotransmitters and neuroendocrine hormones. These properties predict, therefore, that these low intensity non-thermal microwave EMFs cause widespread changes in the nervous system, causing, in turn, diverse neuropsychiatric effects.

2. Elevated VGCC activity, produced by an allele of the CACNA1C gene which encodes the channel of the main L-type VGCC in the brain, produces various neuropsychiatric effects (Table 1). This predicts, that low intensity non-thermal microwave frequency EMFs which also produce elevated L-type and other VGCC activity, therefore produce widespread neuropsychiatric effects.
3. Studies reviewed in the Tolgskaya and Gordon, 1973 publication (Table 2) have shown that the cells of the mammalian nervous system show high sensitivity to various non-thermal microwave and lower frequency EMFs, being apparently more sensitive than any other organ in the body of rodents. These studies predict that the human nervous system is likely to be similarly sensitive to these EMFs, predicting, therefore, widespread neuropsychiatric effects in humans.

We not only have biological credibility but also more importantly, each of these distinct but interrelated biological considerations predicts that low-intensity, non-thermal microwave EMFs produce widespread neuropsychiatric effects. That common prediction is verified by extensive data summarized in citations provided by the Naval Medical Research Institute Research Report (June 1971), data provided by The Raines (1981) NASA report, and by 26 epidemiological studies summarized in Table 3.

The most commonly reported neuropsychiatric symptoms from these studies are summarized in Table 4.

A total of 22 different studies described in Table 3 were used for data for this table, but not 4 others that only assessed a single neuropsychiatric end point. The Altpeter study which only assessed sleep disturbance/melatonin depletion and the three studies listed under Chu et al. which only assessed headache occurrence following long cell phone calls, listed in Table 3 were not included. Because many of the studies only assessed from 3 to 7 specific symptoms, it is not surprising that the numbers of studies reporting a specific symptom fall far below 22. Where several symptom descriptions were included under one heading, such as dysesthesia, if a study had more than one of these symptom descriptions, it was only counted once.

All the symptoms listed in Table 4 should be considered established parts of microwave syndrome (Hocking, 2001; Johnson Liakouris, 1998). Even if the statistical significance in each study was of the lowest statistical significance ($p < .05$) one would expect only 1 positive study to occur at random out of the 22 studies included here. Because many individual symptoms were not surveyed in many individual studies, the expectation is substantially lower than that. Each of these, having shown positive results in 5 or more studies are highly unlikely, therefore, to have occurred by chance. Stong statistical significance is also seen for individual neuropsychiatric effects reported to have $p < 0.001$ in the Eger and Jahn (2010) and Oto et al. (1994) studies (see Table 3).

Table 4
Commonly reported neuropsychiatric symptoms following microwave EMF exposure.

Symptom(s)	Numbers of studies reporting
Sleep disturbance/insomnia	17
Headache	14
Fatigue/tiredness	11
Depression/depressive symptoms	10
Dysesthesia (vision/hearing/olfactory dysfunction)	10
Concentration/attention/cognitive dysfunction	10
Dizziness/vertigo	9
Memory changes	8
Restlessness/tension/anxiety/stress/agitation/feeling of discomfort	8
Irritability	7
Loss of appetite/body weight	6
Skin tingling/burning/inflammation/dermographism	6
Nausea	5

EEG changes may well be part of microwave syndrome, as well. While none of the studies described in Table 3 measured EEGs, six studies of human occupational exposure cited in the Raines (1981) showed EEG changes (Baranski and Edelwejn, 1975; Bise, 1978; Dumanskij and Shandala, 1974; Lerner, 1980; Sheppard and Eisenbud, 1977). Murbach et al. (2014) cited 10 human studies in support of their statement that "the most consistently reported effects (of mobile phone use) in various studies conducted by different laboratories are changes in the electroencephalogram (EEG) power spectrum." Three recent studies (Lustenberger et al., 2013; Schmid et al., 2012a,b) and several earlier studies cited in Wagner et al. (1998) have each shown EEG changes in sleeping humans exposed to non-thermal pulsed microwave fields. Two recent studies showed EEG changes in persons exposed to Wi-Fi fields (Maganioti et al., 2010; Papageorgiou et al., 2011). Lai (1997) described 8 animal studies showing changes in EEG patterns in animals exposed to non-thermal EMFs and three additional animal studies were described in Tolgskaya and Gordon (1973). With the exception of the 6 studies cited in the second sentence in this paragraph, all of these are direct experimental studies which are not, therefore, susceptible to the questions of causality that can be raised about epidemiological studies. It is the author's view that future studies should consider studying EEG changes as an objectively measurable assessment of brain physiology and that before and after increased exposure studies should be considered when a new EMF source is to be introduced into human populations. While such studies must be done carefully, given the complexity of EEGs, even very small numbers of individuals may produce highly statistically significant results in well designed studies analyzed with paired *t*-tests.

One of the citations from the previous paragraph, Bise (1978) reviewed earlier studies of low level microwave frequency exposures in humans and concluded that such EMFs produced the following neuropsychiatric effects: headache, fatigue, irritability, dizziness, loss of appetite, sleepiness, sweating, difficulty of concentration, memory loss, depression, emotional instability, dermographism, tremor, hallucinations and insomnia. The strong similarity of this list from 37 years ago and the list in Table 4 should be noted. The Bise (1978) list is based on occupational exposure studies whereas the current list in Table 4 is based primarily on EMF exposures from cell/mobile phone base stations, from heavy cell phone usage and from smart meters, *three types of exposures that did not exist in 1978*. The strong similarity between the Bise (1978) list and the current one 37 years later alone produces a compelling argument that the 11 neuropsychiatric effects found on both lists are caused by exposure to multiple types of low-intensity microwave EMFs.

The pattern of evidence is compelling in support of the earlier statement of Levitt and Lai (2010) that "the primary questions now involve specific exposure parameters, not the reality of complaints or attempts to attribute such complaints to psychosomatic causes, malingering or beliefs in paranormal phenomena."

We can barely imagine how the combinations of neuropsychiatric effects, including those in Table 4, will influence human behavior and social interactions, now that the majority of the human populations on earth are exposed to ever increasing intensities and diversity of microwave frequency EMFs. You may recall that three of the occupational exposure studies cited in (Raines, 1981 showed increasing prevalence of neuropsychiatric symptoms with years of exposure to consistent patterns of EMF exposure intensities (Dwyer and Leeper, 1978; Sadcikova, 1974;

Baranski and Edelwejn, 1975). With ever increasing exposures in human populations, we have no idea what the consequences of these ever increasing exposures will be.

Conflict of interest

The author declares no conflict of interest.

Review

Microwave frequency electromagnetic fields (EMFs) produce widespread neuropsychiatric effects including depression

Martin L. Pall

Professor Emeritus of Biochemistry and Basic Medical Sciences, Washington State University, 638 NE 41st Avenue, Portland, OR 97232-3312, USA

Keywords:
Excessive calcium effects
Oxidative/nitrosative stress
Low-intensity microwave electromagnetic fields

ABSTRACT

Non-thermal microwave/lower frequency electromagnetic fields (EMFs) act via voltage-gated calcium channel (VGCC) activation. Calcium channel blockers block EMF effects and several types of additional evidence confirm this mechanism. Low intensity microwave EMFs have been proposed to produce neuropsychiatric effects, sometimes called microwave syndrome, and the focus of this review is whether these are indeed well documented and consistent with the known mechanism(s) of action of such EMFs. VGCCs occur in very high densities throughout the nervous system and have near universal roles in release of neurotransmitters and neuroendocrine hormones. Soviet and Western literature shows that much of the impact of non-thermal microwave exposures in experimental animals occurs in the brain and peripheral nervous system, such that nervous system histology and function show diverse and substantial changes. These may be generated through roles of VGCC activation, producing excessive neurotransmitter/neuroendocrine release as well as oxidative/nitrosative stress and other responses. Excessive VGCC activity has been shown from genetic polymorphism studies to have roles in producing neuropsychiatric changes in humans. Two U.S. government reports from the 1970s to 1980s provide evidence for many neuropsychiatric effects of non-thermal microwave EMFs, based on occupational exposure studies. 18 more recent epidemiological studies, provide substantial evidence that microwave EMFs from cell/mobile phone base stations, excessive cell/mobile phone usage and from wireless smart meters can each produce similar patterns of neuropsychiatric effects, with several of these studies showing clear dose–response relationships. Lesser evidence from 6 additional studies suggests that short wave, radio station, occupational and digital TV antenna exposures may produce similar neuropsychiatric effects. Among the more commonly reported changes are sleep disturbance/insomnia, headache, depression/depressive symptoms, fatigue/tiredness, dysesthesia, concentration/attention dysfunction, memory changes, dizziness, irritability, loss of appetite/body weight, restlessness/anxiety, nausea, skin burning/tingling/dermographism and EEG changes. In summary, then, the mechanism of action of microwave EMFs, the role of the VGCCs in the brain, the impact of non-thermal EMFs on the brain, extensive epidemiological studies performed over the past 50 years, and five criteria testing for causality, all collectively show that various non-thermal microwave EMF exposures produce diverse neuropsychiatric effects.

Chemicals having roles:

Calcium(2+)
Nitric oxide (NO)
Oxido nitrite (peroxynitrite)

1. Introduction

Microwave syndrome (Hocking, 2001; Johnson Liakouris, 1998), a combination of various neuropsychiatric symptoms originally described in persons with occupational exposures to microwave frequency EMFs, has been disputed largely because of the lack of an apparent mechanism for generating these symptoms. It is reported to often include such symptoms as fatigue, headache, insomnia, dysesthesia (impaired sensation), irritability, lack of concentration and other symptoms (Hocking, 2001; Johnson Liakouris, 1998). Similar but more extensive combinations of symptoms have been reported following occupational exposures in two U.S. government reports from the 1970s/1980s (Naval Medical Research Institute Research Report, 1971; Raines, 1981) and following environmental exposures as described in two more recent reviews (Khurana et al., 2010; Levitt and Lai, 2010).

The goal here is not just to review the epidemiology, however, but more importantly to consider the issue of possible physiological mechanism(s). Hennekens and Buring (1989), on p. 40 in their textbook Epidemiology in Medicine state "The belief in the existence of a cause and effect relationship is enhanced if there is a known or postulated biologic mechanism by which the exposure might reasonably alter risk of developing disease." It is of critical importance therefore to assess possible biological mechanism before considering the epidemiological evidence.

Accordingly, this paper considers the mechanism by which low intensity microwave EMFs impact the cells of our bodies, how that mechanism may be predicted to impact the nervous system, evidence for such impact from experimental animal studies, genetic polymorphism evidence for that mechanism acting in humans to produce neuropsychiatric effects and finally, the epidemiological evidence for such effects in human populations with repeated low level microwave EMF exposure. Consideration of each of these types of evidence influences the overall interpretation presented in this paper.

2. Microwave/lower frequency EMFs act to activate voltage-gated calcium channels

In 24 different studies reviewed earlier (Pall, 2013) and two additional studies (Li et al., 2014; Lisi et al., 2006), microwave and lower frequency low intensity EMF effects were blocked or greatly lowered by calcium channel blockers, agents thought to be specific for blocking voltage-gated calcium channels (VGCCs). In these 26 studies, a total of 5 distinct types of channel blockers were used, with each type having a distinct structure and binding to a distinct site, such that it is essentially certain that these must be acting by blocking VGCCs, which is their only known common property. In each of these 26 studies, each of the responses studied, were blocked or greatly lowered by calcium channel blockers, showing that VGCC activation has roles in producing a wide variety of EMF effects. There is a large literature on changes in calcium fluxes and in calcium signaling following microwave EMF exposure (partially reviewed in Walleczek, 1992; Adey, 1993); each of these, including calcium efflux changes, can be explained as being due to VGCC activation, again suggesting a widespread role of VGCC activation in producing biological responses to EMFs. Pilla (2012) showed that pulsed microwave field exposure, produced an almost instantaneous increase in calcium/calmodulin-dependent nitric oxide (NO) signaling, providing strong evidence that these fields can produce an almost instantaneous VGCC activation. It is likely, that these EMFs act directly on the voltage sensor of the VGCCs to produce VGCC activation (Pall, 2015) with the voltage sensor being exquisitely sensitive to these EMFs because of its physical properties and location in the plasma membrane.

EMFs have been proposed to act to produce a wide variety of responses in the cell, via downstream effects of VGCC activation (Pall, 2013, 2014, 2015), including elevated intracellular calcium [Ca2+]i, excessive calcium and nitric oxide signaling and also excessive peroxynitrite, free radicals and oxidative stress.

VGCC activation has been shown to have a universal or near-universal role in the release of neurotransmitters in the brain and also in the release of hormones by neuroendocrine cells (Berridge, 1998; Dunlap et al., 1995; Wheeler et al., 1994), with such release being produced by calcium signaling. There are high densities of diverse VGCCs occurring in neurons throughout the nervous system. Both the high VGCC density and their function in neurotransmitter and neuroendocrine release throughout the nervous system suggests that the nervous system is likely to be highly sensitive to low intensity EMFs.

3. Genetic polymorphism studies

Genetic polymorphism studies are powerful tools for looking at the roles of specific proteins in human populations. In Table 1, a series of genetic polymorphism studies have been performed that show that an allele producing increased expression of the gene encoding the channel of the main L-type VGCC in the brain, produces diverse neuropsychiatric effects. These studies clearly show that excess L-type VGCC activity can cause neuropsychiatric effects. They also predict, therefore, that increased VGCC activity produced by microwave EMFs may be able to also produce widespread neuropsychiatric effects.

4. Histological and functional changes in central nervous system (CNS) and peripheral nervous system (PNS) in animals exposed to microwave EMFs

The most extensive literature on histological and functional changes in animals is from the Soviet literature from the 1950s/1960s with additional Western literature from the same time period. Both Soviet and non-Soviet literature were reviewed in an English language Publication by Tolgskaya and Gordon (1973). This publication is, therefore, the main focus of this section. That publication was divided into thermal and non-thermal exposure studies, with the non-thermal studies which occupy the majority of the text (pp. 53–137) being of sole interest here.

Krug et al. (2014)	Polymorphism producing increased expression of CACNA1C L-type VGCC subunit	Influences episodic memory and retrieval
Soeiro-de-Souza et al. (2012)	Polymorphism producing increased expression of CACNA1C L-type VGCC subunit	Produces impaired facial emotion recognition
Tesli et al. (2013)	Polymorphism producing increased expression of CACNA1C L-type VGCC subunit	Produces increased activation of the amygdala during emotional processing
Thimm et al. (2011)	Polymorphism producing increased expression of CACNA1C L-type VGCC subunit	Associated with attention deficits including alerting, orienting and executive control of attention

These were all derived from the Tolgskaya and Gordon (1973) review and page numbers listed are page numbers from that document. All refer to changes produced by non-thermal exposures in the nervous system of experimental animals, with most being in rats.

This discussion scrolls down through Table 2.

The majority of the histological changes seen in these mostly rodent studies, are seen in the nervous system, despite its being less than 2% of the rodent cell mass. There are statements made that the nervous system, both central and peripheral, is the most highly sensitive tissue to these non-thermal microwave and lower frequency EMFs. Following the nervous system in sensitivity are the myocardium and the testis; myocardial cells are known to have very high densities of VGCCs with especially high densities in the pacemaker cells and the testis is known to have high densities specifically of the T-type VGCCs. Pulsed EMFs are more active in producing histological changes in the brain than are non-pulsed fields, in two studies reviewed; there is a much larger literature showing that in most cases pulsed fields are more biologically active (Pall, 2015; Pangopoulos et al., 2013; Belyaev, 2015).

A wide variety of brain and peripheral nervous system tissues show histological changes following non-thermal exposures. Among the important tissues impacted are the hypothalamus and pituitary gland, where both show similar patterns of changes in neuroendocrine activities. There Is an initial increase in neuroendocrine activity (this may be produced directly by VGCC stimulation of secretion), followed over time by "exhaustion" of neuroendocrine activity (this may be produced by tissue damage produced from long term intracellular calcium [Ca2+]i elevation).

There are widespread histological changes produced in neuronal and neuroendocrine tissues. These were repeatedly reported to be largely reversible on cessation of EMF exposure. They become, however, irreversible when exposure is extended in time. There are changes in EEG activity, which may be an easily measurable monitor of neurological damage.

In a summary statement, Tolgskaya and Gordon (1973) state, "This does not confirm the view, so widely held in the past among Soviet investigators and still maintained to a large extent even at the present time in the West, that the action of microwaves is entirely thermal."

While there were many studies of brain impact of non-thermal EMFs performed in the 1950s/60s that make the information content of Tolgskaya and Gordon (1973) quite high, there is also a substantial recent literature on brain effects of non-thermal microwave EMF exposures (see, for example: Ammari et al., 2008a,b; Bas et al., 2009; Brillaud et al., 2007; Carballo-Quintás et al., 2011; Eberhardt et al., 2008; Dasdag et al., 2009, 2012; Grafström et al., 2008; Kumlin et al., 2007; López-Martín et al., 2006; Mausset-Bonnefont et al., 2004; Odaci et al., 2008; Rağbetli et al., 2010; Salford et al., 2003; Sonmez et al., 2010).

5. Older epidemiological reviews and other related studies

Two U.S. Government reports each listed many apparent neuropsychiatric effects of microwave/radiofrequency EMFs and a third recognized the role of non-thermal effects on our bodies, but had only a little consideration of neuropsychiatric effects.

The earliest to these was a Naval Medical Research Institute (NMRI) Research Report (1971) which listed 40 apparent neuropsychiatric changes produced by non-thermal exposures including: 5 central/peripheral nervous system (NS) changes, 9 CNS effects, 4 autonomic system effects, 17 psychological disorders, 4 behavioral changes and 2 misc. effects. This NMRI report also provided a supplementary document listing over 2300 citations documenting these and other effects of microwave exposures in humans and in animals.

The Raines (1981) NASA report reviewed extensive literature based on occupational exposures to non-thermal microwave EMFs, with that literature coming from U.S., Western European and Eastern European studies. There are no obvious differences in the literature coming from these different regions. Based on multiple studies, Raines (1981) reports 19 neuropsychiatric effects to be associated with occupational microwave/radiofrequency EMFs.

The Bolen (1994) report put out by the Rome Laboratory of the U.S. Air Force, acknowledged the role of non-thermal effects of microwave EMFs on humans. This report states in the Conclusion section that "Experimental evidence has shown that exposure to low intensity radiation can have a profound effect on biological processes. The nonthermal effects of RF/MW radiation exposure are becoming important measures of biological interaction of EM fields." Clearly Bolen (1994) rejects the claim that only thermal effects occur. Bolen (1994) discusses a specific non-thermal neuropsychiatric effect, where anesthetized animals are awakened when the head is irradiated with microwave EMFs. This suggests a similar mechanism to that acting in humans where such EMFs produce insomnia (see below).

6. Specific epidemiological studies on neuropsychiatric effects of microwave EMFs

There are 26 different epidemiological studies described in Table 3. Although 4 of these only studied a single neuropsychiatric effect, 22 of these each provide substantial evidence for the pattern described in the earlier U.S. reports, that a wide range of

Table 2
Histological and functional changes in brain function in animals following exposure to non-thermal microwave EMFs.

Observations including page numbers	Comment from Author
The majority of the histological changes seen following non-thermal exposures, occurred in the nervous system, despite its being only about 2% of the tissue mass in rodents; this suggests that the nervous system is highly sensitive to such exposures. Elsewhere (pp. 129, 136), it is suggested that the nervous system is the most sensitive tissue, followed by the heart and the testis, among all of the tissues of the body. The most severe histological changes produced by these non-thermal EMF exposures occur in the nervous system (pp. 136).	High CNS sensitivity to EMFs is predicted by the high density of VGCCs that occur in neurons throughout the nervous system, plus the VGCC role in neurotransmitter and neuroendocrine release.
Pulsed fields were more active than non-pulsed fields in producing histological changes (pp. 71, 97).	Pulsed fields have often been found to be more biologically active than are non-pulsed fields in many different studies from many countries (Pall, 2015; Pangopoulos et al., 2013; Belyaev, 2015).
Nervous system regions impacted by non-thermal microwave and lower frequency fields include: cortex, diencephalon including the hypothalamus and thalamus, hippocampus, autonomic ganglia, sensory fibers, pituitary gland including neurohypophysis.	
Neuroendocrine changes seem to undergo change over increased time of exposure. Neurosecretion in the hypothalamus and in the pituitary each go through a complex sequence over time, where EMF exposure initially produces increased hormone secretion but where over time, the neurosecretory cells become "exhausted", leading to lowered secretion and in some cases cell death (pp. 77–96).	Elevated [Ca2+]i stimulates hormone secretion. However when such elevated [Ca2+]i occurs over extended time periods it is highly damaging to the cell, leading in some cases to apoptosis; thus this time course of action should not be surprising.
Histological changes include boutons/argyrophilia, smaller neurons, vacuole formation in neuroendocrine cells, bead-like thickening along dendrites (pp. 66, 70, 71, 73, 97, 98, 100, 111, 115–117, 121–125). Spines near the ends of dendrites become deformed and with still more sessions of irradiation, disappeared entirely (p. 70). Sensory neurons, following exposures, developed changes characteristic of irritation, with "marked tortuosity of the nerve fibers." Many histological changes are seen in the hypothalamic cells (pp. 87–92) as their neuroendocrine function becomes impacted. Histological changes were found even with exposures that produced no apparent functional changes.	
Many histological and functional changes are reported to initially be reversible, following cessation of exposure, but progressively become irreversible with longer exposure. (pp. 64, 72, 74). Paralleling the development of irreversibility, it is found that "Repeated exposure leads to gradual increase in severity of observed changes." . . . including "increasingly severe disturbance of conditioned reflex activity in the animals, changes in responses of animals particularly sensitive to acoustic stimulation. . .." (p. 104).	If this is also true in humans, then claims that there cannot be non-thermal effects, claims which act to prolong exposures, may be causing irreversible damage to many humans.
EEG changes (pp. 55, 60, 102), including seizure activity following sensory provocation.	Lai (1997) has an extensive review of EEG changes in animals following non-thermal microwave EMF exposures
Neurodegeneration is reported in a number of places in this review (pp. 72, 83, 117).	
Synaptic connections in regions of the brain are disrupted (pp. 65–74, 97, 113, 121, 136), and at the extreme, some neurons are completely asynaptic (p. 73).	Synaptic connections are known to be disrupted in autism; could this suggest that autism may be generated by EMF exposure? No doubt, we need much more evidence on this.
"after prolonged and repeated irradiation with low-intensity centimeter waves, with no elevation of the body temperature and when the animal's condition remained satisfactory, changes were nevertheless found in the sensory fibers of the skin and viscera in the form of irritation phenomena. These findings concur with the view in the literature that the receptor system as a whole and, in particular its preterminal portions are highly sensitive." p. 76. This description is similar to what is reported to occur in electromagnetic hypersensitivity (EHS). Other such studies are described and include cumulative changes over time, that may also explain changes reported in EHS (pp. 75, 99, 100, 104).	One wonders whether almost 60 years ago, the Soviet literature may have already described a possible animal model for EHS. None is known to exist today, and because of that, EHS studies are severely constrained. Clearly one needs to be skeptical about this interpretation, but it is of great importance that this be further studied.

neuropsychiatric effects are produced by exposure to various non-thermal microwave frequency EMFs. Perhaps the most important of these 26 is the Santini et al. (2003) study of people living near cell phone base stations.

