PUBLIC SERVICE COMMISSION

Dear Kentucky PSC,

I'm making this clear first and foremost! You do not have my permission to post any of my personal information on the internet!

In regards to Case No. 2020-00349:

I am writing you again in regards to Kentucky Utilities **trying to force dangerous wireless meters on our homes**. I am asking you to review all previous case files (**Kentucky PSC: Case Files 2012-00428 , 2016-00394, 2016-00187, 2016-00152, 2016-00370**) connected to this and all prior documentation and complaints.

Kentucky PSC is well aware that these wireless meters are dangerous. They not only are a fire hazard, but a health hazard and they have plenty of documentation (as do you) that proves this!

I'm requesting that you permanently stop these dangerous meters from being forced on us and stop any and all fees that KU tries to force on us for not having a radiation emitting wireless utility meter.

Andy Beshear already stood against these useless, wasteful, and dangerous meters that have to be replaced every 3 to 4 years.

They are known to cause fires, violate privacy and they are labeled a class 2b carcinogen! Insurance will not cover any property damage or health damage caused by these wireless meters.

Refuse all wireless meters and only allow SAFE ANALOG UTILITY METERS in Case No. 2020-00349 ! Protect our health, property, privacy, and protect meter readers jobs!

My property and the entire neighborhood has already been destroyed by the radiation being blasted from the wireless water meters that Kentucky American Water installed in 2013. We are loosing our trees, shrubs, and our flora. Birds, Bees, and Butterflies are disappearing since they were installed!

Read the documentation and letters from the thousands of doctors, and research scientists!

Sincerely,

D.C.

Re: Case files 2012-00428, 2016-00370, 2016-00187, 2016-00152 and all other Utility Company Case Files regarding Wireless Utility Meters (ie., AMI, AMR, AMS, ERT, Wireless, Smart Meters, etc.)

Dear Kentucky Public Service Commission, All Electric, Gas and Water Utility Companies, President, Agents, Officers, Employees, Contractors and Interested Parties:

We, the undersigned, are scientists and health professionals who together have co-authored many peer-reviewed studies on the health effects of radiofrequency radiation (RFR). We are aware that the Kentucky Public Service Commission is considering a proposed smart meter opt-out fee from Duke Energy. Smart meters, along with other wireless devices, have created significant public health problems caused by the radiofrequency radiation (RFR) they produce, and awareness and reported problems continue to grow. With Duke Energy being America's largest utility provider and, consequently, having the largest potential smart meter implementation reach, it is imperative that the Kentucky Public Service Commission be fully aware of the harm that RFR can cause and allow utility customers to opt out of smart meter installation with no penalty.

The majority of the scientific literature related to RFR stems from cell phone studies. There is strong evidence that people who use a cell phone held directly to their ear for more than ten years are at significantly increased risk of developing gliomas of the brain and acoustic neuromas of the auditory nerve. There is also evidence that the risk of developing these cancers is greater in younger than older people. The May 2016 report from the US National Toxicology Program showing that rats exposed to cell phone radiation for nine hours per day over their life-span develop gliomas of the brain and Schwannoma of the heart (the same kind of cancer as acoustic neuroma) adds proof to the conclusions from the human health studies that radiofrequency radiation increases risk of cancer.

East Campus, 5 University Place, Room A217, Rensselaer, NY 12144-3429
PH: 518-525-2660 FX: 518-525-2665
www.albany.edu/ihe

Smart meters and cell phones occupy similar frequency bands of the electromagnetic spectrum, meaning that cell phone research directly applies to smart meter RFR. Smart meter RFR consists of frequent, very intense but very brief pulses throughout the day. Because smart meter exposure over a 24 hour period can be very prolonged (pulses can average 9,600 times a day), and because there is building evidence that the sharp, high intensity pulses are particularly harmful, the cell phone study findings are applicable when discussing adverse health impacts from smart meters.

While the strongest evidence for hazards coming from RFR is for cancer, there is a growing body of evidence that some people develop a condition called electro-hypersensitivity (EHS). These individuals respond to being in the presence of RFR with a variety of symptoms, including headache, fatigue, memory loss, ringing in the ears, "brain fog" and burning, tingling and itchy skin. Some reports indicate that up to three percent of the population may develop these symptoms, and that exposure to smart meters is a trigger for development of EHS.

In short:

- Smart meters operate with much more frequent pulses than do cell phones, increasing the potential for adverse health impacts.
- Smart meter pulses can average 9,600 times a day, and up to 190,000 signals a day. Cell phones only pulse when they are on.
- Cell phone RFR is concentrated, affecting the head or the area where the phone stored, whereas smart meter RFR affects the entire body.
- An individual can choose whether or not to use a cell phone and for what period of time. When smart meters are placed on a home the occupants have no option but to be continuously exposed to RFR.

The Public Service Commission should not be relying on industry representatives for assistance, due to their obvious conflict of interest. Too often they rely on biased research and hold opinions that are not consistent with medical evidence. The symptoms and illnesses experienced from wireless utility meters are related to length and accumulation of exposure and therefore not everyone will exhibit symptoms immediately. In addition, as with many other diseases, not everyone is equally susceptible. There are a number of double-blind studies which clearly show that some people with EHS will develop symptoms when exposure to RFR is studied in a double blinded experimental protocol, in which the subject do not know whether or not the RFR is being applied. These individual are not suffering from a psychosomatic disease, but rather one that is induced by the exposure to RFR. Public health agencies that label these symptoms as being only psychosomatic are ignoring this evidence and are not working to ensure fair treatment of and protection of the public.

The adverse health impacts of low intensity RFR are real, significant and for some people debilitating. We want to stress three fundamentals as your agency proceeds to consider a smart meter opt-out:

- The Federal Communication Commission's safety standards do not apply to low intensity RFR.
- There is no safe level of exposure established for RFR.
- People around the world are suffering from low intensity RFR exposure, being at increased risk of developing both cancer and EHS.

Citizens rely on their government agencies for protection from harm. Accordingly, we urge the Kentucky Public Service Commission to reject any fees or tariffs associated with smart meter opt-out and allow citizens to opt out without penalty.

Thank you for your attention and consideration. What you do in this instance affects the lives of many in Kentucky and beyond.

Yours sincerely,

David O. Carpenter, M.D.

Email from Dr Robert Baan, the principal author of the 2011 IARC Monograph on the **carcinogenicity of radiofrequency radiation, in which he interprets the 2B classification of RFR as applicable to all form of RFR exposures, including Smart Meters and Wi-Fi:**

Subject: ***EMF Class 2B Classification***

Dear Dr Hudson,

*Thank you for your message, which was forwarded to me, and to which I would like to respond as follows. The IARC Working Group classified "Radiofrequency Electromagnetic Fields" (RF-EMF) as possibly carcinogenic to humans (Group 2B). The information that formed the main basis for this evaluation was found in epidemiological studies on cell-phone use, where a slightly increased risk for glioma (a malignant form of brain cancer) and acoustic neuroma (a non-cancerous type) was reported among heavy users. There were some indications of increased cancer among radar-maintenance workers(occupational exposure), but no reliable data from studies among, e.g., people living close to base-station antennas, radio/TV towers, etc (environmental exposure). Although the key information came from mobile telephone use, the Working Group considered that the three types of exposure entail basically the same type of radiation, and decided to make an overall evaluation on RF-EMF, covering the whole radiofrequency region of the electromagnetic spectrum.In support of this, information from studies with experimental animals showed that effects on cancer incidence and cancer latency were seen with exposures to different frequencies within the RF region. So the classification 2B, possibly carcinogenic, holds for all types of radiation within the radio frequency part of the electromagnetic spectrum, including the radiation emitted by base-station antennas, radio/TV towers, radar, **Wi-Fi, smart meters**, etc. An important point is the radiation level. The exposure from cellular phones (personal exposure) is substantially higher and much more focused (usually on the brain) than exposures from radio/tv towers, antennas, or Wi-Fi. I hope this is useful. Thank you for your interest in our work.*

Sincerely yours,
Robert A Baan PhD The IARC Monographs IARC, Lyon, FRANCE

ROBERT KENNEDY, JR.'S LEGAL TEAM SUES FCC OVER WIRELESS HEALTH GUIDELINES

Robert Kennedy Jr.'s Legal Team Sues FCC – The team includes RFK, Jr., IRREGULATORs' Attorney Scott W. McCollough & Dafna Tachover, CHD's Director of Stop 5G & Wireless Harms

Reprinted with permission from Children's Health Defense, Inc.

February 18, 2020 (San Diego's East County) -- Robert Kennedy, Jr., Chairman of Children's Health Defense (CHD), is committed to be proactive on the concerns regarding excessive exposure of our children to 5G and wireless radiation. To fulfill this promise, CHD submitted a lawsuit on February 2, 2020 against the FCC for its December 4, 2019 decision to decline to review its 1996 guidelines, and for its determination that the guidelines are protective of human health.

To have the best chances of succeeding, they have assembled a team of attorneys to lead this case. Each one brings different strengths to the case:

Robert F. Kennedy Jr., CHD's Chairman, is a leading Environmental Attorney who has been involved with many groundbreaking lawsuits including the recent successful cases against Monsanto. He was a senior attorney for the NRDC and now leading cases for the protection of children's health rights.

Scott W. McCollough is the Attorney who is representing the **IRREGULATORS** in their lawsuit against the FCC, a case that will help expose a multi-billion-dollar fraud by Telecom companies. Scott has decades of experience as a Telecommunications and Administrative Law Attorney, leading the type of lawsuits we are submitting against the FCC.

Dafna Tachover is an expert on wireless and 5G health effects and has recently been brought on board at CHD to spearhead the Stop 5G effort. Dafna brings specialized knowledge and experience for this case. She is an Attorney, and holds a MBA, and has a Telecommunications background. She has been involved in cases focusing on wireless harms including a Supreme Court case in Israel against Wi-Fi in schools, a case that led to the first limitations on Wi-Fi worldwide!

About The Case

On December 4, 2019, the FCC adopted an order affirming the adequacy of their 1996 wireless radiation exposure safety guidelines. These guidelines are at the core of the fraud perpetrated on the public that wireless technology is safe. Their guidelines ignore the overwhelming evidence of harm, scientific and human. By adopting and maintaining irrelevant guidelines, the FCC has enabled and forced the uncontrolled proliferation of wireless technology and now 5G. This has led to a growing epidemic of sickness among children and adults, and it has caused harm to animals, plants and the ecosystem at large.

In 2012, the General Accountability Office of Congress published a report, recommending that the FCC reassess its 1996 guidelines. As a result, in 2013, the FCC opened docket 13-84 asking for public comment. This docket was open for 6 years. On December 4, 2019, the FCC officially closed the docket and affirmed the adequacy of its guidelines without proper assessment.

Now that the docket is closed, they [are] suing the FCC under the Administrative Procedure Act (APA). The petition will ask the court to set aside the FCC order, asserting that the order is arbitrary, capricious and an abuse of discretion. **The case had to be submitted by February 3rd.**

Barrie Trower, former Cold War spy debriefer and academic, warned members of the Irish Doctors Environmental Association (IDEA) about the dangers of microwave based communications systems.
Image courtesy of Jim Ronan, Stresscare.ie.

Cites end of national sovereignty

Expert tells doctors of impending tragedy from EMF radiation as health of nations laid waste by technology

Barrie Trower lives in a world different to the rest of us. His world is every bit as dangerous as anything Tolkien could have dreamed up and with each passing day inches closer to engulf us. Very occasionally he surfaces to warn us but returns back to his world largely ignored.

While his words are reasoned and motivational - much like Tolkein's wizard, Gandalf - Trower is stoically centered. He sat alone for more than a hour waiting to address the annual general meeting of the Irish Doctors Environmental Association (IDEA) amid stacked chairs against the stark white walls between two tall Georgian windows with only a glass of water molecules to bring clarity before speaking to the group.

A lecturer in Advanced Physics at South Dartmoor College and living in a village in rural Devon - not unlike Tolkein's beloved Shires - Trower has travelled to 27 countries around the world explaining the unseen wonders of physics and the perilous ways mankind is commercially exploiting the invisible for profit and political power.

From the outset, Trower is courageous. Here is a truth-teller, not just an ordinary whistleblower, but a man who came out of retirement with a warning for all humanity. "I'll tell you very briefly where I'm coming from very before I start," began Trower, "In 1959 I studied my first paper on microwaves for my entry examination into the military. I studied all aspects of microwaves in the military - radar, health issues. Microwaves then were being used, as they are today, as stealth weapons. Stealth weapons specifically to cause severe neurological and physiological damage. There never, ever was any safe level of microwave radiation." Trower began his career with the British Royal Navy before his peacetime duties with the Secret Service. In addition to his experience he is uniquely

qualified to discuss microwaves due to education with a degree in physics, a second degree in research, as well as a teaching diploma in physiology.

Common sense tells us electricity is dangerous. Less generally known are the principles surrounding magnetism which, according to experts like Davis and Rawls in their book *Magnetism on Its Effects on the Living System*, can be equally dangerous. Combine the two principles, electricity and magnetism, into electro-magnetic frequencies (EMF) and there is a recipe for untold misery, pain, death and destruction. Electromagnetic frequencies (EMFs) are the signals used in modern communications systems, from the billions of cell phones and masts that service them to the pulsed signals of WiMAX and Tetra which are stronger still.

Although Trower came to the subject late, the Russians had been studying microwaves from as early as 1920, according to Czech writer Mojmir Babacek, founder of the International Movement Against Manipulation of Central Nervous System. Babacek told *El Spectador* that Russia was well advanced in the 20's investigating phenomena such as telepathy, telekinesis and clairvoyance, and that during the 60's and 70's there existed a real arms race between Russia and the U.S. in this area which supports Trower's explanation of debriefing victims for the British military - cold war spies - following their microwave radiation exposure. And as recently as April 2013, Russian President Vladimir Putin admitted that Russia plans to ramp up its arsenal with the development of "psychotronic" weapons.[1]

"Following my time in the military - we're into the cold war here - and those of you who remember the Cold War it was a very, very tense time for the world, I can specifically remember two occasions when we were within one second of total global nuclear war. A part of my job when I left the military because I had microwave knowledge, and they were being used as weapons, was to question captured spies or agents which I did for eleven years and in my defense and, might I please say, that the program, run by Sir William Melville, I never used pain, humiliation embarrassment, drugs, hypnosis, nothing. I treated the ladies and gentlemen as I would talk to you. It was nothing more than a conversation over a cup of coffee."

Melville is the real 'M', founding father of MI-5 and the inspiration for Ian Fleming's character in James Bond books and films.

Trower explained that during the Cold War, less than 20 years after the death of Nikola Tesla, the genius of electricity, and less than 15 years after the end of WWII, governments were already researching the effects of pulsed microwave signals in the 1960's. "I gathered the information," he said, "because different pulsed systems were being used to cause different neurological and physiological damage." As a former insider Trower is giving first hand fact-based evidence that microwave signals and radiation cause damage to living organisms and the built environment. Furthermore he is living testimony that governments have used that evidence to inflict pain and suffering on their opponents.

Trower claims that there is no defense against a microwave assault and that by alternating pleasure and pain frequencies broadcast from a van parked nearby "anyone can be broken in 30 hours." His statement is backed up by Drs. P.D. Whissell and M.A.

---

[1] Staff writers. *Russia working on electromagnetic radiation guns.* Herald Sun. Melbourne, Au. 4 April 2013. *http://www.heraldsun.com.au/technology/sci-tech/russia-working-on-electromagnetic-radiation-guns/story-fn5iztw3-1226317396841*

Persinger of Laurentian University, Ontario. who said in a 2007 paper, that "experiments showed a role of opiates in simple and pulsed EL-EMF response, but opiate-like effects induced by VHF-MF and microwave (MW) field also exist and have been characterized for more than a decade."[2]

Trower's testimony flies in the face of "Product Defense Consultant" Dr. William H. Bailey, advisor to the Irish government, power companies in Nevada and British Columbia as well as companies like Toyota that experience electromagnetic interference with their services or manufactured goods.

Shortly after embarking on a career in education, Trower explained that he was contacted by a police authority in the U.K. to review the literature and explain the implications of the proposed switch to a new communications system using Tetra technology - a microwave signal developed by the Motorola Corporation, a major U.S. military contractor based outside of Chicago, Illinois. "That resulted in me being commissioned to write the first safety report on the Tetra system for the emergency services which I condemned," said Trower. "Nine years later I was approached by another police union with the increased cancers and other neurological problems, saying would I update my report which I did."

Before launching into proof that low level microwave radiation causes disease and death, Trower said that he has never charged for his public engagements because once you accept money you can be told what to say and, secondly, even the poorest can afford to hear his message. The idealism of Trower's position is growing around the world against what is becoming increasingly the most powerful industry on the planet. While her husband has endorsed the electromagnetic Smart Meter, Michelle Obama, quietly contacted Trower for information through an agent in New York. After all, she has two daughters to protect. The hand that rocks the cradle may, yet again, rule ...

"Let's deal with the most important question first," he said as he stood behind a pile of documents neatly grouped and tied with string. "With low level microwaves, and lower level is actually more dangerous than a high level, with low level microwaves is there any proof? Let's deal with the proof argument first. More than you would probably imagine - there are 8,300 military papers proving microwaves cause severe neurological and physiological damage. There are seven high court cases now against the industry showing that they will cause this. There are 12 epidemiological studies. There are another 19 legal judgements around the world - by mayors, magistrates or people who have the ability to make a legal judgement. The industry themselves, this is what they say about the microwaves that children are walking around using."

Trower quoted a document prepared by the German Ecolog Institut on behalf of the T-Mobile holding company for Deutsche Telecom with its estimated 150 million customers world-wide. Reading from Section 7 of the document, Trower bridged direct quotes from the Ecolog study with his own links, "These are their actual words. 'It can be concluded that electromagnetic fields used in the mobile telecoms range do play a role in the development of cancer'... On the cellular level, a multitude of studies found these waves can induce the cancer initiation, cancer promotion agents to act in the body. 'DNA

---

[2] Whissell, P.D. and Persinger, M.A., Emerging Sunergisms between Drugs and Physiologically-Patterned Weak Management Fiels: Implications for Neuropharmacology and the Human Population in the Twenty-First Century. Current Neuropharmacology. 2007. P. 279.

synthesis and repair mechanisms' for continuous or pulsed fields can influence or directly damage the DNA.'"[3]

Trower referenced the ruling of an Italian court against the microwave industry. "I had to read this a few times just to believe it ... it was in the transcript of the judgement against the industry for cancer, and it actually states that if you use a cell phone five to six hours a day for 10 - 12 years you are more likely to develop ipsilateral cancer, that is from the direction of the source of the radiation, you are more likely to develop ipsilateral cancer than the survivors of the atomic bomb in Japan in 1945. There is no doubt microwaves are causing cancer, neurological and physiological damage. No doubt." said Trower.

If microwave radiation is causing so much damage, why is the public so unaware of the dangers? Before answering the question, Trower again lists the effects from still more sources - some top secret:

- TOP SECRET: From a U.S. conference, 1986. "Concerning low level microwaves, we can change behaviour of cells, tissue... Whole organisms have a six times higher fetal mortality rate, birth defects and induce malignant tumours in human cells."

- TOP SECRET: Course No. 11, 2001-07. "Students (scientists) will be familiar with current knowledge, ie. cancer, memory, brain function damage to the eye, skin, birth defects from low level microwave radiation."

- TOP SECRET: Naval Medical Research Institute: *Biological and Clinical Manifestations Attributed to Microwave Radiation (Low-Level)* which lists 2,000 medical references with the main paper, *Altered Menstrual and Fetal Development*.

- TOP SECRET: World Health Organization (W.H.O.), 1973. Biological Effects: Health and Excess Mortality from Artificial Irradiation of Radio Frequency, Microwave Radiation. The paper was the result of a symposium held in Warsaw and has been referred to by experts such as Dr. Magda Havas, Trent University, Canada, Henry Lai, of the University of Washington and by the Seletun Declaration signed by Prof. Olle Johansson, of the Karolinska Institute, among others.

"The damage caused by microwave radiation is irrefutable," says Trower, "There never is any doubt. There never was."

In reference to the Warsaw document, Trower held it high, telling the audience, "Again, top secret paper. This is a surprise This is actually from the World Health Organization and it says *Biological Effects: Health and Excess Mortality from Artificial Irradiation of Radio Frequency, Microwave Radiation*. They list pages upon pages of ill effects and when the W.H.O published this it was stamped Top Secret and hasn't seen the light of day since."

As it emerges from the shadows of secrecy, the document is becoming a cornerstone of the global reaction to microwave radiation, giving credence to the fact that dangers to human and animal health were established more than 40 years ago and that the evidence has been suppressed. In a sworn affidavit to the State of Oregon, Trower told the court

---

[3] http://www.hese-project.org/hese-uk/en/papers/ecolog2000.pdf. In context: " it can be concluded that electromagnetic fields with frequencies in the mobile telecommunications range do play a role in the development of cancer... Direct damage on DNA as well as influences on DNA synthesis and DNA repair mechanisms were demonstrated"

that health effects from microwave radiation had been noted as early as 1932 when it was called "radiowave sickness".

A 2006 Freedom of Information request by Donald Friedman of Napa, California[4] supports Trower implicitly. The buried document revealed both the theory and practice behind inducing neurological events from subjects "hearing things" - the Frey Effect - to suffering epileptic seizures of varying severity.[5] The U.S. Army document, *Bioeffects of Selected Non Lethal Weapons*, which notes that human beings have been used as guinea pigs and the physical effects are a reality, states:

> Human subjects listened to very high levels of low-frequency noise and infrasound...Two minute duration as high as 140 to 155 dB produced a range of effects from mild discomfort to severe pressure sensations, nausea, gagging, and giddiness. Effects also included blurred vision and visual field distortions in some exposure exposure conditions..."

Naturally, by virtue of the fact that Friedman had to officially request the document and that it was originally labeled "Secret Noforn" until it was stamped unclassified clearly indicates that information is being suppressed and kept well away from public scrutiny. The label "SECRET NOFORN" means documents are designed to never be shown to non-US citizens.

According to Trower, the reason is simple. "The question is, 'Why?' Why has all of this damage which is known to be caused to children, why is it being suppressed? And the answer is here," said Trower, holding before him yet another document.

"And I have said this was incredibly top secret. It is from the United States Defense Intelligence Agency. It's dated 1971 and basically they list all of the illnesses which you can expect at this time from low level radiation including blood-brain barrier damage but it is the first three lines which I think are the most dangerous lines since the declaration of war and it's certainly going to cause more casualties.... Those three lines of text from the U.S. Naval Centre are telling indeed: 'If the governments of the more advanced nations of the West are strict in enforcement of stringent exposure standards, there could be unfavourable effects on industrial output and military effects.'[6]" The possibility / probability of costly law suits moved Swiss Re to refuse insurance to companies using microwave

---

[4] *Bioeffects of Selected NonlethalWeapons.* 1998. "Application of electromagnetic pulses is also a conceptual nonlethal technology Uiat uses electromagnetic energy to induce neural synchrony and disruption of voluntary muscle control. The effectiveness of this concept has not been demonstrated. However, from past work in evaluating the potential for electromagnetic pulse generators to affect humans, it is estimated that sufficiently strong internal fields can be generated within the brain to trigger neurons. Estimates are that 50 to 100 kV/m free field of very sharp pulses (~ 1 nS) are required to produce a cell membranic potential of approximately 2 V; this would probably be sufficient to trigger neurons or make them more susceptible to firing. The electromagnetic pulse concept is one in which a very fast (nanosecond timeframe) high voltage (approximately 100 kV/m or greater) electromagnetic pulse is repeated at the alpha brain wave frequency (about 15 Hz), It is known that a similar frequency of pulsing light can trigger sensitive individuals (those with some degree of light-sensitivity epilepsy) into a seizure and it is thought that by using a method that could actually trigger nerve synapses directly with an electrical field, essentially 100% of individuals would be susceptible to seizure induction." http://www.kat97305.byethost3.com/Bioeffects_of %20Selected_Non_Lethal_Weapons.html

[5] http://sigint.files.wordpress.com/2008/02/bioeffects_of_selected_non-lethal_weapons.pdf

[6] Army Medical and Information Agency. Defense Intelligence Agency. Report No. DST-181 0S-074-76. March 1976.

technology. The risk-averse insurance sector bases it's assessment on risk, the concept explored by Australian Don Maish in his book, *The Procrustean Approach: setting exposure standards for telecommunications frequency electromagnetic radiation.* Maisch was savaged by the legal team representing FortisBC during hearings in British Columbia in March 2013 to consider deployment of the contentious Smart Meter. The contentious William Bailey, naturally enough, testified on behalf of the industry.

Blame for the paucity of public safety standards rests with the U.S. government, claims Trower. "The United States government are advising Western governments, namely us, to have such a relaxed safety level that the industry can never be taken to court," he said. "They also say that if we don't it will have a disastrous effect on industrial profit and, of course, line them up for law suits. Following this, if the American government says 'Jump', the English government says, 'How high?'"

Trower explained that the English government adopted a six-minute heating effect as the official standard and the rest of the world followed suit. There is, however, ample evidence of global financial interests bringing enormous pressure to bear. Names like Motorola. Westinghouse, JPMorgan and Rockefeller litter the resume of Nikola Tesla, the undisputed pioneering genius in the application of electricity and magnetism. Indeed, it was Tesla himself who alerted President Franklin Roosevelt of the theory behind creation of a death ray to end WWII and all wars while a friend petitioned Eleanor Roosevelt for financial help for the inventor who died penniless in January 1943.

Trower's assertion regarding the arbitrary adoption of the heating or so-called "Thermal Effect" caused by microwaves was expressed as early as 1981 by the World Health Organization. Titled *Environmental Health Criteria 16, Radiofrequency and Microwaves,* the report notes, "Thermal mechanisms seem wholly inadequate to account for the results of studies indicating that cerebral tissue, exposed to weak electromagnetic fields, responds only over a limited range of intensities and modulation frequencies of the RF carrier field. There appears to be evidence for both amplitude and modulation frequency windows, outside which effects are not observed."[7]

"And that is still the only standard today," said Trower, "six minutes of heating. In other words, providing you don't feel too warm, after six minutes of being near a transmitter or on the phone or whatever, it is deemed safe, that is it. That is the only safety level and today in the U.K. and the United States they'll have got away with that."

In Canada, Dr. Havas[8], of Trent University, Ontario, forced admission from health authorities that while they say they are using standards below the Thermal Effect, they are at wide variance with practice. In February 2013, Havas reported: "I just returned from a hearing in Montreal in front of the Superior Court of Quebec where Health Canada scientist, James McNamee, admitted that the Safety Code 6 guideline for microwave radiation (which includes radiation from most of the devices we are concerned about like mobile phones, cell phone antennas, Wi-Fi, wireless toys and baby monitors, smart meters etc.) is based ONLY on preventing a heating effect! Let me state that again. Health Canada admits that Safety Code 6 for frequencies between 100 kHz and 300 GHz are based ONLY on heating."

[8] http://www.magdahavas.com/health-canada-admits-safety-code-6-guideline-for-microwave-radiation-is-based-only-on-thermal-effects/

Trower is right again and Dr. Havas proved it.

Limits don't protect children

The problem with heating standards, if they can be called standards at all - except in a microwave oven - is the vulnerability of children. Tolerance is a more appropriate term. "Children are much more vulnerable than adults," says Trower, "for two reasons: one, they have a higher water content in the body which means they absorb around 10 times more radiation than adults and the other is that the mitochondrial DNA suffers 10 times more stress than other bodily DNA. If you look at the child, the child is taking a 20-fold increase in danger than adults. This is also before we get onto their size.They also absorb more radiation because they are nearer the size of the wavelength and they act as aerials."

In a court deposition presented in Portland, Oregon in 2011, Trower explained the phenomenon of children as aerials. "Children act like antennas and absorb more radiation than adults because they are smaller, and their very dimensions approximate the deployment's wavelength."[9]

As Trower explained it in Oregon, "A basic receiving antenna can be thought of as an apparatus that converts electromagnetic waves into electrical current. It turns out that the human body is also a very effective antenna over a broad frequency range. As an electrical conductor, when exposed to electromagnetic fields, it behaves as an antenna with a frequency resonance determined by various factors including height, posture, etc. Children are not merely small adults. They are physiologically and neurologically immature; their systems have not yet formed. Microwave radiation alters the blood-brain barrier so that toxins leak into the brain. This can cause neurologic and psychologic amongst many other problems more easily in children. A child's immune system, which fights off infection, takes 18 years to develop. Additionally, 122 layers of protein - myelin - insulate the electrically generated signals used by the nervous system to control muscles and organs. These layers of protein take 22 years to develop. MW radiation has been shown to affect protein synthesis. This could lead to muscular dystrophy-like symptoms in later life."

Trower's greatest concern about children is the fact that the blood-brain barrier in the human brain does not completely develop until the age of 18 months. "The blood brain barrier has been known to enlarge and let toxins in and out of the brain," he claims. "That takes 18 months before it is even made. Similarly the myelin sheet protein synthesis is known to be interfered with as well as the marrow within the bone which has a high water content"

Protect your daughters

"I want to talk at length about one particular problem which I believe is very, very important," said Trower, asking the audience to imagine themselves as young girls sitting at their school desks being irradiated by wi-fi, laptops and electronic tablet textbooks. "The problem with children and I think it is the most important question or topic now to deal with

---

[9] See example of humans acting as antennae: Cohn G, Morris D, Patel S, Tan D, Your Noise is My Command: Sensing Gestures Using the Body as an Antennae, http://research.microsoft.com/en-us/um/redmon d/groups/cue/publications/chi20 ll_rfgestures _cohn. pdf:

microwaves," he explained "With all of the research papers, the first thing that springs to mind (and I've already read them) is birth defects and we're looking, not just in humans, but right across the mammalian species, right across the planet. To explain this I need to keep it simple for myself. I would like you to imagine, please, that you are all five years old and you are all girls and you're sitting in a classroom and a wi-fi is plonked in front of you ...

"The wi-fi is transmitting as is the router on the wall. Now the wi-fi is transmitting generally through your ovaries and you have around 400,000 ovarian follicles - not fully developed - sitting there. They are being irradiated. Let's move the clock forward to the point where you are now 18. You have been through many years of having your ovaries irradiated. And let's say now you are 18 and you are pregnant and I have taught many pregnant students. In the first 100 days of your embryo the embryo is developing its own ovarian follicles. By 100 days, as you will probably know, they are virtually formed. " said Trower.

The ovarian follicles of the 18-year-old have been damaged and this damage is passed down to her daughter and her daughter. In short, the stage is being set for a catastrophe unseen before in human history.

"They have no defense mechanism at all against microwaves," said Trower. "There is no Protein 53 which are four protein structures. There is no nuclear core complex. Those are defense structures we have developed through evolution to protect us against electric storms when we were living in caves. They have nothing. So the ovarian follicles of the embryo and the mother may not even know she's pregnant at this stage - the ovarian follicles have no defense mechanism - and what we are looking at is when your child is born, which may or may not have genetic damage, it is that child's birth where the real problem is going to come out. And we are already seeing this with other mammalian species and if you're wondering how many people are going to be involved - there is only one paper I know of in the world written by a professor, oddly enough, by an advisor with the W.H.O. and he found when women were being deliberately microwaved the rate of stillbirth, miscarriage, genetically damaged children was 57.7 percent and this was at a level of radiation lower than a child would get in a classroom with 20 wi-fis (desktop units). We know a minimum of 57 percent. Now that's the good news."

The mitochondrial cells are where the cell takes in nutrients, breaks it down to create energy at the cellular level. Thus, if the mitochondrial cells are damaged, the cell can not function properly. Logically, when this occurs in the cells of ovarian follicles, eggs will not be healthy or even produced. At a personal level, infertility is unfortunate. At a social level, where a country needs healthy workers to prosper, damaged embryos can lead to widespread social problems. On a global scale, the consequences can be catastrophic. Trower is an academic who shies away from politics. He deals in theory.

Trower's assertions are, however, supported by sound science from researchers such as Prof. Olle Johansson at the Karolinska Institute in Stockholm who posits that after five generations, laboratory animals became infertile. As for DNA damage, Dr. Dimitris Panagopoulos at the University of Athens proved DNA damage to annoying creatures such as fruit flies. In a recent paper, Panagopoulos reported:

> ... external EMFs of varying/alternating nature, modulated and pulsed fields such as those associated with modern wireless telecommunications or produced by power lines, would not be expected to have beneficial action. Rather as demonstrated in the present chapter, these can be expected to be detrimental even at intensities thousands

or even millions of times smaller than those of the current exposure limits. Ways of direct and indirect electromagnetic interaction between environmental fields and living systems are described in the present chapter.

"The bad news, as most of you will know," said Trower, "is that the mitochondrial DNA is irreparable. So what we're saying to your children is if we damage your mitochondrial DNA it is their children and their children and their children. As long as there is a female line you will have this genetic damage. So, by putting wi-fi in school classrooms, what you're actually doing is sentencing 57 percent of your children to some form of birth defect forever. This is where the joke stops. It isn't a decision we have the right to make."

Ireland's Minister for Education and Skills, Ruairi Quinn, T.D., disagrees. An architect and town planner, Quinn was quoted in February, 2013 by Breakingnews.ie, saying, "All of our (European Union) classrooms, right across the 27, soon to be 28 member states, have to embrace that technology because the rest of the world is doing so and we have to do so as well. It won't change education per se, but it will change the way in which we do education."

Mr. Quinn was proved wrong a month later when the French Assemblée Nationale voted to keep radiofrequency electromagnetic fields away from schools. As part of an amendment to the bill for the 'rebuilding the schools of the Republic', MPs voted to promote wired Ethernet connections in schools and not wi-fi, supporting the precautionary principle and protecting children's health.[10]

In addition to France, the Public Health Department of Salzburg has warned that wi-fi should not be put in schools or nurseries. The Austrian Medical Association is lobbying against the deployment of wi-fi in schools. In a letter to the parents of Salzburg, Dr. Gerd Oberfeld, who addressed the Irish Doctors Environmental Association two years ago, said, "Based on first empirical evidence from sensitive people, the signal seems to be 'very biologically active' The symptoms seen so far are the same seen in base station studies: headaches, concentration difficulty, restlessness, memory problems etc.The official advice of the Public Health Department of the Salzburg Region is not to use WLAN and DECT in School or Kindergardens." WLAN is an acronym for Wireless Local Area Network or the ubquitous wi-fi proposed for Irish schools and DECT stands for Digital European Cordless Telecommunications, the wireless phones found in homes and offices.

In Germany, too, the Bavarian Parliament has recommended that no schools in the province use wireless LAN (Local Area Network) networks. The Frankfurt City government said that it would not install wi-fi in its schools until it had been shown to be harmless.

From Russia, Prof. Yury Grigoriev, a member of the WHO International Advisory Committee on EMF and Health, said, "The short-term and long-term potential consequences for society from exposing children to microwave radiation from cellular communication devices must be immediately acknowledged globally, and responsibly addressed."[11]

---

Emanuel Institute of Biochemical Physics, Russian Academy of Sciences, Moscow, 119334 Russia. 2011. http://electromagnetichealth.org/electromagnetic-health-blog/russian-res-children-emf/

In North America, David Morrison took court action to block wireless in schools in Oregor, he explained, "I brought a federal law suit against the school board of Portland OR. for installing wi-fi in the schools. The suit was based on 14th amendment rights to a safe environment for my daughter's education. My research led me to Barrie and he generously agreed to be a witness in our action. As a result we traveled to London to meet him for depositions and at another time spent three days interviewing him. The suit has been defined by the judge as a complaint against the FCC and not suitable for the courts. Of course it was an easy out for the judge. We are now preparing an action to reignite the case."

Support for Trower and a growing numbers of experts is growing around the world.

Trower's unmet challenge

It is at this point that Trower issues his first challenge - one that has never been taken up anywhere he has spoken, whether on television or at public meetings. "Now I have been right around the world lecturing and in every country in the last however many years," he said, "When I appear on television or radio I make a challenge and I say what I want. I want this country's top scientists, government scientists, industry scientists, I don't care how many there are...I want them to humiliate me live, on air, and would they please come and do it. I have one question, just one question. What is the safe level of microwave irradiation for the ovarian follicles of an embryo? Drug companies can tell you if they have produced a drug for a child but to date in all of the years in every country not one person will meet me live on television and tell me, not one And the reason is there isn't one. I know there isn't one because there can not be. There isn't one. My reaction is, well, Why are we putting wi-fi in schools? Simple as that."

Statistics

Trower relentlessly throws out statistics. When transmitters went up there were 200 cancer clusters in schools. The Council of Europe is recommending wired systems in schools. Eight other countries are negotiating or taking wi-fi out of schools.

"Unicef, a charity, the children's charity that I think is beyond reproach," noted Trower, "they did their own survey research for children and they found there was an 85 percent increase in central nervous system disorders, a 36 percent increase in epilepsy, 11 percent in psychiatric problems, 82 percent in blood / immune disorders in children and risk to the fetus," he said. "Recent news came in within the last few days, how big a part I played in this I don't know, but I have been in touch with various people over there, but 60,000 pediatricians in the U.S. have petitioned Congress to take wi-fi out of schools. 60,000. That is not a small body of knowledge. If you add that to the 40,000 similar bodies who signed the Freiberger agreement - hospital consultants and people like yourselves - we have 100,000 of the most educated professionals in the world - probably the most educated professionals in the world - 100,000 saying, 'Protect our children and get wi-fi out of schools'."

"In China, parotid cancer from the cell phone - up 3,000 percent. Other countries are now listing huge increases in childhood brain tumours," said Trower. "They are actually saying it is down to cell phones. Neurologically, and it is published here in the *Journal of Neurological Science*, on tens of thousands of children explaining why low level microwaves are causing all of the neurological problems they are in children. If you think of

some of the chemicals, just a few of them, whizzing around the brain, anandimide, encephalin, orexin, the balance between the frontal cortex and the amygdala, the frontal cortex and the ventral paradigm if you look at those and I'm going down from the morphine substitutes, the marijuannas, the severe hunger, the severe hopelessness and the severe anger just with those alone...

"The current used by that part of the brain to release those chemicals into the brain is around 2 milliamps. Under certain conditions, ordinary everyday conditions, that can be increased 17-fold by microwaves. 17-fold. It's not surprising when you have neurological papers saying it's causing this or it's causing this or this or this. We know it's going to because it's been used in stealth warfare to do this. So we know it but it can be increased 17-fold under normal, everyday household conditions." he said.

Trower displays photographs of a woman who carried her cell phone in her bra. He admitted that one woman suffering a breast tumour does not prove the cause of her tumour was where she placed her cell phone. "But," noted Trower, "I have on a disc in here, I have 45 peer reviewed research studies showing that the breast tissue is particularly sensitive to microwave radiation. Women suffer more than men because they have 13 circadian rhythms / frequencies in their bodies in which microwaves interact with that men don't have. They have much more complex hormones, again which are more susceptible to women so women do suffer more than men and obviously girls more more than boys."

It is relevant to note that University College in Dublin hosted a series of seminars supported by the Irish Cancer Society to address the issue of female breast cancer in October, 2012. The issue of microwave radiation was not included in the the group's focus, however, psychotherapy was. It is also relevant that the Irish Cancer Society is heavily supported by the microwave industry.

ICNIRP

In addition to the intentional suppression of evidence, there is the contentious issue posed by recognition of the Thermal Effect and standards issued by the International Commission on Non-Ionizing Radiation Protection (ICNIRP). It is a high-sounding title which wreaks of Orwellian *Newspeak*. "Some of the countries I have been to have asked where can we go from here? Can we actually fight the industry? The answer is, 'Yes'," said Trower. "Generally what I find when I talk to the people involved in the countries, generally they have been lied to. And if you have been lied to, you have obviously, through barristers and people, a recourse and one of the things that have been thrown in my face right around the world is what they call call the ICNIRP certificate...

ICNIRP was ostensibly established to set standards for public protection under the voluntary *Precautionary Principle*. "When we go to these countries they say, 'Ha' six minutes of heating, but that is not true and this is where the lie comes in. Generally the industry goes to a school or a body and say the levels are up here and we're down here and everything is okay. That is actually not true and I have fought two international cases on this. My first question when I have this thrown in my face is, 'Have you read it?' (ICNIRP guidelines)and to date, again around the world, I have never met a single person who's read the guidelines they are throwing in my face. Well, I have," said Trower.

Again citing official documentation, Trower chokes them with their own admissions. "Here, " he said, "on page 545 it says, for example, some children, the elderly and chronically ill people might have a lower tolerance for the radiation than the rest of the population. They need separate guidelines and they go on to say, even under those guidelines, there will be other people which they call sensitive individuals who need, again, separate guidelines. In other words, the electro-sensitive. And it goes on... Page 546... this is the bit they don't like, it says that decision-makers should read current scientific literature and set an exposure level at a tolerance lower than what is know to be causing illness and that is not the ICNIRP level which is up there. In other words you should set a safety level lower than what is known to be causing illness and they don't do that."

The international battle between the Thermal Effect advocates and those pressing for stricter guidelines and regulations has become heated in Canada where Health Canada proposed that Canadians are protected by vaunted and violated Safety Code 6 Guidelines. The debate exploded when it was learned that those guideline are also based on the Thermal Effect. Jerry Flynn, a former military man like Trower, offers parallel evidence. Flynn, too, is challenging the Canadian government and Dr. David Butler-Jones, chief Public Health Officer of Canada's Public Health Agency.

Flynn, a retired Canadian Armed Forces captain, spent 22 of his 26-years-and-a-day years service in Electronic (EW) and Radio Warfare.. He spent two years as Executive Officer & Operations Officer at an ultra-sensitive radio station directly employing 200-plus specially-trained radio operators and technicians and another two years' National Defense Headquarters, in the Directorate of Electronic Warfare, as the Staff Officer EW for Canada's only Army EW Squadron. He has conducted Electronic Warfare at sea with the Royal Canadian Navy and on land with NATO army units.

Trower, Flynn and the former SAS member Victor Nixon who died last year, age 59, in Idaho, are just three military men to step forward and challenge government. Like Trower and Nixon - each working from separate perspectives and unknown to each other, they challenge authority. Flynn is challenging the health authorities in Canada. "I would like Dr. Butler-Jones to answer for me, please - in unambiguous language - how Health Canada can continue telling the public that they are protected by Safety Code 6 when Canada's own internationally respected and independent National Research Council (who are also based in Ottawa but report to Industry Canada), the Council of Europe (47 countries, 800 million people) and the Russian Federation all say Canada's Exposure Limits - being based solely on thermal effects of EMR/RFR - are amongst the highest, i.e., most dangerous in the world! I would appreciate an acknowledgement of receipt from Dr. Butler-Jones, please," said Flynn.

For military men to step forward to defend themselves and their people against the actions of the governments they served is a remarkable act of courage.

Trower, Flynn and Nixon - all military men - raise the Roman poet, Juvenal's question, "*Quis custodiet ipsos custodes*?" ("Who will guard the guards themselves?"). Indeed, who is protecting the military and the police who are using Tetra.

Nearly imperceptively, Trower is building a case. From his personal history to scientific evidence of experimentation on humans - forbidden by international agreement in the post-WWII Nuremberg Code, he moves to the complex - perhaps purposely so - issue of the disappearance of bees.

Obviously, it's not just people," explained Trower, "there are papers here we are looking at – birth problems and deformities researched by government veterinary clinics and we have something called the Glastonbury Festival in England. Twice I've been the guest speaker for the Glastonbury Festival and I spoke to university professors who are beekeepers and I cited 14 references as to why the bee can not survive in microwaves - or any other flying insects. We have birds are affected and it has appeared in *Nature* for the scientists here it's the cryptochrome mechanism in the brain. There have been further state government studies in cattle with birth defects – horses are particularly vulnerable to everything I've spoken of, whales, and there is a list here, cats, dogs, hamsters and they cite immune system birth problems, just about every animal there is on the planet is going to be affected which isn't surprising because, if you think about it, at the cellular level when you get down to the DNA and the four bases, we are really all the same. And if you're going to affect human cells you're going to affect tree cells, buttercup cells, even germ cells," he said.

"Unfortunately, the situation with the bees is a page out of the playbook that we deal with all the time with the mobile phone industry," said George Carlo[12], an epidemiologist and head of the Science and Public Policy Institute in Washington, D.C. "When the bee story first broke, it was based on a German study that showed information carrying radio waves disrupted the ability of bees to make it back to their hives. Most people in the public don't know the back story, so they do not see the manipulation coming or have the necessary bases for skepticism to see through it."

Carlo attributes the disappearance of bees (or CCD, Colony Collapse Disorder) to five factors: 1) timing, the speed at which the phenomenon has spread; 2) the absence of adequate scientific research to support chemical or biological causes; 3) The factthat microwaves interfere with intercellular communications; 4) the suggestion we are near a saturation point of these waves in the ambient environment with bees as the likely the harbinger or the proverbial 'canaries in the coal mine'; and 5) although there is at least one peer-reviewed study that supports it, the pattern is global which suggests a cause that is globally present.

"Taken together," said Carlo, "EMR is the only explanation that makes sense regarding the disappearing bees: the timing is correct -- the problem has occurred primarily within the past two years....when we have nearly tripled the background level of information carrying radio waves; the pattern is global so that suggests a cause that is globally present; there is at least one peer-reviewed study that supports it, and there is a mechanism documented that lends biological plausibility."

---

[12] Dr. George L. Carlo, Science and Public Policy Institute, 1101 Pennsylvania Ave. NW -- 7th Floor, Washington, D.C. 20004

"In our view, this is a serious 'red flag' of risk that should be heeded. This is yet another example of mobile phone industry orchestration aimed at distracting the public from data that can save lives," said Carlo.

In the winter of 2006-2007, CCD killed 32 percent of America's honeybees. The next winter, another 36 percent—more than a million hives—died. In 2009 Rowan Jacobson, editor of the Art of Eating reported from Vermont:

> "At first I was in denial," Olson recalled. "Then I just felt weak and had to lean against my truck. A year's hard work for naught!" Olson wound up losing all 50 hives that had overwintered in one particular bee yard. That's bad enough, but it pales next to some operations. Adee Honey Farms of South Dakota, the largest beekeeping business in the country, lost 28,000 of its 70,000 hives. That's about a billion bees gone missing. "It's off the charts," said Bret Adee. "It's not a sustainable thing, what's happening now."
>
> At first it looked as though the United States was the sole sufferer of CCD, but the rest of the world quickly reported losses also. "The situation for bees in Europe is no better than for bees in North America," says Bernard Vaissière, a pollination specialist with the French National Institute for Agricultural Research. A report issued last August by the European Food Safety Authority estimates that the UK lost about 30 percent of its honeybees in 2007, while Italy lost 40 to 50 percent. Whatever is taking down bees has gone global.[13]

And it isn't only bees that are disappearing. In the British Isles the ubiquitous Busy Lizzie or Impatiens beloved by millions of gardeners has disappeared from D.I.Y. shops and garden centers - ostensibly due to a fungal attack. Unofficial trials in unaffected areas are proving the plant does not want to germinate. A group of 9th grade school children found the same phenomenon in Denmark. Cress seeds placed next to a wi-fi router did not grow and some of those that did were mutated or died.[14]

"Now again," noted Trower, "very, very recently *Scientific American* published an article of the 27 greatest risks to the planet, I can link low level microwaves to 18 of them direct. 18 of the 27, 67 percent."

Sinister Course

Although Trower makes a concerted effort to avoid politics, he makes what is, perhaps, the most political statement of all – and it is of Biblical proportions. "Now, just to finish off," perhaps literally and figuratively, Trower says, "microwaves are taking a very, very sinister course at the moment. They are used in global weather warfare. A few years ago three papers were published showing that that the greatest contributor to carbon dioxide in the atmosphere now is the communications industry. They put more carbon dioxide into the atmosphere than any other industry even more than the aviation industry. 110 million tones, 29 million cars – that was a few years ago before all your iPods and iPods came along."

---

[13] *Jacobsen, Rowan., The Importance of Bees to Our Food Supply* March/April 2009 http://www.eatingwell.com/food_news_origins/green_sustainable/the_importance_of_bees_to_our_food_supply

[14] http://mastsanity.org/health-52/research/324-experiments-with-cress-in-9th-grade-attracts-international-attention-denmark-16th-may-2013.html

Trower finds himself at the epicentre of conflict between the Global Warming crowd and the Deniers. "Now you may or may believe in global warming, I'm not going into that here," he said, "but one thing cannot be disputed. When you have carbon dioxide in the atmosphere, and it mixes with rainwater, you have carbolic acid. And the carbolic acid comes down into the oceans. And again, *Scientific American* or *Nature*, have published that the acidity of the oceans has reached critical levels for the photosynthesisers in the ocean and they produce about 50 percent of the world's oxygen. A lot of people don't realize that."

... for the punchline he adds, "We are really running the risk of losing our planet."

Trower: The King and I

Were it not so serious, it would be laughable. Trower's observation that if half of the world's scientists are employed by the military, then the scientific world is nearly evenly divided between those who want to help humanity and those who want to harm us. "Microwaves are used in microbiological warfare, atmospheric warfare, environmental warfare," said Trower. "It seems that when you have half the world's scientists engaged by the military, who have nothing else to do but to dream up 'how can I harm someone else' it's not surprising that we have all of these things now. And to finish off, I'm not boasting when I say this, I have probably met around 40 royals, leaders of governments, leaders of peoples, other important people around the world and they started to tell me as I was going around. I was picking up a familiar theme."

A true English academic in a much-photographed green tweed sports jacket and matching everything else in green, Trower is not given to the playfulness of British whimsy or wishful thinking, however he does admit that he had a crystal ball. "And I always wished I was the one who was clever enough to think this up but I wasn't. It was a king who had an Oxbridge (Oxford-Cambridge) law degree and we were having lunch in his garden. He leaned forward and he said, 'I can tell you one thing, Barrie,' he said, 'I am losing the viability of my country.' And then the pieces started to fall in. He said, 'Since the mobile industry moved in I lost a vast number of my insects which means I have to start importing fruits or we get scurvy. We grow vitamin C plants. I'm losing my cattle which means I'll have to start importing other cattle. I'm losing my trees and all my other plants. My people are becoming sick and I have a paper that shows it could be as much as another 40 percent on your health bill. My people are becoming sick which means I'll have to start importing medicines.' He said, 'Now if you think – let's assume you have 10 million cell phone users in my country and the daily bill one euro a day, I'm losing the best part of 10 million euros a day going out. Admittedly tax comes off and they run shops and things but the majority of the money goes out.' And he said, 'Any child who knows how a money box works can tell you that I as a country am going to go bankrupt. Sooner or later I've got to go bankrupt.

"'He said, when it gets worse, he said, the very countries that bring the cell towers in and cause the damage are the very countries - namely the Americans and the Indonesians - He said they are the very countries, the first in, to offer aid, a very generous package. He said, but there is a price for aid., He said they want mining rights, they want mineral rights, they want land rights and they want immigration rights. It's a trickle but it's a non-stop trickle. 'So I have all of this going out and all of this coming in and,' he said, 'I'm going to lose the viability of my country. I might still be king but I will not be king of my country and my people and really that sums it up.'"

Trower's prediction (for Ireland and other countries) is not far removed from the experience the king outlined. "So, if you were to say to me," said Trower, "What's going to happen to Ireland? It's simple, you are going to see an epidemic of birth defects, with livestock and children that will put Thalidomide way into the shade. That is going to happen without a shadow of a doubt. You are also going to lose the viability of your country, that can't be helped as well - unless you do something."

There is a parallel to the king's story in Ireland where the cell phone industry with 5.5 million subscribers is worth €1.65 billion[15] according to the Central Statistics Office. In a country "bailed out" by the so-called Troika of financial interests and where the government pledged to save failed banks to the tune of €70 billion there is ample evidence of the king's saga being repeated. At present, Shared Access, a North American Company founded with backing from from financial powerhouses GoldmanSachs and JPMorgan, is attempting to buy the income stream from farmers who earn an income from having masts on their lands. For a once-off payment to the farmer, Shared Access will acquire all the income and the earnings will be lost to the Irish economy.

The issue is compounded by a relationship with the Irish Farmers Association which has agreed to a confidential arrangement. As a not-for-profit Non-Governmental Organization (N.G.O.) the organization is beyond the reach of government and any business arrangements a completely legal in site of the fact that individual farmers, fee-paying members of the group, are not allowed to ask questions

"What can you do?" asked Trower perhaps optimistically hanging onto an old fashioned concept of democracy. "One suggestion - you may have better suggestions - one suggestion is you get me back here to talk to your full Parliament for one hour. It sounds absurd but other than e-mails and you approaching people. If I could talk to them and I could make them realize the proof. If I could talk to your Parliament it may work. It may not but at least they know what is coming and their children and it is their country and it won't cost them a penny because I work for free. They can't say 'We can't afford it'. I'll even pay out of my own old age pension if that's what they want but it will cost them one hour of their time and that is all."

It all boils down to timing and money. In a time of austerity, money speaks louder than the health and well-being of the population. While Trower's advice may, in the long term be priceless, talk, they say, is cheap - even on a Tetra radio, a cell phone or a wireless network in a classroom.

---

[15] http://www.cso.ie/en/newsandevents/pressreleases/2012pressreleases/statisticalyearbookofireland2012/

While Trower was talking in Dublin...

While Trower was speaking in Dublin, a group of the world's top scientists [16] simultaneously came to a similar explanation and conclusion called the Potenza Piceno Resolution during a conference in Italy.

The resolution underscores Trower's warnings with scientists issuing the following conclusions:

- stricter safety standards for EMF needs to be adopted by governments and public health agencies because the existing ones are obsolete and they are not based on recent literature about biological effects.

- RF sources should be reduced as low as possible because at now it is not possible to establish a safe limit under which no biological effects can be observed.

- RF sources should be kept far from residential areas. For pulsed RF sources, such radars and Wi-Max antennas, the distance from the EMF source should be even greater because they cause more biologically effects than non pulsed signals.

- Wi-Fi should not be placed in schools and in public areas since they have characteristics of pulsed signals.

Five days after Trower gave his testimony to the audience in Dublin, the Federal Communications Commission in the United States waived objections to the use of Tetra in the United States.

Yet another young man, age 23, died in his bed of a heart attack in Ireland. The only country in the world that is monitoring the emergence of a "new" disease, Sudden Adult Death Syndrome (SADS).

It was less than a month after the Sepura company in the U.K. announced plans to deploy Tetra for the first time in North America in Washington State.

Re: ET Docket No. 13-84

Dear Federal Communications Commission Commissioners:

The American Academy of Environmental Medicine is writing to request that the FCC review radiofrequency (RF) exposure limits (reference is made to the FCC's NOI sections 48, 51, 52, 53, 56, 60, 65 and 69), recognize non-thermal effects of RF exposure (NOI sections 66 and 69), and lower limits of RF exposure to protect the public from the adverse health effects of radiofrequency emissions (NOI sections 48, 52, 54, 65 and 71).

Founded in 1965 as a non-profit medical association, the AAEM is an international association of physicians and scientists who study and treat the effects of the environment on human health. With an elite membership of highly trained physicians and clinicians, AAEM is committed to education, public awareness and research regarding Environmental Medicine.

It became clear to AAEM physicians that by the mid 1990's patients were experiencing adverse health reactions and disease as a result of exposure to electromagnetic fields. In the last five years with the advent of wireless devices, there has been an exponential increase in the number of patients with radiofrequency induced disease and hypersensitivity.

Numerous peer reviewed, published studies correlate radiofrequency exposure with a wide range of health conditions and diseases. (NOI sections 54, 59, 60 and 65) These include neurological and neurodegenerative diseases such as Parkinson's Disease, ALS, paresthesias, dizziness, headaches and sleep disruption as well as cardiac, gastrointestinal and immune disease, cancer, developmental and reproductive disorders, and electromagnetic sensitivity. The World Health Organization has classified RF emissions as a group 2 B carcinogen. This research is reviewed and cited in the following attached documents: *AAEM Electromagnetic and Radiofrequency Fields Effect on Human Health* and *AAEM Recommendations Regarding Electromagnetic and Radiofrequency Exposure*.

The scientific literature proves that non-thermal adverse effects of RF exposure exist and negatively impact health and physiology. New guidelines based on measurements of non-thermal effects and lowering limits of exposure are needed and critical to protect public health.

In fact, electromagnetic sensitivity and the health effects of low level RF exposure have already been acknowledged by the federal government. In 2002, the Architectural and Transportation Barriers Compliance Board stated:

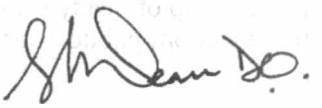
> *"The Board recognizes...electromagnetic sensitivities may be considered disabilities under the ADA if they so severely impair the neurological, respiratory or other functions on an individual that it substantially limits one or more of the individual's major life activities"*

Additionally, in 2005, the National Institute of Building Sciences, an organization established by the U.S. Congress in 1974, issued an Indoor Environmental Quality Report which concluded:

> *"For people who are electromagnetically sensitive, the presence of cell phones and towers, portable telephones, computers,... wireless devices, security and scanning equipment, microwave ovens, electric ranges and numerous other electrical appliances can make a building inaccessible."*

By recognizing electromagnetic sensitivity, the federal government and affiliated organizations are clearly acknowledging the existence of non-thermal effects. The AAEM urges the FCC to recognize that non-thermal effects of RF exposure exist and cause symptoms and disease. (NOI sections 66 and 69) The AAEM also requests that the FCC base guidelines of RF exposure on measurements of non-thermal effects and lower the limits of RF exposure to protect the health of the public. (NOI sections 48, 52, 54, 65 and 71)

Sincerely ,



Amy L. Dean, DO, FAAEM, DABEM, DAOBIM
President

Actual or potential effects of ELF and RF/MW radiation on enhancing violence and homicide, and accelerating aging of human, animal or plant cells.

Dr Neil Cherry
Lincoln University
New Zealand

17/6/98, revised 30/8/02

Abstract:

The brain is a very sensitive Bioelectromagnetic organ sat through classical resonance processes can be halted and damage of external electromagnetic fields and radiation. This review will explore the possibility that this could result in violence enhanced rates of homicide. The evidence that electromagnetic fields and radiation electromagnetic are genotoxic means that exposure to any electromagnetic fields and radiation will enhance cell death (Apoptosis). The natural ageing process involves oxygenated free radicals from the breathing process causing enhanced rates DNA damage, cancer and cell death. Exposure to electromagnetic fields and radiation also reduces melatonin which limits a body's ability to scavenge the free radicals and therefore contributes to enhanced Apoptosis and cancer rates. Melatonin is also necessary for a healthy immune system. Reduced melatonin is also associated depression and suicide and therefore is likely to be associated with violence of homicide. Since electromagnetic radiation damages the DNA and reduces melatonin it is scientifically logical that it also enhances many of the natural paging process in people, animals and plants. These conclusions are strongly supported by robust evidence that natural weather related effects are caused by natural electromagnetic fields and radiation with extremely small intensities. Therefore it is logical and proven that humanly generated fields and radiation at intensities from a thousand to many billion times higher, also significantly enhance a wide range of adverse health effects, including cancer, heart disease, sleep disturbance, depression, suicide, anger, rage, violence, homicide, neurological disease and mortality.

1. Introduction:

1.1 Brief:

This report was commissioned by Bruce Ratcliff on behalf of Ratcliff Company Inc. in a letter dated 30 March 1998, with the following brief:

"We would like to know more about any possible relationship between microwave radiation as given off from relay towers and cell phones and premature, rapid ageing of humans, animals and/or plants. Please see page 22 in Firstenberg report on plants.

We recently had three news events which startled the public here in the U.S. They are listed as follows:

1. One where two apparently normal 11 and 13 year old boys shot and killed 4 people and wounded many others apparently with no known cause.

Started after Installation of Wireless

Violent Crime Is Up For 2nd Straight Year

By Dan EggenWashington Post Staff Writer
Tuesday, December 19, 2006

A surge in violent crime that began last year accelerated in the first half of 2006, the FBI reported yesterday, providing the clearest signal yet that the historic drop in the U.S. crime rate has ended and is being reversed.
Reports of homicides, assaults and other violent offenses surged by nearly 4 percent in the first six months of the year compared with the same time period in 2005, according to the FBI's latest Uniform Crime Report.
The numbers included an increase of nearly 10 percent for robberies, which many criminologists consider a leading indicator of coming trends.
The results follow a 2.5 percent jump in violent crime for 2005, which at the time represented the largest increase in 15 years.
The latest numbers suggest that those results were not an anomaly but rather part of the first significant uptick in violent crime since the early 1990s, according to criminal justice experts.
Many communities, particularly those in urbanized areas, may be headed into a period of sustained crime increases, they said. While no one is certain of the causes, experts cited an increase in the number of young men in their crime-prone years, diminished crime-fighting assistance from the federal government, fewer jobs for people with marginal skills and even the ongoing growth in methamphetamine use in some places.

The numbers come amid heightened criticism of the federal government from many police chiefs and state law enforcement officials, who complain that the Bush administration has retreated from fighting traditional crime in favor of combating terrorism and protecting homeland security. Justice officials dispute those contentions and pointed yesterday to an ongoing study designed to identify solutions to the rise in violent crime.
"This confirms what law enforcement has been seeing and saying on a more anecdotal level: that crime is on the way up," said David A. Harris, a law professor at the University of Toledo who studies crime trends. "While it's still too early to be sure, you've certainly got things pointing in one direction."
One positive piece of news came in the category of car thefts and other property crimes, which dropped 2.6 percent overall. Even that portion of the report contained some bad tidings, however: Burglaries, another key indicator, rose 1.2 percent nationwide.
Homicide and assault rates rose by more than 1 percent overall, while the number of reported rapes dipped slightly.
The FBI's six-month report does not include statistics for the District, which reports crime statistics to the FBI only on an annual basis, officials said. Baltimore's overall violent-crime rate remained unchanged, the report showed. Data for individual states were not part of the analysis.
Rising homicide rates have prompted particular concern among law enforcement officials, and a surge in killings and other violent attacks in the Midwest played a significant role in driving up rates in 2005. But Alfred Blumstein, a criminologist at Carnegie Mellon University in Pittsburgh, noted that, unlike 2005, homicide rates plunged in many smaller and medium-size cities for the first half of 2006.
"Obviously these big cities are accounting for a big piece of the action in this report," he said.
The increase was especially dramatic in many cities of 500,000 residents or more, the FBI report showed, including a 28 percent increase in Houston that appears attributable in part to an influx of residents displaced by Hurricane Katrina in 2005. Homicides in New Orleans, whose population was greatly reduced after the storm, plunged by more than 60 percent in the same time period.

The numbers are certain to increase pressure on the Bush administration, whose detractors say local police concerns have been slighted by the focus on homeland security and counterterrorism.

The Justice Department inspector general's office has reported sharp declines in the number of FBI agents and investigations dedicated to traditional crimes since the Sept. 11, 2001, terrorist attacks. In addition, the International Association of Chiefs of Police says that law enforcement programs at the Justice Department have been cut by more than $2 billion since 2002 and that overall funding for such programs has been reduced to levels of a decade ago.

"We've been looking at some pretty discouraging numbers, and we've always been concerned that as funding decreases, crime rates will increase," said Gene Voegtlin, the association's legislative counsel.

James Alan Fox, a criminologist at Northeastern University in Boston who has been critical of the Bush administration's crime-fighting strategies, said the overall rise in violent crime should be expected given dramatic cuts in assistance to local police and simultaneous increases in the population of males in their teens and 20s.

"We have many high-crime areas where gangs have made a comeback, where police resources are down and where whatever resources there are have been shifted to anti-terrorism activity," Fox said. "It's robbing Peter, and maybe even murdering Peter, to pay Paul."

Justice Department officials have repeatedly rejected such criticism, arguing that the causes and trajectory of the crime increase is still unclear. Nonetheless, Attorney General Alberto R. Gonzales has launched a series of anti-drug and anti-gang initiatives at Justice, and he acknowledged at a crime conference in Boston last week that local police are struggling with "increased responsibilities" since Sept. 11, 2001.

Justice Department spokesman Brian Roehrkasse said yesterday that the department's ongoing study of crime trends in 18 cities will help determine "what is causing this increase" and "which crime-fighting efforts are most effective."

"We are encouraged by the drop in property crime seen in most areas around the country, but we are again concerned about the increase in violent crime in some cities and towns," Roehrkasse said.

Child Commits Suicide after School chooses to do nothing about Wireless Causing Illness

Please watch this short video by Dr. Mallery Blythe. It is a great overview on wireless radiation and addresses the Wi-Fi in school problem with children. Highlighted in our news right now is a lawsuit (many news stations covering it) by a family trying to protect their child, who is being made sick by school Wi-Fi. This presentation is dedicated to ***Jenny Fry***, the 15 year old girl with EHS who recently committed suicide.

Video: Erica Mallery-Blythe, MD at the Commonwealth Club of CA, June 22, 2015 (hd)

NIH Study Finds Cell Phone/Smart Meter Radiation Causes Brain & Heart Cancers

The National Toxicology Program (NTP) under the National Institutes of Health has completed the largest-ever animal (rats and mice) study on nonionizing radiation and cancer. Partial results released on May 26th confirm whole body exposures to low level radiofrequency radiation (RFR) of the type emitted by cell phones, smart meters and other wireless devices and within currently allowable safety limits, are the "*likely cause*" of brain and heart cancers in these animals, according to Dr. John Bucher, Associate Director of the NTP.

The $25 million dollar study planned since 1999 showed one in twelve (12) male rats (8.3%) developed either malignant cancer (brain and rare heart tumors) or pre-cancerous lesions that can lead to cancer. Tumors called schwannomas were induced in the heart, and in the same kind of brain cells that have led to acoustic neuromas seen in human studies. The NTP says it is important to release these completed findings now given the implications to global health. No cancers occurred in the control group.

Dr. Lennart Hardell, MD, PhD of Sweden's Orebro University and an expert witness in the Maine Smart Meter Health Investigation says "*(T)he animal study confirms our findings in epidemiological studies of an increased risk for glioma and acoustic neuroma among people that use wireless phones, both cell phones and cordless phones (DECT). Acoustic neuroma is a type of Schwannoma, so interestingly this study confirms findings in humans of increased risk for glioma and acoustic neuroma. In 2013 we called for upgrading the risk in humans to Group 1, the agent is carcinogenic to humans. It is now time to re-evaluate both the cancer risk and other potential health effects in humans from radiofrequency radiation and also inform the public," says Hardell. "This NTP evidence is greatly strengthening the evidence of risk, is sufficient to reclassify cell phone radiation as a known cancer-causing agent, and confirms the inadequacy of existing public safety limits.*"

Dr. Christopher Portier, formerly with the NTP commented this is not just an associated finding—but that the relationship between radiation exposure and cancer is clear. *"I would call it a causative study, absolutely. They controlled everything in the study. It's [the cancer] because of the exposure. This is by far—far and away—the most carefully done cell phone bioassay, a biological assessment. This is a classic study that is done for trying to understand cancers in humans".*

We have written in Merrymeeting News since 2011about the dangers of radiofrequency radiation from wireless devices, particularly smart meters which bring exposures to rural Maine. Birds, bees, other insects and mammals all show adverse responses to low-level electromagnetic field exposures. As levels of "electrosmog" grow with wireless proliferation not only from land sources but now also space-based platforms, the harbinger of an "Electronic Silent Spring" should alarm anyone who cares about our wildlife and civilization, much the same as Rachel Carson's alarm did in bringing the effects of pesticide exposure to the public eye.

Dr. Jerry Phillips, PhD, is biochemist and director of the Excel Science Center at the University of Colorado at Colorado Springs. An educator and research scientist, Phillips conducted Motorola-funded research into the potential health impacts of cell phones during the 1990s while he was with the U.S. Department of Veterans Affairs' Pettis VA Medical Center in Loma Linda, California. Phillips and his colleagues looked at the effects of different radiofrequency signals on rats, and on cells in a dish. Phillips also testified for health advocates in Maine's smart meter investigation.

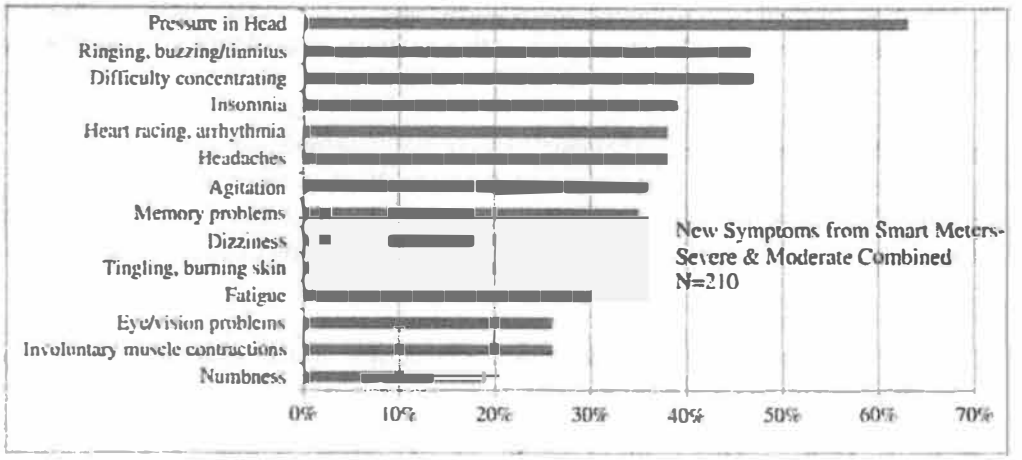
"The most troublesome finding to Motorola at the time is that these radiofrequency signals could interact with living tissues, which is what we saw in the rats," he said in a recent Scientific American interview, adding:

"But you have to realize that this issue opens up a much bigger can of worms than cell phones. If this radiation, this form of energy can interact with biological tissue then it's going to reopen a lot of what were supposedly settled issues regarding the safety of wireless communications. If we're going to be bathed in a whole new electromagnetic environment, how safe is it?"

While cancers from RFR are certainly of great concern, perhaps of greater concern are debilitating non-cancer symptoms disorienting and causing avoidance behavior and other biological and behavioral responses in wildlife and humans. In people,

NTP Study (continued)

relationships have commonly been stressed and destroyed, jobs have been lost and homes of many years sold or abandoned as a result of sensitivities to RFR. Consider if you suffer any or a number of the common RFR symptoms found in an international survey of those affected by smart meters as shown in this chart:



Conrad & Friedman, 2013. Smart Meter Health Effects Survey & Report

Smart meters in particular have sensitized many to any wireless device including routers and cell phones. The inability to use these common tools severely inhibits folks in their personal and economic lives. Their ability to live normal lives in the 21st century has been severely compromised immediately versus 10-30 year latency periods typical in cancer development. This change in ability to use these devices is directly correlated to smart meter exposure.

The suffering and the social and economic effects of chronic debilitating symptoms victims have experienced since smart meter exposure simply cannot be ignored, and provides ample evidence there is something about smart meters (evidence suggests the RF from up to 170,000 transmissions/day is conducted on home wiring) causing extreme harm to at least some, and possibly eventually all persons. While there is obviously only a portion of our population manifesting acute electromagnetic hypersensitivity (EHS) symptoms now (the canaries), and even fewer recognizing their source, we are all being exposed and are all susceptible.

"This is a game changer, there is no question," said Dr. David Carpenter, MD, PhD, director of the Institute for Health and the Environment at the University of Albany and also an expert witness in Maine. *"It confirms what we have been seeing for many years —though now we have evidence in animals as well as in humans."* Quoted in Microwave News, Carpenter went on to add, *"The NTP has the credibility of the federal government. It will be very difficult for the naysayers to deny the association any longer."*

Kennebec and Androscoggin Proposed Critical Habitat for Atlantic Sturgeon

NOAA Fisheries announced June 2, two proposed rules designating critical habitat for five distinct population segments [DPS] of federally listed Atlantic sturgeon. The proposed areas provide important protected river habitats for the threatened Gulf of Maine population segment and the endangered population segments of the New York Bight, Chesapeake Bay, Carolina and South Atlantic. NOAA Fisheries listed the Atlantic sturgeon under the Endangered Species Act in 2012. The two local designations include the Kennebec to Lockwood dam in Waterville and the Androscoggin to the Brunswick-Topsham dam.

The ESA requires NOAA Fisheries [formerly and often still known as the National Marine Fisheries Service or NMFS] designate critical habitat when a species is listed as threatened or endangered. Under the ESA, critical habitat is defined as geographic areas occupied by the species, and containing features essential to the conservation of that species. Critical habitat can also include geographical areas that are not currently occupied by the species, but that are essential to its conservation, historical habitat for example.

Critical habitat does not create preserves or refuges. Instead, when a federal agency is carrying out funding or authorizing an activity that may affect the critical habitat, the federal agency works with NOAA NOAA Fisheries to avoid or minimize

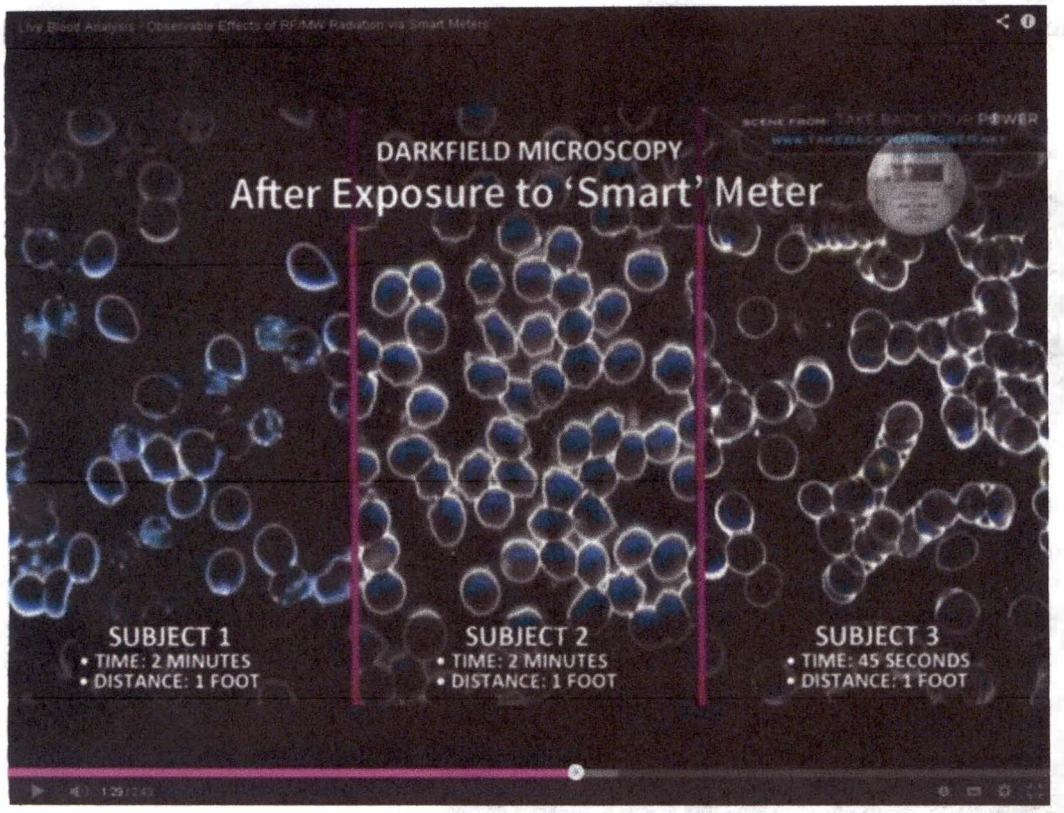
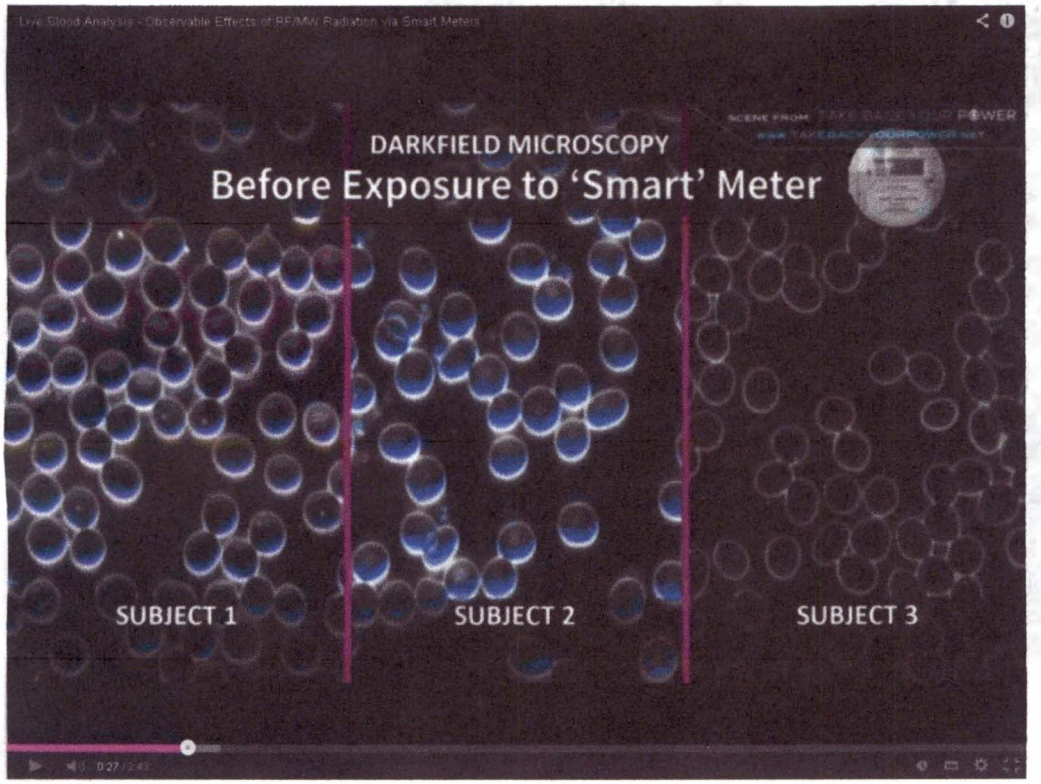
Live Blood Analysis – Observable Effects of RF/MW Radiation from 'Smart' Meter



Live Blood Analysis – Observable Effects of RF/MW Radiation from 'Smart' Meter

The following clip (https://www.youtube.com/watch?v=y4JDEspdx58)
is an excerpt from upcoming documentary, Take Back Your Power – a critical investigation of the Smart Metering phenomenon and Smart Grid. It shows observable effects of the RF/MW radiation from a Smart Meter on human blood cells using dark-field microscopy.
Please watch and and take action to share this information as widely as possible.
More than 5,000 studies now show RF/MW radiation to be harmful to human biology, animals and plants. Acute and chronic exposure to RF (radio-frequency) and MW (microwave) radiation can, even at very low power-densities, lead to not only the negative health effects shown in this video, but calcium ion damage in cells, endothelial cell dysfunction, nitric oxide depletion, oxidative stress, melatonin disruption, blood-brain-barrier leakage, DNA damage, sperm damage and more.
Glucose metabolism changes within the brain are observable after just minutes of cell phone use.

The mechanisms for damage from non-thermal, non-ionising radiation exposure are now becoming clear. Unfortunately, so-called "safety" thresholds maintained in the UK are woefully out of date and obsolete, permitting a deluge of highly-profitable, RF-emitting technologies to be introduced into our lives. Whilst attempts by campaigners in every country are being made to stem and reverse the tide of these environmental toxins, you can take positive action to protect yourself and your family by limiting your own exposure to RF and MW-emitting devices, such as Smart Meters, cell phones, WiFi routers and devices, wireless baby monitors, wireless alarm systems, wireless games consoles, etc.
For more information on Smart Meters, visit www.StopSmartMeters.org.uk. To watch the Take Back Your Power documentary, from 5 September 2013, visit www.StopSmartMeters.org.uk/film
You have the lawful right to refuse a Smart Meter. www.DontSmartMeter.me
Please alert your neighbours, friends and families to this important information.



Electromagnetic Cover-Up

Attempts to water down a US Government report linking exposure to electromagnetic fields to cancer have provoked charges of a cover-up.

A two-year study commissioned by the US Environmental Protection Agency (EPA) has concluded that there is a significant link between exposure to extremely low frequency (ELF) radiation and the occurrence of human cancer. The study group's report *An Evaluation of the Potential Carcinogenicity of Electromagnetic Fields*, was made available in June amid much publicity.[1] However, it has emerged that the conclusions of the EPA assessors have been watered down significantly in the published version of the report, prompting charges of a cover-up.

Early drafts of the report, which were leaked to various sections of the American media, recommended that ELF electromagnetic fields (EMFs) be classified as "probable human carcinogens".[2] The EPA assessors also recommended that radio-frequency and microwave radiation be designated as "possible" carcinogens.[3]

As originally drafted, the summary of the report stated that although the biological mechanisms by which non-ionizing radiation might cause cancer in humans are unknown, animal tests and epidemiological studies "are suggestive of a causal relationship". According to the New York-based newsletter *Microwave News*, the following paragraph concluded the draft summary — until it was deleted in mid-March by Dr William Farland, Director of EPA's Office of Health and Environmental Assessment, the body which prepared the report:

> "Concerning exposure to fields associated with 60 Hz electrical power distribution, the conclusion reached in this document is that such exposure is a 'probable' carcinogen risk factor, corresponding to 'B1' degree of evidence that it is a risk factor. This conclusion is based on 'limited' evidence of carcinogenicity [in] humans which is supported by laboratory research indicating that the carcinogenic response observed in humans has a biological basis, although the precise mechanisms [are] only vaguely understood."[4]

As published, however, the report concludes that studies of leukaemia, lymphoma and brain cancer in children and adults occupationally exposed to extremely low frequency EMFs, "show a consistent pattern of response that suggests, but *[does] not prove*, a causal link." The recommendation that ELF radiation be classified as a "probable human carcinogen" has also been deleted from the officially-released version, as has the recommendation on classifying radio-frequency and microwave radiation as "possible" carcinogens. The deletions were made by Farland because there was, in his judgement, an absence of both a mechanism of interaction and an observed dose-response relationship.

Positive Association

Despite the deletions ordered by Farland, other sections in the report underline the original conclusions. For example, after evaluating the 28 studies of occupational exposure to EMFs, the report states:

> "The occupational studies seem to suggest the likelihood that there exists a positive association of leukaemia and central nervous system cancer with employment in jobs that have a high potential for exposure to EMFs."

And assessing six studies of childhood cancer and EMFs, the report concludes:

> "The case-control studies of children residentially exposed to magnetic fields provide evidence of a positive association of a risk of certain types of cancer, namely leukaemia, central nervous system cancers and lymphoma. Because these measured risks are low in all of these studies the possibility that some unknown confounder is responsible cannot be eliminated. However, because of the consistent positive findings and suggested site concordance, chance is not likely to be the explanation."

Referring to the work of both the Polish researcher Szmigielski, and Dr Bill Guy at the University of Washington, on the effects of radio-frequency radiation, it is stated that:

> "The clear positive findings of Szmigielski et al. show that radio-frequency fields without low frequency components stimulate the growth of tumours and indicate that they may act as a tumour promoter, or a modifying factor in the development of tumours, the role of tissue heating as a mechanism for this effect is not clear."

Comments such as these are the strongest yet made by a US government agency on the connection between human cancer and chronic exposure to electromagnetic fields from sources such as powerlines, visual display units, household appliances, radio broadcast and microwave systems. It is reported that the question of how to deal with EMFs is being debated at the highest levels of the Bush Administration. Indeed, the White House was briefed in early March by EPA officials on the report's original recommendations.

Simon Best

Notes and References

1. Copies of the report can be obtained from: The Environmental Protection Agency, 401 Main Street SW, Washington, DC 20460, USA. Tel: (202) 382-5898. Currently, there are five independent studies on the link between childhood cancer and EMFs being carried out in Europe and North America.
2. *Nature* 345, 7 June, 1990, p.463.
3. Other substances currently listed under classification B (probable human carcinogen) of the EPA's five-fold "weight of evidence" categorization, include PCBs, DDT and formaldehyde, while category C (possible human carcinogen) includes methyl chloride and saccharin. Class A (human carcinogen) includes asbestos and benzene, while Classes D and E refer to lack of evidence of carcinogenicity.

Symptoms after Exposure to Smart Meter Radiation

People from coast to coast in the USA, and from one side of the world to the other, are becoming ill after exposure to the radiofrequency radiation emitted by Wireless Smart Meters. Attached are the results of two surveys of the symptoms being reported.