There are three recent studies on the generation of headache during or shortly following long mobile phone calls (listed under Chu et al., 2011 in Table 3). The timing of development of these headaches and the finding that they occur on the ipsilateral side of the head, the side receiving much higher EMF exposure during the call, both argue strongly that these headaches are caused by the long mobile phone calls. Such causality was concluded earlier by Frey (1998) based on earlier studies and is now still more strongly documented.

7. Criteria for assessing causality in epidemiological studies

It is important to consider the different criteria that allow one to judge whether a cause and effect relationship is justified by the studies listed in Table 3 and the individual studies cited in Raines (1981). There are five such criteria that should be considered in making that judgment (see pp. 39–43 in Hennekens and Buring, 1989):

Strength of Association: Is there a strong correlation between exposure and the neuropsychiatric symptoms? There clearly is for several studies cited in Raines (1981). One example is the Dwyer and Leeper (1978) study (see Table 3) where there is a large increase in symptoms and where that increase is greater with longer occupational exposure. Another example is the Lerner (1980) study of 1300 microwave workers, where workers with relatively low exposure levels had an approximate doubling of neurological complaints and where those with substantially higher exposure levels had an approximate tripling of neurological complaints over controls. Sadcikova (1974) found that 7 of 8 neuropsychiatric symptoms studied, showed a statistically significant rise in prevalence with longer occupational exposure (see Table 3). Sadcikova (1974), also found that microwave workers had increases of 3 to over 10-fold in: feeling of heaviness in the head; tiredness; irritability; sleepiness; partial loss of memory; and skin sensitivity. There is also a strong association where important new exposures occur – this is clearly the case with all of the studies of people living near cell/mobile phone base

Table 3
Neuropsychiatric symptoms apparently produced by exposure to various electromagnetic fields.

Citation	EMF exposure	Apparent neuropsychiatric symptoms
Abdel-Rassoul et al. (2007)	Living near mobile phone base station	Significant increases in neuropsychiatric complaints included: headache, memory changes, dizziness, tremors, depressive symptoms, sleep disturbance; attributed to effects of EMFs on the human nervous system.
Al-Khlaiwi and Meo (2004)	Mobile phone use	Higher prevalence of fatigue, headache, dizziness, tension and sleep disturbance; the authors conclude that mobile phone use is a risk factor for developing these symptoms.
Altpeter et al. (2000)	Short-wave broadcasting tower, ranging from 6.1 to 21.8 MHz	Sleep disruption shown to occur, correlated with exposures and apparent increase over time; short term suppression of melatonin shown, based on melatonin increases during a 3 day period when the tower was turned off.
Bortkiewicz et al. (2004)	Living near cell phone base station EMFs	Sleep disturbance, irritability, depression, blurred vision, concentration difficulties, nausea, lack of appetite, headache, vertigo.
Bortkiewicz et al. (2012)	Living near mobile phone base stations	Dose response relationships for sleep disturbance, irritability, depression, blurred vision, concentration difficulties, nausea, lack of appetite.
Chu et al. (2011), also Chia et al. (2000), Oftedal et al. (2000)	Mobile phone use	Headache during prolonged mobile phone use or within an hour following such use, with pain occurring on the ipsilateral side of the head; similar observations obtained in each of the 3 studies in column 1; see also Frey (1998).
Conrad (2013)	Smart meter EMF exposure	14 common new symptoms (both severe and moderate) among those exposed and symptomatic, 13 apparent neuropsychiatric: Insomnia, tinnitus, pressure in the head, concentration difficulty, headaches, memory problems, agitation, dizziness, fatigue, skin tingling/burning, involuntary muscle contractions, eye/vision problems, numbness; These ranged in prevalence from 63% to 19% of those experiencing symptoms, such that most symptomatic people experienced multiple symptoms.
Dasdag et al. (1992)	People working in MW broadcasting or at a television transmitter station	These groups suffered from headache, fatigue, irritability, stress, sleepiness, loss of appetite, loss of hearing.
Dwyer and Leeper (1978)	People working in radiofrequency EMFs	Headache, eyestrain, dizziness, disturbed sleep, daytime sleepiness, moodiness, mental depression, memory impairment, muscle and/or cardiac pain, breathing difficulties, increased perspiration, difficulty with sex life.
Eger and Jahn (2010)	Living near mobile phone base station	Neuropsychiatric symptoms, with most showing dose–response relationships: depression; headache; cerebral symptoms; dizziness; disorders of optical and acoustic sensory systems; sleep disturbance; skin changes; with the exception of dizziness, all of these had $p < 0.001$.
Johnson Liakouris (1998)	Study of personnel in U.S. embassy in Moscow exposed to microwave EMFs	Statistically significant increases in neurological (peripheral nerves and ganglia), dermographism (skin responses), irritability, depression, loss of appetite, concentration difficulties, peripheral ganglia and nerve dysfunction.
Khan (2008)	Excessive mobile phone use	Complaints of headache, fatigue, impaired concentration, memory disturbance, sleeplessness, hearing problems.
Kolodynskii and Kolodinska (1996)	Children living near a Radio Location Station, Latvia	Memory dysfunction, attention dysfunction, lowered motor function, slowed reaction time, lowered neuromuscular endurance.
Lamech (2014)	Exposure to wireless smart meter radiation in Victoria, Australia	The most frequent symptoms to develop after smart meter radiation exposure were insomnia, headache, tinnitus, fatigue, cognitive disturbances, dysesthesias (abnormal sensation), dizziness.
Navarro et al. (2003)	Living near cell phone base station	Statistically significant dose response relationships for fatigue, irritability, headache, nausea, loss of appetite, sleep disorder, depressive tendency, feeling of discomfort, difficulty of concentration, loss of memory, visual disorder & dizziness.
Oberfeld et al. (2004)	Living near cell phone base station	Statistically significant dose–response relationships for headache, fatigue, irritability, loss of appetite, visual disorder, nausea, sleeping disorders, dizziness, poor concentration, memory loss.
Oto et al. (1994)	Occupational exposure of 25 workers to either UHF television broadcasting (10) or to 1062 kHz medium wave broadcasting (15)	10 neuropsychiatric changes were assessed, all showing statistically significant changes compared with controls: Somatization*, obsessive compulsivity*, interpersonal sensitivity, depression, anxiety*, hostility*, phobic anxiety*, paranoid ideation, psychoticism*, sleeping disturbance. *$p < 0.001$.
Sadcikova (1974)	Occupational exposure to microwave radiation, including at $<.07$ mW/cm^2	Heaviness in head*, fatigue*, irritability*, sleepiness, memory loss*, cardiac pain*, dermographism (skin sensitivity)*, hyperhidrosis* * significant increase with time of exposure.
Salama and Abou El Naga (2004)	High cell (mobile) phone use	Most common effects were headache, ear ache, sense of fatigue, sleep disturbance, concentration difficulty, face burning sensation. The first three of these had very high statistical significance for correlation with extent of cell phone use.
Santini et al. (2003)	Living near cell phone base stations	Each of the following neuropsychiatric symptoms showed statistical significant dose–response relationships: nausea, loss of appetite, visual disturbance, irritability, depressive tendencies, lowered libido, headache, sleep disturbance, feeling of discomfort, fatigue.
Schüz et al. (2009)	Mobile phone use	Found a small, statistically significant increase in migraine and vertigo. Also found an apparent lowered occurrence of Alzheimer's, other dementia, Parkinson's and epilepsy – these latter were interpreted as being due to perhaps early symptoms of the developing diseases lowering probability of acquiring a mobile phone.
Söderqvist et al. (2008)	Use of mobile phone among adolescents	Increased mobile phone use was associated with increases in tiredness, stress, headache, anxiety, concentration difficulties and sleep disturbances.
Thomée et al. (2011)	High mobile phone use	High mobile phone use was associated with statistically significant rises in stress and sleep disturbance, with somewhat weaker association with depression.
Waldmann-Selsam et al. (2009)	Digital TV signaling	Constant headaches, pressure in head, drowsiness, sleep problems, tightness in chest, shortness of breadth, depressive mood, total apathy, loss of empathy, burning skin, inner burning, leg weakness, pain in limbs, stabbing pain in various organs, weight increase.

stations, listed in Table 3 and also with the two studies of people who become exposed to radiation from smart meters. The studies listed in Table 3 under Chu et al. (2011) (see also Chia et al., 2000; Oftedal et al., 2000) are of a special type. Here people making very long (over 1 h) cell/mobile phone calls develop headaches an hour or more following the initiation of the long call. So these occur within a specific time range following initiation of these long calls, such that headache would only occur very infrequently in that time frame by chance. So here again, there is a strong association. While there is no question that many of these studies show high strength of association, it is also clear that it is becoming progressively more difficult to do these studies. As exposures become almost universal in countries around the world, it is getting difficult if not impossible to find good negative controls. There may be a similar problem in doing animal studies, such that it may be necessary to raise animals in Faraday cages in order to avoid exposures that would otherwise occur as a consequence of our near ubiquitous EMFs.

Biological credibility is extremely strong here, with three aspects of the biology predicting that these low intensity fields cause widespread neuropsychiatric effects. This was discussed above and is reconsidered in the following section.

Consistency within the different epidemiological studies and with other types of studies. The epidemiological studies listed in Table 3 and also those showing neuropsychiatric effects that were cited in Raines (1981) have been performed in many different countries with different cultures. They have been performed in multiple countries in Western Europe, Eastern Europe, the Middle East and in East Asia, as well as in the U.S. and Australia. They are, therefore, not limited to one or two cultural contexts. This is deemed, therefore, an important indicator of causality. We also have a surprising consistency of apparent neuropsychiatric effects of different fields, including various occupational exposures and exposures to cell/mobile phone base stations, exposure to the phones themselves, exposure to smart meter pulses, and other EMFs (see Table 3). Pulsation patterns, frequencies and exact intensities may produce various biological responses (Pall, 2015; Pangopoulos et al., 2013; Belyaev, 2015) so it is a bit surprising that we have as much consistency as we do have across different types of exposures. We also have consistency with the biology discussed in the previous section. Because elevated VGCC activity produced by genetic polymorphism (Table 1) produces diverse neuropsychiatric effects, it is not surprising that elevation of VGCC activity produced by microwave EMF exposure apparently also produces diverse neuropsychiatric effects. Similarly because non-thermal EMF exposures produce widespread changes in brain structure and function in animals (Tolgskaya and Gordon, 1973), it is not surprising that the neuropsychiatric symptoms, which are produced as a consequence of brain dysfunction are produced by such EMFs.

Time sequence: It is clear that the all of these effects follow exposure in the various studies that have been published. In some studies, it is also clear that longer occupational exposure times produce increased symptom prevalence. These include Dwyer and Leeper (1978) and Baranski and Edelwejn (1975). These observations all support a causal relationship between exposure to EMF and the development of neuropsychiatric symptoms.

Dose–response relationship: It is assumed, here, that biological effects have a positive correlation with the intensity of the apparent causal stressor. This is not necessarily true of EMF effects, because it has been shown that there are "window effects" where specific intensities have larger biological effects, than *do either lower or higher intensities* (Pall, 2015; Pangopoulos et al., 2013; Belyaev, 2015). Nevertheless, where different intensities were studied in these epidemiological studies, they do show the dose–response relationship assumed here including Altpeter et al. (2000), Dwyer and Leeper (1978), Eger and Jahn (2010), Lerner (1980), Navarro et al. (2003), Oberfeld et al. (2004), Salama and Abou El Naga (2004), Santini et al. (2003) and Thomée et al. (2011). Thus these data do fit well to the assumed dose–response relationship, found in most causal roles. The Altpeter et al. (2000) study showed a special type of evidence for causality: during a 3-day period when the broadcasting tower was turned off, the melatonin levels recovered to near-normal levels. The studies of headache occurrence on prolonged cell/mobile phone calls (typically well over one hour) listed under Chu et al. (2011) in Table 3 also suggest the assumed dose–response relationship (see also Chia et al., 2000; Oftedal et al., 2000 and earlier citations listed in Frey, 1998). Because such headaches only occur with prolonged cell/mobile phone calls, these studies also provide evidence for a dose–response relationship because low doses are ineffective. Furthermore these same studies provide evidence for such a dose–response relationship from another type of observation. Because the headaches occur predominantly on the ipsilateral side of the head which receives much higher EMF exposure intensity, rather than on the contralateral side of the head, which receives much lower intensities, this provides an additional type of evidence for the predicted dose–response relationship.

While the evidence is convincing that the various neuropsychiatric apparent consequences of microwave EMF exposure are in fact caused by such exposures, there may be somewhat more controversy about another EMF-neuropsychiatric linkage. Havas et al. (2010) have reported a similar list of neuropsychiatric symptoms in electromagnetic hypersensitivity (EHS) patients. They found that each of the following symptoms were common in EHS: poor short term memory; difficulty of concentration; eye problems; sleep disorder; feeling unwell; headache; dizziness; tinnitus; chronic fatigue; tremors; body pain; difficulty speaking; tingling sensation in feet or hands; difficulty writing; difficulty walking; migraine. The similarity of these symptoms to the most commonly found symptoms following non-thermal microwave EMF exposures (Table 3), suggests that EHS is a genuine sensitivity to EMFs. In the bottom row in Table 2, sensitivities were found in rodent studies following non-thermal exposure that suggest a possible animal model for the study of EHS. Each of these EHS-related issues needs to be followed up experimentally.

8. Discussion and conclusions

In the previous section, each of the five criteria for assessing whether an epidemiological association is causal, were considered. Those five are (Hennekens and Buring, 1989): (1) strength of association; (2) biological credibility; (3) consistency; (4) time sequence; (5) dose–response relationship. Each of these five provide strong support for causality such that the combination of all five provides compelling evidence for causality. Low-intensity microwave frequency EMFs do cause diverse neuropsychiatric symptoms. While each of these five is important here, the one that is most important is the criterion of biological credibility.

Three related sets of biological observations each predict that low-intensity microwave EMFs produce widespread neuropsychiatric effects:

1. Such EMFs act via activation of VGCCs, acting through the VGCC voltage sensor which is predicted to be exquisitely sensitive to these EMFs (Pall, 2015). VGCCs occur in high densities throughout the nervous system and have essential roles throughout the nervous system in releasing neurotransmitters and neuroendocrine hormones. These properties predict, therefore, that these low intensity non-thermal microwave EMFs cause widespread changes in the nervous system, causing, in turn, diverse neuropsychiatric effects.

2. Elevated VGCC activity, produced by an allele of the CACNA1C gene which encodes the channel of the main L-type VGCC in the brain, produces various neuropsychiatric effects (Table 1). This predicts, that low intensity non-thermal microwave frequency EMFs which also produce elevated L-type and other VGCC activity, therefore produce widespread neuropsychiatric effects.
3. Studies reviewed in the Tolgskaya and Gordon, 1973 publication (Table 2) have shown that the cells of the mammalian nervous system show high sensitivity to various non-thermal microwave and lower frequency EMFs, being apparently more sensitive than any other organ in the body of rodents. These studies predict that the human nervous system is likely to be similarly sensitive to these EMFs, predicting, therefore, widespread neuropsychiatric effects in humans.

We not only have biological credibility but also more importantly, each of these distinct but interrelated biological considerations predicts that low-intensity, non-thermal microwave EMFs produce widespread neuropsychiatric effects. That common prediction is verified by extensive data summarized in citations provided by the Naval Medical Research Institute Research Report (June 1971), data provided by The Raines (1981) NASA report, and by 26 epidemiological studies summarized in Table 3.

The most commonly reported neuropsychiatric symptoms from these studies are summarized in Table 4.

A total of 22 different studies described in Table 3 were used for data for this table, but not 4 others that only assessed a single neuropsychiatric end point. The Altpeter study which only assessed sleep disturbance/melatonin depletion and the three studies listed under Chu et al. which only assessed headache occurrence following long cell phone calls, listed in Table 3 were not included. Because many of the studies only assessed from 3 to 7 specific symptoms, it is not surprising that the numbers of studies reporting a specific symptom fall far below 22. Where several symptom descriptions were included under one heading, such as dysesthesia, if a study had more than one of these symptom descriptions, it was only counted once.

All the symptoms listed in Table 4 should be considered established parts of microwave syndrome (Hocking, 2001; Johnson Liakouris, 1998). Even if the statistical significance in each study was of the lowest statistical significance ($p < .05$) one would expect only 1 positive study to occur at random out of the 22 studies included here. Because many individual symptoms were not surveyed in many individual studies, the expectation is substantially lower than that. Each of these, having shown positive results in 5 or more studies are highly unlikely, therefore, to have occurred by chance. Stong statistical significance is also seen for individual neuropsychiatric effects reported to have $p < 0.001$ in the Eger and Jahn (2010) and Oto et al. (1994) studies (see Table 3).

Table 4
Commonly reported neuropsychiatric symptoms following microwave EMF exposure.

Symptom(s)	Numbers of studies reporting
Sleep disturbance/insomnia	17
Headache	14
Fatigue/tiredness	11
Depression/depressive symptoms	10
Dysesthesia (vision/hearing/olfactory dysfunction)	10
Concentration/attention/cognitive dysfunction	10
Dizziness/vertigo	9
Memory changes	8
Restlessness/tension/anxiety/stress/agitation/feeling of discomfort	8
Irritability	7
Loss of appetite/body weight	6
Skin tingling/burning/inflammation/dermographism	6
Nausea	5

EEG changes may well be part of microwave syndrome, as well. While none of the studies described in Table 3 measured EEGs, six studies of human occupational exposure cited in the Raines (1981) showed EEG changes (Baranski and Edelwejn, 1975; Bise, 1978; Dumanskij and Shandala, 1974; Lerner, 1980; Sheppard and Eisenbud, 1977). Murbach et al. (2014) cited 10 human studies in support of their statement that "the most consistently reported effects (of mobile phone use) in various studies conducted by different laboratories are changes in the electroencephalogram (EEG) power spectrum." Three recent studies (Lustenberger et al., 2013; Schmid et al., 2012a,b) and several earlier studies cited in Wagner et al. (1998) have each shown EEG changes in sleeping humans exposed to non-thermal pulsed microwave fields. Two recent studies showed EEG changes in persons exposed to Wi-Fi fields (Maganioti et al., 2010; Papageorgiou et al., 2011). Lai (1997) described 8 animal studies showing changes in EEG patterns in animals exposed to non-thermal EMFs and three additional animal studies were described in Tolgskaya and Gordon (1973). With the exception of the 6 studies cited in the second sentence in this paragraph, all of these are direct experimental studies which are not, therefore, susceptible to the questions of causality that can be raised about epidemiological studies. It is the author's view that future studies should consider studying EEG changes as an objectively measurable assessment of brain physiology and that before and after increased exposure studies should be considered when a new EMF source is to be introduced into human populations. While such studies must be done carefully, given the complexity of EEGs, even very small numbers of individuals may produce highly statistically significant results in well designed studies analyzed with paired *t*-tests.

One of the citations from the previous paragraph, Bise (1978) reviewed earlier studies of low level microwave frequency exposures in humans and concluded that such EMFs produced the following neuropsychiatric effects: headache, fatigue, irritability, dizziness, loss of appetite, sleepiness, sweating, difficulty of concentration, memory loss, depression, emotional instability, dermographism, tremor, hallucinations and insomnia. The strong similarity of this list from 37 years ago and the list in Table 4 should be noted. The Bise (1978) list is based on occupational exposure studies whereas the current list in Table 4 is based primarily on EMF exposures from cell/mobile phone base stations, from heavy cell phone usage and from smart meters, *three types of exposures that did not exist in 1978*. The strong similarity between the Bise (1978) list and the current one 37 years later alone produces a compelling argument that the 11 neuropsychiatric effects found on both lists are caused by exposure to multiple types of low-intensity microwave EMFs.

The pattern of evidence is compelling in support of the earlier statement of Levitt and Lai (2010) that "the primary questions now involve specific exposure parameters, not the reality of complaints or attempts to attribute such complaints to psychosomatic causes, malingering or beliefs in paranormal phenomena."

We can barely imagine how the combinations of neuropsychiatric effects, including those in Table 4, will influence human behavior and social interactions, now that the majority of the human populations on earth are exposed to ever increasing intensities and diversity of microwave frequency EMFs. You may recall that three of the occupational exposure studies cited in (Raines, 1981 showed increasing prevalence of neuropsychiatric symptoms with years of exposure to consistent patterns of EMF exposure intensities (Dwyer and Leeper, 1978; Sadcikova, 1974;

Baranski and Edelwejn, 1975). With ever increasing exposures in human populations, we have no idea what the consequences of these ever increasing exposures will be.

Conflict of interest

The author declares no conflict of interest.

Air Force Plan: Hack Your Nervous System

TOPICS:BizarroLasers and Ray Guns

Posted By: February 13, 2006

This is the first of a two-part series on plasma and electromagnetic weapons by David Hambling, author of Weapons Grade: How Modern Warfare Gave Birth to Our High-Tech World.

The brain has always been a battlefield. New weapons might be able to hack directly into your nervous system. "Controlled Effects" (see image, right) is one of the Air Forces ambitious long-term challenges. It starts with better and more accurate bombs, but moves on to discuss devices that "make selected adversaries think or act according to our needs… By studying and modeling the human brain and nervous system, the ability to mentally influence or confuse personnel is also possible."

The first stage is technology to remotely create physical sensations. They give the example of the Active Denial System "people zapper" which uses a high-frequency radiation similar to microwaves as a non-lethal means of crowd control.

Other weapons can affect the nervous system directly. The Pulsed Energy Projectile fires a short intense pulse of laser energy. This vaporizes the outer layer of the target, creating a rapidly-expanding expanding ball of plasma. At different power levels, those expanding plasmas could deliver a harmless warning, stun the target, or disable them – all with pinpoint laser precision from a mile away.

Early reports on the effects of PEPs mentioned temporary paralysis, then thought to be related to ultrasonic shockwaves. It later became apparent that the electromagnetic pulse caused by the expanding plasma was triggering nerve cells.

Details of this emerged in a heavily-censored document released to Ed Hammond of the Sunshine Project under the Freedom if Information Act. Called Sensory consequence of electromagnetic pulsed emitted by laser induced plasmas, it described research on activating the nerve cells responsible for sensing unpleasant stimuli: heat, damage, pressure, cold. By selectively stimulating a particular nociceptor, a finely tuned PEP might sensations of say, being burned, frozen or dipped in acid — all without doing the slightest actual harm.

The skin is the easiest target for such stimulation. But, in principle, any sensory nerves could be triggered. The Controlled Effects document suggests it may be possible to create synthetic imagesto confuse an individual' s visual sense or, in a similar manner, confuse his senses of sound, taste, touch, or smell.

In other words, it may be possible to use electromagnetic means to create overwhelming 'sound' or 'light', or indeed 'intolerable smell' which would exist only in the brain of the person perceiving them.

There is another side as well. The sensory consequences document also notes that the nervous system which controls muscles could be influenced to cause what they call Taser-like motor effects. The stun guns ability to shock the muscles into malfunction is relatively crude; we might now be looking at are much more targeted effects.

Tomorrow: Moscow moves in. Remote-controlled heart attacks, anyone?

— David Hambling

Moscow's Remote-Controlled Heart Attacks

TOPICS:BizarroLasers and Ray Guns

Posted By: February 14, 2006

This is the second of David Hambling's two-part series on plasma and electromagnetic weapons. Check out part one here.

The American military may want to attack the nervous system, with pain rays and laser plasma pulses. But they're not the only ones. The Russians have long studied such systems, too — including one weapon that could, in theory, remotely trigger heart attacks.

In 2003, at the 2nd European Symposium on Non-Lethal Weapons, Anatoly Korolev and his colleagues from Moscow State University presented a paper with the snappy title "Bioelectrodynamic Criterion of the NLW Effectiveness Estimation and the Interaction mechanisms of the multilayer Skin Tissues with electromagnetic Radiation." This is a study of how radio-frequency weapons — like the American Active Denial System — affect the skin. After wading through a mass of technical data showing how complex the interactions are we reach the punch line:

The sensations modality (pricking, touch, pressure, gooseflesh, touch, burning pain etc) depends on the field parameters and individual concrete human being factors. As a matter of fact, we can really choose the non-lethal bioeffect.

The effects include sensations similar to those discussed previously, and more besides. The paper discusses effects on cell membranes and affecting the bodys normal function, including "information transfer to the organs of control."

At the same conference, V Makukhin of the Trymas Engineering Center in Moscow described "Electronic equipment for complex influence on biological objects." And when he says "biological objects," he means you and me.

His laboratory apparatus uses a modulated beam of radio waves to produce what he terms "disorder of autonomic nervous system," put forward as a possible non-lethal weapon. Makhunin notes that there is no general agreement on how EM waves disrupt nerves – he mentions ion channels similar to those in the plasma paper – but he certainly seems to be seeing the same effects as American researchers.

But it need not be a non-lethal weapon. Makhunin also mentions the effects of "change of electrocardiogram" and what he calls "function break of heart muscle."

The vulnerability of the heart to electrical stimulation (including that produced by EM waves) is well documented. A lethal device would interfere with the electrical potentials that keep the chambers of the heart synchronized, producing fibrillation and rapid death. A death ray doesnt need to be a truck-sized laser that reduces the target to smoking heap; a small device that stops the heart will do the job.

Little has been openly published in this area in the public domain, but this may be the tip of the iceberg. We are likely to be hearing more in future – especially if the Russians manage to find funding.

I dont think we need tinfoil hats just yet. But a layer of conducting mesh built into body armor might save a lot of heartache in years to come.

(If you want more, theres a whole chapter on different non-lethal directed energy weapons and where the technology might lead in my book Weapons Grade.)

— David Hambling

MYSTERY IN THE SKIN

Screen dermatitis, the effect of computer work on human skin.

An interview with associate professor Olle Johansson at the Experimental Dermatology Unit, Department of Neuroscience, Karolinska Institute, Stockholm, Sweden.

Mr. Helge Tiainen, former head of the Nokia Consumer Electronics in Sweden once said that "The results of Olle Johansson's research could very well deeply shake the world's electronics industry, but mankind still has to know!"

Some interests might feel threatened by the results of his research, but professor Johansson has been outspoken and committed to this scientific field. He started in the 1980's and he has since been continuously very productive and an advocate for the electrosensitive persons in Sweden as well as around the world. This interview will go into what professor Johansson has discovered in the skin of those injured by computer monitors, and also what remains to be done.

He has written a number of important scientific original articles as well as a great number of commentaries and debate articles in the daily newspapers. He has been awarded a series of prestigious awards, such as the Nokia Monitor Award, the Environmental/Medicin Award from the Swedish Cancer and Allergy Foundation and the SIF-Award (The Swedish Clerical and Technical Employees Union).

Altogether, his publication list within the field of neuroscience contains more than 450 original papers, review articles and conference summaries, and he has been a co-author of papers in high-impact journals, such as Nature and Science. His skill as a lecturer is very well documented and his overall knowledge in the areas of the neurosciences, health effects of electromagnetic fields, and in experimental dermatology is esteemed at the highest level.

FEB:
What made you first interested in studying people who had suffered injuries from working in front of computer monitors?

Professor Johansson:
It all started in the 1980's after having listened to a radio programme in which Ms Kajsa Vedin from Gothenburg, herself very active from a union point of view and the author of an excellent analysis entitled "In the shadow of a microchip" (about the occupational risks involved in computer-based work), asked for expertise in neurology. As a neuroscientist I thought I was close enough, and I strongly believed that the issues she wanted to highlight, using the conventional repertoire of scientific "tools", ought to be easily investigated. I did not realise at all that there were other forces not wanting to see such studies initiated, but very soon I understood that these very clear-cut and simple and obvious investigations proposed by Kajsa Vedin would be very, very hard to start.
The same type of propositions soon were brought forward by many other persons including the two journalists Gunni Nordstrom and Carl von Schéele, who later published their first book, "Sjuk av bildskarm" ("Ill from VDT work"; Tidens Forlag, 1989, ISBN 91-550-3484-5). Unfortunately, most of these proposed studies are still not brought into life, 15 years later.

FEB:
Many people abroad think that because electrosensitivity is so well known in Sweden, that we have conducted many important studies also. But this is not the case. Why is this?

Professor Johansson:
The reason is simple, I am afraid. It is not because of lack of ideas and projects, on the contrary, the only reason is lack of funding. This fact has been very important, thus, more or less putting a dead end to the pursuit of knowledge here in Sweden. It is sad, very sad, since I strongly believe a lot would have been understood today if scientists could have been in a situation to properly investigate this enigmatic disease. And, a great deal of unnecessary suffering among the patients could, thus, have been avoided.

FEB:
Did you ever doubt the people who claimed to have been injured using computer monitors?

Professor Johansson:
For me it was immediately clear that persons claiming skin reactions after having been exposed to computer screens very well could be reacting in a highly specific way and with a completely correct avoidance reaction, especially if the provocative agent was radiation and/or chemical emissions -- just as you would do if you had been exposed to e.g. sun rays, X-rays, radioactivity or chemical odours. The working hypothesis thus became that they reacted in a cellularly correct way to the electromagnetic radiation, maybe in concert with chemical emissions such as plastic components, flame retardants, etc., something later focussed upon by professor Denis L. Henshaw and his collaborators at Bristol University (this is covered in Gunni Nordstrom's book " Morklaggning - Elektronikens rattslosa offer" (Hjalmarson & Hogberg Forlag, 2000, ISBN 91-89080-41-6)).

Very soon, however, from different clinical colleagues a large number of other 'explanations' became fashionable, e.g. that the persons claiming screen dermatitis only were imagining this, or they were suffering from post-menopausal psychological abberations, or they were old, or having a short school education, or were the victims of classical Pavlovian conditioning. Strangely enough, most of the, often self-made, 'experts' who proposed these explanations had themselves never met anyone claiming screen dermatitis and these 'experts' had never done any investigations of the proposed explanatory models. The explanations were soon revealed to be excuses of a scientifically fraudulent nature! It is interesting to see that science at that time was mere witchcraft. It remains for skilful journalists to inquire how this came about.

FEB:
You created the name "screen dermatitis", a clinical term to explain the cutaneous damage developed in the late 1970's when office workers, first mostly women, began to be placed in front of computer monitors. Many of them became ill and developed cutaneous and neurological problems. Several clinical dermatologists, headed by the late professor Sture Lidén, instead talked about union-driven fears, mass media-based psychoses, imagination phenomena, Pavlovian conditioning and so forth. But you came to a totally different conclusion. Why?

Professor Johansson:
I refused to reduce people to an ill-defined psychologic home-made diagnosis, without any support even among experts in psychology and psychiatry. Instead, I called for action along lines of occupational medicine, biophysics and biochemistry, as well as neuroscience and experimental dermatology.

I support the democratic principle that citizens are allowed to be ill even in a disease, i.e. a new diagnosis, that is not yet acknowledged by the medical establishment. All diseases were once a "new diagnosis", and the medical profession strongly has doubted asbestosis, cold urticaria, AIDS, the mad cow disease, skin lice, etc. I usually end my lectures with a quotation from Albert Einstein "The important thing is not to stop questioning".
I have never stopped asking questions and I am using the answers to put into place the ever-growing number of pieces of a very, very complicated and enigmatic puzzle.

FEB:
Mr. Helge Tiainen, former head of the Nokia Consumer Electronics in Sweden, in February 23, 1994, said that "The results of Olle Johansson's research could very well deeply shake the world's electronics industry, but mankind still has to

know!" You have received death threats, and been generally harassed. Do you think this has anything to do with your attempts to let "mankind know" ?

Professor Johansson:
Unfortunately, yes.

FEB:
Your Ph.D. thesis was about neuropeptides in the central and peripheral nervous system. Are they also involved in the reactions in the skin of the electrically sensitive?

Professor Johansson:
This is a very important question you bring up! This is something we have wanted to study for many years, but so far we have not been able to pursue these lines of interest due to lack of funding. Since the persons claiming electrosensitivity/screen dermatitis report cutaneous sensations, such as itch, pricking pain, redness, etc., of course the peripheral as well as the central nervous system must be involved. And, by understanding alterations in the chemical neurotransmitter or neuromodulator levels, synthesis, break-down, release and re-uptake, much could be learnt and understood about the basis for these avoidance reactions based upon signals transmitted via the classical sensory and autonomic pathways.

The reaction pattern definitely points to a true biophysical effect, and not to anything else. And, finally, if you take into consideration the large number of publications showing severe changes or damages from low- or high-frequency irradiation of cells, tissues and non-human experimental animals, such alterations cannot ever be understood as "post-menopausal stress reactions", "imagination" or "techno-stress alterations"!

FEB:
You have in 1995 shown that histamine can exist in nerves in the skin. What does this mean?

Professor Johansson:
Already in 1953, the Swedish Nobel Laurate, professor Ulf von Euler had shown that peripheral nerves biochemically could contain histamine. It was argued at that time that it only was due to a contamination of histamine from mast cells present around the peripheral nerves. However, further physiological experiments indicated that maybe there could be both central neurons containing histamine (recently proved) as well as peripheral nerves in various target organs.

Using a histamine-based immunohistochemistry we could then, in 1995, show images revealing the presence of histamine-immunoreactive nerves in the skin (1). Naturally, such a finding is of paramount importance, since all studies on histamine effects in the skin have been based on the assumption that the histamine only is released from local mast cells. So, for instance regarding itch, now we have had to reconsider the function of nerve terminal-derived histamine, something also of the greatest impact for areas such as electrosensitivity.

(1) Johansson O, Virtanen M, Hilliges M, "Histaminergic nerves demonstrated in the skin. A new direct mode of neurogenic inflammation?", Exp Dermatol 1995; 4: 93-96

FEB:
When you look at a biopsy from an electrically sensitive person, what do you usually find?

Professor Johansson:
We are right now in the process of examining a larger number of facial skin samples, and from them the most common finding is a profound increase of mast cells. Nowadays we do not only use histamine, but also other mast cell markers such as chymase and tryptase, but the pattern is still the same as reported previously for other electrosensitive persons

(2). Furthermore, increases of similar nature have now been demonstrated in an experimental situation employing normal healthy volunteers in front of visual display units, including ordinary house-hold television sets (3).

Among earlier studies, one paper (4) ought to be mentioned. In it, facial skin from so-called screen dermatitis patients were compared with corresponding material from normal healthy volunteers.
The aim of the study was to evaluate possible markers to be used for future double-blind or blind provocation investigations.
Differences were found for the biological markers calcitonin gene-related peptide (CGRP), somatostatin (SOM), vasoactive intestinal polypeptide (VIP), peptide histidine isoleucine amide (PHI), neuropeptide tyrosine (NPY), protein S-100 (S-100), neuron-specific enolase (NSE), protein gene product (PGP) 9.5 and phenylethanolamine N-methyltransferase (PNMT).
The overall impression in the blind-coded material was such that it turned out easy to blindly separate the two groups from each other. However, no single marker was 100% able to pin-point the difference, although some were quite powerful in doing so (CGRP, SOM, S-100). However, it has to be pointed out that we cannot, based upon those results, draw any definitive conclusions about the cause of the changes observed. Whether this is due to electric or magnetic fields, a surrounding airborne chemical, humidity, heating, stress factors, or something else, still remains an open question.
Blind or double-blind provocations in a controlled environment (3) are necessary to elucidate the underlying causes for the changes reported in this particular investigation.

FEB:
You made a sensational finding when you exposed two electrically sensitive individuals to a TV monitor. When you looked at their skin under a microscope, you found something that surprised you. What?

Professor Johansson:
I guess that you are aiming at one of the early papers (5). In this article, we used an open-field provocation, in front of an ordinary TV set, of 2 patients regarding themselves as suffering from skin problems due to work at video display terminals. Employing immunohistochemistry, in combination with a wide range of antisera directed towards cellular and neurochemical markers, we were able to show a high-to-very high number of somatostatin-immunoreactive dendritic cells as well as histamine-positive mast cells in skin biopsies from the anterior neck taken before the start of the provocation. At the end of the provocation the number of mast cells was unchanged, however, the somatostatin-positive cells had seemingly disappeared. The reason for this latter finding is discussed in terms of loss of immunoreactivity, increase of breakdown, etc. The high number of mast cells present may explain the clinical symptoms of itch, pain, edema and erythema. Naturally, in view of the present public debate, the observed results are highly provocative and, I believe, have to be taken much more seriously.

(5) Johansson O, Hilliges M, Bjornhagen V, Hall K, "Skin changes in patients claiming to suffer from "screen dermatitis": a two-case open-field provocation study", Exp Dermatol, 1994; 3: 234-238

FEB:
You mention mast cells in the skin. A doctor, John Holt, in Australia has written to us saying that when working with

microwaves (to irradiate cancer cells) he has observed that the microwaves from cell phones cause a doubling of histamine (which are released from mast cells) and that such electrosmog from mobile phones could be the cause of the ever increasing asthma and other allergies.
Does his reasoning make any sense?

Professor Johansson:
It certainly does! I have put forward this hypothesis many years ago, in public here in Sweden, and I am now happy to finally see more and more data gathering to support this idea. I and my collaborator, dr. Shabnam Gangi, have also addressed this in two recent publications (see below).

FEB:
You and your partner Shabnam Gangi have presented a theoretical model for how mast cells and substances secreted from them (e.g. histamine, heparin and serotonin) could explain sensitivity to electromagnetic fields. Could you, please, explain this? And also, please, explain the function of the Langerhans cells and how long it takes for them to return.

Professor Johansson:
Yes, we have published two papers of theoretical nature (6,7). They bounce off from known facts in the fields of UV- and ionizing irradiation-related damages, and use all the new papers dealing with alterations seen after e.g. power-frequency or microwave electromagnetic fields to propose a simple summarizing model for how we can understand the phenomenon of electrosensitivity. I strongly recommend the readers of this interview to familiarize themselves with these publications, since I fully believe they have a lot to offer as food for further thoughts.

In the first paper, in the journal Experimental Dermatology (6), we describe the fact that an increasing number of persons say that they get cutaneous problems as well as symptoms from certain internal organs, such as the central nervous system and the heart, when being close to electric equipment. A major group of these patients are the users of video display terminals, who claim to have subjective and objective skin- and mucosa-related symptoms, such as pain, itch, heat sensation, erythema, papules, and pustules. The central nervous system-derived symptoms are, e.g. dizziness, tiredness, and headache. Erythema, itch, heat sensation, edema and pain are also common symptoms of sunburn (UV dermatitis).
Alterations have been observed in cell populations of the skin of patients suffering from so-called screen dermatitis similar to those observed in the skin damaged due to ultraviolet light or ionizing radiation. In screen dermatitis patients a much higher number of mast cells have been observed.
It is known that UVB irradiation induces mast cell degranulation and release of TNF-alpha. The high number of mast cells present in the screen dermatitis patients and the possible release of specific substances, such as histamine, may explain their clinical symptoms of itch, pain, edema and erythema. The most remarkable change among cutaneous cells, after exposure with the above-mentioned irradiation sources, is the disappearance of the Langerhans' cells. This change has also been observed in screen dermatitis patients, again pointing to a common cellular and molecular basis. The results of this literature study demonstrate that highly similar changes exist in the skin of screen dermatitis patients, as regards the clinical manifestations as well as alterations in the cell populations, and in skin damaged by ultraviolet light or ionizing radiation.

In the second publication (7), from the journal Medical Hypotheses, the relationship between exposure to electromagnetic fields and human health is even more in focus. This is mainly because of the rapidly increasing use of such electromagnetic fields within our modern society. Exposure to electromagnetic fields has been linked to different cancer forms, e.g. leukemia, brain tumors, neurological diseases, such as Alzheimer's disease, asthma and allergy, and recently to the phenomenon of electrosensitivity and screen dermatitis. There is an increasing number of reports about cutaneous problems as well as symptoms from internal organs, such as the heart, in people exposed to video display terminals. These people suffer from subjective and objective skin and mucosa-related symptoms, such as itch, heat sensation, pain, erythema, papules and pustules (cf. above). In severe cases, people can not, for instance, use video display terminals or artificial light at all, or be close to mobile telephones. Mast cells, when activated, release a spectrum of mediators, among them histamine, which is involved in a variety of biological effects with clinical relevance, e.g. allergic hypersensitivity, itch, edema, local erythema and many types of dermatoses.

From the results of recent studies, it is clear that electromagnetic fields affect the mast cell, and also the dendritic cell, population and may degranulate these cells. The release of inflammatory substances, such as histamine, from mast cells in the skin results in a local erythema, edema and sensation of itch and pain, and the release of somatostatin from the dendritic cells may give rise to subjective sensations of on-going inflammation and sensitivity to ordinary light.
These are, as mentioned, the common symptoms reported from patients suffering from electrosensitivity/screen dermatitis. Mast cells are also present in the heart tissue and their localization is of particular relevance to their function. Data from studies made on interactions of electromagnetic fields with the cardiac function have demonstrated that highly interesting changes are present in the heart after exposure to electromagnetic fields.

(6) Gangi S, Johansson O, "Skin changes in "screen dermatitis" versus classical UV- and ionizing irradiation-related damage--similarities and differences.
Two neuroscientists' speculative review", Exp Dermatol 1997; 6: 283-291

(7) Gangi S, Johansson O, "A theoretical model based upon mast cells and histamine to explain the recently proclaimed sensitivity to electric and/or magnetic fields in humans", Med Hypotheses 2000; 54: 663-671

FEB:
Some electrically sensitive have symptoms similar to heart attacks after exposure to electromagnetic fields. Any comment on that?

Professor Johansson:
One could speculate that the cardiac mast cells are responsible for these changes due to degranulation after exposure to electromagnetic fields. However, it is still not known how, and through which mechanisms, all these different cells are affected by electromagnetic fields. In this article (7), we present a theoretical model, based upon the above observations of electromagnetic fields and their cellular effects, to explain the proclaimed sensitivity to electric and/or magnetic fields in humans.

FEB:
You have been called a scientist who has climbed down from his ivory tower to get in contact with the real world people live in. Has this been a hindrance to you?

Professor Johansson:
Unfortunately, yes, to a very, very large degree. For readers interested in this, I warmly recommend the books by Gunni Nordstrom and Carl von Scheele (8-10). They are of great value for persons wanting to acquaintance themselves with the political implications and impact of the phenomenon of new diagnoses in our society.

(10) "Morklaggning - Elektronikens rattslosa offer" by Gunni Nordstrom (Hjalmarson & Hogberg Forlag, 2000, ISBN 91-89080-41-6)

FEB:
How would you depict the world the electrically sensitive live in?

Professor Johansson:
As a healthy individual it is always very hard to try to describe patients' own situation, so I would rather have someone else to answer this. But, in essence, it must be a very tough daily life, having to always (very much as an allergic or

asthmatic person) look out for situations of provocative nature. And, where today would you find an electric environment equal to e.g. the 1950's? Or, even more mind-buggling, where would you find a high-frequency milieu the same as last year? Nowhere, I guess, since the growth of all such systems is so rapid and quickly covers us all.
Therefore, to enable the basic freedom of choosing where to live, where to work, etc., is impossible in relation to the electrosensitive persons' requirements. And, thus, the question of electrosensitivity becomes a question about democracy!

FEB:
Why do you think some people become electrically sensitive and others do not?

Professor Johansson:
This is also a most important and interesting question. As you know, in any kind of disease, not everyone is ill, and not at the same time. Everyone will not get cancer, everyone will not break a leg, everyone will not have malaria. This is governed by the biological statistical rules of the natural variation. But, maybe you should turn the issue around somewhat.
Perhaps all healthy persons, i.e. in the sense not being electrosensitive, ought to be extra happy for the electrosensitive ones, since they have acted as a warning for all of us? It could be, that we will owe them a lot since they reacted in time to something which the main bulk of mankind did not. Furthermore, the possibility is also that the electrosensitive persons will turn out to be tomorrow's great winners, given the fact that this Summer, twentyone world-leading scientists during a gathering in the French city Lyon, within IARC's (IARC = International Agency for Research on Cancer) expert panel, have concluded low-frequency magnetic fields as a possible cancer risk (=group 2B, containing in addition i.a. diesel and petrol fumes, chloroform, welding fume, lead and DDT). For children exposed to such low-frequency magnetic fields above 0.4 microTesla the cancer risk is doubled. (Therefore, I ask myself: How will people feel after having spent their everyday working hours at or around Vasagatan in Stockholm where the low-frequency magnetic field 1.2 meters above ground is between 0.3 and 2.2 microTesla, or in the commuter trains having levels between 1 and 100 microTesla in the traveller's compartment!?)

FEB:
Does it worry you that children use mobile telephones?

Professor Johansson:
Yes, definitely. And, as you know, also the British government has, in December last year, taken firm action in respect to this question.

FEB:
How will we look on mobile telephones in ten years?

Professor Johansson:
Hopefully without any remaining questions, scepticism or fear. I look forward to see the question-marks around this technology resolved, and a well-documented and 100% responsible, human-friendly technology being presented. And, hopefully, tomorrow's human-friendly technology will be made by Swedish companies, in that way creating a 'healthy wealth' for our country.

FEB:
What do you tell people who suggest that electric sensitivity is purely imagined or psychological?

Professor Johansson:
Well, I always ask them to then, in parallel, explain all the peer-review-published results around effects of, often very weak, electromagnetic fields on molecules, cells, tissues, organs and various non-human experimental animals, i.e. situations which cannot at all be understood in terms of imagination or psychology. In failing this task, I then ask them to

return to the first statement regarding humans, and to scrutinize and re-evaluate it. As you understand, people at that moment suddenly lack scientifically sound arguments, and most of them also confess this. As you know, in the same way it is also very easy to say that all Finns carry knives, but when you look upon this statement in a scientific way it is even easier to show that it is not true!

FEB:
There are many self-appointed 'experts' who have made life difficult for the electrically sensitive. Are they always scientists?

Professor Johansson:
I am, and have always been, very surprised to see how sloppy some of my colleagues address important issues such as the above. Very often one has to realize that all 'experts' are not true scientists and scholars.
Furthermore, it is also very annoying to see that 'experts' claiming, for instance, "that the best way to treat electrosensitive persons is to completely ignore them through silence", did not have to face any personal consequence...!? Nothing happened to them, their position was not questioned, their competence as physicians was not questioned, their suitability as representatives for the medical profession was not questioned. Nothing! What kind of society is that?

I am also very disturbed by the fact that even if the electrosensitive persons were victims of an illusion, where in the Swedish health and law system does it say that you can treat them so badly as several have done?
When I attended the medical school I was taught the very opposite: You should always address patients with kindness, a will to learn and help, support them, meet them and their concerns in a most respectful way, and so on. Where did that disappear? It seems as our world-famous Swedish health insurance policy contains very big gaps through which electrosensitive people, as well as other new diagnoses, fell, and still fall, head down!