The first survey comes from the United States and includes 318 adults, from 28 states from California to New York, and addresses wireless utility meters that are principally Wireless Smart Meters. The second survey comes from the other side of the world, Victoria, Australia, and includes 92 adults and children, and addresses Wireless Smart Meters exclusively. Altogether, 410 adults and children are included. Both surveys report new or worsened symptoms after the installation of wireless utility meters in a given individual's environment.

The attached two graphs show the percentage of individuals in each survey who experienced each symptom. The two surveys group the symptoms into somewhat different clusters, but these clusters are similar enough to enable comparison between the surveys. Of the top seven clusters of symptoms in both surveys, six clusters are similar in both description and order of occurrence: (1) sleep disruption; (2) headaches; (3) ringing or buzzing in the ears; (4) fatigue; (5) loss of concentration, memory, and learning ability; and (6) disorientation, dizziness, and loss of balance. Most individuals in the surveys developed multiple symptoms.

The surveys do not tell us how likely a given individual is to become symptomatic after exposure to the radiation from Wireless Smart Meters. But the surveys do tell us which symptoms a person who does become symptomatic is most likely to experience. The many symptoms found reflect the many body systems that are disrupted by such radiation.

A symptom, of course, is something that can be sensed by an individual, and thus can serve as a warning. Unfortunately, many health effects caused by radiofrequency radiation have no early symptoms and thus give no warning. These health effects become evident only after significant harm has been done. Examples are DNA damage, cancer, and reproduction effects.

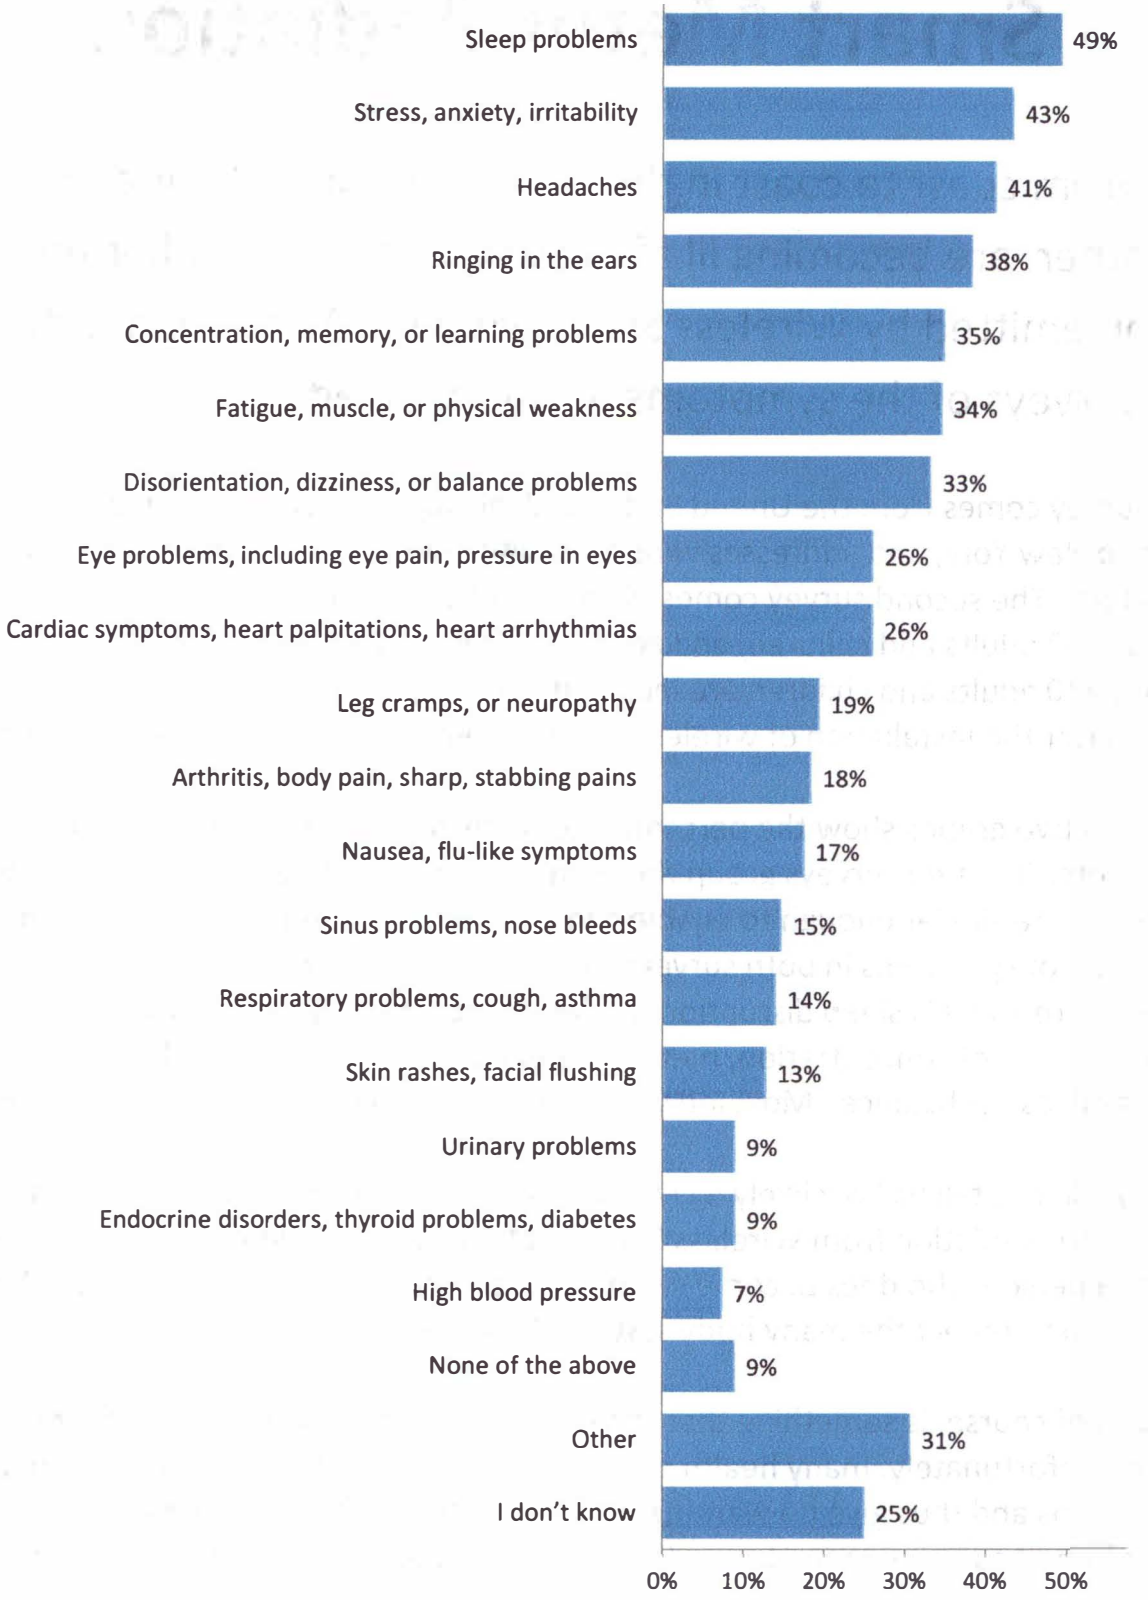
During his Government career, he worked for the Executive Office of the President, the National Science Foundation, and the National Institute of Standards and Technology.

New or Worsened Symptoms Reported by 318 Individuals after Exposure to Wireless Utility Meters in the USA[1]



[1] Ed Halteman, Ph.D., statistics, Final Results Summary: Wireless Utility Meter Safety Impacts Survey, September 13, 2011, p. 22 (http://emfsafetynetwork.org/wp-content/uploads/2011/09/Wireless-Utility-Meter-Safety-Impacts-Survey-Results-Final.pdf). 97 percent of respondents to full survey were in the USA, from 28 states with most in California (78 percent) and New York (16 percent).

Executive Summary by Ed Halteman, Ph.D.
Wireless Utility Meter Safety Impacts

OBJECTIVES

- To investigate reported public health and safety complaints about wireless utility meters.
- To evaluate the impacts on health and safety due to wireless utility meters.
- To determine whether further study is warranted.

METHODS

- Survey was designed by the EMF Safety Network (Network).
- The survey was circulated online through various social media outlets including Network's email list, Facebook, and the California EMF Safety Coalition (a discussion group).
- The survey was also posted on Network's website: www.emfsafetynetwork.org where visitors were invited to take the survey.
- 443 responses were received from 7/13/2011 through 9/2/2011. *(318 of the 443 answered the health questions that formed the basis for the bar chart on symptoms. RMPowell)*
- Network commissioned Survey Design and Analysis (SDA) to provide this report of the survey findings.

RESPONDENT MAKEUP

- 93% are over 40 years old and 43% are over 60 years old.
- 73% are women.
- 78% are from California.
- 68% have Pacific Gas and Electric (PG&E) as their utility provider.
- 49% are EMF Sensitive.
- 41% have had a new wireless meter installed in their home; of these . . .
  - 56% have had it installed for at least six months
  - 89% have electric meters, 53% gas meters and 10% water meters
  - 35% saw an increase in their utility bill
  - 26% have experienced some type of interference
  - 8% experienced burned out appliances or damaged electronics including TV, stereo, computer, refrigerator and other.
- 76% indicated they have wireless utility meters installed in their neighborhood, town or city.
  - 44% near their home
  - 36% in town

TOP HEALTH ISSUES SINCE NEW METERS INSTALLED

- Sleep problems (mentioned by 49%)
- Stress, anxiety and irritability (43%)
- Headaches (40%) *(Intentionally listed at 41% on symptoms bar graph, rounded up from 40.9%. RMPowell)*
- Ringing in the ears (38%)
- Heart problems (26%)

UTILITY and PUBLIC UTILITY COMMISSION INTERACTIONS *(Title inserted by RMPowell.)*

- 40% (111 people) of those having wireless meters in their homes or community have complained to their utility provider.
  - 96% of these people were either "Unsatisfied" or "Very Unsatisfied" with the handling of their complaint.
- 32% (88 people) complained to the utilities commission.
  - 96% of these people were either "Unsatisfied" or "Very Unsatisfied" with the handling of their complaint
- 94% of respondents want to retain or restore their analog meters and 92% of these respondents do not think they should have to pay any additional money.

STATISTICAL TESTING SHOWS THE TOP HEALTH SYMPTOMS ARE POSITIVELY ASSOCIATED WITH

- EMF Sensitivity
- Wireless meters installed in the home

New or Worsened Symptoms Reported by 92 Individuals after Exposure to Wireless Smart Meters in Australia[1]

[1] Federica Lamech, MBBS, Self-Reporting of Symptom Development from Exposure to Radiofrequency Fields of Wireless Smart Meters in Victoria, Australia: A Case Series. Alternative Therapies, Nov/Dec 2014, Vol. 20, No. 6, pages 28-38. NIH PMID 25478801 (http://www.alternative-therapies.com and http://www.ncbi.nlm.nih.gov/pubmed/25478801).

Abstract of Dr. Federica Lamech's Article from the National Institutes of Health PubMed Index

Altern Ther Health Med. 2014 Nov-Dec;20(6):28-39.

Self-reporting of symptom development from exposure to radiofrequency fields of wireless smart meters in Victoria, Australia: a case series.

Lamech F.

Abstract

CONTEXT:

In 2006, the government in the state of Victoria, Australia, mandated the rollout of smart meters in Victoria, which effectively removed a whole population's ability to avoid exposure to human-made high-frequency nonionizing radiation. This issue appears to constitute an unprecedented public health challenge for Victoria. By August 2013, 142 people had reported adverse health effects from wireless smart meters by submitting information on an Australian public Web site using its health and legal registers.

OBJECTIVE:

The study evaluated the information in the registers to determine the types of symptoms that Victorian residents were developing from exposure to wireless smart meters.

DESIGN:

In this case series, the registers' managers eliminated those cases that did not clearly identify the people providing information by name, surname, postal address, and/or e-mail to make sure that they were genuine registrants. Then they obtained consent from participants to have their deidentified data used to compile the data for the case series. The author later removed any individual from outside of Victoria.

PARTICIPANTS:

The study included 92 residents of Victoria, Australia.

OUTCOME MEASURES:

The author used her medical experience and judgment to group symptoms into clinically relevant clusters (eg, pain in the head was grouped with headache, tinnitus was grouped with ringing in the ears). The author stayed quite close to the wording used in the original entries. She then calculated total numbers and percentages for each symptom cluster. Percentages were rounded to the nearest whole number.

RESULTS:

The most frequently reported symptoms from exposure to smart meters were (1) insomnia, (2) headaches, (3) tinnitus, (4) fatigue, (5) cognitive disturbances, (6) dysesthesias (abnormal sensation), and (7) dizziness. The effects of these symptoms on people's lives were significant.

CONCLUSIONS:

Review of some key studies, both recent and old (1971), reveals that the participants' symptoms were the same as those reported by people exposed to radiofrequency fields emitted by devices other than smart meters. Interestingly, the vast majority of Victorian cases did not state that they had been sufferers of electromagnetic hypersensitivity syndrome (EHS) prior to exposure to the wireless meters, which points to the possibility that smart meters may have unique characteristics that lower people's threshold for symptom development.

Re: Specific Absorption Rate Missing Science, Smart Meters and Advanced Wireless Services

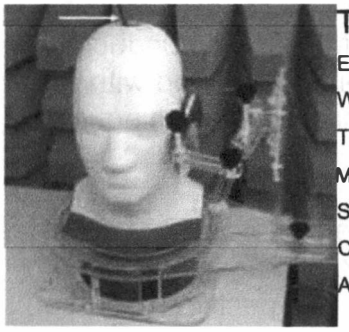
Dear Sir/Madam:

Health Canada's Safety Code 6, the FCC and international governing bodies all use the same science standards for limits of human exposure electromagnetic and radio frequencies (EMF/RF). Unfortunately, science standards and the Safety Code admit to missing the link between the frequencies and adverse health effects.

Please take note that the FCC didn't consider the science linking EMF/RF to adverse health effects was reported by the Canadian Electrical Professionals through Health Canada and by expert witness at the request of the Canadian Parliament's Standing Committee on Health.

Following the reporting of the mechanisms linking the frequencies to adverse health effects, the dangers of wireless frequencies is lectured in the United States for education credits required for ongoing medical licensing. The medical education program is applicable in all 50 states and literally changes the scope of medical diagnosis. Wireless environments have to be considered in medical diagnosis or there is a real risk of misdiagnosis.

The FCC as well as other governing bodies adopted the Specific Absorption Rate to determine the limits of human exposure.

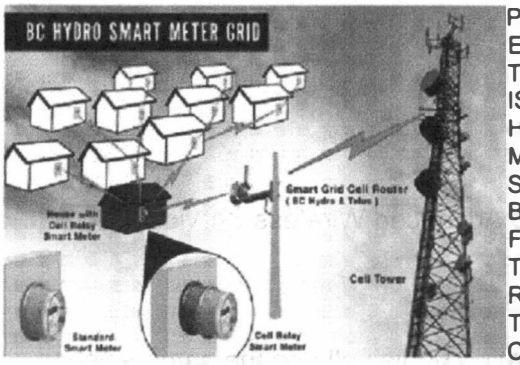


THIS PICTURE SHOWS HOW THE SPECIFIC ABSORPTION RATE IS USED TO DETERMINE EXPOSURE LIMITS. THE RED ARROW SHOWS THE POSITION OF THE CELL PHONE AND THE WHITE ARROW HIGHLIGHTS THE HOLE IN THE TEST MODEL WHERE LIQUID THAT SIMULATES TISSUE IS POURED. THE BLACK WIRE INSIDE THE HEAD IS THE TEMPERATURE PROBE MEASURING FOR HEAT EFFECT. THIS IS THE SCIENCE USED GLOBALLY AND BECAUSE SMART METERS AND/OR WIRELESS COMPUTERS AREN'T HELD AGAINST THE HEAD LIKE A CELL PHONE, 24/7 EXPOSURE IS CONSIDERED SAFE FOR EVERYONE INCLUDING CHILDREN AND PREGNANT WOMEN.

The Specific Absorption Rate calculation only considered the end use device. It didn't include smart meter routers, relays, tower antennas and other wireless infrastructure radiating large geographical areas to communicate with wireless devices. The Specific Absorption Rate didn't incorporate the bio electricity of humans, their vulnerability and left out millions of frequencies in a frequency equation.

When you incorporate the errors or omissions in safety, you have causality, biological plausibility and reproducibility that links the frequencies to adverse health effects.

Directly below is a utility's diagram of the wireless smart grid showing what they didn't incorporate into the Specific Absorption Rate for safety.



PACEMAKER RECIPIENTS ARE TOLD TO STAY OUT OF ELECTROMAGNETIC FIELDS: HOWEVER, THE AREA COVERAGE WILL TAKE THE EMFS DIRECTLY INTO THEIR HOMES. THAT IS A SEPARATE ISSUE FROM UTILITIES USING UNQUALIFIED INSTALLERS WITH A FEW HOURS TRAINING TO SWAP ELECTRICAL METERS. CHANGING A METER UNDER LOAD ON A METER BASE THAT HAS NEVER BEEN SERVICED IS VERY DANGEROUS AND FURTHER COMPROMISES BUILDING OWNERS' PROPERTIES. IN THE CASE OF SMART METER FIRES, UTILITIES BLAME HOME OWNERS FOR THE FIRES BECAUSE THE HOMEOWNER OWNS THE METER BASE WHEN THE ELECTRICAL REALITY IS THE METER SWAP ACTUALLY CAUSED THE FIRE. BELOW IS THE ADDRESS FOR TESTIMONY PROVIDED TO THE TEXAS SENATE COMMITTEE ON SMART METERS.
http://www.thermoguy.com/pdfs/Texas_Senate_Committee_Meeting_on_Smart_Meters.pdf

Municipalities are presently absorbing costs and liabilities that are not theirs to absorb. The FCC, PUC and utility companies are not incorporating health, building or infrastructure costs and haven't even considered the agricultural, forestry, groundwater, fish spawning, economic or ecosystem damage consequences. The frequencies are illegal as applied and the peer-reviewed science substantiating that spans many sciences; electricity, engineering, biology, chemistry and is taught in continuing medical education programs.

Our electrical grid is 60 Hz frequencies and is compatible with our 60 Hz appliances and devices. The radio frequencies at 900 million Hz are not electrically compatible with **any** biological frequencies. Cell tower construction is exceeding land use with antenna frequencies blanketing municipalities and adversely affecting other land use as well as infrastructure.

Residents have valid concerns for themselves and their building investments. The complete science has not been communicated fully to municipalities. My opinion is not singular. The margin of error is zero. The peer-reviewed science qualifying the EMF interactions is called "electricity." To generate electricity requires an electromagnetic field (EMF) and a conductor. With current FCC standards and utility applications, entire areas are being blanketed with EMFs and human/animal, vegetable/mineral kingdom – almost everyone and everything is a conductor.

Health Canada is presently revising Safety Code 6 and has retained the Royal Society as an independent body. The United States has a draft bill H.R. 6358 in which congressional members are asking specifically for a revision of the scientifically deficient Specific Absorption Rate test. I recommend the same approach be applied.

Sincerely,

Humanity on the BRINK –

Research Report from

Barrie Trower -

Frequencies that KILL . . .

Barrie Trower

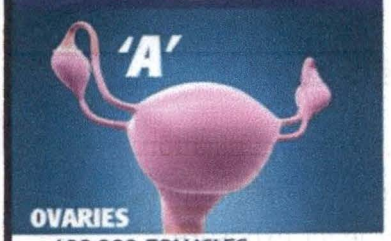
September 2013

With Deference to all Scientists: this Research Report has been written for all students and non-scientists to understand.

Abstract

As stated by University Researchers, Government Scientists and International Scientific Advisors; a minimum of 57.7% of schoolgirls exposed to low-level microwave radiation (Wi-fi) are at risk of suffering stillbirth, foetal abnormalities or genetically damaged children, when they give birth. Any genetic damage may pass to successive generations.

1



OVARIES
- 400,000 FOLLICLES
- 400 TO MATURE
- 14 EACH CYCLE TO PRODUCE EGG(S) WHICH CAN BE FERTILIZED

CHILD 'A' 5-16 YEARS EXPOSED TO WI-FI IN SCHOOL
Possible damage to first and subsequent generations.

Microwave irradiation can cause oxidative and nitrosative stress to mitochondria - this DNA is 10x more susceptible to low level chronic microwave radiation than other DNA.

Low histone protein content i.e. mitochondropathy N_2 O_2 is essential for brain / immune system, any DNA damage is irreparable and can pass to every female hence forth.

57.7%

2

* PHOTOSENSITIVE GANGLIONS ABSORB RAD: EFFECT BODY FUNCTIONS

CHILD 'B' FOETUS FROM CHILD 'A' NOW AS A PREGNANT STUDENT/ADULT
With possible DNA damage

- 100 days for follicles to form: no definite structure thence 150+120 d. to mature
- No protein 53 (x4) to fight radiation
- No nuclear core complex (x30) proteins for defence
- No factor 1 protein* (apoptosis)
- Of 100,000 protein structures only 600 are known

7d = 100 Cells
28d = Heart
*40d = Eye
47d = fingers / toes

Body is initially inside out, i.e. major organs are the most irradiated

Woman may not know she is pregnant at this stage: Hence no precautions taken

3

CHILD 'B' IS NOW PREGNANT CHILD 'C'
Adult Child C may already have been irradiated

- Every aspect of Child 'C"s life has been at maximum risk from stages 1,2 & 3.
- The greatest risk is yet to come. Biggest danger from school wi-fi irradiation on students and teachers

1st 56 days is when all embryos are most vulnerable. During the first 4-6 weeks, the mother may not know she is pregnant, therefore will not shield the embryo from radiation

25+ years

Wifi – a Thalidomide in the Making – Who Cares?

Professor John R Goldsmith, International / Advisor Consultant for R.F. Communication, Epidemiology and Communications Sciences Advisor to the World Health Organisation, Military and University Advisor, Researcher; wrote concerning the low level exposure of microwave irradiation (below thermal level) incident upon women:

> *"Of the microwave-exposed women, 47.7% had miscarriages prior to the 7th week of pregnancy...."*(1)

The level of irradiation incident upon the women was stated, as from, five microwatts per centimetre squared. This level of irradiation may seem meaningless to a non-scientist; however, when I say that it is below what most schoolgirls will receive in a classroom of wi-fi transmitters, from the age of approximately five years upwards, this level becomes more meaningful.

A distinction here must be made and a very important one: schoolgirls are not women. Schoolgirls are children and children are both neurologically and physiologically different from adults. A child's brain tissue / bone marrow has different electrical conductivity properties than adults due to the higher water content (2) (this renders the Specific Absorption Rate obsolete). Children's absorption of microwave radiation can be ten times higher than adults. Permanent low-level microwave exposure can induce chronic nitrosative and oxidative 'stress' thence, damage the cellular mitochondria (mitochondropathy). This 'stress' can cause irreversible mitochondrial DNA damage (mitochondrial DNA is ten times more susceptible to oxidative and nitrosative 'stress' than the DNA in the cell nucleus). Mitochondrial DNA is irreparable due to its low histone protein content, therefore any damage (genetic or otherwise) can be transmitted to all successive generations through the maternal line. (3)

Hence, we are subjecting each successive female generation to harm. Whether these two ten-fold increases 'merge' to become 57.7% or are additional, thence equal 67.7% of those to suffer, is a moot point. Either way we are facing the equivalent of a pandemic. I was invited to present a lecture at Brighton University recently and one Doctor commented on a +60% foetal birth rate damage from exposed farm animals. All mammalian species will of course suffer the same consequence resulting from low-level microwave irradiation. There is very little difference 'biologically' between our embryonic cells.

I invite the Reader to peruse my diagram and / or read my simple explanation concerning the microwaving of the ovarian follicles in schoolgirls.

USP # 6,506,148 (January 14, 2003)
Nervous System Manipulation by EM Fields from Monitors
Loos, Hendricus
Abstract --- Physiological effects have been observed in a human subject in response to stimulation of the skin with weak electromagnetic fields that are pulsed with certain frequencies near 1/2 Hz or 2.4 Hz, such as to excite a sensory resonance. Many computer monitors and TV tubes, when displaying pulsed images, emit pulsed electromagnetic fields of sufficient amplitudes to cause such excitation. It is therefore possible to manipulate the nervous system of a subject by pulsing images displayed on a nearby computer monitor or TV set. For the latter, the image pulsing may be imbedded in the program material, or it may be overlaid by modulating a video stream, either as an RF signal or as a video signal. The image displayed on a computer monitor may be pulsed effectively by a simple computer program. For certain monitors, pulsed electromagnetic fields capable of exciting sensory resonances in nearby subjects may be generated even as the displayed images are pulsed with subliminal intensity.
USP # 6,488,617 (December 3, 2002)
Method and Device for Producing a Desired Brain State
Katz, Bruce
Abstract--- A method and device for the production of a desired brain state in an individual contain means for monitoring and analyzing the brain state while a set of one or more magnets produce fields that alter this state. A computational system alters various parameters of the magnetic fields in order to close the gap between the actual and desired brain state. This feedback process operates continuously until the gap is minimized and/or removed.
USP # 6,487,531 (November 26, 2002)
Signal Injection Coupling into the Human Vocal Tract...
Tosaya, Carol
Abstract --- A means and method are provided for enhancing or replacing the natural excitation of the human vocal tract by artificial excitation means, wherein the artificially created acoustics present additional spectral, temporal, or phase data useful for (1) enhancing the machine recognition robustness of audible speech or (2) enabling more robust machine-recognition of relatively inaudible mouthed or whispered speech. The artificial excitation (a) may be arranged to be

audible or inaudible, (b) may be designed to be non-interfering with another user's similar means, (c) may be used in one or both of a vocal content-enhancement mode or a complimentary vocal tract-probing mode, and/or (d) may be used for the recognition of audible or inaudible continuous speech or isolated spoken commands.

USP # 6,430,443 (August 6, 2002)

Method and Apparatus for Treating Auditory Hallucinations

Karell, Manuel

Abstract--- Stimulating one or more vestibulocochlear nerves or cochlea or cochlear regions will treat, prevent and control auditory hallucinations.

USP # 6,426,919 (July 30, 2002)

Portable and Hand-Held Device for Making Humanly Audible Sounds...

Gerosa, William

Abstract--- A portable and hand-held device for making humanly audible sounds responsive to the detecting of ultrasonic sounds. The device includes a hand-held housing and circuitry that is contained in the housing. The circuitry includes a microphone that receives the ultrasonic sound, a first low voltage audio power amplifier that strengthens the signal from the microphone, a second low voltage audio power amplifier that further strengthens the signal from the first low voltage audio power amplifier, a 7-stage ripple carry binary counter that lowers the frequency of the signal from the second low voltage audio power amplifier so as to be humanly audible, a third low voltage audio power amplifier that strengthens the signal from the 7-stage ripple carry binary counter, and a speaker that generates a humanly audible sound from the third low voltage audio power amplifier.

USP # 6,292,688 (September 18, 2001)

Method and Apparatus for Analyzing Neurological Response to Emotion-Inducing Stimuli

Patton, Richard

Abstract--- A method of determining the extent of the emotional response of a test subject to stimului having a time-varying visual content, for example, an advertising presentation. The test subject is positioned to observe the presentation for a given duration, and a path of communication is established between the subject and a brain wave detector/analyzer. The intensity component of each of at least two different brain wave frequencies is measured during the exposure, and each frequency is associated with a particular emotion. While the subject views the presentation, periodic variations in the intensity component of the brain waves of each of the particular frequencies selected is measured. The change rates in the intensity at regular periods during the duration are also measured. The intensity change rates are then used to construct a

graph of plural coordinate points, and these coordinate points graphically establish the composite emotional reaction of the subject as the presentation continues.

USP # 6,258,022 (July 10,2001)

Behavior Modification

Rose, John

Abstract--- Behavior modification of a human subject takes place under hypnosis, when the subject is in a relaxed state. A machine plays back a video or audio recording, during which the subject is instructed to activate a device to create a perceptible stimulation which is linked, through the hypnosis, with a visualization of enhanced or improved performance. After the hypnosis, the user can reactivate the device at will, whenever the improved performance, such as an improved sporting performance, is desired. This will again create the perceptible stimulation and thus induce the required visualization.

USP # 6,239,705 (May 29,2001)

Intra-Oral Electronic Tracking Device

Glen, Jeffrey

Abstract--- An improved stealthy, non-surgical, biocompatable electronic tracking device is provided in which a housing is placed intraorally. The housing contains microcircuitry. The microcircuitry comprises a receiver, a passive mode to active mode activator, a signal decoder for determining positional fix, a transmitter, an antenna, and a power supply. Optionally, an amplifier may be utilized to boost signal strength. The power supply energizes the receiver. Upon receiving a coded activating signal, the positional fix signal decoder is energized, determining a positional fix. The transmitter subsequently transmits through the antenna a position locating signal to be received by a remote locator. In another embodiment of the present invention, the microcircuitry comprises a receiver, a passive mode to active mode activator, a transmitter, an antenna and a power supply. Optionally, an amplifier may be utilized to boost signal strength. The power supply energizes the receiver. Upon receiving a coded activating signal, the transmitter is energized. The transmitter subsequently transmits through the antenna a homing signal to be received by a remote locator.

USP # 6,167,304 (December 26, 2000)

Pulse Variability in Electric Field Manipulation of Nervous Systems

Loos, Hendricus

Abstract--- Apparatus and method for manipulating the nervous system of a subject by applying to the skin a pulsing external electric field which, although too weak to cause classical nerve stimulation, modulates the normal spontaneous spiking patterns of certain kinds of afferent nerves. For certain pulse frequencies the electric field stimulation can

excite in the nervous system resonances with observable physiological consequences. Pulse variability is introduced for the purpose of thwarting habituation of the nervous system to the repetitive stimulation, or to alleviate the need for precise tuning to a resonance frequency, or to control pathological oscillatory neural activities such as tremors or seizures. Pulse generators with stochastic and deterministic pulse variability are disclosed, and the output of an effective generator of the latter type is characterized.

USP # 6,135,944 (October 24, 2000)

Method of Inducing Harmonious States of Being

Bowman, Gerard D., et al.

Abstract--- A method of inducing harmonious states of being using vibrational stimuli, preferably sound, comprised of a multitude of frequencies expressing a specific pattern of relationship. Two base signals are modulated by a set of ratios to generate a plurality of harmonics. The harmonics are combined to form a "fractal" arrangement.

USP # 6,122,322 (September 19, 2000)

Subliminal Message Protection

Jandel, Magnus

Abstract--- The present invention relates to a method and to a system for detecting a first context change between two frames. When a second context change between a further two frames occurs within a predetermined time interval, the frames accommodated within the two context changes are defined as a subliminal message. An alarm is sent to an observer upon detection of a subliminal message.

USP # 6,091,994 (July 18, 2000)

Pulsative Manipulation of Nervous Systems

Loos, Hendricus

Abstract--- Method and apparatus for manipulating the nervous system by imparting subliminal pulsative cooling to the subject's skin at a frequency that is suitable for the excitation of a sensory resonance. At present, two major sensory resonances are known, with frequencies near 1/2 Hz and 2.4 Hz. The 1/2 Hz sensory resonance causes relaxation, sleepiness, ptosis of the eyelids, a tonic smile, a "knot" in the stomach, or sexual excitement, depending on the precise frequency used. The 2.4 Hz resonance causes the slowing of certain cortical activities, and is characterized by a large increase of the time needed to silently count backward from 100 to 60, with the eyes closed. The invention can be used by the general public for inducing relaxation, sleep, or sexual excitement, and clinically for the control and perhaps a treatment of tremors, seizures, and autonomic system disorders such as panic attacks. Embodiments shown are a pulsed fan to impart subliminal cooling pulses to the subject's skin, and a silent device which induces periodically varying flow past the subject's skin,

the flow being induced by pulsative rising warm air plumes that are caused by a thin resistive wire which is periodically heated by electric current pulses.

USP # 6,081,744 (June 27, 2000)

Electric Fringe Field Generator for Manipulating Nervous Systems

Loos, Hendricus

Abstract--- Apparatus and method for manipulating the nervous system of a subject through afferent nerves, modulated by externally applied weak fluctuating electric fields, tuned to certain frequencies such as to excite a resonance in neural circuits. Depending on the frequency chosen, excitation of such resonances causes in a human subject relaxation, sleepiness, sexual excitement, or the slowing of certain cortical processes. The electric field used for stimulation of the subject is induced by a pair of field electrodes charged to opposite polarity and placed such that the subject is entirely outside the space between the field electrodes. Such configuration allows for very compact devices where the field electrodes and a battery-powered voltage generator are contained in a small casing, such as a powder box. The stimulation by the weak external electric field relies on frequency modulation of spontaneous spiking patterns of afferent nerves. The method and apparatus can be used by the general public as an aid to relaxation, sleep, or arousal, and clinically for the control and perhaps the treatment of tremors and seizures, and disorders of the autonomic nervous system, such as panic attacks.

USP # 6,052,336 (April 18, 2000)

Apparatus and Method of Broadcasting Audible Sound Using Ultrasonic Sound as a Carrier

Lowrey, Austin, III

Abstract--- An ultrasonic sound source broadcasts an ultrasonic signal which is amplitude and/or frequency modulated with an information input signal originating from an information input source. If the signals are amplitude modulated, a square root function of the information input signal is produced prior to modulation. The modulated signal, which may be amplified, is then broadcast via a projector unit, whereupon an individual or group of individuals located in the broadcast region detect the audible sound.

USP # 6,039,688 (March 21, 2000)

Therapeutic Behavior Modification Program, Compliance Monitoring and Feedback System

Douglas, Peter, et al.

Abstract--- A therapeutic behavior modification program, compliance monitoring and feedback system includes a server-based relational database and one or more microprocessors electronically coupled to the

server. The system enables development of a therapeutic behavior modification program having a series of milestones for an individual to achieve lifestyle changes necessary to maintain his or her health or recover from ailments or medical procedures. The program may be modified by a physician or trained case advisor prior to implementation. The system monitors the individual's compliance with the program by prompting the individual to enter health-related data, correlating the individual's entered data with the milestones in the behavior modification program and generating compliance data indicative of the individual's progress toward achievement of the program milestones. The system also includes an integrated system of graphical system interfaces for motivating the individual to comply with the program. Through the interfaces, the individual can access the database to review the compliance data and obtain health information from a remote source such as selected sites on the Internet. The system also provides an electronic calendar integrated with the behavior modification program for signaling the individual to take action pursuant to the behavior modification program in which the calendar accesses the relational database and integrates requirements of the program with the individual's daily schedule, and an electronic journal for enabling the individual to enter personal health-related information into the system on a regular basis. In addition, the system includes an electronic meeting room for linking the individual to a plurality of other individuals having related behavior modification programs for facilitating group peer support sessions for compliance with the program. The system enables motivational media presentations to be made to the individuals in the electronic meeting room as part of the group support session to facilitate interactive group discussion about the presentations. The entire system is designed around a community of support motif including a graphical electronic navigator operable by the individual to control the microprocessor for accessing different parts of the system.

USP # 6,017,302 (January 25, 2000)

Subliminal Acoustic Manipulation of Nervous Systems

Loos, Hendricus

Abstract--- In human subjects, sensory resonances can be excited by subliminal atmospheric acoustic pulses that are tuned to the resonance frequency. The 1/2 Hz sensory resonance affects the autonomic nervous system and may cause relaxation, drowsiness, or sexual excitement, depending on the precise acoustic frequency near 1/2 Hz used. The effects of the 2.5 Hz resonance include slowing of certain cortical processes, sleepiness, and disorientation. For these effects to occur, the acoustic intensity must lie in a certain deeply subliminal range. Suitable apparatus consists of a portable battery-powered source of weak subaudio

acoustic radiation. The method and apparatus can be used by the general public as an aid to relaxation, sleep, or sexual arousal, and clinically for the control and perhaps treatment of insomnia, tremors, epileptic seizures, and anxiety disorders. There is further application as a nonlethal weapon that can be used in law enforcement standoff situations, for causing drowsiness and disorientation in targeted subjects. It is then preferable to use venting acoustic monopoles in the form of a device that inhales and exhales air with subaudio frequency.

USP # 6,011,991 (January 4, 2000)
Communication System & Method Including Brain Wave Analysis...
Mardirossian, Aris

Abstract--- A system and method for enabling human beings to communicate by way of their monitored brain activity. The brain activity of an individual is monitored and transmitted to a remote location (e.g. by satellite). At the remote location, the monitored brain activity is compared with pre-recorded normalized brain activity curves, waveforms, or patterns to determine if a match or substantial match is found. If such a match is found, then the computer at the remote location determines that the individual was attempting to communicate the word, phrase, or thought corresponding to the matched stored normalized signal.

USP # 6,006,188 (December 21, 1999)
Speech Signal Processing for Determining Psychological or Physiological Characteristics. ..
Bogdashevsky, Rostislav, et al.

Abstract--- A speech-based system for assessing the psychological, physiological, or other characteristics of a test subject is described. The system includes a knowledge base that stores one or more speech models, where each speech model corresponds to a characteristic of a group of reference subjects. Signal processing circuitry, which may be implemented in hardware, software and/or firmware, compares the test speech parameters of a test subject with the speech models. In one embodiment, each speech model is represented by a statistical time-ordered series of frequency representations of the speech of the reference subjects. The speech model is independent of a priori knowledge of style parameters associated with the voice or speech. The system includes speech parameterization circuitry for generating the test parameters in response to the test subject's speech. This circuitry includes speech acquisition circuitry, which may be located remotely from the knowledge base. The system further includes output circuitry for outputting at least one indicator of a characteristic in response to the comparison performed by the signal processing circuitry. The characteristic may be time-varying, in which case the output circuitry

outputs the characteristic in a time-varying manner. The output circuitry also may output a ranking of each output characteristic. In one embodiment, one or more characteristics may indicate the degree of sincerity of the test subject, where the degree of sincerity may vary with time. The system may also be employed to determine the effectiveness of treatment for a psychological or physiological disorder by comparing psychological or physiological characteristics, respectively, before and after treatment.

USP # 5,954,630 (September 21, 1999)

FM Theta-Inducing Audible Sound...

Masaki, Kazumi, et al.

Abstract--- An audible sound of modulated wave where a very low-frequency wave of about 20 hertz or lower is superposed on an audio low-frequency wave effectively stimulates Fm theta in human brain waves to improve attention and concentration during mental tasks when auditorily administered. The audible sound is also effective in stimulation of human alpha wave when the very low-frequency wave lies within the range of about 2-10 hertz. Such audible sound is artificially obtainable by generating an electric signal which contains such a modulated wave, and transducing it into audible sound wave.

USP # 5,954,629 (September 21, 1999)

Brain Wave Inducing System

Yanagidaira, Masatoshi, et al.

Abstract--- Sensors are provided for detecting brain waves of a user, and a band-pass filter is provided for extracting a particular brain waves including an .alpha. wave included in a detected brain wave. The band-pass filter comprises a first band-pass filter having a narrow pass band, and a second band-pass filter having a wide pass band. One of the first and second band-pass filters is selected, and a stimulation signal is produced in dependency on an .alpha. wave extracted by a selected band-pass filter. In accordance with the stimulation signal, a stimulation light is emitted to the user in order to induce the user to relax or sleeping state.

USP # 5,935,054 (August 10, 1999)

Magnetic Excitation of Sensory Resonances

Loos, H.

Abstract--- The invention pertains to influencing the nervous system of a subject by a weak externally applied magnetic field with a frequency near 1/2 Hz. In a range of amplitudes, such fields can excite the 1/2 sensory resonance, which is the physiological effect involved in "rocking the baby".

USP # 5,922,016 (July 13, 1999)

Apparatus for Electric Stimulation of Auditory Nerves of a Human Being

Wagner, Hermann Abstract--- Apparatus for electric stimulation and

diagnostics of auditory nerves of a human being, e.g. for determination of sensation level (SL), most conformable level (MCL) and uncomfortable level (UCL) audibility curves, includes a stimulator detachably secured to a human being for sending a signal into a human ear, and an electrode placed within the human ear and electrically connected to the stimulator by an electric conductor for conducting the signals from the stimulator into the ear. A control unit is operatively connected to the stimulator for instructing the stimulator as to characteristics of the generated signals being transmitted to the ear.

USP # 5,868,103 (February 9, 1999)

Method and Apparatus for Controlling an Animal

Boyd, Randal

Abstract--- An apparatus for controlling an animal wherein the animal receives a control stimulus of the release of a substance having an adverse effect upon the animal as a corrective measure. The apparatus includes a transmitter for producing a transmitted field, and a releasable collar for attaching to the neck of the animal. The collar includes a receiver for receiving the transmitted field and for producing a received signal, a control circuit for determining when the received signal indicates that the animal requires a corrective measure and for producing a control signal, a container for containing the substance having an adverse effect upon the animal, and a mechanism for releasing the substance from the container into the presence of the animal upon the production of the control signal by the control circuit. In use, the transmitter is set to produce the transmitted field and the collar is attached to the neck of the animal. As the animal moves about, the receiver in the collar receives the transmitted field and produces a received signal. The control circuit determines when the received signal indicates that the animal requires a corrective measure. A control signal is produced by the control circuit when the determination is made that the animal requires a corrective measure. Upon the production of the control signal, the substance having an adverse effect upon the animal is released from the container and into the presence of the animal.

USP # 5,784,124 (July 21, 1998)

Supraliminal Method of Education...

D'Alitalia, Joseph A., et al.

Abstract--- A method of behavior modification involves having a patient view supraliminal video messages superimposed upon an underlying video presentation. The video messages incorporate messages wherein at least some of the messages link a desired modified behavior to positive feelings of the patient. A supraliminal message generator and superimposer iteratively selects individual messages for display from the sequence of messages, decompressing the messages as required, and places

the selected messages in a buffer memory of a video generation device. A processor of the supraliminal message generator and superimposer then fades the selected message from an invisible level to a visible level on the video display, and then fades the selected message from the visible level back to the invisible level.

USP # 5,649,061 (July 15, 1997)

Device and Method for Estimating a Mental Decision

Smyth, Christopher

Abstract--- A device and method for estimating a mental decision to select a visual cue from the viewer's eye fixation and corresponding single event evoked cerebral potential. The device comprises an eyetracker, an electronic biosignal processor and a digital computer. The eyetracker determines the instantaneous viewing direction from oculometric measurements and a head position and orientation sensor. The electronic processor continually estimates the cerebral electroencephalogra mic potential from scalp surface measurements following corrections for electrooculogramic, electromyogramic and electrocardiogramic artifacts. The digital computer analyzes the viewing direction data for a fixation and then extracts the corresponding single event evoked cerebral potential. The fixation properties, such as duration, start and end pupil sizes, end state (saccade or blink) and gaze fixation count, and the parametric representation of the evoked potential are all inputs to an artificial neural network for outputting an estimate of the selection interest in the gaze point of regard. The artificial neural network is trained off-line prior to application to represent the mental decisions of the viewer. The device can be used to control computerized machinery from a video display by ocular gaze point of regard alone, by determining which visual cue the viewer is looking at and then using the estimation of the task-related selection as a selector switch.

USP # 5,644,363 (July 1, 1997)

Apparatus for Superimposing Visual Subliminal Instructions on a Video Signal Mead, Talbert Abstract--- A subliminal video instructional device comprises circuitry for receiving an underlying video signal and presenting this signal to horizontal and vertical synchronization detection circuits, circuitry for generating a subliminal video message synchronized to the underlying video signal, and circuitry for adding the subliminal video message to the underlying video signal to create a combination video signal.

USP # 5,586,967 (December 24, 1996)

Method & Recording for Producing Sounds and Messages to Achieve Alpha & Theta Brainwave States... Davis, Mark E. Abstract--- A method and recording for the use in achieving alpha and theta brainwave states and effecting positive emotional states in humans, is provided which includes

a medium having a musical composition thereon with an initial tempo decreasing to a final tempo and verbal phrases recorded in synchrony with the decreasing tempo.
USP # 5,562,597 (October 8, 1996)
Method & Apparatus for Reducing Physiological Stress
Van Dick, Robert C.
Abstract--- Physiological stress in a human subject is treated by generating a weak electromagnetic field about a quartz crystal. The crystal is stimulated by applying electrical pulses of pulse widths between 0.1 and 50 microseconds each at a pulse repetition rate of between 0.5K and 10K pulses per second to a conductor positioned adjacent to the quartz crystal thereby generating a weak electromagnetic field. A subject is positioned within the weak electromagnetic field for a period of time sufficient to reduce stress.
USP # 5,551,879 (September 3, 1996)
Dream State Teaching Machine
Raynie, Arthur D.
Abstract--- A device for enhancing lucidity in the dream state of an individual. The device includes electronic circuitry incorporated into a headband for the user to wear while sleeping. The circuitry includes a detector for fitting adjacent to the eye of the sleeping individual, for detecting Rapid Eye Movement (REM), which occurs during the dream state. The detector emits a signal that is evaluated by additional circuitry to determine whether or not REM sleep is occurring. If REM sleep is occurring, a signal is generated to operate a recorded, which typically plays prerecorded messages through the headphones engaging the ear of the sleeping individual.
USP # 5,539,705 (July 23, 1996)
Ultrasonic Speech Translator and Communication System
M. A. Akerman, M., et al.
Abstract--- A wireless communication system, undetectable by radio-frequency methods, for converting audio signals, including human voice, to electronic signals in the ultrasonic frequency range, transmitting the ultrasonic signal by way of acoustic pressure waves across a carrier medium, including gases, liquids and solids, and reconverting the ultrasonic acoustic pressure waves back to the original audio signal. This invention was made with government support under Contract DE-ACO5-840R2l400, awarded by the US Department of Energy to Martin Marietta Energy Systems, Inc.
USP # 5,507,291 (April 16, 1996)
Method & Apparatus for Remotely Determining Information as to Person's Emotional State ~ Stirbl, et al. Abstract--- In a method for remotely

determining information relating to a person's emotional state, an waveform energy having a predetermined frequency and a predetermined intensity is generated and wirelessly transmitted towards a remotely located subject. Waveform energy emitted from the subject is detected and automatically analyzed to derive information relating to the individual's emotional state. Physiological or physical parameters of blood pressure, pulse rate, pupil size, respiration rate and perspiration level are measured and compared with reference values to provide information utilizable in evaluating interviewee' s responses or possibly criminal intent in security sensitive areas.

USP # 5,522,386 (June 4, 1996)

Apparatus for Determination of the Condition of the Vegetative Part of the Nervous System Lerner, Eduard Abstract--- Apparatus for use in the determination of the condition of the vegetative part of the nervous system and/or of sensory functions of an organism, i.e. a human being or animal. The apparatus comprises devices for generating and supplying to said organism at least one sensory stimulus chosen from a group of sensory stimuli, such as visual, sound, olfactory, gustatory, tactile or pain stimuli, and devices for measuring the skin potential and the evoked response of the organism to a stimulus. The measured data are processed by processing devices for automatically controlling the supply of at least one stimulus for providing a non-rhythmical sequence of stimuli. Preferably, pairs of stimuli are supplied for developing a conditioned reflex.

USP # 5,480,374 (January 2, 1996)

Method and Apparatus for Reducing Physiological Stress

Van Dick, Robert

Abstract--- Physiological stress in a human subject is treated by generating a weak electromagnetic field about a grounded electrode by the application of pulses of between 5 and 50 microseconds each at a pulse rate of between 0.5K and 10K pulses per second to a power electrode, the power electrode and grounded electrode being coupled to high voltage pulse generation means. A subject is positioned within the weak electromagnetic field for a period of time sufficient to cause an increase in his or her alpha or theta brain wave levels.

USP # 5,479,941 (January 2, 1996)

Device for Inducing Altered States of Consciousness

Harner, Michael

Abstract--- A rotating device for producing altered states of consciousness in a subject is provided. The subject's body rotates about a point in the center of the body support means at a speed between about 10 and about 60 revolutions per minute. In a preferred embodiment the direction of rotation is periodically reversed.

USP # 5,392,788 (February 28, 1995)
Method and Device for Interpreting Concepts and Conceptual Thought...
Hudspeth, William J. Abstract--- A system for acquisition and decoding of EP and SP signals is provided which comprises a transducer for presenting stimuli to a subject, EEG transducers for recording brainwave signals from the subject, a computer for controlling and synchronizing stimuli presented to the subject and for concurrently recording brainwave signals, and either interpreting signals using a model for conceptual perceptional and emotional thought to correspond EEG signals to thought of the subject or comparing signals to normative EEG signals from a normative population to diagnose and locate the origin of brain dysfunctional underlying perception, conception, and emotion.
USP # 5,356,368 (October 18, 1994)
Method & Apparatus for Inducing Desired States of Consciousness
Monroe, Robert E.
Abstract--- Improved methods and apparatus for entraining human brain patterns, employing frequency following response (FFR) techniques, facilitate attainment of desired states of consciousness. In one embodiment, a plurality of electroencephalogra m (EEG) waveforms, characteristic of a given state of consciousness, are combined to yield an EEG waveform to which subjects may be susceptible more readily. In another embodiment, sleep patterns are reproduced based on observed brain patterns during portions of a sleep cycle; entrainment principles are applied to induce sleep. In yet another embodiment, entrainment principles are applied in the work environment, to induce and maintain a desired level of consciousness. A portable device also is described.
USP # 5,352,181 (October 4, 1994)
Method & Recording for Producing Sounds and Messages...
Davis, Mark E.
Abstract--- A method and recording for use in achieving Alpha and Theta brain wave states and effecting positive emotional states in humans to enhance learning and self-improvement, is provided which includes a medium having a musical composition recorded thereon with an initial tempo decreasing to a final tempo and verbal phrases, comprising between approximately 4 and approximately 8 words, recorded in synchrony with the decreasing initial tempo.
USP # 5,330,414 (July 19, 1994)
Brain Wave Inducing Apparatus
Yasushi, Mitsuo
Abstract--- A random signal generator outputs a random noise signal to a band pass filter which selectively passes frequency components in the frequency range of a desired brain wave from a subject. The output of the band pass filter is supplied to an automatic level controller. The

automatic level controller sets the output of band pass filter to a predetermined amplitude. Then, the output of the automatic level controller is fed to a stimulating light generator, which converts the output of the automatic level controller into a light signal for stimulating the subject in order to induce the desired brain wave from the subject. The light signal is then emitted into the subject's eyes.

USP # 5,289,438 (February 22, 1994)

Method & System for Altering Consciousness

Gall, James

Abstract--- A system for altering the states of human consciousness involves the simultaneous application of multiple stimuli, preferable sounds, having differing frequencies and wave forms. The relationship between the frequencies of the several stimuli is exhibited by the equation g = 2.sup.n/4 .multidot.f where: f = frequency of one stimulus; g = frequency of the other stimuli or stimulus; and n = a positive or negative integer which is different for each other stimulus.

USP # 5,245,666 (September 14, 1993)

Personal Subliminal Messaging System

Mikell, Bruce T.

Abstract--- A personal subliminal messaging system includes a wide range linear subliminal modulator (43), a digital audio recording or play device (46), a microphone (51) to pick up the sound at the ear, and an earpiece (50) to deliver the subliminal message. The sound level at the user's ear is detected and measured. After risetime and decay conditioning of the varying dc control signal, the wide range linear modulator (43) uses this signal to control the level of the message to the earpiece (50). The user adjusts the system for a liminal of a subliminal level. The psychoacoustic phenomena of Post Masking is used to increase the integrity of the message in subliminal messaging systems.

USP # 5,270,800 (December 14, 1993)

Subliminal Message Generator

Sweet. Robert L.

Abstract--- A combined subliminal and supraliminal message generator for use with a television receiver permits complete control of subliminal messages and their manner of presentation. A video synchronization detector enables a video display generator to generate a video message signal corresponding to a received alphanumeric text message in synchronism with a received television signal. A video mixer selects either the received video signal or the video message signal for output. The messages produced by the video message generator are user selectable via a keyboard input. A message memory stores a plurality of alphanumeric text messages specified by user commands for use as subliminal messages.

This message memory preferably includes a read only memory storing predetermined sets of alphanumeric text messages directed to differing topics. The sets of predetermined alphanumeric text messages preferably include several positive affirmations directed to the left brain and an equal number of positive affirmations directed to the right brain that are alternately presented subliminally. The left brain messages are presented in a linear text mode, while the right brain messages are presented in a three dimensional perspective mode. The user can control the length and spacing of the subliminal presentations to accommodate differing conscious thresholds. Alternative embodiments include a combined cable television converter and subliminal message generator, a combine television receiver and subliminal message generator and a computer capable of presenting subliminal messages.

USP # 5,224,864 (July 6, 1993)

Method of Recording and Reproducing Subliminal Signals that are 180 Degrees Out of Phase

Woith, Blake F.

Abstract--- A subliminal recording includes both subliminal message and mask signals applied to both tracks of a two track recording medium. The subliminal message signals are identical in content, and are recorded in an out-of-phase relationship. The mask signals are recorded in phase. The resulting recording may be utilized in the conventional manner for subliminal recordings. By combining the composite signals in an inverted relationship, the mask signals cancel while the subliminal message signals are additive, thus allowing the presence of the subliminal message signal to be confirmed on the recording.

USP # 5,221,962 (June 22, 1993)

Subliminal Device having Manual Adjustment of Perception Level of Subliminal Messages

Backus, Alan L., et al.

Abstract--- A method and apparatus for presenting subliminal visual and/or audio messages which allows user verification of message content and presence, as well as proper adjustment of message obviousness while accounting for ambient conditions and user sensitivities is disclosed. This method and apparatus also presents synchronized reinforced sensory input of subliminal messages. This is performed by simultaneously overlaying images received from a VCR over a plurality of television signals. This apparatus directs overlay images over RF television signals having both audio and video components

USP # 5,215,468 (June 1, 1993)

Method and Apparatus for Introducing Subliminal Changes to Audio Stimuli

Lauffer, Martha A., et al. Abstract--- A method and apparatus for

introducing gradual changes to an audio signal so that the changes are subliminal. The changes can involve tempo and volume, for example, and can take the form of a gentle gradient having ever increasing/decreasi ng ramp-like changes over a sufficient duration, or a more complex program involving several gentle gradients. In the preferred embodiment, an enhanced audio play-back device such as a portable audio cassette recorder can be programmed to subliminally alter the characteristics of a standard pre-recorded tape containing music, for example. As a motivational tool during walking, jogging or other repetitive exercise, the tempo is gradually increased over a period of time to encourage a corresponding gradual (and subliminal) increase in physical exertion by a user whose rate of movement is proportional to the tempo of the music. The tempo can be either manually changed in conjunction with a subliminal program, or by itself in an override mode, or by itself in a version of the present-inventive audio play-back device which allows only manual tempo alternation. In an alternate embodiment, a special pre-recorded tape contains subliminal changes in tempo, for example, for play-back on a standard audio cassette recorder (which operates at one speed, only) to cause the same effect as the preferred embodiment.
USP # 5,213,562 (May 25, 1993)
Method of Inducing Mental, Emotional and Physical States of Consciousness.
.. Monroe, Robert A. Abstract--- A method having applicability in replication of desired consciousness states; in the training of an individual to replicate such a state of consciousness without further audio stimulation; and in the transferring of such states from one human being to another through the imposition of one individual's EEG, superimposed on desired stereo signals, on another individual, by inducement of a binaural beat phenomenon.
USP # 5,194,008 (March 16, 1993)
Subliminal Image Modulation Projection and Detection System and Method
Mohan, William L., et al. Abstract--- Weapon training simulation system including a computer operated video display scene whereon is projected a plurality of visual targets. The computer controls the display scene and the targets, whether stationary or moving, and processes data of a point of aim sensor apparatus associated with a weapon operated by a trainee. The sensor apparatus is sensitive to non-visible or subliminal modulated areas having a controlled contrast of brightness between the target scene and the targets. The sensor apparatus locates a specific subliminal modulated area and the computer determines the location of a target image on the display scene with respect to the sensor apparatus
USP # 5,175,571 (December 29, 1992)
Glasses with Subliminal Message
Tanefsky, Faye, et al.

Abstract--- A pair of subliminal imaging spectacles is provided with a matched pair of visual subliminal images designed and placed so as to merge into one image due to the stereoscopic effect of human vision and thus to impart a subliminal message to the wearer.
USP # 5,170,381 (December 8, 1992)
Method for Mixing Audio Subliminal Recordings
Taylor, Eldon, et al.
Abstract--- Audio subliminal recordings are made in which in addition to using a primary carrier, such as music, two audio channels are used to deliver subliminal messages to the brain. On one channel, accessing the left brain hemisphere, the message delivered is meaningfully spoken, forward-masked, permissive affirmations delivered in a round-robin manner by a male voice, a female voice and a child's voice. On the other channel, accessing the right brain, directive messages, in the same voices, are recorded in backward-masked (or meta-contrast) . The three voices are recording in round-robin fashion with full echo reverberation. The audio tracks are mixed using a special processor which converts sound frequencies to electrical impulses and tracks the subliminal message to synchronize the subliminal message in stereo with the primary carrier. The processor maintains constant gain differential between the primary carrier and the subliminal verbiage and, with the subliminal verbiage being recorded with round-robin, full echo reverberation, ensures that none of a message is lost. The primary carrier should be continuous music without breaks or great differences in movements.
USP # 5,159,703 (October 27, 1992)
Silent Subliminal Presentation System
Lowery, Oliver
Abstract--- A silent communications system in which nonaural carriers, in the very low or very high audio frequency range or in the adjacent ultrasonic frequency spectrum, are amplitude or frequency modulated with the desired intelligence and propagated acoustically or vibrationally, for inducement into the brain, typically through the use of loudspeakers, earphones or piezoelectric transducers. USP # 5,151,080 (September 29, 1992) Method & Apparatus for Inducing & Establishing a Changed State of Consciousness Bick, Claus Abstract--- An electroacoustic device includes a sound generator as well as a system for producing synthetic human speech, connected to a modulation stage for superimposing the output signals thereof. The superimposed output signals are applied via an amplifier stage to one of a headphone system or loudspeaker system.
USP # 5,135,468 (August 4, 1992)
Method & Apparatus of Varying the Brain State of a Person by Means of an Audio Signal Meissner, Juergen P. Abstract--- A method of varying the brain state of a person includes the steps of supplying the first audio

signal to one ear of the person, supplying a second audio signal to the other ear of the person, and substantially continuously varying the frequency of at least one of the first and second audio signals to vary the brain state of the person.
USP # 5,134,484 (July 28, 1992)
Superimposing Method & Apparatus Useful for Subliminal Messages
Willson, Joseph
Abstract--- Data to be displayed is combined with a composite video signal. The data is stored in a memory in digital form. Each byte of the data is read out in sequential fashion to determine: the recurrence display rate of the data according to the frame sync pulses of the video signal; the location of the data within the video image according to the line sync pulses of the video signal; and the location of the data display within the video image according to the position information. Synchronization of the data with the video image is derived from the sync pulses of the composite video signal. A similar technique is employed to combine sound data with an audio signal. Data to be displayed may be presented as a subliminal message or may persist for a given time interval. The data may be derived from a variety of sources including a prerecorded or live video signal. The message may be a reminder message displayed upon a television screen to remind the viewer of an appointment. The data may be stored in a variety of different memory devices capable of high speed data retrieval. The data may be generated locally on-line or off-line and transferred to memory which stores the data necessary to create the message.
USP # 5,128,765 (July 7, 1992)
System for Implementing the Synchronized Superimposition of Subliminal Signals Dingwall, Robert Abstract--- An apparatus and system for the controlled delivery of a subliminal video and/or audio message on to a source signal from a video tape player or similar. The source signal is divided into audio and video portions. A video processor reads sychronization information from the source signal. A controller transmits a stored subliminal image at designated times to a mixer amplifier fully synchronized with the source signal. Concurrently, an audio subliminal message is applied to the source audio at a volume level regulated at some fraction to the source audio. The combined signals are transmitted to a monitor for undistracted viewing.
USP # 5,123,899 (June 23, 1992)
Method & System for Altering Consciousness
Gall, James
Abstract--- A system for altering the states of human consciousness involves the simultaneous application of multiple stimuli, preferable sounds, having differing frequencies and wave forms. The relationship

between the frequencies of the several stimuli is exhibited by the equation g = s.sup.n/4 .multidot.f where: f = frequency of one stimulus; g = frequency of the other stimuli of stimulus; and n=a positive or negative integer which is different for each other stimulus.

USP # 5,052,401 (October 1, 1991)

Sherwin, Gary

Product Detector for a Steady Visual Evoked Potential Stimulator and Product Detector

Abstract--- An automated visual testing system is disclosed which presents an alternating steady state visual stimulus to a patient through an optical system that modifies the stimulus image. As the image changes, the patient produces evoked potentials that change. The evoked potentials are detected by a product detector which produces the amplitude of the evoked potentials. The product detector includes filters which isolate the patient's evoked potentials, a modulator which detects the response using the stimulus source frequency and a demodulator that determines the amplitude of the response. The product detector detects the level of the steady state evoked potential signals even in the presence of substantial background noise and extraneous electroencephalogra hic signals. These detectors can be used to monitor the evoked potential produced by visual, aural or somatic steady state stimuli. The components described above can be used to produce a system that can determine to which of several different displays an observer is paying attention by providing images that blink at different frequencies and product detectors for each of the stimulus frequencies. The product detector producing the highest output indicates the display upon which the observer is focused.

USP # 5,047,994 (September 10, 1991)

Supersonic Bone Conduction Hearing Aid and Method

Lenhardt, Martin, et al.

Abstract--- A supersonic bone conduction hearing aid that receives conventional audiometric frequencies and converts them to supersonic frequencies for connection to the human sensory system by vibration bone conduction. The hearing is believed to use channels of communications to the brain that are not normally used for hearing. These alternative channels do not deteriorate significantly with age as does the normal hearing channels. The supersonic bone conduction frequencies are discerned as frequencies in the audiometric range of frequencies.

USP # 5,036,858 (August 6, 1991)

Method & Apparatus for Changing Brain Wave Frequency

Carter, John L., et al.

Abstract--- A method for changing brain wave frequency to a desired frequency determines a current brain wave frequency of a user,

generates two frequencies with a frequency difference of a magnitude between that of the current actual brain wave frequency and the desired frequency but always within a predetermined range of the current actual brain wave frequency, and produces an output to the user corresponding to the two frequencies. One apparatus to accomplish the method has a computer processor, a computer memory, EEG electrodes along with an amplifier, a programmable timing generator responsive to the computer processor for generating the two frequencies, audio amplifiers and a beat frequency generator driving a visual frequency amplifier.

USP # 5,027,208 (June 25,1991)

Therapeutic Subliminal Imaging System

Dwyer, Jr., Joseph, et al.

Abstract--- A therapeutic subliminal imaging system wherein a selected subliminal message is synchronized with and added to an existing video signal containing a supraliminal message. A television receiver or video recorder can be used to provide the supraliminal message and a video processing circuit varies the intensity of that perceptible message to incorporate one or more subliminal images.

USP # 5,017,143 (May 21, 1991)

Method and Apparatus for Producing Subliminal Images

Backus, Alan, et al.

Abstract--- A method and apparatus to produce more effective visual subliminal communications. Graphic and/or text images, presented for durations of less than a video frame, at organized rhythmic intervals, the rhythmic intervals intended to affect user receptivity, moods or behavior. Subliminal graphic images having translucent visual values locally dependent on background values in order to maintain desired levels of visual contrast.

USP # 4,958,638 (September 25, 1990)

Non-Contact Vital Signs Monitor

Sharpe, Steven, et al.

Abstract--- An apparatus for measuring simultaneous physiological parameters such as heart rate and respiration without physically connecting electrodes or other sensors to the body. A beam of frequency modulated continuous wave radio frequency energy is directed towards the body of a subject. The reflected signal contains phase information representing the movement of the surface of the body, from which respiration and heartbeat information can be obtained. The reflected phase modulated energy is received and demodulated by the apparatus using synchronous quadrature detection. The quadrature signals so obtained are then signal processed to obtain the heartbeat and respiratory information of interest.

USP # 4,924,744 (May 15, 1990)

Apparatus for Generating Sound through Low Frequency and Noise Modulation
Lenzen, Reiner Abstract--- In an apparatus for generating sound, there are provided a plurality of channels for generating sounds. Each of the channels includes a memory for storing waveform data, and at least one of the channels includes a noise generator so that various kinds of sounds including rhythm sound-effects sound, effects sound-vibrato etc. are generated. There is further provided a controller by which voice sound signal is passed through the channels so that artificial sound, voice sound etc. are generated. There is still further provided a circuit for adjusting an amplitude level of a whole sound which is obtained by mixing output sounds of the channels so that far and near sound is produced. Further, each of the channels includes left and right attenuators which divide a channel sound into left and right channel sounds. Still further, the apparatus comprises a low frequency oscillator for controlling a depth of frequency modulation, and a controller for writing sampling data of a predetermined waveform into serial addresses of a memory.
USP # 4,889,526 (December 26, 1989)
Non-Invasive Method & Apparatus for Modulating Brain Signals...
Rauscher, Elizabeth A.
Abstract--- This invention incorporates the discovery of new principles which utilize magnetic and electric fields generated by time varying square wave currents of precise repetition, width, shape and magnitude to move through coils and cutaneously applied conductive eletrodes in order to stimulate the nervous system and reduce pain in humans. Timer means, adjustment means, and means to deliver current to the coils and conductive eletrodes are described, as well as a theoretical model of the process. The invention incorporates the concept of two cyclic expanding and collapsing magnetic fields which generate precise wave forms in conjunction with each other to create a beat frequency which in turn causes the ion flow in the nervous system of the human body to be efficiently moved along the nerve path where the locus of the pain exists to thereby reduce the pain. The wave forms are created either in one or more coils, one or more pairs of electrodes, or a combination of the two.
USP # 4,883,067 (November 28, 1989)
Method & Apparatus for Translating the EEG into Music...
Knispel, Joel, et al.
Abstract--- A method and apparatus for applying a musical feedback signal to the human brain, or any other brain, to induce controllable psychological and physiological responses. A signal representing the ongoing electroencephalogra phic (EEG) signal of a brain preferably is obtained from the electrode location on the scalp known as CZ or P3 in clinical notation. A signal processor converts the ongoing EEG into electrical signals which are converted into music by synthesizers. The

music is acoustically fed back to the brain after a time delay calculated to shift the phase of the feedback in order to reinforce specific or desired ongoing EEG activity from the scalp position of interest. The music is comprised of at least one voice that follows the moment-by-moment contour of the EEG in real time to reinforce the desired EEG activity. The music drives the brain into resonance with the music to provide a closed loop or physiological feedback effect. Preferably, the musical feedback comprises additional voices that embody psychoacoustic principles as well as provide the content and direction normally supplied by the therapist in conventional biofeedback. The invention contemplates numerous applications for the results obtained.

USP # 4,877,027 (October 31, 1989)

Hearing System

Brunkan, Wayne B.

Abstract--- Sound is induced in the head of a person by radiating the head with microwaves in the range of 100 megahertz to 10,000 megahertz that are modulated with a particular waveform. The waveform consists of frewuency modulated bursts. each burst is made up of 10 to 20 uniformly spaced pulses grouped tightly together. the burst width is between 500 nanoseconds and 100 microseconds. The pulse width is in the range of 10 nanoseconds to 1 microsecond. The bursts are frequency modulated by the audio input to create the sensation of hearing in the person whose head is irradiated.

USP # 4,858,612 (August 22, 1989)

Hearing Device

Stocklin, Philip L.

Abstract--- A method and apparatus for stimulation of hearing in mammals by introduction of a plurality of microwaves into the region of the auditory cortex is shown and secribed. A microphone is used to transform sound signals into eletrical signals which are in turn analyzed and processed to provide controls for generating a plurality of microwave signals at different frequencies. the multifrequency microwaves are then applied to the brain in the region of the auditory cortex. By this method sounds are perceived by the mamal which are representative of the original sound received by the microphone.

USP # 4,834,701 (May 30, 1989)

Apparatus for Inducing Frequency Reduction in Brain Wave

Masaki, Kazumi

Abstract--- Frequency reduction in human brain wave is inducible by allowing human brain to perceive 4-16 hertz beat sound. Such beat sound can be easily produced with an apparatus, comprising at least one sound source generating a set of low-frequency signals different each other in frequency by 4-16 hertz. Electroencephalogra phic study

revealed that the beat sound is effective to reduce beta-rhythm into alpha-rhythm, as well as to retain alpha-rhythm.

USP # 4,821,326 (April 11, 1989)
Non-Audible Speech Generation Method & Apparatus
MacLeod, Norman

Abstract--- A non-audible speech generation apparatus adn method for producing non-audible seech signals which includes an ultasonic transducer or vibrator for projecting a series of glottal shaped ultrasonic pulses to the vocal track of a speaker. The glottal pulses, in the approximate frequency spectrum extending from 15 kilohertz to 105 kilohertz, contains harmonics of approximately 30 times the grequency of the acoustical harmonicsgenerated by the vocal cords, but which may nevertheless be amplitude modulated to produce non-auduble speech by the speaker's silently mouthing of words. The ultrasonic speech is then received by an ultasonic transducer disposed outside of the speaker's mouth and electronically communicated to a translation device which down converts the ultrasonics signals to corresponding signals in the audible frquency range and synthesizes the signals into artificial speech.

USP # 4,777,529 (October 11, 1988)
Auditory Subliminal Programming System
Schultz, Richard M., et al.

Abstract--- An auditory subliminal programming system includes a subliminal message encoder that generates fixed frequency security tones and combines them with a subliminal message signal to produce an encoded subliminal message signal which is recorded on audio tape or the like. A corresponding subliminal decoder/mixer is connected as part of a user's conventional stereo system and receives as inputs an audio program selected by the user and the encoded subliminal message. The decoder/mixer filters the security tones, if present, from the subliminal message and combines the message signals with selected low frequency signals associated with enhanced relaxation and concentration to produce a composite auditory subliminal signal. The decoder/mixer combines the composite subliminal signal with the selected audio program signals to form composite signals only if it detects the presence of the security tones in the subliminal message signal. The decoder/mixer outputs the composite signal to the audio inputs of a conventional audio amplifier where it is amplified and broadcast by conventional audio speakers.

USP # 4,734,037 (March 29, 1988)
Message Screen
McClure, J. Patrick

Abstract--- A transparent sheet is disclosed having a message thereon. The sheet has a first side adapted to be attached facing a plate which is normally viewed by a viewer and a second side facing the viewer. The

message is arranged to be readably intelligible from the second side but is not liminally visible to the viewer when viewed from a normal viewing distance from the second side under normal viewing conditions. The message has a subliminal effect upon the viewer when viewed from the normal viewing distance from the second side under normal viewing conditions. A viewer can electively subject him or herself to subliminal messages while viewing television at leisure.

USP # 4,717,343 (January 5, 1988)
Method of Changing a Person's Behavior
Densky, Alan B.

Abstract--- A method of conditioning a person's unconscious mind in order to effect a desired change in the person's behavior which does not require the services of a trained therapist. Instead the person to be treated views a program of video pictures appearing on a screen. The program as viewed by the person's unconscious mind acts to condition the person's thought patterns in a manner which alters that person's behavior in a positive way.

USP # 4,699,153 (October 13, 1987)
System for Assessing Verbal Psychobiological Correlates
Shevrin, Howard, et al.

Abstract--- A system for assessing psychobiological conditions of a subject utilizes a plurality of words which are selected to be in four categories as critical stimuli. The words are presented by a tachistoscope to the subject in subliminal and supraliminal modes of operation. Subliminal stimulation of the subject is achieved by presenting the selected words for an exposure period of approximately one millisecond. The supraliminal exposure time is approximately thirty milliseconds. Prior to stimulation, the subject is diagnosed in accordance with conventional psychoanalytical techniques to establish the presence and nature of a pathological condition. The words are selected and categorized in four groups: pleasant words, unpleasant words, words related to a diagnosed conscious pathological condition, and words related to a diagnosed unconscious pathological condition. The brain wave responses which are evoked by the stimulation are collected via electrodes and analyzed in accordance with a transinformation technique which is based on information signal theory for establishing a probabilistic value which corresponds to the information content of the evoked responses.

USP # 4,692,118 (September 8, 1987)
Video Subconscious Display Attachment
Mould, Richard E.

Abstract--- An apparatus and method for introducing messages to the subconscious mind is disclosed, which includes a panel positioned adjacent a television screen, with the panel having non-distractive

messages imprinted thereon, such that as the subject consciously focuses his attention on the video screen, his subconscious mind records the message from the panel that is within his peripheral vision.

USP # 4,616,261 (October 7, 1986)

Method & Apparatus for Generating Subliminal Visual Messages

Crawford, James R., et al.

Abstract--- A system for generating a subliminal message during the display of a normal television program on a television receiver utilizes a personal computer to generate an RF carrier modulated with video signals encoding the subliminal message. The computer runs under the control of an application program which stores the subliminal message and also controls the computer to cause it to generate timing signals that are provided to a single pole double-throw switch. The source of the normal television program and the video output of the computer are connected to the two switch inputs and the switch output is connected to the television receiver antenna system. The timing signals cause the switch to normally display the conventional television program and to periodically switch to the computer output to generate the subliminal message. The video output of the computer includes horizontal and vertical synchronizing signals which are of substantially the same frequency as the synchronizing signals incorporated within the normal program source but of an arbitrary phase.

USP # 4,573,449 (March 4, 1986)

Method for Stimulating the Falling Asleep and/or Relaxing Behavior of a Person Warnke, Egon F. Abstract--- A method and apparatus is provided with which a person suffering from sleeplessness can be more easily relaxed and may more rapidly fall asleep. In particular, sound pulses are emitted by an electro-acoustic transducer, according to the cadence of which, the person seeking to fall asleep is induced to breathe in and out over a predetermined period of time. By suitably selecting the pulse sequence frequency, the pitch and the amplitude of the sound pulses may be adjusted thereby enhancing the process of falling asleep.

USP # 4,508,105 (April 2, 1985)

Shadow Generating Apparatus

Whitten, Glen, et al.

Abstract--- Disclosed is an apparatus for inducing various brain wave patterns through visual stimulation. The apparatus comprises a pair of spectacles or other viewing apparatus having a liquid crystal display embedded in each lens. By repetitively activating and deactivating the liquid crystals, shadows are generated which are perceived by the subject individual wearing the viewing apparatus. Responding to the frequency of shadow generation, the subject's brain is thereby induced to generate sympathetic brain wave frequencies. The apparatus finds particular utility

in the generation of alpha waves. Because learning is enhanced when the brain is in the alpha state, activities such as listening to tapes or lectures and the like can be carried out with greater facility. Shadow generation is accomplished through the use of a timing mechanism for each liquid crystal display and the frequency for each is adjustable over a wide range, permitting synchronous or asynchronous timing.
USP # 4,395,600 (July 26, 1983)
Auditory Subliminal Message System & Method
Lundy, Rene R., et al.
Abstract--- Ambient audio signals from the customer shopping area within a store are sensed and fed to a signal processing circuit that produces a control signal which varies with variations in the amplitude of the sensed audio signals. A control circuit adjusts the amplitude of an auditory subliminal anti-shoplifting message to increase with increasing amplitudes of sensed audio signals and decrease with decreasing amplitudes of sensed audio signals. This amplitude controlled subliminal message may be mixed with background music and transmitted to the shopping area. To reduce distortion of the subliminal message, its amplitude is controlled to increase at a first rate slower than the rate of increase of the amplitude of ambient audio signals from the area. Also, the amplitude of the subliminal message is controlled to decrease at a second rate faster than the first rate with decreasing ambient audio signal amplitudes to minimize the possibility of the subliminal message becoming supraliminal upon rapid declines in ambient audio signal amplitudes in the area. A masking signal is provided with an amplitude which is also controlled in response to the amplitude of sensed ambient audio signals. This masking signal may be combined with the auditory subliminal message to provide a composite signal fed to, and controlled by, the control circuit.
USP # 4,388,918 (June 21, 1983)
Mental Harmonization Process
Filley, Charles C.
Abstract--- A state of relaxation or mental harmonization in a subject is created by exposing a color solely to one field of vision of a subject and the complement of that color solely to the other field of vision of the subject while simultaneously exposing an audible tone solely to one ear of the subject and a harmonious tone solely to the other ear of the subject. The color and tones employed are subjectively comfortable and compatible. Preferably, the frequency difference between the two audible tones is one-half the frequency of the audible tone having the lowest frequency.
USP # 4,354,505 (October 19, 1982)
Method of and Apparatus for Testing and Indicating Relaxation State of a Human Subject Shiga, Kazumasa Abstract--- In a self-training biofeedback system, a physiological signal representing the state of relaxation of a

person using the system is applied to a time counter to generate a binary count output representing the relaxation period. A visual indicator connected to the time counter provides the self trained person with a quick display of the measured time period so he can gauge the depth of his relaxation.

USP # 4,335,710 (June 22, 1982)
Device for the Induction of Specific Brain Wave Patterns
Williamson, John

Abstract--- Brain wave patterns associated with relaxd and meditative states in a subject are gradually induced without deleterious chemical or neurological side effects. A white noise generator (11) has the spectral noise density of its output signal modulated in a manner similar to the brain wave patterns by a switching transistor within a spetrum modulator and converted to an audio signal by acoustic transducer. Ramp generator gradually increases the voltage received by and resultant output frequency of voltage controlled oscillator whereby switching transistor periodically shunts the high frequency components of the white noise signal to ground.

USP # 4,315,501 (February 16, 1982)
Learning-Relaxation Device
Gorges, Denis E.

Abstract--- Disclosed is a device for relaxing, stimulating and/or driving brain wave form function in a human subject. The device comprises, in combination, an eye mask having independently controlled left and right eyepieces and a peripheral light array in each eyepiece, an audio headset having independently controlled left and right earpieces and a control panel which controls light and sound signals to the light arrays and earpieces, respectively. Various control functions allow simultaneous or alternating light and sound pulsations in the left and right light arrays and earpieces, as well as selective phasing between light and sound pulsations.

USP # 4,227,516 (October 14, 1980)
Apparatus for Electrophysiologica l Stimulation
Meland, Bruce C., et al.

Abstract--- Apparatus for the electrophysiologica l stimulation of a patient is provided for creating an analgesic condition in the patient to induce sleep, treat psychosomatic disorders, and to aid in the induction of electrohypnosis and altered states of consciousness. The foregoing is achieved by repetitive stimuli in the patient for whom external influences, namely those of sight and sound, are intentionally excluded. The apparatus produces electrical stimulation of the patient in the form of a modulated wave which produces impulses in the delta, theta, alpha and beta regions of the brain's electrical activity, the electrical

stimulation being accompanied by two sources of audio stimulation, one of which is a sinusoidal tone modulated by and synchronized with the electrical stimulation, and the other is derived from sound recordings.
USP # 4,191,175 (March 4, 1980)
Method & Apparatus for Repetitively Producing a Noise-like Audible Signal
Nagle, William L. Abstract--- A digital pulse generator and shift register repetitively produce bursts of digital pulses at a first adjustable repetition frequency. The repetition frequency of the pulses in each burst is also adjustable. A pink noise filter accentuates the lower burst frequency components near 7 hz and substantially attenuates all frequency components of the bursts above a first cut-off point near 10 Khz. A tunable band pass amplifier having a center frequency adjustable over a preselected range of frequencies optimally detectable by the average human ear accentuates the pink noise filter output near 2.6 Khz. The tunable amplifier drives an audible signal source with noise-like pulses of varying amplitudes and frequency components. A low pass amplifier may be connected to the pink noise filter to generate a train of pulses having a repetition frequency near 7 hz which pulses a light source in synchronism with the audible noise-like signal.
USP # 4,141,344 (February 27, 1979)
Sound Recording System
Barbara, Louis J.
Abstract--- In recording an audio program, such as music or voice, on a magnetic tape recorder an A.C. signal generator operating at a frequency below about 14 Hz provides an AC baseline for the audio program signal. This 14 Hz or lower AC signal is sensed by the listener's ear to create an Alpha or Theta state in his brain when the tape is played back.
USP # 4,082,918 (April 4, 1978)
Audio Analgesic Unit
Chang, Roland W., et al.
Abstract--- An audio analgesic unit for use in masking sounds and substituting another sound which includes earmuffs to be used by a dental patient in which speakers are arranged and connected to a patient operated remote control unit to control the sound levels and a master control unit to override the patient remote control unit and operated by an operator, such as a dentist. A beeper indicates operation mode change.
USP # 4,034,741 (July 12, 1977)
Noise Generator & Transmitter
Adams, Guy E., et al.
Abstract--- An analgesic noise generator employs a circuit that can be switched to provide a variable waveform from an active noise source out of an integrated circuit amplifier. USP # 3,967,616 (July 6, 1976)

Multichannel System for & Multifactorial Method of Controlling the Nervous System of a Living Organism Ross, Sidney A. Abstract--- A novel method for controlling the nervous system of a living organism for therapeutic and research purposes, among other applications, and an electronic system utilized in, and enabling the practice of, the invented method. Bioelectrical signals generated in specifictopological areas of the organism's nervous system, typically areas of the brain, are processed by the invented system so as to produce a sensory stimulus if the system detects the presence or absence, as the case may be, of certain characteristics in the waveform patterns of the bioelectrical signals being monitored. The coincidence of the same or different characteristics in two or more waveform patterns, or the non-coincidence thereof, may be correlated with a certain desired condition of the organism's nervous system; likewise, with respect to the coincidence or non-coincidence of different characteristics of a single waveform pattern. In any event, the sensory stimulus provided by the invented system, typically an audio or visual stimulus, or combination thereof, is fed back to the organism which associates its presence with the goal of achieving the desired condition of its nervous system. Responding to the stimulus, the organism can be trained to control the waveform patterns of the monitored bioelectrical signals and thereby, control its own nervous system. The results of the coincidence function permit results heretofore unobtainable.
USP # 3,951,134 (April 20, 1976)
Apparatus & Method for Remotely Monitoring & Altering Brain Waves Malech, Robert G.
Abstract--- Apparatus for and method of sensing brain waves at a position remote from a subject whereby electromagnetic signals of different frequencies are simultaneously transmitted to the brain of the subject in which the signals interfere with one another to yield a waveform which is modulated by the subject's brain waves. The interference waveform which is representative of the brain wave activity is re-transmitted by the brain to a receiver where it is demodulated and amplified. The demodulated waveform is then displayed for visual viewing and routed to a computer for further processing and analysis. The demodulated waveform also can be used to produce a compensating signal which is transmitted back to the brain to effect a desired change in electrical activity therein.
USP # 3,884,218 (May 20, 1975)
Method of Inducing & Maintaining Various Stages of Sleep in the Human Being Monroe, Robert A. Abstract--- A method of inducing sleep in a human being wherein an audio signal is generated comprising a familiar pleasing repetitive sound modulated by an EEG sleep pattern. The volume of the audio signal is adjusted to overcome the ambient noise and a subject can

select a familiar repetitive sound most pleasing to himself.
USP # 3,837,331 (September 24, 1974)
System & Method for Controlling the Nervous System of a Living Organism
Ross, S. Abstract--- A novel method for controlling the nervous system of a living organism for therapeutic and research purposes, among other applications, and an electronic system utilized in, and enabling the practice of the invented method. Bioelectrical signals generated in specific topological areas of the organism's nervous system, typically areas of the brain, are processed by the invented system so as to produce an output signal which is in some way an analog of selected characteristics detected in the bioelectrical signal. The output of the system, typically an audio or visual signal, is fed back to the organism as a stimulus. Responding to the stimulus, the organism can be trained to control the waveform pattern of the bioelectrical signal generated in its own nervous system.
USP # 3,835,833 (September 17, 1974)
Method for Obtaining Neurophysiological Effects
Limoge, A.
Abstract--- A method and apparatus for obtaining neurophysiological effects on the central and/or peripheral systems of a patient. Electrodes are suitably positioned on the body of the patient and a composite electric signal is applied at the electrodes. The composite signal is formed by the superpositioning of two signals: a first signal which is a rectified high-frequency carrier modulated in amplitude to about 100 percent by substantially square-shaped pulses whose duration, amplitude and frequency are chosen according to the neurophysiological effects desidered, and a second signal which has a relatively white noise spectrum. The mean value of the first electric signal has a predetermined sign which is opposite the sign of the mean value of the second electric signal.