FEB:
Do you know of anyone else in the world who has taken biopsies of electrically sensitive individuals?

Professor Johansson:
Yes, the assistant professor and histopathologist Bjorn Lagerholm at the Karolinska Hospital in Stockholm did that already in the middle of the 1980's. He also found an increase in the mast cell number, but, unfortunately, he could never publish it.

As a matter of fact, his interest very much started with a female bank employee that had received a work injury compensation for skin changes after sitting in front of a visual display monitor. Bjorn Lagerholm described in great detail her skin changes, which turned out to be very similar to the kind of cutaneous alterations you may encounter in connection with ultraviolet light or X-ray damage. It is to be noted that Bjorn Lagerholm's reputation as a histopathologist was, and is, undisputed. He had examined at least 10,000 biopsies from other skin diseases before this particular case. In addition to her, he also examined nearly 100 further screen dermatitis cases, all having the same skin changes.

Bjorn Lagerholm wrote an article in the Swedish Medical Journal ("Lakartidningen") to describe his observations. Apart from this he was never able to pursue his ground-breaking and very elegant studies. They would be burried for several years, until I and my collaborators re-initiated them in the early 1990's.

FEB:
Some doctors say that the radiation from a computer monitor could not possibly affect the human skin. The nerves are not that superficial, but what do you say?

Professor Johansson:
This is completely wrong! The idea of the deeply burried nerve fibers were put forward by the late professors David Ingvar and Bernard Frankenheuser.

However, we shortly after published the first true demonstration of the epidermal nerves in human skin (11), followed by an ultrastructural identification (12) as well as a detailed description and quantification of these very superficial nerves (13).

(11) Wang L, Hilliges M, Jernberg T, Wiegleb-Edstrom D, Johansson O, "Protein gene product 9.5-immunoreactive nerve fibres and cells in human skin", Cell Tissue Res 1990; 261: 25-33

(12) Hilliges M, Wang L, Johansson O, "Ultrastructural evidence for nerve fibers within all vital layers of the human epidermis", J Invest Dermatol 1995; 104: 134-137

(13) Johansson O, Wang L, Hilliges M, Liang Y "Intraepidermal nerves in human skin: PGP 9.5 immunohistochemistry with special reference to the nerve density in skin from different body regions", J Peripher Nerv Syst 1999; 4: 43-52

FEB:
Exactly how superficial are these nerves in the skin? When a person places his or her hands on a computer keyboard which gives off electromagnetic fields, can these fields affect the person enough to cause RSI (Repetitive Strain Injury). In Sweden this phenomenon is called "mouse arm" and is quite common.

Professor Johansson:
The nerves come as close as 10-40 micrometers from the stratum corneum, which could be, in e.g. the face, in itself very thin, thus, these nerves are very superficially located. Whether this is the cause for RSI, I honestly do not know, but, naturally, it is definitely a possibility to take into careful consideration.

FEB:
The skin is the largest organ of the body. It is also our foremost protector against the outside world. How does this protection-process work?

Professor Johansson:
This is a very large question, and it would take too much space and time to answer it in full detail. But, in brief, one could understand the skin as a very sensitive 'antenna system' containing, in addition, special sensory organs, such as the eyes, the nose and the ears. The function of the skin is, among many, to always guide us in an ever-changing environment, thus, enabling us to avoid tissue-damaging threats, such as heat, cold, UV-light, X-rays, radioactivity, etc. In the center of this avoidance system is, of course, our nervous system which will help us to go in the right direction, away from some situations, maybe including e.g. electromagnetic fields from computer screens and cellular telephones? The future will tell us if I was right or wrong.

FEB:
Does it seem alarming to you that so many people have reactions in their skin that point to the skin having defensive reactions from say computer work. What of the risk of developing cancer if the skin is always in a defensive mode?

Professor Johansson:
Yes, the whole concept of skin reactions is frightening, especially since the skin cancer forms, such as malignant melanoma and basalioma, are so quickly increasing their incidence. I have asked, over and over again, many colleagues if they really can rule out the surrounding electromagnetic fields as an important background factor for such cancers, and mostly they just do not even answer me.

FEB:
Helmut Kohls wife recently committed suicide due to a severe and lengthy light sensitivity condition. She had to remain in total darkness and could never go out. Many electrically sensitive have experienced precisely the same light sensitivity

after their work with computers. You have written about a woman who became so light sensitive after working with a computer that she had to live in total darkness. Could you tell us more about what goes on in the skin to cause such sensitivity to light.

Professor Johansson:
Yes, to begin with, light sensitivity is increasing as a general problem in the population, and reports have been published in several countries about this. The reason behind it is not known, but from our work one could just speculate around the heat-, light- and UV-adsorbing cellular layer in the epidermis, the so-called melanocytes and their production of the pigment melanin. In the above-mentioned case-report (14), it was evident that this layer, for some unknown reason, was, more or less, completely gone. We used protein S-100 and HLA-DR (human histocompatibility complex class II (subregion DR)) as markers, and it was found that the immunoreactive dendritic cells were dramatically decreased in number, especially in the epidermis.

One could imagine that e.g. increased levels of light or UV-light, or increased levels of other frequencies of electromagnetic fields, such as microwaves, have led to a wear-down of the protective cellular shield in the skin after a long-term continuous irradiation period. If such a damage takes place, maybe the first sign would be light sensitivity in parallel to a modest electrosensitivity. However, if the damage proceeds naturally the situation could be very difficult for the patient, finally leading to a life in basically complete darkness. Several such cases have been reported, but too few studies have been done, again due to lack of funding. In our own case report (14), we could also demonstrate that vitamin A was effective as a treatment for the patient. During the vitamin A treatment, the patient was to a large extent rehabilitated regarding her general light sensitivity, however, she was still sensitive to the presence of electric equipment, although not as much as before. The metabolism of vitamin A should be considered, since, in the human visual system, vitamin A is converted to alpha-cis-retinol, which is an essential chromophore component of rhodopsin, the photoreceptor protein of the retinal rods and is therefore essential for human vision. Maybe vitamin A influences cutaneous (as well as other) cellular systems similar to the retina. One explanation is that the patient for a time lost her melanocytes (or melanocytic content) as seen with the S-100 immunofluorescence, in response to an external or internal provocation. As a reaction to this, also her HLA-DR positive dendritic cells were affected. The vitamin A may have been capable of restoring this balance, as least partially.

(14) Johansson O, Liu P-Y, Enhamre A, Wetterberg L, "A case of extreme and general cutaneous light sensitivity in combination with so-called 'screen dermatitis' and 'electrosensitivity' - a successful rehabilitation after vitamin A treatment - a case report", J Aust Coll Nutr & Env Med 1999; 18: 13-16

FEB:
You conducted a blind test to see if electrically sensitive persons reacted to microwaves from mobile phones, What was the outcome?

Professor Johansson:
I, and my collaborators, have done a series of such tests, some done here in Stockholm, some in Goteborg and also some in Linkoping. The experiments in Stockholm and Goteborg failed, maybe due to the fact that the surrounding environment could not be controlled from the point of low- and high-frequency signals, which may have interacted with the tests subjects.
However, the study in Linkoping (15) was done in the country-side, more than 1 kilometer from the nearest live electric power source. One person was actually able to respond correctly to a mobile phone-based double-blind provocation experiment, 9 times out of 9 tests ($p<2/1000$), both in the 'acute' phase as well as in the 'chronic' phase ($p<1/1000$). This would mean that there may very well be negative health effects from such mobile telephones, most likely depending on their high-frequency fields.

(15) Johansson O, "Eloverkanslighet samt overkanslighet mot mobiltelefoner:
Resultat fran en dubbel-blind provokationsstudie av metodstudiekaraktar", Enheten for Experimentell Dermatologi, Karolinska Institutet, Stockholm, Rapport nr. 2, 1995; ISSN 1400-6111

FEB:
The author and journalist Gunni Nordstrom has in an interview expressed herself in the following way:
"The government seems to listen to those who have the right message, the message they wish to hear. Sometimes one wonders if the authorities have these reports custom-made or if someone in the background is masterminding all important positions and is handing out investigations to those with the correct beliefs or to the untalented. The independent thinkers get their heads chopped off as soon as possible at any rate."
Do you find this to be true?

Professor Johansson:
This is, naturally, impossible to precisely know at this stage, but from a speculative point of view one must say that it is odd, very odd to say the least, that the appointed experts nearly always seems to be persons that, for instance, you in the FEB would not propose. And, also when it comes to representatives in international organizations only 'yes-sayers' are invited, and never any 'whistle-blowers'. From a philosophical point of view this can prove to be sad and badly wrong, since, without the latter, companies, authorities as well as governments can be fooled and tricked into the completely wrong corner. And, to fool your own government is, as far as I know, high treason, right? Personally, if I were the prime minister, I would be very afraid never to listen to the 'whistle-blowers' since it could be a big, big mistake, from a public health point of view, not to!

FEB:
You mentioned "whistleblowers". There have been many attempts to wear you down. Most recently you were asked to move your laboratories to a corridor containing all the rooms for household garbage, radioactive vaste, dead animal carcasses, etc.! Does it come a time when it is no longer worth being a "whistleblower"?

Professor Johansson:
For the future, I would like to propose to governments and likewise to ensure that scientists dealing with new, provocative research, even with a great impact on the general economy, that they should be given a 'safety net', i.e. their personal situation, their career possibilities, etc., must be protected and not in any way hampered by the fact that they deal with the 'wrong' kind of scientific field. How, otherwise, would you have future young scientists wanting to throw away all their personal possibilities?
Otherwise, I am deeply afraid that there will come a time when it is no longer worth being a "whistleblower".

FEB:
Have you received sufficient funding?

Professor Johansson:
No, never. And if not the Swedish Cancer and Allergy Foundation would have been around, I do not think I would have had the strength to carry on. But they have always argued for the importance of new, courageous and daring science, and along the lines of cancer, allergy and their connection to the environment. This has also become a leading star for me.

FEB:
What if you suddenly got unlimited funds. What would you like to pursue?

Professor Johansson:
I guess, to begin with, that I would try to accurately characterize the electrosensitive patients from a clinical as well as cellular point of view. Depending on the results, I would then continue with more detailed studies based on theories emanating from the above data. It is, more or less, impossible to say at this point what such studies would be. One thing I would, for sure though, is to employ some additional personnel since I have been very much left alone through-out the years.

FEB:
What about the EU work for a safer electromagnetic environment?

Professor Johansson:
Within this context, one very interesting, and on-going, movement is the EC-based "The European framework for protection from exposure to electromagnetic fields". About it, to begin with, there are some general comments to be made. The EC does not seem to be interested in yet another 'BSE scandal', therefore they are carefully keeping an eye on the issues around health effects and health risks (N.B. Note the difference between health effects, identified and calculated health risks and unknown health risks) from electromagnetic fields, especially from high-frequency telecommunication, such as mobile telephony. Furthermore, the EC does not regard the above-mentioned irradiation systems to be proven safe. On the contrary, I believe they strongly understand it could be a major mistake to whole-body irradiate the whole European (as well as the world's) population, 24 hours around.

FEB:
We often hear about "safe levels" of exposure and that there is "no proof of health effects". What is your response to these seemingly reassuring statements?

Professor Johansson:
It is very important to realize, from a consumer's point of view, that "no accepted proof for health effects" is not the same as "no risk". Too many times, 'experts' have claimed to be experts in fields where actually the only expert comment should have been: "I/we just do not know". Such fields were e.g. the DDT, X-ray, radioactivity, smoking, asbestos, BSE, heavy metal exposure, depleted uranium, etc., etc., etc., where the "no risk"-flag was raised before true knowledge came around. Later on, the same flag had to be quickly lowered, many times after enormous economic costs and suffering of many human beings. Along those lines, it is now (regarding "the protection from exposure to electromagnetic fields" issue) very important to clearly identify the background and employment (especially if they sit, at the same time, on the industry's chairs) of every 'expert' in different scientific committees, and likewise. It is, of course, very important (maybe even more important?) to also let 'whistleblowers' speak at conferences, to support them with equal amounts (or even more?) of economical funding as those scientists and other 'experts' who, already from the very beginning, have declared a certain source or type of irradiation, or a specified product, to be 100% safe.

FEB:
Should the precautionary principle always be our guide?

Professor Johansson:
In the case of "protection from exposure to electromagnetic fields", it is of paramount importance to act from a prudence avoidance/precautionary principle point of view. Anything else would be highly hazardous! Total transparency of information is the key sentence here, I believe consumers are very tired of always having the complete truth years after a certain catastrophy already has taken place. It shall be noted, that today's recommendation values for mobile telephony, the SAR-value, are just recommendations, and not safety levels. Since scientists observe biological effects at as low as 20 microWatts/kg, is it then really safe to irradiate humans with 2 W/kg (i.e., with 100.000 times stronger radiation!), which is the recommendation level for us? And, furthermore, it is very strange to see, over and over again, that highly relevant scientific information is suppressed or even left out in various official documents, as high up as at the governmental level of society. This is not something that the consumers will gain anything good from, and, still, the official declaration or explanation (from experts and politicians) very often is: "If we (=the experts) would let everything out in the open, people would be very scared and they would panic." Personally, I have never seen this happen, but instead I have frequently seen great disappointment from citizens who afterwards have realized they have been fooled by their own experts and their own politicians...

Another misunderstanding is the use of scientific publications (as the tobacco industry did for many years) as 'weights' to balance each other.
But you can NEVER balance a report showing a negative health effect with one showing nothing! This is a misunderstanding which, unfortunately, is very often used both by the industrial representatives as well as official

authorities. The general audience, naturally, easily is fooled by such an argumentation, but if you are bitten by a deadly poisonous snake, what good does it make for you that there are 100 miljon harmless snakes around?

FEB:
In her book " Morklaggning - Elektronikens rattslosa offer " (10), the author and journalist Gunni Nordstrom has identified a group of Swedish obfuscators, mainly Lidén, Berg, Hillert, Arnetz and Bergkvist, who have attempted to put a psychological stamp on what you would term "screen dermatitis". These people have, Gunni Nordstrom claims, written a series of articles in international journals, always quouting one another, always making sure not to mention your findings. This has, as FEB has evidence of, hindered doctors and others to understand the electrically sensitive in other countries, causing them much suffering. How can one prevent a similar scenario for future health risks, or does one always have to go through an obfuscating or denying phase before admitting to the true facts?

Professor Johansson:
Well, I certainly hope not! According to the work of professor Klas Amark at the Stockholm University this has, unfortunately, always been the case previously, but, of course, this tendency must be completely altered in the future. No democratic and humanitarian society can hold up such principles as you indicate in your question. We have to meet the future health problems in a much more 'grown-up' fashion!

FEB:
What do you see in the future?

Professor Johansson:
The future is not dark, not at all, but bright for all kind of "human-friendly technologies", including low-irradiation and low-emitting products. For, after all, who could sell a computer screen today with the slogan: "THIS IS A HIGH-LEVEL IRRADIATION SCREEN"!?

Professor Johansson will gladly answer your questions, but due to a heavy workload, he might not be able to answer all questions. Therefore, try to be as brief as possible.

International Journal of Vaccines and Vaccination

New Quality-Control Investigations on Vaccines: Micro- and Nanocontamination

Abstract

Vaccines are being under investigation for the possible side effects they can cause. In order to supply new information, an electron-microscopy investigation method was applied to the study of vaccines, aimed at verifying the presence of solid contaminants by means of an Environmental Scanning Electron Microscope equipped with an X-ray microprobe. The results of this new investigation show the presence of micro- and nanosized particulate matter composed of inorganic elements in vaccines' samples which is not declared among the components and whose unduly presence is, for the time being, inexplicable. A considerable part of those particulate contaminants have already been verified in other matrices and reported in literature as non biodegradable and non biocompatible. The evidence collected is suggestive of some hypotheses correlated to diseases that are mentioned and briefly discussed.

Keywords: Vaccine; Disease; Contamination; Protein corona; Biocompatibility; Toxicity; Nanoparticle; Immunogenicity; Foreign body; Environment; Industrial process; Quality control

Introduction

Vaccines are one of the most notable inventions meant to protect people from infectious diseases. The practice of variolation is century-old and is mentioned in Chinese and Indian documents dated around 1000 A.D. Over time, variolation has been replaced by vaccination, vaccines have been enhanced as to technology, and the vaccination practice is now standardized worldwide.

Side effects have always been reported but in the latest years it seems that they have increased in number and seriousness, particularly in children as the American Academy of pediatrics reports [1,2]. For instance, the diphtheria-tetanus-pertussis (DTaP) vaccine was linked to cases of sudden infant death syndrome (SIDS) [3]; measles-mumps-rubella vaccine with autism [4,5]; multiple immunizations with immune disorders [6]; hepatitis B vaccines with multiple sclerosis, etc.

The notice of Tripedia DTaP by Sanofi Pasteur reports "Adverse events reported during post-approval use of Tripedia vaccine include idiopathic thrombocytopenic purpura, SIDS, anaphylactic reaction, cellulitis, autism, convulsion/grand mal convulsion, encephalopathia, hypotonia, neuropathy, somnolence and apnea". The epidemiological studies carried out did not show a clear evidence of those associations, even if in 2011 the National Academy of Medicine (formerly, IOM) admitted: "Vaccines are not free from side effects, or adverse effects"[7].

Specific researches on components of the vaccines like adjuvants (in most instances, Aluminum salts) are already indicated as possible responsible of neurological symptoms [8-10] and in some cases, in-vivo tests and epidemiological studies demonstrated a possible correlation with neurological diseases [10,11]. Neurological damages induced in patients under hemodialysis treated with water containing Aluminum are reported in literature [12].

Recently, with the worldwide-adopted vaccines against Human Papillomavirus (HPV), the debate was reawaken due to some adverse effects reported by some young subjects.

Specific studies communicated the existence of symptoms related to never-described-before syndromes developed after the vaccine was administered. For instance, Complex Regional Pain Syndrome (CRPS), Postural Orthostatic Tachycardia Syndrome (POTS), and Chronic Fatigue Syndrome (CFS) [13]. The side-effects that can arise within a relatively short time can be local or systemic.

Pain at the site of injection, swelling and uncontrollable movement of the hands (though this last symptom can also be considered systemic) are described. Among the systemic effects, fever, headache, irritability, epileptic seizures, temporary speech loss, lower limbs dysaesthesia and paresis, hot flashes, sleep disorders, hypersensitivity reactions, muscle pain, recurrent syncope, constant hunger, significant gait impairment, incapacity to maintain the orthostatic posture are reported [14].

It is a matter of fact that every day millions of vaccine doses are administered and nothing notable happens, but it is also irrefutable that, regardless of the amount of side effects that are not recorded and the percentage of which remains in fact unknown, in a limited number cases something wrong occurs. No satisfactory explanation or, in many cases, no explanation at all has been given and it seems that those adverse effects happen on a random and stochastic basis.

Those situations induced us to verify the safety of vaccines from a point of view which was never adopted before: not a biological, but a physical approach. So, we developed a new analysis method based on the use of a Field Emission Gun Environmental Scanning Electron Microscope investigations to detect possible physical contamination in those products.

Materials and Methods

44 types of vaccines coming from 2 countries (Italy and France) were analyzed. Table 1 groups them in terms of name, brand and purpose.

Table 1: List of vaccines analyzed, according to their purpose.

N	Name	Brand Name, Country of Distribution	Description	Production Batch, Expiry Date
1	Vivotif Berna	Berna Biotech SA, Italy	Anti-Thyphoid Vaccine (Live), group Ty21a	3000336 [2004]
2	Typhim Vi	Aventis Pasteur MSD, Italy	Anti-Salmonella typhi Vaccine	U1510-2 [2004]
3	Typherix	GlaxoSmithKline S.p.a., Italy	Anti-Thypoid Vaccine (polysaccharide Vi)	ATYPB061BB [2009]
4	Anatetall	Chiron (now Novartis) Italy	Adsorbed anti-Tetanus Vaccine	030106 [2004]
5	Anatetall	Novartis Vaccines and Diagnostics, Italy	Adsorbed anti-Tetanus Vaccine	060510 [2009]
6	Tetabulin	Baxter AG, Italy	Adsorbed anti-Tetanus Vaccine	VNG2G006A [2009]
7	Dif-Tet-All	Novartis Vaccines and Diagnostics, Italy	Adsorbed anti-Tetanus and diphtheria Vaccine	070501 [2009]
8	Infanrix	GlaxoSmithKline S.p.a., Italy	Anti-Diphtheria, tetanus and pertussis vaccine	AC14B071AJ [2009]
9	Infanrix hexa	GlaxoSmithKline Biologicals s, Italy	Anti-diphtheria, tetanus, pertussis, hepatitis B, poliomyelitis and disease caused by Haemophilus influenzae type b	A21CC512A [2017]
10	Infanrix hexa	GlaxoSmithKline Biologicals s. a. France	Anti-diphtheria, tetanus, pertussis, hepatitis B, poliomyelitis and disease caused by Haemophilus influenzae type b	A21CC421A [2017]
11	M-M-R vaxPro	Sanofi Pasteur MSD, Italy	M-M-R vaxPro (measles, mumps, and rubella) analyzed in Cambridge	L012437 [2017]
12	Repevax	Sanofi Pasteur MSD, France	Anti-diphtheria-tetanus-pertussis-polio-vaccine	L0362-1 [2017]
13	Repevax	Sanofi Pasteur MSD SNC France	Anti-diphtheria-tetanus-pertussis-polio-vaccine	L0033-1 [2016]
14	Priorix	GlaxoSmithKline S.p.a., Italy	Anti--measles-mumps, and rubella (MMR) vaccine	A69CB550A [2009]
15	Morupar	Chiron (now Novartis,), Italy	Anti-measles- mumps, and rubella (MMR) vaccine	7601 [2004]
16	Varilrix	GlaxoSmithKline S.p.a., Italy	Anti-Chicken pox vaccine (group OKA)	A70CA567A [2009]
17	Stamaril Pasteur	Sanofi Pasteur MSD, Italy	anti-yellow fever vaccine	A5329-6 [2009]
18	Allergoid-Adsorbat 6-Graser Starke B.	Allergopharma, Germany	Antiallergic vaccine	Ch-B.:30005999-B [2006]
19	Engerix-B	GlaxoSmithKline S.p.a., Italy	Adsorbed anti-hepatitis B vaccine	AHBVB468BD [2009]
20	Prenevar 13	Pfizer, Italy	Antipneumococcal vaccine	G79324 [2013]
21	Prevenar 13	Pfizer, France	Antipneumococcal vaccine	N27430 [2018]
22	Mencevax Acwy	GlaxoSmithKline, Italy	anti-Neisseria meningococcal group A, C, W135 and Y vaccine	N402A47B 12 [2004]
23	Meningitec	Pfizer, Italy	(group C 10) (adsorbed on Al-Phosphate)	H92709 [2015]
24	Meningitec	Pfizer-Italy	Anti-meningococcus (group C 10) vaccine (adsorbed on Al-Phosphate)	H20500 [2014]

25	Meningitec	Pfizer-Italy	Anti-meningococcus vaccine sequestred by Procura della Repubblica	G76673 [2014]
26	Meningitec	Pfizer-Italy	Anti-meningococcus vaccine sequestred by Procura della Repubblica	H99459 [2015]
27	Meningitec	Pfizer-Italy	Anti-meningococcus vaccine sequestred by Procura della Repubblica	H52269 [2015]
28	Menjugate	Novartis Vaccines and Diagnostics	Anti-meningococcus group C	YA0163AB [2010]
29	Menveo	Novartis Vaccines and Diagnostics	Antimeningococcus groups A, C, W135, Y	A15083 [2017]
30	Meningitec	Wyeth Pharmaceutical - France	Anti-meningococcus group C vaccine	E83920 [2011]
31	Inflexal V	Berna Biotech	Anti-flu vaccine 2008/2009	3001463-01 [2009]
32	Vaxigrip	Sanofi Pasteur MSD	Anti-flu vaccine 2008/2009	D9703-1 [2009]
33	Vaxigrip	Sanofi Pasteur	Anti-flu vaccine 2012/2013	J8401-1 [2013]
34	Vaxigrip	Sanofi Pasteur, Italy	Anti-flu vaccine, with inactivated and split virus	M7319-1 [2016]
35	Focetria	Novartis Vaccines and Diagnostics	Anti-pandemic flu H1N1 vaccine	0902401 [2010]
36	Agrippal	Novartis	Anti-flu vaccine 2012/2013	127002A [2013]
37	Agrippal	Novartis vaccines, Italy	Anti-flu vaccine with inactivated and split virus 2015/2016 -	152803 [2016]
38	Agrippal S1	Novartis Vaccines and Diagnostics	Anti-flu inactivated/superficial antigene v - 2014/2015	147302A [2015]
39	Fluarix	GlaxoSmithKline - GSK	Anti-flu vaccine 2013	AFLUA789AA [2014]
40	Fluad	Novartis Vaccines and Diagnostics	Anti-flu inactivated/superficial antigene vaccine - 2014/2015	142502 [2015]
41	Gardasil	Sanofi Pasteur MSD, Italy	Anti-HPV types 6,11,16,18 vaccine	NP01250 [2012]
42	Gardasil	Sanofi Pasteur MSD, Italy	Anti-HPV (types 6,11,16,18) vaccine	K023804 [2016]
43	Cervarix	GlaxoSmithKline Biological, Italy	Anti-HPV (type 16,18)	AHPVA238AX [2017]
44	Feligen CRP	Virbac S.A. - Carros - Italy	anti-panleucopenia, infectious rhinotracheitis and infections by Calcivirus, veterinary Vaccine for cats	3R4R [2013]

Some vaccines, in fact a minority, are meant to deal with a single bacterium or virus, while others are multi-valent. The list of vaccines we analyzed may contain repeated names, because we considered different batches and years of production of the same vaccine: the ones against influenza in particular.

The study was aimed at verifying a possible physical contamination. To do that, we performed a new kind of investigation based on observations under a Field Emission Gun Environmental Electron Scanning Microscope (FEG-ESEM, Quanta 200, FEI, The Netherlands) equipped with the X-ray microprobe of an Energy Dispersive Spectroscope (EDS, EDAX, Mahwah, NJ, USA) to detect the possible presence of inorganic, particulate contaminants and identify their chemical composition.

A drop of about 20 microliter of vaccine is released from the syringe on a 25-mm-diameter cellulose filter (Millipore, USA), inside a flow cabinet. The filter is then deposited on an Aluminum stub covered with an adhesive carbon disc. The sample is immediately put inside a clean box in order to avoid any contamination and the box is re-opened only for the sample to be inserted inside the FEG-ESEM chamber. We selected that particular type of microscope as it allows to analyse watery and oily samples in low vacuum (from 10 to 130 Pa) at a high sensitivity.

When the water and saline the vaccine contains are evaporated, the biological/physical components emerge on the filter and it is then possible to observe them. This type of microscope

(low-vacuum observations) prevents the possible sample contamination and the creation of artefacts. The observations are made with different sensors (SE: secondary-electron sensor and BSE: backscattered-electron sensor), and are performed at a pressure of 8.9 e-1 mbar, at energies ranging from 10 to 30kV to detect the particulate matter's size, morphology and its elemental composition. The method identifies clearly inorganic bodies with a higher atomic density (looking whiter) than the biological substrate. So, organic entities are visible and easy to distinguish from inorganic ones. The method cannot distinguish between proteins and organic adjuvants (e.g. squalene, glutamate, proteins, etc.) or viruses, bacteria, bacteria's DNA, endo-toxins and bacteria's waste, but their comparatively low atomic density allows us to identify these entities as organic matter. In some vaccines, the organic matter contains white-looking debris named aggregates, while a high concentration or inorganic debris is called a cluster.

Single inorganic particles or organic-inorganic aggregates are identified, evaluated and counted. The counting procedure is repeated three times by three different operators, with an error lower than 10%. When a layer of salts (Sodium chloride or Aluminum) is detected, we record the situation but we do not do body count.

Results

The investigations verified the physical-chemical composition of the vaccines considered according to the inorganic component as declared by the Producer. In detail, we verified the presence of saline and Aluminum salts, but further presence of micro-, sub-micro- and nanosized, inorganic, foreign bodies (ranging from 100nm to about ten microns) was identified in all cases, whose presence was not declared in the leaflets delivered in the package of the product (Table 2).

Table 2: List of the vaccines according to their manufacturers with the chemical composition of the debris identified in each sample. The elements most represented are reported.

N	Company	Name	Alluminum	Elements Identified
1	Allergopharma - Germany	Allergoid	yes	Al
2	Aventis Pasteur MSD Lyon - Francie	Typhim Vi	no	BrKP, PbSi, FeCr, PbClSiTi
3	Baxter AG	Tetabulin	no	SiMg, Fe, SiTiAl, SBa, Zn
4	Berna Biotech	Vivotif Berna	no	FeAl, ZrAlHf, SrAl, BiAlCl
5	Berna Biotech	Inflexal V	no	CuSnPbZn, Fe, CaSiAl, SiAl, NaPZn, ZnP, AlSiTi
6	Chiron	Anatetall	$Al(OH)_3$	FeAl, SZnBaAl
7	Chiron	Morupar	no	/
8	GlaxoSmithKline- Belgium	Mencevax ACWY	no	FeCrNi, ZrAl, FeCrNiZrAlSi
9	GlaxoSmithKline	Infanrix	$Al(OH)_3$	Al, AlTi, AlSi
10	GlaxoSmithKline Biologicals	Infanrix hexa	$Al(OH)_3$	SBa, FeCu, SiAl, FeSi, CaMgSi, AlCaSi, Ti, Au, SCa, SiAlFeSnCuCrZn, CaAlSi
11	GlaxoSmithKline Biologicals	Infanrix hexa	$Al(OH)_3$,$AlPO_4$. $2H_2O$	W, FeCrNi, Ti
12	GlaxoSmithKline	Typherix	no	Ti, TiW, AlSiTiWCr, SBa, W, SiAl, AlSiTi
13	GlaxoSmithKline	Priorix	no	WCa, WFeCu, SiAl, SiMg, PbFe, Ti, WNiFe
14	GlaxoSmithKline	Engerix-B	no	Al (precipitates)
15	GlaxoSmithKline	Varilrix	no	FeZn, FeSi, AlSiFe, SiAlTiFe, MgSi, Ti, Zr, Bi
16	GlaxoSmithKline	Fluarix	no	AlCu, Fe, AlBi, Si, SiZn, AlCuFe, SiMg, SBa, AlCuBi, FeCrNi, SPZn
17	GlaxoSmithKline Biologicals	Cervarix	$Al(OH)_3$	AlSi,FeAl, SiMg,CaSiAl, CaZn, FeAlSi, FeCr, CuSnPb
18	Novartis Vaccines and Diagnostics	Anatetall	$Al(OH)_3$	Al, FeCrNi, AlCr, AlFe, BaS, ZnAl
19	Novartis Vaccines and Diagnostics	Dif-Tet-All	$Al(OH)_3$	Fe,SBa, SiSBa, AlZnCu, AlZnFeCr

Figure 1a shows a layer of crystals of Sodium chloride (NaCl) embedding salts of Aluminum phosphate ($AlPO_4$) in a drop of Gardasil (anti-HPV vaccine by Merck) as the EDS spectrum (Figure 1b) shows. Saline is the fluid base to any vaccine preparation and Aluminum salts or Aluminum hydroxide [$Al(OH)_3$] are the adjuvants which are usually added.

Looking at the area outside these precipitates but inside the liquid drop, we identified other things: single particles, clusters of particles and aggregates (organic-inorganic composites) that are due to an interaction of the inorganic particulate matter with the organic part of the vaccine.

Figure 2a-2f shows the different typology of entities identified in the vaccines (Repevax, Prevenar and Gardasil); single particles, cluster of micro- and nanoparticles (<100nm) and aggregates with their EDS spectra (Figure 2d-2f). The images (Figure 2a & 2d) show debris of Aluminum, Silicon, Magnesium and Titanium; of Iron, Chromium, Silicon and Calcium particles (Figure 2b & 2e) arranged in a cluster, and Aluminum -Copper debris (Figure 2c & 2f) in an aggregate.

As can be seen, the particles are surrounded and embedded in a biological substrate. In all the samples analyzed, we identified particles containing: Lead (Typhym, Cervarix, Agrippal S1, Meningitec, Gardasil) or stainless steel (Mencevax, Infarix Hexa, Cervarix. Anatetall, Focetria, Agrippal S1, Menveo, Prevenar 13, Meningitec, Vaxigrip, Stamaril Pasteur, Repevax and MMRvaxPro).

Figure 3a-3d show particles of Tungsten identified in drops of Prevenar and Infarix (Aluminum, Tungsten, Calcium chloride).

Figure 4a-4d present singular debris found in Repevax (Silicon, Gold, Silver) and Gardasil (Zirconium).

Some metallic particles made of Tungsten or stainless steel were also identified. Other particles containing Zirconium, Hafnium, Strontium and Aluminum (Vivotif, Meningetec); Tungsten, Nickel, Iron (Priorix, Meningetec); Antimony (Menjugate kit); Chromium (Meningetec); Gold or Gold, Zinc (Infarix Hexa, Repevax), or Platinum, Silver, Bismuth, Iron, Chromium (MMRvaxPro) or Lead,Bismuth (Gardasil) or Cerium (Agrippal S1) were also found. The only Tungsten appears in 8/44 vaccines, while Chromium (alone or in alloy with Iron and Nickel) in 25/44. The investigations revealed that some particles are embedded in a biological substrate, probably proteins, endo-toxins and residues of bacteria. As soon as a particle comes in contact with proteic fluids, a nano-bio-interaction [6] occurs and a "protein corona" is formed [7-10]. The nano-bio-interaction generates a bigger-sized compound that is not biodegradable and can induce adverse effects, since it is not recognized as self by the body.

Figure 5a-5f show examples of these nano-bio-interactions. Aggregates can be seen (stable composite entities) containing particles of Lead in Meningitec, (Figure 5a & 5b) of stainless steel (Iron, Chromium and Nickel, Figure 5c & 5d) and of Copper, Zinc and Lead in Cervarix (Figure 5e & 5f). Similar aggregates, though in different situations (patients suffering from leukemia or cryoglobulinemia), have already been described in literature.

The link between these two entities generates an unfolding of the proteins that can induce an autoimmune effect once those proteins are injected into humans.

Figure 6a & 6b show one of the foreign bodies identified in Agrippal. The particle is composed of Cerium, Iron, Titanium and Nickel. (Figure 7a & 7b) present an area of Repevax where the morphology of red cells - we cannot tell whether they are human or animal- is clearly visible.

Table 3 summarizes the number and morphology of the debris identified, in term of single particles, clusters of particles or aggregates (organic-inorganic compounds), while Figure 8 shows the graph obtained calculating the total number of particles (particles plus clusters plus aggregates) identified for 20 microl of every vaccine.

Similar aggregates were already described by other scientists who identified them in the blood e.g. in leukemic patients [15] and in subjects affected by cryoglobulinemia [16].

Not all the vaccines analyzed contain the same contamination, though the same vaccine belonging to different batches and, in some cases, coming from different countries can contain a similar contamination (e.g. the vaccines by Glaxo Infarix, Typherix and Priorix contain Tungsten. Tungsten was also identified in Menjugate kit by Novartis, and Prevenar, Meningitec by Pfizer and Meningitec by Wyeth).]

Feligen, the only veterinary vaccine tested, proved to be the only sample free from inorganic contamination, while Allergoid generates a layer of inorganic salts so thick that it does not allow to detect other particulate contaminants.

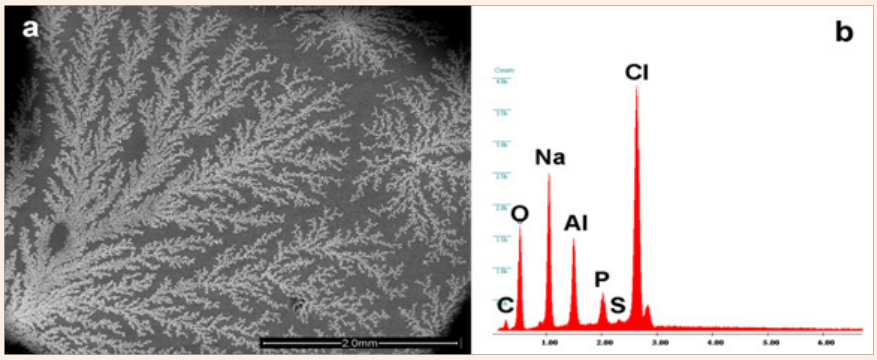

Figure 1: Crystals of saline solution and Aluminum Phosphate and corresponding EDS spectra.

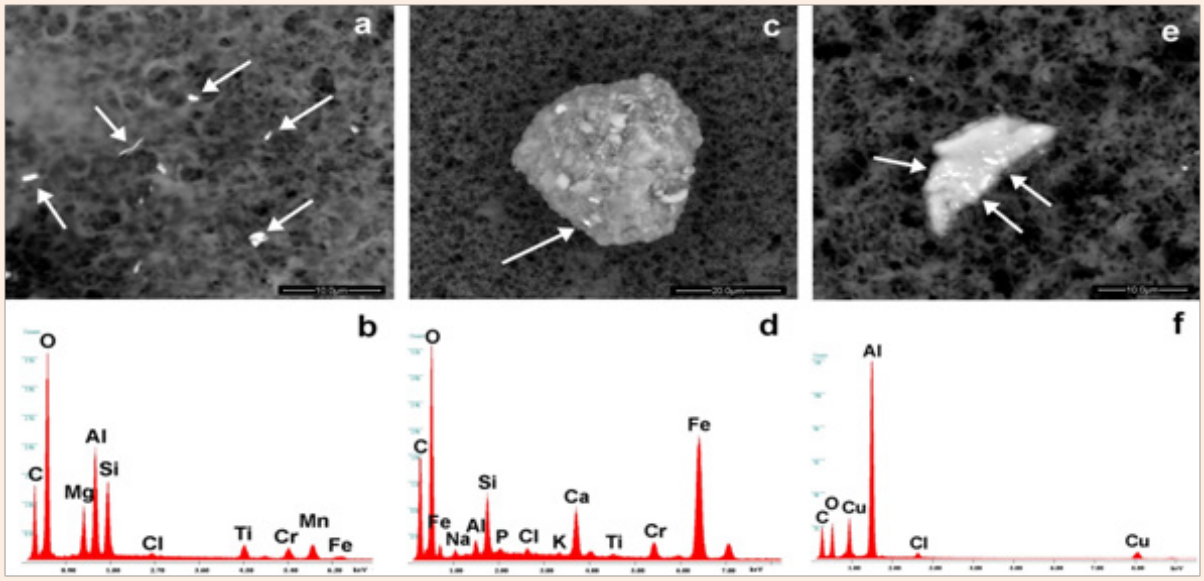

Figure 2: Images of single particles, cluster of micro- and nanoparticles (<100nm) andaggregates with their EDS spectra. They are respectively composed of (a,b) Aluminum, Silicon, Magnesium, Titanium, Chromium, Manganese, Iron, (c,d) Iron, Silicon, Calcium Titanium, Chromium, (e,f) Aluminum, Copper. The arrows show the points where EDS spectra were taken.

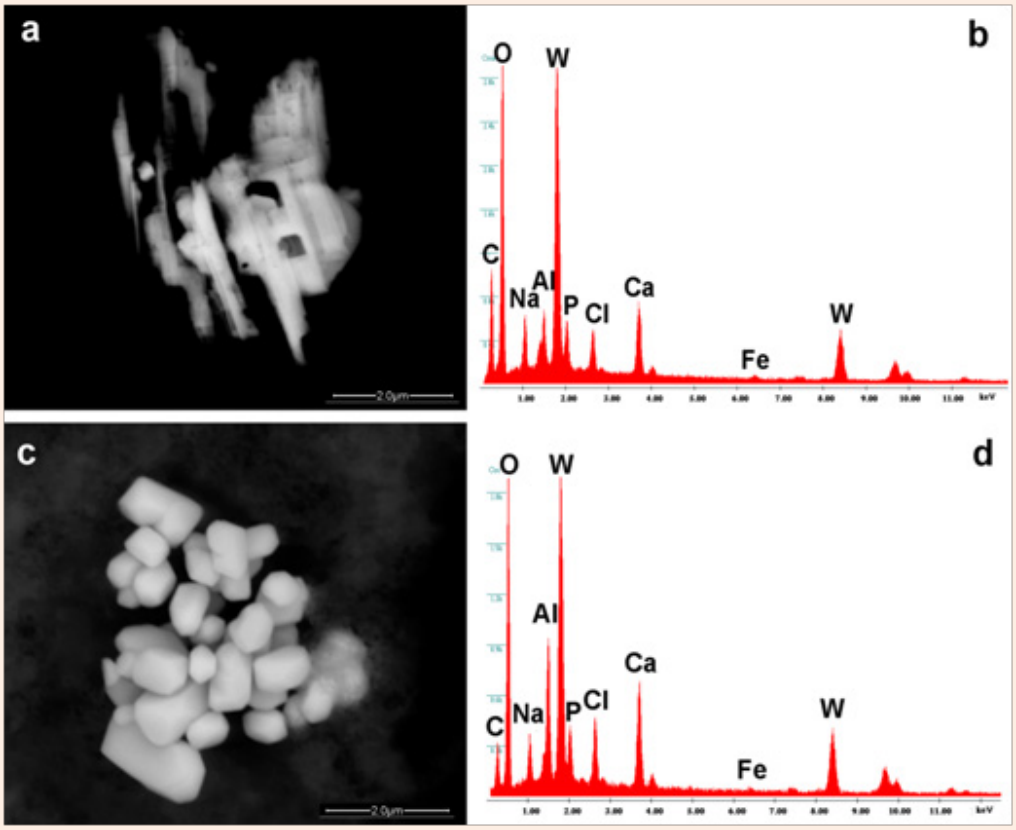

Figure 3: Images of Tungsten particles identified in drops of Prevenar and Infarix. They are composed respectively of Tungsten, Aluminum, Iron but in different concentrations. The arrows show the points where EDS spectra were taken.

Discussion

The quantity of foreign bodies detected and, in some cases, their unusual chemical compositions baffled us. The inorganic particles identified are neither biocompatible nor biodegradable, that means that they are biopersistent and can induce effects that can become evident either immediately close to injection time or after a certain time from administration. It is important to remember that particles (crystals and not molecules) are bodies foreign to the organism and they behave as such. More in particular, their toxicity is in some respects different from that of the chemical elements composing them, adding to that toxicity which, in any case, is still there, that typical of foreign bodies. For that reason, they induce an inflammatory reaction.

After being injected, those microparticles, nanoparticles and aggregates can stay around the injection site forming swellings and granulomas [17]. But they can also be carried by the blood circulation, escaping any attempt to guess what will be their final destination. We believe that in many cases they get distributed throughout the body without causing any visible reaction, but it is also likely that, in some circumstances, they reach some organ, none excluded and including the microbiota, in a fair quantity. As happens with all foreign bodies, particularly that small, they induce an inflammatory reaction that is chronic because most of those particles cannot be degraded. Furthermore, the protein-corona effect (due to a nano-bio-interaction [18]) can produce organic/inorganic composite particles capable of stimulating the immune system in an undesirable way [19-22]. It is impossible not to add that particles the size often observed in vaccines can enter cell nuclei and interact with the DNA [23].

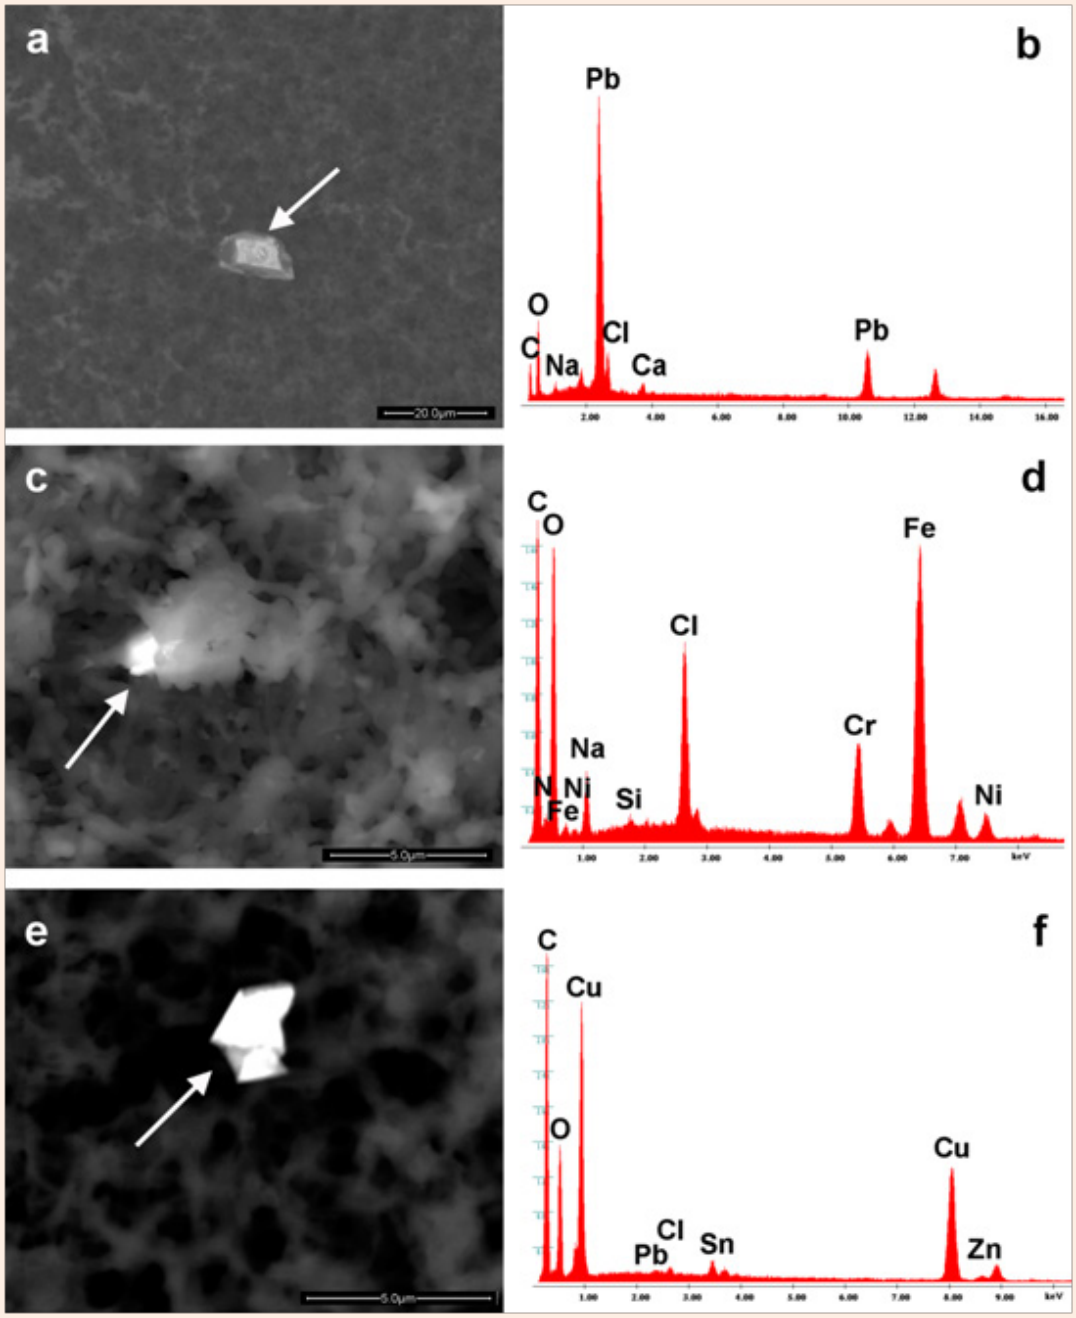

Figure 5: show particles surrounded by an organic compound. They are composed of Lead (a,b), Iron, Chromium, Nickel (stainless steel; c,d), Copper, Tin, Lead (e,f). The arrows show the points where EDS spectra were taken.