Slow wave sleep;
Rapid eye movement sleep

Abstract In the present study, the alteration in the sleep EEG in rats due to chronic exposure to low-level non-thermal electromagnetic radiation was investigated. Two types of radiation fields were used; 900 MHz *unmodulated* wave and 900 MHz *modulated* at 8 and 16 Hz waves. Animals has exposed to radiation fields for 1 month (1 h/day). EEG power spectral analyses of exposed and control animals during slow wave sleep (SWS) and rapid eye movement sleep (REM sleep) revealed that the REM sleep is more susceptible to modulated radiofrequency radiation fields (RFR) than the SWS. The latency of REM sleep increased due to radiation exposure indicating a change in the ultradian rhythm of normal sleep cycles. The cumulative and irreversible effect of radiation exposure was proposed and the interaction of the extremely low frequency radiation with the similar EEG frequencies was suggested.

Introduction

The widespread of radiofrequency radiation (RFR) sources in domestic use has increased over the last decades, especially in the communication field, and public concern has been raised to quantify the health hazard problems that may occur due to the exposure to such type of non-ionizing radiation.

Tissue heating is the most widely accepted mechanism of microwave radiation with biological systems. These effects can result from elevations of tissue temperature induced by radiofrequency (RF) energy deposited or absorbed in biological systems through local, partial-body or whole-body exposures. However, a large bulk of literature have evidenced that several biological effects of RF can be formed without tissue heating which are known as non-thermal biological effects of radiation [1].

EEG considered to be a sensitive tool to asses quantify and classify sleep stages as well as study their changes due to radiation interaction with the brain. In human and most animals, EEG appears as low-amplitude fast waves during awake state, high-amplitude slow waves during SWS and low amplitude fast waves during REM sleep.

It has also been repeatedly reported that exposure to low-level microwaves produces alterations in the resting or sleep EEG signal and brain physiology [2–4]. It has been demonstrated that exposure to pulse-modulated microwaves alters not only the EEG but also regional cerebral blood flow [5,6]. Furthermore, it has been reported that modulation is crucial for radiofrequency electromagnetic field-induced alterations in brain physiology [6].

Sleep function is hypothesized to be the reprocessing and consolidation of memory traces [7,8]. There is also some recent evidence suggesting that sleep may help to protect declarative memories from subsequent associative interferences [9].

Sleep is one of the biological phenomena that can be affected by RF radiation exposure. Mann and Roschke [10] reported reduction in latency to sleep onset and the percentage of REM sleep due to exposure to GSM-like signals. Loughran et al. [11] reported a decrease in REM sleep latency after 30 min of 894.6 MHz radiation exposure.

In the present study, several aims have been addressed. First, the non-thermal effect of electromagnetic radiation was studied by the application of low-level radiation ($0.025\ mW/cm^2$). Second, the differences in the effect of the continuous and the modulated wave's electromagnetic radiation were checked out by application of these two types of radiation. The modulation frequencies were selected to be within the physiological range of the brain's EEG signals to assess the interaction of theses similar frequencies. Finally, the chronic exposure of radiation rather than the acute exposure was used to investigate the cumulative nature of radiation effects on the biological system.

Material and methods

Experimental animals

The experimental animals used in the present study were adult male Wistar albino rats, weighing 175–250 g. The animals were obtained from the animal house of the National Research Center, Egypt. They were maintained on stock diet and kept under fixed conditions of housing and handling. They were under controlled light-dark cycle (on at 7 a.m. and off at 7 p.m.) and temperature conditions (25 ± 2 °C). All experiments were carried out in accordance with the research protocols established by the Animal Care Committee of the National Research Center, Egypt which followed the recommendations of the National Institutes of Health Guide for Care and Use of Laboratory Animals (Publication No. 85-23, revised 1985).

Experimental design

A total of 40 rats were divided into four groups. Three groups were irradiated with electromagnetic radiation either 900 MHz continuous wave or frequency-modulated (8 and 16 Hz) wave on a daily basis, (1 h per day) for 1 month. The fourth group served as a control group with the same experimental conditions except radiation exposure.

The exposure setup

The radiofrequency (RF) generator (Aeroflex company, Model: 2025, UK) connected to a power amplifier (Stealth Microwave, Model: SM 0520-36, SSB Technologies, Inc., NJ, USA) was used to generate the electromagnetic radiation. The amplifier, in turn, was connected to a circular monopole antenna designed so that the reflection coefficient at its input should not more than -12 dBm and fed by a coaxial line through a Bayonet Neill-Concelman (BNC) connector. The spatial distribution of the electromagnetic radiation power density was measured with a field meter (Narda, EMR200, frequency from 0 to 4 GHz, Germany).

The specific absorption rate (SAR) distribution in the rat head was determined by using the finite different time domain (FDTD) method, with the aid of the XFDTD Bio-pro software (version: 6.3.8.4, NY, USA). Geometric/electric model was constructed for the animal's head from the stereotaxic atlas of Paxinos and Watson [12]. An ellipsoid model with the internal anatomic layers was used. The standard dielectric properties [13] were assigned to each layer. The animal head model was subjected to RFR with the same power density as that measured by the field meter through the experimental exposure process. The FDTD algorithm was then applied to calculate the electric field distribution everywhere inside the head model. The SAR was calculated at the desired points as $\sigma DED^2/2\rho$, where E is the electric field peak value at the point (V/m), σ is the conductivity of the tissue at this point (S/m) and ρ is the density of the tissue (Kg/m^3). The calculated spatial peak SAR averaged over 1 g was found to be 0.245 W/kg.

As shown in Fig. 2, rats were housed in a circular plastic tray (50 cm diameter) which is divided into equal sectors to ensure that all rats were equally exposed to radiation. The antenna emitting the electromagnetic radiation was fixed in the center of the tray. To avoid stress, an aperture (1.5 cm in diameter) was made in the upper lid of each sector tip toward the antenna for animal breathing and this design make the animals freely direct their heads toward the radiation antenna.

EEG recording and analysis

Under Na-pentobarbital anesthesia (40 g/kg of animal), animals were positioned in the stereotaxic device (David Kopf instruments, Tujunga, California, USA) and implanted with three epidural stainless steel electrodes, of 1 mm diameter, Electrodes were implanted over the frontal cortex at 3.9 mm anterior to the Bregma and 2 mm lateral (right) to the midline, the other electrode was implanted at 6.4 mm posterior to the Bregma and 4 mm lateral (right) to the midline, whereas, the third electrode (reference electrode) was implanted over the cerebellum 1 mm posterior to Lambda, on the extension of the midline [12]. The three electrodes were connected to a multipin connector base, and the entire assembly was fixed to the skull and isolated with dental cement (zinc polycarboxylate non-irritating dental cement, purchased from Spofa-Dental-Praha, Czech Republic).

During EEG recordings, rats were housed in a sound attenuated, aerated and electrically shielded cage ($25 \times 25 \times 30$ cm). They were left 30 min prior to recording for acclimatization to the laboratory environment. EEG recordings were performed at fixed time of the day under the following conditions; 50 Hz notch filter and sampling rate of 200 sample/s.

REM sleep was characterized by low-voltage (desynchronized) EEG activity and continuous high theta power (4–8 Hz) [14,15]. SWS was characterized by high-voltage (syn-

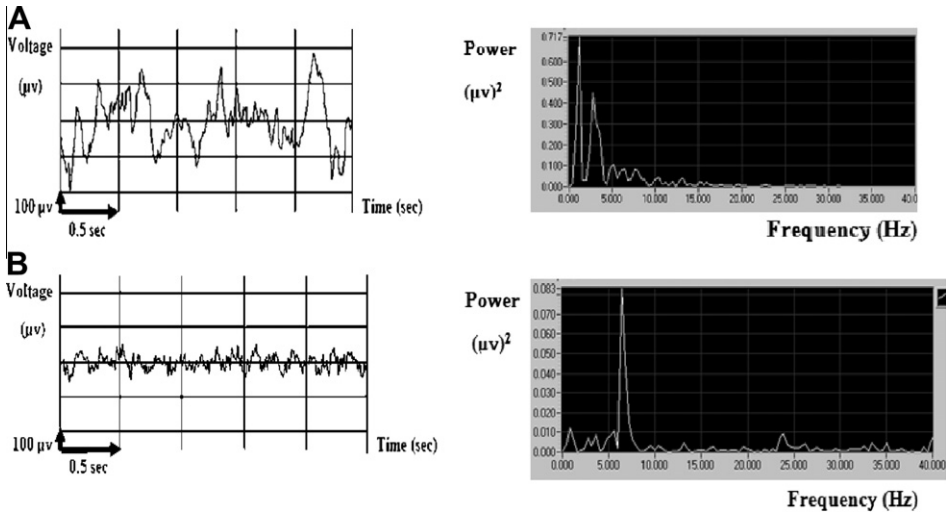

Fig. 1 EEG time domain signals and their corresponding power spectra during: (A) SWS and (B) REM sleep in an unexposed rat.

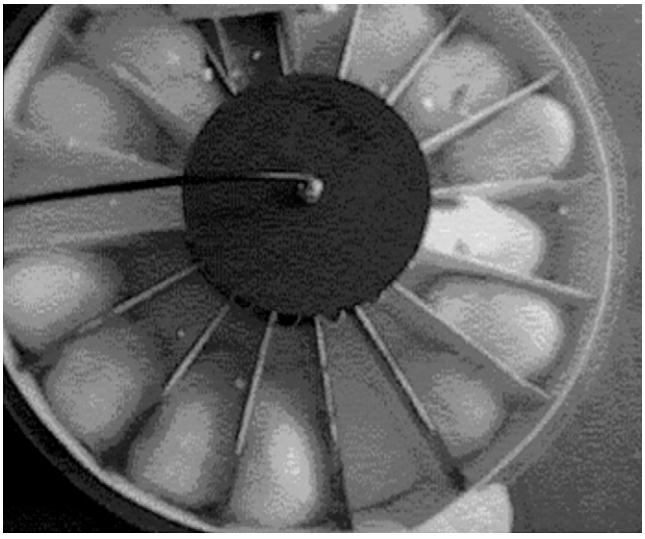

Fig. 2 Exposure set-up of the animals with the antenna placed in the center.

chronized) EEG activity and high delta power (1–4 Hz). Using both the time and frequency domains criteria, the two different sleep states were distinguished over 1 h of EEG recording session.

The Fast Fourier Transform (FFT) was used to convert data from the time domain to the frequency domain to obtain power spectra for each of the SWS and REM sleep samples. The obtained power spectrum of each sample was segmented into five frequency bands, delta (1–4 Hz); theta (4.1–8 Hz); alpha (8.1–13 Hz); beta-1 (13.1–18 Hz); beta-2 (18.1–30 Hz). The band power (BP), which is the integration of the power in certain EEG band, for SWS and REMS states were calculated, then an average was estimated over 1 h of EEG session. For comparison purpose and to overcome the inter-individual variations, a normalization of band power was achieved by dividing value of the individual band power by the total power of all bands for each animal.

The latency of REM sleep, which is the period of time between the onset of sleep and the appearance of the first REM, was measured. Statistical analysis between control and irradiated animals were determined by using student's *t*-test.

Results

Identification of SWS and REM sleep patterns

The base line recording of rat's EEG during SWS and REM sleep is illustrated in Fig. 1A and B, respectively. As shown in Fig. 1A, the pattern of the EEG recorded during SWS is generally characterized by high amplitude and slow frequency in contrast to the pattern of EEG recorded during REM sleep which is characterized by lower amplitude and higher frequency as shown in Fig. 1B. On the basis of amplitude and frequency analysis the two types of sleep (SWS and REM) were identified.

Effect of continuous and modulated RFR on EEG bands power during SWS

The effect of RFR on the EEG band power (BP) values during SWS in adult male rats is presented in Table 1 and Fig. 3. Generally, The RFR resulted in non-significant changes in the BP values during SWS. At continuous RF, the BP values of both theta and alpha frequency bands showed increases (+7.477% and +19.093%, respectively) with respect to the control values, while the delta BP value showed a decrease of (−13.857%) below the control value. Beta-1 and beta-2 frequency bands showed nearly control-like values (+0.512% and 0.416%, respectively).

At 8 Hz modulated RF, there was an increase in the band power (BP) value of the delta and theta waves (+6.205% and +3.673%, respectively). However, The BP values of alpha, beta-1 and beta-2 frequency band showed decreases with respect to the control group, the highest decrease was observed for the beta-2 (−19.351%), followed by beta-1 (−8.738%) and the least decrease (−6.315%) was recorded for the alpha band.

Table 1 Effect of RFR on the EEG band power during SWS.

SWS	EEG band	Control	900 MHz	900 MHz modulated at 8 Hz	900 MHz modulated at 16 Hz
	Delta	37.84 ± 2.27	32.59 ± 2.39	40.18 ± 3.45	37.75 ± 3.7
	Theta	28.04 ± 0.92	30.14 ± 0.66	29.07 ± 2.30	27.11 ± 0.58
	Alpha	17.91 ± 1.54	21.33 ± 1.11	16.73 ± 2.55	20.09 ± 2.12
	Beta-1	9.18 ± 0.99	9.23 ± 0.50	8.37 ± 1.22	9.62 ± 1.51
	Beta-2	6.97 ± 0.64	6.99 ± 0.70	5.62 ± 0.61	5.59 ± 0.84

Mean ± SEM values.
*Significant $P < 0.05$.

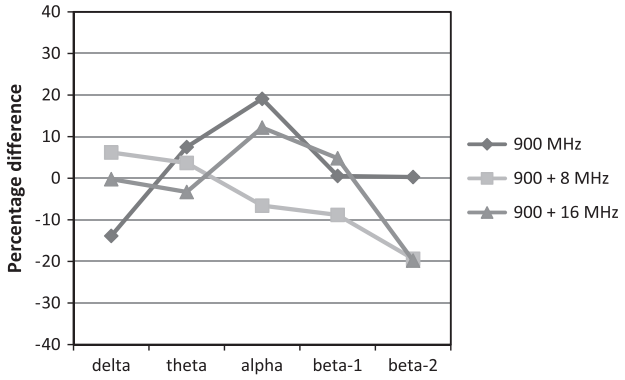

Fig. 3 Percentage differences between control and irradiated groups of EEG bands power at 900 MHz un-modulated wave and 900 MHz modulated at 8 and 16 Hz during SWS.

At 16 Hz modulated RF, The increase was detected in the alpha and beta-1 frequency band, (+12.185% and +4.859, respectively) whereas, delta, theta and beta-2 BPs showed decreases with respect to control values (−0.216%, −3.313% and −19.824% respectively).

Effect of continuous and modulated RFR on EEG bands power during REM sleep

The data showing the effect of RFR on the BP values during REM sleep of adult male rats is presented in Table 2 and Fig. 4. At continuous RF, non-significant changes were recorded, however the low frequency delta BP showed a moderate increase (+18.567%) above the control value, the theta and beta-2 BPs were recorded nearly normal-like values (+2.234% and −1.144%, respectively). Meanwhile, the BPs of alpha and beta-1 showed moderate decreases (−19.904% and −18.223%, respectively).

At 8 Hz modulated RF, there was a significant decrease (−15.698%) in the BP value of the theta frequency band. In beta-2 BP value a considerable but non-significant increase (+27.646%) was recorded with respect to the control group. Moderate and slight increases in the BPs of delta and beta-1 were observed (+14.222% and 8.628%, respectively). Meanwhile, the alpha BP was recorded as nearly a control-like value (−1.834%).

At 16 Hz modulated RF, The theta BP showed a significant increase (+19.464%) and beta-1 band power showed a significant decrease (−27.794%) with respect to the control group. Considerable decreases were observed in beta-2 and alpha waves (−22.223% and −28.097%, respectively). Delta BP showed an increase by +6.349% above the control value.

Effect of continuous and modulated RFR on REM sleep latency

The effect of RFR on the REM sleep latency period (the time between the onset of the rat's sleep and the appearance of the first REM period) during 1 h of sleep in adult male rats is presented in Table 3 and Fig. 5. The three irradiated groups showed increases in the REM sleep latency period with respect to control. At continuous RF and 8 Hz modulated waves, a considerable increase above the control value were obtained, (+28.220% and +13.794%, respectively) compared to the control value. However, at 16 Hz modulated RF a significant increase in the REM sleep latency period (+94.252%) was determined as compared to the control.

Discussion

The spectrum of rodent sleep is typically divided into two categories: slow wave sleep (SWS) and rapid-eye-movement (REM) sleep [16,17]. Both these states of sleep could be easily distinguished from each other by inspection of sleep EEG signals amplitudes and frequencies (see Material and methods section). Based upon this sleep phenomenon, the present study aimed to investigate whether these two states of sleep could be affected differently by electromagnetic radiation field's exposure.

Table 2 Effect of RFR on the EEG band power during REM sleep.

REM	EEG bands	Control	900 MHz	900 MHz modulated at 8 Hz	900 MHz modulated at 16 Hz
	Delta	23.36 ± 2.02	27.69 ± 2.86	26.68 ± 1.16	24.84 ± 3.73
	Theta	41.13 ± 2.10	42.05 ± 2.09	34.67 ± 1.53*	49.14 ± 1.66*
	Alpha	17.44 ± 2.09	13.97 ± 2.09	17.12 ± 1.82	12.54 ± 2.59

The current safety standards of electromagnetic radiation are based on thermal effects only and completely ignoring the non-thermal biological and health effects [18]. Several studies have showed that the low level non-ionizing radiation has adverse effects on different biological levels [19–22]. In the present study, we used low level electromagnetic radiation (0.025 mW/cm^2) which resulted in low SAR value (0.245 W/Kg) to investigate the effect of such non-thermal radiation on the sleep patterns of rat. Generally, the changes induced in the sleep EEG frequency bands, either with continuous or modulated low level radiation fields in irradiated animals with respect to control animals in the present study, provide evidence about the hypothesis of non-thermal effects of electromagnetic on the brain physiology. The mechanism of non-thermal RFR on biological tissues still under investigation, however, calcium efflux and free radical production are among the candidates of the possible mechanism responsible for non-thermal effects of RFR.

In the present study the exposure of the animals to 900 MHz RFR either continuous or modulated at 8 and 16 Hz resulted in non-significant changes of all EEG bands during SWS. However, significant changes have been recorded during REM sleep especially with modulated electromagnetic radiation fields. This result denotes that the REM sleep is more sensitive to changes due to electromagnetic radiation exposure than SWS. One possible mechanism for interpretation of the sensitivity of the REM sleep for RFR is the interaction of the RFR with the central cholinergic system that known to control both REM sleep and waking state in the animal [23]. On the other hand, many studies have shown the importance of REM sleep for successful memory consolidation and learning in rats [24–27]. Therefore, the alteration in REM sleep due to RFR may compromise memory and learning process in rat.

During REM sleep, in the present study, exposure to RFR modulated at 8 Hz resulted in significant decrease in Theta BP (−15.7%) and exposure to RFR modulated at 16 Hz resulted in a significant decrease in the beta-1 BP (−27.79%). Both of these suppressed frequency bands have a frequency range which is similar to the used modulation frequency, respectively. It has earlier been reported that inhibitory as well as excitatory influences of high frequency electromagnetic fields are dependent on the kind of signal modulation [28]. Recently, Hinrikus et al. [29] have found that exposure of humans to 450 MHz microwave modulated at 14, 21, 40, 70 and 217 Hz affects the EEG frequencies lower or close to the modulation frequency and that no significant effect was detected at EEG frequencies higher than the modulation frequency. A review on animal studies suggested that pulse modulations between 8 and 16 Hz might be critical for physiological effects of GSM mobile phone signals [30]. It could be suggested that the presence of such extremely low frequencies, which are within the physiological range of the brain signals, may play a role in enhancing the interaction of RFR with the brain physiology. However, the mechanism of interaction between these frequencies and brain signals still unclear.

Using of acute rather than chronic exposure to RFR led several studies to report negative effects of exposure on the brain physiology [31–34]. In the present study; the animals were exposed to RFR for 30 consecutive days. This relatively long period of exposure allows the radiation effects to be accumulated and ends up with effects that may have not appeared in acute experiment. Furthermore, this may explain the discrepancy of results in the literature between the acute and the chronic exposure to radiation fields.

The irradiated groups, in the present study, showed a large increase in the REM sleep latency. The change in the REM sleep latency may suggest initial alterations to the ultradian rhythm of the SWS/REM sleep cycle [35]. Numerous findings confirmed that cholinergic mechanisms are essential for the generation of REM sleep and its physiologic signs [36,37]. The alterations in the cholinergic neurons or their innervations by the interaction with RFR may lead to changes in the REM latency.

Conclusions

In the present study, it can be concluded that exposure to electromagnetic radiation in awake animals can alter their subsequent sleep structure. The REM sleep considered to be more sensitive for RF radiation than SWS as indicated from sleep EEG data analyses. The using of frequencies similar or close to the biological frequencies could result in more adverse effect than other frequencies which lie far from biological frequencies. The increase in REM latency after irradiation denotes change in the sleep pattern of the exposed animals and provides evidence about the adverse effect of non-thermal electromagnetic radiation fields on brain physiology. Further studies are needed to explore the mechanism of interaction between electromagnetic radiation fields and the biological phenomena.

Acknowledgments

This study was a part of a project entitled ''a study on the influence of mobile phone radiation on some function of central nervous system''. The project was granted by the sector of ''International cooperation with USA'', Foreign Ministry, Egypt.

Opinion and Debate

Terrorism and Mental Health: The issue of psychological fragility

Amin A. Muhammad Gadit
Discipline of Psychiatry, Memorial University of Newfoundland, St. John's, NL A1B 3V6 Canada.

It is rightly said that the world is no longer a safe place to live due to the growing terrorism. According to the U.S. Department of State report, 'Terrorism is premeditated, politically motivated violence perpetrated against noncombatant targets by subnational groups or clandestine agents, usually intended to influence an audience.[1] A universal medical and public health definition was proposed which is: "The intentional use of violence, real or threatened, against one or more non-combatants and/or those services essential for or protective of their health, resulting in adverse health effects in those immediately affected and their community, ranging from a loss of well-being or security to injury, illness or death."[2]

The terrorist incidents of Pan Am Flight 103, Oklahoma City bombing and attack on World Trade Centre has shaken the mental health of children and adults in United States. The incidence of Post-Traumatic Stress Disorder (PTSD) has been recorded to be quite high among adults while children exhibited depressive disorder, separation anxiety disorders, grief reactions as well as PTSD. A survey conducted on 512 participants out of whom 84 had been directly exposed to a terrorist attack and 191 had a family member or friend exposed to such an attack revealed PTSD among 48 participants, acute stress disorder by one participant and 299 reported depression.[3]

In a study[4] among Vietnamese refugees, people who were exposed to more than three trauma events had heightened risk of mental illness after 10 years compared to people with no trauma exposure. Results[5] from a meta-analysis indicates that in a year following terrorist incidents, the prevalence of PTSD in directly affected populations varies between 12% and 16%. A national household survey[6] on 4,023 people revealed six-months PTSD prevalence to be 3.7% for boys and 6.3% for girls, Major Depressive Episode among boys was 7.4% and 13.9% in girls, Substance Abuse Disorder had a six-month prevalence of 8.2% among boys and 6.2% for girls. In a study by Wanda,[7] children's responses to terrorism include acute stress disorder, posttraumatic stress disorder, anxiety, depression, regressive behaviours, separation problems and sleep difficulties. Adults, adolescents and children do get the effects from violence and terrorism depending upon the type of event and psychological endurance. However, it is important to note the fact that the experience of violence does not necessarily lead to psychiatric morbidity.[8] W.H.O. estimated that, in the situation of armed conflicts throughout the world "10% of the people who experience traumatic events will have serious mental health problems and another 10% will develop behaviour that will hinder their ability to function effectively. The most common conditions are depression, anxiety and psychosomatic problems such as insomnia, or back and stomach aches."[9]

The matters in terms of violence are advancing with the passage of time that may possibly bring in more serious issues related to both physical as well as mental health.

Of late, there are reports of a new and dreadful invention of weapons of violence that are called Bio-electromagnetic Weapons. According to the description by an Institute of Science in Society, these weapons operate at the speed of light, can kill, torture and enslave without making physical appearance. It further adds that voices and visions, daydreams and nightmares are the most astonishing manifestations of this weapon system, it is also capable of crippling the human subject by limiting his/her normal range of movement, causing acute pain the equivalent of major organ failure or even death and interferes with normal functions of human senses. It can cause difficulty with breathing and induce seizures besides damage to the tissues and organs.

Through this form of terrorism, it is possible to persuade subjects that their mind is being read; their intellectual property is being plundered and can even motivate suicide or murder. Pulsed Energy Projectiles (PEPs) are another form of weaponry that is used to paralyze a victim with pain. According to Peter Philips, a scientist from USA, circumstances may soon arrive in which anti-war or human right protestors suddenly feel a burning sensation akin to touching a hot skillet over their entire body. Simultaneously they may hear terrifying nauseating screaming, which while not produced externally, fills their brains with overwhelming disruption. This new invention is dreadful addition to the armamentarium of weapons of abuse and torture. Manifestations of the effects of these occult weapons can mimic mental ill health and add further to the misery of the victims.

The potential threat from use of biological warfare agents is more devastating as they are not detectable before the attack and can lead the possible victims to a state of constant vigilance and anxiety.

Pakistan has witnessed numerous episodes of terrorism and the common people are unable to see light at the end of the tunnel in terms of a termination point. This includes suicide bombing, killings, threats and violent intimidations. Horrendous acts of terrorism were video recorded and released on internet sites.

We have yet to see the psychological morbidity among the surviving victims and witnesses of Islamabad Marriot Attack and similar multiple attacks in numerous cities of Pakistan.

There are a number of questions that would arise: Do we have national figures on mental health morbidity leaving aside few publications and recorded personal observations? Are there any national empirical studies being conducted on terror related mental health morbidity? Do we have enough capability to address the psychological disaster resulting from this state of affairs? Are the mental health professionals adequately trained in terms of 'disaster Psychiatry'? What is the magnitude of the problem among those who do not report the mental ill-health symptoms? Is there a need to equip the health system with the means and strategies to help the sufferers of terrorism? What can be done at the Family Practice level to begin with? Living in the midst of violence, should we not find effective ways to address the mental health morbidity before it is too late?

Fact Sheet — Microwaves — April 2015

The Danger of Microwave Technology

Interview by Dr. Zac Cox, The World Foundation for Natural Science for England, of Mr. Barrie Trower, a globally recognized expert in the impact of wireless technologies on life.

November 13th, 2010, Ulm, Germany at the 15th Scientific World Congress of The World Foundation for Natural Science

In this interview Mr. Trower talks in detail about the legal and ethical implications and the physical impact of the use of wireless technologies on humans, on the environment, on cellular life, mammalian life, birds and bees … he makes it obvious, that we urgently have to stop the unchecked proliferation of the unnatural microwave technology and that we immediately have to develop a new technology for mobile communications and data transmission that is in accord with nature.

About Barrie Trower

Mr. Barrie Trower received his first degree in Physics from the University of Exeter, a second degree (research) from the Council for National Academic Awards and a teaching diploma in human physiology. He trained at the Government's microwave warfare establishment for the Royal Navy and worked with the R.N. underwater bomb disposal unit, which involved training in microwave warfare.

Barrie Trower also served in the conflicts in Borneo, Aden and the British West Indies. He was a teacher at the country's top secure unit which housed spies and a part of his brief was to obtain information on matters relating to microwaves. Mr. Trower is the author of the TETRA report for the Police Federation of England & Wales. During the last years Mr Trower has advised royalty, governments, lawyers and scientists in over 40 countries about the impact of wireless technologies and microwave radiation on man and nature.

Dr Zac Cox: Back in 1993 the World Foundation for Natural Science began to warn the world about the dangers of microwave technology, and today I'm glad to say, that I'm joined by scientist and microwave expert, Barrie Trower. Barrie, thank you for joining us.

Barrie Trower: It's my pleasure. This really is my pleasure.

Dr Zac Cox: I understand you have a wealth of experience with microwaves. Can you begin by explaining to us, how you began your career in microwave technology?

Barrie Trower: Yes, of course. In 1960 I was in the Royal Navy. I worked partly with the underwater bomb disposal unit, partly with microwave warfare and some of the other time with radar. Microwaves were involved in all of those three different areas. So, whilst I was in the Royal Navy I trained in all aspects of microwave technology. And, as anybody will tell you that's been in the forces, the training you receive, is second to none. You practice it, you talk about it all day, you sleep it – so, since 1960 I have been involved in all aspects of microwave technology. After that, a part of my job, because I had microwave expertise, was to question captured spies during the Cold War when Russia and America were within seconds of global nuclear war. And microwaves by then were really sophisticated stealth weapons. And a part of my job was to find out from any spies who had been captured, what the current knowledge was in that part of the world. Since then, I've taught advanced physics, which of course involves microwave lectures and technology. I was commissioned by the Police Federation to write the safety reports on their microwave equipment twice, the last one was the updated one. And I have had a series of papers published, which are all on the internet, and currently, I travel the world free of charge, trying to advise governments, counsels, people, royalty, anybody, about the sensible way to use microwaves and not the dangerous way, which involves children, animals being harmed.

Dr Zac Cox: Thank you. Just for the benefit of people who aren't fully aware, in what walks of life nowadays can you expect to encounter microwaves?

Barrie Trower: Microwaves are used instead of radio waves for all communication systems: your mobile telephone or cell phone uses microwaves, the microwave towers are almost on every street corner, along the motorway you have the emergency services microwave transmitters – microwaves are now everywhere. And microwaves succeeded radio waves because microwaves will penetrate buildings, that they will go through concrete, brick, anything, whereas radio waves won't. You need an aerial on the roof for radio waves, but for microwaves you don't,

they would just go straight through your house. And of course what people don't understand is, if they are going straight through your house, they're also going straight through you.

Dr Zac Cox: And is that dangerous? We are told by our government that they are safe. Is there scientific proof to show they're not safe?

Barrie Trower: There are some 8,300 papers, to my knowledge, going back to 1971, where it was proven in government documents, that low level microwaves will cause injury. The main symptom for microwave sickness it is usually a suppression of the immune system, first, followed by neurological problems where the brain is being affected, depression, suicidal tendencies. You will have more colds, more coughs, longer colds, longer coughs, and then at the other end of the line if you are unfortunate, lymphoblastic leukaemia or something in that area. It affects, in order of people, it is always the embryo and children who are affected most seriously first, followed by women, without being sexist, because they have very complicated hormonal systems, they are affected by microwave technology; then, usually, the sick and the elderly and finally fit young men. So, there is in fact an established pattern for microwave sickness.

Fig. 1: A cell tower in a neighbourhood in the USA. The large number of different antennas lead to a very strong electromagnetic field in the bedrooms of the houses around the tower.

Dr Zac Cox: You mentioned cancers, are we seeing an increase in the number of cancers?

Barrie Trower: Oh yes, and going back to your previous question, there is absolute proof, there are to my knowledge, to date, there are four high court judgements proving that low level microwaves will cause cancer. There are twelve epidemiological studies showing that people who live around transmitters, particularly within 500 metres, will get more cancer, more neurological and psychiatric illnesses than people who don't. And there are, to my knowledge, 19, 20, if you count my latest one, there are 19 published legal judgements, not high court but legal judgements from mayors, counsels, magistrates ordering transmitters to be taken down where it is believed that they have caused cancer to the local population. So there is lots of proof. And two of the epidemiological studies, and by that I mean, for anyone who is not sure of the word, a study for about ten years, studying all of the doctor's records, all of the population's; two of them were carried out by the industry itself on its own product. And its own conclusion was that these microwaves can cause cancer. So there is plenty of proof: government proof, legal proof, research proof. There is enough proof as to win high court cases and people are.

Dr Zac Cox: Can I just clarify that the industry's own research has shown that their product – mobile phones, Wi-Fi, transmitters – cause cancer?

Barrie Trower: Oh, absolutely. The most famous one was the Eclog, known as the Eclog-Report. And their conclusion, it was carried out by T-Mobile, and their conclusion was that these microwaves can trigger the cancer promoters and cancer initiators in the body and one of the industry's other research projects showed that microwaves affected children to the point where children would lose sleep, because they can activate the brain, the microwaves can accelerate and activate the brain. And children would lose sleep. And published research in "Scientific American Mind" actually shows that when children lose sleep they can become depressed and suicidal, very, very quickly. In fact, I can tell you one story, if I may. When I was in South Africa speaking, a teacher of 30 years – and this is on the internet – a teacher of 30 years was the speaker behind me. And he said, in South Africa, he said, childhood suicides were unknown. Misbehaviour to the extent of severe aggression was unknown in South Africa, and he said as soon as the transmitter went up near his school, they started to have psychiatric problems with the children and he said, today, he said, all of my children, all 30 in my class are now on Ritalin for poor behaviour. The whole class is on Ritalin!

Dr Zac Cox: That's incredible.

Barrie Trower: Absolutely.

Dr Zac Cox: I am speechless. So we have the industry admitting that their technology is causing disease.

Barrie Trower: Cancer.

Dr Zac Cox: We're seeing children being affected in hyperactivity.

Barrie Trower: Yes.

Dr Zac Cox: Why then do we still have this technology? What's stopping it being removed?

A multibillion dollar industry

Barrie Trower: The industry is believed to be earning some 3 trillion United States Dollars a year, 3,000 billion dollars a year. And it is my opinion, I will have an opinion because it protects me legally, it is my opinion, that when you have that amount of money coming in, I mean, just imagine on a daily basis how much is flowing in, you have the ability to not only hire Land Rovers full of top-lawyers who can argue cases for you, you can buy governments. And you can threaten people with all sorts of things because you have so much power. And

the allies of the industry are the secret services of the governments, hence the governments. Because with this technology not only can the secret services of any country listen to every single thing you are saying through your cell phone, but they can also follow everywhere you go. So they know everywhere you go and everything you are saying and they can monitor the words of every single meeting that you sit down at.

Dr Zac Cox: You're not seriously telling me that my government is following everybody's movements?

Barrie Trower: They have the ability to. I do know that every single phone call is recorded and logged. Every single mobile phone call is recorded, every single one. Whether they are interested in you, I don't know. Whether they want you followed, I don't know. But they have the ability to do it. So if you have… let's just say you have people who legally and rightfully oppose government policy, like me, what they can do is, they can have everywhere you go followed, every single phone call recorded, they can monitor everybody you talk to. So they will know your whole operation, which gives them an advantage if they want to clamp down on you.

Dr Zac Cox: This sounds worse than the Watergate scandal.

Barrie Trower: Well it is. So, I mean, you have the secret services, you have the money; the governments themselves love this system because it allows them to snoop on the people. And you have the most powerful industry on the planet. So, you can see why people are resisting cutting down the power and cutting down what they're doing. And it's probably worth…we know three per cent of populations always become seriously ill from microwaves. It may be worth the money and the advantages to the government to lose three per cent of the populations, for the benefits that they are going to get.

Dr Zac Cox: Three per cent of the population of the UK must be quite large numbers?

Barrie Trower: It's about 1.8 million.

Dr Zac Cox: So 1.8 million people will be sacrificed so they can snoop on everyone and take control of…?

Barrie Trower: And take the money, I mean, a colossal amount of money. If you think just the population of the UK, 60 million people, we know we have 60 million cell phones, imagine each cell phone the bill is just one pound a day, that's 60 million pounds somebody is making a day. And the bills will be much higher than that. I mean the money and the power you get from this is phenomenal. And in fact, if we go back fifteen years, hypothetically, if we could go back fifteen years, if the government said in any country, if the government said: "We are going to make it law, that every single person carries a little tiny box in their pocket, we're going to listen to every single conversation you have, every business meeting, every consultant meeting in a doctor's surgery, every single word you say, we are going to record, whether your phone is on or off, we have the ability to record. We're also going to monitor everywhere you go, so we're going to know everything you say and everywhere you go. Ah, but there is an advantage. Apart from paying us, which you won't like, you do have the ability to push a few buttons and talk to somebody; we will of course listen to it." There would have been riots in the streets to say we are not having this. But the marketing was so clever, that it's gone out and people are paying them to do this. You must admire them, you know, for the cleverness that it's gone out. But this is the problem. And of course they're addictive.

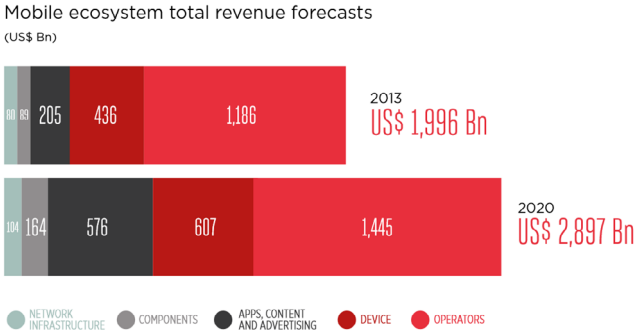

Fig. 2: The total revenue of the mobile ecosystem is forecasted close to 3,000 billion dollars by 2020 by the GSMA mobile economy report 2014.

Dr Zac Cox: Chemically addictive? They cause release of hormones in the body?

Barrie Trower: They are electrically… the average person works on the lowest level of energy. And, if there is a telephone box half a mile down the road and you have a cell phone in your pocket, the average person will pull out the cell phone and say: Well, this one won't hurt me, dong, dong, dong, dong…hello Mister Smith, rather than walk down the road. So, there is that, you become more lazy. The other addiction is that, there are numerous experiments, I have pages upon pages of experiments, where the microwaves going into the brain they accelerate and, if you like, increase the natural rhythms of the brain, it's called entrainment, they actually accelerate the brain and excite the brain. And we know that a child that uses a cell phone for just two minutes, the brain is accelerated and not back to normal for two hours, around two hours afterwards, and that's just for two minutes. Now you imagine a child in a playground at a school that spends twenty minutes on the cell phone. The brain is not going to be in a learning state for the rest of that period of the day in the classes. The child is probably going to be hyperactive, misbehave….

Dr Zac Cox: And a general pain.

Barrie Trower: And a general pain, yep.

Dr Zac Cox: And is there something you can see on an EEG? Do you see a change in the brain waves?

Barrie Trower: Oh yes. It is guaranteed. I have pages upon pages of this type of experiment, it's so easy to do. Most people in this research area have done it many, many times, and anybody, anybody can do this. Just don't expose your brain to any microwave cell phones or anything for a couple of hours, take an EEG, take one from your heart, an ECG, at the same time, make a call for ten minutes, and take another one. And then, see how long it takes your brain to come back to normal. You'll be absolutely amazed. The Delta-, Theta-, Alpha-, Beta-Brainwaves you'll be amazed how long it takes them to come back to a normal state.

Microwaves used for weapons

Dr Zac Cox: This technology is truly frightening, really frightening.

Barrie Trower: Well, this is why it's... microwave weapons were introduced from the 1950s, 60s, 70s to the present day. And this is another level of proof. They are so effective, if you are not in a hurry to get rid of somebody, they are so effective as a stealth weapon, to beam

somebody. And this has been done many times and it's recorded. You can beam people you don't like as a government, to give them cancer, breast cancers, neurological illnesses, you can choose what you want them to get.

Dr Zac Cox: You can choose?

Barrie Trower: Oh, you can choose. You can choose which pulse frequency you want to affect the brain with, you can choose the level of microwave irradiation and the speed that you want them to become ill, it really is a perfect stealth weapon. And all you need to do is rent a house opposite someone you want to get rid of or a group of people you want to get rid of and just beam them. The most famous case during the cold war was the Moscow embassy siege, where in Moscow they beamed the entire American embassy and gave them cancer.

Dr Zac Cox: Did they cause cancers in all the staff or in a lot of the staff or…?

Barrie Trower: Most of the staff, most of the children got leukaemia, the women developed breast cancer, the gentlemen developed cancers. I think after about 18 months the entire staff was changed and then a following 18 months the entire staff was changed again. And by that time people realised what was going on. And they found that they were being eradiated by microwaves. And rather than say: "Ooh, isn't this disgusting. What have we sunk to?" They thought: "Isn't this wonderful? Let's develop this for ourselves!" And governments today are still perfecting microwave warfare.

Dr Zac Cox: Still to this day they're working on the weaponry.

Barrie Trower: Still to this day, 2010, they are still perfecting the pulse frequencies, it's got very, very sophisticated, the pulse frequencies, the 'how-long-they-can-transmit', whether it can be one country to the other, bouncing the microwaves off the ionosphere. So you don't even have to be in the same country.

Dr Zac Cox: Bouncing the microwaves off the ionosphere? A lot of people won't have heard about this technology. You're talking about the HAARP.

Barrie Trower: If you have a super-transmitter, the microwaves, if you beam them, it's only simple basic trigonometry. But, let's say I want to bring economic ruin to a country that grows all of the world's wheat, okay? All I have to do, is, beam microwaves up to the ionosphere, which is like an invisible cloud around the planet, an ion cloud around the planet, the microwaves going up this angle will reflect off down onto this country. And if I continue to beam, the wheat in this field or the cattle or the sheep I can harm, I can reduce the immune system of the plants, so that they won't be healthy and they will die. And I can stop their growth. And I can bring economic ruin to that country. I can harm all of the animals, the cows, the sheep... It's so easy to do. You only have to push a button and you can bring economic ruin to a country.

Dr Zac Cox: What countries have this technology already available? Is it all the countries in the world or just a couple of them?

Barrie Trower: It may not be a wise thing to say on a live broadcast, but you can take my word for it, that I know at least two super-transmitters in the world that have this capability, and there are probably more in areas that I do not have access to and I cannot go to. But I know there are at least two.

Dr Zac Cox: I need to just go back a little bit, back to your early days in the military. This technology was used by the British government? It was used by the British government against terrorist groups?

Barrie Trower: We have 8,300 papers, I have knowledge of 2,300 myself, and what the governments found was, that you could induce, by changing the pulse frequency, like Morse code, of the microwaves going into the brain and interfering with the brain, by specialising on the pulse frequency, you could induce psychiatric illnesses to the point where a psychiatrist could not tell if it is a genuine psychiatric illness or an induced psychiatric illness. So what you can do, theoretically, is you can target an individual's brain. They may have auditory hallucinations where they hear things, which is actually quite common with microwaves, or show signs of schizophrenia. For instance, 6.6 pulses a second can induce severe sexual aggression in men. So, you could induce somebody to commit a really horrific sexual rape. So, technically, what you could do is have somebody committed to a psychiatric hospital or a jail for a crime just by somebody saying that they had a psychiatric problem whereby they didn't. There is that. You can target other parts of people's bodies. You can target the heart and cause heart seizures. You can target the lungs and cause bleeding. You can target, if you're clever enough, some of the essential glands in the body that control all of the whole hormone systems. So, if you have dissidents or people that you don't like as a government it's very, very easy these days to irradiate them and either have them wind up in jail or in a psychiatric hospital. And of course there's no comeback on you.

Dr Zac Cox: Yeah. These weapons the governments have and are still using, are they more powerful than for example the Wi-Fi I might have in my front room or my cordless phone or a mobile phone transmitter?

Barrie Trower: No. In fact, actually the power is slightly less.

Dr Zac Cox: Less?

Barrie Trower: The power is slightly less. The difference is, where you might use Wi-Fi, you might go in after work and do a couple of hours and then leave. And the Wi-Fi is going out in all directions. Here they are targeting you probably with a beam and it is on you all day, it can follow you everywhere you go and it can target you when you're asleep as well. So you're really getting a concentrated dose. It's a bit like putting the light on in your house and sitting with the light or have somebody follow you with a search light and beaming the search light on you all the time. So there is a difference between that. But in fact the power can be less. It just takes longer.

Dr Zac Cox: So, I would imagine then that the devices that we have in our houses nowadays are extremely dangerous?

Barrie Trower: Not all of the research, because there is research that has been carried out where they have failed to show it is dangerous, but we do have documentary proof, from the governments, one specific paper from the government that lists all of the illnesses that you can get from microwave sickness including severe neurological disorders. We have a government document that actually says, this needs to be kept secret from the Western governments because it will affect the efficiency of the military, the weapons industry and it will also affect industrial profits.

Dr Zac Cox: We have the government telling us this technology is dangerous?

Barrie Trower: This is the United States Defence Intelligence Agency advising the Western governments to keep this

secret so that they can protect industrial profits and military functions. If you're in the military and a lot of people do start developing tumours you could start suing because the equipment you're using is not safe. So, to avoid that and to protect the industrial profits they put this document out.

Children need protection

Dr Zac Cox: Going back a little bit to children now, just moving away from the military aspect for a while, why are children more at risk? Are they more at risk?

this, if you wish to ask about that risk, if we look at the average infant in school or small child in school – I'll only concentrate on just a couple of areas of the body – the immune system of a child, a child has soft bones, so the microwaves penetrate the bones, no trouble at all, and microwaves are attracted to water, which is most of what bone marrow is, the immune system of a child takes 18 years to develop. And the first thing we know from microwave irradiation is that it attacks the immune system. So with children, who are not small adults, they are neurologically and physiologically immature adults, the immune system

going to happen. We're probably going to get an epidemic of the muscular dystrophy type diseases later on in life for these children, because of a damaged myelin sheath or insulating coating around their nervous systems.

The other, what I think is the most serious aspect of a child's development… there are experiments that show the ovarian follicles in young girls. Unlike boys who produce sperm as and when they're required on a daily basis, young girls are born with all of the 400 eggs they are going to need to develop into fully grown eggs and children. Now, we know that microwaves affect the ovarian follicles and can affect the ovarian eggs. We know that the microwaves, there are papers on this, can cause genetic damage. If you think of a young girl at school, she's sitting here and she has the Wi-Fi sets transmitting straight through the uterus into the ovaries. Now, if the young girl damages the ovarian eggs, and we are not going to know this for another fifteen years, if the ovarian eggs are damaged, these are irreparable. They can never ever be repaired. The mitochondrial DNA in girls is irreparable. So when that girl, if she has a daughter, that daughter will carry the genetic damage that has been caused by the microwaves. And when she has a daughter, that daughter will carry the same disease, and her daughter, and her daughter… so we're now not saying we're risking this generation, we're risking the future generations of all of the children in the world from genetic damage. And that's a scary prospect.

Fig. 3: Children and especially babies need to be protected from microwave radiation! The immune system of a child needs 18 years to be fully developed. It is well know that microwave radiation attacks the immune system which will be damaged before it is ready to protect the health of the child. The number of devices using microwave technology is increasing rapidly. The cordless phones, Wi-Fi routers, baby monitors and smart meters we have in our homes are just the most well known electrosmog producers.

Dr Zac Cox: That's extremely, extremely frightening.

Barrie Trower: It is.

Dr Zac Cox: So to clarify that: The eggs cannot repair the mitochondrial DNA.

Barrie Trower: No.

Dr Zac Cox: And so, if a girl grows up with a genetic defect she'll pass on to her daughter…

Barrie Trower: Yes.

Dr Zac Cox: …and on, and on, and on.

Barrie Trower: And on, and on, and on until there is no more female line left in that family.

Barrie Trower: As I said earlier, it's always the children that suffer first. A lot of people make the mistake in believing that children are small adults. And unlike medication where you have an adult dose and a children's dose with microwaves there is the adult dose but there is no known safe dose of microwave irradiation anywhere in the world published for a child. And the reason is, and embryos are a special case after

of children is being damaged before it is anywhere near up and running. The nervous system that runs through the body has 122 layers of protein. There is a system of protein synthesis that lays 122 layers around a nervous system. It takes 22 years for this to fully develop. So, all through a child's development what you have is the microwaves affecting the protein synthesis of this system. Now, goodness only knows what's

Dr Zac Cox: This is surely a good enough reason to remove Wi-Fi from schools.

Barrie Trower: Wi-Fi should be wiped out of schools at a stroke today to protect all of the children.

Dr Zac Cox: Why are schools persisting in Wi-Fi if they know it's a risk?

Governments cover-up the truth!

Barrie Trower: Ignorance. It's what I call "intentional ignorance". It seems that government ministers that are trying to promote the telecommunications industry and governments, and it's not difficult in our country, the UK, to find a school where, if every child has their own Wi-Fi that they can walk around with, when the school inspectors come in, they get extra ticks, in extra boxes, and it's what I call "intentional ignorance". They will only look at and believe the research they want to, they will not acknowledge most of the real research and most of the risks. And this is why I think we have this problem. There is such a pressure on advertising and hype to get this technology and then this technology, and this technology. I can remember when I was a child, our king, the King of England, I can remember our king encouraging people to hold smoking parties, because it was good for you. We seem to be in that situation now. People believe that if you get the latest technology it's going to benefit the children. What they do not do, I call them "silly boys" and I'm being disrespectful, I think our prime minister and certainly the head of MI6, our secret service, and I really hope he gets to look at this, they are so young that when we were making major decisions on the dangers of this, they were wondering what their nappies were for. And they have now got into the position of power but they don't have the intelligence to come back and talk to people like me and say: "Look, what's the truth behind this?" They listen to the government advisers who are usually people brought in from the industry. And they believe that the government advisers are right. And I have yet to find a government adviser to make a single sensible sentence anywhere, and I will defy anyone to show me an intelligent sentence from a government adviser. There seems to be so much what I call "blind corruption" and you know as I do, we have just got rid of possibly the most corrupt government the world has known. And is it any wonder that we are in this situation? And I blame the prime minister and the head of MI6 in my mind because they are too young, they are too ignorant and they are too silly to come to people like me and ask what the truth is.

Dr Zac Cox: That's all we want, it's the truth. Would you like to speak to the prime minister personally?

Barrie Trower: I, as soon as we had the new government, I went straight along and saw my member of parliament. I gave him a document with all of the references, listing every danger there was to the planet, the eco systems, the environment, children, embryos, that we haven't yet discussed, and I'm sorry we should come back to that, my fault. I asked him and I said, in case he thinks I'm just a total nutter and mad, I want to see the prime minister, I want to explain this, I want to take with me a consultant solicitor, I want to take with me a doctor from Imperial College, both whom are experts in radiation law and radiation. And I would like to see the prime minister. And to cut a long answer short the prime minister does not have twenty minutes to give me in the next four years. And I think that it pathetic, absolutely pathetic and disgraceful.

Fig. 4: Children have thinner skulls and receive 2x the exposure that adults do in the brain and 10x in the bone marrow of the skull.

Dr Zac Cox: I agree. Do they have any idea of what sort of damage they're doing to the world, to children?

Barrie Trower: No. And this is where I come back to me, they are silly boys. You have the prime minister who is young, you have the head of MI6 who is young, you have these, what I call young boys, with no disrespect to their age, coming out of university with these electronic degrees and they think, aha, I can make a microwave box that will do this and do this, and they sell them and they go on the market but they don't have the wherewithal to come back to people of my generation that grew up with microwave irradiation, to say, well, just give me one hour of your time before you do this and let me explain what is really going on. – Would you like me to go back to embryos?

Dr Zac Cox: Is there a cover up on the numbers of cancers that we're seeing related to microwaves?

Barrie Trower: The word "cover up" I would not agree with, maybe I would, maybe I'm not clever enough to understand the full implications. There is certainly statistical anomalies. Whereby I have one document where 40,000, in one year, 40,000 brain tumours were re-diagnosed as endocrine cancers, so they do not go on the brain tumour statistical list. So what the industry can actually say, and the government, is, okay, so you're using a phone but look at the mobile phone brain tumour statistics, they're actually going down. And I know one person that said: "This proves, that they're actually preventing brain cancers."

Dr Zac Cox: That is most definitely a statistical anomaly. So 40,000 brain tumours in the UK are re-classified…

Barrie Trower: …whether they are in the UK the document didn't say, it probably did, but it's a huge tome, and I cannot be sure whether it was one country or several countries. I just know it's from a brain tumour registry, and I just know that 40,000 are being re-classified

as endocrine cancers and the brain tumour registry is horrified by this. But I could not be specific whether it was just one country.

Dr Zac Cox: Okay. That would obviously skew the statistics. If those 40,000 brain tumours were there in the stats it would be fairly blatantly obvious to most people that mobile phones are causing brain cancers.

Barrie Trower: Oh, it's only half the story. If you look at some of the studies where they have shown that there are no cancer rises from transmitters or mobile phones, what the industry and governments are very, very good at doing is, they will do a study, they will write up the study, they will give it to the press, the press will publish it; what they do not do is what I have to do. If I write a research paper, for instance I've had one, I've just finished one, you then send it to an independent magazine for peer- review. The independent magazine they have said to me, we will now take about eight weeks with our experts to go through every word, every reference. If we deem it o.k., we will publish it, if not, we will send it back for something to be re-written. Now, what the governments are good at doing, one government scientist will peer-review another government scientist's own document. Or a government will go to a university with specific instructions for the university to carry out a specific experiment. But what they do not do is, send these experiments to an independent top level magazine like "Nature" and say, we found this, will you publish it? What they will do is, they will give it to the press, the press bring it out the next day: "Cancers are going down, mobile phones are found to be safe." But then, when you get hold of the paper, and this was one particular experiment on mobile phones, and you find they discounted everybody under a certain age, they then discounted everybody over a certain age, they discounted people who use mobile phones for work, they discounted people who had two, they discounted people for some other reason, and in fact you ended up with, this particular paper, you only ended up with sixteen per cent of the total people that were being tested being on the statistics. And then when you enlarge the sixteen per cent, it's like saying, we've looked at sixteen per cent of the people in Germany, enlarging it for the whole population and saying, you know, cancers have gone down. You know, it's easy, you can manipulate statistics until you go blue in the face, they're so easy to mess around. What they will not do is, send their results to a magazine, a world leading magazine like "Nature" or "Scientific America" or "Scientific American Mind" and have them independently peer-reviewed and published, like I have to do.

Dr Zac Cox: So, in other words you're saying, a) they rig the experiment, or well, make the experiment very favourable for themselves and b) They cherry-pick the statistics.

Barrie Trower: Not necessarily. There are some genuine experiments that have shown that microwave irradiation has not been shown to cause illness. And I can explain this. We're in Germany now. If I made every single person in Germany smoke twenty cigarettes a day and drink ten pints of beer a day some people would have no effect, some people would have some effect, other people would be violently ill. People are not homogeneous, they do not all follow the same path. And so you can concentrate on people, there will be experiments where the majority of people have not shown an ill effect. But when you look at all of the experiments, in fact we know, we looked at the World Health Organization database a couple of years ago, on all of the experiments, the ones that showed nothing and the ones that did show things, and the overall result was that 80 per cent, eight out of ten of the papers on the World Health Organization database showed from low level continuous microwave irradiation cancers, an increase in cancers for people living near transmitters, microwave sickness and neurological problems, eight out of ten. And there will always be experiments, done properly, that show nothing. But overall, eight out of ten do show something.

Dr Zac Cox: So, if the WHO's own library of research shows that eight out of ten studies confirm that mobile phones, Wi-Fi, cordless phones, etc. etc. are dangerous, what is their stance then?

Barrie Trower: The World Health Organization were challenged by the European Parliament to make a decision on the health of the world concerning all of this. And in the written reply, which I have, from the European Parliament the World Health Organization said that they will not comment on the effects on adults until 2015. They only started studying children in 2009, last year. So, they will not be able to comment on the effect on children possibly for another fifteen to twenty years. So, the World Health Organization will say nothing on adults until 2015 and nothing on children probably until 2020, 2025. So, there is absolutely no guidance from the WHO.

Dr Zac Cox: So, the implications of that are, your children could be getting very sick but we won't be able to tell you for another fifteen, twenty years.

Barrie Trower: Absolutely.

Dr Zac Cox: Good luck.

Barrie Trower: Absolutely. Yes, you're absolutely correct, yep that's it.

Dr Zac Cox: Kind of startling really, isn't it?

Barrie Trower: It is so horrific, that if it wasn't real, if somebody wrote a book on this, I would say, this is so stupid, you could never make up a story like this. But, and it all goes back, it goes back to the 50's, the 60's and the 70's, when microwaves were found to be such a perfect weapon and so dangerous to the military that the United States Defence Intelligence Agency told the Western governments to keep this quiet. And they did. And this is why we have this. We have documents that show that governments pay people to experiment on people against their wishes, well not against their wishes, without even telling them. And we have all this information going back to 1976. Everything was known by 1976, everything. We needed no more proof, no more research, nothing was needed then. You see, when the industry or a government says: "Wow, this could be quite a problem. We will carry out research." What they're actually saying is: "We really know what it's going to do, but what we will do, we will run some research, that gives us another fifteen years." So we will come back in fifteen year's time, and then they've bought themselves another fifteen years. And if it's like the last research, so many countries disagreed over the statistical analysis of what was going on that the whole experiment, the world wide experiment, was con-

sidered null and void. So, once they brought in the statisticians the whole of this experiment, that lasted ten years or if not fifteen years, was just wiped out, successfully.

Babies and Embryos must be protected

Dr Zac Cox: Okay Barrie. So, we know that microwaves damage children. What are the effects on developing babies and on embryos?

Barrie Trower: Embryos are a special case, for two reasons. One is that they are the smallest type of human being. And with microwave irradiation, generally for the communication system, the smaller you are the more radiation you absorb, because the nearer you are to the size of the aerial that would receive it. And the embryo is specifically the size that can absorb quite a lot of the radiation. That is the first thing. The second is, and I'm going to use an analogy here, because I think it points out what the real problem is. If you could imagine – I'm going to talk about the embryo's brain – if you could imagine leaving here and going back to your house and picking up a magic telephone book that had the telephone numbers of every single person in Germany. Now imagine you pick up a telephone book of every single person in the world with their cell phones, home phones, office phones, every single person in the world and then imagine you could push a button and all of these telephones would be dialled at the same time. That is roughly the number of connections going on in an embryo's brain every single second, that number.

Dr Zac Cox: Wow.

Barrie Trower: It is a phenomenal, it is a phenomenal amount of connections with the most incredible accuracy. If you then imagine, if that's just the brain, what about the spinal cord and all of the organs? Now, if you expose an embryo to microwave irradiation what you are doing is, you are giving the brain thousands of millions of miniscule electric shocks every single second. So if a pregnant lady uses a cell phone, the microwaves are going into the body, they will travel through the body, straight through the embryo and, if it's an ordinary cell phone, you would have roughly 1,800 million electric shocks per second, every second, going through the embryo. So they are a very special case. And the world should really take note, that embryos, whatever happens, must be protected from microwave irradiation.

Dr Zac Cox: And what is a safe dose for an embryo to absorb?

Barrie Trower: There is no safe dose of microwave irradiation for any child, anywhere in the world, no safe dose at all, not one. There is no safe dose. It's a bit like, theoretically, passing a cigarette into the womb and saying: "Have a smoke." You know, it is that dangerous.

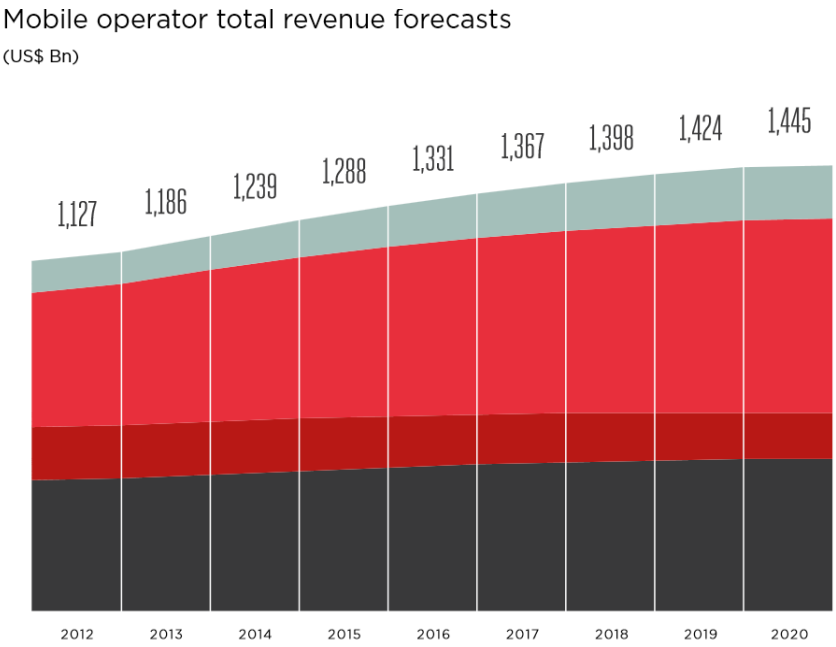

Fig. 5: The revenues of mobile operators are countinously growing even though the prices for the service are declining. This leads to the conclusion that usage is increasing, which leads to bigger networks and more antennas.

Dr Zac Cox: So what laws do the governments and the mobile phone industry hide behind?

Barrie Trower: What usually happens if they want to come and put a transmitter outside your house or on the corner of your road or somewhere they will usually come along, they will usually say: "We follow the ICNIRP guidelines." (Which is the International Commission for Non Ionizing Radiation Protection.) They say: "We're well within the ICNIRP guidelines, we are well within the law, there's nothing you can do about this, zonk, there it is, live with it." But in fact, they are lying, they are lying. I have travelled all over the UK and all over the world and I have never yet met a single decision maker that has read the international certificate, not one. And yet they will decide planning issues. You can see hospitals with transmitters above the maternity ward! I've never met a single person that has read it. Well, I have. And on page 546 it specifically says that decision makers should take special account of children, the elderly, the sick…it says that some people may be especially sensitive to microwave irradiation. So, before any transmitter goes up, what they should really do is a survey of the area to find out how many children there are, how many pregnant ladies, how many elderly, how many sick, to find out whether they're going to affect them. And on the next page it specifically says that decision makers should read current scientific literature, up to date, scientific literature. And they should set an exposure standard which is below the threshold currently known to be causing illness from microwaves. What they will do, is they will come along and they'll say, and I can guarantee, what they've said, they'll say: "These are radio waves, there's no problem, we've had radio for years, we're well within the ICNIRP guidelines, zonk." And that is a lie, that is a lie. What they should show is evidence of looking at the population, evidence of reading and why they set the level that they have set. But they don't. They set the maximum level which is

allowable within the international commission's guidelines and all of them are set, usually, to the maximum, the maximum guidelines. Whereas in fact, they should set a minuscule level if they have read the papers. And they should show evidence of reading. You're a doctor. If I came to you and said "show me evidence of your research" you would show research papers, books, writings, calculations…and convince me that you knew what you were doing. And this is what the planners would do and if they have lied then there may be a good legal argument for having this transmitter taken down.

Dr Zac Cox: It's entirely obscene that they put these things on hospital roofs when ICNIRP says, the elderly and the sick can be affected.

Barrie Trower: They tend to target, and if you look at this – people will say I'm wrong but I don't believe I am – have a look where most of the transmitters are. They tend to be in areas where people need money. They will choose the poor areas around cities because they know the poor people do not have the means to take on the most powerful industry on the planet and fight them. Hospitals are desperate for cash, because the government keeps them poor. So they go on hospital roofs. Schools are even more desperate for cash, because the government keeps them poor. So you will get them in school playgrounds. Because the industry will come along and say: "This is safe, they're only radio waves, here's a nice cheque, zonk." Colleges will have them on the roof, because they're poor. Universities will have them by the hundreds, because universities are desperately poor. So, have a look and you will find that most of the transmitters are in areas where people are poor. You will be very hard pressed to find one in a wealthy person's garden.

Dr Zac Cox: What I wanted to ask you Barrie was, who drew up ICNIRP? And do they have any connection with the mobile phone industry?

Barrie Trower: There is a large body of government scientists, if you look at the list, it's been published, it is, there is a large body of the same scientists that sit on our government advisory panel, the international commission panel, the World Health Organisation panel. So it is largely the same scientists. And they have very bombproof qualifications. And when you have a "Sir Professor" standing up, saying: "I do not believe there's proof for this." That is all the counsels need. Compared to somebody like me, that is all the counsels need. And they will say, well, we'll go with "Sir Professor". But you will find, it has been published, but you will find the same names appearing on the same lists.

Dr Zac Cox: Thank you. So from a legal point of view, is there any way that people can have transmitters removed? Have you had any successes with having transmitters removed?

Barrie Trower: We have had successes with having them moved, and there are several legal arguments here. And I'm not trained in law, so I'm assuming that what I say is correct. There are a few legal arguments. Some of the decision makers say to the populations, that they are not required to consider health in planning decisions, especially the UK. That contravenes the European law. There are two European laws which say health must be considered and it must be a major consideration. There is a United Nations law, under the United Nations Charter number 22 that says:

Fig. 6: Embryos can absorb a lot of the radiation because they are small therefore close to the size of the aerial that would receive the microwave radiation.

"Persons with disabilities, i. e. electro-sensitivity, people who are sensitive to microwaves, they cannot be discriminated against." So if you go to a road and you go zonk, there is a transmitter, I'm sorry that three in a hundred of you, and it may not be three in a hundred, it may be… the Irish Doctor's Association, who are an incredibly clever, a knowledgeable group of doctors and are really tip top when it comes to radiation, they believe it may be as high as fifteen in a hundred. So when the industry puts up a transmitter and says: "I'm sorry you're electro-sensitive, you're just gonna have to suffer or move." Under United Nation's law that is illegal. They cannot do that. And we have the draw-up in this country, the Nuremberg treaty, and the Nuremberg treaty was signed by all of the nations of the world and it is a very specific treaty. And what it says is that no human being will be experimented upon without his or her consent. And before they give consent they have the legal right to understand all of the implications, the health problems, the future health problems and they have the legal capacity to say "no".

There is only one exception with the Nuremberg treaty. And that is, a doctor, such as yourself, may experiment on him or herself only. That is the only exception, it is section 5. So no human being is allowed to be experimented upon. Now, what the World Health Organisation have said, is that they are watching the adult population till 2015, the children's population from 2009. They are watching to see, how many cancers, how many illnesses, how much neurological damage… it is a scientific health medical experiment. And in their wording you can read that it is an experiment, the wording they gave to the European parliament. So, what I would suggest to countries or people, they can – and again, I'm not trained in law but I would argue – they can invoke the Nuremberg treaty and say: "I do not wish to be a part of this global experiment. We signed the treaty and therefore you're breaking international law." That is my interpretation of what can be done.

There is also one environmental law, which very few people know of, I think it was published in 2004 but seemed to have been lost and buried. But it is definitely there, and it's a very good one. It actually says that anybody who damages an environmental water supply, a habitat, an environment, any animals, any nature conservation area, they say, that is against European law, now, to damage any eco-system, any environment. It is against European law. And it says the causer will pay the principle. In other words, if we have caused the bees

to die, the crops to fail, the farm animals to die, the whole of the reparation bill can be sent straight to the mobile industry, if they are taken to court and it is proven in front of a jury that they are guilty. They can be made to pay the principle. And not many people know that law exists, but it is law and it exists and I have a copy of it.

The extinction of the honey bee

Dr Zac Cox: You raise some very, very interesting points there, not least the disappearance of the bees, the colony collapse. Are they linked to the mobile phone industry?

Barrie Trower: Yes, without a shadow of a doubt, and I'll tell you why. There are numerous papers now from bee keeping professors and scientists and there are even, there is a brilliant mathematical paper, which I read, there is everything about the poor bee is designed to be irritated by microwaves. The distance between the antenna, the size of the brain, the size of the body… they will all suffer resonance or unnatural vibration from microwave irradiation. The immune systems will collapse. The directional finding mechanism of the bee is destroyed. But what the industry and the governments will say is that not a single bee has been killed by microwave irradiation. And, technically, they are correct. The same that we can say that not a single person has died from AIDS, technically, that is correct. What we do know, from analysis of bees – and we have the papers to show this – is that when the bees are found, they have five or six different infections including invasion by the varroa mite. But when the blood and the body is analysed they find five or six infections, which clearly indicates that the bees have suffered massive immune symptom suppression and invasion by the varroa mite. The same that people suffer immune system suppression from AIDS and then it is whatever virus or bacteria comes along that actually kills you. But there can be absolutely not a shred of doubt that microwave irradiation is disorientating the bees and the birds and other flying insects, and there are 250 of them that pollinate plants. There can be not a shred of doubt that the microwave communications industry is responsible. And there is even, apart from the research, absolute concrete evidence of proof. You can go to any research paper anywhere in the world, pick it up and look at the experiments that have been carried out on cells. And most of them have been carried out on small mammals, insects, birds, even bigger mammals and they have found cancers, immune system problems, this, this and this… and it's documented. So the problem is, you have these huge laboratories and they say, well, we have found that microwaves will cause this and this and this and here are all the lists of the animals we used, but they forget one crucial sentence. They forget to say: "Aha, but these microwaves are actually outside the laboratory. And the animals are outside the laboratory. Therefore we are going to damage the world's eco-systems and the environment. Because we've proved it here, now what's going to go on out there?" And you can go to any research paper and you will see thousands and tens of thousands of experiments carried out on animals that show all of this. And it goes on outside. And there can be absolutely no doubt. And we can take this right back to the government proof from the government scientists, 50s, 60s and 70s.

Dr Zac Cox: Why then do the governments continue to say: "It's… the mites, it's a virus, it's the pesticides…."

Fact Sheet — Bees — October 2014

The worldwide disappearance of the bees

Why their dying threatens our own survival

Without bees our world would not be so colourful, our dinner tables would not be so richly set and the grounds would be eroded. Our lives would not be worth living and we would hardly be capable of surviving. Man owes one third of his food to the honey bee. Whole ecosystems depend on the bee – the world's most efficient pollinator. In collaboration with many other insects the bee also fosters biodiversity which is so important for nature and for man. Furthermore, man and bee are connected by many similarities and their way of organising themselves, in nursing their offspring and in communicating with each other; all this indicates a highly developed intelligence. Bees use electromagnetic fields in many ways and are also able to create them themselves, and it is because of this astonishing ability, that they react so sensitively to any manipulation of these finely tuned systems. For this reason, it is the almost comprehensive global microwave contamination by mobile communications that is the ultimate cause for the worldwide bee deaths. These manmade microwaves disturb the bee's fundamental senses on a massive scale, and thus its immune system, too. With a weakened immune system, the bee is no longer capable of fighting off any additional strain caused it by pesticides, unbalanced diet caused by monoculture farming practices, parasites and illnesses. In this hard-pressed position it is not only extremely important for a bee colony to have a sensitive beekeeper supporting them in every way in their essential task of pollination, but it also takes every single one of us to do some re-thinking and taking action in order to ensure the survival of the bees and so that our world remains colourful and worth living in. We are a part of the ecosystem called Earth where everything is connected, and just like the bees so do we as well have our individual duty. Let us fulfill our duty once again, thus securing the survival of the bees and, hence, our own survival!

All the things bees accomplish

The honeybee is the most efficient pollinator in the world. No other insect is capable of using such a variety of flowers. 80% of flowering plants are pollinated by honey bees. Man owes about one third of his food to the bee. Only the harvest of wind-pollinated plants like rice, grains, grapes and maize are not influenced by the bees. They ensure the reproduction of thousands of plant species and hence secure the diversity and flowerage of the landscape as well as providing the nutritional base for birds, other insects and many other animal species. Consequently, the service of the bees is the beginning of a long chain of interactions among species and if it was not for the bee, many of nature's performances would not be possible. Performances, which we take for granted, for the most part, such as a protective plant covering the soil from water or wind erosion, the transformation of organic matter into their primal nutrients by micro-organisms, or the water cycle of trees that draw up water from the ground and let it evaporate through their leaves.

Fig. 1: About one third of our food depends on the pollination by the honey bees.

Bees, therefore, not only keep the food chain alive but support fundamental ecological cycles, too.

But if you consider the abundance that nature has brought forth, it is clear that one insect alone cannot possibly pollinate all the different plants all by itself. Wild bees, of which there are more than 740 different species altogether in Germany, Austria and Switzerland (KREMS AND AMIET 2012), are often specialist pollinators, only approaching certain plant families. Their adapted body shape and small size enables them to crawl deeper into the blossoms. So, optimal pollination

October 2014 — www.naturalscience.org — Page 1

Fig. 7: The World Foundation for Natural Science Fact Sheet "The worldwide disappearance of the bees" describes exactly how microwave communication harms the bees and why it is causing the bees to disappear.

Barrie Trower: I think, and I'm coming back to my "silly boy"-mentality, governments are usually only in for four years, or five years, and this is such a lucrative benefit for the people – this is my own theory – I believe that certainly for the UK government and some other governments the ordinary members of parliament are really powerless. Because like when we've had members of parliament standing up saying we've had child cluster of leukaemia cluster after leukaemia cluster and I have a list of something like 200 clusters, not 200 children, 200 leukaemia clusters around transmitters mostly near schools. And the MPs have stood up and asked about these and at the end a minister stands up and says: "We are within international guidelines, sit down." And the whole thing is lost. So I believe that there are people above the ministers, maybe top civil servants, maybe top industrialists, I don't know, but I believe they are the real power behind what is going on and they can direct governments. And I really believe that the governments do not have a choice. It comes down in a threatening way from people who really have power. And I believe that is the problem, and we're back to my silly boy. When you look at the chief of our MI6 and our Prime Minister, as I said, who were wondering what nappies were for, when we were making the real decisions. And they do not have the wherewithal to come and talk to people like me. And I'm sure, if they did, we could change things. But they won't see me and that's the way it is. And I think that is the problem. They are only in for four or five years, they can live with it, they will get their knighthoods, they will get their reward, whatever their reward is, and they will pass the problem on to the next person. And I think, that is the problem, is that they are not directly accountable. They inherited the problem, they will reap some of the benefits, they will pass it on. They are not being held directly responsible. If we said, if there was a law that said, every civil

servant involved in this and everybody who makes a decision, if there was a single death from microwave irradiation, we would have you in court. And we would try you and if you're guilty for manslaughter you would go to jail. I'm sure they would change their minds. But they won't. They are immune, they can get away with it, they're only in for however long, and my impression – and I may be biased and angry and old and stupid – but my impression is that the leaders they like to go around the world, shake hands, convince the world that they are making treaty after treaty after treaty…not one of which has succeeded, but they take all the accolades and they come back. And they pass on the problem to the next person. And I think that is the problem with the government, is that they will not be accountable, that they are immune from this.

Dr Zac Cox: Thank you. I read recently that the honey bee in West Sussex in England is on the verge of extinction. What implication does it have for the rest of the environment should the honey bee become extinct?

Barrie Trower: It varies country to country. If you take a country like Africa, that I was in earlier this year, they have lost whole fields, and their fields can be the size of one of our counties, they have lost whole fields of honey bees. Now, the honey bee tends to pollinate vitamin C-producing plants. So in countries like Africa that relies on its own produce to eat, they are going to lack vitamin C. Which means, they now run the risk of scurvy. Which means, they have to start importing vitamin C. Globally, if we were to lose all of our pollinating insects it has been estimated that if the – and this was published in "Nature" – if the total world's eco-systems brake down the cost would be about 33 thousand billion United States dollars a year on the price of food. So, what would happen is, food would become so expensive that the poor wouldn't be able to afford it. And in our country what it actually means if we lose the bee – and if we lose the bee, we also lose the other pollinating insects, because what affects one insect actually affects all the others right down to ants – if we lose them, we have to start importing food.

Now if I could give you an analogy of how this would affect a country globally – and I know this to be correct: we're in Germany. So let's say that for Germany we look at the situation for Germany from the telecommunications industry's effects. Let's say there are 60 million cell phones in Germany and let's say the average bill is 1 Euro a day. Germany is now losing 60 million Euros every single day to the four main telecommunication industries. So 60 million is going out every day, and that's not coming back. Now you have the medical bills of the people, which is between three and fifteen per cent, the medical bills of the people who are sick, that cannot work. Now you have Germany's share of 33 trillion United States dollars at its extreme end. So if you start looking at the price of food is going to rocket, the price of health care is going to rocket and you've got this money flowing out, any child in the bottom primary school math class, if you say: "Here is your money box. This is what is coming in. This is what is going out, this is what is going out and this is what is going out. " Any child will say: "My money box sooner or later is going to be empty." And this is going to happen to Germany and any country in the world, and I don't care which country it is. At the rate you are losing money to the industry, at the rate that you are going to start importing food, the rate you are going to have your health care costs, which means importing more drugs, so the pharmaceutical industry are going to benefit on an enormous scale with the communications industry here, any country depending over how much time has to go bankrupt. Any country and I don't care who they are.

And the added effect is the carbon footprint from all of this. It was shown that, a couple of years ago some scientists…, and there were three papers published on this and they all came up roughly with the same result. A couple of years ago it was shown that the carbon released into the atmosphere needed to power all of the cell phones, all of the transmitters, all of the Wi-Fi, everything, comes to about 110.7 million tons of carbon-dioxide a year. It's the equivalent of 29 million cars every year going onto the roads. And what that makes now especially with Wi-Fi going everywhere, they're trying to Wi-Fi entire cities, what this means is that the telecommunications industry produces more carbon-dioxide into the atmosphere than the aviation industry. It is the biggest polluter of the planet, in terms of carbon-dioxide, and not a single word has been said against the telecommunications industry. We hear lots about not building more airports, not building more runways. In the United Kingdom, our government has said, they're going to put seven pence or eight pence on each gallon of petrol to cut down the amount drivers are driving, to cut down the carbon footprint. But not a single word has been published by any government anywhere in the world against the telecommunications industry. And the result of all of this carbon-dioxide – and this has been published in "Scientific American", this year – and it's not just from this industry, it is all the industries, carbon-dioxide (you're a doctor, you will know this) and water together produce carbonic acid. So the carbon-dioxide in the atmosphere sinking onto the oceans and the seas they have actually changed – they're not changing – they have changed the acidity of the oceans and the seas. And the microbes and the fish in the seas have a very, very low tolerance for the alkalinity and the acidity of water. And what we are now doing is we are physically destroying all of the living species in our oceans and our seas and the telecommunications industry is the major polluter now, and not a single person is doing anything about it, to stop them. In fact, they're doing as much as they can to encourage them to make it worse. In London, the mayor has boasted that he is going to turn the whole of the city into a Wi-Fi zone for the 2012 Olympics. Now, other cities are also trying to be Wi-Fi, we're trying to get every single school, it seems, in the Western world Wi-Fi and all this could do is exacerbate the problem we have with the environment, the problem we have with the oceans, and the bottom line, and we have the proof, we have absolute, indisputable proof and it goes back to 1971, which is when we had it, and everything since has confirmed it. We had it and what we are doing is, we are physically destroying not just our children's health by illness and genetic illness, we are destroying the health of the planet, we are destroying every living being from the largest mammal in the oceans to the smallest slime mould in the soil, we are destroying, slowly, not even slowly now, we are destroying everything, because this industry is not being controlled by governments. And that is the problem.

Dr Zac Cox: That has such far reaching and massive implications. You are saying it's not just brain tumours, it's not just leukaemias, we're talking about total collapse of our environment, all the ecological system is collapsing…

Barrie Trower: Absolutely, absolutely.

Dr Zac Cox: …we're talking worse than nuclear war.

Barrie Trower: Oh, much worse than nuclear war. Absolutely, and as a doctor you will know this, that when you look at human cells, animal cells, plant cells, even bacteria cells, when you look and you go down to the genetic structure and look at what the genetic structure is made of, there is absolutely no difference, no difference at all between the, the atomic and nuclear level, there is no difference between what we are all made of. Every living thing in the oceans, on land, every living thing is made of exactly the same small particles. So if you are damaging humans – and we had all the government proof we wanted in the 70's – it stands to reason that you are going to damage the animals, that are made of the same, and the plants, that are made of the same, and the oceans, that are made of the same… you are going to damage everything. And I wish somebody in government would actually talk to somebody like me, and credit where it's due, some governments have sent for me and asked me to explain this and some royal families and leaders of communities, and there are now countries in the world that are reducing levels and trying to change things. But the Western commercial governments, the UK especially, not only are they not trying to control this, but before our last government left a few months ago, they gave the industry permission to increase its power three-fold. And we already had the highest levels on the planet. So they are encouraging the industry. Where these people think they're going to go and live when they have their knighthoods and all of this money and whatever other trappings, Rolls-Royces and yachts they think they've got, where they think they're going to take them to live, I don't know. Maybe they haven't thought that far ahead. And maybe they should come and talk to us. But they are going to end up living on the same planet. And their generations are going to end up paying the same price as our generations.

Breast cancer

Dr Zac Cox: Truly, truly disturbing stuff. – Would you like to explain a little bit about breast cancer and microwaves?

Barrie Trower: Breast cancer is not totally understood. Research has shown that microwaves seem to induce breast cancer in women, but not in men, very, very rarely in men. Now, there are a few reasons, we believe, for this. We know that from epidemiological studies and they have specifically said at the end of an epidemiological study when they look at cancers and in fact there's one here in Berlin, they said that there was a seven-fold increase in breast cancers in women. But most of the epidemiological studies you look at they say there is generally an increase in eight different types of cancer, specifically breast cancer in women. And whether because the breasts are bigger than men the mammary cells absorb more radiation… I have been told today by Karin that she read an article, and I did mention this, that the metal in bras, the cups which are parabolically shaped in bras, they are metal, and women tend to carry the phones in a bag over the shoulder which transmit straight through the breast. Your phones can transmit when they're on stand-by, but these days they can be made to transmit even when they're totally off. So assume, if you've got a phone, it is transmitting all day and all night. Now women tend to carry them over a shoulder bag into the breast. Now, we know – and this cannot be disputed – that metal will absorb microwaves. It's why you cannot put metal into a microwave oven. When the metal absorbs microwaves it re-emits it straight away, so it's coming in and going out, straight away. And it re-emits it at a slightly different wave length and we don't know what that wave length is. I haven't seen a paper that has measured it. But we know it's being emitted. So what you have, and we know this cannot be disputed, we know that if the bra of a lady is being microwaved the metal cups will be absorbing the microwaves, they have to do that. We know they will be re-emitting it in a parabolic focus. So what you will have with your cup is the waves will be reflected like a magnifying glass into a small area. So the area may be a few hundred or a few thousand mammary cells big. I would like to see, I know Karin said that there's a paper, I haven't seen one published, the research may be in for peer-review, but it would be a very, very good experiment for a PhD student to do, sent to somebody like "Nature" and have peer-reviewed. But theoretically what we can argue is the microwaves are being reflected with a parabolic focal point somewhere in the mammary cells in the breast. And that is what we believe may be causing the increased breast cancer in women. Any epidemiological study will show that women get more breast cancer when they are microwaved, any woman. And in fact there are really good experiments. And you were there when I spoke, doctor, at Swindon. I mentioned a really clever study, carried out in Estonia, where two professors, and this was published in the "Austral-Asian Journal for Environmental Health", it was published in there, they took a whole country, Estonia, and they looked at all of the cancers, and all of the people, and all of the health – two professors. Then the mobile industry moved in. And then, years later, they looked at the cancers again. And they found an increase of all of the main types of cancer and their conclusion was that the telecommunications industry was responsible and they also said a very interesting sentence, which I've since read in other papers, that women are more susceptible than men. A: because of the breast tissue and B: because women have much more complicated hormonal systems, the reason for which isn't scientifically fully understood yet. We're not clever enough to understand all of these miracles that go on inside the female body. But they are obviously being disrupted. And at the Swindon talk a counsellor, a gentleman stood up and said: "Aha that was probably due to the Chernobyl radiation drifting across Estonia and causing the cancers." Now, I have never embarrassed a child in any of my classes in twenty years of teaching. And I did not want to embarrass this counsellor in front of a room full of people, so I kept quiet. But any senior school child can tell you the difference between cancer from Plutonium, Cobalt 60, Uranium 235, Uranium 238 and microwaves.

Fig. 8: Mobile phones carried close to the breast and metal wires in bras are believed to cause the increase in breast cancer.

Any child in my school class would tell you that. Now if two professors, experts in radiation, are going to make that mistake, I won't believe it. So we can rule out Chernobyl. And I believe their conclusion is the correct one and it matches the epidemiological studies. Women do suffer more than men, they do get as we showed in Berlin, here, in Berlin a seven-fold increase in breast cancer, we're not sure why, and the reason we're not sure why, if I may go on, is that no safety tests were done on cell phones before they were given to the general public. Not a single safety test was done. Unlike drugs or anything else, it has to pass a safety test, not a single test was done. This is the test now. Every single embryo, every single lady, every single child is now a part of this global experiment which is showing… What it is showing? That we are failing to protect the entire planet. And that is the problem. The only specification in the UK, the only specification was that if you used a cell phone or lived near a tower you would not get too warm in six minutes. That is the only legal European requirement. That is it. The World Health Organisation, the ICNIRP or the International Certificate, the only legal requirement is that you do not get too warm in six minutes. That is it.