In some cases, e.g. as occurs with Iron and some Iron alloys, they can corrode and the corrosion products exert a toxicity affecting the tissues [24-26].

The detection of presence of Aluminum and NaCl salts is obvious as they are substances used by the Producers and declared as components, but other materials are not supposed to be in the vaccine or in any other injectable drug, at that, and, in any case, Aluminum has already been linked with neurological diseases [27-29].

Given the contaminations we observed in all samples of human-use vaccines, adverse effects after the injection of those vaccines are possible and credible and have the character of randomness, since they depend on where the contaminants are carried by the blood circulation. It is only obvious that similar quantities of these foreign bodies can have a more serious impact on very small organisms like those of children. Their presence in the muscles, due an extravasation from the blood, could heavily impair the muscle functionality [30,31].

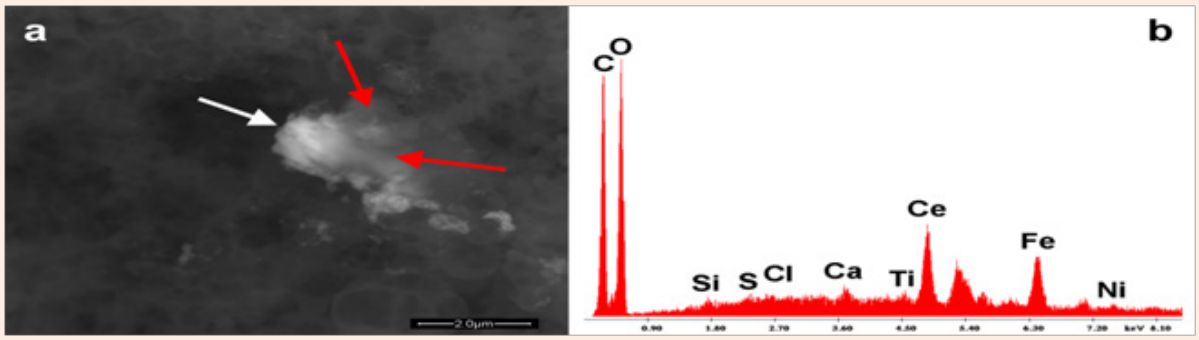

Figure 6: show an organic aggregate containing a debris made of Cerium, Iron, Nickel, Titanium. The red arrow indicates the organic layer (less atomically dense) that covers the Cerium particle.

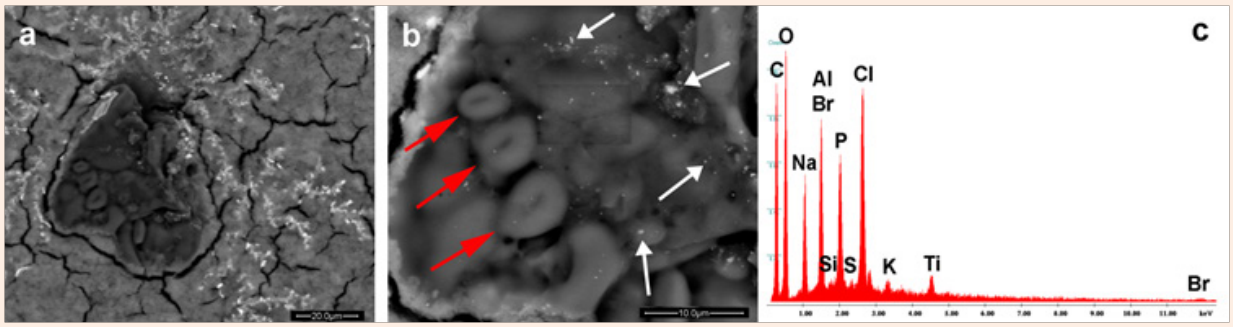

Figure 7: Image of an area in a Repevax drop where the morphology of red cells (red arrows) were identified. It is impossible to know whether they are human or animal origin. Among the debris of saline and Aluminum phosphate, there is the presence of debris (white arrows) composed of Aluminum, Bromine, Silicon, Potassium, Titanium.

We come across particles with chemical compositions, similar to those found in the vaccines we analyzed, when we study cases of environmental contamination caused by different pollution sources. In most circumstances, the combinations detected are very odd as they have no technical use, cannot be found in any material handbook and look like the result of the random formation occurring, for example, when waste is burnt. In any case, whatever their origin, they should not be present in any injectable medicament, let alone in vaccines, more in particular those meant for infants.

Other forms of so-far unknown contaminations have recently been observed and, in any case, vaccines contain components that could themselves be the cause of adverse effects. It is a well-known fact in toxicology that contaminants exert a mutual, synergic effect, and as the number of contaminants increases, the effects grow less and less predictable. The more so when some substances are unknown.

As a matter of fact, no exhaustive and reliable official data exist on the side-effects induced by vaccines. The episodic evidence reported by people allegedly damaged by vaccines is twofold: some say the damage occurred and became visible within a few hours from administration, and some maintain that it was a matter of some weeks. Though we have no indisputable evidence as to the reliability of those attestations, we can put forward a hypothesis to explain the different phenomena. In the former case, the pollutants contained in the drug have reached the brain and, depending on the anatomical site interested, have induced a reaction. If that is the case, the whole phenomenon is very rapid. In the latter circumstance, the pollutants reached the microbiota, thus interfering with the production of enzymes necessary to carry out neurological functions [32-35]. That possibility takes time, as it involves the production of chemical compounds in a sufficient quantity, and an elapse of some weeks between injection and clinical evidence is reasonable. Of course, ours is no more than a hypothesis open to discussion and in need of proof, hoping that a chance of further investigation is allowed.

Conclusion

The analyses carried out show that in all samples checked vaccines contain non biocompatible and bio-persistent foreign bodies which are not declared by the Producers, against which the body reacts in any case. This new investigation represents a new quality control that can be adopted to assess the safety of a vaccine. Our hypothesis is that this contamination is unintentional, since it is probably due to polluted components or procedures of industrial processes (e.g. filtrations) used to produce vaccines, not investigated and not detected by the Producers. If our hypothesis is actually the case, a close inspection of the working places and the full knowledge of the whole procedure of vaccine preparation would probably allow to eliminate the problem.

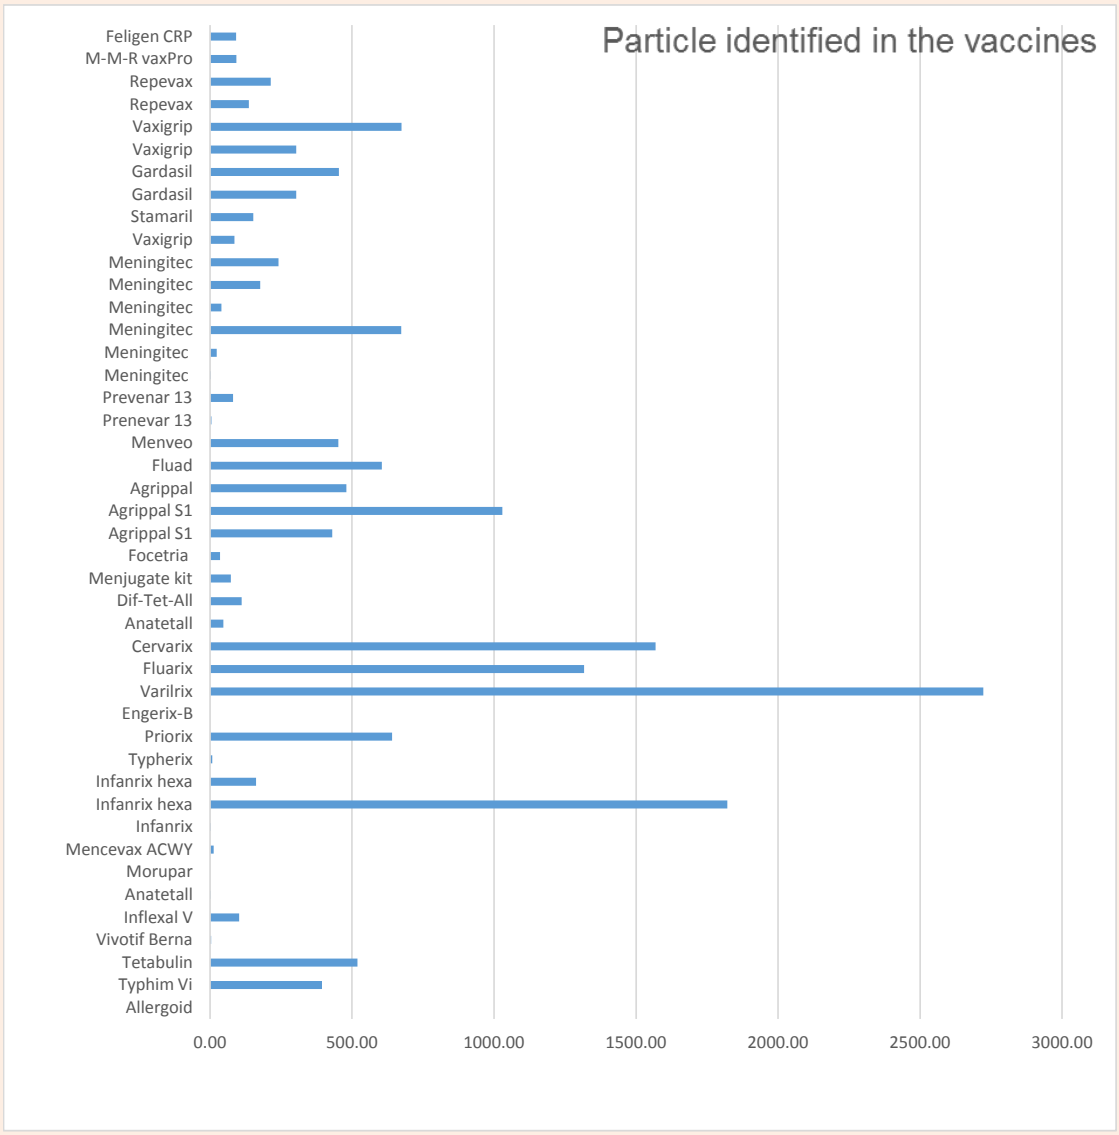

Figure 8: Graph of the debris' quantities identified in a 20 microl drop of every vaccine.

A further purification of the vaccines could improve their quality and could probably decrease the number and seriousness of the adverse incidental effects.

THIS PRESENTATION

- **Is meant to incite thought/ discussion**
- **Is based in all cases upon existing data/trends/analyses/technologies (e.g., NO PIXIE DUST)**
- **Provides in some cases a somewhat broader view of prospective developments and issues**

Utilization/Application of 2025+ Projections

- Inputs to Future Warfighting Concepts Development(s) (Enemy After Next & Blue)
- Inputs to New Procurement Decision (15+ years to Produce, 40+ years in Inventory
- "Heads Up" for Intel Community ("Watches and Warnings")
- Inputs to DOD R&D Planning

"Going In" Assumptions

- Politics can/does change "overnight" (e.g. Russia, Iran, Iraq, Pakistan, etc.), Potential CAPABILITIES is the future warfare issue, not Who but WHAT

Need to Plan "Differently"

- **WORLD is in the throes of triple/exponential (IT/Bio/Nano) Technological Revolutions**
- **Changes occurring at scales of months (instead of decades)**
- **Zeroth order potential effects upon Defense/Offense equipment/conops/threat**

Future Strategic Issues, 7/01

"SPACESHIP EARTH"

The crew are:

- **Plundering the ship's supplies**
- **Tinkering with the temperature and life-support controls**
- **Still looking for the instruction manual**
- **Engaging in bloody skirmishes in every corner of the vessel**
- **Increasing the size of the crew by 2 million PER WEEK**

P. Creola

Future Strategic Issues, 7/01

Humans Have "Taken Over" and Vastly Shortened "Evolution"

- **Of the Planet**
  - **Global Warming/Pollution/Deforestation**
  - **Huge "Public Work" (e.g. 3 Gorges Dam)**
- **Of the Human Species**
  - **Genomic Design and Repair**
  - **"Mind Children" (Moravec)**
- **Products/Life Forms**
  - **Cross Species Molecular Breeding**
  - **"Directed Evolution" (Maxygen etc.)**

Future Strategic Issues, 7/01

CURRENTLY

- **Order of 70% of Worlds Research conducted outside of U.S. (to first order, a % of GDP, U.S. produces order of 18% of worlds GDP)**
- **Order of 70% of U.S. Research now "Commercial" (as opposed to Government sponsored)**

NanoTechnology Research

- 29% in Europe
- 28% in Japan
- 27% in U.S.
- 16% “Other(s)”

Future Strategic Issues, 7/01

Technological Ages of Humankind

- Hunter/Killer groups [Million BC~10K BC]
- Agriculture [10K BC~1800 AD]
- Industrial [1800~1950]
- IT [1950~2020]
- Bio/NANO [2020-?]
- Virtual

- **IT/BIO/Nano - Automating Industry/Agriculture**
- **Virtual - Robotization of IT/Bio/Nano/Industry/Agriculture**

Future Strategic Issues, 7/01

KEY "FUTURE TECHNOLOGIES"

(all highly synergistic/at the frontiers of the small, in a "feeding frenzy" off each other)

- **IT**
  - **Silicon/bio/optical/quantum/nano computing ("no end in sight," another 10^6 +)**
  - **(Virtual reality/holographic) immersive ubiquitous comms., hyperspectral sensors, "virtual presence"**
  - **Automatic/robotic "everything"**
  - **Huge cost reductions**
- **Bio**
  - **Life span doubling**
  - **Genetic engineering before birth**
  - **Plants irrigated by seawater (food, petro-chem feed stock, minerals, terraforming)**
- **Nano**
  - **Carbon nanotubes (600X strength-to-weight of steel)**
  - **"Assemblers"/"living factories"**
  - **Huge cost reductions**

Future Strategic Issues, 7/01

Worldwide IT Revolution

- **Comms/Computing/Sensors/Electronics**
- **U.S. Commercial IT R&D ~ $100B/yr.**
- **Factor of 1 Million further improvement [Silicon,Molecular,Quantum,Bio,Optical]**
- **Beyond Human AI?**
- **Automatics/Robotics "in the large"**
- **Immersive multi-sensory VR/"Holodecks"**
- **Ubiquitous multi physics/hyperspectral sensors [land/sea/air/space]**
- **Micro/Nano sats/GNC/sensors,etc.**

[Worldwide] Impacts of Ongoing IT Revolution Upon Society

- **Tele-commuting**
- **Tele-shopping**
- **Tele-entertainment**
- **Tele-travel**
- **Tele-Education**
- **Tele-medicine**
- **Tele-commerce**
- **Tele-politics**
- **Tele-socialization**

IT Status

- 10E6 improvements in Computing since '59, 10E8 further possible next 30 years (10E3 provides "better than Human" capabilities)
- 100 Million Telecommuters Worldwide NOW (expected to at least double in 15 years)
- India graduates three times more software engineers than the U.S., More software written in Bangalore than Southern CA
- IW effectively constitutes a 4th WMD

Future Strategic Issues, 7/01

SOME IT "PREDICTIONS"

- Quantum computing initially available in 5 years
- 15% of all power today is used by computers, will reach 60% by 2010
- Wearable/implantable (on-person) electronics--comms, computing, sensory augmentation, health monitoring, brain stimulation

Future Strategic Issues, 7/01

AI (AND BEYOND) COMPUTING

Human Brain Characteristics/Capabilities

- 100 billion neurons
- 100 trillion connections
- 200 calculations/second, (slow) speed of neural circuitry
- 20 million billion calculations/second
- Excellent at (parallel-computing) pattern recognition, "poor" at sequential thinking
- Operates via "random tries"

Machine Capabilities

- Currently, 10,000 billion calculations/second; 100,000 billion by 2004
- By 2010, 20 million billion is available (by 2025, on a PC)
- By 2030, PC has collective computing power of a town full of human minds

Future Strategic Issues, 7/01

U.S. "HUMAN BRAIN PROJECT"

- **Begun in early 90's, funded by 16 organizations across 5 agencies (NIH, NSF, DOD, NASA, DOE)**
- **AKA "Neuroinformatics" (intersection of neuroscience and informatics)**
- **"Exploding field;" 10,000 individual presentations at annual meeting of Society for Neuroscience (from molecular geneticists to cognitive psychologists)**
- **Determining detailed neuroanatomy of human brain ("digital brain atlas")**
- **Use of IT to study brain, use of brain info to aid IT/AI**

Future Strategic Issues, 7/01

THE "IMAGINATION ENGINE"

aka "Creativity Machine," aka "Creative Agent"

- **Current AI "best bet," not a rule based/expert system**
- **GENERATES new ideas/concepts via starving a trained neural net of meaningful inputs, forcing it to "dream"/"cavitate," create new concepts, etc. An attendant neural net used to capture/record/evaluate and report on these "writings."**

"In this [Worldwide] economy our ability to create wealth is not bounded by physical limits/resources but by our ability to come up with new ideas"

[However,even "universal wealth" will not obviate the other causes of warfare which include Politics,"Face",Religion, Megalomania and Territorial Disputes]

Future Strategic Issues, 7/01

Global Problems/"Solutions"

- (Serious) Problems
  - Energy (2)
  - Water (2)
  - Food (2)
  - Land (2)
  - Population Growth (1)
  - Wealth Generation (1)
  - "Pollution/Warming" (2)
- "Killer Ap Solutions"
  - **(1)** Motivational/inexpensive Web-based Asynchronous "Distance Learning"
  - **(2)** Bio mass/food via seawater irrigation in current "wastelands"

Inexpensive Motivational Asynchronous Web-Based Distance Education Enables:

- Demise of the U.S. "underclasses"
- Wealth Creation from enabled "Invention"
- Stabilization of World Population
- [Even More] Rapid Technology Diffusion
- Equalization of "Haves" and "Havenots"
- Altered Political/military outlooks Worldwide
  - I.E. Changes "Everything"

Future Strategic Issues, 7/01

Motivational learner/web-based asynchronous distance learning ~~allows~~ only method of providing requisite/improved educational

- BREADTH
- DEPTH
- QUALITY
- RESPONSIVENESS to shifting global economic warfare requirements/ accelerated increase in knowledge

At orders of magnitude

(1) reduced societal/individual cost

(2) increased convenience/accessibility

Future Strategic Issues, 7/01

By ~ 2025, 40% of Private and 15% of Public Colleges and Universities are Expected to Close Due to Web-Based Competition

A Northern VA Business man recently donated ~ $100M to set up a FREE Ivy League Class On-Line University

Future Strategic Issues, 7/01

The "Ultimate" Education Approach - Plug and Play

Direct Silicon (or other such) device connection to brain, (very rapid) uploads, Education in minutes instead of (many) years

Future Strategic Issues, 7/01

Advantages of Shallow Sea/Desert Production of Biomass (Via Seawater Irrigation)

- Closed CO2 Cycle (Obviates Global Warming)
- Food
- Petro-chemical feedstock
  - Materials/clothing, etc.
  - ENERGY (end reliance on Middle East)
- Terraforming, alter desertification etc.
- Preservation/Production of Fresh Water
- Rich Mineral source (Seawater)
- Utilization of "Wastelands" (Sahara, etc.)

Future Strategic Issues, 7/01

Probable Circa 2025 Societal Changes

- (Much) Increased Life Span (Bio)
- "Solution" to Energy/Water/"Warming" (Bio)
- (Far More) Global Distribution of Technology, Education, Economics, Wealth (IT)
- (Tremendous) Increases in Capability of Automatic/Robotic "Everythings" (IT/Bio/Nano)
  - Resulting in Reduced Tensions Associated with "Have/Have Nots" and Historical/Religious Issues
  - Also Resulting in (Greatly) Increased Individual destructive power (Bio, IW, etc.) and General Societal Disaffection WRT "Machines"

Future Strategic Issues, 7/01

Major Emerging Law Enforcement "Issues"

- Privacy (Ubiquitous micro/nano sensors)
- IT/Net Crime (wide spectrum)
- Bio Crime (binary pathogens, genetics)
- Protection of Human Electronic Implants
- Protection of CONUS (Beyond Terrorism)
- Societal Disaffection/Upheaval Caused by Rapid Technological Change(s) (Road/Air Rage, Psychosomatic Illnesses, Withdrawal)

Future Strategic Issues, 7/01

Of Particular Concern

Uncontrolled/Uncontrollable

SELF-REPLICATION

Of

- Brilliant Robots (IT)

- Nano-Replicators (Nano)

- Rampant Recombinant Bio

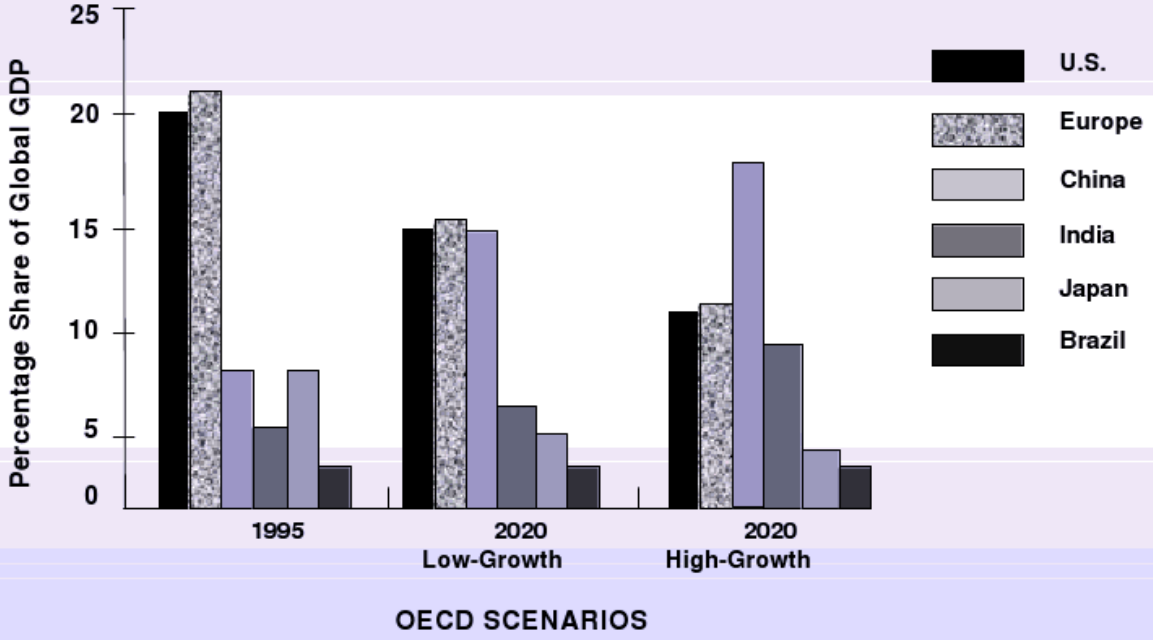
Future Strategic Issues, 7/01

Current Competitive Landscape

- U.S. produces only 18% of Worlds GDP
- ~70% of Research conducted offshore
- $400B/yr trade deficit
- 32 other nations devote a larger % of their GDP to Research
- 5th in No of R&D personnel/labor unit
- 3% savings rate vs. 30% in Asia
- 13th out of 30 - Student Math/Science Scores

Future Strategic Issues, 7/01

AN EMERGING MULTIPOLAR ECONOMIC WORLD



Source: OCED, The World in 2020, p. 92

Future Strategic Issues, 7/01

Bio Revolution Applications

- "Pharm Animals" [drugs, spare parts]
- Fast Growing plants on/near sea surface & sea water irrigated plants for biomass energy/closed CO2 cycle
- Polymer growing plants
- Spider genes in goats allow spider silk spinning from goat milk for "Biosteel", 3.5X strength of aramid fibers for Armor
- Binary Bio-weaponry

Future Strategic Issues, 7/01

Examples
Confluence of IT/Bio/Nano

- **Brain of a sea lampry inserted/connected to body of a robotic fish (an initial cyborg)**
- **"Chew-Chew" - a flesh/plant eating robot that hunts/bio-digests "natural foods" to "live off the land"**

Carbon Nanotubes

- C1,000,000, Buckminister Fullerine Carbon
- 100X strength, 1/6 weight of steel
- 8X better Armor
- Low energy Molecular/Petaflop Computing (10^{-4} En. Usage)
- Ultra Capacitor/High Temperature SC

Revolutionary Power Generation/Storage Opportunities

- Ultracapacitors
- Adv. Fuel Cells (e.g. Lithium/water/air)
- HEDM (e.g. Solid H2, Isomers, anti-matter, etc.
- Adv. PV (50%?)
- Room Temperature SC/SMES
- C-Nanotube storage of H2 (non-cryo)?
- Offshore Methane Hydrate
- Black light power?
- LENR
- ZPE

Future Strategic Issues, 7/01

Free Form Fabrication

- **Powder/Wire Metallurgy using robotic magnetically steered electron beams to create accreting local melts - GROW instead of CUT**
- **No fasteners, no strong backs for fasteners**
- **Nearly infinite fatigue life, excellent metallurgy**
- **(Repairable) metals at lower weight than far more expensive composites**

Future Strategic Issues, 7/01

Aluminum/Vortex Combustor

- **Micro powdered Aluminum fed into a vortex combustor "burns" SEAWATER**
- **Provides AIP with high energy density/efficiency for:**
  - **-inexpensive SS with "near SSN" perf.**
  - **-Transoceanic UUV's**
- **Would allow "Enemy After Next" to AFFORDABLY Threaten CONUS via Multitudinous in-shore short-time-of-flight "popups"**

Future Strategic Issues, 7/01

(Sample) New(er) Sensors

- Lidar w/ 50% efficiency via S-C optical Amplifiers, Also Fempto-second Lasers
- Molec./Bio Sensors
- Nanotags
- Smart Card Sensors
- Sensors implanted during Manuf./Servicing
- Nano IR (10E-6 Sensitivity)
- Smart Dust

Future Strategic Issues, 7/01

Some Sensor "Swarms"

- SMART DUST
  - Cubic mm or less
  - Combined sensors, comms and power supply
  - Floats in air currents
- NANOTAGS
  - Placed on everything/everywhere
  - Identification and Status Info
- Co-opted INSECTS

Future Strategic Issues, 7/01

Some "Explosive" Smart Dust Opportunities

- **Optimal Positioning of Explosive Dust - Dust/Air Explosives**
- **Formation of "Explosive Lenses"**
- **Infiltration of Deeply Buried/other such targets**

Micro Dust Weaponry

A Mechanical Analog to Bio, Micron sized mechanized "dust" which is distributed as an aerosol and inhaled into the lungs. Dust mechanically bores into lung tissue and executes various "Pathological Missions."

A Wholly "New" class of Weaponry which is legal.

Future Strategic Issues, 7/01

"Givens" (Now-to-"Soon")

- Gb data transfer rates, optical comms
- Petaflop + computing
- Exceptional AI (from Bioinfomatics, biomimetics)
- Wonderous/Ubiquitous land/sea/air/space multiphysics/hyperspectral sensor swarms (military/commercial/scientific)
- Survival requires dispersion/size reduction and concealment
- Robotic/swarm technologies primarily commercial/endemic worldwide

Future Strategic Issues, 7/01

(Agreed Upon) Assumptions, Combat in 2025

- Proliferation of TBM's, IT, Precision strike/targeting, ubiquitous micro sensors, camo/spoofing, robotics, bio/chem munitions
- Logistic assets highly vulnerable in or out of theater
- In and near theater ports/airfields possibly unusable
- Beam weapons increasingly prevalent

Future Strategic Issues, 7/01

Cruise Missiles (Current Status)

- **Range/payload similar to TBM at fraction of the cost and far greater accuracy**
- **75,000 in inventory of 75 countries, 130 different versions produced in 19 countries (10 "exporting" countries)**
- **German V-1 cruise killed 5,000; injured 40,000**
- **LO, launchable "anywhere/from anything," highly maneuverable**
- **"Then Year" costs potentially reduced to 10K - 25K**
- **Warhead(s) de jour/de hour (HE/carbon fibers/EMP/sub munitions/CNB/volumetric)**

Future Strategic Issues, 7/01

Cruise Missiles (Potential Outlook)

- **Any RPV/UAV (or UUV) is a potential "cruise missile" (50 countries have UAV's!)**
- **Low cost and "ready availability" of requisite technology/components essentially ensure the "Enemy after Next" will have/inventory/ field "hordes" of very capable/easily concealed/very difficult (and expensive) to counter/accurate cruise "missiles" with a potential "devil's brew" of warheads.**

Future Strategic Issues, 7/01

"Volumetric" Weaponry

[Alternatives to HE]

- EMP
- Info/Net/Psy warfare
- Miniature brilliant sensor/mine combo's
- Fuel/air & dust/air/Thermobarics
- RF
- Chem/bio Antifunctionals/antifauna
- Isomers, Strained Bond Energy Release, etc.
- Carbon fibers and "Blades," Acoustics etc.

Future Strategic Issues, 7/01

Antipersonnel MW/RF Weaponry

- **Heating [High Power Requirements(s)]**
- **Surface Effects**
- **Brain Interactions [Low Frequency Modulation]**

EFFECTS OF LOW POWER MICROWAVES (U.S. ARMY, SRI, WALTER REED)

- Behavioral performance decrements
- Seizures
- Gross alteration in brain function
- 30% to 100% increases in brain blood flow
- Lethality
  - Interactions between low power (microwatts per sq. cm./.4 to 3 GHz) MW and brain function

Future Strategic Issues, 7/01

Often "Fingerprintless" Bio Archipelago

- Bacteriological
- Viruses
- Prions
- Parasites
- Fungi
- Carcinogens
- Toxins
- Hormones/Regulators

- Fatal-to-disabling
- Short-to-long time scales
- Anti-flora/fauna/functional
- Direct and (undetectable) Binary
- Natural, Genomic
- Bio-Hacking

Future Strategic Issues, 7/01

Some Interesting "Then Year" BW Possibilities

- Aflatoxin - ("natural," parts-per-billion, carcinogen)
- Airborne varieties of Ebola, Lassa, etc.
- Binary agents distributed via imported products (Vitamins, Clothing, Food)
- Genomicaly (individual/societal) targeted pathogens
- Long term/fingerprintless campaign (as opposed to "shock and awe" BW)

An (Existing Bio Calmative - VEE (Venezuelan Equine Encephalitis)

- Ideal Incap. BW Agent
- Weaponized by U.S. & USSR in 50's/60's
- Easily transmitted via Aerosol
- Highly infectious, Low Fatality Rate
- 1 to 5 day incubation, 3 week recovery
- Tested on Humans (Operation Whitecoat)
- No Treatment Available

Future Strategic Issues, 7/01

Frontiers of (Rapidly Growing/Genomic/Insitu) "Bio on the Battlefield"

- **Sustainment:**
  - Food
  - Water (soil/air/purif.)
  - Energy (HC, H2, PV)
  - Meds/"Health"
  - Computing, Clothing

GREATLY REDUCES "LOGISTICS TAIL" & ENHANCES CAPABILITIES

- **Lethality**
  - Capabilities Enhancement
  - Armor
  - Concealment (living camo)
  - Sensors, FOF ID
  - Bio-weaponry (anti-personnel/functional, bio virus into bio computer)
  - Explosives (e.g. N2 fixation, grow overnite)

Future Strategic Issues, 7/01

What is Apparently "Legal"

- **Microwave/RF Anti-Functional and Anti-Personnel Weaponry**
- **Chemical Anti-Functional Weaponry**
- **Chemical "Psychological Effects" via Sensory Organs Weaponry (e.g. smell)**
- **Chemical Personnel Incapacitation Weaponry ["Non-Warfare" (e.g. Hostage/Terrorism) only]**
- **PSYWAR**
- **Acoustic Weaponry**
- **Mechanical Micro Dust**

Future Strategic Issues, 7/01

(FUTURE) NON-NUCLEAR EXPLOSIVES FOR "VOLUMETRIC"/ WEAPONS OF "MASS EFFECT"

- Metastable interstitial composite (MIC/Cubanes)
  - Order of 6 x TNT
- Fuel-air/dust-air explosives
  - Order of 15 x TNT
- Strain-bond energy release (SBER)
  - Order of 100 x TNT
- Hafnium (metastable) isomers
  - Order of 1,000 to 100,000 x TNT
- Atomic boron, carbon, hydrogen

Future Strategic Issues, 7/01

High Energy Density Materials (HEDM) (Power, Explosives, Propellants)

- Tetrahedral N (Isp → 600+ sec)
- Atomic Born, C, H (Isp → 600+ sec)
- Metastable He (Isp → 1500 sec)
- Metallic Hz (Isp → 2000 sec)
- ISOMERS (→ 10^5 x TNT)
- Anti-matter, LENR's

Future Strategic Issues, 7/01

Transoceanic UAV's

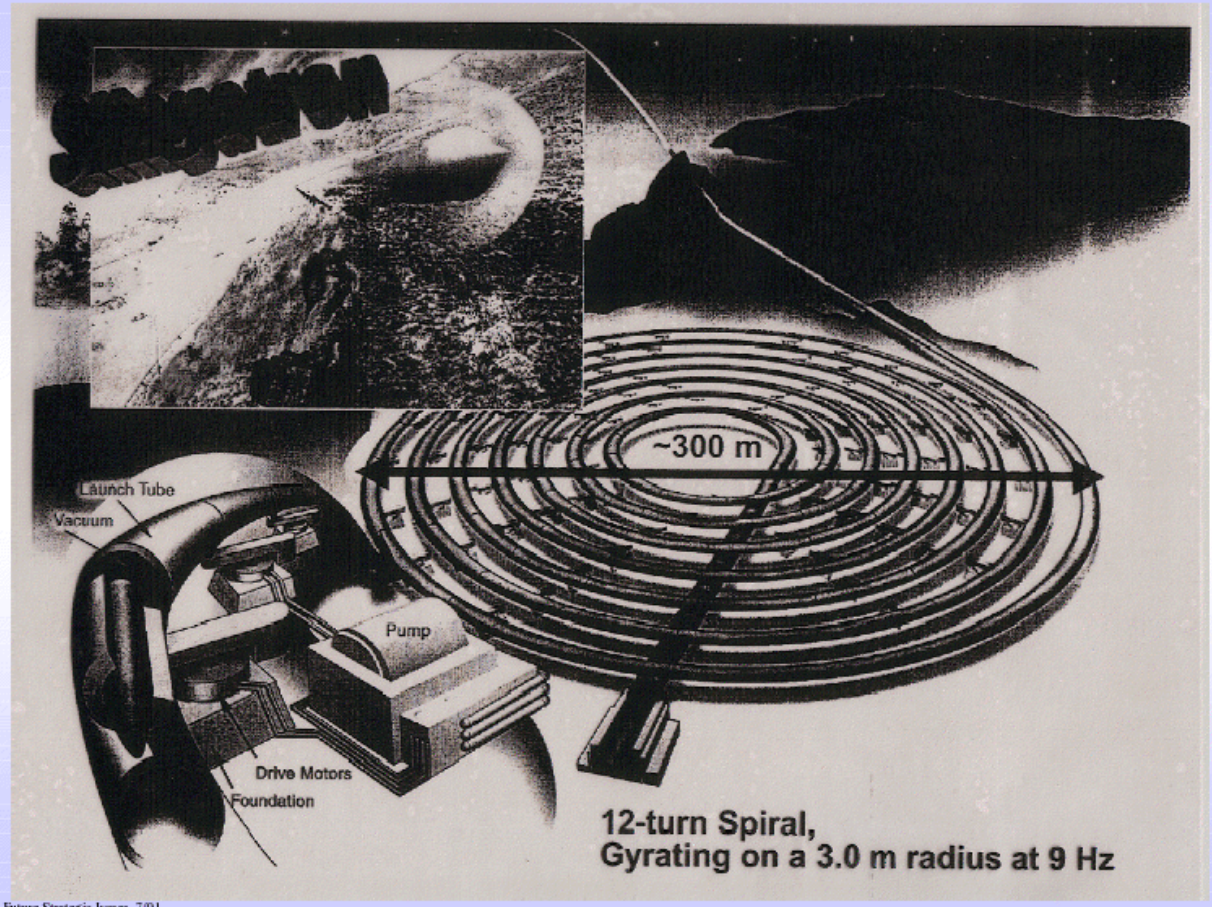
- **Current Capability - ('98 - 29 lbs, 2000 mi., 1.5 gals. Fuel; '01 - Transpac, 5000 mi.**
- **Provides Capability for Undetectable Ultra-inexpensive Swarms Against CONUS**
- **Interesting (Precision) "Payloads"**
  - **ISR**
  - **Smart Dust/Explosive**
  - **Target/explode Hazmat Trucks, Chem. Plants, Oil Storage/Refineries, etc.**
  - **Bio Dispensers (Anti-People, Things, Plants)**
  - **IW/EMP**
  - **Brilliant/Miniature sensor/Mine Combos**
  - **CNT's (Power Lines, "Wire Blade")**

Future Strategic Issues, 7/01

Blast Wave Accelerator

- Global Precision Strike "On the Cheap"
- No barrel, ~200 ft. notched rails, sequentially detonated Distributed HE
- Mach 21 or less as desired, up to 3000 lb
- Base anywhere, ~$200/lb of projectile
- Excellent stealth [no plume], affordability, ferocity, reaction time, survivability, recallability, effectiveness
- Being worked at Aberdeen and NASA MSFC for lofting of Fuel and Nanosats

Future Strategic Issues, 7/01



Future Strategic Issues, 7/01

"Slingatron" for Global Precision Strike

- 10Kg projectiles, up to thousands/minute
- Global, or less, range
- $20M/device, 80m diameter
- Mechanical "on-the-ground" propulsion via Gyrating Spiral Guide Tube (a multiple "hula hoop"
- "Poor Mans" Global Precision Strike/"Takedown Weapon"

Future Strategic Issues, 7/01

Then Year Targeting/ Connectivity etc.

- **MILITARY overheads/systems**
- **Ubiquitous COMMERCIAL overheads/systems**
- **SCIENTIFIC overheads/systems**

IN the context of:

- **Inexp. Reconstitution via micro/nano sats**
- **Optical comms /GPS etc.**
- **Ubiquitous inexp. UAV/HALE adjuncts**

EXAMPLE: POTENTIAL "COMPETITOR" MILITARY (SURVELIANCE/INTELLIGENCE/TARGETING/DAMAGE ASSESSMENT) UTILIZATION OF INTERNATIONAL SCIENTIFIC "GLOBAL CHANGE" PROGRAMS/ASSETS

- Extensive/increasing international assets (land-based, ship, aircraft (conventional/HALE), spacecraft) dedicated to measuring, on a global scale, details of land, atmospheric, ice, ocean, biota status/"dynamics" (to understand total Earth "system" and effects of humans on the global environment)
- Extensive/magnificent/often redundant wide coverage and detailed instrumentation suite(s) (imaging radars/SARS/LIDARS/radar altimeters/laser altimeters/radiometers/scatterometers/spectrometers/IR sensors/ magnetomiters/etc.
- Terrabites+ of data archived/readily/publicably available increasingly in near real time
- Sample measurements include: OH, O_3, HCI, NO, NO_2, N_2 O, CO, CH_2 , HNO_3 , CO_2, H_2 O, aerosols, wind speed/vector/profile(s), vegetation type, temperature profile(s), humidity profile(s), soil moisture/composition, snow cover/depth/moisture content, cloud/surface reflectance, sea ice type/coverage/temperature, ocean temperature(s)/sediments/topography/salinity/currents, magnetic field(s), surface emissivities/reflectance, leaf area index, land topography/use/temperature/cover, ice sheet elevation/topography gravity field/gradients, fires extension/temperature, 3-D cloud distributions/temperatures/ice content, pressure distribution(s), ocean wave heights/period(s)/direction(s)

Future Strategic Issues, 7/01

Then Year, Global Targeting Capabilities are a Given - Major Issue is "Legs"/Range for Increasingly Miniaturized Affordable Payloads/Systems

- **Range Enhancement Approaches:**
  - **Airbreathing or "water breathing," to first order doubles range**
  - **Initial boost for cruise (ala Blast Wave Acceleror)**
  - **HEDM Fuels [Atomic Boron, Carbon, Isomers, etc.)**
  - **Drag Reduction (Wave/Friction/Drag-due-to-lift, Increased Dia.)**
  - **Hypersonic Maneuvering Boost-Glide**

Future Strategic Issues, 7/01

Summary - Major Influences of IT/Bio/Nano Upon Future Warfare

- Ubiquitous miniaturized/networked multi physics,hyperspectral sensors
- Robotics/Automatics "in the large"
- Long range precision strike/targeting
- Info/net Warfare
- Mini/micro/nano Sats, Cruise, UAV's
- Binary Bio Weaponry
- Miniature/ubiquitous "smart mines"

Future Strategic Issues, 7/01

Increasingly Critical Human Limitations/Downsides

- **Large**
- **Heavy**
- **Tender**
- **Slow (Pysically, Mentally)**
- **Require Huge Logistic Train(s)**
  i.e. Humans have rapidly decreasing-to-negative "Value Added"

Future Strategic Issues, 7/01

ROBOTICS "IN THE LARGE"

(saves lives, enhances affordability, redefines risk/threat environment, enhances effectiveness)

"Unattended"

- Munitions
- Sensors
- Platforms
  - Air (UAV's)
  - Sea (UUV's)
  - Land (UGV's)

- Logistics
- Spoofing/obscurants
- RSTA (including NBC)
- Defense (across the board including counter recon/ambush)
- Offense
  - Obstacle breaching
  - "The Shooter" (especially Mout)
  - Mine Clearing

Future Strategic Issues, 7/01

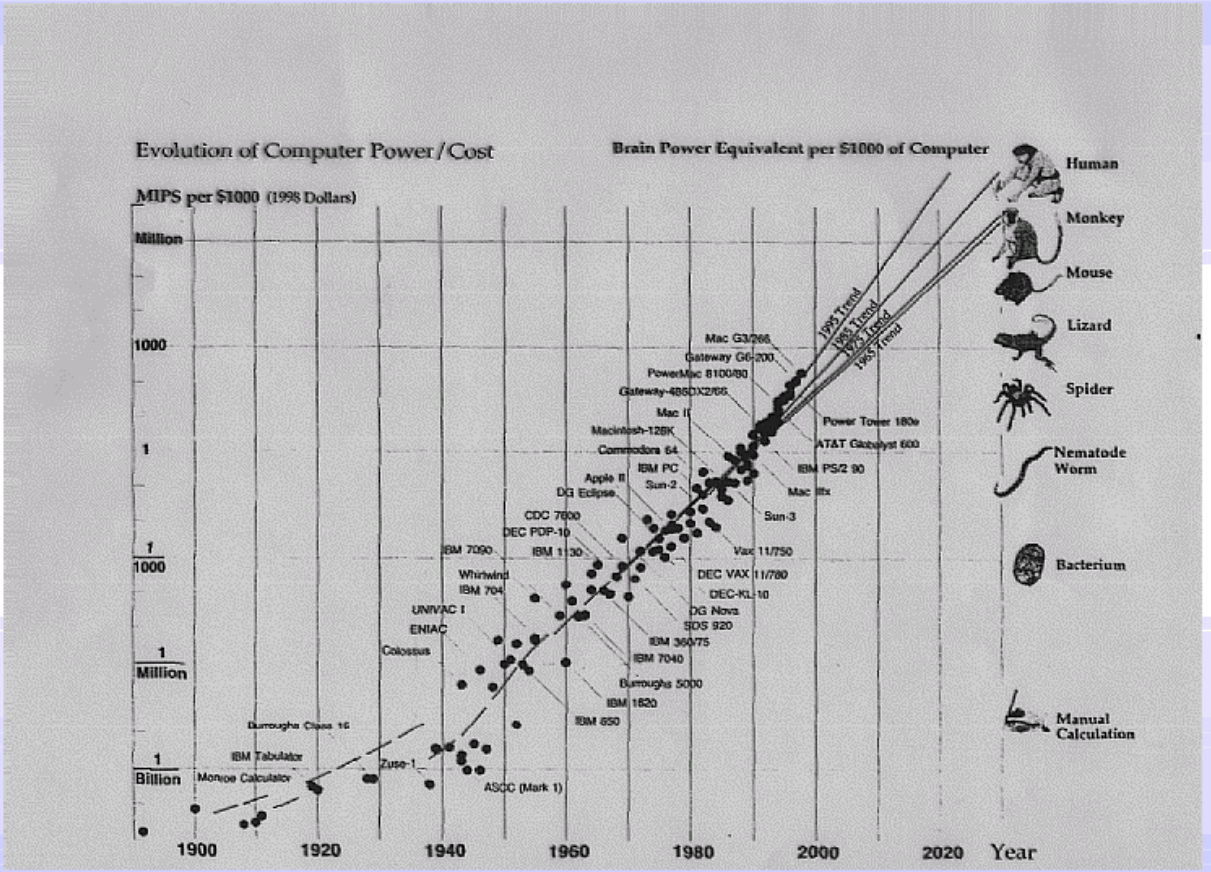
Emerging Characteristics of Robotic Systems (Enabled by Ongoing IT Revolutions- Comms/Sensors/Computation/Miniaturization

- From expert systems toward AI and beyond
- Much more reactive than humans, greatly increased tempo
- Greatly improved hyperspectral sensors/data fusion
- Greatly improved accuracy and lethality
- Greatly improved affordability/miniaturization
- Redefines "risk," minimal casualties, salutes CNN syndrome
- Greatly reduced logistics

Future Strategic Issues, 7/01

Robotic Intelligence

- Two "flavors
  - Traditional AI - Rule Based
  - Experiential - Behavior Based (Neural Nets/other "Soft Computing"
- Combination of these is current "best bet" (per Moravec) to produce artificial/cyber "life" which will possibly-to-probably be sentient but will not be anthropomorphic



Future Strategic Issues, 7/01

WHAT IS BEYOND ROBOTIC SYSTEMS (SENSORS/PLATFORMS/WEAPONS/ MUNITIONS)

- Robotic/automatic → autonomous warfare?
  - Computer capability will exist (beyond terra flop) to do "AI" (or better?), required connectivity is a "given"
  - Competitor capabilities /tempo sidelines the innate inadequacies of human interactions/education/conscious decision timelines
  - Little-to-no "troops" → "Acme warfare Ltd."
  - Flat hierarchy → demise of "main in the chair?"
  - High level/"soft sciences" human aspects "boundary conditions"
    - Sociological/"humanitarian"
    - Political
    - Environmental
    - Religious
    - Psychological
    - Economics
    - Etc.