Dr Zac Cox: That's not a heck of a lot of protection.

Barrie Trower: No. And it was based on the, sadly, it was based on the radiation absorbed from the bombs dropped on Nagasaki and Hiroshima in World War II. It was based on calculations from there. But a very, very clever mathematician, and I have his paper, actually showed that almost every step of the way when they did their mathematical calculation with what we have with today's knowledge was incorrect. And the World Health Organisation and the ICNIRP certificate their calculations for the six minutes are wrong.

Dr Zac Cox: Can I just clarify on the wire in the bra. As far as I can see from my simple knowledge of physics, the wire being curved acts partly like a section of a satellite dish, which has a focal point which focuses the radiation to a point, rather like when using a magnifying glass to set leaves on fire.

Barrie Trower: Absolutely correct. I mean the radiation will come out in all directions but the part that comes out in the middle section, the middle of the horseshoe if you like, you're right, it's like a satellite dish, and it will have the same focal point. If, and my wife won't mind me saying this, when a lady, and I hope I'm not being too personal here, when a lady gets a bra that is really, really comfortable, they tend to wear it a lot, because it's comfortable. And if you're wearing the same bra all of the time because it's comfortable you are then having the same focal point in the mammary cells week after week after week after week.

Dr Zac Cox: Yes. So women should not wear a wire in a bra as far as you're concerned?

Barrie Trower: As far as I'm concerned I would not have wire in bras, I certainly would not if I were a lady. I certainly wouldn't carry a cell phone in a bag over my shoulder, I definitely wouldn't sleep with a cell phone beside my bed or a DECT-phone, because they transmit all day and all night. If you have a cell phone, assume it is on. If I had a cell phone I would carry it in a metal box or put it in a metal box and only use it when I needed to. Assume it's transmitting, but if I were a lady I wouldn't sleep with one beside me, I certainly wouldn't carry one, and if I were pregnant I would treat cell phones like cigarettes. I wouldn't let anybody near me with a cell phone, if I were pregnant.

Fig. 9: DECT-phones and mobile phones must not come close to a foetus. Microwave raditation can cause severe damage to the unborn child.

Dr Zac Cox: You raise an interesting point there. Are you saying if you stand close to someone making a phone call you're being subjected to passive radiation as if in passive smoking?

Barrie Trower: Oh, absolutely. They can have a range of two kilometres. And this is what people don't realise. You could have a pregnant lady on the bus or on the train or sitting next to you and you can pull out your cell phone and make a twenty minute call and from an arc that part of the radiation is going through the foetus. It's like passive smoking. People don't realise it. You're absolutely correct. And if you've got a person either side of you – and this is why people are not being educated and why we are having this problem. And we're not just talking the foetus in a human, the foetus in an animal: a cat, a dog, a rabbit, a bird… all the foetuses will be affected. So if you have a DECT-phone or a mobile phone in your house and an animal or a lady is pregnant they are going to have continuous irradiation in the foetus. So, you really shouldn't use a phone or a Wi-Fi, horrifies me, supposing you have a student, I mean I teach advanced level students who are sixteen, seventeen, eighteen. Now, some of those young ladies are married or engaged and some of them are pregnant. Or the teacher who may be a lady may be pregnant and will be eradiating herself all day. You may have a pregnant lady in an office block, where everybody uses… these days they don't have landlines, they have these walkie-talkie-things. And the worst thing – and I'm not going to namedrop because it will be embarrassing – but coming on to this, the worst thing that I have been involved in with ladies and pop stars – and I have been involved with a few, if not more than a few pop stars – watch lady pop stars, they don't carry microphones, they will have a transmitter. And they put the transmitter in the cleavage and then they go on stage. And how many lady pop stars are we now seeing with breast cancer? Other stars they put transmitters… usually they conceal the transmitters and they're on stage and they're very powerful transmitters, these. And how many pop stars or actors, actresses, theatre people are we now seeing with tumours? I have been called in to give scientific documentary evidence with quite a few theatrical stage pop stars with tumours. And when I explain the proof from microwave irradiation and I say: "Where do you keep your transmitter and how powerful is it, show me what the power is? How long are you on stage for? How often? How

often are you on your mobile which is about twenty hours a day." And it horrifies me, and you and I can think of certain pop singers this year that have gone down with breast cancer. It's now not unusual.

Dr Zac Cox: Yeah, it's very common now.

Barrie Trower: Oh yeah. And this is one of the things, horrifies me, it's that, apart from the fact they have no knowledge, it's the accumulative effect of people not respecting and not having the knowledge if they see a pregnant lady not to use, not to text or not to use their phone. And you even have pop stars on stage saying: "Text me all at once." And you text something to go on a screen. And I see comedians who say: "Text questions and we'll pick them up at the end." And you've got the entire theatre texting! All at once!

Dr Zac Cox: Yeah, that's gonna be dangerous.

Barrie Trower: Now, if you've got a pregnant lady there and you have thousands of people all texting all at once, you might as well take the embryo out and put it in a microwave oven and put it on fry for two minutes! It's that serious. And then we wonder why we have all of these deformities and miscarriages and problems. And there are several pop stars now who are texting, everybody texting the stage is a good idea.

TETRA mobile radio communications system for emergency organisations

Dr Zac Cox: Barrie. The police and emergency services use this system called "Tetra" or "Air waves". I've read a lot about this system, there's been lots of complaints. People are getting sick around the transmitters. Is it a good system?

Barrie Trower: It's a very interesting question and a very good question. I was initially called in and commissioned by the police federation to write the first report, the first safety report, on the Tetra communication system, which is now on the internet. I condemned the system as far too dangerous for two reasons: One, that you have…they tend to carry the system here [points to his shoulder] and it is transmitting through the brain and through the neck and some of the police do fourteen-hour-shifts. And secondly, the pulse frequency of Tetra, which is around 16 pulses a second, is too close to the brain's natural frequency, which is 17, just over 17 pulses a second. The natural frequency, the Beta frequency of the brain is responsible for making decisions in emergency situations. And if you mess up that, you cannot make decisions, and the very job of the police, the ambulance and the fire brigade is to make emergency decisions in emergency situations. And you are affecting that one part of the brain that they need. The other danger of that particular pulse frequency is that it is what's known as the "cyclotronic resonance frequency" of the calcium in the body. Now, what that means, is that as the Tetra is going through, the calcium is being knocked from the surface of cells and the calcium keeps the cells stable. The calcium is replaced by potassium, which only has a single bond as opposed to the calcium's double bond. And the potassium will cause the cell to leak. And I think we now have something like 18 experiments showing this. So you now have what's known as "calcium efflux" or a calcium leakage in officers wearing Tetra. I said it is far too dangerous a) because of the pulse frequency b) because of the microwaves going through the neck and the brain and it should not be allowed. The chairman of the police federation and the staff who commissioned me to write the report, the chairman retired, he was replaced by a lady who sacked me, said I didn't exist, said I wasn't commissioned to write the report, called a conference, that I was allowed to attend but not allowed to speak, she called a conference and her opening words were: "Nothing is going to stop Tetra." The government doctor stood up at the same meeting and said to the police union: "If you don't like it, resign. That is your choice." And that is in fact an illegal thing to say, this is illegal. But that was it. And they published papers to say I didn't exist, and that I'm mad and I'm wrong and everything else you can read about me, and recently, only this year, another union that represents mostly the ambulance and the fire brigade but some police officers, usually special branch, they commissioned me to write an updated report. And in this report which…the first report is on the internet, this report which was highly confidential for the legal department of the union, I quoted our government scientist saying how much you can expect to develop a brain tumour compared with the radiation you are getting, for an ordinary person. And that's based on what is known as "average use", and you'll probably be surprised to learn that average safe use for a mobile phone is considered to be about twenty minutes spread over a whole week. Now police officers have these for fourteen hours a day. So when you start looking at the maths – and my first degree I specialised in nuclear and atomic physics – now when you look at the maths, what the chief government's science officer is actually showing is, that today we could have as many as 7,000 plus lady and gentlemen officers walking around with slow growing tumours. They are not told of the warning of this, they are not told of the dangers, they do not know the risk they are taking, they do not know that there could be 7,000 of them with slow growing tumours, and they will only find this out when they come up to retirement age. And this is the government's figures, not mine, I actually had it at slightly less. And this is being kept from them. 7,000 tumours. But which is absolutely incredible. I wrote an open letter which anybody can read on the internet, it's "Open letter to the Police Federation". And I said, this was last Christmas, and I said: "In the last three months," I believe, "I have had five lady police officers come to my house, all independent of each other, and they have all had neck tumours, where the transmitter is." And when I say to them: "Have you ap-

Fig. 10: TErrestrial Trunked RAdio (TETRA) is a digital trunked mobile radio standard developed to meet the needs of emergency organisations.

proached your federation?" They all say, they cannot, because the federation will not help them, they are victimized, they are bullied; any police officer who raises this is very heavily brought down by senior officers and threatened with being moved, threatened with losing their job, there are bullying tactics from the government and the senior officers on the officers. And the police federation published a document that I have referenced in my latest report, and it actually says: "We know that this system is now dangerous and causing these ill effects, but as it is up and running, we cannot do anything about it." And I think, well, why are the police paying you to represent them, if you'll not? And the other thing I find incredible, and I've got the documents for this, and I've referenced them in this document, a government document actually says that a scientific experiment should be carried out on the police and the emergency services, because they are all young, they have a well-defined work pattern, they are fit and they will be ideal for an experiment to see, how much cancer and how much brain damage is caused by this system. And they actually say: "We cannot rule out that some officers will develop cancer and some will develop brain damage from this system." And then we get another message, which I've also got, that says: "We welcome (this is from our government's radiation board!), we welcome the study that you have set up on the police officers." So they are a living experiment for cancer and brain damage from this system. And the government have written it, put it in writing. And we have sold this system to, to my knowledge, thirty countries. Now, this is going to take place in thirty countries around the world. They are going to find the brain damage and the cancers without being told. And I think that is a crime.

Dr Zac Cox: That is truly, truly horrifying.

Barrie Trower: And this is the Tetra Airwave System. And my report, the original report is on the internet, my open letter with documentary proof of most of this is on the internet, the highly confidential paper I wrote for the Union is not on the internet, but it probably will be soon. But that is the situation, it is now, it has been sold to 30 countries using the British police as the finest police force in the world: "This is the finest police force with the finest system, buy it." And this is the power of money and what I call "spin" or I prefer to call it "lies". But every country is going to suffer what we are now exposing our officers to, our fire brigade, our ambulance service, the MI5, the MI6, the government body, there are, I think, in the UK, 52 organisations that are now using this system, and 52 organisations, theoretically, in these other 30 countries, the coast guards, the security services….52 organisations, that have to tie in with the police for emergency work. And if you look world-wide, it's thirty countries – I can't do the math, I'm too tired now – 30 countries, probably 300,000 people using it in each country, if you look at the 52 organisations, 7,000 in each, probably, according to our government's figures, developing tumours… it's beyond belief, I mean, like you said earlier, it's worse than the atomic bomb, much worse.

Fig. 11: You may also obtain this interview from us in full length (approx. 130 minutes) as a DVD or CD in English. Furthermore, we are glad to offer you a CD with exclusive documents, containing dates and facts, which form and support the basis of Barrie Trower's discourse. Barrie Trower kindly has given these documents to us for use and distribution, as it is his heartfelt wish to warn as much people as possible of this dangerous technology.

And the truth will come out eventually, not in my lifetime, but it will come out. But that is the situation and what I would like, and this is happening, what I would like is for countries using this system to read the reports I've written on it, before they make a decision or before they go ahead. It's what I would like. If they think I'm wrong and they want to use it, fine, but what I would like is, you show what I've written to your officers and what the governments say to your officers and if nothing else, let the officers…credit them with the intelligence they have, let the officers say: "Yes, we want to take this risk or no, we don't." And that is all I've ever said to any of the emergency services. "Let me publish an article for the officers to read. You publish an article. Let them vote. It's not difficult. Let them vote. And if they don't want it, whatever they decide, is final." If they say: "We don't like this."… There are systems, there are systems used by other European police and emergency services that have nowhere near the risk of this system, Tetra Airwave. And just say to them: "Here is one point of view, here is another, tell us what you want." And the unions are doing what they are paid to do, which is represent their officers. And that is all I've ever asked. It's that people are given a say. The same with Wi-Fi in schools, we make the truth known to the parents and we say… I could write the truth in 240 words, one side of A4, the industry or the governors write their side, the parents and the children read it and they have a vote. Do you want it? If they say: "We want it and we want to take the risk." I don't have a problem with that. But when the truth is concealed, and they are lied to, then I have a problem with it and this is what is happening with the Tetra Airwave System. And I know they have lied, because our MPs have stood up in parliament and said: "This industry is lying." They have said "lying" in parliament and I've got the document. So we know they are lying. We know they are liars. And we know that the senior officers somewhere in the police are complicit with the industry. I don't know why – they should be protecting their officers – but they're not. And that is all I've asked for. And this worries me about the Tetra being sold to the 30 countries.

We need to be mindful in our actions!

Dr Zac Cox: So, to summarise, mobile phones, cordless phones, Wi-Fi, our entire telecommunication system is not only causing cancer and deaths in children, in adults, it is also destroying the eco-systems, it is killing the bees, it's responsible for the destruction of our oceans…

Barrie Trower: Exactly.

Dr Zac Cox: It's the biggest threat on this planet we've ever seen.

Barrie Trower: You're absolutely right. And what we need is, we need the industry to be controlled. There is a level

that the industry can function. It won't be totally safe, but it will be acceptably safe. It will not be safe for pregnant women, it will not be safe for children. It's like having motor cars on roads: we know, every year there are going to be deaths. It's like having aeroplanes: we know every year so many are going to crash. There is a level which is acceptable. And let's be honest: cell phones can save lives. If you are a lady and your car breaks down on a dark road and you have a child in the car or you're pregnant, you could pull out your cell phone, dial a number and they can be there. There is, there is a use for them, and I would not like to see them go. But at the current level it's what I call "blind corruption with intentional ignorance" from senior people. People are being lied to and money is being made at the expense of children and people becoming ill and dying. The solution is to have a workable system that the entire world will agree. And the level of…the level has already been found. We don't have to think up what it is, the Bio-Initiative Report has already come up with a level, a level that the nearest person to a transmitter must not exceed. So if there are two transmitters they have a half of that, four transmitters they have a quarter. But the nearest person must not exceed that level. That's the option. And all we need now is somebody clever enough and brave enough to be able to say to the world: "Look, this is what is happening. We all have to live here, and this is the danger that is going on. Let's have an international agreement, one that actually works, where globally not a single person anywhere in the world is exposed to more than this Bio-Initiative level." And in fact, since it was agreed on, a lot of scientists are now saying: "No, no, it has to come down by a factor of ten." So already they are questioning that it's too high. But let's settle with the Bio-Initiative level. If we could have that, globally, the industry could still function, your cell phone would still function. You may not be able to download pornography or movies or sport in your house, you would have to use a landline. But they would work outdoors, which is where you want them to work. The children lying on their beds would not be able to text each other all night, they would have to pick up

Fig. 12: It is our individual choice to be an ambassador for the health of nature and mankind and making other people aware of the danger of microwave technology.

a landline and use real words. But the system, there is a way for the system to work and everybody to be able to use it sensibly, and instead of a wire going into your ear or having the phone on your body or holding it here [points to his ear], you can use an air tube like a doctor's stethoscope and hold it away from your body. There are mechanisms that people who carry phones… that protects the body from the radiation. There are mechanisms, they are just not used. The patent was taken out by, in fact, the mobile industry to show that they could be made safer. But of course they don't tell you this, because if they tell you, they have to admit that there is an element of danger. So, I'm not saying we have to scrap the industry, all I'm saying is, we have to turn the knob down. That is all. To a level that is internationally agreed. There will be casualties, but there are casualties with road accidents, plane accidents… there are always casualties with everything we do and there will be with this. But there is a level where the level of casualties is acceptable to the human population, but the eco-system will be saved, the bees will be saved. We have no transmitters within several kilometres of any bee hive. We have no transmitters within several metres of farms, where pollinating insects have to work; definitely no transmitters on hospitals, schools, old people's homes, which is where most of them are. It can be done. There is a way out of this, but I fear, like every single international agreement since, to my knowledge, 1992, to try and protect the environment, the eco-systems, the bio-diversity, global warming…every single agreement has failed or been ignored or left to fizzle out. And I suspect that if we had an international agreement, because prime ministers love to be seen together, they love the photographs, they love all the cameras and they love to come away to say: "Look, we're going to save the planet," they go away and then it is left to fail. And my fear is that this is left to fail. And what we really need is an organisation that can pull the world together. And if we have leukaemia clusters in schools, then somebody is legally accountable; at the moment, they're not. Somebody is legally accountable. And if the government allow a transmitter to be too powerful, the government are put in court and they are tried. And if the person has been made sick, they are sentenced. They must be legally responsible for what they do. That is what we need.

Dr Zac Cox: Barrie, thank you for this interview.

Jan. 24, 2017

Dear Public Service Comission,

I want to opt out on any smart meter applied to my home. It is a violation of my privacy and proof that endangers the health of citizens, and is also instrumental in killing our bee population.

I have a SMART water meter in front of my home and it have been invaded by spiders.

We don't need more government interference.

Rand Paul stood up against this but not long enough.

Mildred Hiles

Today's Date is Jan. 24/17

Dear Kentucky Public Service Commission, Kentucky Utilities, all other utility companies, and all agents, officers, employees, contractors and interested parties regarding: Case File 2016- 00370

This letter is to be **posted as public comment and a request that:**

1. Case No: 2016-00370

Application of Kentucky Utilities Company for an Adjustment of its Electric Rates and for Certificates of Public Convenience and Necessity.

Be Denied

2. That no wireless devices of any kind be permitted to be installed by Kentucky Utilities or any other utility companies due to their numerous violations, unaffordable costs, and the health damages they cause to people, animals, plants, trees, and the environment. They are not federally mandated and violate my Constitutional Rights. (http://www.electricsense.com/wp-content/uploads/2014/05/Legal-Constitutional-and-Human-Rights-Violations-of-Smart-Grid-and-Smart-Meters1.pdf)

I request that all complaints, unbiased medical research and documentation, as well as all doctors letters, public comments, fire and electrical malfunction documentation be read in detail regarding the complaints filed in the following cases:

Kentucky PSC: Case Files 2012-000428 , 2016-00394, 2016-00187, 2016-00152, 2016-00370

Ohio PSC : Case File 14-1160-EL-UNC, Case MMAI111315OO

North Carolina PSC: Case File Docket No. E-7 Sub 1115 (Note: This was originally Case File Docket No. E-100, SUB 141)

South Carolina PSC: Docket 2017-19-8, Docket No. 2013-59-E , Docket No. 2016-366-E , Docket No. 2016-354-E

Florida PSC: Case File Docket No. 130223

In 2015 KU and PG& E were Offering wireless meters to residents while having full knowledge of and ignoringthe dangers of these wireless meters. The published promotions have been deceptive and lacking in information.

In 2006 (Case 2008-00408) Ky PSC started to consider the Wireless Technologies and then continued these considerations in Case 2012-00428.

You held a public meeting in December 2014 (http://migration.kentucky.gov/Newsroom/psc/pscpr12-05-2014.htm) which very few people found out about and then on 4/13/16 (http://psc.ky.gov/agencies/psc/press/042016/0413_r01.pdf) you ignored all documentation regarding the dangers of these wireless meter, the privacy violations, and the fires and explosions caused by these meters.

In your announcement on 4/13/16 you stated that:

"The PSC, while saying that it opposes allowing opt outs, nevertheless said utilities could, if they wish, develop programs to allow their customers to refuse three types of meters."

It was also stated that: "The utilities suggested that no opt outs should be permitted for digital or amr meters" and that the additional costs such as having to read the meters directly (as they have always done) rather than remotely, be borne by the individual customers choosing to opt out."

This is Called Extortion!

Based on the complaints filed across the U. S. (http://www.sanantoniosmartmeterawareness.org/ , http://stopsmartmeters.org/frequently-asked-questions/faq-health-issues/ , http://emfsafetynetwork.org/smart-meters/smart-meter-health-complaints/ , just to name a few thousand…) the outdated FCC regulations, the numerous privacy violations, health issues reported, deaths, sky-rocketing utility bills, and lawsuits filed, it is obvious that these wireless meters are not and will not be safe and reliable as stated by the utility companies and the Kentucky PSC.

It is your job to protect us and this not only is extortion, but violates my constitutional rights as a citizen.

I have no other Utility company I can get my services from, and choosing to remain healthy becomes impossible if these wireless meters are installed on my home, let alone the bills from all the damages.

I can not afford to pay "opt-out" fees, and never agreed to "opt-in" to dangerous Class 2b Carcinogenic Wireless Technologies!

There is no federal mandate requiring anyone to have these wireless utility meters and therefore it is illegal for you to force them on us. (https://sites.google.com/site/nocelltowerinourneighborhood/home/wireless-smart-meter-concerns/first-and-foremost-are-wireless-meters-mandatory)

Please deny all requests of Kentucky Utilities and all other Utility Companies in regards to installing these wireless utilities on property owners homes and businesses without their written permission.

"Opt-outs" are extortion fees, because the precedence has always been set for analog meters to be read by meter readers and customers have only agreed to having analog meters. Therefore charging a fee to continue using an analog meter is extortion, and ignores the safety and privacy features which have long been available with analog meters.

Sincerely,

Mildred Hiles

January 19, 2012

Decision Proposed Decision of Commissioner Peevy (Mailed 11/22/2011)
BEFORE THE PUBLIC UTILITIES COMMISSION OF THE STATE OF CALIFORNIA
On the proposed decision 11-03-014

Dear Commissioners:

The Board of the American Academy of Environmental Medicine opposes the installation of wireless "smart meters" in homes and schools based on a scientific assessment of the current medical literature (references available on request). Chronic exposure to wireless radiofrequency radiation is a preventable environmental hazard that is sufficiently well documented to warrant immediate preventative public health action.

As representatives of physician specialists in the field of environmental medicine, we have an obligation to urge precaution when sufficient scientific and medical evidence suggests health risks which can potentially affect large populations. The literature raises serious concern regarding the levels of radio frequency (RF - 3KHz – 300 GHz) or extremely low frequency (ELF – 300Hz) exposures produced by "smart meters" to warrant an immediate and complete moratorium on their use and deployment until further study can be performed. The board of the American Board of Environmental Medicine wishes to point out that existing FCC guidelines for RF safety that have been used to justify installation of "smart meters" only look at thermal tissue damage and are obsolete, since many modern studies show metabolic and genomic damage from RF and ELF exposures below the level of intensity which heats tissues. The FCC guidelines are therefore inadequate for use in establishing public health standards. More modern literature shows medically and biologically significant effects of RF and ELF at lower energy densities. These effects accumulate over time, which is an important consideration given the chronic nature of exposure from "smart meters". The current medical literature raises credible questions about genetic and cellular effects, hormonal effects, male fertility, blood/brain barrier damage and increased risk of certain types of cancers from RF or ELF levels similar to those emitted from "smart meters". Children are placed at particular risk for altered brain development, and impaired learning and behavior. Further, EMF/RF adds synergistic effects to the damage observed from a range of toxic chemicals. Given the widespread, chronic, and essentially inescapable ELF/RF exposure of everyone living near a "smart meter", the Board of the American Academy of Environmental Medicine finds it unacceptable from a public health standpoint to implement this technology until these serious medical concerns are resolved. We consider a moratorium on installation of wireless "smart meters" to be an issue of the highest importance.

The Board of the American Academy of Environmental Medicine also wishes to note that the US NIEHS National Toxicology Program in 1999 cited radiofrequency radiation as a potential carcinogen. Existing safety limits for pulsed RF were termed “not protective of public health” by the Radiofrequency Interagency Working Group (a federal interagency working group including the FDA, FCC, OSHA, the EPA and others). Emissions given off by “smart meters” have been *classified by the World Health Organization International Agency for Research on Cancer (IARC) as a Possible Human Carcinogen*.

Hence, we call for:

- An immediate moratorium on “smart meter” installation until these serious public health issues are resolved. Continuing with their installation would be extremely irresponsible.

- Modify the revised proposed decision to include hearings on health impact in the second proceedings, along with cost evaluation and community wide opt-out.

- Provide immediate relief to those requesting it and restore the analog meters.

Members of the Board
American Academy of Environmental Medicine

Electro-sensitivity: The cause in the rise of ADD, ADHD?

Posted on May 27, 2013

Marti Oakley ©copyright 2013 All Rights Reserved

April 4, 2013

Have any of the parents of these children diagnosed with ADD or ADHD or school officials or, these psychiatric quacks considered the possibility that these children who are obviously in an agitated state are responding to radio frequencies that permeate the schools, neighborhoods and homes: anywhere and every where?

As the number of SMART meters, cell towers and hidden antennas, rise, so does the number of children diagnosed with so-called attention deficit disorders. These same children appear to be responding to some invisible force that makes it impossible for them to think clearly and stay focused, or to remain still in their seats at school. At home they appear hyper-active and uncontrollable. Many are unable to achieve adequate sleep which adds to the overall distress the child appears to be suffering from.

You can go to www.antennasearch.com and find out just how many cell towers and antennas have been installed and/or hidden in a four mile radius around your home. This information may give you a clue about what might actually be wrong with your child. It may also explain tinnitus, headaches, blurred vision, anxiety attacks, muscle cramping, and a general feeling of dis-ease…experienced by you!

ADD & ADHD

According to Northwestern University:

"*ADHD is now a common diagnosis among children and teens," said Craig Garfield, M.D., first author of the study. "The magnitude and speed of this shift in one decade is likely due to an increased awareness of ADHD, which may have caused more physicians to recognize symptoms and diagnose the disorde*r."

And it is just as likely, if not more so, that what is being diagnosed as ADD or ADHD is actually a physical response to wi-fi, pulsing microwaves from SMART meters and the massive ongoing installation of cell towers and antennas; all of it engulfing every area of our communities. Maybe what these children are really responding to is the continual exposure to microwave radiation.

It is entirely possible that these children are suffering the same adverse side affects of electro-sensitivity that many adults report, especially those living within 100 miles of the GWEN towers stationed across the country. Around the GWEN towers are clusters of affected individuals, all reporting bizarre and extraordinary things, including physical symptoms that either no one can explain or, no one will explain.

Northwestern also reports:

"*The number of American children leaving doctors' offices with an attention deficit hyperactivity disorder (ADHD) diagnosis has risen 66 percent in 10 years, according to a new Northwestern Medicine study. Over this same timeframe, specialists, instead of primary care physicians, have begun treating an increasing number of these young patients, the study found.*"
"*According to the study, in 2010, 10.4 million children and teens under age 18 were diagnosed with ADHD at physician outpatient visits, versus 6.2 million in 2000."*
That is 10.4 million children who were forcibly medicated with stimulant psychotropic drugs, the effects of which have not been thoroughly investigated and it is unknown what kind of lifetime damage these medications might cause. Maybe what is really needed is to remove these children from these toxic microwave/radio frequency bathed environments, to a safe place where they are protected from the waves. I think it highly probable that in short order many of the symptoms of these so-called mental disturbances would most likely disappear.

Our kids don't stand a chance

We truly are raising an entire generation of damaged children. Between deadly and useless "vaccines" many of which contain human diploid cells (gathered from the lung tissue of aborted babies), our children now have as many as 1 million strands of someone else's dna in their bodies.
"*The injections* *also contain carcinogens, heavy metals, wild viruses, mutated proteins, and the dna in the vaccine can be transfective and recombinant, meaning it can combine with human DNA and mutate.*"
Alliance for Natural Health reports:
"And we've seen cross-species transfer of DNA happen before. A significant percentage of human DNA is actually viral DNA that became part of us over 40 million years ago. There is concern that virally transmitted DNA may cause mutations and psychiatric disorders such as schizophrenia and mood disorders. GE organisms may exacerbate this phenomenon."
We also feed them genetically modified foods that can contain the DNA of other species and that DNA can transfer over to our DNA, along with pesticides, herbicides and fluoridated water. Aspartame which big dairy producers want added to milk and dairy products for absolutely no reason, is a deadly poison; yet it is in more than 5,000 products already, even though the FDA knows it is extremely harmful.
As if all this was not enough to cause agitation, lets throw a big load of microwave radiation into the mix. Just to make sure they get their share, lets put one or more SMART meters on their homes and on every home in their neighborhood. Then lets put wi-fi in our schools so they can be exposed to it all day long. Then lets add dozens of cell towers and antennas in close proximity to their homes.
Gosh…….I wonder what is wrong with these kids? Electro-sensitivity, too?

Joint Non-Lethal Weapons Program

Non-Lethal Human Effects Fact Sheet

http://jnlwp.defense.gov

What are they?

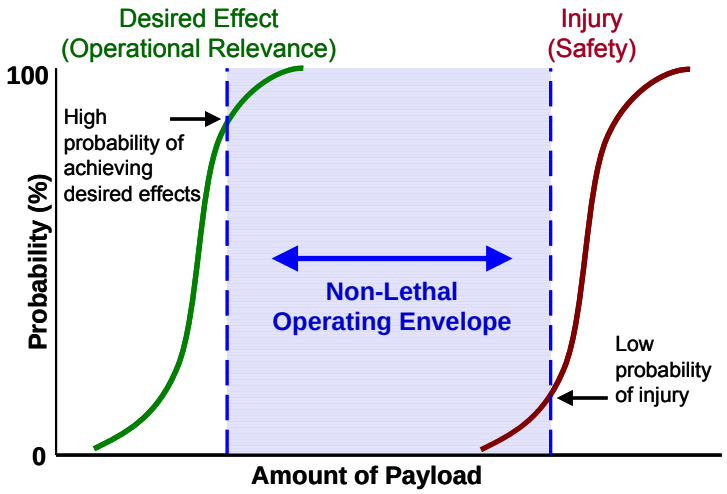
Non-lethal human effects are the physiological and behavioral responses produced by non-lethal weapons employment. Non-lethal human effects research identifies risk of permanent injury and characterizes the technology dependent limits of the non-lethal weapons "operating envelope." This process ensures the development and fielding of non-lethal weapons capabilities that are both safe and effective.

Human effects are key to the development of non-lethal weapons tactics, techniques, and procedures; they provide operational commanders with the understanding of risk to support informed employment decisions. Knowledge gained and products developed through human effects research also transition to the warfighter through extensive non-lethal training.

How are they characterized?

The Joint Non-Lethal Weapons Program (JNLWP) strives to develop non-lethal weapons through effects-based design, where promising new technologies are designed and developed based on non-lethal human effects. The JNLWP adopted the Human Effects Risk Characterization framework, an approach based on the National Academy of Sciences framework for risk assessment, to characterize the intended and unintended effects of non-lethal weapon technologies and payloads. The Human Effects Risk Characterization process establishes the baseline human effects understanding for a particular technology/payload, identifies knowledge gaps, and facilitates communication among human effects researchers, material developers, and non-lethal weapon operators.

When commercial off-the-shelf non-lethal weapon technologies are considered for non-lethal mission application, human effects assessments are conducted to identify the technology's anticipated physiological responses and risk of significant injury to the target, bystander, and operator. This includes understanding any possible collateral effects with the use of this non-lethal weapon.



Non-Lethal Weapons Operating Envelope

Non-lethal human effects are further characterized through assessments of operational relevance of non-lethal weapon technologies and payloads. Assessments are achieved with a combination of literature research, analytical and statistical analyses, and focused human effects and effectiveness experiments. The purpose of this type of developmental testing is to understand human behavioral response to non-lethal weapon stimuli. This understanding is important because non-lethal weapons are viable operational solutions only if their application elicits a desired response and has minimal risk of significant injury. This area between effect and risk of significant injury is the operating envelope developed using dose response curves. All JNLWP-sponsored research is conducted in accordance with federal regulations and Department of Defense policy.

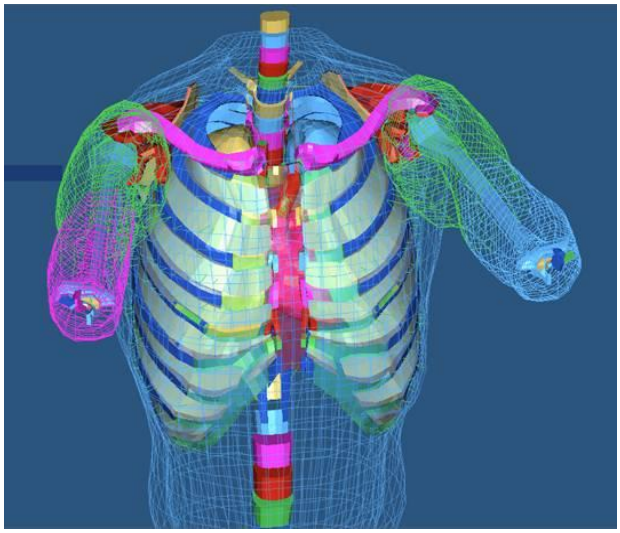
Human Effects Models

Human effects models are also used to characterize and assess non-lethal weapon systems. Non-lethal human effects models are developed from dose-response relationships generated by experimentation and from the refinement of existing models for non-lethal weapon application. Primary non-lethal human effects models include the Advanced Total Body Model for blunt impact injury assessment and the Optical Effects Model for broadband optical effects analysis.

Non-Lethal Human Effects

The non-lethal human effects models support risk assessments, effects-based design of emerging non-lethal technologies, design optimization of existing non-lethal weapons and payloads, and non-lethal weapons training.

Non-lethal human effects model development continues through the Human Effects Modeling Analysis Program. Efforts continue to validate and verify current models, as well as to interface the various capabilities as a non-lethal human effects suite of models. Additionally, future model development will include behavioral outcomes displayed in a modeling, simulation, and gaming environment.



Advanced Total Body Model

Review Boards

Following the recommendations of a 2001 National Academy of Sciences review of non-lethal weapon research and development, the JNLWP has established two human effects review boards to facilitate non-lethal human effects review, interpretation, and recommendation. These bodies provide guidance to program managers and material developers to help ensure that emerging non-lethal weapon technologies meet mission needs while minimizing the risk of injury.

The JNLWP Human Effects Review Board was established to independently review non-lethal human effects research and analyses associated with specific non-lethal weapon systems or technologies.

The Human Effects Review Board consists of representatives from the Offices of the Services' Surgeons General, the Medical Officer of the Marine Corps, and the Services' Safety Officers and includes legal, treaty and Department of Defense policy participation. The board provides non-lethal weapon program managers and milestone decision authorities with an independent measure of health risks and recommendations for mitigating potential risks.

The Human Effects Advisory Panel is another independent advisory panel supporting the joint non-lethal weapons community. Panel members consist primarily of non-governmental senior subject matter experts from academia, the medical community, and law enforcement. The panel provides an assessment of non-lethal human effects and makes risk mitigation recommendations to program managers prior to major acquisition program milestone decisions. The panel also reviews non-lethal human effects research plans, provides recommendations to program managers on how to address technical challenges, and addresses any open human effects issues identified by the Human Effects Review Board.

Similarly, the Technology Effectiveness Advisory Panel is an independent group of government and non-government personnel that conducts technical assessments of the counter-materiel or counter-personnel effectiveness of developmental non-lethal technologies and programs. The panel includes Service operators and test and evaluation engineers, as well as subject matter experts in bio-effects, weapons, and legal, treaty, and policy. Panel evaluations often focus on advanced concept non-lethal technologies, and they generally have broad applicability throughout other JNLWP projects.

Human Effects Center of Excellence

The Human Effects Center of Excellence was created in 2001 via memorandum of agreement between the Air Force Research Lab and the JNLWP. The center provides consultation and guidance to program mangers, as well as recommendations on laboratories and field activities best suited to execute human effects research. The Center also manages human effects assessments, non-lethal weapon safety and risk assessments, and risk characterizations.

(57) **ABSTRACT**

A method and device to temporarily incapacitate a subject for a prolonged period by first applying to said subject a continuous pulsed electric waveform to incapacitate the subject, followed by applying a second intermittent pulsed electric waveform to the subject, which safely maintains the incapacitation of the subject with forced breathing.

METHOD FOR PRODUCING ELECTROMUSCULAR INCAPACITATION

CROSS-REFERENCE TO RELATED APPLICATION

[0001] This application claims the benefit of U.S. Provisional Application No. 61/448,708 filed Mar. 3, 2011, which is hereby incorporated in its entirety.

BACKGROUND OF THE INVENTION

[0002] The present invention relates generally to a non-lethal method to control and subdue a subject and, more specifically, to a device and method for delivering an electric waveform to a subject in order to induce a prolonged non-lethal electromuscular incapacitation (EMI) of the subject.

[0003] Electrical discharge weapons (EDW) have also become fairly common in recent years. A number of non-lethal electrical discharge weapons have been developed to subdue and control a subject. Numerous U.S. patents have issued for invention of such weapons and for their further improvement, including U.S. Pat. No. 3,523,538 issued to Shimzu on Aug. 11, 1970; U.S. Pat. No. 3,803,463 issued to Cover on Apr. 9, 1974; U.S. Pat. No. 4,253,132 issued to Cover on Feb. 24, 1981; U.S. Pat. No. 5,473,501 issued to Claypool on Dec. 5, 1995; U.S. Pat. No. 5,654,867 issued to Murray on Aug. 5, 1997; U.S. Pat. No. 5,698,815 issued to Ragner on Dec. 16, 1997, U.S. Pat. No. 6,053,088 issued to McNulty, Jr. on Apr. 25, 2000, U.S. Pat. No. 6, 782,789 issued to McNulty, Jr. on Aug. 31, 2004, U.S. Pat. No. and U.S. Pat. No. 7,143,539 issued to Cerovic et al. on Dec. 5, 2006.

[0004] The TASER® X26 which is the dominant device in the area and is produced by TASER® International, and its sister devices all produce a similar bi-polar waveform whose shape is mimic the ringdown observed in a capacitor discharge through a transformer. The pulse repetition rate in 19 Hz with each pulse having approximately 125 micro-Coulombs, and a duration of roughly 125 micro-seconds. The duration of stimulation is either a constant (5 sec for the X26, 20 sec for the X-rep, or 30 sec for the X26c) for each activation of the trigger, or for the law-enforcement version of the X26 will stimulate continuously if the trigger is held in the on position.

[0005] These devices provide an effective but non-lethal form of force, which may be used in self-defense and in law enforcement as well as military operations. Generally, there are two types of non-lethal electrical discharge weapons: those designed for use in close proximity to another, and those having a relatively long range of 10 feet or more.

[0006] The close proximity weapons typically have two separated electrodes affixed to the weapon. The weapon must be moved toward a perpetrator so that the electrodes contact the target at two spaced-apart locations. Trained operators can apply the weapon electrodes with precision to the most responsive areas of the target anatomy.

[0007] The long range weapon usually provides two launchable, wire-tethered conductive darts, which are propelled at a fixed angle from each other by gun powder to a remote target some distance away. If the two darts contact the perpetrator, the discharge occurred through the wire tethers, and the darts will disable the target.

[0008] Each type of the non-lethal electrical discharge weapons has its respective advantages. For example, the close proximity weapon is more effective in situations where a perpetrator is already in contact with the weapon's user, such as in a surprise attack scenario or for a potential robbery victim who is within reach of a threatening perpetrator. On the other hand, where time and distance permit, a long range weapon can be very effective before a perpetrator gets too close to the user. However, how to precisely apply the long range weapon's contacts to more responsive areas of the target anatomy remains a serious design challenge, which needs to be addressed.

[0009] There are some weapons available that have both long range and close proximity capability. They have a dart cartridge and a pair of attached "feeler probes" with two switches permitting actuating one or the other. However, these weapons are only available if purchased with this dual function capability or as an after-market addition.

[0010] Notwithstanding the improvements made to the electrical stimulation (or stun) devices (ESD), there has been little improvement or change in the current EMI approach. The voltage and peak current is quite high in commercial ESDs. With increasing usage and deployment of ESDs, growing number incidents of electrical injuries related to the use of stun devices have been observed, and morbidities/mortalities linked to the usage of ESDs are also on the rise.

[0011] Electrical discharge produces a complex set of injuries including thermal burns, cell membrane damage and rupture, and macromolecule (protein and glycosaminoglycans) denaturation or alteration. The nature and extent of the injuries appears to be related, at least in part, to the strength and duration of the discharge, its anatomic location and path through the tissues of the body, and the characteristics of the current applied (i.e., AC, DC, mixed). The organ- and organism-level effects may include skin burns, skeletal muscle death, cardiac dysrhythmia, osteocyte and osteoblast death, blood vessel endothelium dysfunction, etc. Moreover, the application of electric currents to a live subject may cause acidosis, which is due to incomplete or inconsistent muscular contraction. Acidosis occurs when the body is incapable of properly clearing lactic acid build-up, and may lead to death in extreme cases. Some types of current (e.g., direct current, DC) can cause little or no injury at low levels, and increasing amounts of damage and disruption of muscle control at higher levels. However, notwithstanding the complex injuries that may be caused by the application of ESDs, there have been few reports of biologically-based studies that characterize specific responses to stun device stimuli or to health effects of a given stun device output with reference to nerves and muscle, both of which mediate the EMI response. Very little objective laboratory data are available describing the physiological effects of stun devices.

[0012] The most commonly used devices, TASER® produced by TASER® international (Scottsdale, Ariz.), can produce 50 kV open circuit voltage, and 3-15 amperes of peak current [1] with electrical pulse durations last between 4.5 to 30 seconds. In order to produce a widespread neural excitation, while maintaining a very low probability of producing undesired effects, the duration of the EMI stimulus is designed to be short (30-80 μs), resulting in a very small conducted charge in each pulse, at about 100 μC [2] [3] [4]. The maximum range of TASER® is 21 feet with operational ranges of 10-15 feet.

[0013] With increasing use of the electrical stimulation devices in military operations, improvements to many features of the ESDs are desirable, for example:

[0014] a. A longer range of operation (5-100 meters), which allows the user to achieve Human Electromuscular Incapacitation (HEMI) effects at greater stand-off distances, and thus increase protection of the user from the threats.

[0015] b. A longer duration of incapacitation (100-180 seconds), which provides sufficient time for the user to close in and take custody of an incapacitated subject if needed.

[0016] c. A self-contained projectile that is not tethered to an electrical generator and upon impact can apply the electrical charge, and pulsing current to incapacitate the subject without causing unnecessary injuries.

BRIEF DESCRIPTION OF THE DRAWINGS

[0017] FIG. **1**. The Effect of Lidocaine on TASER® X26-induced EMG recorded on the right, left hind limbs (top tracing) and left front limbs (bottom tracing).

[0018] FIG. **2**. CAMPs amplitudes recorded in all three extremities during a simultaneous, direct stimulation of SN, and FN with electrical pulses of increase widths.

[0019] FIG. **3**. Side view of animal in ventral recumbency (artist's rendition).

[0020] FIG. **4**. Side view of animal in dorsal recumbency (artist's rendition).

[0021] FIG. **5**. Ventral view of animal, showing electrodes attachments.

[0022] FIG. **6**. Examples of pulse waveforms tested in the monophasic pulse experiment. From top to bottom, the left panels show a monophasic Gaussian pulse, a monophasic square pulse, and a polyphasic pulse. From top to bottom, the right panels show a biphasic sine pulse and a biphasic square pulse

[0023] FIG. **7**. Examples of pulse waveforms tested in the threshold experiment.

[0024] FIG. **8**A. Pulse waveforms with positive initial phase tested in the biphasic pulse experiment. Top, left: Schematics of pulses with 20-μs phases and the indicated interphase delays. Top, right: Schematics of pulses with 100-μs phases and the indicated interphase delays. Bottom: An example of a current waveform from an oscilloscope recording for phase duration 20 μs and interphase delay of 50 μs. The 8-μs delay (second row) represented a minimum delay that was later measured to be closer to 6 μs.

[0025] FIG. **8**B. Pulse waveforms with negative initial phase tested in the biphasic pulse experiment. Top, left: Schematics of pulses with 20-μs phases and the indicated interphase delays. Top, right: Schematics of pulses with 100-μs phases and the indicated interphase delays. The 8-μs delay (second row) represented a minimum delay that was later measured to be closer to 6 μs.

[0026] FIG. **9**. Examples of pulse waveforms tested in the pulse burst experiment for different pulse repetition frequencies.

[0027] FIG. **10**. Examples of responses measured in the threshold pulse experiment.

[0028] FIG. **11**. Strength-duration relationships for the right front limb from the threshold pulse experiment for pulse positive charge, total charge, peak current, and energy. The ED_{50}'s with corresponding 95% fiducial limits are shown for each pulse waveform and phase duration tested. Results are not shown for the 10-ms polyphasic pulse for reasons explained in the text. For energy of the 10-ms sine pulse, the lower fiducial limit is 0.00017 mJ.

[0029] FIG. **12**. Latencies to peak limb responses for different waveforms and phase durations tested in the threshold pulse experiment. These graphs utilize data from individual responses, the number of which is given at the bottom of each panel.

[0030] FIG. **13**. Sample responses for monophasic square pulses of different durations. Stimulus application was at time 0. Each example has three graphs, each with a different time scale. The bottom graph in each panel includes threshold force and its multiple as well as a zero reference for the background-adjusted forces shown.

[0031] FIG. **14**. Stimulus energy and total charge for the monophasic pulse experiment, including energy and energy normalized to the 100-μs pulse energy; charge and charge normalized to the 100-μs pulse charge. Mean±SEM.

[0032] FIG. **15**. Latencies to peak and latencies to onset for limb responses in the monophasic pulse experiment. These graphs represent one sample for each stimulus condition from each animal. Pulses had durations of 20, 50, 100, or 250 μs, the data for which appear in sequence for each pulse type. Pulse type is labeled with a negative sign as a reminder of the negative polarity of the stimuli. Increasing exponential and decreasing exponential pulses with 20-μs duration were not applied.

[0033] Pounds of pull produced by each limb during stimulation with an X26. The right front limb (top line) is closest to the most anterior electrode.

[0034] FIG. **16***a*. Sample responses from the biphasic pulse experiment shown at three different time scales. Stimulus application was at time zero.

[0035] FIG. **16***b*. Shows latency differences for monophasic (top and bottom panels) versus biphasic pulses (middle panel).

[0036] FIG. **17**. Stimulus energy, energy ratio, total charge, and total charge ratio, (ratios were normalized to the results for a 100 μs monphanisc response), for the biphasic pulse experiment at three delays (labeled "Min", 50, and 500 μs) are compared to monophasic results (labeled "Monophasic" or "M"). Phase duration for both monophasic and biphasic results were 20 or 100 μs. Initial phase polarity was positive (anodic) or negative (cathodic).

[0037] FIG. **18**. Latencies to peak and latencies to onset for each limb responses in the biphasic pulse experiment. Monophasic results are shown for comparison in the left side of each panel. These graphs represent one sample for each stimulus condition from each animal. Stimuli were monophasic or biphasic with the indicated interphase delay. B8 refers to biphasic stimuli with minimum interphase delay. Stimuli had either 20- or 100-μs phase duration and either positive or negative initial

[0038] FIG. **19**. Sample responses from the pulse burst experiment. Application of each pulse is indicated by a tick near the time axis. The vertical lines demark the nominal burst duration. Examples are from one animal and are typical of responses of other animals. One time scale is used in all panels. The top two panels are represent responses to single pulses while the bottom two represent responses to bursts at 10 Hz and 20 Hz.

[0039] FIG. **20**. Onsets of sample responses from the pulse burst experiment. These responses are the right front and left rear limb responses. The top panel shows the responses to a

single pulse with subsequent panels showing the responses to 10 pulses presented at 10 Hz, 20 Hz, and 40 Hz.

[0040] FIG. **21***a*. Stimulus energy for the pulse burst experiment. The vertical lines divide a graph by the type of stimulus applied: single pulse, 10 pulses, and 1-s. Top: Burst energy.

[0041] FIG. **21***b*. Burst energy normalized to energy of the single 100-μs pulse on a logarithmic scale (top) and a linear scale (bottom).

[0042] FIG. **22***a*. Stimulus total charge for the pulse burst experiment. The vertical lines divide a graph by the type of stimulus applied: single pulse, 10 pulses, and 1-s. Top: Burst Charge.

[0043] FIG. **22***b*. Top and Bottom: Burst charge normalized to charge of the single 100-μs pulse on a logarithmic scale and a linear scale, respectively.

[0044] FIG. **23**. Latencies to peak and latencies to onset for responses of each in the pulse burst experiment. The vertical lines divide a graph by the type of stimulus applied: single pulse, 10 pulses, and 1-s.

[0045] FIG. **24**. Force integral of responses in the pulse burst experiment for different burst stimuli. Data are shown only for the 0.150- and 1.150-s integration periods for clarity. The vertical lines divide a graph by the type of stimulus applied: single pulse, 10 pulses, and 1 s.

[0046] FIG. **25**. Normalized force integral for the 0.150- and 1.150-s integration periods for different burst stimuli in the pulse burst experiment. Responses were normalized by dividing by the force integral of the single 100-μs pulse for respective limbs. The vertical lines divide a graph by the type of stimulus applied: single pulse, 10 pulses, and 1 s.

[0047] FIG. **26**. Energy effectiveness, the ratio of force integral to pulse burst energy, for different stimuli in the pulse burst experiment. The vertical lines divide a graph by the type of stimulus applied: single pulse, 10 pulses, and 1 s.

[0048] FIG. **27**. Charge effectiveness, the ratio of force integral to pulse burst total charge, for different stimuli in the pulse burst experiment. The vertical lines divide a graph by the type of stimulus applied: single pulse, 10 pulses, and 1 s.

[0049] FIG. **28**. Force on each limb in pounds of pull during the course of a thress second stimulation with either a TASER X26 (top panel) or the HEMI stimulus parameters (bottom panel).

[0050] FIG. **29**. Normalized results showing pounds of pull produced by right front limb during stimulation with inventive method at different levels of charge per pulse. Response is normalized to that produced by a TASER X26 pulse. The right front limb is closest to the most anterior electrode.

[0051] FIG. **30**. Normalized results showing pounds of pull produced by the right all limbs in response to inventive stimulation divided by the pull produced by the same animal during TASER X26 stimulation as a function of charge per inventive pulse. Each panel represents the results for a single animal. Values above the horizontal line are responses greater than that produced following X26 stimulation. A regression line is plotted in dark blue. The intersection of these two lines was considered an equivalent response.

[0052] FIG. **31**. Block diagram of the HEMI stimulation hardware.

[0053] FIG. **32**. Normalized pO_2 measured after single pulse stimulation every 15 s. Shot number 0 is the average baseline pull from shots occurring before 1:1, 2:1, or 3:1 cycled stimulation. Shot 1 occurred 0.5 s after the conclusion of the test stimulation. Shot 2 occurred 18.3 s later and each proceeding shot occurred every 15 seconds.

[0054] FIG. **33**. Swine 1958's arterial pressure, lung volume under TASER®-X26 stimulation from 0 to 2 minutes. Black trace is arterial pressure (upper curve, scale on left axis). Grey trace is inflow volume (lower curve, scale on right axis). Increase in inflow volume indicates inhalation and decrease inflow volume, exhalation. Shaded grey area indicates TASER®-X26 stimulation is on.

DETAILED DESCRIPTION OF THE INVENTION

[0055] Human Electromuscular Incapacitation (HEMI) is a bioeffect caused by a high voltage charge, passing into the body. The electrical charge is carried as an ionic current through the body producing an intense throbbing sensation, and causes an involuntary contraction of skeletal muscles. When the charge is repeatedly pulsed at a sufficiently rapid rate, repeated muscle contractions occur, voluntary control of skeletal muscles is lost, the body loses posture and incapacitation occurs for the duration of the stimulus.

[0056] Spinal reflexes are graded behaviors that can result from stimulation of either cutaneous sensory fibers or sensory afferents in muscles and tendons. The strength of the stimulus and consequent degree of neural recruitment, as well as its repetition pattern, determine the amplitude of the response. A cumulative effect in the spinal neural circuitry determines the onset of complex reflex responses that produce whole body muscle activity.

[0057] While pain and loss of postural control effects from the use of Electro Stimulation Device are readily observable, the neuromuscular mechanisms linking exposure to the ESD and neuromuscular response have remained undetermined. A conducted charge of 100 μC is about 100 times of that needed to produce pain in human laboratory subjects, and well above the thresholds of motor reactions [6]. According to many sources [7] a shock of half a second duration from an ESD will usually cause intense pain and muscle contractions. Two to three seconds will typically prevent intentional muscle control during the passage of current, cause the subject become dazed, and drop to the ground. Thus, knowledge of bio-mechanism of the muscle incapacitation by electrical stimuli is the key to optimizing the effectiveness and safety of ESDs.

[0058] The uncoordinated muscular activity induced by an ESD is a generalized whole-body neuromuscular effect that prevents voluntary actions, and results in loss of postural control. This uncoordinated muscular activity can be assessed by measuring the amplitude of the electromyographic response or compound muscle action potential (CMAP) in muscles of the extremities of the body.

[0059] To examine whether EMI effect is a manifestation of multiple simultaneous spinal reflexes induced by stimulating multiple afferent nerves with electric pulses applied to a small anatomical region. Dr. Reilly and Dr. Comeaux carried out the spinal reflexes experiments to investigate the biomechanisms responsible for the electrical muscle incapacitation response. 60 kg Yorkshire pigs was selected as the animal model because in this body size range, the pig's heart size to body weight ratio is equivalent to that in humans [Detweiler, 1966]. The coronary artery anatomy also resembles that of humans [Pluth, 1983]. In addition to cardiovascular similarities, the cerebral cortex, spinal cord and peripheral nerves and the muscles, including the myofibrils, and sarcomeres are anatomically very similar to humans. Pig skeletal muscle

cells are also more similar in physical size and electrical space constant to humans than other smaller lab animals.

[0060] Each pig was received in the animal care facility at least 48 hours ahead of each procedure, to permit health assessment of the animal prior to entering the protocol procedure. Each experiment was initiated with administration of a pre-anesthetic (Atro-pine 0.04 mg/kg body weight [BW] IM) 10-15 min prior to induction of general endotracial anesthesia. A surgical plane of gas anesthesia induction with 2.2 mg/kg (BW) of each of tiletamine, zolazopam and xylazine (standard Telazol, mixed with 2.5 ml each of sterile water and 100 mg/kg xylazine, dosed at 1 ml/25 Kg IM). Endotracheal intubation, was followed by 1% iso-flurane to effect in 100% oxygen mechanical ventilation. Dextrose (5%)-Lactated Ringer solution was infused via an IV catheter (¾-1 in 20-22 ga. Intramedic polyethylene tubing) placed in the marginal ear vein.

[0061] Depth of anesthesia was verified by loss of palpebral reflex (touching the eye to ensure the animal does not blink). A twitch monitor was used to monitor the depth of anesthesia, and ensure that electromotor response level remained constant during experiments and was consistent from one animal to the next. Isoflurane administration was titrated between 1% and 1.4% of inhaled gas. A Datex-Ohmeda monitor was used to record heart rate, respiration rate, EKG, body temperature, pulse oximetry, end-tidal CO2, and blood pressure (non-invasive cuff). The corneas were protected with a layer of ophthalmic petrolatum or other suitable ointment. The animal was placed and secured in dorsal recumbence. During each experiment, vital signs were noted continuously in the manner stated above in 15 minutes intervals before the application of electrical signals, and 30 min intervals during the surface myography. The body temperature was maintained at 37° C. using a Bear-Hugger blanket (Arizant, Eden Prairie, Minn.).

[0062] Both mixed nerves containing sensory and motor nerves and pure sensory peripheral nerves were stimulated to compare the responses [Pasquini et al., 2003]. A mixed nerve refers to a peripheral nerve containing both cutaneous sensory and motor nerve axons. Mixed nerve stimulated included the Femoral nerve (FN), the Saphenous nerve (SN), the Ulnar nerve (UN) and Intercostal nerves (INs). Femoral nerve (FN) is located just below the inguinal ligament in the proximal thigh and is adjacent to the Femoral Artery. It is a mixed nerve providing both sensory and motor axons to the hindlimb. For purposes of investigating the effects of ESD stimulation of a motor nerve, the FN distal was stimulated to the point of separation from the saphenous nerve at which point it contains mostly fibers to innervate hindlimb muscles. The Saphenous nerve (SN) is a cutaneous sensory nerve containing pain, pressure and temperature sensitive afferent nerve fibers. It courses through the medial thigh, hindlimb and foot. The Ulnar nerve (UN) is a mixed motor and sensory nerve in the distal forelimb before it reaches the hoof. The UN controls the muscles in the distal forelimb below the knee and muscles in the forefoot. Intercostal nerves (INs) are positioned at the inferodorsal surface of the ribs and provide efferents and afferent innervation for intercostal muscles and sensory innervation of soft tissues in the region of the nerves' path. As the nerve extends toward the center of the chest over the sternum, it becomes pure sensory and provides sensation to the skin over the sternum.

[0063] Electrical pulses were generated by a function generator (DS345, Stanford Research Systems, Sunnyvale, Calif.) driving a bipolar power operational amplifier (Kepco BOP 200-1M, Flushing, N.Y.). Stainless steel bipolar surgical forceps electrodes were used to contact the gel. The electrical pulse thus was confined to the space between the bipolar electrodes. The amplifier case was grounded to the pig using a standard surgical grounding pad. Possible common mode current passing through the ground pad was monitored to ensure that it was too small to trigger reflexes.

[0064] To apply ESD pulses to a specific peripheral nerve, it was surgically isolated. To minimize artifact caused by direct muscular stimulation by the ESD pulse the nerves are electrically isolated from skeletal muscle by inserting a sterile latex sheet between the nerve and surrounding tissue. This procedure eliminated direct muscular activation and secondary reflexes. A 1 cm thick layer of 4 M KCL conducting electrode gel was placed in the latex barrier around the nerve at the point selected for electrical stimulation. The bipolar electrodes were inserted into the surface of the conducting gel and maintained at a 4-5 mm distance from the nerve. This obviated harmful effects of electrochemical byproducts of electrode reactions. The electrodes were equidistant from the nerve, and oriented such that the electric field was applied parallel to the nerve.

[0065] Electrical pulses were used to stimulate a 1 cm partial thickness skin wound over the sternum at the level of 6th rib insertion. The wound oriented in a craniocaudad fashion and the electric field pulses were applied parallel to the wound. The CMAP activity was recorded, again, in all the pig's extremities.

[0066] The effect of electrical stimulus with various amplitudes, pulse durations, waveforms and frequencies and resulting EMI responses were measured to determine the dose-response functionality. Based on different stimuli/EMI response data, an optimum signal waveform was selected and was used to demonstrate that the spinal reflex can be shaped to produce EMI. To verify that the stimulated nerve is responsible for the motor reflexes, the nerve was blocked with 1% lidocaine. The lidocaine was injected adjacent to, but not directly into the nerve, at a point proximal to where the nerve was stimulated. In addition, the lidocaine was also infiltrated around the point of electrical stimulation. Thus, at some point, ~10 cc of 2% lidocaine hydrochloride (4 mg/kg (BW)) was injected intramuscularly beneath the stimulating electrode, to determine if it blocked the generalized responses.

[0067] A four channel 5 Gigahertz LeCroy digital oscilloscope (Chestnut Ridge, N.Y.) with 10× and 100× probes (10 Mega OM input impedance) was used to record ESD stimulus signals. A Faraday coil was used to monitor current output from stimulus or potential ground loops. To reduce CMAP stimulation artifact, the animal was well grounded using an electrocautery grounding pad. The skin was abraded to remove stratum corneum and 4 M KCl conducting gel was applied to increase the conductivity.

[0068] Transcutaneous compound muscle action potentials were measured with a Dantec CounterPoint III clinical electrophysiology system (Dantec, Denmark). Care was taken to standardize the position of the electrodes and the position of the animals. The CMAP recording electrodes were positioned to measure both extension and flexion muscle activity. The Dantec has high-impedance front-end FET amplifiers connected to a 12 bit A/D digitizer. The data analysis including noise filters are software preprogrammed.

[0069] Each experiment was repeated three to five times. The CMAP data was analyzed by measuring the steady state amplitude of the CMAP response to a specific input stimulus.

The steady state CMAP amplitude at 20 Hz stimulation was the graphical average of 10 peaks of the CMAP recording. This graphical average was defined as the CMAP response.

[0070] The recording shown in FIG. **1** is an exemplary CMAP measurement following the subcutaneous injection of lidocaine beneath the skin site of the electrical stimulation as well as the supcostal location adjacent to the intercostal nerves. Rib blockage by lidocaine completely removed muscular activity. The CMAP values measured in the hind limbs and left forelimbs shown decreased below the resting values.

[0071] The CMAP signals in the three extremities monitored during a simultaneous, direct stimulation of SN and FN with electrical pulses widths of 100μ, 200μ, and 400μ are shown, FIG. **2**A-C. All other parameters of the electrical stimuli were kept constant. The saturation of the CMAP response depends on the pulse width. The stimulation amplitude required to set a maximum CMAP response decreases to about 60 V for a pulse width of 200μ and to about 40 V for a pulse width of 400μ. Similar results were obtained for stimulations of saphenous, femoral, ulnar, and intercostal nerves (not shown).

[0072] The fact that peripheral CMAP responses to ESD stimulation in the torso could be abolished by blockage of nerves innervating the region is compelling evidence that peripheral nerve excitation is an essential mechanism of generalized EMI responses. Lidocaine injection will not alter the anatomical electrical field distribution. Therefore, the hindlimb CMAP response to TASER® X26 stimulation on the chest is not due to direct electrical field stimulation of hindlimb muscles. Rather, the hindlimb CMAP excitation was mediated by spinal reflexes.

[0073] One feature of typical stun devices or electrical stimulation devices (ESD) is the expectation of instantaneous and full incapacitation upon termination of the stimulation. In the prior art, the EMI stimulus was designed to elicit a fast target response, typically above the "let-go response", after which no further increases in incapacitation are possible, except lengthening the duration of the incapacitation while the circuit is maintained by repeated trigger pulls. In many cases, instantaneous full incapacitation may not be required or warranted, particularly in cases with vulnerable populations where full incapacitation would put the target at danger of falling, and sustaining an injury. In these cases, short and repeated periods of contact with an EMI stimulus may be preferable. Prolonged electromuscular stimulation may cause persistent contraction of respiratory muscles, resulting in injury or death of the subject due to suffocation.

[0074] The embodiments of the present method of nonlethal electromuscular incapacitation avoid injuries caused by prolong electromuscular stimulation of current ESDs. Longer incapacitation is safely achieved via applications of a two-phase electromuscular stimulation, which comprising:

[0075] (a) an initial threshold stimulation phase to initiate an almost instantaneous incapacitation, and sustain exhaustion; and

[0076] (b) a second intermittent stimulation phase to pace or force the target subject's breathing at a natural rate while maintaining incapacitation, therefore increase the safety of the targeting subject and extend maximum incapacitation time.

[0077] An embodiment of the inventive method comprising the steps of:

[0078] (a) generating a continuous pulsed electric waveform; and

[0079] (b) applying said continuous pulsed electric waveform to a subject at a first frequency and for a first time period sufficient to induce involuntary muscular contraction;

[0080] (c) generating an intermittent pulsed electric waveform; and

[0081] (d) applying said second intermittent pulsed electric waveform to said subject at a second frequency and for a second time period sufficient to safely incapacitate the subject with forced breathing.

[0082] The application of the first continuous pulsed electric waveform aims to elicit almost instantaneous full incapacitation of the targeted subject upon the completion of the electrical circuit for a time period of approximately 30 seconds. This is followed by an application of a second intermittent pulsed electric waveform to the subject aims to safely maintain the incapacitation, which may last up to approximately 150 seconds. During this second phase of electromuscular stimulation, the pulsed electric waveform is applied to the target subject in an ON/OFF pattern, allowing the muscles time to relax between contractions and pace the subject's breathing. In one embodiment, the second pulsed electric waveform is cycled in a pattern of ON for 1-3 seconds, and OFF for 1 second. This intermittent application of pulsed electric waveform forces the subject to breath at a rate resembling the natural breathing cycle. For a safely incapacitated human, a breathing cycle of approximately 12 breaths/minutes allows the subject to sustain an acceptable oxygen level in blood.

[0083] The pulsed waveform may have same or different parameters in the continuous and intermittent phases of electrical stimulation. Pulse frequency (pulse repetition rate) may range from about 40 Hz to about 80 Hz. In one embodiment the pulse frequency is 40 Hz. This higher rate produces greater muscle tetany which limits the mobility of the target. Charge per pulse may be up to 50 micro-Coulombs. Simulations and scientific literature reviews suggests that pulses less that 100 microsecond in duration will require greater charge per pulse to produce a given effect, while pulses greater than 100 microsecond will produce an increasing risk to the target. Pulse shape may vary, possible waveform used for the inventive method include but not limited to: square pulse, Gaussian pulse, increasing exponential, and decreasing exponential pulses. An experimental comparison of pulse shapes (Example 1-4) showed that the defining characteristic of a pulse's effectiveness was its net charge. That is, biphasic components of a pulse tend to cancel each other out. Among waveforms the square wave pulse delivers the highest amount of charge at the least voltage. In an embodiment, square wave monophasic pulse with pulse duration of about 100-microsecond with a total charge of 50 micro-Coulombs per pulse was selected.

[0084] An embodiment of the inventive device, comprising an electrical circuit, which is adapted to generate a continuous pulsed electric waveform for a period of time sufficient to induce almost instantaneous involuntary muscular contraction of the subject, and is adapted to generate an second intermittent pulsed electric waveform during the rest of incapacitation duration, sufficient to safely maintain exhaustion while forcing the subject to breath at a rate that resembles the natural breathing cycle. The embodiment device may further comprise a power source, such as a battery and a plurality of electrical contacts for delivering electric waveforms to a subject and a switch to selectively activate the electrical circuit. The contact may include but not limited to a pad, a button, a

nub, a prong, a needle, and a hook, which may deliver the electric waveform subcutaneously or to the outer surface of the targeted subject. Alternatively, the contact may be a self-contained projectile that is not tethered to an electrical generator, and upon impact can apply the electrical charge and pulsing current to incapacitate the subject without causing unnecessary injuries. The device may further comprise a release mechanism for releasing the plurality of contacts from the device. Example of such release mechanism may include gunpowder or electrical propelled releasing mechanism. The inventive device may further comprise an elongate body having the contacts is located approximately at one end, and the switch is located on the other end.

[0085] The threshold (first) continuous pulsed electric waveform applied by the inventive device can last up to **30** seconds, followed by a period of application of intermittent pulsed waveform. In one embodiment, the device generates intermittent pulsed waveform with pulses (stimulation) cycling in an ON/OFF pattern. The pulse waveform is cycling ON for approximately 1-3 seconds and OFF for approximately 1 second, allowing the muscle time to relax between contractions. Thus forcing the incapacitated subject into a breathing cycle resembles natural breathing. This intermittent pulsed stimulation phase may last up to 150 seconds resulting in safe incapacitation of the subject for a total period up to 3 minutes. Although, lethality studies suggest that total time of incapacitation may be safely maintained beyond 3 minutes. Durations as much as 30 minutes have been survived by anesthetized swine.

[0086] In general, an embodiment of this invention have the following hardware: 1) a power source, typically a battery; 2) pulse forming circuitry; 3) a step-up transformer/capacitor which increases the voltage and decreases the current of the pulse; 4) two conductors with at least one contact point each to deliver the stimulating stimulus to the target. See FIG. **31**.

Example 1-4

Pulse Waveform and Pulse Frequencies Studies

[0087] Four animal experiments were conducted to investigate the effectiveness of different pulse waveforms and pulse repetition frequencies in eliciting limb responses. Two experiments were conducted to examine the effectiveness of monophasic pulses of different waveforms and durations in eliciting limb responses. Threshold response was examined in the first experiment and equal peak response was examined in the second experiment. The threshold experiment examined two waveforms with positive and negative phases.

[0088] The third experiment compared single square pulses with paired square pulses of different polarities in eliciting equal peak responses. Polarity of monophasic pulses and initial pulses in biphasic pairs was either positive or negative. Two pulse durations were tested. In addition, different interphase delays in the biphasic pairs were tested.

[0089] A fourth experiment is conducted to compare the effectiveness of bursts of square monophasic pulses in eliciting equal responses. Both 10-pulse and 1-s trains of pulses were tested at four pulse repetition frequencies.

Common Materials and Methods

Animals

[0090] Yorkshire swine 41-69 kg were used. The animal was initially anesthetized with TELAZOL® (6 mg/kg (BW)) and given atropine (0.1 mg/kg (BW)) and BUPRENEX® (0.01 mg/kg (BW)) by intramuscular (IM) injection. Isoflurane (1-4% in oxygen) was delivered using a ViP3000 Isoflurane anesthesia machine (MDS Matrix, Orchard Park, N.Y., USA) by nose cone if intubation is needed. A satisfactory plane of anesthesia was subsequently maintained with isoflurane through the endotracheal tube. After initial induction of anesthesia, isoflurane was delivered at 1.0-3.5% (2.5±0.6%) (mean±SD) for the threshold pulse experiment, 2.0-3.5% (2.9±0.4%) (mean±SD) for the monophasic pulse experiment, 1.5-4.0% (2.4±0.5%) (mean±SD) for the biphasic pulse experiment, and 0.5-3.0% (1.7±0.8%) (mean±SD) for the pulse burst experiment.

[0091] An animal was placed in one of two positions during the experimental procedures. In the threshold pulse experiment, anesthetized animals were placed in ventral recumbency on a platform that was 21 cm wide and a channeled foam block for side support. Foam block under the head is not shown in FIG. **3**. The platform was made from polyvinyl chloride (PVC) and supported by a metal frame. Tubes were used to deliver isoflurane. Each limb was connected to a force transducer (T) by a nylon rope. The metal frame to which the platform and transducers were attached is shown in faded relief. For increased stability, the animal was placed in a V-shaped channel in a block with the head resting on another block. In the monophasic pulse, biphasic pulse, and pulse burst experiments, animals were placed in dorsal recumbency on a platform with a channeled foam block for side support. The platform was made from polyvinyl chloride (PVC) and Fiberglas® and supported by a Fiberglas® frame. Tubes were used to deliver isoflurane. Each limb was connected to a force transducer (T) by a nylon rope. The Fiberglas® frame to which the platform and transducers were attached is shown in faded relief. A Vet/Ox G2 Digital Monitor (HESKA, Loveland, Colo.) was used to display arterial oxygen saturation (SpO_2), heart rate, respiration rate, and body temperature. The SpO_2 and heart rate were detected by an oximeter sensor (HESKA) placed over a labial artery. Respiratory air movement was detected by a thermistor-based Vet/Sensor (HESKA) attached to the end of the endotracheal tube. Body temperature was detected by a thermistor probe (HESKA) inserted into the rectum. Displayed values of the Vet/Ox monitor were monitored continuously and recorded at 15-min intervals.

Stimulus Generation and Application

[0092] Stimulus waveforms were programmed on an Agilent 33250A arbitrary waveform generator (AWG) (Agilent Technologies, Santa Clara, Calif.). The output of the AWG was connected to a voltage source specific to each experiment to produce the needed stimulus.

[0093] Similar stimulus controls were used in monophasic pulse, biphasic pulse, and pulse burst experiments. Experiment-specific LabVIEW software (v8.5, National Instruments, Austin, Tex.) was used to program waveform or pulse burst settings in the Agilent AWG. LabVIEW also sampled force signals at 1 kHz per channel (200 Hz, one animal in the biphasic experiment) and stored along with stimulus information in text files. LabVIEW displayed force responses versus time and the peak of the right front limb response as a single number to assist in selecting the next stimulus amplitude. In the threshold pulse experiment, LabVIEW (v7.0) was used for many of the same functions, and interacted with another data acquisition system described below.

[0094] Stimulus was delivered through two electrodes consisting of darts supplied with TASER® X26 (TASER® International, Inc., Scottsdale, Ariz., USA) on the ventral surface of the animal at locations shown in FIG. **5**. One dart location was 7.6 cm left of the umbilicus. The other dart location was 12.7 cm rostral and 5.1 cm right of the xiphoid, placing it near the right forelimb. The same electrode locations were used in all experiments. The barbed end of a dart was inserted through the skin such that its tip was subcutaneous, but not penetrating other tissue. Darts were inserted as soon as possible after placing the animal on a platform and were checked before application of stimuli. Stimulus polarity was defined as the voltage applied at the rostral electrode referenced to the caudal electrode. For clarity, supporting structures are not shown or shown in faded relief in FIG. **5**. Connections to the limbs for one experiment are shown as an example in FIG. **5**. The two X's mark electrode sites used in all experiments to deliver stimulating pulses.

Recorded Variables

[0095] Digital oscilloscopes were used to measure stimulus voltage and current, which were recorded. The oscilloscopes and their connections were specific to each experiment, but in all cases programs were written in C++ (GCC v 4.1.2, Free Software Foundation, Boston, Mass.) were used to convert oscilloscope data files to text files and to perform automated pulse measurements. Programmed phase durations were confirmed by measuring the time between the times of 50% peak phase voltage for square waveforms and 10% peak phase voltage for other waveforms. In all but the threshold pulse experiment, current resulting from the applied voltage pulse was measured with a Pearson Model 110 Current Monitor (Pearson Electronics, Palo Alto, Calif., USA), through which an electrode wire passed.

[0096] Forces at the limbs were detected by SSM AJ 150 force sensors (Interface Manufacturing, Scottsdale, Ariz.). A nylon rope was used to connect each sensor to a strap securely fastened to the distal portion of a limb. In the threshold pulse experiment, connections to force sensors were adjusted to pull forelimbs backward and hindlimbs forward to achieve a steady background force of 0.7-2 N. Positive force was then detected for forelimbs in a rostral direction and for hindlimbs in a caudal direction. In the monophasic pulse, biphasic pulse, and pulse burst experiments, connections to the force sensors were adjusted to have a steady background force of 4-8 N on each limb. Positive force was detected for forelimbs in a caudal direction and for hindlimbs in a rostral direction.

[0097] Force sensors were calibrated in pounds before each experiment and measured forces were converted to newtons during data analysis. Regardless of the instruments used to record force response data, text files with force data were analyzed with programs written in R (v2.5.0, R Development Core Team, 2007).

Data Analysis

[0098] Additional stimulus parameters were computed from the stimulus voltage and current recorded by digital oscilloscopes using programs written in C++. Charge was calculated as the time integral of the current. Positive charge and negative charge were determined separately for each stimulus. The algebraic sum of positive and negative charge was designated as net charge; the sum of their absolute values, as total charge. Pulse energy was calculated as the time integral of the product of voltage and current. Excel® spreadsheets (Microsoft Corporation, Bellevue, Wash.) were used to compile data summaries and to generate files for further analysis. In pilot analyses, net charge was found not to be a reliable stimulus measure and was not included in final analyses. Quantitative measures of stimulus parameters were plotted as mean±standard deviation (SD).

[0099] Processing of recorded forces was done with programs written in R. Forces were first converted from pounds to newtons and the start of the stimulus application was set as time 0. Data were further organized and analyzed using R programs and various versions of Excel spreadsheets.

[0100] Statistical testing was done using SAS (v9.1 SP2, SAS Institute, Cary, N.C.). Normality of data was examined using Shapiro-Wilk and Kolmogorov-Smirnov tests. Testing for a significance difference in an effective stimulus variable or a response variable between experimental conditions was done using a linear mixed model with the conditions as fixed effects and animal as a random effect. When appropriate, this testing was followed by pair-wise testing with Tukey-Kramer correction for multiple comparisons. P-values are provided in many cases. A p-value of less than 0.05 was considered to indicate a significant difference.

[0101] Stimulus and response data in the monophasic pulse, biphasic pulse, and pulse burst experiments were analyzed for a number of experimental conditions. In the course of determining equivalent responses, these data were collected multiple times for the same condition in a given animal subject. For analysis, these data were reduced to one sample per subject by using the average value for 3 equivalent responses for a given condition. This reduced data set was then graphed and used for analysis. Graphs of the full data sets appear quite similar to graphs of the respective reduced data sets. Data were included only from stimuli that were similar for a given condition and for responses that were also within two standard deviations of the mean for that condition over all animals. The advantages of using a reduced data set included equal weighting of animals in the analysis. The reduced data were also found to be more likely to be normally distributed, and thus more appropriate for testing with the linear model. The mixed model used on a reduced data set was also used on the corresponding full data set with similar results in all cases.

Example 1

Threshold Experiment

[0102] Seven Yorkshire swine weighing 41-63 kg (47.1±8.4 kg, mean±SD) were used in the threshold experiment. They were positioned in ventral recumbency. The Agilent AWG output was connected to a Model 7500 amplifier (Krohn-Hite, Avon, Mass., USA) using DC input coupling and gain of 100. The amplifier output delivered stimuli to the animal with the positive terminal connected directly to the rostral electrode and the negative terminal connected to the caudal electrode through a 1-ohm resistor.

[0103] The Krohn-Hite amplifier output voltage was measured using a Model TDS7404 Digital Phosphor Oscilloscope (Tektronix, Beaverton, Oreg.) with Tektronix Model TCA-1MEG High Impedance Buffer Amplifiers. A second 1-MΩ channel indicated current by being connected to the animal side of the 1-ohm resistor.

[0104] The five waveforms were tested including: monophasic Gaussian, a monophasic square pulse, a biphasic single-cycle sine, a biphasic square pulse, and a polyphasic

pulse (FIG. **6**). The polyphasic pulse waveform was modeled after a TASER® X26 pulse. The selection of waveforms was based on results of earlier experiments on frog muscles (Comeaux & Jauchem, 2008). Each pulse waveform was delivered with an initial, or only, positive phase at the three nominal durations of 30 μs, 100 μs, and 10 ms. Each waveform was tested at three durations with six amplitudes that were expected to be above and below the threshold for muscle stimulation. Thus, 90 different stimuli were used: 5 waveforms times 3 durations times 6 amplitudes.

[0105] A BIOPAC MP150 system (MP150 hardware and AcqKnowledge v3.7.3 software, BIOPAC Systems, Santa Barbara, Calif., USA) was used to record signals. Each of the four force sensors was connected to a BIOPAC DA100C differential amplifier with gain 1000 and low-pass cutoff frequency 300 Hz and was sampled at either 312.5 or 1250 Hz in different animals. One channel recorded a signal derived from a second respiration sensor on the endotracheal tube with sampling at 312.5 Hz. One channel with sampling of 5000 Hz recorded a signal that indicated the trigger signal for the applied stimulus. Respiration and trigger signals were connected directly to the MP150.

[0106] The BIOPAC system initiated stimulus application and data acquisition every 30 s. LabVIEW software (v7.0, National Instruments, Austin, Tex., USA) randomly selected and record, without redundancy, one of the 90 stimuli for the Agilent AWG to produce. The series of 90 applications was repeated 4 times, with separately randomized waveforms in each series, resulting in a total of 360 stimulus applications per animal. LabVIEW retrieved voltage and current waveforms for each stimulus application from the oscilloscope and stored them in files.

[0107] Monitored physiological variables remained within acceptable ranges throughout experimental procedures. The 15-min readings of the 7 animals showed heart rate 77-154 bpm (109.1±15.7 bpm, mean±SD), respiration rate 15-46 breaths/min (29.0±7.4 breaths/min, mean±SD), oxygen saturation 86-99% (96.8±1.8%, mean±SD), and rectal temperature 36.6-38.6° C. (37.3±0.5° C., mean±SD).

[0108] FIG. **10**, shows examples of responses measured in the threshold pulse experiment. These examples illustrate the different response magnitudes and typical time courses. In each panel, forces of the four limbs are shown as they were recorded and the respective steady background forces were later subtracted. The tick mark at time zero marks the time of stimulus application. For animal 1918, stimulus 180 was a biphasic sine pulse with phase duration of 10 ms and a maximum of 88.9 V. For animal 1910, stimulus 192 was a biphasic sine pulse with phase duration of 10 ms and a maximum of 60.0 V.

[0109] FIG. **11** presents the strength-duration relationships derived from four stimulus parameter ED_{50}'s (ED_{50} is an estimate of the stimulus parameter amplitude with a 50% probability of producing a response). All waveform-duration combinations are represented except the 10 ms polyphasic pulse for which unreliable results were obtained. For 30-μs pulses, all estimated ED50's are near 1 μC and have overlapping fiducial limit ranges. For 100-μs pulses, ED50's are 1-1.4 μC except for the Gaussian, which was 0.59 μC. All pulses but the Gaussian has overlapping fiducial limit ranges. For 10-ms pulses, respective overlapping fiducial limit ranges are seen for Gaussian and monophasic square pulses, monophasic square and sine waveforms, and sine and biphasic square waveforms. The smallest to largest ED50 order for the 10-ms pulses is Gaussian, monophasic square, sine, and biphasic square, with values ranging from 8.3 to 43.5 μC. Positive charge increases as pulse duration increases. Positive charge of the 100-μps phase duration is 0.7-1.5 times of the 30-μs pulse duration, and the positive charge of 10-ms pulse duration are 9-36 times larger for the 10-ms pulse duration.

[0110] For ideal monophasic waveforms, one would expect total charge ED50's to be the same as the positive charge ED50's. In FIG. **11**, this is observed for Gaussian and monophasic pulses for the 30-μs phase duration (i.e., about 1 μC). However, at 100-μs and 10-ms phase durations, the total charge ED50 is roughly 2-5 times larger than expected for these same pulses, most likely due to the non-ideal pulses used as stimuli. For ideal biphasic waveforms, one would expect total charge ED50's to be twice the positive charge ED50's based on a negative phase similar to the positive phase. In FIG. **11**, this is seen to be the case for biphasic sine and square pulses at all three phase durations. The total charge polyphasic waveform ED50 is seen to be similar to the respective positive charge ED50: approximately 1 μC for the 30-μs phase duration and 1.3-1.7 μC for the 100-μs phase duration.

[0111] The peak current strength-duration graph based on ED50 in FIG. **11** was determined primarily for comparison with traditional strength-duration curves for pulsed stimulation of nerve and muscle. A similar trend of decreased ED50 is seen for waveform tested. The ED50's for the 30-μs phase duration are 56.7, 82.2, 48.3, 85.3, and 144.9 mA for the Gaussian, monophasic square, sine, biphasic square, and polyphasic waveforms, respectively.

[0112] The pulse energy ED50 in FIG. **11** was determined in order to make comparisons between waveforms as well as between phase durations. For the 30-μs pulse duration, the monophasic Gaussian and square pulses and the polyphasic waveform have overlapping fiducial limit ranges. The biphasic sine and square waveforms have overlapping fiducial limit ranges at 30 μs, with ED50's of 0.0833 and 0.1109 mJ (83.3 and 110.9 μJ), respectively, and their ED50's are larger than ED50's for the other three waveforms. For the 100-μs pulse duration, all five waveforms have overlapping fiducial limit ranges, an indication that their energy ED50's were not statistically different at this pulse duration. Note that for each waveform the ED50's for 30- and 100-μs phase durations have overlapping fiducial limit ranges, an indication that the ED50's were not different between the durations. For the 10-ms phase duration, fiducial limit ranges were considerably larger than for the shorter phase durations. The monophasic Gaussian and square pulses and the biphasic square waveform have overlapping fiducial limit ranges at the long duration and their ED50's range between 0.191 and 0.569 mJ (191 and 569 μJ).

[0113] Latencies to peak of response for the threshold experiment are shown in FIG. **12** for each limb. Although these latencies are necessarily for suprathreshold responses in the experiment, they were quite variable resulting in large standard deviations. This variability is primarily due to the small responses and resulting uncertainty in identifying the response peak. For each limb, the latency is not obviously different across the five waveforms or the three phase durations.

Example **2**

Monophasic Pulse Experiment

[0114] Four Yorkshire swine weighing 50-57 kg (53.0±3.6 kg, mean±SD) were used in the monophasic pulse experi-

ment. They were positioned in dorsal recumbency. The Agilent AWG was used to drive a custom-made high voltage HEMI Stimulator fabricated by the James Franck Institute (University of Chicago, Chicago, Ill.) that was connected to the electrodes. The stimulator "output" terminal was connected to the rostral electrode with the wire passing through a Pearson current monitor. The stimulator "return" terminal was connected to the caudal electrode. The caudal electrode was grounded internally at the stimulator. Settings on the stimulator required manual adjustment each time the pulse waveform was changed. All pulses had a negative polarity (i.e., only a negative phase). The stimulator output was measured by a 1-MΩ channel of a TDS5104 Digital Phosphor Oscilloscope (Tektronix, Beaverton, Oreg., USA) using a Tektronix P5100 high voltage probe connected at the rostral electrode. A second 1-MΩ channel was connected to the Pearson current monitor.