Extent/scale, projected effects/ Damage(s), personnel attrition (general-to-specific)

Future Strategic Issues, 7/01

"Non-Explosive Warfare"

- IW/IO
- PSYWAR "In-the-Large"
- Anti-Functionals
  - MW
  - Chem
  - Bio
  - Micro-Mechanical
- Anti-Personnel MW/RF, Micro-Mechanical

Future Strategic Issues, 7/01

"Natural Warfare"

- **Sensors:**
  - **Utilize insitu plants/animals/insects as sensor platforms/instruments to indicate presence/movement/characteristics**
- **Weapons/Munitions:**
  - **Utilize animals (e.g. urban rats)/insects as "delivery systems"/munitions ("feeding," swarming, biting, poisoning)**
  - **Utilize insitu explosive/destructive capability (e.g. offshore Methane Hydrate, Dams, etc.)**

Characteristics - Future/Emerging Sensors/Munitions/Weapons/Platforms

- Inexpensive
- Numerous-to-Hordes/Clouds/Swarms
- Small/light/ubiquitous
- Readily Available (Largely Comm. Tech.)
- Long Range
- "Volumetric" or "Precise"
- Both "Explosive" and "Non-Explosive"
- Smart-to-Brilliant

Future Strategic Issues, 7/01

Potential Future "Orders of Magnitude" Increases in Overall Weapon Effectiveness/Availability at Orders of Magnitude Reduced Cost(s)

- Bio/Chem/Molec./Nano Computing - (E6)
- Ubiquitous Optical Comms - (E4)
- Micro/Nano/Ubiquitous Sensors - (E4)
- BioWeaponry - (EN)
- Co-operative Swarms of Cheap/Small Weapons/Sensors - (E4)
- Volumetric Weaponry - (E4)
- Cyber/Artificial Life (Beyond AI) - (E?)

Future Strategic Issues, 7/01

Major (Anti-U.S.) Asymmetries

- Long increasingly vulnerable logistics chain
- Long, "undefendable" coastline (esp. against underwater threats)
- Sensitivity to casualties (greatly enhanced by the "CNN syndrome")
- Vulnerabilities to "terrorism" (esp. IT, bio)
- Increasing over reliance upon vulnerable "overhead" assets

Future Strategic Issues, 7/01

Potential En-route Logistic Vulnerabilities

Logistic surface ships and aircraft are non-LO and undefended, could be targeted and attrited inside the continental shelf by:

- **"Eggs" [subsurface floating encapsulated missiles implanted by freighters/SS/air]**
- **SS [torps/missiles/subsam]**
- **Transoceanic UUV's, UAV's, USV's**
- **Blast wave accelerator**
- **Cruise, TBM's**
- **MINES**

Future Strategic Issues, 7/01

Fundamental Problem With Future U.S. Power Projection

- **"EAN" can have "country sized magazines" filled with hordes of inexpensive Precision strike "Munitions" - Area Denial**
- **U.S. Forces run out of "bullets" and die**

  [Beam weapons not panacea, inexpensive workarounds available]
- **Deep Water Subs with large loadout/"swimin" weaponry only survivable "Close-in" platform**

Future Strategic Issues, 7/01

Sampling of TBM/Cruise Missile "Penaids" (Derived from Extensive Worldwide ICBM/IRBM RV Cold War Defensive/Offensive Studies Over Some Three Decades

- **Decoys (anti-sensor)**
- **Ablative/subliming coatings (thermal [laser/mw] protection)**
- **Fluid injection (laser protection)**
- **Wake modification(s) (anti-sensor)**
- **Electronic/optical "shielding" (MW protection)**
- **RAM/RAS/shaping (anti-sensor)**

e.g., current efforts involving beam weapons (laser, MW) "kills" of undefended"/"unpenaided" "dumb" incoming NOT REALISTIC

Future Strategic Issues, 7/01

Potential "Workarounds" for Beam Weapon Effects on Missile Sensors/Comms

- **Off board sensors (networked, everywhere, on everything)**
- **Optical Comms**
- **Optical/fluidic Computing**
- **Optical GPS**

Future Strategic Issues, 7/01

Example 'Then Year" Direct Conus Attack Capabilities

[~80% of CONUS population/infrastructure within ~ 50 Miles of a "coastline"]

- Inexp. Transoceanic UUV's/UAV's/Cruise
- Inexp. Blast Wave Accelerators
- Inexp. Info/Net/Psywar
- Inexp. Inshore AIP SS [mines/torps/SLCM]
- Inexp. Binary Bio into Food Supply
- Inexp. Semi-submerged Missile "eggs"
- Inexp. 'Trojan Horse" "civilian" systems

[Above in addition to ICBM/TBM]

Future Strategic Issues, 7/01

"Unconventional" Nuc Delivery

- Sink a ship offshore, detonate to produce Tidal Waves with Radioactive spume
- Transcontinental UAV's, UUV's (nano, AI)
- Ballons with GPS sport 'chutes
- Ganged Micro Rockets (ala MIT)
- Trojan Horse Everything (ships, boats, planes, cars, trucks, packages, cargo, containers)
  - Targeted "Effects" include Tidal Waves, EMP, Earthquakes, Radiation, Blast

Future Strategic Issues, 7/01

(Civilian) IW Examples/CONUS

- (National) Banking System Computers
  - 3 sites/nodes - HE/EMP/IW/C/B (attack buildings, power, software, hardware)
  - Interruptions in National/International Payments system irrecoverable
- Railroads
  - 4 sites, attack options as above
  - All freight cars networked, "everyone" on "just in time," no reserves/stockpiles
  - Takes down Auto Industry, power grid, chicken farms, all movements of "War Materials," ETC!!!

The Revolutionary Size/Capability/Cost Warfighting Spiral

1. **Commercial electronics/GNC/Comms/Sensors (Much smaller/cheaper/better - Allows:**
2. **IO and "Precision" - Reduces Reqd. munition size and Numbers much-Leads to:**
3. **Small/Light/Deadly/Inexpensive Munitions -**
4. **Which Reduces requisite Platform size/cost -**
5. **Which is reduced still further by (also enabled) "Automatics/Robotics" - Uninhabited**
6. **Combined with Much lighter/cheaper Revol. Materials/Fabrication for structure and energetics (propul./warhead) - Yields "Cheap Warfare"**

Future Strategic Issues, 7/01

And Then There Is NANO ...

Future Warfare
"On The Cheap"

- Info/net warfare
- Binary bio [anti-functional/fauna]
- Non-lethals
- Miniature brilliant sensor-mines
- Micro/Nano Sats
- LO/Long leg/precision UUV's/UAV's/Cruise
- Inexp./Superb/survivability ISR/comms
- Blast wave accelerator

Future Strategic Issues, 7/01

"Then Year"
"Peer Competitors"

Peer Competitor no longer defined by "megatonnage" of obsolescent Industrial age steel and aluminum Artifacts. The Drastically reduced entry investment enabled by "Warfare on the Cheap" ensures almost any nation or sizable organization can be a very worrisome Military "peer."

Future Strategic Issues, 7/01

SOME INTERESTING POSSIBILITIES

- **Surreptitious nano "tagging" (with MW interrogation) of "everything/everyone" (imprinted during manufacture/maintenance etc.)**
- **Detonation of offshore seabed methane hydrate deposits to produce tactical/strategic level tidal waves against littoral regions**
- **Demise of "stealth" via ubiquitous multi-static, multi-physics sensors operated on "take-a-vote"**

Future Strategic Issues, 7/01

"Anti-Access"

- MINES
- Hordes/Swarms (country-sized/dispersed magazines) of small/inexpensive/brilliant cruise/UAVs, micro rockets, BWA/slingatron projectiles, UUVs (e.g. RPGs on jet skis)
- Tyvek nets
- Attrite/"take out"/threaten APODS/SPODS
- EMP, IW/IO
- TBM/Cruise/HPM/Lasers
- "The Sensor Web"

Future Strategic Issues, 7/01

Counters to U.S. "Information Dominance"

- EMP ("conventional," Isomers/other HEDM, Nuc.)
- Jammers "in the Large"
- "Fry" (MW, Lasers), "Blowup"
- Anti-Sensor (various, include D&D)
- "Software" (subvert/deception/decimation/Trojan Horse/viruses/etc., other IO/IW)
- "Chaos" (Excite circuit nonlinearitys)
- PSYWAR

Future Strategic Issues, 7/01

Counter U.S. Logistics

- **Take out pre-positioned everything**
- **Ubiquitous nano inexpensive multiphysics, hyperspectral land/sea/air/space military, scientific, commercial sensors; Nano tags (aka "The Sensor Web")**
- **Target/attrite logistic air/sea lift over continental shelf via Brilliant mines, cruise, UAVs, UUVs, TBMs, Micro missiles, prepositioned semi-submerged missile "eggs," AI/vortex SS weaponry (include Subsam), BWA, slingatron, Automatic MANPADS in CONUS (via Blast/EMP etc.)**
- **Small number of military ports/airfields in CONUS; C-17/5/141, Ro-Ro/other ships, trains inside CONUS are non LO, undefended**

Future Strategic Issues, 7/01

Anti-U.S. RMA "Strategies/Tactics"

- Threaten Bio to force "suit-up"/degrade effectiveness
- Keep forces beyond range of short-legged fighters
- Attrite JSTARS/AWACS/ABL/Missile "cows" etc. platforms
- Miniaturize/Disperse EVERYTHING - no large/massed/ interesting targets
- Use "Hard to Degrade"/Jam optical Comms/GPS
- Operate out of cities/International Commercial Entities
- Degrade U.S. Info Dominance
- Machine Intell. "automatic warfare," (much) tighter OUDA loop (faster than Human ops)

Future Strategic Issues, 7/01

Exploit "CNN Syndrome"

- Sink Carrier(s) via "swarm attacks"
- Capture/torture Americans in living color on prime time
- "Terror" attacks within CONUS (binary bio, critical infrastructure "takedown," IO/IW, EMP, RF against Brain, etc.)
- Serious "Psywar" (collateral damage exploitation, etc.)

Future Strategic Issues, 7/01

The Key Technologies

- **Free form/"point of use" fabrication**
- **Beyond silicon computing (quantum, optical, bio, nano, molec.**
- **Optical comms/nav**
- **Nano sensors/tags/materials/bots/GNC**
- **HEDM explosives and propellants (NANO POWDERS, CUBANES, SBER, ISOMERS, LENR, THERMOBARICS, F-S LASERS/4TH GEN NUCS)**
- **Anti-personnel/material (Binary) Bio, MW**
- **Robotics/Machine Intelligence**
- **Miniaturized/brilliant/lightweight/low-power/inexpensive swarms of <u>everything</u> (SATS, weapons, robots, sensors, mines, etc.)**

Future Strategic Issues, 7/01

Fundamental Military Issues/Metrics

- **Affordability** ["Warfare on the Cheap"]
- **Survivability** ["Can see everything, Anything you can see you can kill"]
- **Effectiveness** [Lethality of Precision and Volumetric weaponry]

I.E. Simultaneous ongoing Revolutions in all three of the major Warfare Metrics

Future Strategic Issues, 7/01

Given the Superb/Ubiquitous World Wide Sensor Suites and Precision Strike Capabilities "Then Year" the Following WILL NOT BE SURVIVABLE

- APODS/SPODS
- Runways
- Surface Ships
- Manned (logistic/combat) Aircraft
- Manned (logistic/combat) Ground Vehicles

Due to their size & (multi-physics) signatures

Future Strategic Issues, 7/01

CONCERNING (CURRENT) FARTHER TERM (U.S.) DEFENSE "STRATEGIC STUDIES"

- **Almost wholly dedicated to/concentrated on offensive operations (DOO?)**
  - **Across the board (Army, Navy, Air Force, Marines, OSD)**
- **(Apparent) wholly inadequate consideration of defense**
  - **Defense of Conus, especially from short time of flight inshore undersea attack**
  - **Defense of the offensive forces [especially in terms of the "enemy after next" capabilities definitization and response(s) thereto]**
  - **Defense of the logistics assets, especially "out of theater"**

Future Strategic Issues, 7/01

Typical Scenario - "Takedown" of U.S. by 10 People and <$10M

- Binary Bio [via (imported Vitamins/Clothing, etc., food supply(s)]
- Terror Bio (e.g. Aflatoxin)
- IW ("usual" plus physical against key nodes such as Railroads - take down the economy)
- Selective anti-personnel RF/MW (Towers)
- Water Supply Contamination via Intercontinental UAV's

Accompanied by SERIOUS "PSYWAR"

Future Strategic Issues, 7/01

Trends Summary

- Tele-everything
- U.S. just "one of the crowd" economically
- "Warfare on the cheap," many potential "peers"
- Warfare Increasingly Robotic
- Survivable/Affordable power projection via deep water subs and Blast Wave Accelerators
- CONUS and Logistics Defense increasingly worrisome

FROM U.S. COMMISSION ON NATIONAL SECURITY/21ST CENTURY

- It will soon be possible to connect human brain cells to silicon chips
- Due to IT technology we will witness the "death of distance"
- More than 2/3rds of the satellites are foreign owned
- Large scale missile attacks will be able to overwhelm defensive systems
- Development of genetically engineered pathogens that will thwart our bio detection/defense measures/cycles

Future Strategic Issues, 7/01

"Circa 2025"

- **Machines as creative/"smart" as humans "Robotics" the "norm"**
- **Zeroth order "warstopper" - Binary bio into nation's agric./food distrib. system (every home/fox hole)**
- **Next level of concern: Ubiquitous/Cheap micro-to-nano EVERYTHING (sensors, munitions, weapons swarms/hordes)**
- **Battlefield attrition/CNN syndrome forces U.S. Army to look/act like SOCOM**

Future Strategic Issues, 7/01

(Suggested) Major U.S. Future (2025) Warfare Issues

- **CONUS Defense (Requirement(s) for, potential approaches)**
- **Logistics Defense/Protection (in/out of theater)**
- **Survivability/Effectiveness of U.S. Forces on/near the "Killing Ground" in an era of affordable ubiquitous multiphysics hyperspectral sensors, precision strike, volumetric weaponry, "swarms" and hardened munitions**

Future Strategic Issues, 7/01

- **"Non-explosive Warfare" (psywar, biowar IT/net war, "anti-operability war," Beam weaponry including RF, Spoofing/Cammo**
- **Robotic Warfare "in the large"/better than human AI/"Cyber life"**
- **Alternative Power Projection Approaches (e.g. Deep Water depth/death sphere, blast wave accelerator, etc.)**

Future Strategic Issues, 7/01

Future "Power Projection"?

- Humans "hold" instead of "take" ground (go in after "Sanitization")
- Sanitization via:
  - IW/Psywar
  - Global Reach "Guns" (BWA/Slingatron)
  - Deep water/large loadout Subs w/"swimins"
  - "Robotic Everything" w/Volumetric weaponry, non-explosive warfare

Future(s) of SOF

- **Becomes THE (only survivable) HUMAN Strike Force (Army/Marines forced to become "SOF-Like")**

- **Increasingly The "Overseas FBI" to counter the increasingly capable (IO/Bio WMD) & horrific destructive power of INDIVIDUALS and Groups**

- **Ops involve increasingly difficult-to-deal-with omni-present/omni-physics sensor/ID suites, Few-to-No exploitable Interstices for Covert/Clandestine "work" - THE Challenge**

Future Strategic Issues, 7/01

Future "Warfare"

- "Defense" against the "then year" multitudinous conventional and unconventional delivery methods for volumetric and precision munitions is essentially neither doable nor affordable.
- Suggested National Defense Approaches:
  - Work Technology, Intel, Diplomacy, SOCOM for detection/interdiction/deflection of the "pre-delivery" phases (causes of war, motivational and decision processes, design and construction, test)
  - Work and ADVERTISE a REALLY EFFECTIVE RETRIBUTION to deter delivery (ala MAD)

Changing Nature of Warfare

Hunter/ Gatherer	*Hunting Grounds*	*Tribal Bands*	*Hand Held/ Thrown*
Agricultural	*Farm Lands*	*Prof. Armies*	*Hand Held/ Thrown*
Industrial	*Natural Resources*	*Mass Levee*	*Mech./Chem.*
IT/Bio/Nano	*Societal Disruption*	*Everyone*	*IT/Bio'Bots*

Future Strategic Issues, 7/01

RMA Planning "Shortfalls" (NPS)

- **"Indications of the innovative paths adversaries might take or how they might adapt technologies from the civilian world"**
  (Being worked in the "Technical War Games")
- **"The path from todays systems and capabilities to those hypothesized for the future (2020+)"**

What is needed is a "Then Year" (~2030) Serious/Holistic Vision of Warfare Changes Resulting from the On-going IT/Bio/Nano/Virtual Technological Revolutions

- Such does not exist, "bumper sticker" attempts extant.
- All are agreed, warfare will become increasingly robotic and probably more affordable, swarms of sensors/shooters are a given.
- A longer term "Vision" of these changes would enable "mapping" from the present, NOT AT ALL CLEAR HOW TO "Get There From Here" as do not know where "there" is!

Future Strategic Issues, 7/01

"War between mass armies weighed down with baroque equipment has become a third world sport. The advanced world, too vulnerable to survive a war of attrition or mass destruction, must learn to conduct its affairs by the Rapier--by the threat or use of small specialized forces exploiting high tempo and strategic surprise"

R. E. Simpkin, "Race to the Swift: 1985

In the second half of the 1900's Nuclear/Bio Warfare was "Unthinkable"

In the first half of the 2000's "conventional" warfare may become so deadly/effective as to become "Unthinkable" ("Killer Aps" available to mitigate the "Causes of War")

Future Strategic Issues, 7/01

Approaches to Countering Group/Individual Deployment of IO/Bio WMD

PREVENTION -

- Universal inexpensive Web based educ.
- Biomass via sea water irrigation

DISCOVERY -

- All Source Intel/Fusion/AI Analysis

PREEMPTION/RETRIBUTION -

- SOF (Foreign)

Future Strategic Issues, 7/01

(Usual) Reactions to this Presentation

- Is in the "Too Hard Box"
- Not being done yet by anyone, therefore, will not be done
- They would not do that
- We have to Hope they would not do that
- Why go there, cannot defend against it
- Some Disbelief, but agreement there is too much there to disregard

This report is a compilation and integration of the first seven supplements, and the alphabetical addenda (appended to the original bibliography), with the revised bibliography of April 1972. The report is a successor to Naval Medical Research Institute (NMRI, Bethesda, MD 20014) Research Report No. 2, completed under Research Work Unit MF12.524.015-0004B in October 1971, by the senior author, and available from National Technical Information Service (Springfield, VA 22151) as AD #734-391. The original report was revised and reprinted in April 1972, and also contains the first three supplements; No. 1 dated October 1971, No. 2 dated November 1971, and No. 3 dated April 1972. The revised report which consists of more than 2300 literature citations, is available from NTIS as AD #750-271, and includes, as the first chapter, an outline of the effects which have been attributed to radio frequency and microwave radiation. Supplement No. 4 (containing 327 citations) was completed in June 1973, as an Electromagnetic Radiation (EMR) Project Office Report, Bureau of Medicine and Surgery (Navy), (Washington, DC 20372), and is available from NTIS as AD #770-621. Supplement No. 5 (containing 497 citations) was completed in July 1974 as an EMR Project Office Report, Naval Medical Research and Development Command (NMR&DC, Bethesda, MD 20014), and is available from NTIS as AD #784-007. The sixth Supplement (containing 241 citations) was completed in June 1975 (also as an EMR Project Office, NMR&DC Report), and is available from NTIS as AD #A015-622. The seventh Supplement (containing 345 citations) was completed in May 1976 as a NMRI Report, and is available from NTIS as AD #A025-354. Supplement No. 8 (not included in this report, but containing 331 citations), was completed in August 1976 as a NMRI Report, and is available from NTIS as AD #A029-430.

27 September 1976

(Supersedes AD #734-391, #750-271, #770-621, #784-007, #A015-622, & #A025-354)

ABSTRACT

More than 3700 references on the biological responses to radio frequency and microwave radiation, published up to May 1976, are included in this bibliography of the world literature. Particular attention has been paid to the effects of non-ionizing radiation on man at these frequencies. The citations are arranged alphabetically by author (where possible), and contain as much information as possible so as to assure effective retrieval of the original documents. Soviet and East European literature is included in detail.

This report is a compilation and integration of the first seven supplements, and the alphabetical addenda (appended to the original bibliography), with the revised bibliography of April 1972. The report is a successor to Naval Medical Research Institute (NMRI, Bethesda, MD 20014) Research Report No. 2, completed under Research Work Unit MF12.524.015-0004B in October 1971, by the senior author, and available from National Technical Information Service (Springfield, VA 22151) as AD #734-391. The original report was revised and reprinted in April 1972, and also contains the first three supplements; No. 1 dated October 1971, No. 2 dated November 1971, and No. 3 dated April 1972. The revised report which consists of more than 2300 literature citations, is available from NTIS as AD #750-271, and includes, as the first chapter, an outline of the effects which have been attributed to radio frequency and microwave radiation. Supplement No. 4 (containing 327 citations) was completed in June 1973, as an Electromagnetic Radiation (EMR) Project Office Report, Bureau of Medicine and Surgery (Navy), (Washington, DC 20372), and is available from NTIS as AD #770-621. Supplement No. 5 (containing 497 citations) was completed in July 1974 as an EMR Project Office Report, Naval Medical Research and Development Command (NMR&DC, Bethesda, MD 20014), and is available from NTIS as AD #784-007. The sixth Supplement (containing 241 citations) was completed in June 1975 (also as an EMR Project Office, NMR&DC Report), and is available from NTIS as AD #A015-622. The seventh Supplement (containing 345 citations) was completed in May 1976 as a NMRI Report, and is available from NTIS as AD #A025-354. Supplement No. 8 (not included in this report, but containing 331 citations), was completed in August 1976 as a NMRI Report, and is available from NTIS as AD #A029-430.

Relevant presentations made at technical meetings are included in a separate section.

The "outline of bio-effects" which appeared in the original Bibliography has been included in this report as an Appendix.