[0115] Four pulse waveforms were tested: square, Gaussian, increasing exponential, and decreasing exponential (FIG. **13**). Durations of 20, 50, 100, and 250 μs were used for square and Gaussian pulses. Exponential pulses could be generated only for the 3 longest durations. Thus, 14 pulse waveforms were tested: 2 waveforms times 4 durations plus 2 waveforms times 3 durations. Under investigator control, the LabVIEW software written for this experiment selected programmed waveform settings in the Agilent AWG.

[0116] A suprathreshold square pulse, 100 μs and 405±65 V (mean±SEM), was applied to obtain a reference response. The average of peaks in 3 successive responses of the right front limb to this reference stimulus was considered a baseline peak to be matched in 2-3 subsequent series of stimuli. The baseline was determined before testing other waveforms and throughout testing to account for possible changes in responsiveness. The minimum time between successive stimulus applications was 90 s.

[0117] A pulse waveform was tested for equivalence to the baseline by delivering it in a series of applications with different amplitudes. The peak of the right front limb response was scored as being either greater than or less than the baseline. A change in score between two successive applications was termed a crossing. Applications were repeated with amplitude adjusted to anticipate a crossing until 3-4 crossings were obtained. The stimulus parameter needed for a response equivalent to the preceding baseline was computed as the average of the parameter used in the last 3 crossings.

[0118] The criterion for a recorded force signal to be a response was a peak-to-peak force in a post-stimulus window of 100 ms greater than 2 times the peak-to-peak force in the 3 s preceding the stimulus. Programs written in R were used to determine which recorded waveforms met this criterion.

[0119] An estimate of the stimulus parameter amplitude with a 50% probability of producing a response (ED_{50}, ED=effective dose) was estimated by fitting response data with probit regression in SAS. Threshold of response is presented here for the right front limb, which shows the most reliable results (Seaman & Comeaux, 2007). ED_{50} was determined for stimulus positive charge, total charge, peak current, and pulse energy.

[0120] Monitored physiological variables remained within acceptable ranges throughout experimental procedures. Over the 7 animals in the threshold pulse experiment the 15-min readings showed heart rate 77-154 bpm (109.1±15.7 bpm, mean±SD), respiration rate 15-46 breaths/min (29.0±7.4 breaths/min, mean±SD), oxygen saturation 86-99% (96.8±1.8%, mean±SD), and rectal temperature 36.6-38.6° C. (37.3±0.5° C., mean±SD).

[0121] Sample responses to stimuli are shown in FIG. **11** to illustrate the range of amplitudes and temporal sequences observed in limb responses. In most cases, the right front limb provided the largest and seemingly earliest response and the left rear limb provided the next largest and next-to-earliest response. These limbs are located closest to the stimulating electrodes.

[0122] In FIG. **14**, energy decreases with longer pulse duration for each pulse type. The square pulse has the lowest energy for 20-, 50-, and 100-μs durations and one of the lowest for the 250-μs duration. The Gaussian pulse has the same energy as the exponential pulses for 50- and 100-μs durations, but is somewhat smaller for the 250-μs duration. The linear mixed model used for testing had fixed effects of pulse type, pulse duration, and their interaction. Results of the mixed-model test indicated that pulse type and duration as well as their interaction were statistically significant (p's<0.001). No significant pair-wise difference was found for any pulse type between the 100- and 250-μs durations. At 250 μs, no pair-wise difference was found between energies of square and Gaussian pulses or between energies of increasing and decreasing exponential pulses. However, energies of square and Gaussian pulses were both smaller than both increasing and decreasing exponential pulses. These results also held for mixed-model testing of energy normalized to the energy of the 100-μs square pulse, with the exception that energies of the decreasing exponential pulse were all different from each other (i.e., a decrease with increasing duration).

[0123] In FIG. **14**, pulse total charge increases with longer duration for each pulse type. Pulse types appear to have similar charge for each pulse duration, except that the charge of the square pulse is noticeably larger at 100- and 250-μs durations. Results of the mixed-model test indicated that pulse type, and duration as well as their interaction were significant (p's<0.001). Pulse type was not significant for 20- and 50-μs durations (i.e., total charge at each duration was not different among pulse types). At 100 μs and 250 μs, square pulse charge was larger than charge of the other three types of pulses.

[0124] Latencies to onset and peak of the baseline response for the monophasic pulse experiment are shown in FIG. **15** for each limb. A latency sample was calculated as the average of latencies of the last three responses for each combination of pulse type and duration, which had peak right front limb responses near the baseline. Latency appears remarkably similar for each limb. Results of the mixed-model tests indicated pulse type and duration and their interaction were non-significant for latency for the right front, right rear, and left rear limbs.

Example 3

Biphasic Pulse Experiment

[0125] Five Yorkshire swine weighing 55-69 kg (59.8±5.5 kg, mean±SD) were used in the biphasic pulse experiment. They were positioned in dorsal recumbency. The Agilent AWG was used to drive a Model AWG188 high voltage source (North Star Power Engineering, Tucson, Ariz.). The output terminals of the transformer in the source were connected to the rostral and caudal electrodes such that a positive input from the Agilent AWG resulted in a positive voltage at

the rostral electrode. The wire connected to the caudal electrode passed through a Pearson current monitor. The AWG188 output was measured by two 1-MΩ channels of a TDS5104 Digital Phosphor Oscilloscope (Tektronix, Beaverton, Oreg., USA) using two Tektronix P5100 high voltage probes, each connected to an output terminal. The differential voltage between these probes was considered the stimulus voltage. A third 1-MΩ channel was connected to the current monitor. There was no connection referencing the subject to ground.

[0126] Biphasic and monophasic waveforms with positive and negative polarities were tested (FIGS. **6**A and **6**B). Square pulses with durations of 20 and 100 μs were used as phases. Biphasic pulses had a leading phase consisting of a positive or negative pulse and a second phase consisting of a pulse with the same respective duration but opposite polarity. Interpulse, or interphase, delays of 0, 50, and 500 μs (off to onset) were used in biphasic pulses. The 0 μs phase delay actually measured about 6 μs at 50% peak amplitudes. Thus, 16 pulse waveforms were tested: 2 phase durations times 2 initial phase polarities times 4 patterns (monophasic, minimum delay, 50-μs delay, and 500-μs delay). Under investigator control, the LabVIEW software written for this experiment selected programmed stimulus waveform settings in the Agilent AWG.

[0127] A suprathreshold positive square pulse, 100 μs and 309±9V, (mean±SE) was applied to obtain a reference response. The average of 3 successive peaks of the right front limb response to this reference stimulus was considered a baseline peak to be used for 2-3 subsequent series of stimuli. The baseline was determined before testing other waveforms and throughout testing to account for possible changes in responsiveness. The minimum time between successive stimulus applications was 60 s.

[0128] An up-down method (Dixon, 1980) was used to determine the stimulus voltage corresponding to the comparable right front limb baseline response. The voltage was changed in a series of applications of a particular pulse waveform by 30 V for 100-μs pulses and 100 V for 20-μs pulses. The P50 value of the method was determined based on 5 stimulus applications, giving a standard error of about 0.61 times the step size.

[0129] Sample responses from the biphasic pulse experiment are shown in FIG. **16**. Because of the experimental design, peak right front force is nearly the same in all responses shown. These samples illustrate, in addition, that each response (4 limbs) has similar shape and time course (top panels) regardless of the stimulus waveform. However, consistent differences in latency appear between the monophasic stimuli and the biphasic stimuli. Longer onset latency and longer peak latency is observed for biphasic stimuli.

[0130] FIG. **16** shows sample response from the biophasic pulse experiments based on stimulus type (monophasic and biphasic with 3 interphase delays), phase duration, and initial phase polarity. FIG. **16**A containing three graphs with different time scales, are responses to a monophasic pulse. FIG. **16**B illustrates onset latencies to other monophasic pulses (left) and biphasic pulses (right). FIG. **16**A shows threshold force and its multiple as well as a zero reference for the background-adjusted forces.

[0131] In FIG. **17**, energy for the 100-μs phase duration (dark gray symbols) is smaller than for the 20-μs phase duration (black symbols). For each pulse duration, except for the monophasic 100-μs pulse, little difference is seen between positive and negative phase polarities. For all pulse duration, the monophasic pulse energy is smaller than energies of all biphasic pulses with the same phase duration.

[0132] The linear mixed model used for testing energy had fixed effects of initial pulse polarity, pulse duration, interphase delay, and their interactions. Results of the mixed-model test indicated that polarity ($p=0.033$), duration ($p<0.001$), and delay ($p<0.001$) were all significant. The polarity-delay interaction ($p=0.028$) and duration-delay interaction ($p<0.001$) were also significant. As already noted, the effects of duration and delay are evident in FIG. **17**. Energy between positive and negative polarities was significantly different only for 100-μs monophasic pulses ($p<0.001$), with the negative pulse having lower energy.

[0133] Pair-wise comparisons for energy and energy ratio across pulse types generally reflected the differences seen in FIG. **17**. The types are designated here by polarity and duration of monophasic and initial phase pulses. For positive 100-μs, energy for the minimum-delay biphasic pulse was larger than energy for the three other pulse types ($p\leqq0.017$), which did not differ among them. For negative 100-μs, energy for the monophasic pulse was smaller than energy for the biphasic pulses ($p\leqq0.025$). For positive and negative 20-μs, as for positive 100-μs, energy for the minimum-delay biphasic pulse was larger than energy for the three other pulse types ($p\leqq0.005$ and $p=0.0052$, respectively), among which energy did not differ. For positive 100-μs, energy ratio had the same differences ($p\leqq0.03$) as energy for 100-μs. For negative 100-μs, energy ratio for the monophasic pulse was smaller than energy ratio for biphasic pulses with interphase delays of 50 and 500 μs ($p\leqq0.002$) but did not differ from the energy ratio for the minimum-delay biphasic pulse. For positive and negative 20-μs, as for positive 10-μs, energy ratio for the minimum-delay biphasic pulse was larger than energy ratio for the three other pulse types ($p\leqq0.002$ and $p=0.0013$, respectively).

[0134] In FIG. **17**, total charge seems to increase from monophasic to biphasic 500-μs delay for both phase durations, and the charge for 20-μs pulses (dark symbols) is the same as or smaller than charge for 100-μs pulses (grey symbols) of the same stimulus type. Polarity seems to influence the charge for 100-μs monophasic pulse.

[0135] Results of the mixed-model test indicated polarity ($p=0.020$), duration ($p<0.001$), and delay ($p<0.001$) were all significant. The polarity-delay interaction ($p=0.003$) and duration-delay interaction ($p<0.001$) were also significant.

[0136] Pair-wise comparisons for total charge and charge ratio across pulse types generally reflected the differences seen in FIG. **17**. The types are designated here by polarity and duration of monophasic and initial phase pulses. For positive 100-μs, charge for the biphasic pulse with 500-μs interphase delay was larger than charge for any other pulse type ($p\leqq0.048$), charge for the minimum-delay biphasic pulse was larger than charge for the monophasic pulse ($p=0.009$). For negative 100-μs, charge for the biphasic pulse with 500-μs interphase delay was larger than charge for any other pulse type (p's<0.001), charge for the biphasic pulse with 50-μs interphase delay was larger than charge for the monophasic pulse ($p=0.014$). For positive 20-μs, charge for the minimum-delay biphasic pulse was larger than charge for the monophasic pulse ($p=0.011$), but this was the only significant difference. For negative 20-μs, charge for the monophasic pulse was smaller than for the minimum-delay biphasic pulse. For

positive 100-μs, except between the minimum-delay biphasic pulse and the biphasic pulse with 500-μs interphase delay, all pair-wise differences of charge ratio were significant ($p \leqq 0.030$), reflecting an increase from monophasic pulse to biphasic pulse with the longest interphase delay.

[0137] Latencies to onset and peak of the baseline response for the biphasic pulse experiment are shown in FIG. **18** for each limb. A latency sample was calculated as the average of latencies of the last three responses for a given combination of initial phase polarity, phase duration, and interphase delay, which had peak right front limb responses near the baseline. Graphs of the latencies to a larger number of selected responses in this experiment are in FIG. **18**. A contributor to the variability in the peak latency of right front and left front limbs was the tendency for responses of these limbs to exhibit two peaks separated by 10's of milliseconds rather than a single peak. The larger of the two peaks would sometimes be the first peak and sometimes the second peak. In FIG. **18**, both onset latency and peak latency of responses to monophasic stimuli are seen to be smaller than respective latencies of responses to biphasic stimuli for each limb. This is consistent with observations made on the sample responses in FIG. **16**. These differences due to stimulus type seem to be considerably larger than any difference due to initial phase polarity or phase duration.

[0138] In pair-wise testing of onset latency differences for each limb, the monophasic pulse had a latency smaller than the latency of any biphasic pulse (p's<0.001). In addition, latencies of biphasic pulses did not differ among different interphase delays (p's>0.071).

[0139] Results of the linear mixed model tests on peak latency revealed that interphase delay (stimulus type) was a significant effect for all four limbs (p's<0.001). In pair-wise testing of peak latency differences for each limb, the monophasic pulse had a latency smaller than the latency of any biphasic pulse (p's<0.001).

Example 4

Pulse Burst Experiment

[0140] Four Yorkshire swine weighing 51-63 kg (55.3±5.7 kg, mean±SD) were used in the pulse burst experiment. They were positioned in dorsal recumbency. The Agilent AWG was used to activate a DEI Model PVM-4150 high voltage switch (Directed Energy, Inc, Fort Collins, Colo., USA) powered by a Lambda Gen600 600 V power supply (Lambda Americas, Neptune, N.J., USA). The center conductor of the coaxial output of the switch was connected to the rostral electrode with the wire passing through a Pearson current monitor. The shield of the coaxial output, which was grounded within the DEI unit, was connected to the caudal electrode. All applied pulses had a positive polarity (i.e., only a positive phase). The DEI output was measured by a 1-MΩ channel of a TDS5104 Digital Phosphor Oscilloscope (Tektronix, Beaverton, Oreg., USA) using a Tektronix P5100 high voltage probe connected at the rostral electrode. A second 1-MΩ channel was connected to the current monitor.

[0141] Only one pulse waveform (100 μs square) was used (FIG. **7**). The waveform was applied individually at 100 μs and 285±0.3V (mean±SE) to obtain a reference baseline response. It was also applied at pulse repetition frequencies (PRFs) of 10, 20, 40, and 80 Hz in two types of bursts. In one type of burst, 10 pulses were applied, resulting in 4 different burst durations: 10/10=1 s, 10/20=0.5 s, 10/40=0.25 s, and 10/80=0.125 s, for PRFs of 10, 20, 40, and 80 Hz, respectively. In the other type of burst, the duration was set at 1 s and the number of pulses varied with the PRF. Thus, 9 types of pulsed stimuli were tested: single pulse, 4 bursts of 10 pulses at different PRFs, and 4 1-s bursts at different PRFs. The minimum time between successive stimulus applications was 90 s. Under investigator control, the LabVIEW software written for this experiment selected programmed stimulus burst settings in the Agilent AWG to apply to the DEI switch.

[0142] As in the monophasic experiment, a baseline response for comparison was determined as the average of peaks in 3 successive reference responses of the right front limb. The baseline was determined before testing other waveforms and throughout testing to account for possible changes in responsiveness. A burst was tested for equivalence to the preceding baseline as done in the monophasic experiment. This involved adjusting stimulus amplitude to obtain **3-4** crossings of response peak with the baseline. The stimulus parameter needed for a response equivalent to baseline was computed as the average of the parameter used in the last 3 crossings. Monitored physiological variables remained within acceptable ranges throughout experimental procedures. Over the 4 animals in the pulse burst experiment the 15-min readings showed heart rate 93-174 bpm (113.4±16.2 bpm, mean±SD), respiration rate 12-78 breaths/min (35.4±14.3 breaths/min, mean±SD), oxygen saturation 87-98% (95.0±3.5%, mean±SD), and rectal temperature 37.2-38.1° C. (37.6±0.2° C., mean±SD).

[0143] Sample responses from the pulse burst experiment are shown in FIG. **19**. In this experiment, pulses were all 100-μs positive monophasic pulses and bursts contained multiple pulses.

[0144] FIG. **20** shows the onsets of responses on an expanded time scale. These are the right front and left rear limb responses. The onsets of responses to the single pulse (top) and the 10-Hz burst (middle left) are nearly identical for about 120 ms after the pulse delivered at time 0. The response to the second pulse in the 10-Hz burst seems to initiate at around 130 ms, which is before the response to the first pulse has ended. The response to the second pulse in the 20-Hz burst is also evident, while the response to the next pulse might only be reflected in the change of response slope around 110 ms. Responses to the 40- and 80-Hz bursts (bottom) are similar in shape and time course with little or no indication of responses to individual pulses.

[0145] FIGS. **21** and **22** show, respectively, energy and total charge eliciting the baseline peak response for the single pulse and pulse bursts in FIG. **21**/**22**A. The ratio of the measure in each burst type to the measure in the single pulse is shown in the FIG. **21**/**22**B using logarithmic and linear scales. These graphs and the analysis of stimulus data are based on 4-5 values for the single pulse and a single value for each burst type from each animal. A response to 10 Hz for 1 s was not obtained from one animal.

[0146] In FIG. **21**, the energy for 10 pulses at 10 Hz was 12-13 times the energy of the single pulse. If responses to individual pulses with the same energy were completely separated, we could expect 10 times the single-pulse energy for a burst of 10 pulses. This is because if one pulse of the burst has the single-pulse energy sufficient to elicit the peak response, the other nine pulses would not affect the peak or have the same peak, resulting in 10 times the stimulus energy for the same peak response. The multiplying of energy by the number of pulses does not apply to responses that are not sepa-

rated in time. This is the case for pulses at higher repetition frequencies, for which responses to individual pulses are additive to a degree depending on repetition frequency. At 20 Hz in this experiment, the responses to sequential pulses are evident and partially additive. At 40 and 80 Hz, the initial increases in response follow a similar time course and do not exhibit responses to individual pulses. This might indicate a saturation effect in summation of individual responses for repetition frequency between 20 and 80 Hz. The energy for 10 pulses at 20 Hz was about twice that of the single pulse. Energies for 10 pulses at 40 Hz and at 80 Hz were both smaller than the energy of the single pulse, about one-half and one-third, respectively. A trend for smaller energy at higher repetition frequencies was also found for the 1-s bursts.

[0147] Results from a linear mixed model with stimulus type (9 levels) as the fixed effect revealed that a significant difference was present ($p<0.001$). In pair-wise testing, only the two 10-pulse-10-Hz energies were significantly different from the single-pulse energy ($p<0.001$ and $p=0.016$). For the 10-pulse bursts, the 10-Hz burst energy was larger than for the higher frequencies, but energies for the 20-, 40-, and 80-Hz bursts were not different from one another. For the 1-s bursts, energies were not different from one another.

[0148] The pattern of differences was only slightly different for energy ratio. In pair-wise testing, the 1-s 20-Hz burst energy ratio was significantly different than the single-pulse ratio ($p=0.032$) in addition to the two 10-pulse-10-Hz ratios ($p's<0.001$). For 10-pulse bursts, the 10-Hz burst ratio was greater than for other repetition frequencies, but ratios of the 20-, 40- and 80-Hz bursts were not different from one another. For 1-s bursts, the energy ratio for the 10-Hz repetition frequency was greater than ratios for the 40- and 80-Hz frequencies ($p=0.003$ and $p=0.002$, respectively), but these were the only differences. The larger number of differences in energy ratio compared to the number found for energy might have been revealed by the normalizing nature of the ratio.

[0149] In FIG. **22**, the patterns of stimulus total charge and charge ratio have many of the same characteristics of stimulus energy and its ratio in FIG. **21**. However, in contrast to the pattern in energy, no burst charge is smaller than charge of the single pulse. For 1-s bursts, charge seems to be similar for all repetition frequencies and showed no obvious decline with increasing repetition frequency as did energy, and all charges were larger than the charge of the single pulse.

[0150] Results from a linear mixed model with stimulus type (9 levels) as the fixed effect revealed that a significant difference was present ($p<0.001$). In pair-wise testing, charge of all bursts was different than the charge of the single pulse ($p's<0.001$) except for charges of the 10-pulse bursts at 40 and 80 Hz. For the 10-pulse bursts, the 10-Hz burst charge was larger than for higher frequencies, but charges for the 20-, 40-, and 80-Hz bursts were not different from one another. For the 1-s bursts, charges were not different from one another.

[0151] For charge ratio, in pair-wise testing, the charge ratio of all bursts was different than the ratio of the single pulse ($p's<0.001$) except for ratios of the 10-pulse bursts at 40 and 80 Hz. For the 10-pulse bursts, the 10-Hz burst ratio was larger than for the higher frequencies ($p's<0.001$) and the 20-Hz burst ratio was larger than for the 40- and 80-Hz ratios ($p=0.009$ and $p<0.001$, respectively). For the 1-s bursts, the two significant differences were that the 40-Hz ratio was smaller than the 20- and 80-Hz ratios ($p=0.034$ and $p=0.025$, respectively). No charge ratio for bursts was smaller than 1, the charge ratio of the reference single pulse.

[0152] Latencies to onset and peak of the baseline response for the pulse burst experiment are shown in FIG. **23**. A latency sample was calculated as the average of latencies of the last three responses for a given stimulus type: single pulse, 10-pulse bursts, and 1-s bursts, which had peak right front limb responses near the baseline force.

[0153] In FIG. **21**, onset latency seems to follow a common pattern for the different limbs. For the 10-pulse bursts and for the 1-s bursts, the onset latency appears to increase for higher repetition frequency. Trends in peak latency are more difficult to identify because of the variability in the measured values. However, peak latencies for burst stimuli seem generally longer than the single-pulse latency, at least for the right front, left front, and left rear limbs.

[0154] For each limb, peak latency results from a linear mixed model with stimulus type (9 levels) as the fixed effect revealed that a significant difference was present ($p's\leqq 0.004$). The peak force response of the right front limb was quite useful in evaluating relative effectiveness of different pulse waveforms and durations for single pulses. Responses in the threshold pulse, monophasic pulse, and biphasic pulse experiments were dominated by single peaks. However, for repetitive stimuli, response peak might not be the best metric for comparison. Because a longer response with a given effective force can be assumed to indicate a more effective incapacitation, peak force would not reflect the importance of stimulus duration.

[0155] An integrated response was used in order to compare limb force responses with different temporal profiles. The idea is that a prolonged response at some force level is a larger response than a shorter response of the same magnitude. Because responses were initially and primarily positive forces, only positive force is integrated. Computationally, this integration was accomplished by summing the positive force occurring during a designated time interval starting at the time of earliest stimulus application. Because responses were sampled at a rate of 1 kHz (once every 1 ms), which was faster than responses, the summation was a good approximation of the integral. A divisor of 1000 was used to account for the 1-ms sampling. The metric had units of newton-seconds (N-s) and corresponded to the area under a positive force curve.

[0156] The force integral response is shown in FIG. **24** for each limb using response data from the pulse burst experiment, in which all responses had about the same peak response in the right front limb. For clarity, only the 0.150- and 1.150-s periods are shown in FIG. **25**.

[0157] Several observations can be made about the force integral in FIG. **25**. For repetition frequencies of 20, 40, and 80 Hz, smaller individual pulse amplitudes were needed to elicit the baseline force. The smaller amplitude pulses resulted in later onset and the area under the force response for the 0.150-s period was smaller than for the response to the single pulse. These longer onset latencies for the higher repetition frequencies are seen in FIG. **25**.

[0158] The force integral was used to compute measures of stimulus effectiveness for each animal. Effectiveness here was defined as the response magnitude divided by the stimulus magnitude. The force integral for the 1.150-s integration period was used as the measure of response magnitude and stimulus energy or total charge was used as the measure of stimulus magnitude. For stimulus energy, the effectiveness measure had units of N-s/mJ; and for stimulus total charge, N-s/μC. FIGS. **26** and **27** show energy effectiveness and charge effectiveness, respectively, for each limb. Note that the

graphs are based on values computed for each animal and are not simply the data in FIG. **22** divided by the respective values in FIG. **19** or FIG. **20**.

[0159] In FIG. **26**, energy effectiveness of the single pulse was between 0.15 and 0.32 N-s/mJ across limbs. Patterns of energy effectiveness in FIG. **26** were similar for the right front, left front, and left rear limbs. For 10-pulse bursts, effectiveness increased with repetition frequency, with either the 20- or 40-Hz burst effectiveness similar to that of the single pulse in these limbs. For 1-s bursts, effectiveness also increased with repetition frequency for the right front and left rear limbs, but appears relatively constant for the left front limb. For the right rear limb, effectiveness appears smaller than the single-pulse effectiveness for all but the 10-pulse 80-Hz burst. For each limb, results from a linear mixed model with stimulus type (9 levels) as the fixed effect revealed that a significant difference was present ($p's<0.001$).

[0160] In FIG. **27**, charge effectiveness of the single pulse is seen to be between 0.040 and 0.085 N-s/μC across limbs. Except for two instances for the left rear limb, the single-pulse effectiveness appears larger than for all bursts in all limbs. Patterns of charge effectiveness in FIG. **27** are similar for the right front and left rear limbs. For 10-pulse bursts, effectiveness for bursts at 10 and 20 Hz is similar and smaller than effectiveness for bursts at 40 and 80 Hz, which also have similar effectiveness in these two limbs. The same pattern also occurs for effectiveness of 1-s bursts. Patterns of charge effectiveness are somewhat similar for the left front and right rear limbs with small effectiveness for 10-pulse bursts with the 10-Hz burst effectiveness appearing possibly largest. For these limbs, effectiveness for 1-s bursts is small and seems to decline with increasing repetition frequency. For each limb, results from a linear mixed model with stimulus type (9 levels) as the fixed effect revealed that a significant difference was present ($p's<0.001$).

Example 5

ON/OFF Pulse Pattern and Forced Breathing Experiment

[0161] Three patterns of electro-muscular stimulation for either one, two, or three seconds respectfully followed by a one second off period were tested using swine model. To emphasize differences between the three parameters, exposures continued the ON/Off cycling for 15 minutes. Experiment procedure follows the common material and procedures described in Example 2-5. All three of these stimulation patterns produced a single breath for each ON/OFF cycle. FIG. **32** show the partial pressure of oxygen (pO2) prior to exposure, the first set of bars, and at 15 s intervals after the 15 minute exposure. The worst recovery was the two second ON one second OFF (The center bars labeled 2:1 in the figure) While the other two patterns, one second ON/ one second OFF (1:1 and the left bars in the figure) and the three second ON and one second OFF (3:1 and the right bars in the figure) recovered more quickly. The one and three second ON times seem to better match the breathing cycle of the subjects. The optimal pattern for humans will likely require some adjustment, but the principal of forced breathing during incapacitation by cycling the stimulus remains can be used to extend the duration of stimulation, saving precious battery power, and increasing safety.

[0162] The ability of a HEMI device to drive breathing is dependant on the ON/OFF pattern. The FIG. **33** is an early example using a TASER X26 as the source, but controlling the ON/OFF pattern. Notice the initial 30 second ON period suppresses breathing (grey line), but that the subsequent 5 second ON 5 second OFF pattern controls the subject's breathing. This pattern is less than optimal which is why the experiment above was done, to develop patterns which were safer for the target.

Example 6

Comparison of Electric Pulses Produced by the Inventive Device and Commercial Available Devices (X26)

[0163] FIG. **28** A and B show the number of pounds of pull exerted by each limb during a brief exposure of X26 stimulation (A) and during a typical stimulation of the inventive device (B). Considering the responses of the right front limb (the top lines in both Figures), each stimulation starts with a high peak probably representing inertia built up while the movement of the swine took up the slack in the lines connecting the animal to the load cells and in the body of the animal itself. Subsequently, it is clear that the 19 Hz stimulation produces an oscillating level of force as the muscles contract, and relax, whereas the force produced by the 40 Hz stimulation under the inventive method is much more continuous and consistent from pulse to pulse. In other words, the muscles do not have time to relax as they do at 19 Hz stimulation.

[0164] The total work produced by the stimulation that is the area under each of these curves. The 37 micro-Coulombs per pulse produced by the inventive method is the same response as X26 stimulation. Because this measure includes the lows of the oscillations which occur between the X26 pulses, it underestimates the response produced by the X26 when the electrical pulses are applied.

[0165] When the average value of the inventive stimulus versus the average of only the peak stimulate of the X26, the results suggest an inventive stimulus of 52 micro-Coulombs is equivalent to that of an X26. The data for the right leg response of four animals are shown in FIG. **29**.

[0166] The data shown in FIG. **30** suggest that by incorporating the response of all four limbs into a single measure, variability, seen as deviations from the regression lines, has been reduced in the two panels on the left while retaining the excellent fits of the data for the two animals on the right. By this analysis the inventive stimulus with 44 micro-Coulombs per pulse is equivalent to an X26 (Reported by Taser International as between 110-135 micro-Coulombs per pulse in tissue).

CONCLUSION

[0167] Given the limitations of these experiments, the following conclusions can be made based on results obtained:

[0168] (a) Monophasic pulses with the same energy, or charge, are equally effective in eliciting threshold responses independent of pulse shape.

[0169] (b) Longer pulses are more energy-efficient up to at least 250 μs.

[0170] (c) Shorter pulses are more charge-efficient down to at most 20 μs.

[0171] (d) Monophasic pulses are more efficient than biphasic pulses.

[0172] (e) Repetition frequencies of 40 and 80 Hz are more effective than 10 and 20 Hz in bursts.

1. An apparatus for incapacitating a subject, the apparatus comprising:

(a) an electric circuitry for

(i) generating a first continuous pulsed electric waveform having a first frequency and over a first time period sufficient to induce involuntary muscular contraction, and

(ii) generating a second intermittent pulsed electric waveform having a second frequency over a second time period sufficient to safely maintain incapacitation of the subject with forced breathing;

(b) a plurality of electrical contacts for delivering electric waveforms to a subject; and

(c) a switch to selectively activate said circuit.

2. The apparatus of claim **1**, wherein said electrical contact is a pad, a button, a nub, a prong, a needle, or a hook.

3. The apparatus of claim **1**, further comprising a release mechanism for releasing the plurality of contacts from the apparatus.

4. The apparatus of claim **1**, wherein the contacts deliver the waveform to a subject subcutaneously.

5. The apparatus of claim **1**, wherein the contacts deliver the waveform to an outer surface of a subject.

6. The apparatus of claim **1**, further comprising an elongate body having a first end and a second end, wherein the contacts are located proximately on the first end and the switch is located proximately on the second end.

7. The apparatus of claim **1**, wherein said first time period is 15-45 seconds.

8. The apparatus of claim **1**, wherein said second intermittent waveform follows the first continuous waveform.

9. The apparatus of claim **8**, wherein said second time period is about 60-150 seconds.

10. The apparatus of claim **1**, wherein said second intermittent waveform switch on and off during the second time period.

11. The apparatus of claim **10**, wherein said second intermittent waveform is on for approximately 1-3 seconds.

12. The apparatus of claim **10**, wherein said second intermittent waveform is off for approximately 1 second.

13. The apparatus of claim **1**, wherein said first and second pulsed electric waveforms are the same.

14. The apparatus of claim **13**, wherein the electrical charge of a pulse of said waveform is approximately 40 to 80 micro-Coulombs.

15. The apparatus of claim **1**, wherein said pulse frequency is approximately 40 Hz to about 80 Hz.

16. The apparatus of claim **16**, wherein said pulse duration is approximately 100 microseconds.

17. The apparatus of claim **13**, wherein said waveform is a square wave.

18. A method for temporarily incapacitating a subject, comprising:

(a) generating a continuous pulsed electric waveform; and

(b) applying said continuous pulsed waveform to a subject at a first frequency and over a first time period sufficient to induce involuntary muscular contraction;

(c) generating an intermittent pulsed electric waveform; and

(d) applying said second intermittent pulsed electric waveform to said subject at a second frequency and over a second time period sufficient to safely maintain incapacitation of the subject with forced breathing.

19. The method of claim **18**, wherein said first time period is 15 to 45 seconds.

20. The method of claim **18**, wherein said second intermittent waveform follows the first continuous waveform.

21. The method of claim **18**, wherein said second time period is 60 to 150 seconds.

22. The method of claim **18**, wherein said second intermittent waveform switches on and off during the second time period.

23. The method of **22**, wherein said second intermittent waveform is on for approximately 1-3 seconds.

23. The method of claim **22**, wherein said second intermittent waveform is off for approximately 1 second.

24. The method of claim **18**, wherein the continuous and intermittent electric waveform are the same.

25. The method of claim **24**, wherein said frequency of said waveform comprises a value in a range of about 40 Hz to about 80 Hz.

26. The method of claim **24**, wherein the charge of a pulse of said waveforms is approximately 40 to 80 micro-Coulombs.

27. The method of claim **24**, wherein said pulse duration is approximately 100 microseconds.

Blunt Impact Technologies

Non-Lethal Weapons Research and Technology Development

Industry Day

22 June 2012

Wesley Burgei

Project Engineer

http://jnlwp.defense.gov

Background

- Non-lethal blunt impact munitions have been widely used by law enforcement and military throughout the world.
- Blunt impact munitions suppress individuals by countering motivation.
- The main limitations of current blunt impact munitions:

  (1) the natural trade-off between increased effective range (min and max) and the risk of significant injury.

  (2) accuracy/dispersion at longer ranges.
- The JNLWP is interested in developing technologies to address these limitations and continuing to develop the blunt impact injury model and instrumented test target as needed.

Technical Objectives

- Develop and demonstrate new blunt impact munitions and/or launchers to address current performance limitations
  - Logistics and supportability issues associated with enabling technology could also be a future development focus.
- Improve capabilities of the blunt trauma test target
  - E.g., develop method to measure aim-point accuracy
- Update blunt impact model as needed to simulate new materials, projectile designs, include impacts with extremities, etc.

Relevant Work

- The JNLWP, working with the Human Effects Center of Excellence (HECOE), developed the Advanced Total Body Model over the span of several years.
  - This computational model can simulate projectile impacts with the human body to predict the probability of causing significant injuries.
  - Industry Performer: L-3 Communications/Jaycor
- JNLWP/HECOE developed an instrumented blunt trauma test target to collect blunt impact data
  - Industry Performer: L-3 Communications/Jaycor
- JNLWP & Naval Surface Warfare Center – Dahlgren designed and tested new 12 gauge blunt impact rounds made from Zorbium® visco-elastic material.

Research & Development Tasks

General types of tasks that may be required for Blunt Impact Research and Development:

- Test target development/improvement

- Prototype development, testing, and demonstration of new projectiles and/or launching systems
  - E.g., new materials, variable velocity launchers, etc.

- Modeling and simulation to predict blunt impact risk of significant injury

- Systems engineering and technology integration

Capabilities

General capabilities and expertise that may be required to execute planned R&D blunt impact technology tasks:

- Engineers/Scientists with expertise in electronic instrumentation, ballistics, mechanics, materials and systems engineering
- Facilities and equipment to build and test prototype systems
- Computational scientists and engineers to build/improve computer based models and run simulations

Non-Lethal Weapons Research & Technology Development ID/IQ Business Approach

Non-Lethal Weapons Research and Technology Development

Industry Day

22 June 2012

Alicia Owsiak

Deputy Technology Division Chief

http://jnlwp.defense.gov

Disclaimer

- This Industry Day is for informational and planning purposes only and does not bind the Government to contract for any supply or service.

- Official requirements and instructions would be provided in a final released Request for Proposal (RFP).

Industry Day Purpose

- Provide industry insight into the Joint Non-Lethal Weapons Program (JNLWP)
- Describe, in general terms, the scope of the anticipated acquisition
- Lay out the notional business approach & timeline
- Respond to select questions received as part of the RFI
- Provide information on the potential technology areas:
  - Background (what and why)
  - Future year technical objectives
  - Examples of relevant work (past and present)
  - Types of potential research and technology development tasks
  - Types of capabilities that may be needed to accomplish tasks

Perceived Benefits of an IDIQ Multiple Award Contract (MAC) Contracting Approach

- Provides flexibility (within limits) for executing a wide range of JNLWP technical objectives
- Increases breadth of expertise readily accessible to work JNLWP technology challenges
- Reduces project initiation timeline
- Reduces overall JNLWP research and technology development project execution schedule risk
- Task orders can be specific within scope of the ID/IQ contract

Potential Scope

- ID/IQ type contract for non-lethal weapons research and technology development:
  - Technical and scientific studies and analyses
  - Systems engineering
  - Systems integration
  - Experimental research (including bioeffects)
  - Test and evaluation
  - Prototype development and demonstration
  - Independent technical reviews, studies
  - Strategic planning

Potential Scope

- ~30 JNLWP FY12 Statements of Work (task orders) would likely have been in scope of potential future R&TD ID/IQ
  - Budget activities 2, 3, & 4
  - Average cost/SoW is ~$600K, with a range of <$100K to >$2M
- ROM potential ceiling: ~$100M (assuming 5 year POP)
- Potential number of contract awards:
  - Anticipate three to five awards, but could be more
  - Must balance breadth/depth of capability to draw from with the administrative burden of many contracts
    - Teaming may be a way to strike a balance
  - Continuing market research will help the Government determine the right balance and scope based on Industry capability

Notional Timeline

- Initial Request for Information (RFI) & Industry Day – May/June 2012
  - Purpose: Provides opportunity for the Government to gauge interest; seek initial Industry input; and convey potential NLW Research and Technology Development requirements to Industry
    - Industry Day Questions Due – 29 June 2012
    - Industry Day Question Responses Posted – Mid July 2012

- Sources Sought – 4th Quarter FY12
  - Purpose: Provides opportunity for Industry (teams) to respond stating their capabilities to address potential requirements; opportunity for the Government to collect valuable market research for drafting a request for proposals

Notional Timeline

- Draft Request for Proposals (RFP) – 1st Quarter FY13
  - Purpose: Give Industry an opportunity to provide comments and feedback on a potential RFP; information will be used to better suit needs/concerns of both Government and Industry
- Request for Proposals – 2nd Quarter FY13
- Contract Award(s) – 3rd Quarter FY13

Check JNLWP website and FedBizOps routinely for updates:

- http://jnlwp.defense.gov/
- https://www.fbo.gov/index?s=opportunity&mode=form&id=caeec6def8d2ad4478c0c6145c28d499&tab=core&_cview=0

Responses to Select Questions

Q1: Will industry be able to submit the same proposal for more than one topic area?

A1: If a single set of IDIQ MACs are pursued, each team should be capable of addressing multiple topic areas.

Q2: How can small and mid-sized businesses participate?

A2: It is envisioned that each prime will have a collaborative team comprised of various strengths/specialties. This will encourage all business sizes to participate. The primes on the IDIQ do not have to be large businesses. This Industry Day and follow-on market research activities (sources sought and a draft RFP) will assist in cultivating an environment that enables all business sizes to compete.

Responses to Select Questions

Q3: Will Industry have the opportunity to propose additional objectives following Industry Day?

A3: Yes. Please include these along with any additional questions you may have after Industry Day. Initial Industry Day questions are requested to be submitted by 29 June 2012. Email questions to wesley.burgei@usmc.mil and alicia.owsiak@usmc.mil.

Q4: What contract type is envisioned?

A4: A firm fixed priced type contract is likely; however, this Industry Day and future market research activities will inform a business case analysis and decision on the most appropriate type of contract.

Q5: Will other Government agencies be able to utilize this contract?

A5: That is yet to be determined.

Responses to Select Questions

Q6: Who will write the requirements for task orders?

A6: The Government will write the requirements for the task orders.

Q7: What Government furnished information or equipment will be provided?

A7: This would depend on the actual task order. However, in general the JNLWD intends to provide the performer with all data necessary to complete the task efficiently. Additionally, if existing equipment is available then this could be furnished to the performer.

Non-Lethal Directed Energy – Radio Frequency (RF) / High Power Microwave (HPM)

Non-Lethal Weapons Research and Technology Development

Industry Day

22 June 2012

Scott Griffiths

Officer of Primary Responsibility, RF/HPM Technologies

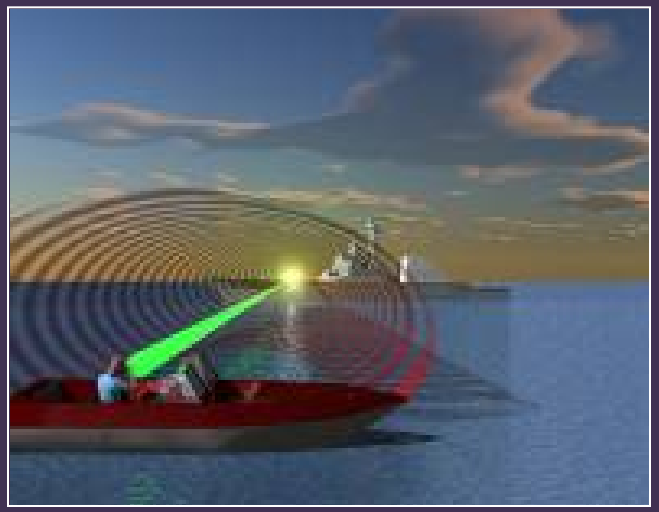
http://jnlwp.defense.gov

Background

- RF/HPM directed energy technologies provide for unique non-lethal (counter-materiel and counter-personnel) effects with extended range.

- Though their operational utility is desirable, the use of RF/HPM directed energy weapons remains limited due operational range, size, weight, and cost.

- The JNLWD is focused on developing advanced RF/HPM technologies to enable smaller, lighter and more capable non-lethal directed energy weapons.



Technical Objectives

- Determine the feasibility of new concepts and technologies that enable smaller, lighter and more capable non-lethal directed energy weapons and address multiple types of targets

- Develop and demonstrate novel RF/HPM technology breadboards and prototypes to address various targets
  - Personnel
  - Vehicles
  - Vessels
  - Aircraft
  - Threat electronics
  - Facilities

- Integrate improved RF/HPM technologies with existing systems and platforms

Relevant Work

- Solid State High Power Microwave (HPM) Source
  - Performers:
    - Los Alamos National Laboratory
    - NSWC Dahlgren
  - Focus/Performance Goals:
    - Develop a 50 MW, dielectric based Non-Linear Transmission Line (NLTL) source for HPM applications
      - Multi-frequency waveforms from a single source vice multiple tubes
    - Perform lab and field testing of a Low Power NLTL breadboard source to verify feasibility
    - Investigate new waveform regime for RF Vehicle Stopping (shorter pulse & multiple frequency)
  - Project terminated due to material science immaturity

Relevant Work

- Short Pulse / Low Duty Cycle Assessment
  - Performers: NSWC Dahlgren
  - Focus/Performance Goals:
    - Identify effective vehicle/vessel stopping waveform parameters with low average power requirements, enabling a substantially smaller RF Vehicle Stopper system
      - Implement effects-based design
    - Complete laboratory and open air vehicle/vessel susceptibility testing
    - Compare results to current vehicle and vessel stopping data
    - Perform a system trade-off analysis to determine the benefits of a short pulse vehicle/vessel stopping system compared to the RFVS demonstrator design in terms of size, weight, and effectiveness

Relevant Work

- Compact, High Gain, HPM Antennas
  - Pennsylvania State University – Meta-materials
  - University of Missouri-Columbia – Advanced Dielectrics
  - Focus:
    - Assess the feasibility of applying dielectrics and meta-materials to enable the development of compact, high-gain antennas for preferred frequencies and output power levels employed by non-lethal high power microwave applications

- Advanced High Energy Density Capacitors
  - University of Missouri-Columbia
  - Focus:
    - Assess feasibility of new materials to develop smaller, high-voltage capacitors to reduce size of high power microwave subsystems

Relevant Work

- Thermal Management Phase I Small Business Innovative Research (SBIR)
  - Topic #: Navy102-110
    - Advanced Cooling Technologies, Inc. (M67854-11-C-6506)
    - Allcomp, Inc. (M67854-11-C-6507)
    - International Mezzo Technologies (M67854-11-C-6508)
    - Altex Technologies (M67854-11-C-6509)
    - Thermal Form & Function, Inc. (M67854-11-C-6510)
  - Focus:
    - Design next generation cooling/thermal management system to meet identified system performance specifications relevant to vehicle stopper systems and the 30 kW ADT systems.
- Thermal Management Phase II SBIR (Pending Award)
  - Focus:
    - Fabricate and test cooling/thermal management design.
    - Conduct system analysis and design tradeoffs.

Research & Development Tasks

Enabling Technologies:

Compact, Steerable High Gain Antenna
Short Pulse Regime Sources
Long Pulse Regime Sources
Prime Power Systems
Thermal Management Systems

- *Reduced size & weight*
- *Improved capability*

Existing System Demonstrators/Prototypes:

Multi-Frequency RF Vehicle Stopper
RF Vessel Stopper
Non-Lethal Unmanned Aerial Vehicle HPM Payload
Pre-Emplaced Electric Vehicle Stopper

Potential Platforms:

Light Tactical Vehicles
Unmanned Vehicles/Vessels
Unmanned Air Vehicles

Research & Development Tasks

General types of tasks required for RF/HPM technology and development:

- Feasibility studies and technology assessments
- Target vulnerability tests utilizing effects-based design approach
- Build, test and demonstration of component technologies
- Comparison of novel approaches with existing technologies
- Integration of component technologies with existing breadboard and prototype systems
- Integration onto various platforms

Capabilities

General capabilities and expertise that may be required to execute planned RF/HPM technology tasks:

- Engineers/Scientists with expertise in
  - High power microwaves
  - Pulsed power
  - High power vacuum tubes
  - Other high power sources (NLTL's, FEGs, etc.)
  - Antennas
  - Prime power
  - Power conditioning
  - Computational electromagnetics
  - Statistical electromagnetics
  - Physics
  - Electrical engineering
  - Materials science
  - Statistics (design of experiment, data Analysis, linear regression, etc.)
  - Systems integration
  - Systems engineering
- Facilities and equipment to develop, build, and test component technologies, subsystems, and systems
- Facilities to perform electromagnetic vulnerability tests, antenna characterizations, and high power source characterizations.

U.S. DEPARTMENT OF DEFENSE

NON-LETHAL WEAPONS

ANNUAL REVIEW

NON-LETHAL CAPABILITIES

FOR COMPLEX ENVIRONMENTS

http://jnlwp.defense.gov

"… these (non-lethal) capabilities truly help minimize casualties while providing escalation-of-force options …

As we drawdown in Afghanistan and look to the conflicts of tomorrow, our use of non-lethal weapons coupled with building partner capacity missions and (military-to-military) exchanges, strategically communicates our commitment to protect innocence and reassures our strategic friends and our allies."

—General James F. Amos
Commandant of the Marine Corps and Executive Agent
U.S. Department of Defense (DoD) Non-Lethal Weapons Program

CONTENTS

ON THE COVER AND ABOVE PHOTO — TRIDENT WARRIOR EXERCISE TESTS NEW NON-LETHAL TECHNOLOGIES

U.S. Fleet Forces Command conducted an experiment at Fort Eustis, Va., to improve non-lethal capabilities available to the fleet. The Navy used an unmanned surface vessel, Powervent, to test non-lethal hailers, lasers, and warning munitions. The Trident Warrior 2012 Spiral 1 experiment had a remote-controlled, rigid-hulled, inflatable boat perform as an aggressor intruding in protected waters during a maritime security mission. Participants used non-lethal capabilities to respond to the simulated intrusion.

U.S. DOD NON-LETHAL WEAPONS PROGRAM

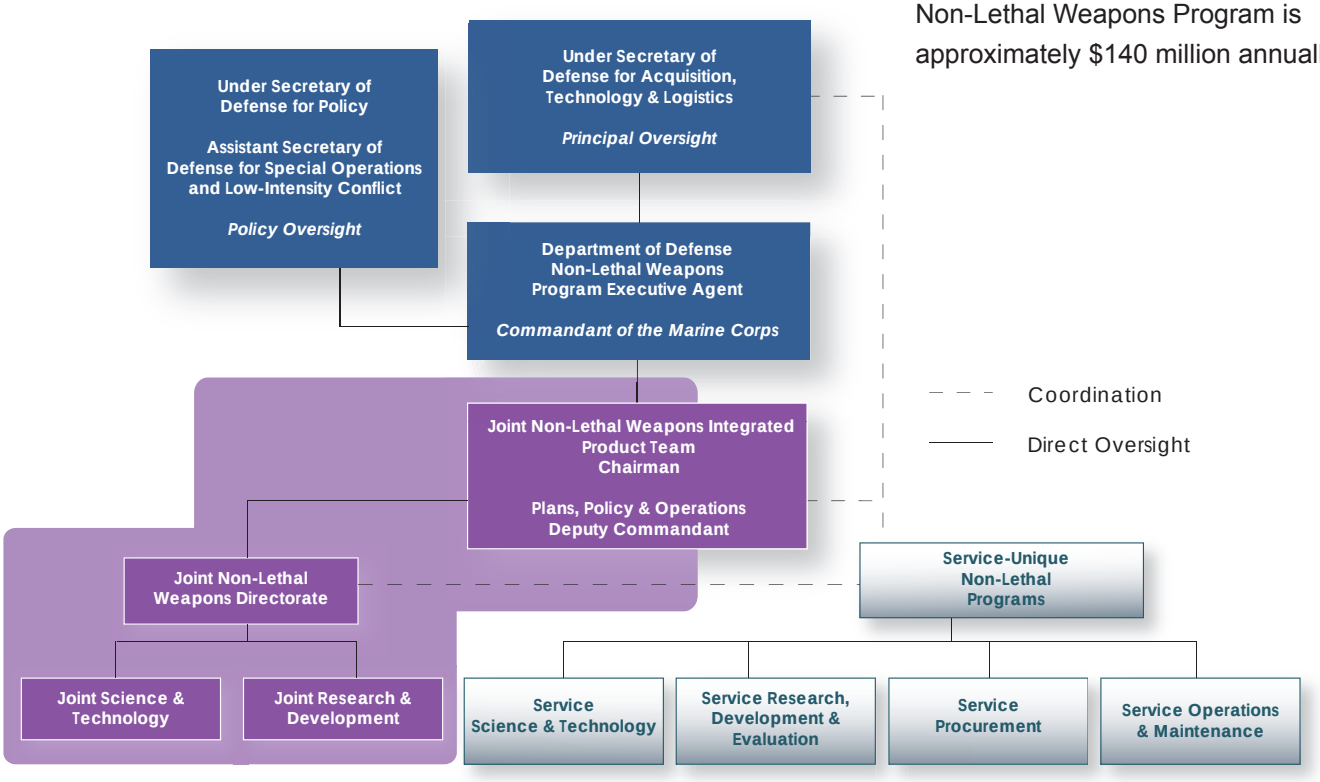
The DoD Non-Lethal Weapons Program stimulates and coordinates non-lethal weapons requirements of the U.S. Armed Services and allocates resources to help meet these requirements. The Assistant Secretary of Defense for Special Operation and Low Intensity Conflict is responsible for policy oversight and the Under Secretary of Defense for Acquisition, Technology and Logistics is responsible for program oversight.

The Commandant of the U.S. Marine Corps serves as the DoD Non-Lethal Weapons Program Executive Agent, facilitating experimentation, development, transition, and fielding of non-lethal capabilities to deliver counter-personnel and counter-materiel with scalable and relatively reversible effects. The Deputy Commandant of the U.S. Marine Corps for Plans, Policies & Operations, Lieutenant General Tryon, serves as the Joint Non-Lethal Weapons Integrated Product Team Chairman. The Integrated Product Team brings the views of the Services, Special Operations Command, and the Coast Guard to DoD non-lethal weapons efforts.

Lieutenant General Richard T. Tryon
Chairman, Joint Integrated Product Team

Located at Marine Corps Base Quantico, Va., the Joint Non-Lethal Weapons Directorate is the Executive Agent's day-to-day management office and serves as a focal point to coordinate non-lethal weapons program activities with the Office of the Secretary of Defense, the Joint Staff, the Services, NATO and other government agencies. The Services work with the Combatant Commanders and the Executive Agent through a joint process to identify non-lethal weapon requirements.

The DoD Non-Lethal Weapons Program budget includes joint funding executed under the direction of the Executive Agent for a wide range of program activities including non-lethal weapons research and development, as well as Service funding for non-lethal weapons procurement, operation and maintenance support. The total budget of the DoD Non-Lethal Weapons Program is approximately $140 million annually.



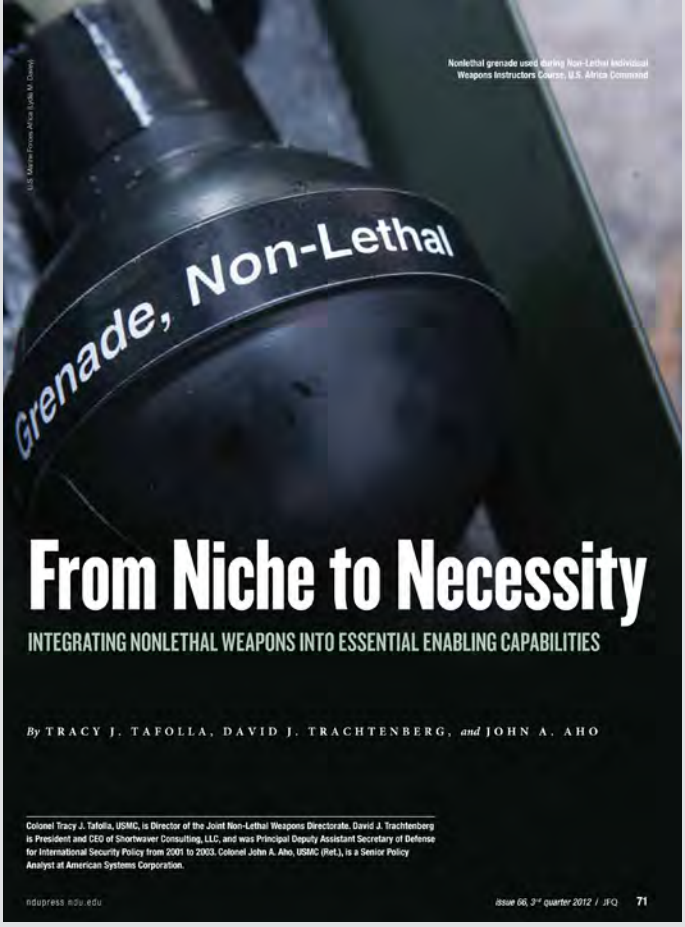
Contemporary military operations are unlike previous wars where success was measured in purely military terms. The importance of winning "hearts and minds" is now growing. Today's wars are mostly irregular conflicts fought not against countries, but in complex environments against terrorists and extremists who wear no uniforms and operate within the civilian populace—often in a deliberate attempt to shield themselves from attack and maximize propaganda opportunities from civilian casualties.

"In both asymmetric and conventional environments, avoiding noncombatant casualties has become increasingly important to the success of military operations."

Non-lethal weapons can play a significant and strategic role in accomplishing this and helping to achieve mission success.

The DoD definition of non-lethal weapons is "Weapons that are explicitly designed and primarily employed so as to incapacitate personnel or materiel, while minimizing fatalities, permanent injury to personnel, and undesired damage to property and the environment." The DoD policy recognizes that the use of non-lethal weapons may occasionally result in injurious or lethal effects, though that is not the intended outcome. Their use reflects an approach to warfare that seeks to reconcile the objective of defeating the enemy with the moral imperative of sparing innocent lives.

The current generation of non-lethal weapons includes counter-personnel and counter-materiel capabilities used for controlling crowds or stopping or diverting vehicles on land and vessels at sea. They provide escalation-of-force options that allow U.S. forces to determine intent of potentially hostile individuals and groups and modify behavior. More sophisticated non-lethal weapons are being developed with greater operational range, scalable to a variety of needs, to provide a layered defense against potential threats.



The edited excerpts on this page are from the Joint Forces Quarterly Issue 66, 3rd Quarter 2012 *article, "From Niche to Necessity: Integrating Nonlethal Weapons into Essential Enabling Capabilities." Photo and graphics are reprinted with permission of* JFQ.

Although applicable to a broad range of contingencies, non-lethal weapons are neither a panacea nor a substitute for lethal force. Their purpose is to complement the lethal capabilities in the warfighter's toolkit.

Colonel Tracy J. Tafolla
Director, Joint Non-Lethal Weapons Directorate

DIRECTED ENERGY

The Joint Non-Lethal Weapons Directorate is exploring the electromagnetic spectrum to identify new and advanced non-lethal directed energy capabilities. Low-energy dazzling lasers, such as the LA-9/P and the GLARE® MOUT 532-M, have been fielded by the U.S. Marine Corps. Both lasers provide Marines non-lethal capabilities to communicate discrete, non-verbal hailing and warning signals to individuals while on patrol, in convoys, at entry control points and at checkpoints. Advancement in safety and effectiveness is ongoing as the Marine Corps is currently developing the Ocular Interruption Device, which will incorporate controls to reduce the risk of unintended lasing by automatically regulating the exposure to the laser.

High-power microwaves are showing promise as a means to non-lethally stop vehicles and vessels—without harming the occupants. The Multi-Frequency Radio-Frequency Vehicle Stopper in concept development is designed to stop vehicles. By allowing a safe and non-lethal "keep-out zone" the Multi-Frequency Radio-Frequency Vehicle Stopper has the potential to support multiple missions including force protection, checkpoints, access control points, roadblocks and mounted patrols. The Multi-Frequency Radio-Frequency Vehicle Stopper system would allow for the maintenance of a safe and non-lethal keep-out zone with the use of high-power microwaves to disrupt vehicle engines by interacting with electrical components causing the engine to stall. Also, on the forefront is the Radio-Frequency Vessel Stopper, which is designed to stop or disable vessels. This technology has the potential to support multiple missions including force protection, port operations and vessel pursuit/stop/interdiction.

There are also operational benefits associated with millimeter-wave technology, such as the Active Denial System, also known as ADS. The ADS is a non-lethal, long-range, counter-personnel directed-energy weapon that uses millimeter-wave energy of a specific radio frequency (95GHz) to provide a "repel" effect against human targets with minimal risk of injury. Currently, there are two Active Denial Systems: Systems 1 and 2. ADS 1, a mobile-technology prototype, has served as a satisfactory demonstrator for approximately eight years; however, the system has reached the end of its utility in its current configuration. ADS 1 is being refurbished into a new and more robust, mobile platform that will also be capable of filling potential operational deployment or demonstration requests. ADS 2 is a containerized version of the technology that is suitable for operational deployment. If an operational user request is received, a plan is in place to deploy the system, train operators, and provide operational support through a field-service representative. With its long-range (1,000 meters), precision and day/night capabilities, ADS 2 is ideally suited for a number of mission applications that includes, but is not limited to, perimeter security of forward-operating bases, air bases, and ports.

.

Active Denial System 2 (left) and Active Denial System 1

DoD SENIOR LEADERS' PERSPECTIVES ON FUTURE NON-LETHAL SYSTEMS

JOSE M. GONZALEZ

Director, Land Warfare and Munitions, Office of the Secretary of Defense
Principal Oversight to DoD Non-Lethal Weapons Program

"Like the Military Operations Other Than War requirements that helped establish the DoD Non-Lethal Weapons Program, today's operations again find U.S. forces operating within close proximity to civilians—this time, to locate, close with and destroy an enemy that seeks to exploit collateral damage. Appreciation for non-lethal weapons' utility within today's irregular warfare operations is growing, as is recognition that non-lethals can help achieve national strategic objectives by minimizing civilian casualties and property destruction. As non-lethal capabilities continue to advance, such as with emerging directed-energy concepts, additional operational applications will ensue. Our use of non-lethal weapons when practicable, coupled with our continued use of non-lethals in building partner capacity missions and mil-to-mil exchanges, strategically communicates our commitment to protect innocents, reassures our strategic friends and allies, and helps to win 'hearts and minds'."

MAJOR GENERAL JOHN N.T. SHANAHAN, U.S. AIR FORCE

Deputy Director for Global Operations, Joint Staff

"The future of non-lethal weapons is brighter than ever. While a great deal of attention is on cyber right now, non-lethal weapons promise to contribute as much or more to successful operations throughout every phase and across the entire spectrum of conflict. In an increasingly complex and chaotic world, every commander needs a healthy mix of both lethal and non-lethal capabilities—in some cases, the only viable solution to defuse a crisis is to employ a precise, non-lethal weapon that achieves the desired effects while minimizing the potential for collateral damage. The DoD Non-Lethal Weapons Program continues to develop innovative directed-energy technologies that allow our deployed joint forces to achieve their objectives while minimizing risk to themselves and non-combatants. We are working closely with the Non-Lethal Weapons Program and the Office of the Secretary of Defense to develop and implement policies and processes that will allow faster review and approval of non-lethal capabilities. Our adversaries are not standing still when it comes to non-lethal technologies; we cannot afford to fall behind. The Non-Lethal Weapons Program must remain on the leading edge."

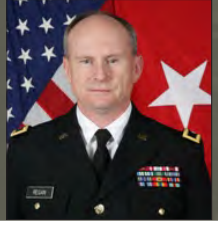
ROBERT C. MARTINAGE

Deputy Under Secretary of the Navy for Plans, Policy, Oversight and Integration

"Emerging non-lethal weapon technologies will provide our Sailors and Marines with a wider range of military response options and could significantly reduce the risk of fatalities and unintentional collateral damage. After participating in a live demonstration, I can personally attest to the effectiveness of the millimeter wave Active Denial technology to repel personnel through its non-damaging, momentary heating sensation. These systems could provide revolutionary capabilities on the battlefield when used in various defensive roles (e.g., checkpoints and perimeter security) or offensive roles (e.g., clearing areas before sending in friendly forces). The recently published U.S. naval directed-energy vision recognizes their importance and has directed the Navy and Marine Corps to develop high-power radio-frequency technologies to support vehicle/vessel stopping and other non-lethal applications."

U.S. ARMY HIGHLIGHTS

Brigadier General
John S. Regan
Joint Non-Lethal Integrated Product Team Representative



DEVELOPING: XM7 SPIDER NON-LETHAL LAUNCHER

In Development:
XM7 Spider
Non-Lethal Launcher

The U.S. Army's development of the XM7 Spider Non-Lethal Launcher, a counter-personnel weapon system, will provide military forces operating in all types of environments and terrain a capability that will enhance operational and tactical flexibility. The Spider's remote control unit, coupled with a transceiver and repeater, will enable the operator to send, receive, and retransmit radio signals over obstructions and longer distances to the system's grenade launcher.

This "man-in-the-loop" system will feature on/off/on capabilities, and allow the warfighter remote control firing of both lethal and non-lethal grenades from a ground-mounted tube launcher. The hand-emplaced, six-tube launcher pod will deliver a high volume of munitions, including flash-bang and sting-ball grenades, at ranges between 25–500 meters. This barrage will enable the warfighter to deny the targeted individuals freedom of movement, while preserving that freedom for friendly forces.

The system will include several additional, unique features. It will detect intrusions and be capable of self-deactivation or self-destruction. These self-protection or anti-tamper mechanisms will help maintain the system's security. Spider will also be recoverable and reusable post employment. These combined features will make Spider a versatile weapon for a variety of military missions.

Spider will be useful in denying access, moving, and/or suppressing individuals across the range of military operations. It will provide early warning, as well as delay and deter enemy forces. The capability will support force protection, including perimeter defense, area security, and crowd control. Although the Spider system will be primarily used as a protective obstacle in local and base security operations, it can offer effective capabilities for offensive and defensive operations before, during, and after hostilities.

FIELDED: X26 TASER®

USES: DETAINEE OPERATIONS | CROWD CONTROL | LAW ENFORCEMENT

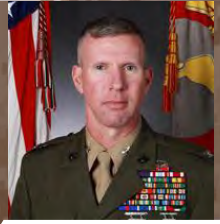
"It's another tool (Taser®) in our kit to protect what matters..."

—Major Christopher W. Armstrong, 773rd Military Police Battalion

The X26 Launched Electrode Stun Device, also known as the X26 Taser®, is a hand-held device that fires tethered probes, which can temporarily disable noncompliant adversaries by delivering a neuro-muscular incapacitating effect at ranges from zero to approximately 8 meters.

Since 2008, the U.S. Army has fielded X26 Tasers® as part of their non-lethal capability sets. In June 2012, X26 Tasers® became the first, non-lethal weapons issued as required unit-specific equipment.

U.S. MARINE CORPS HIGHLIGHTS



Brigadier General
Eric M. Smith
Joint Non-Lethal Integrated Product Team Representative

DEVELOPING: NON-LETHAL INDIRECT FIRE MUNITION

Insurgents often blend in with the local populace and use civilians to shield themselves from U.S. forces. Warfighters must be able to engage insurgents, while minimizing civilian casualties and collateral damage. Current non-lethal weapons have limited ranges and/or require line of sight to engage targets. Systems in development provide the capability to engage targets at ranges of approximately 150 meters or less, which can still put our forces at risk because of the compressed decision and response times. These capabilities lack the range, area coverage, and effectiveness required against many potential threats.

In response to the need to immediately neutralize or incapacitate insurgents at greater standoff ranges while minimizing collateral damage, the U.S. Marine Corps, in coordination with the Joint Non-Lethal Weapons Directorate, the U.S. Army, and the Human Effects Center of Excellence, is developing the Non-Lethal Indirect Fire Munition. This munition effort will produce an 81mm mortar that will provide suppressive fires with minimal risk of injury from the kinetic energy of the mortar and its payload. The result will be a non-lethal capability that can engage area targets with indirect fires at significant ranges.

The Non-Lethal Indirect Fire Munition initiative is currently in the science and technology phase of the development cycle and is making significant progress. In addressing the major challenge of reducing the risk of injury from the projectile that delivers the non-lethal payload, the Human Effects Center of Excellence has modeled mortar payloads and designs to identify attributes that will produce the desired effect, while limiting collateral damage. A proof-of-concept demonstrated that reducing the kinetic energy of existing mortars is feasible. Next, the program will integrate a flash-bang effect into the existing M252 81mm mortar.

In Development: Non-Lethal Indirect Fire Munitions

FIELDED: LA-9/P

USES: ENTRY CONTROL POINTS | VEHICLE CHECKPOINTS | CONVOY AND/OR PERIMETER SECURITY URBAN PATROLLING MISSIONS | SHIP-TO-SHIP ENCOUNTERS BY THE NAVY

"I have personally used it (dazzling laser) about 50 times for EOF (escalation-of-force) situations, and each time the situation was neutralized."

—Corporal Christopher Martinez, Military Policeman
Security Company, Marine Wing Support Squadron-373

The LA-9/P is a medium-range, green-beam optical distracter intended to provide Marines and Sailors a safer alternative than warning shots or pen flares. The LA-9/P is capable of delivering a visual warning more than 500 meters during day, and beyond 1,000 meters at night. With a fixed-beam divergence, the LA-9/P will deliver a spot size of approximately one-half meter, and expand to approximately two meters with increased distance. With an attached safety control module, the risk of permanent eye injury has been reduced as the LA-9/P automatically shuts off the dazzling beam when a target interrupts it at a non-eye-safe distance.

DoD implemented laser safety review boards to help ensure the safety of the operators and targets of military dazzling lasers. The LA-9/P is the first dazzling laser to be fully approved by the Naval Laser Safety Review Board for non-lethal weapons use.

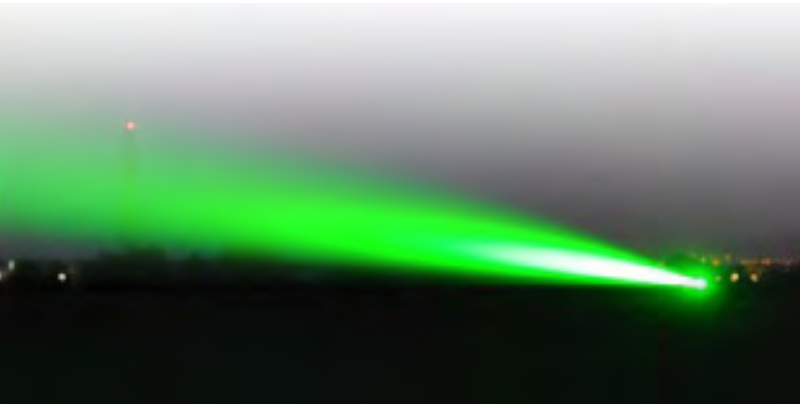
U.S. NAVY HIGHLIGHTS

Major General
Timothy C. Hanifen
Joint Non-Lethal Integrated Product Team Representative

DEVELOPING: LONG RANGE OCULAR INTERRUPTER

The Long Range Ocular Interrupter, or LROI, will provide a significant enhancement in capabilities beyond current shorter-range, non-lethal optical distracters. Its extended range capability will increase decision-making time in assessing the intent of a suspected target, as well as the time to determine if or how to escalate the use of force. This increased time will enable naval personnel to control potential threats sooner and minimize unintended casualties.

LROI's bright beam of human visible light will cause an intense, glare effect that can warn and/or suppress potential threats through increasing levels of visual degradation. The LROI will provide a controlled, high-intensity light beam at two levels. A lower level will serve as a visual warning, and a higher level will provide temporary, visual suppression.



The extended-range effect of the developing Long Range Ocular Interrupter at night.

U.S. Navy maritime expeditionary security group uses a laser distracter to warn a simulated vessel to keep its distance.

The U.S. Navy's near-term focus is to develop a man-portable LROI that expeditionary forces in severe maritime and desert environments could use. The optical distracter's effect could also be valuable for vessel protection, entry control points, checkpoints, convoys, maritime ports, and security zones. Future shipboard development may evolve as requirements are defined.

The LROI will provide a controlled, high-intensity light beam at two levels.

FIELDED: ACOUSTIC HAILING DEVICE

USES: ESTABLISH INTENT OF APPROACHING VESSELS | CROWD CONTROL
UNIVERSAL WARNING | FORCE PROTECTION OF SURFACE SHIPS

In response to the terrorist attack on the USS Cole, acoustic hailing devices were developed to help determine the intent of nearby craft by providing warning messages to keep unidentified vessels and personnel out of established safety zones. Acoustic hailing devices provide high-intensity directional sound for long-range, clear-hailing, notification and unmistakable warning. Warning signals may either be input by microphone, pre-recorded messages in numerous languages from an MP3 player, or by activating an alert tone. Since 2006, the Navy has successfully used acoustic hailing devices as a non-lethal means to protect naval ships.

U.S. AIR FORCE HIGHLIGHTS

Brigadier General
Allen J. Jamerson
Joint Non-Lethal Integrated Product Team Representative

FIELDED: TASER X26®

To date, U.S. Air Force Security Forces have purchased more than 5,000 Tasers®, and have deployed the Taser X26® model to most of their bases. The Taser X26® is an electronic control device that uses a nitrogen-air-cartridge propulsion system to launch two probes tethered to an electrically charged cartridge. The hand-held device delivers an incapacitating pulse that can temporarily overcome the sensory and motor functions of a targeted individual's nervous system.

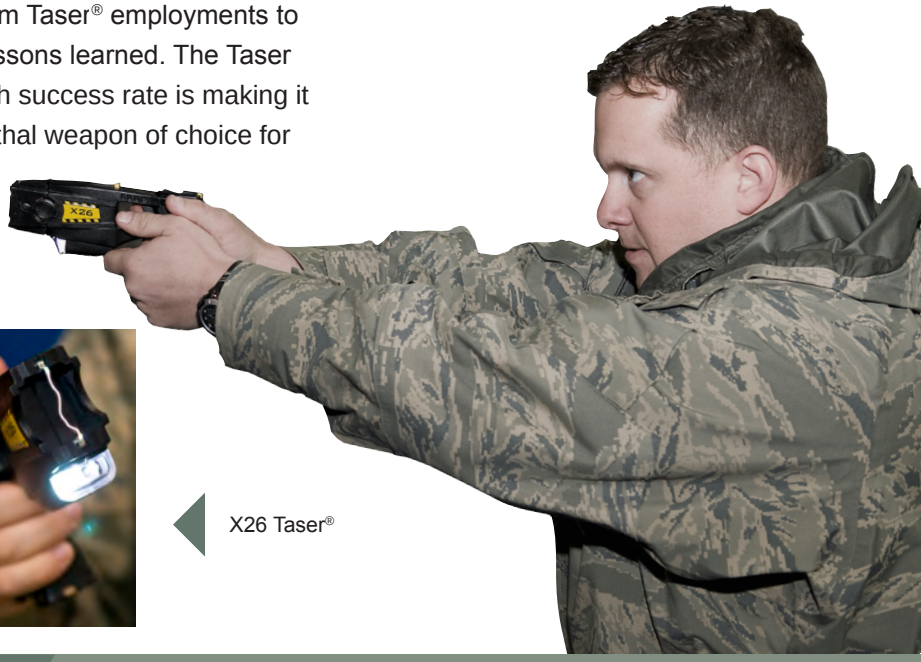
Throughout the past three years, the U.S. Air Force has employed the Taser X26® more than 15 times, all with positive results. During these incidences, the Taser X26® was credited with saving the lives of two individuals who were threatening suicide.

Headquarters Air Force Security Forces Center reviews all after-action reports from Taser® employments to capture lessons learned. The Taser X26's® high success rate is making it the non-lethal weapon of choice for U.S. Air Force Security Forces in a police services role.

The U.S. Air Force's Taser® training program follows the guidelines provided by TASER International, Inc. Lesson plans, study guides, volunteer exposure guidelines, and Taser® back-up responder duties and expectations are included in the Air Force's, electronic Tactics, Techniques and Procedure guides.

"The Taser® has proven to be one of security forces most successful fielding of a weapons system. Our Airmen are getting training, issued Tasers®, and using sound judgment when employing the devices. I review all the after-action reports for Taser® employment, and our folks are very confident of the Taser's® capabilities, and their skills due to our training program."

—Sal Hernandez
U.S. Air Force Chief,
Non-Lethal Weapons



X26 Taser®

FIELDED: OLEORESIN CAPSICUM SPRAY

USES: DETAINEE OPERATIONS | CROWD CONTROL

Oleoresin capsicum spray, known as OC or pepper spray, is a non-lethal aerosol spray made from peppers. It can incapacitate targeted individuals by irritating the eyes causing tears and visual impairment.

The need for OC spray is based on U.S. Air Force Security Forces requirements to protect resources and facilities, and to maintain stability in detention facilities. OC spray provides a force option to minimize fatalities, permanent injury, and undesired collateral damage to property and environment.

A Taser® flammability test was conducted by the Air Force Operational Test and Evaluation Center, to identify non-flammable OC sprays. The Air Force Research Laboratory and the Army's Edgewood Chemical Biological Center completed the characterization and health assessments of the physical and chemical properties. The joint testing efforts covered three variations of canisters (1-oz, 4-oz, and 46-oz) and has been approved by the Non-Nuclear Munitions Safety Board and Air Force Surgeon General. The U.S. Air Force anticipates final approval by end of 2012.

U.S. COAST GUARD HIGHLIGHTS

Rear Admiral Mark E. Butt
Joint Non-Lethal Integrated Product Team Representative

DEVELOPING: LA-51 WARNING DEVICE

USCGC SENECA (WMEC-906) participates in Operation New Frontier, the Coast Guard's operation to employ armed helicopters and non-lethal use of force technology to stop drug-laden go-fast vessels.

The U.S. Coast Guard's Service-wide approval of the LA-51 warning device in February 2012 has provided its operators with an enhanced capability to hail, warn, and determine intent in heavily populated and controlled U.S. ports. The Coast Guard is responsible for enforcing established security zones along the coastline and navigable waterways. When boaters get too close or illegally enter a zone, the Coast Guard will intercept the boat to determine its intent, and direct it to leave the area. The LA-51 is used to get a boater's attention if they are not obeying Coast Guard instructions to stop.

The LA-51 is considered an alternative to the current inventory of warning methods Coast Guard personnel use. The device has a short range, and its flash and noise are more prominent and safer than a splash in the water caused by an M-16 tracer round. The LA-51 is a plastic and aluminum projectile fired from a 12-gauge shotgun. It flies for approximately 100 meters, and ignites in mid-air, producing a bright flash and loud noise similar to that of a medium-sized firework. This warning device is not designed to strike or injure boaters or their vessels. It has little to no impact on the environment—an essential requirement for Coast Guard employment in U.S. waters.

The LA-51 has proved effective in its operational uses. The device gives both operational commanders and operators the confidence to employ the non-lethal capability when they need it during operations.

The Coast Guard plans to build on the device's success through its public outreach program, which incorporates the LA-51 into a larger, waterborne, security-zone awareness program. Along with increased public awareness, the LA-51 greatly enhances the Coast Guard's ability to conduct port, waterways and coastal security as well as counter-drug missions.

FIELDED: SMALL NAVAL ARRESTING ROPE ENTANGLER

USES: VESSEL PURSUIT MISSIONS

The Small Naval Arresting Rope Entangler, also known as SNARE, is a handheld, pneumatic launcher that propels a specially configured net in front of a vessel to entangle its propeller. The Coast Guard has been involved with SNARE's development since 2009, and has continued to test its effectiveness through extensive evaluations.

U.S. SPECIAL OPERATIONS COMMAND HIGHLIGHTS

EVALUATING: TACTICAL NETWORK TESTBED

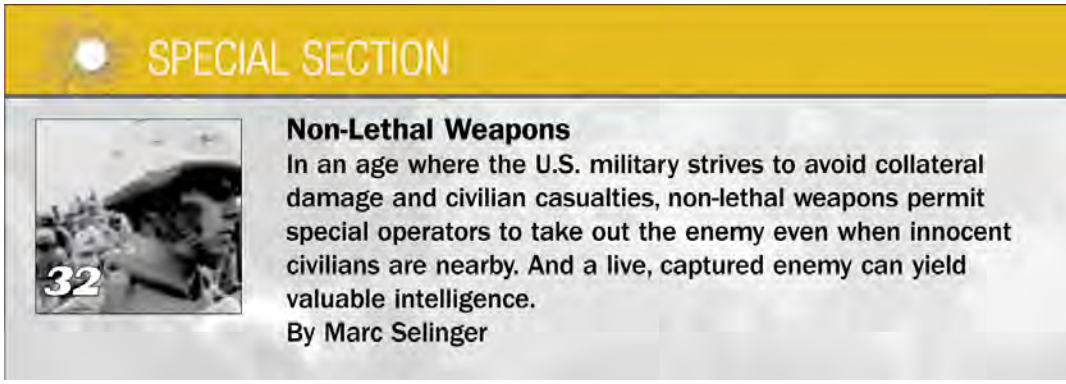
U.S. Special Operations Command conducted its third-quarterly Tactical Network Testbed this past May in cooperation with the Naval Postgraduate School at Camp Roberts, Calif. The theme for the testbed was weapons and munitions, and included experiments with multiple non-lethal weapons, munitions, and devices.

Testbed experiments are conducted with representatives from government research and development organizations, academia, and private industry. The experiments enable technology developers to interact with Special Operations Forces personnel to determine how their technology developments and ideas may support or enhance the command's capability needs, as well as potentially accelerate the delivery of needed technologies.

The Tactical Network Testbed included mission-based and capability-based experimentation events. Mission-based experimentation provides solutions to identified high-priority Special Operations Forces' mission needs. Capability-based experimentation provides technology developers an oppurtunity to identify potential technology solutions, impacts, limitations, and utility to meet the Special Operations Forces' technical objectives. Both types of experimentation involve evaluating selected technologies in expeditionary-like conditions. Technology developers conducted 51 experiments, nine of which were non-lethal weapons-related, during the ten-day testbed.

Special Operations warfighter tests non-lethal 40mm munition during the Tactical Network Testbed.

The "Non-Lethal Weapons" article is featured in the September 25, 2012 edition of the Special Operations Technology magazine.



The featured article focuses on the DoD Non-Lethal Weapons Program, and its engagement with industry. Reprinted with permission by Special Operations Technology magazine.

DEMONSTRATIONS & ASSESSMENTS

Sergeant Major of the Marine Corps Micheal P. Barrett reacts to the momentary heat from the Active Denial System.

Active Denial System

Marine Corps Base Quantico, Va.
March 2012

This year, General James F. Amos, Commandant of the U.S. Marine Corps, invited senior members of the Marine Corps, other Services and the news media to Marine Corps Base Quantico, Va., for a demonstration of the DoD Non-Lethal Weapons Program's Active Denial System.

The Active Denial System, known as ADS, is a non-lethal, counter-personnel technology that projects a long-range, man-sized beam of millimeter waves to produce a reversible heating sensation to the skin. The system's 95-gigahertz, millimeter-wave beam deters or repels individuals at a range of up to approximately 1,000 meters.

The demonstration provided attendees the opportunity to witness the effectiveness of the system in dispersing an unruly crowd during a staged angry mob scenario. Volunteers were also given the first-hand opportunity to experience the effects of the state-of-the-art technology.

Vehicle Stopping

Naval Surface Warfare Center Dahlgren, Va.
November 2011 & November 2012

Based on U.S. Marine Corps and Air Force interest, demonstrations of current and developing vehicle-stopping capabilities were held at the Naval Surface Warfare Center Dahlgren Division to solicit feedback, and facilitate a decision on a lead Service request for the Pre-emplaced Electric Vehicle Stopper. Representatives from Marine Expeditionary Forces and other interested parties witnessed the effectiveness of the Pre-emplaced Electric Vehicle Stopper, Radio-Frequency Vessel Stopper, Distributed Sound and Light Array, M2 Vehicle Lightweight Arresting Device, spike strips, and LA-9/P during the demonstrations. They also viewed a display of caltrops and the Vehicle Lightweight Arresting Device Single Net Solution with Remote Deployment Device.

As a result of these demonstrations, the Pre-emplaced Electric Vehicle Stopper and the Radio-Frequency Vehicle Stopper will be included in new Marine Corps analysis of alternatives to evaluate the initiative's potential technologies.

Soldiers employ a series of non-lethal devices, including warning munitions and optical distracters, at a traffic control point.

Vehicle Checkpoint Military Utility Assessment

U.S. Army's Maneuver Battle Laboratory Fort Benning, Ga.
April 2012

The DoD's Non-Lethal Weapons Program, supported by the Marine Corps Forces Pacific Experimentation Center, conducted a Military Utility Assessment at the U.S. Army's Maneuver Battle Laboratory at Fort Benning, Ga. This assessment was the first in a two-year long assessment program conducted at the direction of Congress to assess the utility and effectiveness of non-lethal weapons in a counter-insurgency environment.

Supported by the U.S. Army's Maneuver Center of Excellence and Soldiers from Fort Stewart, Ga., this evaluation used a scenario in which infantry Soldiers set up a hasty traffic control point and then stopped random vehicles as they approached. This was first done without the benefit of non-lethal systems and then conducted with them. The non-lethal capabilities employed included: LA-9/P optical distracter, Magnetic Acoustic Device, M2 Vehicle Lightweight Arresting Device, and Joint Non-Lethal Warning Munitions. The assessment found that integrating non-lethal weapons in the escalation-of-force continuum when conducting vehicle checkpoints dramatically improved mission effectiveness, including reducing the likelihood of civilian wounding and killings. Vehicles were also more likely to stop before lethal force was used and less likely to be damaged.

Foot Patrol Military Utility Assessment

Bellows Air Force Station, Hawaii
August 2012

Members of the 3rd Marine Regiment participated in an evaluation by the DoD Non-Lethal Weapons Program supported by the Marine Corps Forces Pacific Experimentation Center. This event was the second of two congressionally directed assessments conducted to help determine the utility and effectiveness of non-lethal weapons within a counterinsurgency environment. This assessment utilized an urban foot patrol scenario to measure and receive feedback on non-lethal capabilities.

Conducted at Marine Corps Training Area, Bellows Air Force Station, Hawaii, the event included classroom training, live fire, practical application exercises, and simulated scenarios. The evaluation demonstrated the usefulness of non-lethal weapons in protecting civilian populations, while maximizing U.S. force protection. Non-lethal weapons, devices and munitions used during the assessment included: GLARE® MOUT, FN-303® launcher, 40mm flash bang, 40mm foam baton, Modular Crowd Control Munition, X26 Taser®, SQ.200 Translation System, pepper spray, spike strips, and sting-ball grenades.

Enhancing the Marine's ability to conduct their assigned mission with the addition of selected non-lethal capabilities was demonstrated throughout the assessment. Of note was the measured reduction of civilian casualties by 33 percent, an increased standoff distance, and the advantage of eight additional levels or options of force escalation.

A role-player (right) throws simulated rocks at U.S. Marine Lance Corporal Tory Martin (left), during non-lethal weapons training in a simulated urban village.

INIWIC

Inter-Service Non-lethal Individual Weapons Instructor Course

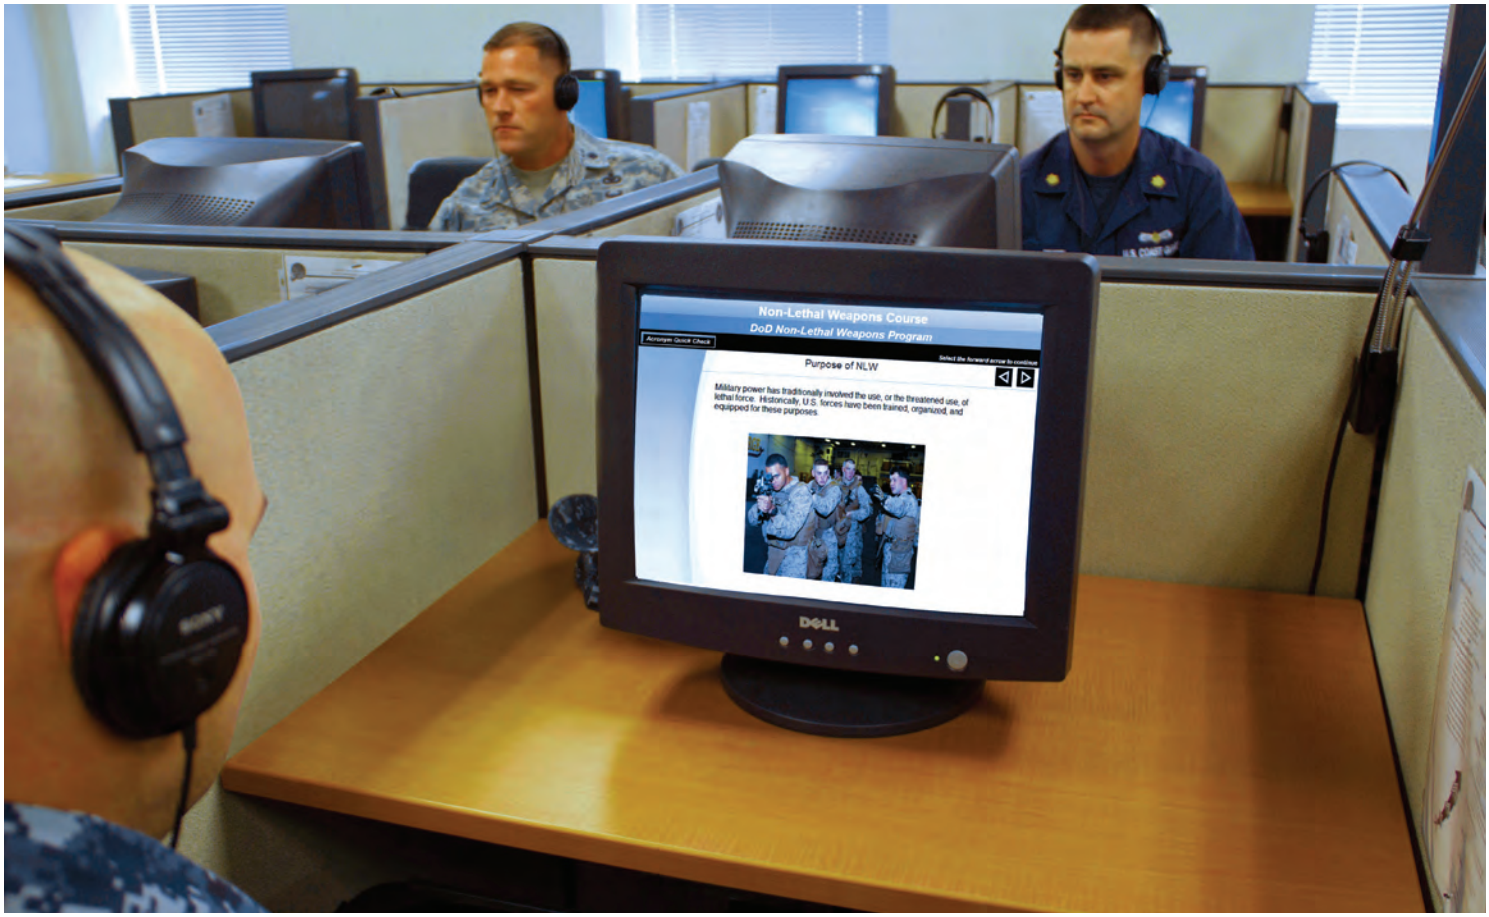
The Inter-service Non-lethal Individual Weapons Instructor Course, known as INIWIC, is the only DoD non-lethal weapons instructor course available to certify military personnel as non-lethal weapons instructors.

For more than 10 years, the rigorous, 10-day training program has prepared military personnel from Service branches,as well as allied nations, to become subject matter experts on non-lethal employment.

The in-depth training is conducted both at the training facilities at Fort Leonard Wood, Mo., and by mobile training teams. Course content focuses on introducing the future instructors to non-lethal weapon systems and equipment. Training consists of tactics, techniques, and procedures for the employment of the X26 Taser®, oleoresin capsicum spray (also known as pepper spray), acoustic hailing and ocular devices, expandable batons, and non-lethal munitions. Topics also include force continuum, riot control formations and techniques, crowd dynamics and control, open-hand control techniques, and communication skills.

Completion of the training enables the newly certified instructors to become subject matter experts for their parent commands, training other unit personnel on the employment of non-lethal capabilities in a diverse range of challenging missions. Such missions include counterpiracy, counterinsurgency, stability, security transition, peacekeeping, humanitarian, and reconstruction operations. The skills attained from the practical experience and thorough instruction at the INIWIC has a force multiplier effect that is applicable to all operating forces. Despite INIWIC's success, U.S. combatant commands have sought to further expand the availability of non-lethal weapons training, though progress has been slow.

The demand for U.S. forces trained and equipped with non-lethal weapons continues to increase. Venues for non-lethal weapons training, in addition to INIWIC, continues to be explored.



ONLINE COURSE

Introduction to Non-Lethal Weapons

This year, the Joint Non-Lethal Weapons Directorate launched a new non-lethal weapons online course. The Introduction to Non-Lethal Weapons Course provides U.S. operating forces with basic knowledge of non-lethal weapons' characteristics, employment, policy, and their applications in a wide variety of military operations.

The approximately four-hour course consists of nine modules and concludes with an exam. The modules' content includes history; strategic impacts; tactical employment; escalation of force; counter-personnel and counter-materiel capabilities; fielded and future non-lethal weapons, munitions and devices; characteristics and usage; and operational vignettes. Available on Joint Knowledge Online, the U.S. Navy's eLearning site and the U.S. Marine Corps' Marine. Net, the course provides worldwide access to instruction. The course requires access via a Common Access Card for active and reserve U.S. Navy, U.S. Marine Corps, and U.S. Coast Guard personnel, as well as Department of the Navy civilians and contractors. U.S. Army and U.S. Air Force personnel can also access the website; however, they must request a Navy eLearning account or a site sponsor. The DoD Non-Lethal Weapons Program is in the process of locating the course on all the Services' Learning Management Systems.

JOINT NON-LETHAL WEAPONS DIRECTORATE-SPONSORED ELECTIVES

The course, titled Non-Lethal Weapons: Support to Irregular Warfare, Complex and Defense Support Civilian Authorities, is taught by The Pennsylvania State University.

- **U.S. Army War College**
  Carlisle, Pa.
- **U.S. Army Command and General Staff College**
  Fort Leavenworth, Kan.
- **U.S. Marine Corps Command and Staff College**
  Marine Corps Base Quantico, Va.
- **U.S. Naval War College**
  Newport, R.I.
- **Air War College**
  Maxwell Air Force Base, Ala.
- **National Defense University's The Dwight D. Eisenhower School for National Security and Resource**
  Fort Leslie J. McNair, Washington, D.C.

UNIFIED COMMANDS

U.S. AFRICA COMMAND

U.S. Marine Corps Forces Africa conducted joint exercise Western Accord 12, in Thies, Senegal, in July 2012. This exercise was a multi-week, multi-lateral training event conducted with the Economic Community of West African States to increase understanding and interoperability, prevent conflict by enabling Africans to provide for their own stability and security, support U.S. national security priorities, and strengthen partner nation relationships.

2012 was the first year non-lethal weapons training was part of exercise Western Accord. Multi-national, infantry battalions preparing for deployments trained on tactics, techniques, and procedures to employ non-lethal capabilities in support of peacekeeping operations and disaster response scenarios.

U.S. TRANSPORTATION COMMAND

Exercise Point Defender, a U.S. Army Surface Distribution and Deployment Command, anti-terrorism exercise was held at Military Ocean Terminal, Sunny Point, N.C., included non-lethal weapons for the first time this year. The Distributed Sound and Light Array, also known as DSLA, was the primary non-lethal system in four different scenarios used during the exercise. Scenarios included using audio to hail and warn trespassers, locating and engaging individuals eluding police, stopping vehicles approaching the gate, and providing optical distraction against targets hiding inside a building. In addition, base personnel witnessed a DSLA demonstration. Other events included FN-303® Launcher and PepperBall® gun familiarizations, and training for the Special Response Team.

U.S. CENTRAL COMMAND

Recent escalation-of-force incidents have highlighted the need for greater U.S. Central Command and supporting Services pre-deployment training. Based on lessons learned, the command is working in partnership with the Joint Chiefs of Staff Directorate for Joint Force Development to assess the Services' training center capabilities for non-lethal weapons. Specifically, they are assessing how each Service conducts their non-lethal weapons escalation-of-force capability training. They anticipate the assessment results will increase the proficient employment of non-lethal capabilities, significantly reducing civilian causalities.

U.S. PACIFIC COMMAND

Cobra Gold, the U.S.'s largest, multilateral exercise in the Asia-Pacific region, included approximately 13,000 Service members from seven participating countries along with military personnel from another 20 countries. This year's annual training included a computer-simulated, command-post exercise, field-training operations, as well as humanitarian and civic-assistance projects.

Non-lethal weapons familiarization live-fire events enhanced the field training. Cobra Gold 12 was the first time any non-lethal weapons were fired during the non-combatant evacuation operations training. Another familiarization fire was conducted with U.S. Army and Thai Army units conducting crowd-control training. These experiences helped participants see how non-lethal capabilities can help control crowds, especially those that may occur in an emergency evacuation.

U.S. NORTHERN COMMAND

Within its missions of homeland defense, civil support, and security cooperation, U.S. Northern Command recognizes the strategic and operational value of non-lethal weapons in avoiding civilian causalities. In support of these objectives, the command held its first-ever, non-lethal weapon training exercise with federal and state interagency partners, and DoD component members. Participants in this one-day event exchanged ideas and gained insights into non-lethal weapons concepts for operators and planners. This interactive participation resulted in lessons-learned documentation that will be applied to U.S. Northern Command strategic planning objectives.

General Carter F. Ham, Commander of U.S. Africa Command, watches a riot-control demonstration during his visit to Western Accord 12.

U.S. EUROPEAN COMMAND

U.S. European Command, along with a team of experts from the DoD Non-Lethal Weapons Program and NATO Allied Command Transformation, developed tactics, techniques, and procedures, or TTP, to address obstacle clearing with non-lethal weapons. The focus of these TTP was to maximize effect by the combined use of currently fielded non-lethal capabilities. The TTP were first exercised using DoD warfare simulation models. Next, they were tested during a field experiment with Soldiers from the Joint Multinational Readiness Center in Hohenfels, Germany. These activities enabled the Command to incorporate feedback, and resulted in an executable set of TTP, which move the use of non-lethal weapons beyond force protection into force application.

U.S. and Thai military police participate in a non-lethal familiarization fire during Cobra Gold 12.

At exercise Point Defender, the Distrubuted Sound and Light Array distracts suspects eluding police during a hostage-rescue scenario.

U.S. SOUTHERN COMMAND

U.S. Naval Forces Southern Command directed exercise Southern Partnership Station 2012 with the goals of enhancing cooperative partnerships and improving operational readiness. The exercise, which is a series of U.S. Navy deployments, involved U.S. military teams working with Caribbean, and Central and South American militaries and civilian security forces. As part of the exercise, U.S. Marines from High Speed Vessel 2 Swift collaborated with United Nations Police to conduct non-lethal weapons training with the Haitian National Police. The training included classroom and practical exercises on crowd control and the escalation of force. The focus of the event's training, military engagements, and community relations projects was to enhance regional stability and security.

European Combatant Command Liaison Officer demonstrates the proper set-up and operation of a Long Range Acoustic Device.

U.S. Senate Armed Service Committee professional staff members gain first-hand experience with non-lethal weapons during a range day this fall at Marine Corps Base Quantico, Va.

CONGRESSIONAL ENGAGEMENTS

Lieutenant General Richard P. Mills, Commanding General, Marine Corps Combat Development Command, looks on as U.S. House Majority Leader Eric I. Cantor is briefed on DoD non-lethal technologies, including the millimeter wave Active Denial Technology, by Susan LeVine, Principal Deputy, Joint Non-Lethal Weapons Directorate, Quantico, Va. Lieutenant General Mills also provided insight on the Marine Corps' research and development efforts.

Throughout the year, the Joint Non-Lethal Weapons Directorate continued its outreach efforts to educate various stakeholders about the unique attributes and role of non-lethal weapons, and how their capabilities support U.S. military strategy and military commander's operational requirements. The Directorate's ongoing engagements with Congress helps ensure that legislators have current information on the status of the DoD Non-Lethal Weapons Program. This is particularly important as Congress continues to express interest in existing and promising non-lethal capabilities, including Active Denial Technology. In coordination with DoD and Service legislative affairs offices, the Joint Non-Lethal Weapons Directorate—as the Executive Agent's focal point for DoD's non-lethal weapons activities—briefed members of Congress at the Directed Energy to DC (DE2DC) Exhibition event held in the Rayburn House Office Building in Washington, D.C., March 2012. The Directed Energy Professional Society organized the event under the sponsorship and support of the Congressional Directed Energy Caucus and the High Energy Laser-Joint Technology Office. The Joint Non-Lethal Weapons Directorate hosted professional staff members from the U.S. House and Senate Armed Services Committees in August and September 2012 for a series of DoD Non-Lethal Weapons Program briefings and demonstrations. In December 2012, the Joint Non-Lethal Weapons Directorate, in coordination with the Marine Corps Warfighting Laboratory, hosted U.S. House Majority Leader Eric I. Cantor and Virginia State Senator Bryce E. Reeves who visited Marine Corps Base Quantico, Va., to learn about the wide range of technologies the two organizations are exploring.

COLLABORATION

A few vehicles approach a checkpoint, which is clearly marked with dual-language signs directing drivers to slow down and to follow directions. As a checkpoint guard, you see a van coming toward you that is not obeying signs or slowing down...

What do you do? Whether it is a military checkpoint, a border crossing, or an entrance to a public venue, military personnel, government agents, and law enforcement officers must routinely determine whether to use lethal force in response to an individual's suspicious behavior. Such similar missions result in comparable non-lethal capabilities requirements for the DoD Non-Lethal Weapons Program and other government agencies. Because of these shared requirements, the Program seeks ways to collaborate with these government agencies on research and development efforts to leverage and maximize overall efficiency and cost-effectiveness.

The **Joint Improvised Explosive Device Defeat Organization** in conjunction with the U.S. Army is developing the Vehicle Borne Improvised Explosive Device System of Systems, which will be an integrated, multi-modal sensing system for use at entry control points and critical points of entry. This effort will evaluate the DoD Non-Lethal Weapons Program's Pre-Emplaced Vehicle Stopper prototype, developed by the Naval Surface Warfare Center, Dahlgren Division. The Pre-Emplaced Vehicle Stopper is a non-intrusive device that provides an electrical pulse through deployed contacts, to shut down power train electrical circuits or components.

A vehicle approaches the Pre-Emplaced Vehicle Stopper.

Engagements WITH Academia

The DoD Non-Lethal Weapons Program values its interaction with industry and academia in conceptualizing and developing state-of-the-art, non-lethal capabilities. The Program engages academic basic science and engineering researchers, product developers, manufacturers, industry representatives, and other government agencies to develop non-lethal, counter-personnel and counter-materiel solutions for our military's requirements.

Working with academic institutions provides the Program with many benefits, including their ability to take a concept and elevate it to a higher technology readiness level for transition to a government laboratory.

The Pennsylvania State University is spearheading the Program's effort to stimulate academic research in next-generation non-lethal weapon technologies. The University plans to nominate five high-priority, non-lethal weapon technology areas and work with academic institutions that are recognized as leaders in these fields. The first of these five technology areas is non-lethal laser induced plasma effects with **the University of Colorado-Boulder**, **the University of Texas at Austin**, and **the University of Arizona**. Nanosecond electrical pulse work with **Old Dominion University** is the second technology effort. The remaining three efforts are under review.

Other academic institutions that recently have worked with the Program in advancing the state-of-the-art non-lethal technologies include:

- **University of California-Davis**
- **University of Maryland**
- **University of Mississippi**
- **University of Missouri**
- **University of New Mexico**

University of New Mexico Research Park

University of California-Davis Millimeter-Wave Research Center

Old Dominion University Innovation Research Park

& Industry

Considerable efforts are being made to bring government and industry together to discuss opportunities in U.S. DoD non-lethal weapons development. The Joint Non-Lethal Weapons Directorate facilitates industry interface through several venues which include: onsite visits by the JNLWD Director and staff; hosting annual industry interface meetings; Advanced Planning Briefs to Industry; and Bi-Annual Joint Integration Program's Non-Lethal Weapons Symposiums and Range Demonstrations.

In June, the Joint Non-Lethal Weapons Directorate hosted a JNLWD Research and Technology Development Non-Lethal Weapons Industry Day at Quantico, Va. Program objectives, technical briefs, a planned business approach, projected schedules, and a selection of responses to posted requests for information were presented. The day-long event drew more than 100 members of industry and academia and provided a forum for industry to learn about and discuss non-lethal weapons research and technology development opportunities. All presentations are available and posted at: http://jnlwp.defense.gov.

Annual industry interface meetings at the Joint Non-Lethal Weapons Directorate are typically scheduled when a manufacturer is scheduled to be in the Washington, D.C. area while on other business. The Directorate's staff facilitates appropriate participation from the Directorate and Service representatives.

During 2012, the Directorate conducted approximately 25 industry interfaces. The Joint Non-Lethal Weapons Directorate teamed with the National Defense Industrial Association's (NDIA) Joint Armaments Conference in Seattle for Non-Lethal Weapons Advanced Planning Briefs. Addressed were requirements for the Directorate's Annual Science and Technology Broad Agency Announcement, as well as programmatic presentations from the Airburst Non-Lethal Munition, Spider Non-Lethal Launcher and Improved Flash Bang Grenade Program Managers. The Joint Non-Lethal Weapons Directorate plans to continue this alliance during May 2013 in Indianapolis, to include government Advanced Planning Briefs to Industry, a human effects tutorial and industry perspective briefings.

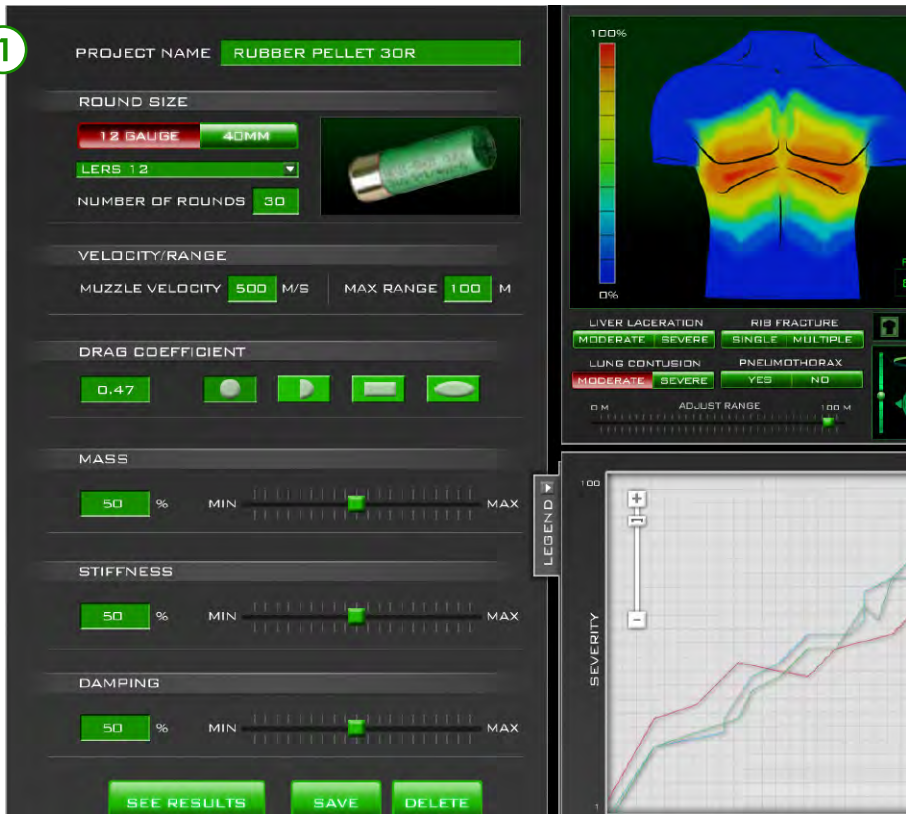
The Joint Integration Program's Non-Lethal Weapons Symposiums and Range Demonstrations allow for the non-lethal weapons industrial base to communicate with non-lethal weapons combat developers (requirements writers), material developers (project / program managers), and testers and evaluators. Also in attendance are warfighters who are either rotating in or recently rotated out of the current theatres of operation. The next event is planned for August 2013 in Harpers Ferry, W. Va. For more information about the DoD Non-Lethal Weapons Program and opportunities to help develop critically needed non-lethal technologies, visit: http://jnlwp.defense.gov.

SOLICITATIONS

The DoD Non-Lethal Weapons Program appreciates organizations that are interested in furthering the development of the next generation of non-lethal weapons, devices, and munitions.

Visit http://jnlwp.defense.gov/solicitations/default.html for lists of current non-lethal capability solicitations, and links to U.S. government federal business and procurement opportunities related to non-lethal weapons.

The Special Operations Forces Industry Conference, in Tampa, Fla., provided military and defense industry representatives an opportunity to discuss non-lethal, and a broad range of other, technological solutions to U.S. forces' capability requirements.



This human effects modeling tool illustrates an assessment of a non-lethal, blunt-impact munition.

1. Adjustable parameters of a blunt-impact munition
2. Visual depiction of the risk of injury to a body region
3. Graphic depiction of the risk of injury as related to ranges

HUMAN EFFECTS

What are Non-Lethal Weapons Human Effects?

Non-lethal human effects are the physiological and behavioral responses produced by non-lethal weapons. Understanding human effects is paramount in the development of non-lethal weapons, as they are often a major driver of non-lethal weapons research and technology development.

Human Effects Characterization Process

Department of Defense Instruction 3200.19, signed May 17, 2012, describes the procedures for human effects characterization in support of non-lethal weapons development. Generally, there are two goals of human effects characterization: determining both the effectiveness and risk of significant injury for non-lethal weapon stimuli. Often, focused research and analysis are required to ensure that the effectiveness and risk of significant injury of a given non-lethal weapon is well understood. A standard metric associated with the human effects characterization process is the Human Effects Readiness Level. Similar to technology readiness levels, which provide an assessment of the technology's maturity, the Human Effects Readiness Levels provide a measure of the availability, sufficiency, and maturity of data and information of the human effects.

Role of Modeling and Simulation

Modeling and simulation plays an important role in the human effects characterization process. Basic and applied human effects research are used to develop conceptual models of the underlying interactions between non-lethal stimuli and the human body. These conceptual models can then be transitioned to computational models and/or instrumented test targets where simulations can then be performed. Often, a large set of validated data are required to ensure that models and simulations of non-lethal stimuli accurately represent the human effects and predict outcomes. However, once in place, these modeling and simulation capabilities can reduce development cycle time and cost, and allow for larger exploration of the weapon design parameters.

To carry out the mission of developing high-quality modeling and simulation capabilities, the DoD Non-Lethal Weapons Program has developed the Human Effects Modeling and Analysis Program. This effort, led by the U.S. Air Force Research Lab's Human Effects Center of Excellence at Fort Sam Houston, Texas, entails a suite of modeling and simulation tools that can be used to characterize the effects and effectiveness of non-lethal stimuli, including light, impulse noise, heat, blunt-impact, and blast pressure. Modeling efforts are currently underway for additional non-lethal stimuli, which will eventually be added the Human Effects Modeling and Analysis Program modeling suite.

NATO's North Atlantic Council identified non-lethal weapons as a critical, additional capability needed to meet the demands of future operations. Interest has increased further as a result of counterinsurgency experience in Afghanistan, peace support operations in the Balkans, and anti-piracy efforts off of the Horn of Africa. Operational experience drives NATO's non-lethal weapons activities. Two such activities are the System Analysis and Studies-094, known as SAS-094, and the Defense Against Terrorism workshop held in conjunction with Counter Terror Expo 2012.

NATO SUPPORTS NON-LETHAL WEAPONS CONCEPT DEVELOPMENT AND EXPERIMENTATION

SAS-094 is providing analytical support for the development and experimentation of NATO and national concepts. SAS-094's work builds on the recently completed NATO Non-Lethal Weapons Capabilities-Based Assessment (known as SAS-078) that identified and characterized NATO's requirements, capability gaps, and potential solutions. SAS-094 has military and technical experts from 10 nations and three NATO organizations addressing:

- **Non-Lethal Weapons Usage —** Examining military and law enforcement uses, NATO and national operational experience, lessons learned, and the role of non-lethal weapons in delivering effects
- **Simulation and Analysis Tools** — Identifying appropriate candidates, comparing their relevance, and assessing the ability to support non-lethal weapons concept experimentation
- **Concept Discovery** — Assessing existing concepts and the future security environment (particularly adversary capabilities and concepts) to identify non-lethal weapons implication
- **Concept Development —** Conducting a workshop to examine a wide range of scenarios, missions, situations, and non-lethal weapon roles to support concept development
- **Concept Experimentation —** Preparing, conducting, and analyzing results from wargames, modeling and simulation, and/or field experiments to assess and refine concepts

NATO's System Analysis and Studies Panel is actively highlighting SAS-094's work. The Panel selected SAS-094 for inclusion in the August 2012 International Symposium on Military Operational Research and the September 2012 Science and Technology Board Symposium on Urban Operations Technologies.

DEFENCE AGAINST TERRORISM WORKSHOP

NATO held its Defence Against Terrorism, or DAT, workshop in conjunction with Counter Terror Expo 2012. The workshop provided an opportunity for DAT's 10 initiatives to report on their status and future plans. Of the 10 initiatives, one known as DAT-11 is on non-lethal capabilities. DAT-11 reported on multiple technology demonstrations (culminating in the October 2011 North American Technology Demonstration), analysis of capabilities relevant to the International Security Assistance Force in Afghanistan, and plans for a new initiative that will begin in December 2012. Of note, most DAT initiatives (specifically those on: Protection of Harbors and Ports; Force Protection/Survivability; Chemical, Biological, Radiological, Nuclear and High-Yield Explosives; Countering Improvised Explosive Devices; Explosive Ordnance Disposal/Consequence Management; and Intelligence, Surveillance, Reconnaissance and Target Acquisition) made direct mention of non-lethal weapons requirements and technologies.

The broader Counter Terror Expo 2012 event drew a record 8,500 members of the global counter-terror community to London in April. Four hundred companies displayed a diverse range of technologies, including non-lethal weapons such as the Long Range Acoustic Device®, blunt-impact munitions, and barrier systems. National defense and security officials, international policy makers, and industrial representatives gave formal presentations, and 12 technical workshops (including the DAT workshop) were held.

MISCONCEPTIONS vs. FACTS

Non-lethal weapons are "niche" capabilities primarily associated with force protection.

Non-lethal weapons can play a critical role in force application and force protection. These broad-based non-lethal technologies fill gaps in the escalation of force in between "shouting and shooting" in the complex missions our Service members face, from peacekeeping and humanitarian scenarios to full-scale combat operations. Non-lethal weapons allow a commander to elevate or decrease his response to a suspected target as the situation changes.

The Active Denial System is a "pain ray."

The Active Denial System, known as ADS, is not a "pain ray." The ADS is a non-lethal directed-energy weapon that provides a quick and reversible heating sensation. The sensation immediately ceases when the individual moves out of the beam.

Non-lethal weapons have legal issues.

Any new weapon the DoD develops is required to undergo a thorough legal, treaty and arms control compliance review prior to fielding. Non-lethal weapons are no exception. All previously and currently fielded non-lethal weapons have undergone legal reviews to ensure consistency with domestic law, and compliance with obligations assumed by the U.S. under applicable treaties, customary international law, and the law of armed conflict.

Non-lethal weapons can replace lethal weapons.

Non-lethal weapons are not a substitute for the application of lethal force. When employed, non-lethal weapons are always backed by lethal means. As an adjunct to lethal force, however, they can be a powerful addition to the warfighter's toolkit.

NON-LETHAL WEAPONS ARE ALWAYS BACKED BY LETHAL FORCE

A U.S. Marine from the ground combat element for Security Cooperation Task Africa Partnership Station 12, loads a 12 gauge sock round into his pump action shotgun during non-lethal weapons training aboard Stone Bay, N.C., April 23, 2012. This training is part of APS-12's special operations capabilities certification in support of their upcoming deployment to Africa.

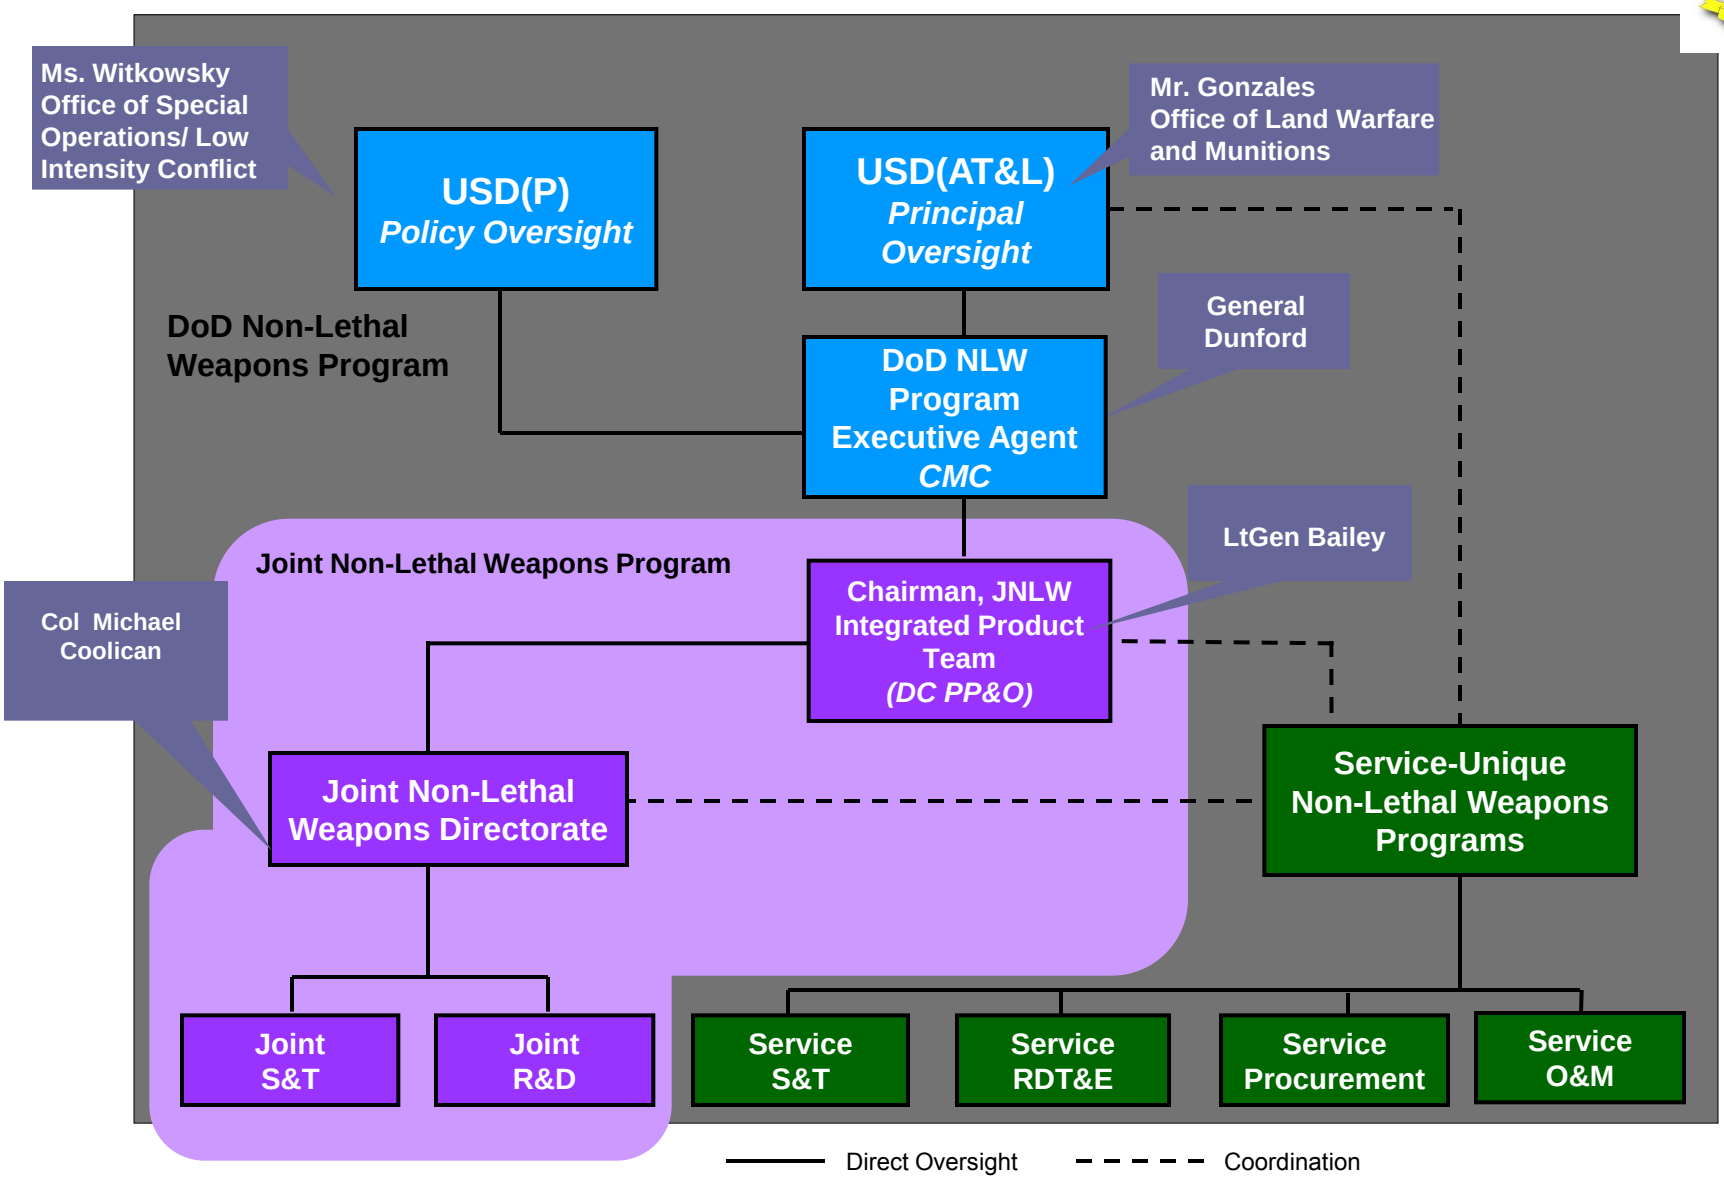
DoD NLW Program Organization



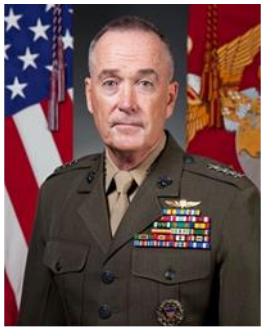
DoD Non-Lethal Weapons Program

DoD NLW Program Established 1996

- Operation United Shield (Somalia): General Anthony C. Zinni pioneered use of NLW
- FY96 National Defense Authorization Act directed DoD to centralize responsibility for NLW

Program Highlights

- CMC designated Executive Agent
- Joint S&T / RDT&E funding
- Services responsible for NLW procurement



General Joseph F. Dunford, Jr. Commandant of the U.S. Marine Corps

Vision

"A fully integrated non-lethal competency within each Service, to complement lethal effects, enhance the Joint Force's adaptability, and support strategic objectives that include minimizing civilian casualties"

Non-Lethal Weapons

- Provide escalation-of-force options
- Minimize civilian casualties
- Reduce collateral damage

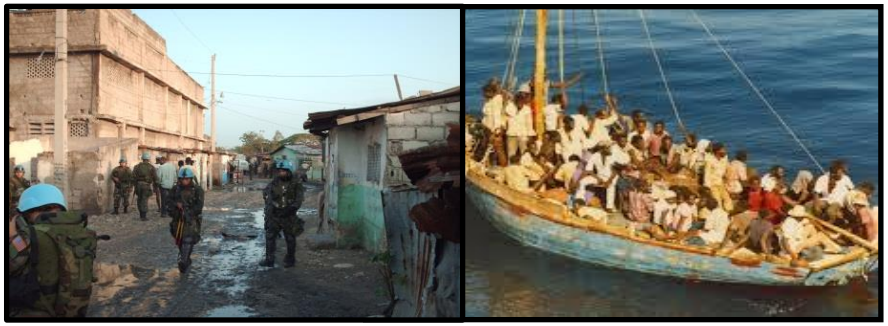
Non-Lethal capabilities assist operating forces in minimizing civilian casualties and collateral damage

NLW Utility in Contemporary Operations 1996 to Present

United Shield – Somalia

Bosnia and Kosovo

Haiti



OIF and OEF

Reverting Back to the "New Normal"

Fielded Non-Lethal Weapons, Munitions& Devices

- Acoustic Hailing Devices
  - Procured by USA, USMC, USN, USAF, USCG
  - Discriminating hail and warn capabilities, up to 300+ m

Acoustic Hailing Devices

- Optical Distraction Devices (Dazzling Lasers)
  - Procured by USA, USMC, USAF, USN, SOCOM
  - Warn/dissuade pedestrians, vehicle drivers
  - Range: 150 + meters (day); 2000+ meters (night)

Optical Distractors

- Non-Lethal Grenades
  - Procured by USA, USMC, USAF, SOCOM

Flash Bang Grenades

Stingball Grenades & Launch Cups

- Blunt Impact Munitions
  - Procured by USA, USMC, USAF

Blunt Impact Munitions

- Modular Crowd Control Munitions
  - Procured by USA

Modular Crowd Control Munitions

Fielded Non-Lethal Weapons, Munitions& Devices (cont.)

- ***40mm & 12 Ga Joint Non-Lethal Warning Munitions***
  - *"Flash Bang" warning shots at 100, 200 or 300 meters*
  - Originally procured by USN; USMC, USCG now obtaining
- **X26 TASER**
  - Effective range 0-35 feet
  - Procured by USA, USAF; Authorized for USMC procurement
- **Portable Vehicle Arresting Barrier**
  - Can stop a 7500lb vehicle moving at 45 mph
  - Procured by USA
- **Vehicle Lightweight Arresting Device M2 Net**
  - Can stop a 5500lb vehicle moving at 30 mph
  - Procured by USA, USMC
- **Other Non-Lethal Devices**
  - Caltrops, Spike strips
  - Pen flares, riot control agent dispensers

Joint Non-Lethal Warning Munitions

X26 Taser

Vehicle Lightweight Arresting Device M2 Net

Portable Vehicle Arresting Barrier

Pen Flares

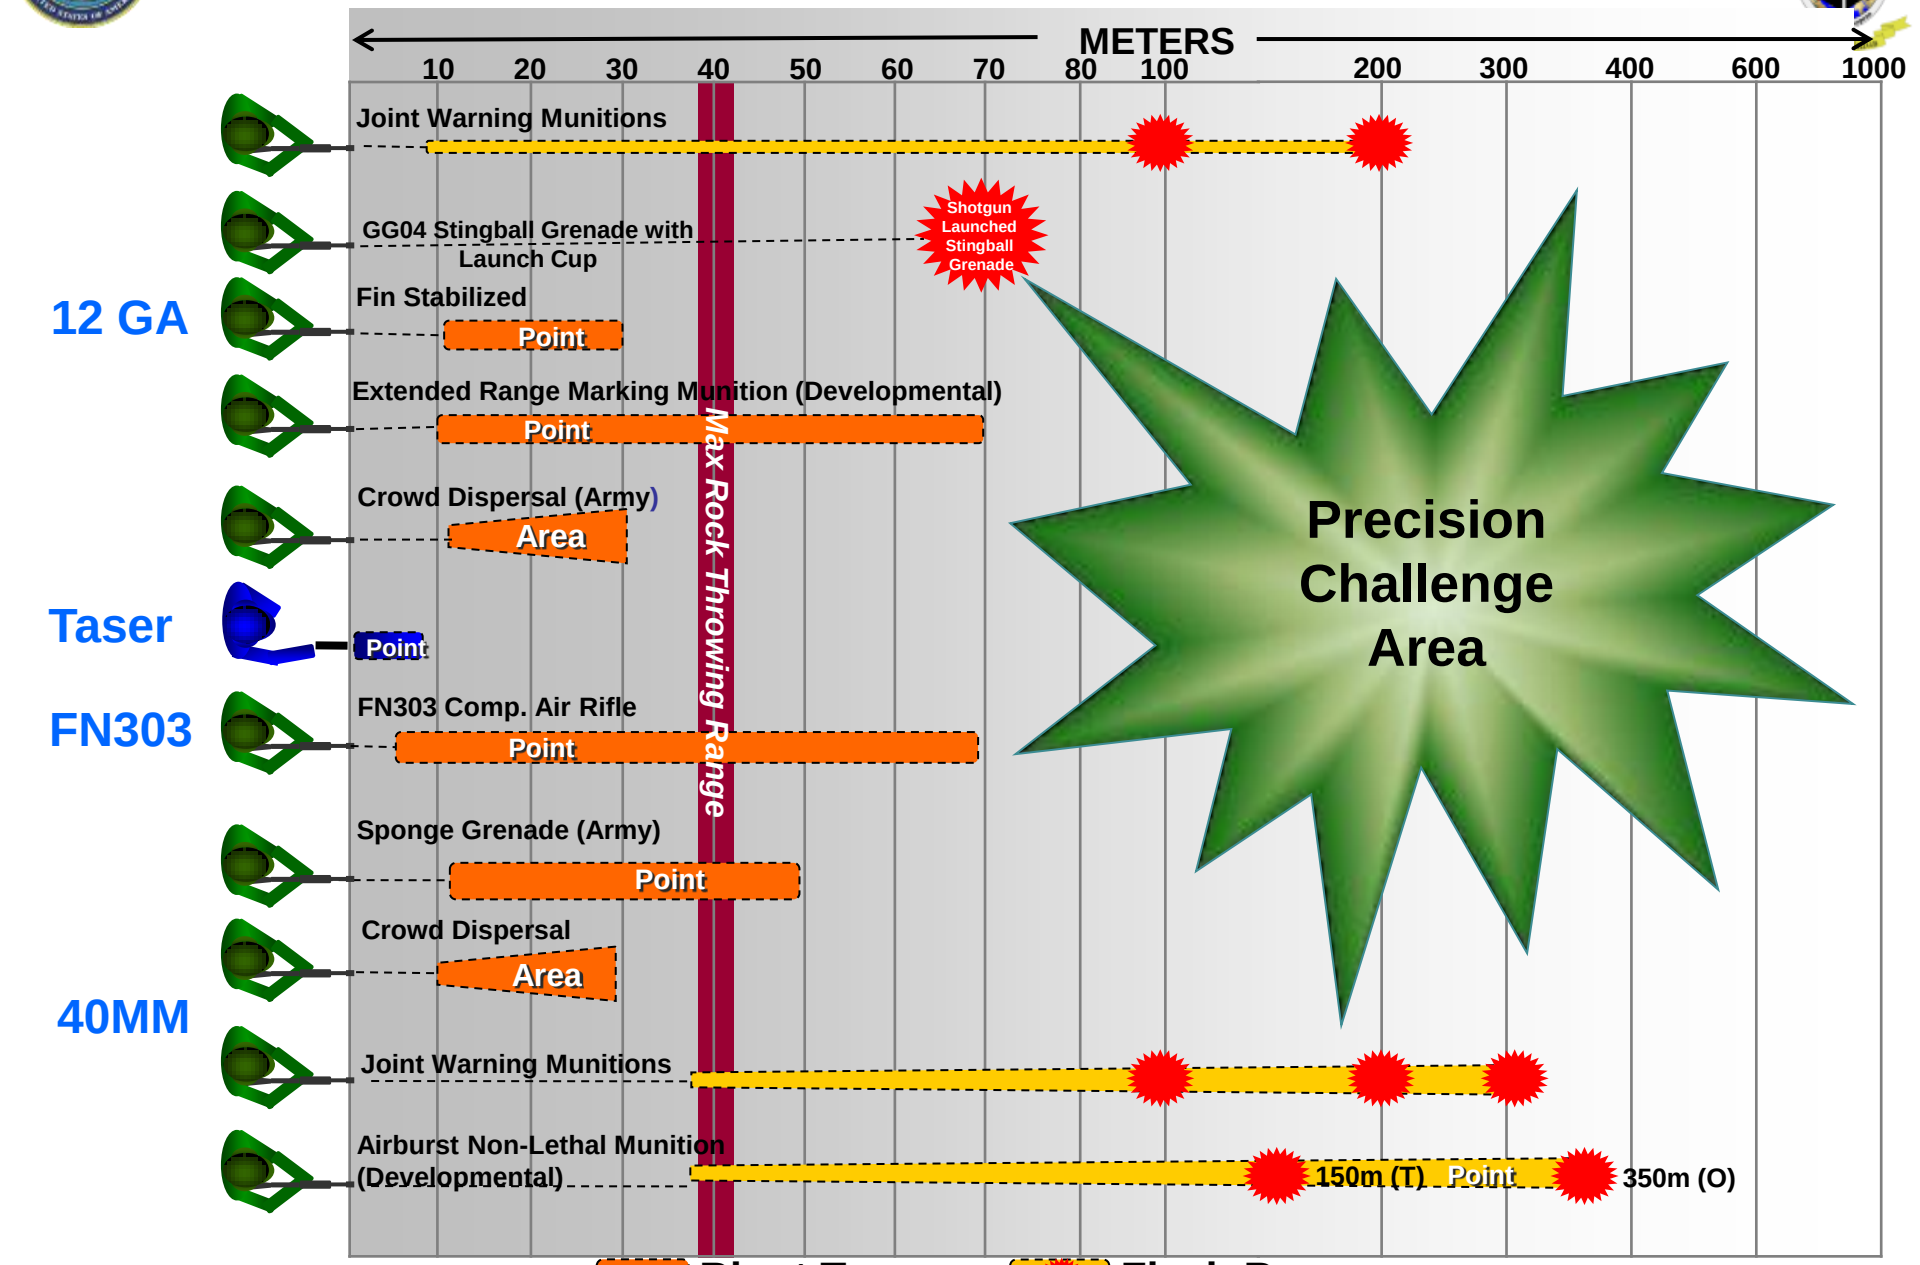
Fielded Non-Lethal Weapons, Munitions& Devices (cont.)

Capability Sets/Escalation-of-Force Mission Modules

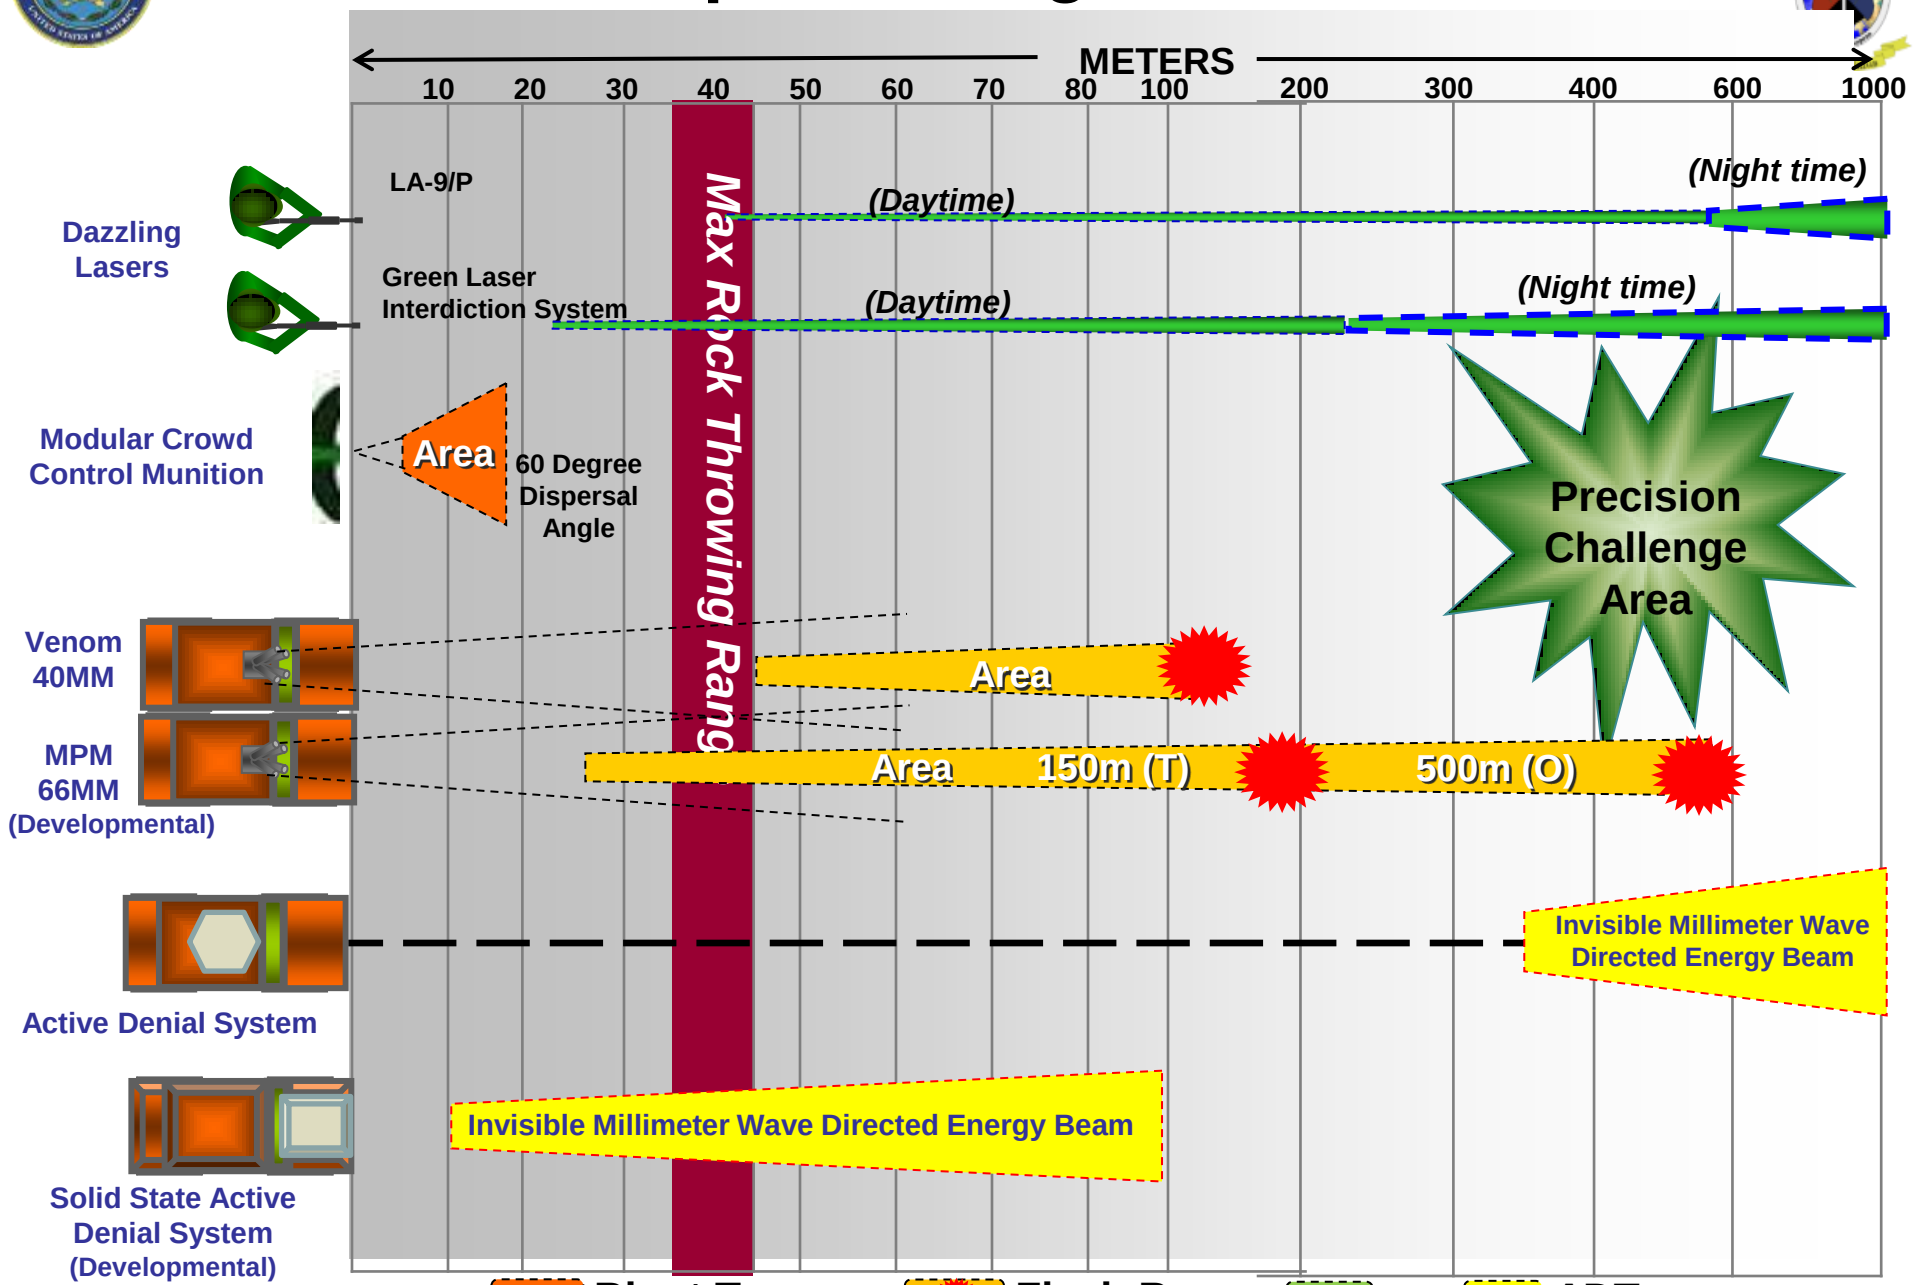
- Procurement and Maintenance funding for non-lethal weapons is the responsibility of the Services (Title 10)
- The Army, Marine Corps, Air Force and National Guard Bureau have procured non-lethal capability sets/escalation of force mission modules; maintenance responsibilities vary among Services (e.g., Army requires individual units to maintain sets)

NLCS/EoF MM applications include checkpoint, convoy, detention and crowd control.

NL Weapons Range Overview



NL Weapons Range Overview



Near-Term/Quick Wins

Airburst Non-Lethal Munition

- 40 mm round for use in systems as the M203 grenade launcher
- Has a fuel enriched pyrotechnic payload, proximity airburst and selectable delay option fuse
- Designed to deny access into/out of an area to individuals, move individuals through and area and suppress individuals
- Potential to support multiple missions:
  - Force protection
  - Room Clearing/denial
  - Crowd control
  - Offensive and defensive operations

Increase Duration, Non-Kinetic

Near-Term/Quick Wins

- Commercial/Non-Developmental Item
- Fills the requirement for a non-damaging dazzling laser
- Employed during the escalation-of-force continuum to deliver a glare effect to warn and/or suppress targeted personnel from 10 meters to 500 meters

Ocular Interrupter

Improved Flash-Bang Grenade

- Greater light output and duration
- Improved environmental, health, and safety compliance
- Used as a counter-personnel tool to move/deny/suppress individuals in breaching and/or other non-lethal force operations

- Focused on a commercial solution
- Flash bang / diversionary grenade that has the capability to bang multiple times within an area to serve as a diversion / distraction

Multi-Bang Flash-Bang Grenade

Increase Duration, Non-Kinetic

Mid-Term/Big Win

Mission Payload Module

- The Mission Payload Module - Non-Lethal Weapons System is a game-changing, non-lethal counter-personnel weapon system that provides both force-application and force-protection capabilities.

- The MPM-NLWS consists of an advanced, suppressive 66 mm munition, launcher and laser sighting system with:
  - extended range (30-500 meters)
  - high volume of fire & capability to transition from non-lethal to lethal engagements within seconds
  - shoot on the move capability
  - vehicle, vessel or ground-mounted/tripod mounted tube launcher

Increase Range, Kinetic/Non-Kinetic

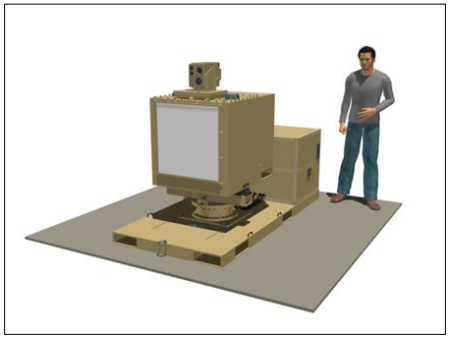
Active Denial Technology

Active Denial System

- Advanced Concept Technology Demonstrator
- Proven Effects – 95 GHz effects
- Effective at long-ranges

Compact ADT

- Demonstrate the same effectiveness in an operationally suitable configuration
- Develop a compact, lightweight second harmonic Gyrotron with a room temperature electropermagnet



Solid State (SS) ADT

- Develop a compact, self-contained, NL SS-ADT demonstrator
- Significant reduction in size and weight
- Cost sharing effort between Army Research and Development Center and JNLWP

DoD Directed Energy Investment

Active Denial System (ADS)

Sergeant Major of the Marine Corps, SgtMaj Barrett experiences the momentary effects of ADS

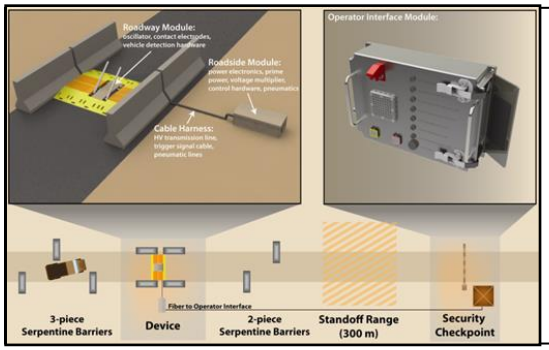
ADS 2: 1,000m range; 1.5m spot size

- Provides ability to repel/suppress personnel and vehicle/vessel operators up to 1,000m
- Uses “millimeter waves” not “microwaves”
- Legal, treaty and arms control compliant
- ADS was recently integrated in I MEF Exercise Valiant Mark (December 2014). Marines from 1/5, 1st Marine Division were engaged with ADS.

Demonstrators

Distributed Sound and Light Array (DSLA)

- Acoustical and optical device
- Provides hailing and warning capabilities
- Combined effects of two integrated sensory stimulators

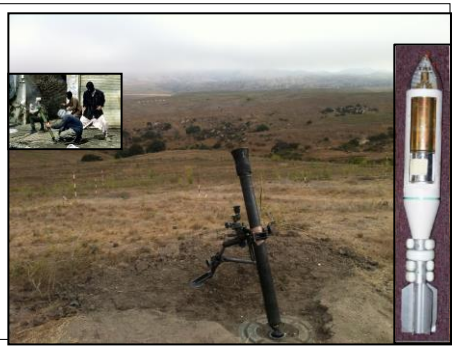


Pre-Emplaced Electrical Vehicle Stopper (PEVS)

- Pre-emplaced, electric, direct injection system
- Non-lethally stop vehicles at significant keep-out ranges
- Reduces risk to personnel from vehicle-born IEDs

Non-Lethal Indirect Fire Munitions (IDFM)

- Non-lethal 81 mm mortar round
- Integrated flash-bang munitions
- Suppress combatants at range with low risk of significant injury



Non-Lethal capabilities assist operating forces in minimizing civilian casualties and collateral damage

Non-Lethal Weapons Summary

- Provide operating forces with escalation-of-force options while minimizing casualties and collateral damage
- Always have lethal force overwatch/back-up
- Help fill the gap between shouting and shooting
- Offer options across the full spectrum of conflict

Non-Lethal capabilities assist operating forces in minimizing civilian casualties and collateral damage

CONTENTS

BACKGROUND

During the three years from 2003 through 2005, 47 states and the District of Columbia reported 1,095 arrest-related deaths proximal to law enforcement's use of force. For many years police leaders have sought alternatives to lethal force and better methods to subdue individuals to limit injuries and death. Less-lethal technologies have been used in law enforcement for this purpose extensively since the early 1990s. In recent years, electro-muscular-disruption (EMD) technology, also known as conducted energy devices (CEDs), have become the less-lethal weapon of choice for a growing number of law enforcement agencies. CED uses a high-voltage, low-power charge of electricity to induce involuntary muscle contractions that cause temporary incapacitation.

Industry reports suggest some 11,500 law enforcement agencies have acquired CEDs. Approximately 260,000 EMD devices are deployed in the operational environments of law enforcement agencies. Studies undertaken by law enforcement agencies deploying CED indicate reduced injuries to officers and suspects resulting from use of force encounters and reduced use of deadly force. However, a significant number of individuals have died after exposure to a CED. Some were normal healthy adults; others were chemically dependent or had heart disease or mental illness.

The leading manufacturer of CEDs is TASER® International of Scottsdale, Ariz. In 2003 TASER International introduced the TASER X26®. The X26 model is the prevailing conducted energy device being acquired by law enforcement today. Other CEDs have been used in incidents in which a death occurred, including the TASER M26®, other stun guns and shields.

These deaths have given rise to questions from law enforcement and the public regarding the safety of CEDs. Because many gaps remain in the body of knowledge with respect to the effects of CEDs, the National Institute of Justice (NIJ), the research, development and evaluation agency of the U.S. Department of Justice, has undertaken a study, *Deaths Following Electro Muscular Disruption,* to address whether CEDs can contribute to or cause mortality and if so, in what ways.

STUDY METHODOLOGY

The study is directed by a steering group with representation from NIJ, the American College of Pathologists, the Centers for Disease Control and Prevention, and the National Association of Medical Examiners. To support the study, the steering group appointed a medical panel composed of physicians, medical examiners, and other relevant specialists in cardiology, emergency medicine, epidemiology, pathology and toxicology.

In formulating the interim findings reported here, the panel conducted mortality reviews of CED-related deaths and reviewed the current state of medical research relative to the effects of CED. Mortality reviews have included analysis of autopsy and toxicology results, findings from the scene investigation, post-exposure symptomatology, post-event medical care, and the extent of natural disease presented in a decedent, if any. This report contains recommendations concerning death investigation arising from the mortality reviews conducted by the panel and a review of currently available research. The panel examined the currently recognized causes of sudden deaths, chiefly physical, cardiac, pulmonary, metabolic and thermoregulatory mechanisms. The medical panel has also consulted stakeholders such as human rights groups, law enforcement professionals, research scientists and manufacturers of CEDs.

Many aspects of the safety of CED technology are not well-known, especially with respect to its effects when used on populations other than normal healthy adults (i.e., at-risk individuals). A significant number of relevant studies are now under way, including studies involving healthy adults, animals and field exposures during actual use-of-force incidents. Additional research is needed to improve the understanding of how CEDs function, their effect on at-risk individuals, complicating medical conditions and related aspects of CED exposure. This report provides a consensus view of the panel members from a complete review of the available, peer-reviewed research literature and extensive information concerning the use of CEDs in the field. The findings have been limited to those conclusions that can be reached based on current understanding. The panel will continue to examine new research and case studies of deaths proximate to the use of CED.

FINDINGS

Although exposure to CED is not risk free, there is no conclusive medical evidence within the state of current research that indicates a high risk of serious injury or death from the direct effects of CED exposure. Field experience with CED use indicates that exposure is safe in the vast majority of cases. Therefore, law enforcement need not refrain from deploying CEDs, provided the devices are used in accordance with accepted national guidelines. (For example: *Electronic Control Weapons*, a model policy of the International Association of Chiefs of Police.)

The potential for moderate or severe injury related to CED exposure is low. However, darts may cause puncture wounds or burns. Puncture wounds to an eye by a barbed dart could lead to a loss of vision in the affected eye. Head injuries or fractures resulting from falls due to muscle incapacitation may occur.

CEDs can produce secondary or indirect effects that may result in death. Examples include deploying a device against a person who is in water, resulting in drowning, or against a person on a steep slope resulting in a fall, or ignition risk resulting from deployment near flammable materials such as gasoline, explosives or flammable pepper spray that may be ignited by a spark from a device.

There is currently no medical evidence that CEDs pose a significant risk for induced cardiac dysrhythmia when deployed reasonably. Research suggests that factors such as thin stature and dart placement in the chest may lower the safety margin for cardiac dysrhythmia. There is no medical evidence to suggest that exposure to a CED produces sufficient metabolic or physiologic effects to produce abnormal cardiac rhythms in normal, healthy adults.

Research shows that human subjects maintain the ability to breathe during exposure to CED. Although there is evidence of hyperventilation in human subjects immediately following CED exposure, there is no medical evidence of lasting changes in respiratory function in human subjects following exposure to CED.

CED technology may be a contributor to "stress" when stress is an issue related to cause of death determination. All aspects of an altercation (including verbal altercation, physical struggle or physical restraint) constitute stress that may represent a heightened risk in individuals who have pre-existing cardiac or other significant disease. Current medical research suggests that CED deployment is not a stress of a magnitude that separates it from the other components of subdual.

Excited delirium is one of several terms that describe a syndrome characterized by psychosis and agitation and may be caused by several underlying conditions. It is frequently associated with combativeness and elevated body temperature. In some of these cases, the individual is medically unstable and in a rapidly declining state that has a high risk of mortality in the short term even with medical intervention or in the absence of CED deployment or other types of subdual.

Excited delirium that requires subdual carries with it a high risk of death, regardless of the method of subdual. Current human research suggests that the use of CED is not a life-threatening stressor in cases of excited delirium beyond the generalized stress of the underlying condition or appropriate subdual.

FINDINGS

In many cases of excited delirium, high body temperature is the primary mechanism of death. There is no medical evidence that exposure to CED has an effect on body temperature.

The purported safety margins of CED deployment on normal healthy adults may not be applicable in small children, those with diseased hearts, the elderly, those who are pregnant and other at-risk individuals. The effects of CED exposure in these populations are not clearly understood and more data are needed. The use of a CED against these populations (when recognized) should be avoided but may be necessary if the situation excludes other reasonable options.

Studies examining the effects of extended exposure in humans to CED are very limited. Preliminary review of deaths following CED exposure indicates that many are associated with continuous or repeated discharge of the CED. The repeated or continuous exposure of CED to an actively resisting individual may not achieve compliance, especially when the individual may be under drug intoxication or in a state of excited delirium. The medical risks of repeated or continuous CED exposure are unknown and the role of CEDs in causing death is unclear in these cases. There may be circumstances in which repeated or continuous exposure is required but law enforcement should be aware that the associated risks are unknown. Therefore, caution is urged in using multiple activations of CED as a means to accomplish subdual.

All CED use should conform to agency policies. The decision to use a CED or another force option is best left to the tactical judgment of trained law enforcement at the scene.

POST-EVENT MEDICAL CARE

Medical evaluation is not mandatory after all CED exposures. Individuals who have been exposed to CEDs may suffer injuries. Appropriate medical care should be provided if this is suspected, especially when probes penetrate vulnerable areas of the head, face, neck, genitals, or female breast regions or in cases of injury from falls, burns or other trauma. In most cases, probes embedded in the skin may be removed by properly trained medical or law enforcement personnel in accordance with local protocols. Medical care should be provided when probes are located in the vulnerable areas noted above or if there is concern for underlying injuries.

Underlying medical conditions may be responsible for behavior that requires subdual by law enforcement, including the use of CEDs. Abnormal mental status in a combative or resistive subject may be associated with a risk for sudden death. This should be treated as a medical emergency. In these cases, medical providers are encouraged to assess body temperature and obtain and retain blood samples and an electrocardiogram as early as possible. If needed, cooling, sedation and hydration should be provided as soon as possible. Emergency medical services protocols specifying these interventions may be useful.

Sudden lack of responsiveness may occur at any time and may indicate a medical crisis. Therefore, individuals should be monitored for changes in condition. Those reporting illness or suspected of having significant medical or psychiatric conditions should be provided with appropriate medical care.

Darts and clothing removed during medical care should be retained for investigative purposes and handled as evidence. When removing embedded darts, care should be taken to avoid exposure to bloodborne pathogens. Detailed records of treatment should be maintained.

CONSIDERATIONS IN DEATH INVESTIGATION

When a death occurs following deployment of a CED by law enforcement personnel who are subduing, restraining or apprehending a subject, the death will be investigated by the appropriate medical examiner's or coroner's office as an in-custody death. Because deaths following CED deployment involve somewhat typical scenarios and complex and predictable issues, the death investigation needs to include consideration of information that may not be gathered in a routine death investigation or in a typical in-custody death investigation. It is not the intent of this Interim Report to provide a comprehensive checklist of tasks that should be performed. Rather, the most crucial areas of helpful information are outlined below.

The information needed for investigation of death following CED use will need to be collected by death investigators from multiple sources and in consultation with the medical examiner or coroner who has ultimate responsibility for the case. Further, the forensic pathologist who performs the autopsy will need to be provided such information for review. Information obtained from the autopsy examination may trigger or require additional investigation. The forensic pathologist who performs the autopsy is an integral part of the investigative team.

The following information can be useful in establishing facts and should be considered during the death investigation:

a. A timeline of all events with attempts to verify, to the extent possible, the accuracy of the dates and times of reported events, with specific emphasis on the interval between CED use, unresponsiveness, and death.
b. Clarification as to whether the CED was used in drive stun and/or cartridge mode(s).
c. Recent activities of the subject prior to the incident.
d. The emotional state of the subject.
e. The subject's medical conditions determined by medical history taking, medical record review and medical conditions determined at autopsy.
f. The subject's drug use history including both prescription and illicit drugs as well as alcohol.
g. Specific inquiry into the subject's cardiac history including review of any electrocardiograms or other cardiac function or laboratory tests that have been performed in the past.
h. Specific inquiry to the subject's seizure history to rule out history of seizures or to clarify the nature of a past seizure disorder.
i. Review of witness accounts, police reports, use of force reports, emergency medical services records, medical and psychiatric records, and any videos, photographs or digital images of the events.
j. When possible, darts should not be removed from the decedent's body or clothing
k. Measure and document body and ambient temperature taken at the scene and other locations such as the hospital.
l. If death occurs after arrival at a hospital, obtain blood drawn upon arrival at the hospital so it may be tested for intoxicants, if needed.
m. Review information downloaded from the CED with special emphasis on number and duration of discharges over the time interval involved.
n. Investigate the subject's place of residence and recent activities to determine if additional medical history or evidence of drug use exists. This may require the coordination of the medical examiner/coroner with law enforcement.

CONSIDERATIONS IN DEATH INVESTIGATION

Assuming that the investigation and autopsy are performed and documented/reported in accordance with NIJ's *Guide for the Death Scene Investigator* and the National Association of Medical Examiners' *Forensic Autopsy Performance Standards*, additional information and procedures that may be helpful are:

a. Performance of a complete autopsy of the scope usually performed for deaths in custody.
b. Comprehensive postmortem toxicology, specifically including tests for alcohol, nervous system stimulants, common drugs of abuse, anti-seizure drugs, and therapeutic drugs often prescribed for psychiatric disorders.
c. Measurement of the thickness of the anterior chest wall from the skin to the rear of the pre-pericardial sternum at intercostal space between the left fourth and fifth ribs.
d. Measurement of the thickness of clothing in the area(s) where CED darts or prongs were applied.
e. Documentation of the CED dart's barb length(s).
f. Consideration of unusual or atypical current flow paths, such as body to ground, body to water, body to metal, etc.
g. Determination of the nature of any other forms of subdual or restraint that were employed in the case in question.
h. Utilization of appropriate consultants such as cardiologists, cardiac pathologists, and neuropathologists as needed.

The medical examiner's or coroner's office conducting the death investigation will ultimately be responsible for certifying the cause and manner of death. This Interim Report does not include guidelines for such certifications.

GLOSSARY OF TERMS

Cardiac Mechanisms
The ways the heart can fail when injured or sick.

Conducted Energy Device (CED)
A weapon primarily designed to disrupt a subject's central nervous system by means of deploying electrical energy sufficient to cause uncontrolled muscle contractions and override an individual's voluntary motor responses.

Darts
Projectiles that are fired from a CED and penetrate the skin; wires are attached to the probes leading back to the CED.

Dart (Barb) Removal
The act of removing a probe from a person's body or clothing.

Deployment
Sending CED devices into the field with law enforcement officers.

Duration
The aggregate period of time that CED shocks are activated.

Dysrhythmia
Any disturbance or irregularity of the heartbeat.

Electrocardiogram
A graphic produced by an electrocardiograph, which records the electrical activity of the heart over time.

Electro Muscular Disruption
Effect CED has on the body. Overrides the brain's communication with the body and prevents voluntary control over the muscles.

Excited Delirium
State of extreme mental and physiological excitement, characterized by extreme agitation, hyperthermia, euphoria, hostility, exceptional strength and endurance without fatigue.

Hyperventilation
Breathing faster and/or deeper than normal, thereby reducing the amount of carbon dioxide, or CO_2, in the blood to below normal.

Less Lethal
A concept of planning and force application that meets an operational or tactical objective, with less potential for causing death or serious injury than conventional, more lethal police tactics.

Less-Lethal Weapon
Any apprehension or restraint device that, when used as designed and intended, has less potential for causing death or serious injury than conventional police lethal weapons.

Metabolic Mechanisms
The ways the metabolism can fail when injured or sick.

Physical Mechanisms
The way in which illness or injury can compromise heart/lung function or put body metabolism at risk.

Pulmonary Mechanisms
The way in which lung function can be compromised by injury or sickness.

Respiratory
Relating to the act or process of inhaling (breathing in) and exhaling (breathing out); breathing, also called ventilation.

Restrain
To control, limit, or prevent movement.

Restraint
A device that restricts movement.

Sensitive Areas
A person's head, neck, and genital area, and a female's breast areas.

Standard CED Cycle
A 5-second electrical discharge occurring when a CED trigger is pressed and released. The standard 5-second cycle may be shortened by turning the CED off. (Note: If a CED trigger is pressed and held beyond 5 seconds, the CED will continue to deliver an electrical discharge until the trigger is released.

Subdual
To bring under control.

Symptomatology
The combined symptoms of a disease: the symptom complex of a disease.

About the National Institute of Justice

NIJ is the research, development, and evaluation agency of the U.S. Department of Justice. NIJ's mission is to advance scientific research, development, and evaluation to enhance the administration of justice and public safety. NIJ's principal authorities are derived from the Omnibus Crime Control and Safe Streets Act of 1968, as amended (see 42 U.S.C. §§ 3721–3723).

The NIJ Director is appointed by the President and confirmed by the Senate. The Director establishes the Institute's objectives, guided by the priorities of the Office of Justice Programs, the U.S. Department of Justice, and the needs of the field. The Institute actively solicits the views of criminal justice and other professionals and researchers to inform its search for the knowledge and tools to guide policy and practice.

Strategic Goals

NIJ has seven strategic goals grouped into three categories:

Creating relevant knowledge and tools

1. Partner with State and local practitioners and policymakers to identify social science research and technology needs.
2. Create scientific, relevant, and reliable knowledge—with a particular emphasis on terrorism, violent crime, drugs and crime, cost-effectiveness, and community-based efforts—to enhance the administration of justice and public safety.
3. Develop affordable and effective tools and technologies to enhance the administration of justice and public safety.

Dissemination

4. Disseminate relevant knowledge and information to practitioners and policymakers in an understandable, timely, and concise manner.
5. Act as an honest broker to identify the information, tools, and technologies that respond to the needs of stakeholders.

Agency management

6. Practice fairness and openness in the research and development process.
7. Ensure professionalism, excellence, accountability, cost-effectiveness, and integrity in the management and conduct of NIJ activities and programs.

Program Areas

In addressing these strategic challenges, the Institute is involved in the following program areas: crime control and prevention, including policing; drugs and crime; justice systems and offender behavior, including corrections; violence and victimization; communications and information technologies; critical incident response; investigative and forensic sciences, including DNA; less-than-lethal technologies; officer protection; education and training technologies; testing and standards; technology assistance to law enforcement and corrections agencies; field testing of promising programs; and international crime control.

In addition to sponsoring research and development and technology assistance, NIJ evaluates programs, policies, and technologies. NIJ communicates its research and evaluation findings through conferences and print and electronic media.

New/Advanced NL Materials, Payloads, and Payload Delivery Systems

Non-Lethal Weapons Research and Technology Development

Industry Day

22 June 2012

David Law

Technology Division Chief

http://jnlwp.defense.gov

Background

- The JNLWD is interested in investigating new non-lethal payloads and delivery systems that can improve the operational performance of non-lethal weapons as compared to existing technology.
- There exists a number of effective non-lethal stimuli but not always effective ways to deliver them on target at operationally relevant ranges.
- Some general desired improvements:
  - Improved accuracy
  - Reduced risk of significant injury
  - Reduced logistical burden (batteries, pneumatics, size, weight, etc.)
  - Reduced cost per engagement

Technical Objectives

- Identify and characterize new materials and non-lethal payloads that could extend the performance envelope of existing non-lethal weapon systems or provide novel non-lethal effects
- Develop and demonstrate generic non-lethal payload delivery platforms that address:
  - Standoff range (min and max)
  - Coverage
  - Accuracy
  - RSI
  - Reversibility
  - Scalability
  - Logistical burden
  - Probability of effect
  - Operator safety

Relevant Work

- Advanced Non-Lethal Projectile
  - NSWC-Dahlgren
  - Focus: Develop and characterize a new 12-gauge non-lethal blunt impact projectile utilizing Zorbium® visco-elastic foam.
- Carbon Nanotubes Acoustic Driver
  - Penn State University; University of Texas at Dallas
  - Focus: Develop and demonstrate a smaller, lighter, and lower cost high-power Carbon Nanotube (CNT) acoustic driver that offers numerous advantages over conventional coil drivers
- Non-Incendiary Flash Bang
  - Performers: Various
  - Focus: Developing and demonstrating a non-sparking flash bang grenade for use in combustible environments

Research & Development Tasks

General types of tasks required for research and development:

- Feasibility studies
- Prototype development, testing, and demonstration
- Materials research and development
- Modeling and simulation
- Systems engineering and technology integration

Capabilities

General capabilities and expertise that may be required :

- General engineers and physical scientists with expertise in ballistics, mechanics, thermodynamics, hydrodynamics, aerodynamics, materials, chemistry, and systems engineering
- Facilities and equipment to build and test prototype systems
- Computational scientists and engineers to build computer based models and run simulations

Human Effects & Effectiveness

Non-Lethal Weapons Research and Technology Development

Industry Day

22 June 2012

Alicia Owsiak

Deputy Technology Division Chief

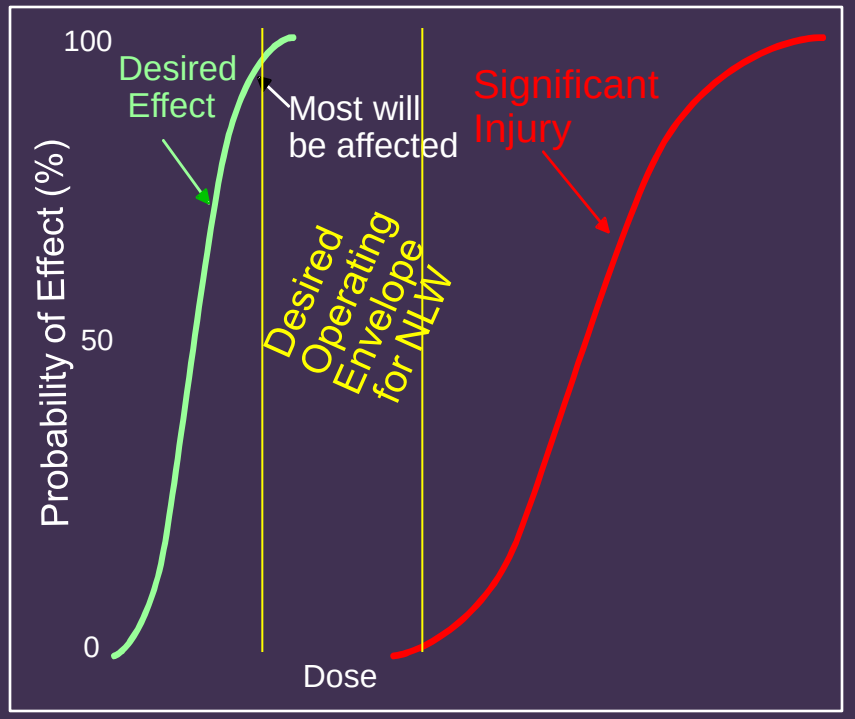
http://jnlwp.defense.gov

Background

- Understanding human effects and effectiveness is paramount in the development of non-lethal weapons.

- For NLW, two competing objectives exist: cause a desired effect, while minimizing permanent injuries or fatalities.

- The JNLWP is focused on all aspects of human effects and effectiveness research, across the breadth of non-lethal stimuli, that enables the development, test and fielding of safe and effective non-lethal weapons.



Technical Objectives

- Determine the ability of stimuli/systems to produce relevant physiological effects
- Identify and quantify risk
  - Risk of significant injury (RSI)
- Characterize effects to help inform effects-based design
- Characterize behavioral response
- Develop, verify and validate predictive models

Relevant Work

- Human Effects Modeling & Analysis Program
  - Performers:
    - Human Effects Center of Excellence (HECOE)
    - L-3 Communications / Jaycor
  - Focus:
    - Develop a suite of validated, verified, and Service-accredited human effects models across all non-lethal stimuli for application to support JNLWP
      - E.g., Advanced Total Body Model
    - Expand model(s) to include prediction of operational outcomes (behavior response)

Relevant Work

- RF Bioeffects
  - Performers: U.S. Air Force Research Lab
  - Focus:
    - Conduct human effects studies to support development of RF non-lethal directed energy weapons technologies (i.e., ADT, RF vehicle/vessel stopping).
      - Characterizing injury risk and effectiveness
      - Facilitate RF directed energy system development, test and evaluation
    - Model effects of RF Vehicle Stopper waveform as relates to size of individual within a vehicle.
    - Model and assess polarization risks associated with the RF Vessel Stopper waveform.

Relevant Work

- Human Effects Risk Assessments
  - Performers:
    - U.S. Air Force Research Lab
  - Focus:
    - Investigate the effects of vertical & horizontal polarization for specific radio frequency sources.
    - Model bioeffects associated with RF system designs.
    - Establish the safety of implanted medical devices for vehicle stopping technologies.
      - RF Vehicle Stopper
      - Pre-Emplaced Electric Vehicle Stopper

Relevant Work

- Underwater Acoustic Bioeffects
  - Performers:
    - Naval Submarine Medical Research Laboratory (NSMRL)
  - Focus:
    - Develop an underwater acoustic bioeffects model for impulse and continuous sound waves.
    - Establish target effectiveness and risk dose-response curves for the Anti-Swimmer Grenade though human subject diver experiments.

Research & Development Tasks

General types of tasks required for human effects and effectiveness research:

- Dose response curve generation for various non-lethal stimuli as relates to risk of injury and efficacy
- Feasibility assessments to determine the ability of stimuli/systems to produce relevant physiological effects
- Risk of injury prediction methodology development for various stimuli
- Quantification of risk of significant injury (RSI) for various systems
- Studies and human subject experimentation to characterize behavioral response
- Bioeffects research to include animal and human subject research
- Model development, verification and validation
- Simulation development
- Assessment of variables that could impact safety and effectiveness

Capabilities

General capabilities and expertise that may be required to execute planned R&D human effects and effectiveness tasks:

- Engineers/Scientists with expertise in:
  - Biophysics
  - Biomedical science
  - Radio frequency bioeffects
  - Veterinary medicine
  - Statistics
  - Electrobiology
  - Medicine
  - Behavioral science
  - Biology
  - Biochemistry
  - Modeling and simulation
  - Physiology
- Facilities and equipment to conduct indoor and outdoor laboratory experiments
- Accredited institutional controls for bioeffects research:
  - Institutional Review Board (IRB)
  - Institutional Animal Care and Use Committee (IACUC)

Independent Technical Reviews

Non-Lethal Weapons Research and Technology Development

Industry Day

22 June 2012

Alicia Owsiak

Deputy Technology Division Chief

http://jnlwp.defense.gov

Background

- Independent review of Government-developed research and technology development plans and products is valuable in ensuring investments are worthwhile:
  - Technically feasible
  - Technically sound
  - Efficient
  - Effective
  - Not redundant

- The JNLWP often seeks facilitators and subject matter experts to organize, conduct, contribute to and report on technical reviews of JNLWP research and technology development plans and products.

Technical Objectives

- Utilize subject matter expert feedback to validate and/or guide research and technology development plans
- Review research and technology development products with respect to:
  - Technology effectiveness / applicability
    - Technical performance specs vs. requirements
    - Threat assessment analyses
    - System trade-off analyses
  - Data completeness / statistical significance
  - Methodology (risk of injury; effectiveness)
  - Model suitability / accuracy
  - Manufacturability
  - Systems engineering/integration
- Document and implement (as resources permit) subject matter expert findings

Relevant Work

- Human Effects Advisory Panel (HEAP)
  - Independent, 3rd party non-biased, blue-ribbon panel that conducts technical assessments of the DoD's non-lethal human effects research plans
  - Penn State University
  - Focus:
    - Identify recognized and credentialed non-biased personnel from industry, academia, and government agencies with relevant expertise
    - Facilitate panel meetings
    - Draft HEAP report based on panelist input
    - Example of recent HEAP topic:
      - Human Electromuscular Incapacitation Risk of Significant Injury Methodology

Relevant Work

- Technology Effectiveness Advisory Panel (TEAP)
  - Independent, 3rd party non-biased, blue-ribbon panel that conducts technical assessments of the counter-material or counter-personnel effectiveness of developmental non-lethal technologies.
  - Penn State University
  - Focus:
    - Identify recognized and credentialed non-biased personnel with the requisite system effectiveness testing expertise and/or system effectiveness evaluation expertise
    - Facilitate panel meetings
    - Draft TEAP report based on panelist input
    - Example of recent TEAP topic:
      - Laser Induced Plasma Effects

Research & Development Tasks

General types of tasks required for independent technical reviews:

- Conduct HEAPs and TEAPs
- Prepare paper study reviews of research and technology development plans and products
- Evaluate the technical effectiveness of a given system/stimuli in a particular mission
  - Modeling & simulation tools
- Assess technology manufacturability

Capabilities

General capabilities and expertise that may be required to execute planned independent technical review tasks:

- Engineers/scientists with a broad set of expertise spanning non-lethal technologies from blunt impact to directed energy
- Facilities and equipment to facilitate panel meetings
- Tools to conduct modeling & simulation-based technology effectiveness assessments
- Technical writers

Headquarters U.S. Air Force

Integrity - Service - Excellence

AF APBI Briefing

19 Nov 14

MR. SAL HERNANDEZ
AFSFC/SFXI
Chief, Innovations Branch

U.S. AIR FORCE

U.S. AIR FORCE

Overview

- AF Warfighter Introductions
- AF Non-Lethal Program
- Vehicle Final Denial Requirement
- Questions

U.S. AIR FORCE

Warfighter Introductions

- SSgt Andrew Caro, ACC, Creech AFB, NV, RTC Trainer/Instructor
  - TASER/OC/Expandable Baton Cert
  - DAGRE Trained
  - Certified AF RAVEN
  - Extensive Deployments: CENTCOM, EUCOM, AFRICOM
- SSgt Jesse Ermer, ACC, Creech AFB, NV
  - TASER/OC/Expandable Baton Cert
  - Combat Arms Instructor
  - Response Mission-Outside the wire, aircraft recovery and security (MQ-9, F-16, HH-60), OPF response to IED and VBIED
  - Extensive Deployments: CENTCOM, EUCOM, AFRICOM

U.S. AIR FORCE

AF Non-Lethal Program

- Instructions mandate a NL device if carrying a 9mm or M4
  - OC
  - TASER (M26/X26E)
  - Expandable Baton
- Maintains NL Capability sets, and building EoF sets
- Authorized use of two 12 gauge rounds, two 40mm rounds, stingball grenade, and flash bang grenade
- NL program magnitude: 170,000+ NL assets valued at $17M
- AF has an active NL program
- AF, through the JCIDS process, validated stopping vehicles and area denial are top challenges

Vehicle Final Denial Requirement

U.S. AIR FORCE

- Current barriers approved on the DOD Anti-Ram Vehicle Barrier List are required to meet American Society for Testing and Material International standards to be certified final denial barriers
- Vehicles can not penetrate further than 98 feet after being engaged by the barrier
- Portable net barriers like Vehicle Lightweight Arresting Device are not certified as final denial barriers since they can't meet the allowable penetration criteria
- Standards have not been defined to allow RF/DE approval/use as vehicle final denial
- AF is interested in a low cost and low maintenance Non-Lethal RF/DE final denial vehicle barrier

Vehicle Final Denial Requirement

U.S. AIR FORCE

Uniform Facilities Code Issues/Considerations

- Limited real-estate before/after the ECP
- Vehicle damage
- Personal injuries
- Nine Second Rule; 3+4+2
- Maximum penetration distance of 98 feet

U.S. AIR FORCE

Questions?

United States Marine Corps
Escalation of Force/Non-Lethal Weapons Capability Presentation

Prepared for the Joint Integration Program

Mr. Christopher Potvin
Capabilities Integration Officer
Christopher.potvin@usmc.mil

Purpose

To provide industry with:

- An overview of the USMC technology challenges identified during multiple capability analyses
- Highlights of on-going efforts to address identified challenge areas

Organizational Structure
Escalation of Force Branch

EoF Branch Head
Mr. Ray Grundy

Capabilities Integration Officer
Mr. Scott Pipenhagen

EoF Branch Deputy
LtCol Nathan Rush

Capabilities Integration Officer
Mr. Brian Fulks

NL Requirements / JCIDS Officer
LtCol / 0302
(Reserve - IMA)
(Vacant)

Capabilities Integration Officer
Mr. Christopher Potvin

Project Analyst
Mr. S. Pat Sweeney, PMP
Team Lead
(Patricio Enterprises)

Project Analyst
Mr. John Schamel
(Patricio Enterprises)

Project Analyst
Mr. Matt Conway
(Patricio Enterprises)

USMC Escalation of Force / Non-Lethal Weapons Vision and Mission

- Vision
  - A U.S. Marine Corps trained and equipped to seamlessly integrate escalation of force capabilities in IW, COIN, Peace Keeping, Stability and HA/DR operations and those operations in which casualties and collateral damage must be limited.
- Mission
  - Providing the Marine Corps with the capacity and capability of integrated EoF systems that supplement lethal systems and allow for increased options for force application that meet the dynamics of future operations across the spectrum of conflict, while limiting collateral damage and lethal effects.
- Traceability
  - Derived from the USMC 2006 NLW & Capabilities Strategic Integration Plan, CMC's V&S 2025 and Task # 17, Implementation Planning Guidance, ICDs for Joint NL effects (CM & CP), ICD for EoF Capabilities, and the POM-14 SPD
  - Supports CMC's V&S 2025 and EUCOM, SOCOM, NORTHCOM, and CENTCOM IPLs

USMC CHALLENGES

Escalation of Force - NonLethal Effects (EoF-NLE)
High-Level Operational Concept Graphic (OV-1)
Warn
Deny
Move
Suppress
Disable
Crowd Control
Establish and Secure Perimeter
Conduct Urban Patrolling
Provide Convoy Security
Conduct Cordon

Solution - 10 Capabilities / 27 Tasks

Escalation of Force (EoF)

Capabilities

Tasks

VCP	Control Crowd	ECP	Convoy Security	Conduct Cordon	Clear Facilities	Urban patrolling	Est & Secure Perimeter	Conduct Search	Detain Personnel
T 1	T 2	T 4		T 6	T 8	T 5	T 17	T 12	T 18
T 3	T 3	T 14		T 7	T 10	T 16	T 25	T 19	T 21
T 5	T 22	T 15		T 9	T 11	T 20	T 27	T 20	T 22
T 13		T 16				T 22		T 26	T 24

Exploded view of Convoy Security tasks

- Incapacitate individuals
- Control by Dissuading
- Detect IED
- Engage Point Targets
- Distract Individuals
- Stop Vehicles
- Determine Safe Dist.
- Comm. w/ personnel

Potential Solutions

- Laser Dazzler
- Acoustics
- Signs
- Non-lethal Effects

T1 Control personnel w/ physical means
T2 Incapacitate Personnel
T3 Control personnel by dissuading
T4 Control human traffic in & out of closed areas
T5 Detect booby traps, IEDs, UXO
T6 Engage point targets with non lethal effects
T7 Engage area targets with non lethal effects

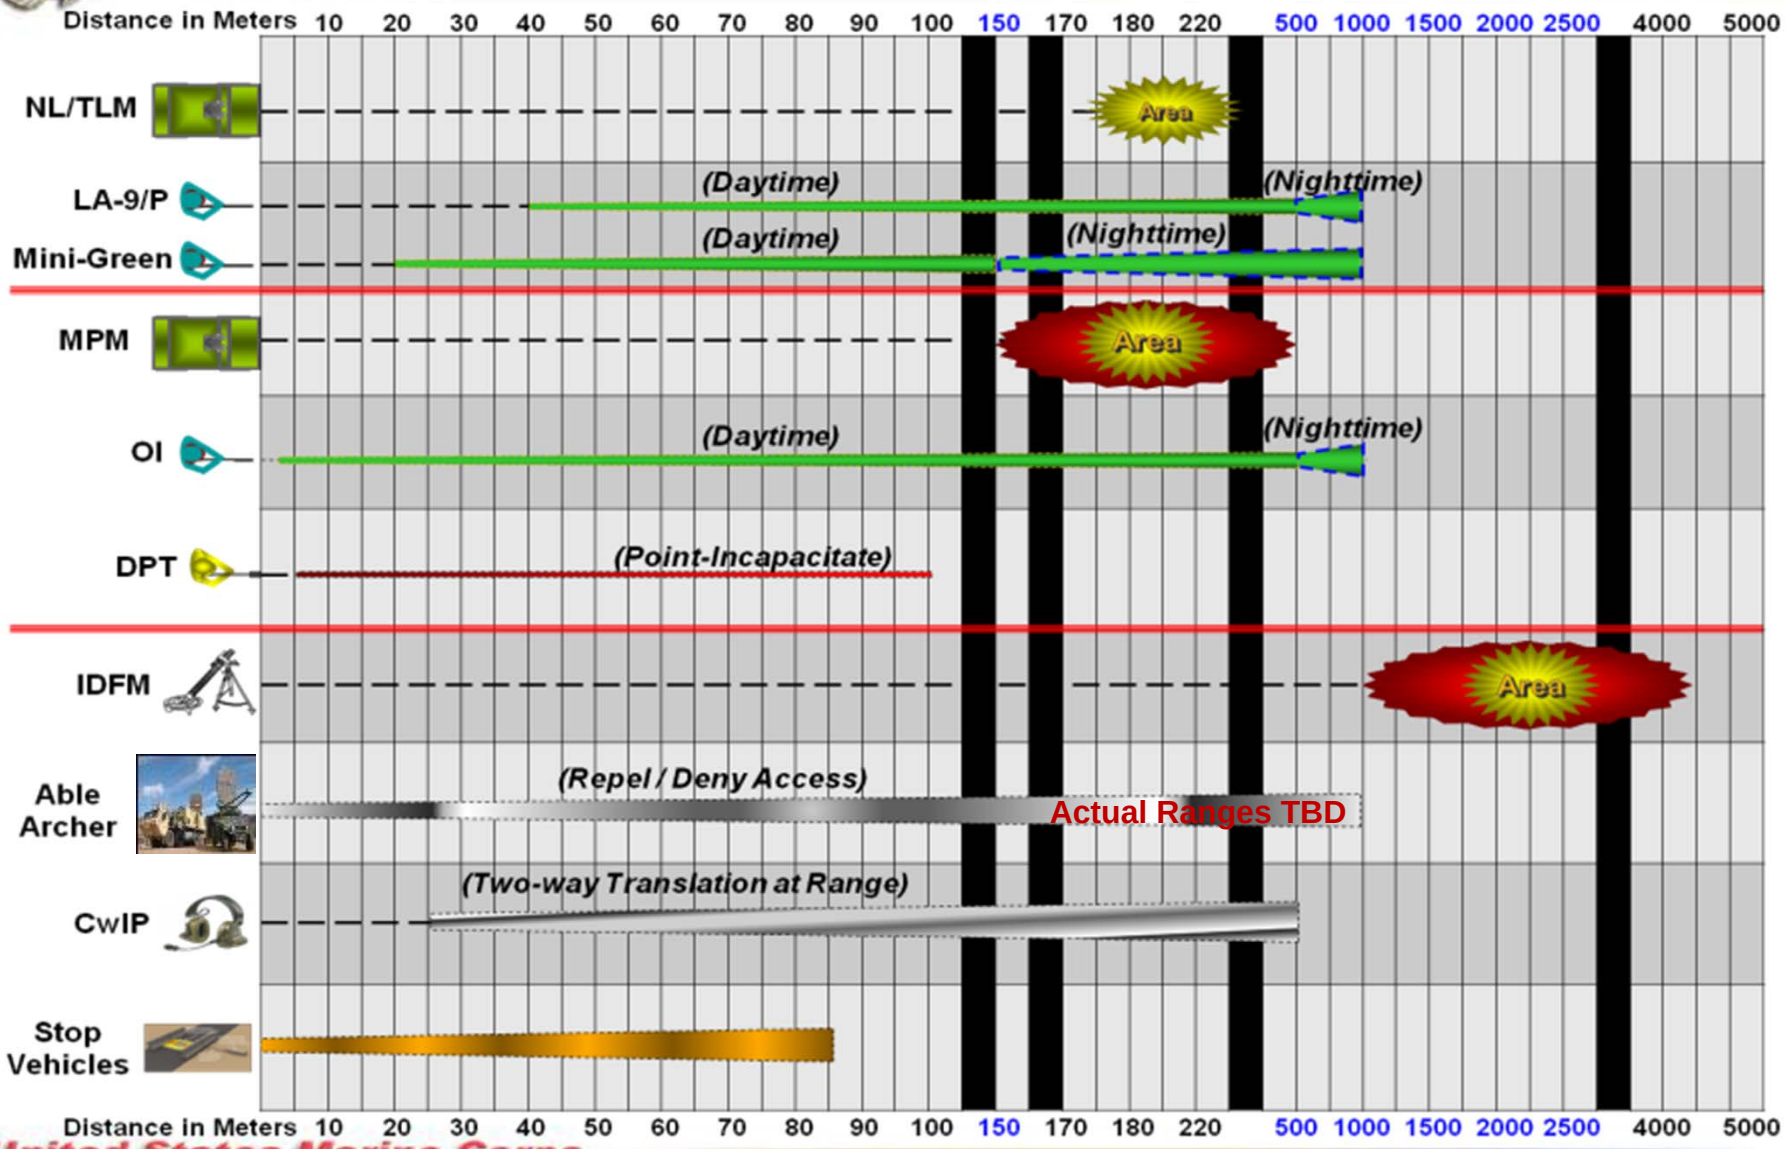
T8 Create entrance
T9 Distract/disorient individuals
T10 Force occupants out of a space w/o entering
T11 Seal spaces and facilities
T12 Sense inside space w/o entering
T13 Stop vehicles
T14 Inspect vehicles

T15 Inspect personnel
T16 Warn vehicles & personnel at safe distance
T17 Impede vehicular movement
T18 Provide emergency or standalone power
T19 Determine safe distances from explosive threats
T20 Secure detained personnel
T21 Detect & Identify Personnel/Vehicles in vicinity of perimeter

T22 **Communicate w/ indigenous personnel**
T23 Register positively identified individua
T24 Identify & detect personnel/vehicle at long range
T25 Provide area denial
T26 Clear space
T27 Stop vessels

USMC PROGRAMS

USMC Programs Overview



Disable Point Target (DPT)

Program Overview

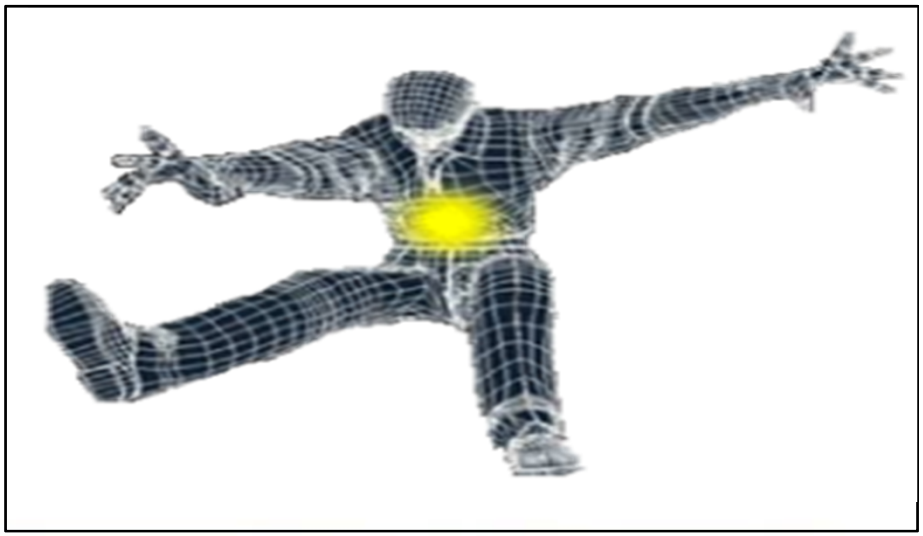
- **Multiple Need Statements:**
  - Untethered Non-Lethal Weapon Capability
  - Electro Muscular Disruption
- **Multiple ICDs:**
  - Incapacitate Targeted Individuals
  - Engage Point Targets with non-lethal effects
- **Currently Limitations:**
  - Current individual personnel incapacitation tethered systems require Marines to be in close proximity to the threat (approximately 21 feet) and limits freedom of movement following engagement
- **Analysis of Alternatives (AoA):**
  - Determined Electro-Muscular Incapacitation (EMI) as the preferred technology

Impacts:

- A non-lethal, untethered, extended range, multi engagement, precision point target, disabling effect in Escalation of Force situations.
- Deployable from a safe standoff distance and capable of rapidly re-engaging the target or engaging multiple targets sequentially.
- Uniquely suited for employment ISO urban patrolling, crowd control, entry control point, perimeter security, clearing facilities and crisis response operations.
- Enhances EoF capabilities by expanding non-lethal options available to the warfighter.

Key Requirements

- Disable – Affect target functionality immediately upon engagement, rendering the individual incapable of voluntary major muscle movement
- Duration of Effect – (T) 30 seconds; (O) 60 seconds
- Effective Range – (T) 10-50 meters; (O) 2-100 meters
- Munition untethered from launching platform
- Weight of Munition – (T) ≤150 grams (each); (O) ≤75 grams (each)



Able Archer

Program Overview:

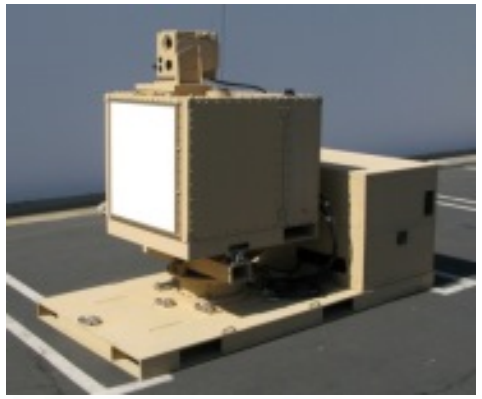
- USMC/Joint capability need to Deny and move individuals into/out of an area while minimizing civilian casualties and limiting collateral damage.
- 2012 Universal Need Statement for a long-range, non-lethal capability to provide a repel effect to targeted personnel**.**
- Initiative currently in the Materiel Solutions Analysis (MS A) Phase.
- Preliminary Analysis of Alternatives determined a version of millimeter wave technology as the preferred technology.

FISCAL YEAR 15 OBJECTIVES:

- Conduct Requirements IPT – Complete
- Complete Engineering Trade Study/Alternative Systems Review
- Complete Life Cycle Cost Estimate
- Complete Cost Analysis Requirements Description
- Receive Analysis of Alternatives approval
- Develop Draft Capabilities Development Documentation

Impacts:

- Radio frequency millimeter waves, traveling at the speed of light, deliver directed energy to personnel targets which penetrates the skin to a depth of only about 1/64th of an inch, or the equivalent of three sheets of paper. The beam produces an intolerable heating sensation, compelling the targeted individual to instinctively move. The sensation immediately ceases when the individual moves out of the beam or when the operator disengages the target. There is minimal risk of injury due to the shallow energy penetration into the skin at this short wavelength and normal human instinctive reactions.
- Non-lethal directed energy using millimeter wave technology has the potential to provide a non-lethal effect at distances up to and beyond small arms range, providing U.S. military forces with additional time and space to assess the intent of potential threats.



Clear Facilities (C-Fac) Project

Program Overview:

- Clear-A-Space Distract/Disorient (CAS D/D) Operational Mode Summary/Mission Profile (OMS/MP), 12 Jan 2004
- Initial Capabilities Document (ICD) for Escalation of Force (EoF) Capabilities
- ICD for Counter Personnel (CP) Joint Non-Lethal Effects, (JNLE)

FISCAL YEAR 15 OBJECTIVES:

- Capabilities Based Assessment (CBA): Complete
- Update CONOPS: On-going
- Develop ICD: On-going

Impacts:

- Pre-Materiel Solutions Analysis (MSA) Phase Activities to address the USMC / Joint capability gaps to Clear Facilities by Non-Lethal Means
- CBA: Forum for warfighters and technical experts to define, update, clarify and/or capture information critical to the development of Joint Capabilities Integration and Development System (JCIDS) documents to ensure the timely delivery of needed capabilities to the warfighter.
- Took a holistic look at clearing facilities in order to identify gaps and/or deficiencies across the DOTMLPF pillars.
- Development of capabilities, conditions, tasks, and standards associated with clearing and controlling facilities will be used to the develop an ICD which will serve as the foundational document from which any identified gaps can be addressed.

QUESTIONS?

Vehicle & Vessel Stopping

Non-Lethal Weapons Research and Technology Development

Industry Day

22 June 2012

Scott Griffiths

Officer of Primary Responsibility, Vehicle & Vessel Stopping

http://jnlwp.defense.gov

Background

- Non-lethal vehicle and vessel stopping remain high priority capabilities for employment in entry control point, convoy operations, snap checkpoint, maritime interdiction, asset protection, and port security scenarios.

- Fielded capabilities, while effective, are limited in capability.

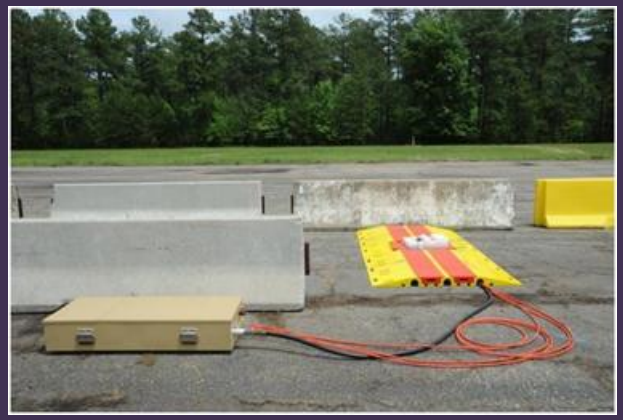
- The JNLWP is focused on developing, prototyping and integrating operationally suitable systems and component technologies capable of stopping a vehicle or vessel at relevant ranges in a variety of employment scenarios.

Technical Objectives

- Develop and demonstrate effective and operationally suitable vehicle stopping technologies that can maintain >100m keep out range and eliminate the need for pre-emplacement.
  - Includes small, medium, and large vehicles
- Develop and demonstrate effective and operationally suitable vessel stopping technologies that extend the range of effects and standoff for employment.
  - Focus is on small (<50ft) to midsize (~125ft) vessels
- Development and integration of systems in stand-alone configurations and onto a variety of delivery platforms depending on mission criteria.

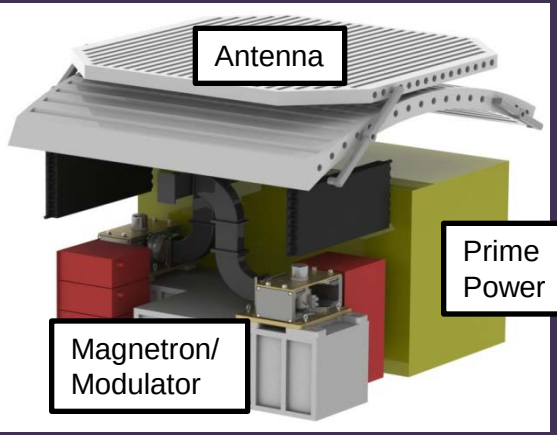
Relevant Work

- Pre-Emplaced Electric Vehicle Stopper (PEVS)
  - Utilizes a pulsed high-voltage waveform to disrupt/damage engine control electronics
  - Performers:
    - NSWC Dahlgren
    - Battelle
    - Miltech
    - Radiance Technologies
  - Focus:
    - Design, build, and test ruggedized prototypes
    - Improve system design
      - Reliability, usability, manufacturability, effectiveness etc.
      - Size/weight/cost reduction
    - Assess system safety
    - Perform prototype demonstrations



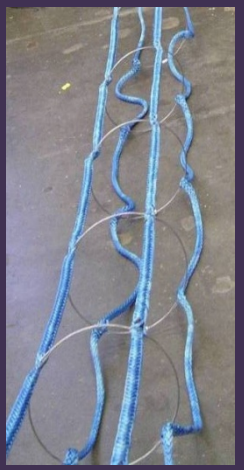
Relevant Work

- Multi-Frequency RF Vehicle Stopper
  - Utilizes a directed beam of high power RF energy to disrupt vehicle engine control electronics causing the engine to shut off.
  - NSWC Dahlgren, L3 Communications EDD
  - Focus:
    - Design, build and integrate prototype system
    - Conduct verification/validation testing of vehicle effects
    - Perform demonstrations
    - System refinement/ruggedization
    - Assess system safety



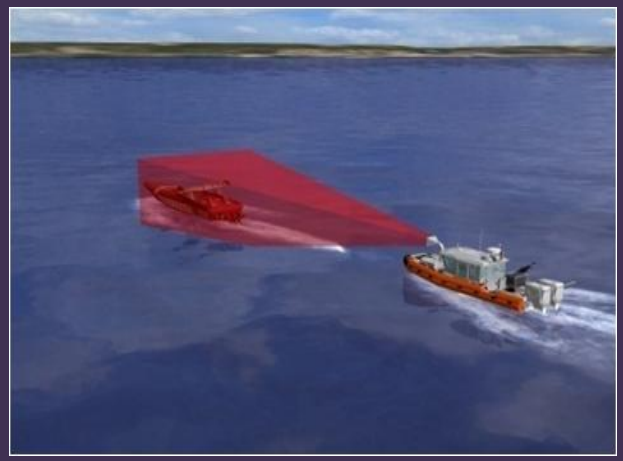
Relevant Work

- Vessel Entanglement
  - Study and development of vessel engine propeller entanglement net and delivery devices
  - NSWC Dahlgren, NSWC Carderock, USCG Research and Development Center
  - Focus:
    - Determine the effectiveness and operational suitability of propeller entanglement to non-lethally stop or slow small (<50 ft) and midsized vessels (<125 ft)
    - Develop a short range, hand held deployment method



Relevant Work

- RF Vessel Stopping
  - Utilizes high power RF energy to target vessel engine electronics to upset and cause the engine to shut off.
  - NSWC Dahlgren
  - Focus:
    - Analyze target effects database to validate effective waveform(s)
    - Conduct modeling & simulation
    - Compile validated user-requirements
    - Develop conceptual designs for priority missions
    - Assess maturity of enabling technologies
    - Assess existing Government and commercial sources/systems



Relevant Work

- Non-Lethal Unmanned Aerial Vehicle (UAV) High Power Microwave (HPM) Payload
  - Aerially delivered HPM payload for vessel stopping
  - NSWC Dahlgren
  - Focus:
    - Conduct vulnerability testing
    - Complete HPM payload specification/documentation package
    - Conduct laboratory source development
    - Assess existing Government and commercial sources/systems
    - Demonstrate payload in simulated UAV-target geometry

Research & Development Tasks

General types of tasks required for vehicle and vessel stopping technology development:

- Feasibility studies and technology assessments
- Comparison of novel approaches with existing technologies
- Target vulnerability assessments and testing to enable specification development
- Design, build, test and demonstration of breadboard and prototype vehicle and vessel stopping systems
- Platform integration

Capabilities

General capabilities and expertise that may be required to execute planned RF/HPM technology tasks:

- Engineers/Scientists with expertise in:
  - Automotive and maritime systems: including engine control electronics and vehicle communications (i.e. telematics)
  - Physics
  - Electrical engineering
  - Mechanical engineering
  - Aerospace engineering
  - Chemical engineering
  - Materials science
  - Statistics (design of experiment, data analysis, linear regression, etc.)
  - Systems integration
  - Systems engineering
- Facilities and equipment to develop, build, and test systems
- Facilities and equipment for target vulnerability assessments and testing

Non-Lethal Laser Technologies

Non-Lethal Weapons Research and Technology Development

Industry Day

22 June 2012

Wesley Burgei

Officer of Primary Responsibility, NL Lasers

http://jnlwp.defense.gov

Background

- Lasers have counter-personnel (CP) and potentially counter-materiel (CM) applications.
- The JNLWP has previously invested in a variety of laser systems for several applications:
  - Low power green, red, and ultraviolet
  - Mid power infrared
  - High energy infrared
  - Short pulsed and ultrashort pulsed

Technical Objectives

- Develop and demonstrate new laser systems, combined effects platforms, and enabling technologies (such as eye safety controls) to address CP and CM applications

  Examples:

  – Long Range Ocular Interruption (e.g., dazzling lasers), > 500m
  – Laser Induced Plasma System for CP or CM applications

- Laser bioeffects research including animal and human subjects
  – Safety and efficacy experiments
  – Modeling laser effects on humans

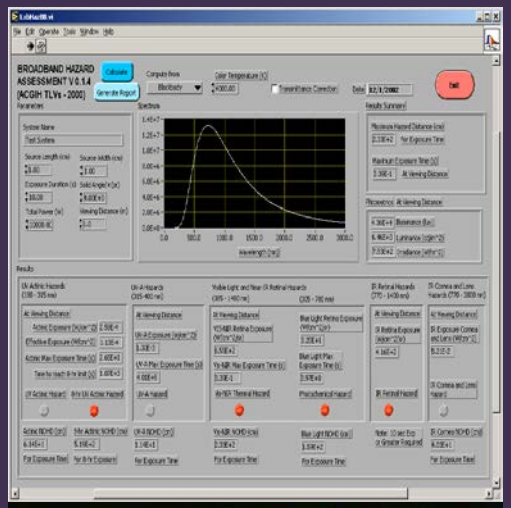
Relevant Work

- Distributed Sound and Light Array
  - The DSLA integrates an acoustic array, bright white lights, and a multi-watt green laser
  - Penn State University, NSWC-Dahlgren
- Non-Lethal Thermal Laser
  - Prototyping and bioeffects effort focused on using an infrared laser to cause a heating sensation similar in effect to Active Denial Technology
  - Air Force Research Laboratory, NP Photonics, Colorado State University

- Laser Induced Plasma Effects
  - Effort focused on demonstrating and characterizing the non-lethal weapons application of laser induced plasmas in air and on material surfaces
  - NSWC-Dahlgren, PM&AM Research, and Stellar Photonics

Relevant Work

- Optical Effects Modeling and Simulation
  - Bioeffects and M&S effort to build suite of models to predict risk of injury and probability of effect for a given laser exposure
  - Air Force Research Lab
- Veiling Glare
  - Bioeffect effort investigating the application of ultraviolet or near-ultraviolet lasers to cause glare effect
  - Air Force Research Lab, Penn State University



Research & Development Tasks

General types of tasks that may be required for Non-Lethal Laser Weapon Research and Development:

- Counter-personnel and counter-materiel prototype system development, non-lethal weapons effects testing, and demonstration

- Laser bioeffects research to include animal and human subject research

- Modeling and simulation to predict atmospheric propagation, target effects at range (including bioeffects), etc.

- Systems engineering and technology integration

Capabilities

General capabilities and expertise that may be required to execute planned R&D non-lethal laser technology tasks:

- Engineers/Scientists with expertise in laser optics, femto/nano-second laser pulses, electronic instrumentation, and systems engineering
- Facilities and equipment to build and test prototype systems
- Biomedical researchers with expertise in laser bioeffects and effectiveness
- Accredited institutional controls for bioeffects research:
  - Institutional Review Board (IRB)
  - Institutional Animal Care and Use Committee (IACUC)
- Computational scientists and engineers to build/improve computer based propagation and bioeffects models and run simulations

Radiofrequency/Micowave Radiation Biological Effects and Safety Standards: A Review

Scott M. Bolen
June 1988

Abstract

The study of human exposure to radiofrequency/microwave radiation has been the subject of widespread investigation and analysis. It is known that electromagnetic radiation has a biological effect on human tissue. An attempt has been made by researchers to quantify the effects of radiation on the human body and to set guidelines for safe exposure levels. A review of the pertinent findings is presented along with the American National Standards Institute (ANSI) recommended safety standard (C95.1-1982) and the United States Air Force permissible exposure limit for RF/MW radiation (AFOSH Standard 161-9, 12 February 1987). An overview of research that was conducted in the Soviet Union and Eastern Europe is also included in this report.

I. INTRODUCTION

In 1956, the Department of Defense (DOD) directed the Armed Forces to investigate the biological effects of exposure to radiofrequency/microwave (RF/MW) radiation. The Army, Navy, and Air Force Departments commissioned a Tri-Service Program under the supervision of the Air Force to meet the DOD directive [14], [15]. The Rome Air Development Center and the Air Research and Development Headquarters were ultimately given responsibility to manage the program. On July 15-16, 1957 the first of four Tri-Service Conferences was held to discuss the effects of RF/MW radiation. These conferences were the first major effort put forth by the scientific community to explore the biological effects of exposure to RF/MW radiation [14]. Since then, researchers have discovered a number of biological dysfunctions that can occur in living organisms. Exposure of the human body to RF/MW radiation has many biological implications. The effects range from innocuous sensations of warmth to serious physiological damage to the eye [1], [2], [5], [6], [8], [15]. There is also evidence that RF/MW radiation can cause cancer [8].

The absorption of RF/MW radiated energy causes biological reactions to occur in the tissue of the human body. In order to determine safe exposure levels and to understand the effect of RF/MW radiation it is necessary to know the absorption characteristics of the human tissue. The National Institute for Occupational Safety and Health (NIOSH) [8] has reported several physical properties that account for energy absorption in biological materials. Factors which govern energy absorption include: (1) strength of the external electromagnetic (EM) field, 2) frequency of the RF/MW source, 3) the degree of hydration of the tissue, and 4) the physical dimensions, geometry, and orientation of the absorbing body with respect to the radiation EM field [8]. There is some disagreement among researchers in determining a specific measure for the dose of RF/MW radiation contracted by

biological materials. The most commonly accepted measure is the Specific Absorption Rate (SAR). The SAR is defined as the rate at which RF/MW radiated energy is imparted to the body - typically in units of watts per kilogram (W/Kg) [4]. The deposition of energy specified in terms of milliwatts per square centimeter (mW/cm^2) over the irradiated surface is also widely accepted [9].

Based on the known absorption rates and the inherent biological effects of RF/MW radiated energy, researchers have put forth a number of standards regarding safe exposure levels. In some instances standards recommended by different examining authorities are in conflict. For example, the USAF Standard 161-9 (enacted 12 February 1987) allows for a permissible exposure level of 10 mW/cm^2 for persons working in restricted areas and 5 mW/cm^2 for persons working in unrestricted areas [10]. The ANSI guideline specifies a maximum safe exposure level of 5 mW/cm^2 over the whole-body area for anyone in contact with RF/MW radiation [9]. These differences reflect the way in which each examining authority has interpreted the available RF/MW radiation exposure data.

II. BIOLOGICAL EFFECTS

Exposure to RF/MW radiation is known to have a biological effect on animals and humans. Damage to major organs, disruption of important biological processes, and the potential risk of cancer represent the dangers of RF/MW radiation to living organisms. Pulsed radiation appears to have the greatest impact on biological materials [8].

The response of biological materials to the absorption of thermal energy is the most perceptible effect of exposure to RF/MW radiation [7]. The energy emitted from an RF/MW source is absorbed by the human tissue primarily as heat. In this case, the radiated energy is disposed in the molecules of the tissue. Dipole molecules of water and protein are stimulated and will vibrate as energy is absorbed throughout the irradiated tissue area. Ionic conduction will also occur in the same area where the radiation is incident. It is from these two natural processes that radiant energy is converted into heat [11]. The thermal effect of continuous wave (CW) and pulsed radiation is considered to be the same [13].

Nonthermal responses can be less noticeable and are often more difficult to explain than thermal effects. These responses are related to the disturbances in the tissue not caused by heating. Electromagnetic fields can interact with the bioelectrical functions of the irradiated human tissue [8]. Research conducted in the Soviet Union and Eastern Europe suggests that the human body may be more sensitive to the nonthermal effects of RF/MW radiation [3].

There are many reported biological effects to humans and animals that are exposed to RF/MW radiation. A review of the important findings is given in the following:

A. Heating Effect on the Skin

Most RF/MW radiation penetrates only to the outer surface of the body. This is especially true for RF/MW frequencies greater than 3 GHz where the likely depth of penetration is about 1-10 mm [3]. At frequencies above 10 GHz the absorption of energy will occur mostly at the outer skin surface. Since the thermal receptors of the body are contained primarily in this region, the perception of RF/MW radiation at these frequencies

may be similar to that of infrared (IR) radiation [3], [6].

In 1937, J. Hardy and T. Oppel published an investigative paper on the thermal effects of IR radiation. Their findings were used by Om Gandhi and Abbas Riazi [6] to explain the thermal effect of RF/MW radiation on the human body (the reference for Hardy and Oppel can be found in [6]). Figure 1 shows the results obtained from the 1937 report. As described by Gandhi and Riazi, the findings presented by Hardy and Oppel show that sensations of warmth begin to occur when the whole-body is irradiated at a CW power density of about 0.67 mW/cm^2. Hardy and Oppel based their work on exposure to IR radiation. From other published reports, Gandhi and Riazi noted that there is a correlation between the radiating frequency of the incident RF/MW energy and the threshold for perception. For example, on an exposed area of the forehead of 37 cm^2 a perception of warmth was reported for incident power densities of 29.9 and 12.5 mW/cm^2 from sources radiating at 3 and 10 GHz respectively [6].

Other observations made by Hardy and Oppel showed that when smaller body areas were irradiated, larger power densities were required to stimulate the thermal receptors in the skin. Gandhi and Riazi were able to confirm this result with reports from recent papers. They found that irradiation of an exposed body area of 40.6 cm^2 to a power density of about 21.7 mW/cm^2 yielded the same thermal perception as did the irradiation of a smaller body area of 9.6 cm^2 to a power density of about 55.9 mW/cm^2. Hardy and Oppel reported that thermal sensations occurred within about 3 seconds after irradiation of the body tissue. More recent findings indicate a reaction time of closer to 1 second [6].

Gandhi and Riazi [6] have also reported that the depth of penetration of RF/MW radiation has an impact on the power density threshold needed to stimulate the perception of warmth. As a comparison, IR radiation will not penetrate the outer body surface as deeply as RF/MW radiation emitted at a frequency of 2.45 GHz. Clinical observations have shown that irradiation of the ventral surface of the arm by an RF/MW source radiation at 2.45 GHz will cause a sensation of warmth when the incident power density is about 26.7 mW/cm^2. For incident IR radiation a perception of warmth occurs at a power density of 1.7 mW/cm^2. They estimated that at millimeter wavelengths the perception of warmth may occur at a power density level of about 8.7 mW/cm^2.

Exposure to higher levels of radiation can cause serious biological effects. Because of the physical dimensions and geometry of the human body, RF/MW radiated energy is nonuniformily deposited over the whole-body surface. Some areas on the skin and outer body surface will absorb higher amounts of the radiated energy. These areas will be marked by "hot spots" of high temperatures [7], [11], [16]. Experiments conducted on laboratory animals have shown, that skin burns typically occur in the areas of hot spots. The penetration of RF/MW radiation also causes skin burns to be relatively deep [11]. In experiments sponsored by the Tri-Service Commission, it was reported that RF/MW radiation burns over the rib cages of dogs caused severe subcutaneous damage that did not visibly appear for weeks after the injury was sustained [20]. Burns can cause increased vascular permeability. This can lead to significant losses of body fluids and electrolytes. Serious burns can suffer fluid losses for a few days. Blood circulation can be altered in the effected area and other biological functions could be indirectly affected [12].

B. Whole-Body Hyperthermia

Thermal energy absorbed by the whole-body can cause a rise in body temperature. When the human body is irradiated by an RF/MW source at an incident power density of 10 mW/cm^2 there will be a rise in body temperature of about 1° C. The total thermal energy absorbed at this power density is about 58 watts. Typically, at rest the human basal metabolic rate is about 80 watts and it is about 290 watts during periods of moderate activity. Exposure of the human body to low power RF/MW radiation does not appear to impose any appreciable thermal hazard. These figures were reported by The U.S. Department of Health, Education and Welfare [3].

Adverse biological effects can occur when the body is subjected to high doses of RF/MW radiation [16]. In this instance large amounts of thermal energy can be absorbed by the body. A dramatic influx of energy can overburden thermoregulatory mechanisms. If excess heat cannot be exhausted the core temperature of the body will rise to a dangerous level resulting in hyperthermia [12], [16]. The biological response to excess heat buildup is the dilation of blood vessels at the surface of the skin and the evaporation of water through sweating. These are the primary mechanisms for heat dissipation. Hyperthermia can cause severe dehydration and the loss of electrolytes such as sodium chloride. Other harmful effects include fever, heat exhaustion, and heat fatigue. Heat stress is the most serious consequence of hyperthermia. Cardiac failure and heat stroke can result from heat stress [12].

It has also been noted that hyperthermia may cause injury to blood-brain barrier (BBB) [19]. This barrier refers to the several biological materials that separate the essential elements of the central nervous system from the blood [18]. High cerebral temperatures exceeding 43°C may damage the BBB. The result can be a disruption of blood vessel continuity or integrity and degradation of the flow of blood and other body fluids in the brain [19].

C. Local Hyperthermia

The nonuniform deposition of RF/MW radiated energy over the whole-body surface causes the body to be heated unevenly. Local areas where temperatures rise above 41.6°C can experience damage to the tissue [16]. In these areas it is possible that harmful toxins could be released as result of the high temperatures. Heating can cause cell membranes and blood capillaries to become more permeable. An increase in capillary permeability can lead to a loss of plasma proteins. The denaturation of proteins can also occur within cells [11], [16]. This can lead to changes in the physical properties and biological functions of proteins [18]. Denaturation of proteins can also cause polypeptide and histamine-like substances to become active [11], [16]. Histamines can stimulate gastric secretion, accelerate the heart rate, and cause the dilation of blood vessels resulting in lower blood pressure [18]. Areas of the body where blood circulation is poor or where thermal regulation is insufficient, are more susceptible to injury [11].

D. Carcinogenic Effects

The carcinogenic effects of exposure to RF/MW radiation are not well known. It is difficult to clinically establish a link to cancer. The problem that researchers have in linking

RF/MW radiation to cancer is that the disease itself is prevalent and can be caused by a variety of environmental factors. In fact cancer is the second leading cause of death in the United States. There are, however, published reports that reveal some insights into the carcinogenic nature of RF/MW radiation. Nonthermal effects may provide important clues to the understanding of carcinogenic reactions in the human body [8],[32].

i. Pathological Reports

In 1962, S. Prausnitz and C. Susskind reported experimental results that showed an increase in cancer among test animals exposed to RF/MW radiation. In the experiment, 100 male Swiss albino mice were irradiated by a 10 GHz RF/MW source at an incident power density of about 100 mW/cm^2. The mice were exposed for 4.5 minutes/day, 5 days/week for a total of 59 weeks. It was noted that irradiation caused the whole-body temperature of the mice to rise about 3.3°C. Upon examination, it was found that 35% of the mice had developed cancer of the white blood cells. The disease was observed as monocytic or lymphatic leucosis or lymphatic or myeloid leukemia. Only 10% of a similar control group had developed cancer [21].

There have been a few allegations that RF/MW radiation has induced cancer in humans [8], [15]. The NIOSH Technical Report [8] cites charges made in the early 1970's against Philco-Ford and The Boeing Corporation that occupational exposure to RF/MW radiation caused cancer among employees. One incident was reported at each company. At Philco-Ford it was claimed that exposure caused a rare form of brain cancer to manifest in one worker that eventually resulted in death. In each case, there was no scientific proof that RF/MW radiation had induced cancer in the company employees. There was also a report that EM fields induced cancer in an individual that worked at the U.S. Embassy in Moscow. Again, there was no scientific evidence that supported the claim [8].

Recently, the Observer Dispatch, a local newspaper published in Utica, New York, reported that a major study has just been completed in Sweden. The study concluded that children who live near high power lines have a greater risk of developing leukemia than children who live farther away from the power lines. The study involved 500,000 people and provided some evidence to link the electromagnetic fields produced by low frequency power lines to cancer. The researchers, however, cautioned against drawing firm conclusions as a result of the research [33]

ii. Effect on Chromosomes

It has been observed that disturbances in chromosomic activity can cause cancerous aberrations to occur in the human body. In 1974, a paper published by K. Chen, A. Samuel, and R. Hoopingarner (reference found in [8]) reported that chromosomal abnormalities can be linked to chronic myeloid leukemia. Serious genetic mutations can also result from such abnormalities that can lead to malignancies in the tissue [8].

In 1976, A. A. Kapustin, M. I. Rudnev, G. I. Leonskaia, and G.I. Knobecva (reference found in [17]) reported alterations in the chromosomes of bone marrow cells in laboratory animals that were exposed to RW/MW radiation. They exposed inbred albino rats to a 2500 MHz RF/MW source at incident power density levels of 50 and 500 uW/cm^2. Irradiation lasted for 7 hours/day for 10 days. Upon examination of the animals, they

observed chromosomal anomalies that appeared in forms described as polyploidy, aneuploidy, chormatic deletion, acentric fragments and chromatic gaps [17].

The NIOSH Technical Report [8] summarizes the findings of several researchers. Chromosomal and mitotic anomalies have been observed in a variety of animal and human cells for varying exposures to RF/MW radiation. Pulsed and CW radiation ranging in frequency from 15 to 2950 MHz and power densities from 7 to 200 mW/cm^2 have caused abnormalities to occur in chromosomes. The reported affects include: linear shortening of the chromosomes, irregularities in the chromosomal envelope, abnormal bridges and stickiness, translocations, chromosomal breaks and gaps, chromatid breaks, acentric chromosomes, dicentric chromosomes, deletions, fragmentation, and ring chromosomes [8].

iii. Mutagenic Effects

Reported evidence indicates that biological interaction with EM fields can cause the formation of mutagens in cells. In 1974, three Soviet researchers, Danilenko, Mirutenko, and Kudrenko (reference found in [8]) published results showing a mutagenic effect of RF/MW radiation. Mutagens were observed to form in cells that were irradiated by a pulsed RF/MW source operating at 37 GHz and 1 mW/cm^2 power intensity. They concluded that irradiation of tissue by pulsed RF/MW sources causes cell membranes to become more permeable to destructive chemical mutagens [8].

Results published in 1963 by G. H. Mickey (reference found in [8]) showed hereditary changes to occur in drosphila germ cells that were exposed to pulsed modulated RF/MW radiation for carrier frequencies between 5-40 MHz [8]. Evidence of RF/MW induced teratogenesis in animals has also been reported by researchers. The effect of exposure to CW radiation was observed by Rugh and McManaway in 1976 (reference found in [8]). They found gross congenital abnormalities in rodent fetuses that were irradiated by a 2450 MHz RF/MW source at an incident power intensity of 107.4 mW/g [8].

iv. Lymphoblastoid Transformations

Lymphoblastoid Transformations refer to changes in the physical nature of lymphoblasts. Mature lymphoblast cells (i.e. lymphocytes) participate in the immune system of the body [18]. Lymphoblastoid transformations induced by RF/MW radiation appear to be similar to transformations present in disorders contributing to abnormal growth in lymphoid tissues and in certain types of leukemia. RF/MW radiation induced transformations, however, do not appear to be malignant and are not likely to spread among healthy cells [8].

W. Stodlink-Baranska reported (reference found in [8]) lymphoblastoid transformations to occur when human lymphocyte cells were exposed to a 2950 MHz pulsed RF/MW source at power density levels of 7 and 20 mW/cm^2. In 1975, P. Czerski also reported (reference found in [8]) observing lymphoblastoid transformations after irradiation of purified human lymphocyte suspensions by an RF/MW source radiating at 2950 MHz for variable power density levels. In addition, Czerski reported acute transformations occurring in adult mice and rabbits that were irradiated by a pulsed RF/MW source radiating at 2950 MHz and at low power density levels of 0.5 and 5 mW/cm^2 respectively [8].

v. Oncogenic Effects

Oncogenic effects have been linked to imbalances in the regulatory mechanisms of the body. A 1974 report published by E. Klimkova-Deutschova (reference found in [8]) claimed that persons exposed to RF/MW radiation experience biochemical reactions. The report indicated alterations in fasting blood sugar levels, a decrease in the ability to dispose of normal metabolic waste, and depressed serum levels of pyruvate and lactate. These biochemical reactions point to the possibility of regulatory malfunctions occurring in the body. It has been suggested that certain regulatory imbalances may promote the growth of tumors. A change in hormonal levels has been observed to cause oncogenic effects in tissues that require hormonal balances to function properly. The presence of hormones in other tissue areas may effect the development of existing tumors in those areas [8].

E. Cardiovascular Effects

Most of the cardiovascular effects of RF/MW radiation have been reported by researchers in the Soviet Union and Eastern Europe. Soviet investigators claim that exposure to low levels of RF/MW radiation that are not sufficient to induce hyperthermia can cause aberrations in the cardiovascular system of the body [7].

One experiment performed on rabbits indicates that several types of cardiovascular dysfunctions could be possible. An RF/MW source radiating at 2375 MHz was used to irradiate rabbits for a test period of 60 days under varying field intensities. For field strengths ranging from 3-6 V/M researchers noted a sharp increase in the heart rate of the animals. This effect was observed to subside with time. Exposure to field strengths of 0.5-1.0 V/M caused the heart rate to become slower than normal. No effect was reported for rabbits that were exposed to EM field intensities below 0.2 V/M [17]. Other effects that have been observed by Soviet researchers, are alterations in EKG and low blood pressure [7], [17].

The NIOSH Technical Report [8] references a Soviet study published in 1974 by M. N. Sadcikoiva that suggests some connection between RF/MW radiation exposure and the potential for cardiovascular disturbances in humans. Researchers examined 100 patients suffering from radiation sickness. It was found that 71 of the patients had some type of cardiovascular problem. Most of these patients had been exposed to RF/MW radiation for periods ranging from 5-15 years. A smaller group of patients exposed for shorter time periods also experienced cardiovascular irregularities. The study concluded that there is a probable link between exposure to RF/MW radiation and cardiovascular disease [8].

F. The North Karelian Project

In response to earlier Soviet reports, the World Health Organization (WHO) decided to conduct a comprehensive study on the biological effects of exposure to RF/MW radiation. In 1976, M. Zaret published the results of the study (reference found in [8]). The WHO investigation focused on the population of North Karelia, a remote area of Finland that borders the Soviet Union. This region was selected because of its close proximity to a then Soviet early warning radar station. North Karelia is geographically located in the path of intercontinental ballistic missiles that would originate from the midwest United States. To

detect these missiles, the Soviets constructed a number of high power tropospheric scattering radar units adjacent to nearby Lake Ladoga. The operation of these units exposes the residents of North Karelia to large doses of ground and scatter radiation. The WHO investigation found evidence linking exposure of RF/MW radiation to cardiovascular disease and cancer. The North Karelian population suffered from an unusually high number of heart attacks and cases of cancer. In addition, it was found that the affliction rate of these diseases was much higher among residents living closest to the radar site [8].

G. Hematologic Effects

There is evidence that RF/MW radiation can effect the blood and blood forming systems of animals and humans. Experiments conducted in the Soviet Union have indicated changes in blood cell levels and alterations in the biological activities of hematologic elements. Other investigators have reported similar effects [7], [8], [17].

The results of an experiment reported in 1979 by V. M. Shtemier showed a decrease in the biological activity of butyryl cholinesterase in rats that were exposed to pulsed RF/MW radiation (reference found in [17]). The experiment subjected 15 rats to a 3000 MHz pulsed RF/MW source with an incident power density of 10 mW/cm^2. The rats were irradiated for 1 hour/day over several days. After 42 days, there was a loss of biological activity of the butyryl cholinesterase enzyme caused by a decrease in the concentration of the enzyme in the bloodstream of the rats [17]. Cholinesterase is a catalyst in the hydrolysis of acetylcholine into choline and an anion. Choline is a useful enzyme that prevents the deposition of fat in the liver [18].

In another experiment, 20 male rats were exposed to a 2376 MHz pulsed RF/MW source with an incident power density of 24.4 mW/cm_2. Each rat was exposed for 4 hours/day, 5 days/week for 7 weeks. Blood samples were taken periodically and examined for anomalies. After repeated exposures, it was discovered that the number of lymphocytes and leukocytes (white blood cells) in the bloodstream of the rats was lower than normal. The biological activity of alkaline phosphatase in neutrophil leukocytes was also found to increase when the rats were irradiated [17].

The results of several other experiments are summarized in the NIOSH Technical Report [8]. RF/MW radiation has been observed to cause: an increase in the amount of exudate in bone marrow, the transient disappearance of fat cells from bone marrow, destruction and loss of essential bone marrow cells, underdeveloped marrow, a decrease in the number of red blood cells, and an imbalance in the number of lymphocytes in the bloodstream [8].

H. Effect to the Central Nervous System

There is documented evidence that exposure to RF/MW radiation can cause a disturbance in the central nervous system (CNS) of living organisms [3], [8], [11], [17]. Soviet investigators claim that exposure to low-level radiation can induce serious CNS dysfunctions. Experiments conducted in the Soviet Union and Eastern Europe have exposed live subjects to radiation levels that are near or below the recommended safe levels prescribed by the ANSI Standard and the USAF AFOSH Standard [17].

i. Pathological Report

Soviet investigators claim that the central nervous system (CNS) is highly sensitive to RF/MW radiation [3], [8], [11], [17]. The NIOSH Technical Report [8] summarized the results of a pathological study published by A. A. Letavet and Z. V. Gordon in 1960. The researchers reported that several CNS related disorders were discovered among 525 workers exposed to RF/MW radiation. The symptoms were listed as: hypotension, slower than normal heart rates, an increase in the histamine content of the blood, an increase in the activity of the thyroid gland, disruption of the endocrine-hormonal process, alterations in the sensitivity to smell, headaches, irritability, and increased fatigue. Other researchers have acknowledged similar biological responses [8].

ii. Soviet Union Experimental Results

Several experiments have been performed in the Soviet Union and Eastern Europe that demonstrate a variety of biological effects that can occur in living organisms. observations of laboratory animals subjected to low power EM fields showed alterations in the electrical activity of the cerebral cortex and disruptions in the activity of neurons [17].

L. K. Yereshova and YU. D. Dumanski (reference found in [17]) exposed rabbits and white male rats to a continuous wave 2.50 GHz RF/MW source. The animals were irradiated for 8 hours/day over a period of 3 to 4 months at power density levels of 1, 5, and 10 uW/cm^2. It was observed that rabbits exposed to the 5 and 10 uW/cm^2 power density levels suffered alterations in the electrical activity of the cerebra cortex and disturbances to the conditioned reflex response. They concluded that exposure to RF/MW radiation caused perturbations in the higher functioning centers of the CNS in the laboratory animals [17].

An experiment conducted by V. R. Faytel'berg-Blank and G. M. Perevalov demonstrated the biological effects of RF/MW radiation on the activity of neurons (reference found in [17]. They subjected chinchilla rabbits to a 460 MHz RF/MW source at incident power densities of 2 and 5 mW/cm^2. Only the heads of the rabbits were irradiated and exposures lasted for 10 minutes. Exposure at the 2 mW/cm^2 power density level caused neuronal activity to increase and evoked an electroencephalogram (EEG) activation reaction. Neuronal activity was observed to decrease at the higher power density level. These results indicated that RF/MW radiation can cause neurophysiological alterations in animals. These biological responses may be dependent on the intensity of the radiation [17].

iii. Behavioral Effects

Exposure to RF/MW radiation has been observed to cause a disruption in the behavior of animals. Experiments conducted on rats and nonhuman primates indicates that conditioned responses can be altered as a result of irradiation. Researchers indicate that behavior may be the most sensitive biological component to RF/MW radiation [1], [7], [9], [29].

D. R. Justesen and N. W. King (reference found in [7]) reported experimental results that demonstrated a degenerative behavioral effect in laboratory animals that were exposed to RF/MW radiation. The results were published in 1970. They exposed rats to a 2450 MHz multimodal resonating cavity system. Exposure was periodic with irradiation times lasting for 5 minutes and recurring every 5 minutes. This cycle as sustained for 60 minutes. The

experiment tested the effect of irradiation at whole-body energy absorption rates of 3.0, 6.2, and 9.2 W/Kg. It was observed that for a SAR of 6.2 W/Kg the behavioral performance of the rats degraded significantly and activity usually terminated at the end of the 60 minute exposure period [7].

In 1977, James Lin, Arthur Guy, and Lynn Caldwell [29] reported experimental results that showed alterations in the behavioral response of rats that were exposed to RF/MW radiation. White female rats were trained to execute a "head raising" movement in return for a food pellet. The total number of such movements was counted during each exposure session in order to quantify the effect of irradiation. The animals were exposed to a 918 MHz RF/MW source at power density levels of 10, 20, and 40 mW/cm^2. Clinical observations showed that baseline responses remained unchanged for irradiation at the lower power density levels of 10 and 20 mW/cm^2. At 40 mW/cm^2, however, behavioral responses decreased rapidly after 5 minutes of continuous exposure. After about 15 minutes of exposure, behavioral activity terminated. It was determined that the peak energy absorption at 40 mW/cm^2 was about 32 W/Kg and the average absorption was 8.4 W/Kg over the whole-body surface [29].

iv. Synergetic Effect of Drugs RF/MW Radiation

In 1979, J. R. Thomas et al. reported that psychoactive drugs and RF/MW radiation may have a synergetic effect on living organisms (references for Thomas can be found in [1]). Experiments were conducted on laboratory animals. Male albino rats were administered dextroamphetamine and irradiated with a pulsed 2450 MHz RF/MW source at 1 W/cm^2 power intensity for periods of 30 minutes. It was found that the number of clinical responses observed per minute in the rats diminished more rapidly under the stimulus of both agents than in the control condition where just the drug was administered. This indicates that the effects of RF/MW radiation may be enhanced by certain drugs [1].

v. Analeptic Effect in Animals

Pulsed RF/MW radiation was reported to have an analeptic effect in laboratory animals. Experimental results presented by R. D. McAfee in 1971 showed that anethesized animals could be awakened by irradiation from a pulsed 10 GHz RF/MW source. The energy incident on the test animals was estimated to have a power density of between 20-40 mW/cm^2. Experiments conducted on rats showed that these animals were aroused from states of deep sleep by irradiation. It was observed that the blood pressure of a rat decreased simultaneously with the arousal response and that laryngeal spasms would occur when the rat was awakened. McAfee reported that the laryngeal spasms would obstruct the airway causing convulsions, asphyxiation, and eventually death. Other experiments performed on rabbits, cats, and dogs showed that these animals could also be awakened by irradiation. The larger animals, however, did not asphyxiate themselves, The blood pressure of the dogs and cats was observed to rise as they were awakened. In all cases, the arousal response was stimulated only when the head of the animal was irradiated. The body temperature of the test animals was not observed to rise as a result of irradiation. This indicates that the analeptic effect of RF/MW radiation may be nonthermal in nature [20].

I. Immunological Effect

Exposure to RF/MW radiation has been observed to cause physical alterations in the essential cells of the immune system and a degradation of immunologic responses [7], [17]. Experimental results published by Soviet and Eastern European researchers indicate that irradiation can cause injury and trauma to the internal body organs that comprise the immune system. Even exposure to low levels of RF/MW radiation can impair immunologic functions [17].

As discussed earlier, lymphoblasts can undergo physical alterations as a result of irradiation. Lymohiblastoid mutagens are similar in structure to leukemia cells [8]. Lymphoblasts are the precursors to leukocyte cells that participate in the immune system [18].

In 1979, N. P. Zalyubovskaya and R. I. Kiselev (reference found in [17]) reported that exposure to RF/MW radiation caused serious damage to the immune system of laboratory animals. They exposed mice to an RF/MW source radiating at 46.1 GHz with an incident power intensity of 1 mW/cm^2 for 15 minutes/day for 20 days, it was observed that the number of leukocytes in the bloodstream of the mice decreased as a result of irradiation. Effective quantities of enzymatic proteins in serum that combine with antigen-antibody complex and antibacterial agents such as lysozyme were also reduced. Zalyubovskaya and Kiselev reported a decrease in the phagocytic activity of neutrophils and a diminished resistance to infections caused by tetanic toxins. Immunity to typhoid and other tetanic toxins induced by vaccination or by the administration of antitoxins was rendered ineffective. Further examination of the mice revealed injury and trauma to the internal body organs. Irradiation had caused physical alterations in the thymus, spleen, and lymph nodes. The lymphoid organs suffered a total loss of mass [17].

J. Effect on the Eye

Clinical studies indicate that exposure to RF/MW radiation causes physiological damage to the eye that can result in loss of sight. It has been observed that irradiation causes the formation of cataracts in the lens of the eye. Tissue damage appears to be the result of thermal trauma induced by the heating property of RF/MW radiation. Experiments conducted on laboratory animals have demonstrated severe ocular damage as a result of exposure [30], [31].

i. Ocular Sensitivity

Exposure of the eye to RF/MW radiation causes physical duress that can lead to damage of the ocular tissue. The incident power intensity and the duration of radiation exposure are factors that determine the amount of tissue damage. The lens of the eye appears to be most susceptible to RF/MW energy radiated at frequencies between 1-10 GHz. For this frequency range, it has been observed that lens fibers will suffer irreversible damage to a greater extent than other ocular elements [30]. Lens fibers are elongated, thread-like structures that form the substance of the lens [18]. In 1979, Stephen Cleary reported [30] that cataracts are formed in the lens as a result of alterations in the paracystalline state of lens proteins. Physical, chemical or metabolic stress may be responsible for opacification of

the lens [30].

ii. Experiments on Rabbits

Severe tissue damage has been observed in rabbits that have been exposed to RF/MW radiation. Stephen Cleary [30] reports that intense radiation exposure can cause "immediate tearing, injection, pupillary constriction, and anterior turbity" in the rabbit eye. Lens opacities can occur when the eye is irradiated by a 2450 MHz RF/MW source at incident power density levels of 100-300 mW/cm^2. At this exposure level, cataracts have been observed to form 24-48 hours after irradiation [30]. In 1976, Kramer, Harris, Emery, and Guy (reference found in [30]) reported observing the formation of cataracts in rabbit eyes that were exposed to 2450 MHz RF/MW radiation at an incident power density level of 180 mW/cm^2 for an exposure time of 140 minutes [30].

Acute ocular damage and the formation of cataracts appears to be the result of local hyperthermia of the eye. It has been observed, however, that trauma induced by heating of the ocular tissue may be unique to the exposure effects of RF/MW radiation [30]. In 1975, Kramer, Harris, Emery, and Guy (reference found in [30]) reported subjecting rabbits to hyperthermia not induced by exposure to RF/MW radiation. Heating caused the intra-ocular temperature of the eye to rise above normal. The retrolental temperature was reported to be about 42°C during the test period. Hyperthermia was sustained for approximately 30 minutes. Despite heating conditions that were similar to exposure from RF/MW radiation, lens opacities did not occur in the rabbit eyes [30]. Similar results have been reported by other researchers [30]. These results indicate that hyperthermia alone may not be sufficient to cause the formation of cataracts. Direct exposure to RF/MW radiation may be necessary to induce opacities in the lens [30].

iii. Cataracts in Humans

Exposure to RF/MW radiation is known to cause cataracts in the human eye. Several cases have been documented that report RF/MW induced cataracts in humans. Typically, lens opacities have resulted from exposure levels that are greater than specified by the various safety standards. However, minimum exposure levels sufficient to cause ocular damage are not certain [30].

In 1970, Zaret, Kaplan and Kay (reference found in [30]) reported a large number of cataracts induced in humans as result of occupational exposure. This report cited 42 cases of chronic exposure to RF/MW radiation. They reported that workers suffered damage to the posterior lens capsule. In one case, exposure periods lasted about 50 hours/week for 4 years. During most of the 4 year period the incident average power density level was approximately 10 mW/cm^2. For one 6 month period, however, power density levels may have reached 1 W/cm^2 [30].

In 1966, S. Cleary and B. Pasternack (reference found in [30]) published the results of an epidemiological study of military and industrial microwave workers. It was reported that minor alterations had occurred in the ocular lenses of the workers as a possible result of chronic RF/MW radiation exposure. Defects were found in the posterior pole of the lens. Cleary and Pasternack noted that the number of minor ocular defects was related to the specific occupational duties of the workers. The greatest number of defects was found

among persons working in research and development jobs. The results of the study were based on a comparison of the microwave workers with a similar control group. The researchers concluded that exposure to RF/MW radiation had caused the lens of the eye to age faster than normal [30].

Similar cases of RF/MW radiation induced ocular damage have been reported by other researchers. In one case, a 22 year old microwave technician was exposed 5 times over a 1 month period to a 3 GHz radiation source. The incident power density level was about 300 mW/cm^2 and irradiation lasted approximately 3 minutes during each exposure time. It was reported that the technician had developed bilateral cataracts as a result of irradiation [30]. In another case, M. Zaret (reference found in [30]) reported that a 50 year old woman had developed cataracts after intermittent exposure to a 2.45 GHz microwave oven. The incident power density levels were about 1 mW/cm^2 during operation of the oven and as high as 90 mW/cm^2 when the oven door was opened [30].

K. Auditory Effect

Individuals exposed to pulsed RF/MW radiation have reported hearing a chirping, clicking or buzzing sound emanating from inside or behind the head. The auditory response has been observed only for pulsed modulated radiation emitted as a square-wave pulse train. The pulse width and pulse repetition rate are factors that appear to determine the type of sound perceived [1], [31].

James Lin [31] reports that the sensation of hearing in humans occurs when the head is irradiated at an average incident power density level of about 0.1 mW/cm^2 and a peak intensity near 300 mW/cm^2. Auditory responses have been observed for a frequency range of 200-3000 MHz and for pulse widths from 1-100 us [32].

III. RF/MW ENERGY DEPOSITION

The absorption of RF/MW radiated energy causes biological reactions to occur in living organisms. In order to understand the potential effects of RF/MW radiation, it is important to quantify the absorption characteristics of biological materials. Researchers have identified several principal factors that govern the absorption of RF/MW energy by the human body. Experimental results have indicated that clothing thickness, physical dimensions, degree of hydration, and the resonance frequency of the human body are important parameters that determine the amount of energy absorbed by the body [1], [8], [9], [16], [22].

A. Specific Absorption Rate (SAR)

The specific absorption rate (SAR) is a measure of the dose of RF/MW energy absorbed by biological materials. It is intended to give a quantitative understanding to the absorption of energy. The SAR is defined as the amount of energy that is imparted to the body as a function of body mass [4]. SAR's are usually expressed in terms of watts of incident power per kilograms of irradiated body mass (W/Kg) [4], [9].

B. Depth of Energy Penetration

It is known that RF/MW radiated energy will be absorbed by the tissue of the human body. The depth of energy penetration into he tissue depends primarily on the wavelength of the incident radiation and the water content of the tissue [3], [6].

Energy emitted in the millimeter-wave band is not likely to penetrate to more than about 1 or 2 mm into the tissue [6]. Essentially, RF/MW energy radiated at wavelengths less than 3 centimeters will be captured in the outer skinsurface. RF/MW wavelengths from 3 to 10 centimeters will penetrate to a depth of about 1 to 10 mm. The greatest depth of penetration into the body will occur at wavelengths between 25 to 200 centimeters. At these wavelengths RF/MW radiated energy can directly effect internal body organs and cause serious injury. The human body is reported to be "transparent" to RF/MW radiated energy emitted at wavelengths greater than 200 centimeters. Also, at frequencies above 300 MHz it has been observed that the depth of energy penetration fluctuates rapidly with changes in frequency. In general, the depth of energy penetration into the body will decline as the frequency of the incident radiation increases. At 10 GHz, the absorption of RF/MW energy will be similar to IR radiation [3]. These figures were published by the U. S. Department of Health, Education and Welfare [3].

The water content of the human tissue will also influence the depth of energy penetration into the body. Millimeter-wave radiation is reported by Ghandi and Riazi [6] to penetrate less than 2 mm into the body because of the "Debye relaxation of the water molecules" in the tissue [6]. The Debye Effect was observed by a Dutch physicist named Peter Debye [23]. He discovered that EM waves are absorbed by a dielectric because of molecular dipoles present in the dielectric material [24]. Water molecules are essentially dipoles constructed from atoms of hydrogen and oxygen. Biological materials such as skin are dielectrics that consist mostly of water. Hence, these dielectrics are rich in molecular dipoles and are able to quickly absorb millimeter-wave radiation. High frequency radiation emissions are not expected to penetrate deeply into the human body [6].

C. Effect of Geometry

The orientation of the human body with respect to the incident EM field will determine the amount of RF/MW energy that is absorbed by the tissue. Experimental results published by Om Gandhi in 1980 indicate that the condition for maximum absorption occurs when the electric field is parallel to the major axis of the body and the direction of the field propagation is from arm to arm. Figure 2 shows the amount of energy absorbed versus the radiating frequency for various EM field orientations [22].

D. Effect of the Resonance Frequency

Researchers have reported that the human body will absorb the greatest amount of RF/MW energy from sources radiating at the whole-body resonance frequency [1], [9], [22], [25], [27]. The ANSI Standard [9] reports that the human body will absorb 7 times more energy from radiation emitted at the resonance frequency than at a frequency of 2450 MHz [9]. Experiments conducted on fabricated human models have been used to determine the resonance frequency of the human body [22]. Partial-body resonances have also been

observed by researchers. Computer simulation techniques have been used to estimate the resonance frequency of the human head [26].

The free space whole-body resonance frequency is reported to be between 61.8-77 MHz for a Standard Model of Man [9], [22], [25]. The standard model depicts an average man standing 175 cm tall [9]. Experimental results tend to differ somewhat from numerical calculations. The ANSI Standard [9] reports the whole-body resonance frequency to be 70 MHZ [9]. Similarly, experimental results presented by Hagman, Gandhi, and Durney [25] indicate the resonance frequency to be between 68-71 MHz. However, calculations put forth by the same researchers place the whole-body resonance at 77 MHz [25]. In 1980, Om Gandhi reported that the maximum absorption of energy will occur at frequencies where the free space wavelength (λ) of the incident radiation is about 2.50-2.77 times greater than the major length (L) of the body (i.e. $\lambda > 23.50L$-$2.77L$). This formula puts the value of the resonant frequency between 61.8-68.5 MHz for a standard model of man. When the human body is in contact with the electrical ground, the whole-body resonance frequency is reduced to about 47 MHz [22]. Figure 3 shows the SAR versus the incident EM field frequency for conditions of free space and grounding [22].

Numerical calculations have been presented by Hagman, Gandhi, D'Andrea, and Chatterjee [26] that indicate the free space resonance frequency of the human head to be about 375 MHz [26]. In a separate report, Gandhi determined that the head resonance will occur when the free space wavelength of the incident radiation is about 4 times the diameter of the head [22]. The condition for maximum energy absorption occurs when the direction of the EM field propagation is parallel to the long axis of the body. This orientation differs from the condition determined for RF/MW energy absorption by the whole-body. Figures 4 and 5 show the absorption of energy versus frequency for different EM field orientations [26].

E. Effect of Clothing

Clothing can act as an impedance matching transformer for RF/MW radiation. In 1986, Gandhi and Riazi [6] reported that the coupling efficiency of clothing may be as high as 90-95 percent for incident radiation in the millimeter-wave band. They determined that the thickness of the clothing and frequency of the incident radiation are important factors in the coupling condition. Figure 6 shows the relationship between clothing thickness and coupling efficiency as a function of frequency. The authors note that wet or damp clothing may actually reduce the amount of energy absorbed by the body because of the Debye relaxation of the water molecules [6].

IV. RF/MW RADIATION EXPOSURE STANDARDS

Exposure of living organisms to RF/MW radiation can have a potentially dangerous biological effect. To ensure the public safety and to safeguard the workplace against unnecessary RF/MW radiation exposure, protective guidelines have been adopted by the United States and several other nations. The maximum safe exposure levels recognized by individual examining authorities tends to vary as a result of differing interpretations of the

available RF/MW exposure data. There is a large distinction between permissible exposure levels observed in the United States and the Soviet Union. East Block countries have set more stringent standards than nations in the West [3], [8], [11], [22].

A. ANSI Standard C95.1-1982

In response to the need for a national RF/MW radiation protection guide, the American Standards Association commissioned the Department of the Navy and The Institute of Electrical and Electronics Engineers to cooperate in formulating an acceptable standard for safe radiation exposure levels. In 1960, the Radiation Hazards Standards Project was established to coordinate the efforts of researchers. Since then, work has progressed and in 1982 a modern RF/MW radiation protection guide was established. The American National Standards Institute (ANSI) designated this guide as C95.1-1982 [9]. Presently, a new ANSI guide is due for publication in May 1993. The new guide is entitled "ANSI/IEEE C95.1-1992". This guide will supersede C95.1-1982 when it is published.

i. Recommendations

The ANSI C95.1-1982 Standard specifies the maximum recommended RF/MW radiation exposure levels over a frequency range of 300 KHz to 100 GHz. Typically, the standard calls for an exposure of no more than 5 mW/cm^2 for frequencies between 1500 MHz to 100,000 MHz. The reader should consult with the actual ANSI publication for the detailed recommendations. In addition, the standard limits the whole-body SAR to 0.4 W/Kg and indicates that the spatial peak SAR should not exceed 8.0 W/Kg over any one gram of tissue. For both CW and pulsed EM fields the exposure time should not exceed 6 minutes at the recommended levels. These maximum safe levels are not intended to apply to the medical treatment of patients where irradiation is sometimes useful in combating diseases like cancer. The standard does pertain to the general public and to persons that work in electromagnetic environments. There are two exceptions to the recommendation: 1) at frequencies between 100 KHz and 1 GHz the maximum exposure levels may be exceeded as long as the stated SAR values are not violated and 2) at frequencies between 300 KHz and 1 GHz the exposure levels may be exceeded if the output power of the radiating device is less than 7 W [9].

ii. Philosophy

An explanation of the recommended maximum exposure levels is given as part of the protection guide. The ANSI Standard is intended to afford the best possible protection of human life against RF/MW radiation exposure. The biological effect on the human body for all RF/MW frequencies and modulation schemes is not known, therefore, investigators sought to interpret the available data in a way that would allow for the construction of the best possible RF/MW radiation protection guide. Investigators emphasized studies that reported harmful or potentially serious biological effects. Unlike past standards, researchers agreed that the modern protection guide would also account for the nonthermal effects of RF/MW radiation [9].

The safe exposure levels expressed by the ANSI guideline were determined for far field exposures. The plane wave model used to specify the maximum exposure levels may not be accurate to describe conditions in the near field. However, the power density levels expressed in the protection guide are not considered great enough to induce EM fields with sufficient energy intensities capable of exceeding the recommend SAR's [9].

In selecting a measure for the dose of RF/MW radiation, it was recognized that the SAR does not encompass all of the important factors necessary to determine safe exposure levels. The modulation frequency and peak power of the incident EM field should also be considered. Some of the investigators warned that extra care should be taken by persons that are subjected to pulsed EM fields or by fields that are modulated near the whole-body resonance frequency [9]

In assessing the biological effects, it was found that behavior was the most sensitive biological component to RF/MW irradiation. It was observed that behavioral effects were reversible for exposure to carrier frequencies between 600 MHz and 2450 MHz when whole-body SAR's were limited to between 4 and 8 W/Kg. For these SAR's, power densities were calculated or measured to range from 10 mW/cm^2 to 50 mW/cm^2. Behavioral effects were considered to be among the most serious consequences of exposure to RF/MW radiation [9].

It was established that in order to ensure an acceptable margin of safety the whole-body average SAR should not exceed 0.4 W/Kg. Most of the researchers concluded that this was a necessary and reasonable standard. The exceptions cited in the recommendations were justified on the basis of the total rate of energy absorption by the human body. The Standard reports that small radio transceivers are able to emit EM fields that exceed the prescribed power density levels. Such devices, however, are not expected to compromise the prescribed maximum SAR levels. In general, compliance with the ANSI RF/MW protection guide is the best safeguard against harmful biological effects [9].

B. USAF PEL (AFOSH Standard 161-9, 12 February 1987)

Since the early investigations of the Tri-Service Commission, the United States Air Force has recognized the need to establish an RF/MW protection standard. The USAF permissible exposure level (PEL) is specified in AFOSH Standard 161-9 enacted 12 February 1987. This standard stipulates maximum safe RF/MW radiation exposure levels over a frequency range of 10 KHz to 300 GHz. The PELs are shown in Figures 7 and 8 [10].

In general, the USAF protection guideline agrees with the ANSI Standard except that a distinction is made between exposure to persons in restricted and unrestricted areas. No explanation for this policy is given in the USAF Standard. The PEL for restricted areas shows only a slight alteration from the ANSI recommendation. For a frequency range of 1500-300,000 MHz the USAF PEL is given as 10 mW/cm^2. The PEL put forth by the USAF is intended to protect personnel from harm by limiting the whole-body SAR to 0.4 W/Kg. Exposure periods at the maximum safe levels should be limited to 6 minutes. It is also recommended that exposure in the near zone to RF/MW sources radiating at less than 30 MHz may require a separate evaluation to determine safe exposure levels of irradiation [10].

C. Canada Western Europe

Concern over safe RF/MW radiation exposure levels has sparked controversy and sharp debate in many countries around the world. The ANSI Standard is currently recognized by most countries of the Free World including Canada, the United Kingdom, Sweden, France, and West Germany [8], [22].

D. Soviet Union & Eastern European Standards

The RF/MW radiation exposure standards prescribed in the Soviet Union and Eastern Europe are more conservative than standards adopted by countries in the West [3], [8], [11]. In the Soviet Union, permissible exposure levels for whole-body irradiation are specified for various time intervals. RF/MW radiation exposures may not exceed 0.01 mW/cm^2 for 3 hours/day, 0.1 mW/cm^2 for 2 hours/day, and 1.0 mW/cm^2 for 15-20 minutes provided that safety goggles be worn [3]. Czechoslovakia has recommended a maximum exposure level of 0.025 mW/cm^2 for an average working day [8].

Investigators in the Soviet Union and Eastern Europe have placed a great emphasis on the nonthermal effects of biological exposure to RF/MW radiation. They contend that electromagnetic interactions with the bioelectrical and biochemical functions of the body constitute a more serious health risk than effects from thermal heating. Nonthermal disruptions have been observed to occur at power density levels that are much lower than are necessary to induce thermal effects. Soviet researchers have attributed alterations in the central nervous system and the cardiovascular system to the nonthermal effect of low level RF/MW radiation exposure [3], [8].

The U. S. Department of Health, Education and Welfare [3] reports that the differing standards put forth by the East and West may be attributed to philosophical differences in basic research. Soviet investigators were intent on examining the effect of RF/MW radiation on the conditioned reflex response of living organisms whereas their counterparts in the West do not view this effect as an appropriate endpoint to research [3]. Recently, however, researchers in the West have sought to account for nonthermal effects in modern permissible RF/MW radiation exposure standards [9].

V. CONCLUSION

Exposure to RF/MW radiation is known to have a biological effect on living organisms. Research conducted over the past 30 years has provided a basis for understanding the effect of irradiation of biological materials. Experimental evidence has shown that exposure to low intensity radiation can have a profound effect on biological processes. The nonthermal effects of RF/MW radiation exposure are becoming important measures of biological interaction with EM fields. Modern RF/MW radiation protection guides have sought to account for the effects of low level radiation exposure. Adherence to the ANSI Standard [9] should provide protection against harmful thermal effects and help to minimize the interaction of EM fields with the biological processes of the human body [9].

It is essentially the absorption of RF/MW energy that causes stress and trauma to biological systems. The greatest amount of energy will be absorbed when the incident radiation is emitted at the resonance frequency of biological material [9], [22]. In this regard, RF/MW radiation emitted at nonresonant frequencies should be absorbed to the

greatest extent when the radiating mode is a pulsed signal. The generation of such signals creates transient responses that will match the resonant frequencies of biological materials. Nonresonant pulsed RF/MW radiation may be more harmful to living organisms than CW radiation emitted at nonresonant frequencies.

MISSION

OF

ROME LABORATORY

Mission. The mission of Rome Laboratory is to advance the science and technologies of command, control, communications and intelligence and to transition them into systems to meet customer needs. To achieve this, Rome Lab:

a. Conducts vigorous research, development and test programs in all applicable technologies;

b. Transitions technology to current and future systems to improve operational capability, readiness, and supportability;

c. Provides a full range of technical support to Air Force Materiel Command product centers and other Air Force organizations;

d. Promotes transfer of technology to the private sector;

e. Maintains leading edge technological expertise in the areas of surveillance, communications, command and control, intelligence, reliability science, electro-magnetic technology, photonics, signal processing, and computational science.

The thrust areas of technical competence include: Surveillance, Communications, Command and Control, Intelligence, Signal Processing, Computer Science and Technology, Electromagnetic Technology, Photonics and Reliability Sciences.

Radiation Review: Some People May be 'Allergic' to Cell Phones, Computers

May 15, 2009 By Lisa Zyga feature

Cell phone tower in Nyakrom, Agona District, Ghana. Credit: Wikimedia Commons.

(PhysOrg.com) -- How exactly does the radiation from electromagnetic fields (EMF) affect the human body? Is it possible that cell phones, computer monitors, TVs, and other electronic devices - which operate within current EMF safety standards - cause illnesses, or are the people who claim to be sensitive to these devices just paranoid? The topic is one of the most controversial subjects in technology today, having important consequences in politics, consumerism, human rights, and health costs.

Olle Johansson, an associate professor and head of the Experimental Dermatology Unit, Department of Neuroscience at the Karolinska Institute in Stockholm, has been investigating the effects of electromagnetic fields on human physiology since the early '80s. Johansson's research has led him to become an outspoken supporter of the view that the dangers of EMF radiation from our gadgets are real, and that existing safety standards, which are based on acute thermal effects only, do not adequately protect public health.

In a review to be published in an upcoming issue of *Pathophysiology*, Johansson has summarized the results from dozens of studies that have investigated the effects of EMFs on the immune system in particular. As he explains, EMFs can act like an allergen, disturbing immune function by eliciting various allergic and inflammatory responses. Johansson hopes that this review, along with the reviews in the extensive Bioinitiative Report published in 2007 that have identified harmful effects from wireless technologies, will urge policymakers to create new public safety limits and limit the future deployment of untested technologies.

“The paper acts like a very strong warning signal and should evoke action,” Johansson told *PhysOrg.com*, noting that the Bioinitiative Report has already had an influence. For example, in the “European Parliament resolution of 4 September 2008 on the mid-term review of the European Environment and Health Action Plan 2004-2010 (2007/2252(INI)),” the European Parliament acknowledges that exposure levels need to be based on biological factors, not just heating effects. A report from the European Parliament on February 23, 2009, “On health concerns associated with electromagnetic fields,” also investigates stricter exposure limits.

In the current review, Johansson explains that the human immune system has evolved to deal with its known enemies, and not with electromagnetic “allergens” (e.g. TV signals, radiowaves, microwaves from cell phones or WiFi, radar signals, X-rays, artificial radioactivity, etc.) which have been introduced within the last 100 years. Our immune systems have developed under the influence of the sun’s radiation and the practically static geomagnetic field, he explains, but not under electromagnetic waves at other frequencies, or the magnetic and microwave pulses generated, for example, by cell phones.

As Johansson explains, antigens are substances that cause the immune system to react in an excessive manner, so that the immune system becomes damaging to local tissue and the entire body in general. Such hypersensitivity reactions can be caused by environmental disturbances that are small enough to enter the immune system. Examples can include dust and drugs, which can enter the respiratory tract or at site-specific locations. Another example is EMFs, which penetrate the entire body.

Different electronic devices produce EMFs that vary in strength, frequency, and pattern. While some studies have found associations between, for example, power lines and leukemia, or brain tumors and cell phones, other studies point out that no biological mechanism causing these illnesses has been identified. As Johansson argues, many studies assume that the only biological mechanism that causes adverse effects is the acute heating of cells and tissues, although he says that non-thermal effects, such as EMFs acting as antigens in the immune system, can occur before heating can be detected, especially after long-term exposure.

In some of the studies that Johansson summarizes, people claim to suffer from subjective and objective symptoms when exposed to electronic devices. Electrohypersensitivity (EHS) affects an estimated 3% to 10% of the population, he says, and often leads to lost work and productivity. In Johansson’s review, some studies hypothesize that people who claim adverse skin reactions after exposure to computer screens or mobile phones may actually have a correct avoidance reaction to the radiation. As he explains, the skin contains mast cells, which are known to react to external radiation such as radioactivity, X-rays, and UV light. Studies have found that skin samples of EHS people after radiation exposure have a higher number of mast cells in the upper dermis, and mast cells infiltrate other layers of the skin that don’t normally have them. EMFs may also cause mast cells to “degranulate,” releasing inflammatory substances that are involved in allergic hypersensitivity, itching, and pain. In previous theoretical studies, Johansson has proposed a model for how a proliferation of mast cells (mastocytosis) could explain sensitivity to EMFs. As in an allergic reaction, EMFs likely affect people differently based on varying immune functions due to variations in genetic make-up.

Johansson points out that some of the studies in his and other's papers have not been included in surveys by the World Health Organization (WHO) and Institute of Electrical and Electronics Engineers (IEEE), suggesting that these organizations have ignored relevant research due to incorrect assumptions of the levels of EMFs that can have a biological influence.

Johansson's overall argument is that more research needs to be done on possible non-thermal mechanisms of EMFs' damage to the human body, and investigations into immune system response in particular could lead to the discovery of a specific mechanism for biological damage. Considering that hundreds of thousands of individuals are estimated to have electrohypersensitivity, there is a lot at stake in the issue, including how to accommodate people with this functional impairment. Understanding the biological effects of EMF also makes economic sense, Johansson says, in terms of future public health costs. Importantly, he argues for a biologically based EMF exposure limit that can be presumed to cause no adverse impacts on human health. A completely protective safety limit based on today's information, he says, would be zero.

"Of course, philosophically we can discuss this forever, but practically one has to allow for a certain level of uncertainty if a specific gadget or technique has unique advantages," Johansson said. "If such unique advantages cannot be proven, then maybe the consumers should demand for a complete ban? It quickly boils down to if, for example, the future public health is less important than people's freedom today to use wireless technologies."

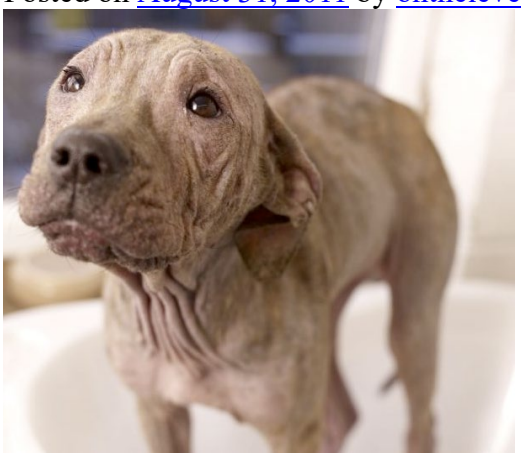
And What of the Animals?

Posted on August 31, 2011 by onthelevelblog



What of animals suffering from 'smart' meter radiation, unable to voice their pain? Originally posted at the La Mesa Patch, an El Cajon woman describes her torturous experience with smart meters and the impacts on her dogs, begging for help, in her own words:

———————————-

August 29, 2011
San Diego Gas & Electric
P.O. Box 25111
Santa Ana, CA 92799-5111
To Whom It May Concern at SDG&E
Smart Meter Complaint Department

I have made three prior telephone requests advising SDGE of the serious side effects concerning my health since the installation of the smart meter device at my home. Three different individuals came out to my house on three separate occasions, all armed with the same propaganda, the same zero concern for my health or the safety of my home.

I was told, “I don’t know. You are the only one that has complained.” (A false statement.)

I was also told, “The smart meter is not causing any problems to your home.” (Another false statement.)

I am a 49-year-old woman and I have never before experienced any of these problems in either this home, or any other home that I have lived in, prior to the smart meter installation.

I came home one day after work, and they had just finished installing my smart meter. I did not think anything of it. I had received a notice a few weeks prior, indicating that a smart meter was going to be installed.

That same evening I awoke between 2:00 and 3:00 in the morning, with ringing in my ears, dizziness, tingling at the upper part of my head that turned into a headache and then nausea. There was also a horrible feeling of uneasiness that I had never experienced before and that prevents me from going back to sleep at night — every night.

One of my dogs awoke at the same time, wandering the hallways whining and crying. This dog refuses to sleep inside at night now, as the pulsed radiation also makes him sick. This dog had slept at the foot of my bed since the day I brought him home until the night

the smart meter was installed. I have numerous friends and family who will testify to this, if called to do so.

The same scenario occurs whenever I sleep in my home, a home that I worked six or seven days a week for most of my life to be able to afford, and now you, the utility company, is FORCING PULSED RADIATION where I live and sleep, which if you do your homework and read the numerous articles that have been published by scientists who were not paid off by a utility company, you will see that radiation causes cancer and I will not stand for a cancer causing device to be attached to my home.

I was gone for two weeks on two occasions over the summer, and I sleep fine whenever I am away from my home. I was in Peru for two weeks without these problems and also in Alaska, where I had no trouble sleeping, no trouble concentrating, no dizziness, no ringing in my ears, no tingling at the upper part of my head that turned into headaches.

I also have noticed a strange humming and buzzing in my home around the appliances, coming from the computer, and around all the intercom panels in my home. I've had three people out from SDGE and they all heard the humming and buzzing and told me to turn the intercom down all the way and then I would not hear it.

I asked them, "How do you explain this? This humming and buzzing was not ever here before the smart meter installation? My kitchen appliances never hummed and buzzed before the smart meter installation." I told them, "I don't think my house is safe. This is not normal."

And I just got the blank stare, the "I don't know what to tell you, " and the "No, I cannot remove the smart meter." I begged them to return my house and home which I loved back to normal, to please, please remove the smart meter and install the old analog meter that worked just fine and that I never had a problem with. The blank stare and the, "No, I cannot do that," was the only answer I could get out of these people.

I asked one of the gentlemen what his job was at SDGE, as it appeared he had no training as an electrician and was not capable of answering any of my questions. He told me, "Well, my job is to handle questions from people like you." I then replied, "I thought you said I was the only one that complained." Of course, he quickly departed after that. We all know that if he had told me anything different, he would have lost his job.

I want the same remedy that Northern Californians have received. I pay my utility bills just like they do and I want to be treated with the same remedy that [they] received: IMMEDIATE REMOVAL OF MY SMART METER AND REMOVAL OF SMART METERS SURROUNDING MY HOME.

How can the utility commission and the utility companies treat Southern Californians who are being made sick by smart meters any different than customers in Northern California? They cannot. This is a formal request for removal of the smart meter illegally attached to my home and to the homes around me.

Copies of this letter are going out to as many people, organizations, and government agencies as I can send it to, so you can't drop this one in the trash and say you never got my letter.

Sincerely,

Richard and Diane XXXXXXXXXXX

(
Addendum, an email from Diane:
Yes, it [is] very sad. I have two dogs and it seems the smart meter bothers one of the dogs more than the other. I came home from work one afternoon and I saw the utility company truck pulling away. I had received a notice two weeks prior that they were going to install a smart meter, but I really did not think too much about it.
That very first night, my dog wandered the hallways whining and crying. … I have learned that the smart meter is more active at night. My dog's face went completely white within a two week period. Usually this happens more gradually. He was also diagnosed with arthritis after two weeks of the smart meter forced radiation and he refuses to sleep inside at night now. He just can't stand it. Which never, ever happened before. He always slept at the foot of my bed in the years prior.
I believe the smart meter is slowly eating away at our health, slowly killing us. I found there is nowhere to run, because all over the United States they are installing these radiation machines on homes. I read on the internet of people selling their homes and moving out of state, only to find that within weeks of moving to a new home a smart meter was slapped on their home when they were at work.
Of course, the utility company came out and told me that none of my problems or the changes in the home were caused by the smart meter. They absolutely refused to investigate or own up to any responsibility at all. **They just looked at me, shrugged their shoulders, and told me that I was the only one that had complained.**
I BEGGED them to put my old meter back on for the sake of my home, the health of my pet and myself and they absolutely refused. I had three different individuals out to my house, telling them about the problems since the very first night of the smart meter installation. They refused to accept responsibility, because if they changed out my meter or accepted responsibility for me, they would have to do it for all the others that complained.
One of them I think did feel sorry for me and he made a call to a supervisor two or three times to his visit to my home and each time he was told absolutely no, that he could not remove my meter and put the old analog meter back on. I'm sure he would have lost his job if he had gone ahead and done what was right. I do not know how these people sleep at night, knowing they are slow-killing us.
I do know that evil flourishes when good men do nothing, which is why we all have to stand up and do whatever we can to fight this, especially for the innocents that cannot defend themselves: our pets, infants in the womb, children, the elderly. *They cannot fight for their right to live in a radiation free environment, so we have to do it for them.*
My dog used to LOVE to go on long walks. He is a retired greyhound and spend the first part of his life in a cage, and so I used to be able to take him on long walks. Since the smart meter was installed (within a two-week period of time) he is only able to go on very short limited walks now due to swelling in his joints (which is a common complaint for a lot of people after smart meter installation).
This all practically happened over night. It was not a gradual progression, where he gradually got older and declined. It was very sudden and not natural at all. I am 49 years old and have pets since I was a child and we all watch our pets gradually get older and understand this. THIS WAS NOT NATURAL FOR A DOG IN PERFECT HEALTH TO GO from one who loved life to a state of torture the very first night that smart meter was

installed.
I know my dog, I know my house, I know myself and none of these have been the same since the smart meter installation.
(reproduced with permission)

Note: Opting Out means getting rid of the wireless smart meter – we think that turning off the transmitters inside (a Northern CA utility proposal) is not enough. We recommend opt-outs that involve nothing less than return to safe mechanical analog meters. To date, only a (forced) proposal has been made by PG&E, in Northern California. No utility has had a formal opt-out plan yet approved by CPUC.
The federal government does not require wireless or smart meters. The state CPUC falsely claims that the federal gov't has mandated smart meters. CPUC has *authorized* smart meters to be placed on every home in California (not required). The utilities in CA claim that smart meters are mandated, rather than authorized. No one in CPUC or utility companies admit that wireless was selected as the cheap option, without health and safety testing.
Utility and CPUC science is outdated and full of industry-produced information that is non-scientific and tainted by conflicts of interest. *Michael Peevey, President of the regulatory commission to oversee the California utilities (CPUC) is a Southern California Edison Vice President, retired.*
On Sept. 14th, 2011 CPUC will hold an Opt-Out Workshop which all major utilities in California have been ordered to attend, to discuss potential opt-out solutions, including SDG&E. Without strong public pressure, such as we have seen in Northern and Central CA, it is doubtful an opt-out plan will be developed for Southern Californians, as the CPUC says it has not had enough complaints, to date, to warrant it. In Northern CA, 44 municipalities have taken out ordinances or a position against smart meters. In Southern California, 2 have done so (Santa Barbara city and County) (Center for Electrosmog Prevention).

> Soapbox Jill says:

> >
> > Animals do react to transmitting utility meters. After the electric AMR meter went in on our house a couple years ago (it sends a signal six times/day), our dog started whining at night, for weeks. He already had a thyroid condition. But he seemed more nervous. Then in 2010 our town put in water meters that pulsed from everyone's basement every 5 seconds. Even tho' our house was exempted due to my doctor's request (I knew I was sensitive, already couldn't use a cell phone, etc.), I got sick when our neighbors' meters went in. And our poor dog then started sleeping more and more, and we found out he had developed Addison's disease (adrenal failure). But there were other "puzzling" symptoms, especially a sodium/potassium imbalance in his urine. The doctor then said maybe he had a rare diabetes that a dog gets from head trauma. Our dog had had no head trauma. His coat also greyed more than you would expect for an active, healthy 6-year-old. His health got worse until one day he could not even raise his head. The vet center couldn't rehydrate him or get his strange sodium levels in range. He was suffering, and we had to say goodbye. (Even tho' I told the vet about the meters as a potential reason, he did not accept or believe it.

[57] **ABSTRACT**

Apparatus for and method of sensing brain waves at a position remote from a subject whereby electromagnetic signals of different frequencies are simultaneously transmitted to the brain of the subject in which the signals interfere with one another to yield a waveform which is modulated by the subject's brain waves. The interference waveform which is representative of the brain wave activity is re-transmitted by the brain to a receiver where it is demodulated and amplified. The demodulated waveform is then displayed for visual viewing and routed to a computer for further processing and analysis. The demodulated waveform also can be used to produce a compensating signal which is transmitted back to the brain to effect a desired change in electrical activity therein.

APPARATUS AND METHOD FOR REMOTELY MONITORING AND ALTERING BRAIN WAVES

BACKGROUND OF THE INVENTION

Medical science has found brain waves to be a useful barometer of organic functions. Measurements of electrical activity in the brain have been instrumental in detecting physical and psychic disorder, measuring stress, determining sleep patterns, and monitoring body metabolism.

The present art for measurement of brain waves employs electroencephalographs including probes with sensors which are attached to the skull of the subject under study at points proximate to the regions of the brain being monitored. Electrical contact between the sensors and apparatus employed to process the detected brain waves is maintained by a plurality of wires extending from the sensors to the apparatus. The necessity for physically attaching the measuring apparatus to the subject imposes several limitations on the measurement process. The subject may experience discomfort, particulary if the measurements are to be made over extended periods of time. His bodily movements are restricted and he is generally confined to the immediate vicinity of the measuring apparatus. Furthermore, measurements cannot be made while the subject is conscious without his awareness. The comprehensiveness of the measurements is also limited since the finite number of probes employed to monitor local regions of brain wave activity do not permit observation of the total brain wave profile in a single test.

SUMMARY OF THE INVENTION

The present invention relates to apparatus and a method for monitoring brain waves wherein all components of the apparatus employed are remote from the test subject. More specifically, high frequency transmitters are operated to radiate electromagnetic energy of different frequencies through antennas which are capable of scanning the entire brain of the test subject or any desired region thereof. The signals of different frequencies penetrate the skull of the subject and impinge upon the brain where they mix to yield an interference wave modulated by radiations from the brain's natural electrical activity. The modulated interference wave is re-transmitted by the brain and received by an antenna at a remote station where it is demodulated, and processed to provide a profile of the suject's brain waves. In addition to passively monitoring his brain waves, the subject's neurological processes may be affected by transmitting to his brain, through a transmitter, compensating signals. The latter signals can be derived from the received and processed brain waves.

OBJECTS OF THE INVENTION

It is therefore an object of the invention to remotely monitor electrical activity in the entire brain or selected local regions thereof with a single measurement.

Another object is the monitoring of a subject's brain wave activity through transmission and reception of electromagnetic waves.

Still another object is to monitor brain wave activity from a position remote from the subject.

A further object is to provide a method and apparatus for affecting brain wave activity by transmitting electromagnetic signals thereto.

DESCRIPTION OF THE DRAWINGS

Other and further objects of the invention will appear from the following description and the accompanying drawings, which form part of the instant specification and which are to be read in conjunction therewith, and in which like reference numerals are used to indicate like parts in the various views;

FIG. **1** is a block diagram showing the interconnection of the components of the apparatus of the invention;

FIG. **2** is a block diagram showing signal flow in one embodiment of the apparatus.

DESCRIPTION OF THE PREFERRED EMBODIMENT

Referring to the drawings, specifically FIG. **1**, a high frequency transmitter **2** produces and supplies two electromagnetic wave signals through suitable coupling means **14** to an antenna **4.** The signals are directed by the antenna **4** to the skull **6** of the subject **8** being examined. The two signals from the antenna **4,** which travel independently, penetrate the skull **6** and impinge upon the tissue of the brain **10.**

Within the tissue of the brain **10,** the signals combine, much in the manner of a conventional mixing process technique, with each section of the brain having a different modulating action. The resulting waveform of the two signals has its greatest amplitude when the two signals are in phase and thus reinforcing one another. When the signals are exactly 180° out of phase the combination produces a resultant waveform of minimum amplitude. If the amplitudes of the two signals transmitted to the subject are maintained at identical levels, the resultant interference waveform, absent influences of external radiation, may be expected to assume zero intensity when maximum interference occurs, the number of such points being equal to the difference in frequencies of the incident signals. However, interference by radiation from electrical activity within the brain **10** causes the waveform resulting from interference of the two transmitted signals to vary from the expected result, i.e., the interference waveform is modulated by the brain waves. It is believed that this is due to the fact that brain waves produce electric charges each of which has a component of electromagnetic radiation associated with it. The electromagnetic radiation produced by the brain waves in turn reacts with the signals transmitted to the brain from the external source.

The modulated interference waveform is re-transmitted from the brain **10,** back through the skull **6.** A quantity of energy is re-transmitted sufficient to enable it to be picked up by the antenna **4.** This can be controlled, within limits, by adjusting the absolute and relative intensities of the signals, originally transmitted to the brain. Of course, the level of the transmitted energy should be kept below that which may be harmful to the subject.

The antenna passes the received signal to a receiver **12** through the antenna electronics **14.** Within the receiver the wave is amplified by conventional RF amplifiers **16** and demodulated by conventional detector and modulator electronics **18.** The demodulated wave, representing the intra-brain electrical activity, is amplified by amplifiers **20** and the resulting information in electronic form is stored in buffer circuitry **22.** From the buffers **22** the information is fed to a suitable visual

display **24,** for example one employing a cathode ray tube, light emitting diodes, liquid crystals, or a mechanical plotter. The information may also be channeled to a computer **26** for further processing and analysis with the output of the computer displayed by heretofore mentioned suitable means.

In addition to channeling its information to display devices **24,** the computer **26** can also produce signals to control an auxiliary transmitter **28.** Transmitter **28** is used to produce a compensating signal which is transmitted to the brain **10** of the subject **8** by the antenna **4.** In a preferred embodiment of the invention, the compensating signal is derived as a function of the received brain wave signals, although it can be produced separately. The compensating signals affect electrical activity within the brain **10.**

Various configurations of suitable apparatus and electronic circuitry may be utilized to form the system generally shown in FIG. **1** and one of the many possible configurations is illustrated in FIG. **2.** In the example shown therein, two signals, one of 100 MHz and the other of 210 MHz are transmitted simultaneously and combine in the brain **10** to form a resultant wave of frequency equal to the difference in frequencies of the incident signals, i.e., 110 MHz. The sum of the two incident frequencies is also available, but is discarded in subsequent filtering. The 100 MHz signal is obtained at the output **37** of an RF power divider **34** into which a 100 MHz signal generated by an oscillator **30** is injected. The oscillator **30** is of a conventional type employing either crystals for fixed frequency circuits or a tunable circuit set to oscillate at 100 MHz. It can be a pulse generator, square wave generator or sinusoidal wave generator. The RF power divider can be any conventional VHF, UHF or SHF frequency range device constructed to provide, at each of three outputs, a signal identical in frequency to that applied to its input.

The 210 MHz signal is derived from the same 100 MHz oscillator **30** and RF power divider **34** as the 100 MHz signal, operating in concert with a frequency doubler **36** and 10 MHz oscillator **32.** The frequency doubler can be any conventional device which provides at its output a signal with frequency equal to twice the frequency of a signal applied at its input. The 10 MHz oscillator can also be of conventional type similar to the 100 MHz oscillator herebefore described. A 100 MHz signal from the output **39** of the RF power divider **34** is fed through the frequency doubler **36** and the resulting 200 MHz signal is applied to a mixer **40.** The mixer **40** can be any conventional VHF, UHF or SHF frequency range device capable of accepting two input signals of differing frequencies and providing two output signals with frequencies equal to the sum and difference in frequencies respectively of the input signals. A 10 MHz signal from the oscillator **32** is also applied to the mixer **40.** The 200 MHz signal from the doubler **36** and the 10 MHz signal from the oscillator **32** combine in the mixer **40** to form a signal with a frequency of 210 MHz equal to the sum of the frequencies of the 200 MHz and 10 MHz signals.

The 210 MHz signal is one of the signals transmitted to the brain **10** of the subject being monitored. In the arrangement shown in FIG. **2,** an antenna **41** is used to transmit the 210 MHz signal and another antenna **43** is used to transmit the 100 MHz signal. Of course, a single antenna capable of operating at 100 MHz and 210 MHz frequencies may be used to transmit both signals. The scan angle, direction and rate may be controlled mechanically, e.g., by a reversing motor, or electronically, e.g., by energizing elements in the antenna in proper synchronization. Thus, the antenna(s) can be of either fixed or rotary conventional types.

A second 100 MHz signal derived from output terminal **37** of the three-way power divider **34** is applied to a circulator **38** and emerges therefrom with a desired phase shift. The circulator **38** can be of any conventional type wherein a signal applied to an input port emerges from an output port with an appropriate phase shift. The 100 MHz signal is then transmitted to the brain **10** of the subject being monitored via the antenna **43** as the second component of the dual signal transmission. The antenna **43** can be of conventional type similar to antenna **41** herebefore described. As previously noted, these two antennas may be combined in a single unit.

The transmitted 100 and 210 MHz signal components mix within the tissue in the brain **10** and interfere with one another yielding a signal of a frequency of 110 MHz, the difference in frequencies of the two incident components, modulated by electromagnetic emissions from the brain, i.e., the brain wave activity being monitored. This modulated 110 MHz signal is radiated into space.

The 110 MHz signal, modulated by brain wave activity, is picked up by an antenna **45** and channeled back through the circulator **38** where it undergoes an appropriate phase shift. The circulator **38** isolates the transmitted signals from the received signal. Any suitable diplexer or duplexer can be used. The antenna **45** can be of conventional type similar to antennas **41** and **43.** It can be combined with them in a single unit or it can be separate. The received modulated 110 MHz signal is then applied to a band pass filter **42,** to eliminate undesirable harmonics and extraneous noise, and the filtered 110 MHz signal is inserted into a mixer **44** into which has also been introduced a component of the 100 MHz signal from the source **30** distributed by the RF power divider **34.** The filter **42** can be any conventional band pass filter. The mixer **44** may also be of conventional type similar to the mixer **40** herebefore described.

The 100 MHz and 110 MHz signals combine in the mixer **44** to yield a signal of frequency equal to the difference in frequencies of the two component signals, i.e., 10 MHz still modulated by the monitored brain wave activity. The 10 MHz signal is amplified in an IF amplifier **46** and channeled to a demodulator **48.** The IF amplifier and demodulator **48** can both be of conventional types. The type of demodulator selected will depend on the characteristics of the signals transmitted to and received from the brain, and the information desired to be obtained. The brain may modulate the amplitude, frequency and/or phase of the interference waveform. Certain of these parameters will be more sensitive to corresponding brain wave characteristics than others. Selection of amplitude, frequency or phase demodulation means is governed by the choice of brain wave characteristic to be monitored. If desired, several different types of demodulators can be provided and used alternately or at the same time.

The demodulated signal which is representative of the monitored brain wave activity is passed through audio amplifiers **50** *a*, *b*, *c* which may be of conventional type where it is amplified and routed to displays **58** *a*, *b*, *c* and a computer **60.** The displays **58** *a*, *b*, *c* present the raw brain wave signals from the amplifiers

50 *a*, *b*, *c*. The computer **60** processes the amplified brain wave signals to derive information suitable for viewing, e.g., by suppressing, compressing, or expanding elements thereof, or combining them with other information-bearing signals and presents that information on a display **62.** The displays can be conventional ones such as the types herebefore mentioned employing electronic visual displays or mechanical plotters **58***b*. The computer can also be of conventional type, either analog or digital, or a hybrid.

A profile of the entire brain wave emission pattern may be monitored or select areas of the brain may be observed in a single measurement simply by altering the scan angle and direction of the antennas. There is no physical contact between the subject and the monitoring apparatus. The computer **60** also can determine a compensating waveform for transmission to the brain **10** to alter the natural brain waves in a desired fashion. The closed loop compensating system permits instantaneous and continuous modification of the brain wave response pattern.

In performing the brain wave pattern modification function, the computer **60** can be furnished with an external standard signal from a source **70** representative of brain wave activity associated with a desired nuerological response. The region of the brain responsible for the response is monitored and the received signal, indicative of the brain wave activity therein, is compared with the standard signal. The computer **60** is programmed to determine a compensating signal, responsive to the difference between the standard signal and received signal. The compensating signal, when transmitted to the monitored region of the brain, modulates the natural brain wave activity therein toward a reproduction of the standard signal, thereby changing the neurological response of the subject.

The computer **60** controls an auxiliary transmitter **64** which transmits the compensating signal to the brain **10** of the subject via an antenna **66.** The transmitter **64** is of the high frequency type commonly used in radar applications. The antenna **66** can be similar to antennas **41, 43** and **45** and can be combined with them. Through these means, brain wave activity may be altered and deviations from a desired norm may be compensated. Brain waves may be monitored and control signals transmitted to the brain from a remote station.

It is to be noted that the configuration described is one of many possibilities which may be formulated without departing from the spirit of my invention. The transmitters can be monostratic or bistatic. They also can be single, dual, or multiple frequency devices. The transmitted signal can be continuous wave, pulse, FM, or any combination of these as well as other transmission forms. Typical operating frequencies for the transmitters range from 1 MHz to 40 GHz but may be altered to suit the particular function being monitored and the characteristics of the specific subject.

The individual components of the system for monitoring and controlling brain wave activity may be of conventional type commonly employed in radar systems.

Various subassemblies of the brain wave monitoring and control apparatus may be added, substituted or combined. Thus, separate antennas or a single multimode antenna may be used for transmission and reception. Additional displays and computers may be added to present and analyze select components of the monitored brain waves.

Modulation of the interference signal retransmitted by the brain may be of amplitude, frequency and/or phase. Appropriate demodulators may be used to decipher the subject's brain activity and select components of his brain waves may be analyzed by computer to determine his mental state and monitor his thought processes.

As will be appreciated by those familiar with the art, apparatus and method of the subject invention has numerous uses. Persons in critical positions such as drivers and pilots can be continuously monitored with provision for activation of an emergency device in the event of human failure. Seizures, sleepiness and dreaming can be detected. Bodily functions such as pulse rate, heartbeat requlrity and others also can be monitored and occurrences of hallucinations can be detected. The system also permits medical diagnoses of patients, inaccessible to physicians, from remote stations.

What is claimed is:

1. Brain wave monitoring apparatus comprising
- means for producing a base frequency signal,
- means for producing a first signal having a frequency related to that of the base frequency and at a predetermined phase related thereto,
- means for transmitting both said base frequency and said first signals to the brain of the subject being monitored,
- means for receiving a second signal transmitted by the brain of the subject being monitored in response to both said base frequency and said first signals,
- mixing means for producing from said base frequency signal and said received second signal a response signal having a frequency related to that of the base frequency, and
- means for interpreting said response signal.

2. Apparatus as in claim **1** where said receiving means comprises
- means for isolating the transmitted signals from the received second signals.

3. Apparatus as in claim **2** further comprising a band pass filter with an input connected to said isolating means and an output connected to said mixing means.

4. Apparatus as in claim **1** further comprising means for amplifying said response signal.

5. Apparatus as in claim **4** further comprising means for demodulating said amplified response signal.

6. Apparatus as in claim **5** further comprising interpreting means connected to the output of said demodulator means.

7. Apparatus according to claim **1** further comprising
- means for producing an electromagnetic wave control signal dependent on said response signal, and
- means for transmitting said control signal to the brain of said subject.

8. Apparatus as in claim **7** wherein said transmitting means comprises means for directing the electromagnetic wave control signal to a predetermined part of the brain.

9. A process for monitoring brain wave activity of a subject comprising the steps of
- transmitting at least two electromagnetic energy signals of different frequencies to the brain of the subject being monitored,
- receiving an electromagnetic energy signal resulting from the mixing of said two signals in the brain modulated by the brain wave activity and retrans-

mitted by the brain in response to said transmitted energy signals, and,

interpreting said received signal.

10. A process as in claim **9** further comprising the step of transmitting a further electromagnetic wave signal to the brain to vary the brain wave activity.

11. A process as in claim **10** wherein the step of transmitting the further signals comprises

obtaining a standard signal,

comparing said received electromagnetic energy signals with said standard signal,

producing a compensating signal corresponding to the comparison between said received electrogagnetic energy signals and the standard signal, and

transmitting the compensating signals to the brain of the subject being monitored.

Electromagnetic Radiation Safety

Health effects of electromagnetic radiation exposure from cell phones, Wi-Fi, and Smart Meters, and strategies to reduce potential harm.

Monday, March 24, 2014

Dept. of Interior Attacks FCC regarding Adverse Impact of Cell Tower Radiation on Wildlife

The Department of Interior charges that the FCC standards for cell phone radiation are outmoded and no longer applicable as they do not adequately protect wildlife.

The Director of the Office of Environmental Policy and Compliance of the United States Department of the Interior sent a letter to the National Telecommunications and Information Administration in the Department of Commerce which addresses the Interior Department's concern that cell tower radiation has had negative impacts on the health of migratory birds and other wildlife.

The Interior Department accused the Federal government of employing outdated radiation standards set by the Federal Communications Commission (FCC), a federal agency with no expertise in health. The standards are no longer applicable because they control only for overheating and do not protect organisms from the adverse effects of exposure to the low-intensity radiation produced by cell phones and cell towers:

> "the electromagnetic radiation standards used by the Federal Communications Commission (FCC) continue to be based on thermal heating, a criterion now nearly 30 years out of date and inapplicable today."

The Department criticized the Federal government's proposed procedures for placement and operation of communication towers, and called for "independent, third-party peer-reviewed studies" in the U.S. to examine the effects of cell tower radiation on "migratory birds and other trust species."

Following are excerpts from the letter, dated Feb 7, 2014:

> "The Department believes that some of the proposed procedures are not consistent with Executive Order 13186 Responsibilities of Federal Agencies to Protect Migratory Birds, which specifically requires federal agencies to develop and use principles, standards, and practices that will lessen the amount of unintentional take reasonably attributed to agency actions. The Department, through the Fish and Wildlife Service (FWS), finds that the proposals lack provisions necessary to conserve migratory bird resources, including eagles. The proposals also do not reflect current information regarding the effects of communication towers to birds. Our comments are intended to further clarify specific issues and address provisions in the proposals.
>
> The Department recommends revisions to the proposed procedures to better reflect the impacts to resources under our jurisdiction from communication towers. The placement and operation of communication towers,

including un-guyed, unlit, monopole or lattice-designed structures, impact protected migratory birds in two significant ways. The first is by injury, crippling loss, and death from collisions with towers and their supporting guy-wire infrastructure, where present. The second significant issue associated with communication towers involves impacts from non-ionizing electromagnetic radiation emitted by them (See Attachment)."

Enclosure A

"The second significant issue associated with communication towers involves impacts from nonionizing electromagnetic radiation emitted by these structures. Radiation studies at cellular communication towers were begun circa 2000 in Europe and continue today on wild nesting birds. Study results have documented nest and site abandonment, plumage deterioration, locomotion problems, reduced survivorship, and death (e.g., Balmori 2005, Balmori and Hallberg 2007, and Everaert and Bauwens 2007). Nesting migratory birds and their offspring have apparently been affected by the radiation from cellular phone towers in the 900 and 1800 MHz frequency ranges- 915 MHz is the standard cellular phone frequency used in the United States. However, **the electromagnetic radiation standards used by the Federal Communications Commission (FCC) continue to be based on thermal heating, a criterion now nearly 30 years out of date and inapplicable today. This is primarily due to the lower levels of radiation output from microwave-powered communication devices such as cellular telephones and other sources of point-to-point communications; levels typically lower than from microwave ovens. The problem, however, appears to focus on very low levels of non-ionizing electromagnetic radiation.** For example, in laboratory studies, T. Litovitz (personal communication) and DiCarlo et al. (2002) raised concerns about impacts of low-level, non-thermal electromagnetic radiation from the standard 915 MHz cell phone frequency on domestic chicken embryos- with some lethal results (Manville 2009, 2013a). Radiation at extremely low levels (0.0001 the level emitted by the average digital cellular telephone) caused heart attacks and the deaths of some chicken embryos subjected to hypoxic conditions in the laboratory while controls subjected to hypoxia were unaffected (DiCarlo et al. 2002). To date, no independent, third-party field studies have been conducted in North America on impacts of tower electromagnetic radiation on migratory birds. With the European field and U.S. laboratory evidence already available, independent, third-party peer-reviewed studies need to be conducted in the U.S. to begin examining the effects from radiation on migratory birds and other trust species."

Radiation Impacts and Categorical Exclusions

"There is a growing level of anecdotal evidence linking effects of non-thermal, non-ionizing electromagnetic radiation from communication towers on nesting and roosting wild birds and other wildlife in the U.S. Independent, third-party studies have yet to be conducted in the U.S. or Canada, although a peer-reviewed research protocol developed for the U.S. Forest Service by the Service's Division of Migratory Bird Management is available to study both collision and radiation impacts (Manville 2002). As previously mentioned, Balmori (2005) found strong negative correlations between levels of tower-emitted microwave radiation and bird breeding, nesting, and roosting in the vicinity of electromagnetic fields in Spain. He documented nest and site abandonment, plumage deterioration, locomotion problems, reduced survivorship, and death in House Sparrows, White Storks, Rock Doves, Magpies, Collared Doves, and other species. Though these species had historically been documented to roost and nest in these areas, Balmori (2005) did not observe these symptoms prior to construction and operation of the cellular phone towers. Balmori and Hallberg (2007) and Everaert and Bauwens (2007) found similar strong negative correlations among male House Sparrows. Under laboratory 'conditions, DiCarlo et al. (2002) raised troubling concerns about impacts of low-level, non-thermal electromagnetic radiation from the standard 915 MHz cell phone frequency on domestic chicken embryos- with some lethal results (Manville 2009). **Given the findings of the studies mentioned above, field studies should be conducted in North America to validate potential impacts of communication tower radiation both direct and indirect - to migratory birds and other trust wildlife species."**

AT&T, UPR and Suzuken Work Together to Improve Pharmaceutical Supply Chain

International / Tokyo, Japan, Nov 14, 2016

Global IoT Solutions from AT&T Help Safeguard Sensitive Medicines in Transit

Suzuken will use UPR WorldKeeper®, integrated with AT&T* Internet of Things (IoT) solutions, to help safely deliver sensitive medicines to hospitals, clinics and pharmacies globally.

The pharmaceutical wholesaler will use new tools to update its distribution. The UPR WorldKeeper, integrated with AT&T Cargo View® with FlightSafe®, will increase visibility for each shipment for Suzken globally. UPR WorldKeeper is a cargo tracking system from one of Japan's leading logistics management firms. AT&T Cargo View with FlightSafe is a global IoT solution that provides customizable alerts which enable customers to quickly react to potential damage, unauthorized entry and other environmental changes that impact the cargo.

Suzuken plans to add an AT&T sensor in each sensitive medical shipment. It will collect and send data on temperature, vibration, shock and other conditions. Suzuken will track the location and near real-time condition of shipments on a mobile device or computer.

Medicines must travel carefully to preserve their quality and effectiveness. Distributors must dispose of any damaged medicines safely. Then they must replace them quickly so they have enough supplies.

Suzuken is overcoming these challenges. Its new IoT distribution solution increases the visibility of the pharmaceutical supply chain globally.

"With UPR WorldKeeper and AT&T's global IoT solutions, we'll help manufacturers, health insurance companies, pharmacies, and medical institutions save expensive medicines and provide safe medicines for

patients. This can improve the quality of medical care," said Hiromi Miyata, president and chief executive officer, Suzuken Co., Ltd.

To comply with industry regulations, medical distributors must carefully track lot numbers and drug expiry dates. For Suzuken, this means managing a complex supply chain that includes manufacturers, hospitals, and pharmacies around the world. The IoT solution lets Suzuken efficiently and closely tracks shipments from manufacturer to medical provider.

"Our IoT solutions can bring near real-time monitoring and efficient control to the medical supply chain globally," said Manabu Oka, president of AT&T Japan. "Pharmaceutical companies are our initial focus. In the future, we want to continue to work with Suzuken to apply IoT to more medical sectors."

AT&T develops IoT technology for a wide range of applications. Its solutions include asset tracking, smart meters, connected vehicles, and traffic management.

*AT&T products and services are provided or offered by subsidiaries and affiliates of AT&T Inc. under the AT&T brand and not by AT&T Inc.

Democratic Pennsylvania Attorney General Convicted On All Counts

September 10, 2016Cellular (Phones), Climate Change, EMF, GHG Emissions, Global Warming, News and Updates, Pacemaker, Radiation, Safety Code 6, Smart Grid, smart meter fires, Smart Meters, WiFi, WirelessThermoguy

This is disgraceful to once again have political party interests take precedence over the people they were elected to represent. **This criminal was convicted, should be jailed without bail and sentenced longer for the abuse of power for what they did in that important office.** Then they should pay back **all** taxpayer dollars and all cost that were spent during their crimes. That includes the gas, oil and maintenance of every vehicle used, all man hours and literally every cent taxpayers spent. **http://www.nytimes.com/2016/08/16/us/trial-kathleen-kane-pennsylvania-attorney-general.html**

Is it true she was smiling leaving the courthouse? Why was this criminal allowed to resign?? The US Attorney General or Obama himself should have fired them and escorted them out of the building. If it were a Republican lawyer, would this Democrat President have allowed them to resign? Do you think Trump asks people who undermine his companies to resign? It doesn't reflect her undermining the office, government, people who elected them and their country.

What else did they get away with while undermining their office, state and country? Then I watch the commercials of the politicians slamming Trump and that he can't be trusted in office?? Do you think Donald allows people on his payroll of 1000s to perform like that? Do you think Warren Buffet, Bill Gates or any private company allows this? Would I hire a staff of political opposition to the direction of my company? The second I found out what they were I would fire them, kick their ass and then hold them liable to the full extent of the law.

CNN runs programs like "Why do they hate us"? How about when the people in power related to justice of the country are criminals. They didn't have leaders in industry globally come to them, it was a military directed by a political agenda. That isn't to blame the military, politics and special interest have no business directing policing or the military. Politicians and special interests should be lobbying behind the scenes on their dollars. I am a science professional specific to energy, engineering and a professor lecturing accredited medical education. I don't and can't trust any politicizing of electricity or any sciences or there would be liability.

I am one of the governments and industries science professional with no options but to perform to the highest standard or I am liable. I have had to carry errors and omission insurance for many millions of dollars per occurrence. That doesn't excuse me for criminal liability for being reckless or negligent. We are codes and standards where there are no politicians or opinion from them. This pisses me off because right now as this is going on, we are dealing with the reality Federal Governments(US Department of Energy) provided stimulus packages for the mass deployment of wireless smart meters that are supposed to save energy.

Not only are the meters not going to save 1 watt of energy, they have RF EMFs in them that are radiating populations, undermining economy, health, all industries, environment, climate change agenda of President Obama, National Security and all the United Nation's Members. The United Nation Climate Change Meeting in Paris came back with a global science consensus(not politics) that a 3.6 deg. F rise in atmospheric temperature would be globally catastrophic. That means man heating the atmosphere the whole world shares. The stimulus package for wireless smart meters and the required smart grid blanketing cities, states, provinces, countries will heat the atmosphere by themselves. When you blast high speed RF EMFs atmospherically, those high speed EMFs will oscillate billions of times per measurable second 24 hours a day. Exponent Inc's Electrical Engineer Yakov Shkolnikov admitted under direct cross examination in BC Government transcripts while under oath that the 900 MHz antenna in smart meters will oscillate 1.8 billion times PER second, the 2.45 GHz antenna for Wi-Fi 4.9 billions times PER second. That creates heat that can not be destroyed, it will mix globally. The stimulus packages of the U.S. and Canadian Government's provided money to states and provinces to mass install smart meters. Electricians can not mass install meters as meter bases can be decades old with very fragile electrical connections. Electrical connections are the weakest point in an electrical circuit and connections are usually maintained regularly.

Utilities in states and provinces used people not qualified to touch electrical as well as no legal authority to trespass to install meters. The utility has no authority or jurisdiction to work on a meter base, that is electrician's jurisdiction and the building owner's property. Now the utilities in states and provinces have created REAL fire issues as well as causing buildings to be non compliant with building codes.

This Attorney General did not protect the citizens of Pennsylvania against the assault with a deadly weapon created by Smart Meter RF EMFs or their properties that are no longer compliant with Building Codes. This Attorney General didn't represent to municipal governments and their critically important Building Inspection that the Specific Absorption Rate Test used to bypass Building Codes is a plastic body part with water in it. When buildings are not compliant with Building Codes, there is no mortgage, insurance, occupancy, no taxes for services and millions of buildings damaged. Pennsylvania and the federal government loses billions in taxes, no one is paying tax on an illegal building they can't live in or sell. The properties will revert back to the lender who will not be insurable.

Just as you see in this article by the NY Times, this Attorney General's actions show what happens when political interests weaken the professional gene pool. **If Obama and Hillary think Donald Trump is out of control, wait till they see what he does when he finds out they put meters on his own properties that will cause accelerated erosion and corrosion of his investments as well as adversely affect the health of his family and people within his investments. Trump will be liable and he will be passing on that liability. If Hillary or Obama think it isn't so, the federal government's lawyers will have to defend a plastic head as science when it should be an aquarium. Making it worse is the US Department of Energy literally blind to the energy they are trying to save and being reactive when they could create millions of taxpaying jobs immediately producing IMMEDIATE energy/emission reduction.**

While some reading this may think it is controversial, the Specific Absorption Rate Test the federal government, FCC, utilities are relying on for safety is a plastic head or body part with water in it. The following link is evidence of the British Columbia Government's BC Utilities Commission calling for the suspension of the smart meter programs. You can see the real energy losses and the U.S., Canada and beyond is wasting trillions of watts per hour reacting to the symptoms of solar EMFs interacting with building development. The UN Member's consensus was 3.6 deg. F rise in atmospheric temperature as globally catastrophic, look at page 18 and 19. It is an 85 deg. F day

and solar exposed building development is as hot as 197.7 deg. F. That means there is atmospheric warming 108 deg. F hotter than the 3.6 deg. F.

Brown outs, power demand wasting trillions of watts per hour and massive natural resource waste reacting to the symptoms of solar interaction making them non compliant with Building Codes. Look at page 19 and shade effect right after sunrise. **http://www.bcuc.com/Documents/Proceedings/2012/DOC_32604_C19-6_WKCC-Submission-RDCK-Nelson-Creston_Suspension.pdf**

Solar EMFs are interacting with absorbent exterior finishes and buildings are generating heat close to boiling temperature. Is that more than 3.6 deg. F? Any Nuclear Power Plants in Pennsylvania? These RF EMFs will cause accelerated erosion and corrosion of Nuclear Power Plants. Here is our unpopular submission to the Canadian Nuclear Safety Commission on the accelerated corrosion and the power plant NOT being compliant with Building Code. The first submission was politically and administratively rejected until the CNSC was informed of their liability. **http://thermoguy.com/submission-for-canadian-nuclear-safety-commission-on-rf-emfs-causing-accelerated-corrosion-making-the-power-plants-non-compliant-with-building-codes/**

Globally, what happens when there are nuclear failures within borders? This won't be popular but this is the real tradeoff. This former Attorney General better stop smiling, this is a very serious problem not being addressed.

Barrie Trower, former Cold War spy debriefer and academic, warned members of the Irish Doctors Environmental Association (IDEA) about the dangers of microwave based communications systems.

Cites end of national sovereignty

Expert tells doctors of impending tragedy from EMF radiation as health of nations laid waste by technology

Barrie Trower lives in a world different to the rest of us. His world is every bit as dangerous as anything Tolkien could have dreamed up and with each passing day inches closer to engulf us. Very occasionally he surfaces to warn us but returns back to his world largely ignored.

While his words are reasoned and motivational - much like Tolkein's wizard, Gandalf - Trower is stoically centered. He sat alone for more than a hour waiting to address the annual general meeting of the Irish Doctors Environmental Association (IDEA) amid stacked chairs against the stark white walls between two tall Georgian windows with only a glass of water molecules to bring clarity before speaking to the group.

A lecturer in Advanced Physics at South Dartmoor College and living in a village in rural Devon - not unlike Tolkein's beloved Shires - Trower has travelled to 27 countries around the world explaining the unseen wonders of physics and the perilous ways mankind is commercially exploiting the invisible for profit and political power.

From the outset, Trower is courageous. Here is a truth-teller, not just an ordinary whistleblower, but a man who came out of retirement with a warning for all humanity. "I'll tell you very briefly where I'm coming from very before I start," began Trower, "In 1959 I studied my first paper on microwaves for my entry examination into the military. I studied all aspects of microwaves in the military - radar, health issues. Microwaves then were being used, as they are today, as stealth weapons. Stealth weapons specifically to cause severe neurological and physiological damage. There never, ever was any safe level of microwave radiation." Trower began his career with the British Royal Navy before his peacetime duties with the Secret Service. In addition to his experience he is uniquely

qualified to discuss microwaves due to education with a degree in physics, a second degree in research, as well as a teaching diploma in physiology.

Common sense tells us electricity is dangerous. Less generally known are the principles surrounding magnetism which, according to experts like Davis and Rawls in their book *Magnetism on Its Effects on the Living System*, can be equally dangerous. Combine the two principles, electricity and magnetism, into electro-magnetic frequencies (EMF) and there is a recipe for untold misery, pain, death and destruction. Electromagnetic frequencies (EMFs) are the signals used in modern communications systems, from the billions of cell phones and masts that service them to the pulsed signals of WiMAX and Tetra which are stronger still.

Although Trower came to the subject late, the Russians had been studying microwaves from as early as 1920, according to Czech writer Mojmir Babacek, founder of the International Movement Against Manipulation of Central Nervous System. Babacek told *El Spectador* that Russia was well advanced in the 20's investigating phenomena such as telepathy, telekinesis and clairvoyance, and that during the 60's and 70's there existed a real arms race between Russia and the U.S. in this area which supports Trower's explanation of debriefing victims for the British military - cold war spies - following their microwave radiation exposure. And as recently as April 2013, Russian President Vladimir Putin admitted that Russia plans to ramp up its arsenal with the development of "psychotronic" weapons.[1]

"Following my time in the military - we're into the cold war here - and those of you who remember the Cold War it was a very, very tense time for the world, I can specifically remember two occasions when we were within one second of total global nuclear war. A part of my job when I left the military because I had microwave knowledge, and they were being used as weapons, was to question captured spies or agents which I did for eleven years and in my defense and, might I please say, that the program, run by Sir William Melville, I never used pain, humiliation embarrassment, drugs, hypnosis, nothing. I treated the ladies and gentlemen as I would talk to you. It was nothing more than a conversation over a cup of coffee."

Melville is the real 'M', founding father of MI-5 and the inspiration for Ian Fleming's character in James Bond books and films.

Trower explained that during the Cold War, less than 20 years after the death of Nikola Tesla, the genius of electricity, and less than 15 years after the end of WWII, governments were already researching the effects of pulsed microwave signals in the 1960's. "I gathered the information," he said, "because different pulsed systems were being used to cause different neurological and physiological damage." As a former insider Trower is giving first hand fact-based evidence that microwave signals and radiation cause damage to living organisms and the built environment. Furthermore he is living testimony that governments have used that evidence to inflict pain and suffering on their opponents.

Trower claims that there is no defense against a microwave assault and that by alternating pleasure and pain frequencies broadcast from a van parked nearby "anyone can be broken in 30 hours." His statement is backed up by Drs. P.D. Whissell and M.A.

[1] Staff writers. *Russia working on electromagnetic radiation guns.* Herald Sun. Melbourne, Au. 4 April 2013. *http://www.heraldsun.com.au/technology/sci-tech/russia-working-on-electromagnetic-radiation-guns/story-fn5iztw3-1226317396841*

Persinger of Laurentian University, Ontario. who said in a 2007 paper, that "experiments showed a role of opiates in simple and pulsed EL-EMF response, but opiate-like effects induced by VHF-MF and microwave (MW) field also exist and have been characterized for more than a decade."[2]

Trower's testimony flies in the face of "Product Defense Consultant" Dr. William H. Bailey, advisor to the Irish government, power companies in Nevada and British Columbia as well as companies like Toyota that experience electromagnetic interference with their services or manufactured goods.

Shortly after embarking on a career in education, Trower explained that he was contacted by a police authority in the U.K. to review the literature and explain the implications of the proposed switch to a new communications system using Tetra technology - a microwave signal developed by the Motorola Corporation, a major U.S. military contractor based outside of Chicago, Illinois. "That resulted in me being commissioned to write the first safety report on the Tetra system for the emergency services which I condemned," said Trower. "Nine years later I was approached by another police union with the increased cancers and other neurological problems, saying would I update my report which I did."

Before launching into proof that low level microwave radiation causes disease and death, Trower said that he has never charged for his public engagements because once you accept money you can be told what to say and, secondly, even the poorest can afford to hear his message. The idealism of Trower's position is growing around the world against what is becoming increasingly the most powerful industry on the planet. While her husband has endorsed the electromagnetic Smart Meter, Michelle Obama, quietly contacted Trower for information through an agent in New York. After all, she has two daughters to protect. The hand that rocks the cradle may, yet again, rule ...

"Let's deal with the most important question first," he said as he stood behind a pile of documents neatly grouped and tied with string. "With low level microwaves, and lower level is actually more dangerous than a high level, with low level microwaves is there any proof? Let's deal with the proof argument first. More than you would probably imagine - there are 8,300 military papers proving microwaves cause severe neurological and physiological damage. There are seven high court cases now against the industry showing that they will cause this. There are 12 epidemiological studies. There are another 19 legal judgements around the world - by mayors, magistrates or people who have the ability to make a legal judgement. The industry themselves, this is what they say about the microwaves that children are walking around using."

Trower quoted a document prepared by the German Ecolog Institut on behalf of the T-Mobile holding company for Deutsche Telecom with its estimated 150 million customers world-wide. Reading from Section 7 of the document, Trower bridged direct quotes from the Ecolog study with his own links, "These are their actual words. 'It can be concluded that electromagnetic fields used in the mobile telecoms range do play a role in the development of cancer'... On the cellular level, a multitude of studies found these waves can induce the cancer initiation, cancer promotion agents to act in the body. 'DNA

[2] Whissell, P.D. and Persinger, M.A., Emerging Sunergisms between Drugs and Physiologically-Patterned Weak Management Fiels: Implications for Neuropharmacology and the Human Population in the Twenty-First Century. Current Neuropharmacology. 2007. P. 279.

synthesis and repair mechanisms' for continuous or pulsed fields can influence or directly damage the DNA.'"[3]

Trower referenced the ruling of an Italian court against the microwave industry. "I had to read this a few times just to believe it ... it was in the transcript of the judgement against the industry for cancer, and it actually states that if you use a cell phone five to six hours a day for 10 - 12 years you are more likely to develop ipsilateral cancer, that is from the direction of the source of the radiation, you are more likely to develop ipsilateral cancer than the survivors of the atomic bomb in Japan in 1945. There is no doubt microwaves are causing cancer, neurological and physiological damage. No doubt." said Trower.

If microwave radiation is causing so much damage, why is the public so unaware of the dangers? Before answering the question, Trower again lists the effects from still more sources - some top secret:

- TOP SECRET: From a U.S. conference, 1986. "Concerning low level microwaves, we can change behaviour of cells, tissue... Whole organisms have a six times higher fetal mortality rate, birth defects and induce malignant tumours in human cells."

- TOP SECRET: Course No. 11, 2001-07. "Students (scientists) will be familiar with current knowledge, ie. cancer, memory, brain function damage to the eye, skin, birth defects from low level microwave radiation."

- TOP SECRET: Naval Medical Research Institute: *Biological and Clinical Manifestations Attributed to Microwave Radiation (Low-Level)* which lists 2,000 medical references with the main paper, *Altered Menstrual and Fetal Development*.

- TOP SECRET: World Health Organization (W.H.O.), 1973. Biological Effects: Health and Excess Mortality from Artificial Irradiation of Radio Frequency, Microwave Radiation. The paper was the result of a symposium held in Warsaw and has been referred to by experts such as Dr. Magda Havas, Trent University, Canada, Henry Lai, of the University of Washington and by the Seletun Declaration signed by Prof. Olle Johansson, of the Karolinska Institute, among others.

"The damage caused by microwave radiation is irrefutable," says Trower, "There never is any doubt. There never was."

In reference to the Warsaw document, Trower held it high, telling the audience, "Again, top secret paper. This is a surprise This is actually from the World Health Organization and it says *Biological Effects: Health and Excess Mortality from Artificial Irradiation of Radio Frequency, Microwave Radiation.* They list pages upon pages of ill effects and when the W.H.O published this it was stamped Top Secret and hasn't seen the light of day since."

As it emerges from the shadows of secrecy, the document is becoming a cornerstone of the global reaction to microwave radiation, giving credence to the fact that dangers to human and animal health were established more than 40 years ago and that the evidence has been suppressed. In a sworn affidavit to the State of Oregon, Trower told the court

---

[3] http://www.hese-project.org/hese-uk/en/papers/ecolog2000.pdf. In context: " it can be concluded that electromagnetic fields with frequencies in the mobile telecommunications range do play a role in the development of cancer... Direct damage on DNA as well as influences on DNA synthesis and DNA repair mechanisms were demonstrated"

that health effects from microwave radiation had been noted as early as 1932 when it was called “radiowave sickness”.

A 2006 Freedom of Information request by Donald Friedman of Napa, California[4] supports Trower implicitly. The buried document revealed both the theory and practice behind inducing neurological events from subjects “hearing things” - the Frey Effect - to suffering epileptic seizures of varying severity.[5] The U.S. Army document, *Bioeffects of Selected Non Lethal Weapons*, which notes that human beings have been used as guinea pigs and the physical effects are a reality, states:

> Human subjects listened to very high levels of low-frequency noise and infrasound...Two minute duration as high as 140 to 155 dB produced a range of effects from mild discomfort to severe pressure sensations, nausea, gagging, and giddiness. Effects also included blurred vision and visual field distortions in some exposure exposure conditions...”

Naturally, by virtue of the fact that Friedman had to officially request the document and that it was originally labeled “Secret Noforn” until it was stamped unclassified clearly indicates that information is being suppressed and kept well away from public scrutiny. The label "SECRET NOFORN" means documents are designed to never be shown to non-US citizens.

According to Trower, the reason is simple. “The question is, ‘Why?’ Why has all of this damage which is known to be caused to children, why is it being suppressed? And the answer is here,” said Trower, holding before him yet another document.

“And I have said this was incredibly top secret. It is from the United States Defense Intelligence Agency. It’s dated 1971 and basically they list all of the illnesses which you can expect at this time from low level radiation including blood-brain barrier damage but it is the first three lines which I think are the most dangerous lines since the declaration of war and it’s certainly going to cause more casualties.... Those three lines of text from the U.S. Naval Centre are telling indeed: ‘If the governments of the more advanced nations of the West are strict in enforcement of stringent exposure standards, there could be unfavourable effects on industrial output and military effects.’[6]” The possibility / probability of costly law suits moved Swiss Re to refuse insurance to companies using microwave

---

[4] *Bioeffects of Selected NonlethalWeapons.* 1998. ”Application of electromagnetic pulses is also a conceptual nonlethal technology Uiat uses electromagnetic energy to induce neural synchrony and disruption of voluntary muscle control. The effectiveness of this concept has not been demonstrated. However, from past work in evaluating the potential for electromagnetic pulse generators to affect humans, it is estimated that sufficiently strong internal fields can be generated within the brain to trigger neurons. Estimates are that 50 to 100 kV/m free field of very sharp pulses (~ 1 nS) are required to produce a cell membranic potential of approximately 2 V; this would probably be sufficient to trigger neurons or make them more susceptible to firing. The electromagnetic pulse concept is one in which a very fast (nanosecond timeframe) high voltage (approximately 100 kV/m or greater) electromagnetic pulse is repeated at the alpha brain wave frequency (about 15 Hz), It is known that a similar frequency of pulsing light can trigger sensitive individuals (those with some degree of light-sensitivity epilepsy) into a seizure and it is thought that by using a method that could actually trigger nerve synapses directly with an electrical field, essentially 100% of individuals would be susceptible to seizure induction.” http://www.kat97305.byethost3.com/Bioeffects_of %20Selected_Non_Lethal_Weapons.html

[5] http://sigint.files.wordpress.com/2008/02/bioeffects_of_selected_non-lethal_weapons.pdf

technology. The risk-averse insurance sector bases it's assessment on risk, the concept explored by Australian Don Maish in his book, *The Procrustean Approach: setting exposure standards for telecommunications frequency electromagnetic radiation.* Maisch was savaged by the legal team representing FortisBC during hearings in British Columbia in March 2013 to consider deployment of the contentious Smart Meter. The contentious William Bailey, naturally enough, testified on behalf of the industry.

Blame for the paucity of public safety standards rests with the U.S. government, claims Trower. "The United States government are advising Western governments, namely us, to have such a relaxed safety level that the industry can never be taken to court," he said. "They also say that if we don't it will have a disastrous effect on industrial profit and, of course, line them up for law suits. Following this, if the American government says 'Jump', the English government says, 'How high?'"

Trower explained that the English government adopted a six-minute heating effect as the official standard and the rest of the world followed suit. There is, however, ample evidence of global financial interests bringing enormous pressure to bear. Names like Motorola. Westinghouse, JPMorgan and Rockefeller litter the resume of Nikola Tesla, the undisputed pioneering genius in the application of electricity and magnetism. Indeed, it was Tesla himself who alerted President Franklin Roosevelt of the theory behind creation of a death ray to end WWII and all wars while a friend petitioned Eleanor Roosevelt for financial help for the inventor who died penniless in January 1943.

Trower's assertion regarding the arbitrary adoption of the heating or so-called "Thermal Effect" caused by microwaves was expressed as early as 1981 by the World Health Organization. Titled *Environmental Health Criteria 16, Radiofrequency and Microwaves,* the report notes, "Thermal mechanisms seem wholly inadequate to account for the results of studies indicating that cerebral tissue, exposed to weak electromagnetic fields, responds only over a limited range of intensities and modulation frequencies of the RF carrier field. There appears to be evidence for both amplitude and modulation frequency windows, outside which effects are not observed."[7]

"And that is still the only standard today," said Trower, "six minutes of heating. In other words, providing you don't feel too warm, after six minutes of being near a transmitter or on the phone or whatever, it is deemed safe, that is it. That is the only safety level and today in the U.K. and the United States they'll have got away with that."

In Canada, Dr. Havas[8], of Trent University, Ontario, forced admission from health authorities that while they say they are using standards below the Thermal Effect, they are at wide variance with practice. In February 2013, Havas reported: "I just returned from a hearing in Montreal in front of the Superior Court of Quebec where Health Canada scientist, James McNamee, admitted that the Safety Code 6 guideline for microwave radiation (which includes radiation from most of the devices we are concerned about like mobile phones, cell phone antennas, Wi-Fi, wireless toys and baby monitors, smart meters etc.) is based ONLY on preventing a heating effect! Let me state that again. Health Canada admits that Safety Code 6 for frequencies between 100 kHz and 300 GHz are based ONLY on heating."

---

[7] http://www.inchem.org/documents/ehc/ehc/ehc016.htm#PartNumber:1ISBN 92 4 154076 1

[8] http://www.magdahavas.com/health-canada-admits-safety-code-6-guideline-for-microwave-radiation-is-based-only-on-thermal-effects/

Trower is right again and Dr. Havas proved it.

Limits don't protect children

The problem with heating standards, if they can be called standards at all - except in a microwave oven - is the vulnerability of children. Tolerance is a more appropriate term. "Children are much more vulnerable than adults," says Trower, "for two reasons: one, they have a higher water content in the body which means they absorb around 10 times more radiation than adults and the other is that the mitochondrial DNA suffers 10 times more stress than other bodily DNA. If you look at the child, the child is taking a 20-fold increase in danger than adults. This is also before we get onto their size.They also absorb more radiation because they are nearer the size of the wavelength and they act as aerials."

In a court deposition presented in Portland, Oregon in 2011, Trower explained the phenomenon of children as aerials. "Children act like antennas and absorb more radiation than adults because they are smaller, and their very dimensions approximate the deployment's wavelength."[9]

As Trower explained it in Oregon, "A basic receiving antenna can be thought of as an apparatus that converts electromagnetic waves into electrical current. It turns out that the human body is also a very effective antenna over a broad frequency range. As an electrical conductor, when exposed to electromagnetic fields, it behaves as an antenna with a frequency resonance determined by various factors including height, posture, etc. Children are not merely small adults. They are physiologically and neurologically immature; their systems have not yet formed. Microwave radiation alters the blood-brain barrier so that toxins leak into the brain. This can cause neurologic and psychologic amongst many other problems more easily in children. A child's immune system, which fights off infection, takes 18 years to develop. Additionally, 122 layers of protein - myelin - insulate the electrically generated signals used by the nervous system to control muscles and organs. These layers of protein take 22 years to develop. MW radiation has been shown to affect protein synthesis. This could lead to muscular dystrophy-like symptoms in later life."

Trower's greatest concern about children is the fact that the blood-brain barrier in the human brain does not completely develop until the age of 18 months. "The blood brain barrier has been known to enlarge and let toxins in and out of the brain," he claims. "That takes 18 months before it is even made. Similarly the myelin sheet protein synthesis is known to be interfered with as well as the marrow within the bone which has a high water content"

Protect your daughters

"I want to talk at length about one particular problem which I believe is very, very important," said Trower, asking the audience to imagine themselves as young girls sitting at their school desks being irradiated by wi-fi, laptops and electronic tablet textbooks. "The problem with children and I think it is the most important question or topic now to deal with

---

[9] See example of humans acting as antennae: Cohn G, Morris D, Patel S, Tan D, Your Noise is My Command: Sensing Gestures Using the Body as an Antennae, http://research.microsoft.com/en-us/um/redmon d/groups/cue/publications/chi20 ll_rfgestures _cohn. pdf:

microwaves," he explained "With all of the research papers, the first thing that springs to mind (and I've already read them) is birth defects and we're looking, not just in humans, but right across the mammalian species, right across the planet. To explain this I need to keep it simple for myself. I would like you to imagine, please, that you are all five years old and you are all girls and you're sitting in a classroom and a wi-fi is plonked in front of you ...

"The wi-fi is transmitting as is the router on the wall. Now the wi-fi is transmitting generally through your ovaries and you have around 400,000 ovarian follicles - not fully developed - sitting there. They are being irradiated. Let's move the clock forward to the point where you are now 18. You have been through many years of having your ovaries irradiated. And let's say now you are 18 and you are pregnant and I have taught many pregnant students. In the first 100 days of your embryo the embryo is developing its own ovarian follicles. By 100 days, as you will probably know, they are virtually formed. " said Trower.

The ovarian follicles of the 18-year-old have been damaged and this damage is passed down to her daughter and her daughter. In short, the stage is being set for a catastrophe unseen before in human history.

"They have no defense mechanism at all against microwaves," said Trower. "There is no Protein 53 which are four protein structures. There is no nuclear core complex. Those are defense structures we have developed through evolution to protect us against electric storms when we were living in caves. They have nothing. So the ovarian follicles of the embryo and the mother may not even know she's pregnant at this stage - the ovarian follicles have no defense mechanism - and what we are looking at is when your child is born, which may or may not have genetic damage, it is that child's birth where the real problem is going to come out. And we are already seeing this with other mammalian species and if you're wondering how many people are going to be involved - there is only one paper I know of in the world written by a professor, oddly enough, by an advisor with the W.H.O. and he found when women were being deliberately microwaved the rate of stillbirth, miscarriage, genetically damaged children was 57.7 percent and this was at a level of radiation lower than a child would get in a classroom with 20 wi-fis (desktop units). We know a minimum of 57 percent. Now that's the good news."

The mitochondrial cells are where the cell takes in nutrients, breaks it down to create energy at the cellular level. Thus, if the mitochondrial cells are damaged, the cell can not function properly. Logically, when this occurs in the cells of ovarian follicles, eggs will not be healthy or even produced. At a personal level, infertility is unfortunate. At a social level, where a country needs healthy workers to prosper, damaged embryos can lead to widespread social problems. On a global scale, the consequences can be catastrophic. Trower is an academic who shies away from politics. He deals in theory.

Trower's assertions are, however, supported by sound science from researchers such as Prof. Olle Johansson at the Karolinska Institute in Stockholm who posits that after five generations, laboratory animals became infertile. As for DNA damage, Dr. Dimitris Panagopoulos at the University of Athens proved DNA damage to annoying creatures such as fruit flies. In a recent paper, Panagopoulos reported:

> ... external EMFs of varying/alternating nature, modulated and pulsed fields such as those associated with modern wireless telecommunications or produced by power lines, would not be expected to have beneficial action. Rather as demonstrated in the present chapter, these can be expected to be detrimental even at intensities thousands

> or even millions of times smaller than those of the current exposure limits. Ways of direct and indirect electromagnetic interaction between environmental fields and living systems are described in the present chapter.

"The bad news, as most of you will know," said Trower, "is that the mitochondrial DNA is irreparable. So what we're saying to your children is if we damage your mitochondrial DNA it is their children and their children and their children. As long as there is a female line you will have this genetic damage. So, by putting wi-fi in school classrooms, what you're actually doing is sentencing 57 percent of your children to some form of birth defect forever. This is where the joke stops. It isn't a decision we have the right to make."

Ireland's Minister for Education and Skills, Ruairi Quinn, T.D., disagrees. An architect and town planner, Quinn was quoted in February, 2013 by Breakingnews.ie, saying, "All of our (European Union) classrooms, right across the 27, soon to be 28 member states, have to embrace that technology because the rest of the world is doing so and we have to do so as well. It won't change education per se, but it will change the way in which we do education."

Mr. Quinn was proved wrong a month later when the French Assemblée Nationale voted to keep radiofrequency electromagnetic fields away from schools. As part of an amendment to the bill for the 'rebuilding the schools of the Republic', MPs voted to promote wired Ethernet connections in schools and not wi-fi, supporting the precautionary principle and protecting children's health.[10]

In addition to France, the Public Health Department of Salzburg has warned that wi-fi should not be put in schools or nurseries. The Austrian Medical Association is lobbying against the deployment of wi-fi in schools. In a letter to the parents of Salzburg, Dr. Gerd Oberfeld, who addressed the Irish Doctors Environmental Association two years ago, said, "Based on first empirical evidence from sensitive people, the signal seems to be 'very biologically active' The symptoms seen so far are the same seen in base station studies: headaches, concentration difficulty, restlessness, memory problems etc.The official advice of the Public Health Department of the Salzburg Region is not to use WLAN and DECT in School or Kindergardens." WLAN is an acronym for Wireless Local Area Network or the ubquitous wi-fi proposed for Irish schools and DECT stands for Digital European Cordless Telecommunications, the wireless phones found in homes and offices.

In Germany, too, the Bavarian Parliament has recommended that no schools in the province use wireless LAN (Local Area Network) networks. The Frankfurt City government said that it would not install wi-fi in its schools until it had been shown to be harmless.

From Russia, Prof. Yury Grigoriev, a member of the WHO International Advisory Committee on EMF and Health, said, "The short-term and long-term potential consequences for society from exposing children to microwave radiation from cellular communication devices must be immediately acknowledged globally, and responsibly addressed."[11]

---

[10] http://wifiinschools.org.uk/

[11] N. I. Khorseva, Yu. G. Grigoriev, N. V. Gorbunova. *Psychophysiological Indicators for Child Users of Mobile Communication. Message 1: Present State of the Problem.* Institution of the Russian Academy of Sciences, N. M. Emanuel Institute of Biochemical Physics, Russian Academy of Sciences, Moscow, 119334 Russia. 2011. http://electromagnetichealth.org/electromagnetic-health-blog/russian-res-children-emf/

In North America, David Morrison took court action to block wireless in schools in Oregor, he explained, “I brought a federal law suit against the school board of Portland OR. for installing wi-fi in the schools. The suit was based on 14th amendment rights to a safe environment for my daughter's education. My research led me to Barrie and he generously agreed to be a witness in our action. As a result we traveled to London to meet him for depositions and at another time spent three days interviewing him. The suit has been defined by the judge as a complaint against the FCC and not suitable for the courts. Of course it was an easy out for the judge. We are now preparing an action to reignite the case.”

Support for Trower and a growing numbers of experts is growing around the world.

Trower’s unmet challenge

It is at this point that Trower issues his first challenge - one that has never been taken up anywhere he has spoken, whether on television or at public meetings. “Now I have been right around the world lecturing and in every country in the last however many years,“ he said, “When I appear on television or radio I make a challenge and I say what I want. I want this country’s top scientists, government scientists, industry scientists, I don’t care how many there are...I want them to humiliate me live, on air, and would they please come and do it. I have one question, just one question. What is the safe level of microwave irradiation for the ovarian follicles of an embryo? Drug companies can tell you if they have produced a drug for a child but to date in all of the years in every country not one person will meet me live on television and tell me, not one And the reason is there isn’t one. I know there isn’t one because there can not be. There isn’t one. My reaction is, well, Why are we putting wi-fi in schools? Simple as that.”

Statistics

Trower relentlessly throws out statistics. When transmitters went up there were 200 cancer clusters in schools. The Council of Europe is recommending wired systems in schools. Eight other countries are negotiating or taking wi-fi out of schools.

“Unicef, a charity, the children’s charity that I think is beyond reproach,” noted Trower, “they did their own survey research for children and they found there was an 85 percent increase in central nervous system disorders, a 36 percent increase in epilepsy, 11 percent in psychiatric problems, 82 percent in blood / immune disorders in children and risk to the fetus,“ he said. “Recent news came in within the last few days, how big a part I played in this I don’t know, but I have been in touch with various people over there, but 60,000 pediatricians in the U.S. have petitioned Congress to take wi-fi out of schools. 60,000. That is not a small body of knowledge. If you add that to the 40,000 similar bodies who signed the Freiberger agreement - hospital consultants and people like yourselves - we have 100,000 of the most educated professionals in the world - probably the most educated professionals in the world - 100,000 saying, ‘Protect our children and get wi-fi out of schools’.”

“In China, parotid cancer from the cell phone - up 3,000 percent. Other countries are now listing huge increases in childhood brain tumours,” said Trower. “They are actually saying it is down to cell phones. Neurologically, and it is published here in the *Journal of Neurological Science*, on tens of thousands of children explaining why low level microwaves are causing all of the neurological problems they are in children. If you think of

some of the chemicals, just a few of them, whizzing around the brain, anandimide, encephalin, orexin, the balance between the frontal cortex and the amygdala, the frontal cortex and the ventral paradigm if you look at those and I'm going down from the morphine substitutes, the marijuannas, the severe hunger, the severe hopelessness and the severe anger just with those alone...

"The current used by that part of the brain to release those chemicals into the brain is around 2 milliamps. Under certain conditions, ordinary everyday conditions, that can be increased 17-fold by microwaves. 17-fold. It's not surprising when you have neurological papers saying it's causing this or it's causing this or this or this. We know it's going to because it's been used in stealth warfare to do this. So we know it but it can be increased 17-fold under normal, everyday household conditions." he said.

Trower displays photographs of a woman who carried her cell phone in her bra. He admitted that one woman suffering a breast tumour does not prove the cause of her tumour was where she placed her cell phone. "But," noted Trower, "I have on a disc in here, I have 45 peer reviewed research studies showing that the breast tissue is particularly sensitive to microwave radiation. Women suffer more than men because they have 13 circadian rhythms / frequencies in their bodies in which microwaves interact with that men don't have. They have much more complex hormones, again which are more susceptible to women so women do suffer more than men and obviously girls more more than boys."

It is relevant to note that University College in Dublin hosted a series of seminars supported by the Irish Cancer Society to address the issue of female breast cancer in October, 2012. The issue of microwave radiation was not included in the the group's focus, however, psychotherapy was. It is also relevant that the Irish Cancer Society is heavily supported by the microwave industry.

ICNIRP

In addition to the intentional suppression of evidence, there is the contentious issue posed by recognition of the Thermal Effect and standards issued by the International Commission on Non-Ionizing Radiation Protection (ICNIRP). It is a high-sounding title which wreaks of Orwellian *Newspeak*. "Some of the countries I have been to have asked where can we go from here? Can we actually fight the industry? The answer is, 'Yes'," said Trower. "Generally what I find when I talk to the people involved in the countries, generally they have been lied to. And if you have been lied to, you have obviously, through barristers and people, a recourse and one of the things that have been thrown in my face right around the world is what they call call the ICNIRP certificate...

ICNIRP was ostensibly established to set standards for public protection under the voluntary *Precautionary Principle*. "When we go to these countries they say, 'Ha' six minutes of heating, but that is not true and this is where the lie comes in. Generally the industry goes to a school or a body and say the levels are up here and we're down here and everything is okay. That is actually not true and I have fought two international cases on this. My first question when I have this thrown in my face is, 'Have you read it?' (ICNIRP guidelines)and to date, again around the world, I have never met a single person who's read the guidelines they are throwing in my face. Well, I have," said Trower.

Again citing official documentation, Trower chokes them with their own admissions. “Here, “ he said, “on page 545 it says, for example, some children, the elderly and chronically ill people might have a lower tolerance for the radiation than the rest of the population. They need separate guidelines and they go on to say, even under those guidelines, there will be other people which they call sensitive individuals who need, again, separate guidelines. In other words, the electro-sensitive. And it goes on... Page 546... this is the bit they don’t like, it says that decision-makers should read current scientific literature and set an exposure level at a tolerance lower than what is know to be causing illness and that is not the ICNIRP level which is up there. In other words you should set a safety level lower than what is known to be causing illness and they don’t do that.”

The international battle between the Thermal Effect advocates and those pressing for stricter guidelines and regulations has become heated in Canada where Health Canada proposed that Canadians are protected by vaunted and violated Safety Code 6 Guidelines. The debate exploded when it was learned that those guideline are also based on the Thermal Effect. Jerry Flynn, a former military man like Trower, offers parallel evidence. Flynn, too, is challenging the Canadian government and Dr. David Butler-Jones, chief Public Health Officer of Canada’s Public Health Agency.

Flynn, a retired Canadian Armed Forces captain, spent 22 of his 26-years-and-a-day years service in Electronic (EW) and Radio Warfare.. He spent two years as Executive Officer & Operations Officer at an ultra-sensitive radio station directly employing 200-plus specially-trained radio operators and technicians and another two years’ National Defense Headquarters, in the Directorate of Electronic Warfare, as the Staff Officer EW for Canada’s only Army EW Squadron. He has conducted Electronic Warfare at sea with the Royal Canadian Navy and on land with NATO army units.

Trower, Flynn and the former SAS member Victor Nixon who died last year, age 59, in Idaho, are just three military men to step forward and challenge government. Like Trower and Nixon - each working from separate perspectives and unknown to each other, they challenge authority. Flynn is challenging the health authorities in Canada. “I would like Dr. Butler-Jones to answer for me, please - in unambiguous language - how Health Canada can continue telling the public that they are protected by Safety Code 6 when Canada's own internationally respected and independent National Research Council (who are also based in Ottawa but report to Industry Canada), the Council of Europe (47 countries, 800 million people) and the Russian Federation all say Canada's Exposure Limits - being based solely on thermal effects of EMR/RFR - are amongst the highest, i.e., most dangerous in the world! I would appreciate an acknowledgement of receipt from Dr. Butler-Jones, please,” said Flynn.

For military men to step forward to defend themselves and their people against the actions of the governments they served is a remarkable act of courage.

Trower, Flynn and Nixon - all military men - raise the Roman poet, Juvenal’s question, “*Quis custodiet ipsos custodes*?” (“Who will guard the guards themselves?”). Indeed, who is protecting the military and the police who are using Tetra.

Why Bees Can't Survive

Nearly imperceptively, Trower is building a case. From his personal history to scientific evidence of experimentation on humans - forbidden by international agreement in the post-WWII Nuremberg Code, he moves to the complex - perhaps purposely so - issue of the disappearance of bees.

Obviously, it's not just people," explained Trower, "there are papers here we are looking at – birth problems and deformities researched by government veterinary clinics and we have something called the Glastonbury Festival in England. Twice I've been the guest speaker for the Glastonbury Festival and I spoke to university professors who are beekeepers and I cited 14 references as to why the bee can not survive in microwaves - or any other flying insects. We have birds are affected and it has appeared in *Nature* for the scientists here it's the cryptochrome mechanism in the brain. There have been further state government studies in cattle with birth defects – horses are particularly vulnerable to everything I've spoken of, whales, and there is a list here, cats, dogs, hamsters and they cite immune system birth problems, just about every animal there is on the planet is going to be affected which isn't surprising because, if you think about it, at the cellular level when you get down to the DNA and the four bases, we are really all the same. And if you're going to affect human cells you're going to affect tree cells, buttercup cells, even germ cells," he said.

"Unfortunately, the situation with the bees is a page out of the playbook that we deal with all the time with the mobile phone industry," said George Carlo[12], an epidemiologist and head of the Science and Public Policy Institute in Washington, D.C. "When the bee story first broke, it was based on a German study that showed information carrying radio waves disrupted the ability of bees to make it back to their hives. Most people in the public don't know the back story, so they do not see the manipulation coming or have the necessary bases for skepticism to see through it."

Carlo attributes the disappearance of bees (or CCD, Colony Collapse Disorder) to five factors: 1) timing, the speed at which the phenomenon has spread; 2) the absence of adequate scientific research to support chemical or biological causes; 3) The factthat microwaves interfere with intercellular communications; 4) the suggestion we are near a saturation point of these waves in the ambient environment with bees as the likely the harbinger or the proverbial 'canaries in the coal mine'; and 5) although there is at least one peer-reviewed study that supports it, the pattern is global which suggests a cause that is globally present.

"Taken together," said Carlo, "EMR is the only explanation that makes sense regarding the disappearing bees: the timing is correct -- the problem has occurred primarily within the past two years....when we have nearly tripled the background level of information carrying radio waves; the pattern is global so that suggests a cause that is globally present; there is at least one peer-reviewed study that supports it, and there is a mechanism documented that lends biological plausibility."

---

[12] Dr. George L. Carlo, Science and Public Policy Institute, 1101 Pennsylvania Ave. NW -- 7th Floor, Washington, D.C. 20004

"In our view, this is a serious 'red flag' of risk that should be heeded. This is yet another example of mobile phone industry orchestration aimed at distracting the public from data that can save lives," said Carlo.

In the winter of 2006-2007, CCD killed 32 percent of America's honeybees. The next winter, another 36 percent—more than a million hives—died. In 2009 Rowan Jacobson, editor of the Art of Eating reported from Vermont:

> "At first I was in denial," Olson recalled. "Then I just felt weak and had to lean against my truck. A year's hard work for naught!" Olson wound up losing all 50 hives that had overwintered in one particular bee yard. That's bad enough, but it pales next to some operations. Adee Honey Farms of South Dakota, the largest beekeeping business in the country, lost 28,000 of its 70,000 hives. That's about a billion bees gone missing. "It's off the charts," said Bret Adee. "It's not a sustainable thing, what's happening now."
>
> At first it looked as though the United States was the sole sufferer of CCD, but the rest of the world quickly reported losses also. "The situation for bees in Europe is no better than for bees in North America," says Bernard Vaissière, a pollination specialist with the French National Institute for Agricultural Research. A report issued last August by the European Food Safety Authority estimates that the UK lost about 30 percent of its honeybees in 2007, while Italy lost 40 to 50 percent. Whatever is taking down bees has gone global.[13]

And it isn't only bees that are disappearing. In the British Isles the ubiquitous Busy Lizzie or Impatiens beloved by millions of gardeners has disappeared from D.I.Y. shops and garden centers - ostensibly due to a fungal attack. Unofficial trials in unaffected areas are proving the plant does not want to germinate. A group of 9th grade school children found the same phenomenon in Denmark. Cress seeds placed next to a wi-fi router did not grow and some of those that did were mutated or died.[14]

"Now again," noted Trower, "very, very recently *Scientific American* published an article of the 27 greatest risks to the planet, I can link low level microwaves to 18 of them direct. 18 of the 27, 67 percent."

Sinister Course

Although Trower makes a concerted effort to avoid politics, he makes what is, perhaps, the most political statement of all – and it is of Biblical proportions. "Now, just to finish off," perhaps literally and figuratively, Trower says, "microwaves are taking a very, very sinister course at the moment. They are used in global weather warfare. A few years ago three papers were published showing that that the greatest contributor to carbon dioxide in the atmosphere now is the communications industry. They put more carbon dioxide into the atmosphere than any other industry even more than the aviation industry. 110 million tones, 29 million cars – that was a few years ago before all your iPods and iPods came along."

---

[13] *Jacobsen, Rowan., The Importance of Bees to Our Food Supply* March/April 2009 http://www.eatingwell.com/food_news_origins/green_sustainable/the_importance_of_bees_to_our_food_supply

[14] http://mastsanity.org/health-52/research/324-experiments-with-cress-in-9th-grade-attracts-international-attention-denmark-16th-may-2013.html

Trower finds himself at the epicentre of conflict between the Global Warming crowd and the Deniers. “Now you may or may believe in global warming, I’m not going into that here,” he said, “but one thing cannot be disputed. When you have carbon dioxide in the atmosphere, and it mixes with rainwater, you have carbolic acid. And the carbolic acid comes down into the oceans. And again, *Scientific American* or *Nature*, have published that the acidity of the oceans has reached critical levels for the photosynthesisers in the ocean and they produce about 50 percent of the world’s oxygen. A lot of people don’t realize that.”

… for the punchline he adds, “We are really running the risk of losing our planet.”

Trower: The King and I

Were it not so serious, it would be laughable. Trower’s observation that if half of the world’s scientists are employed by the military, then the scientific world is nearly evenly divided between those who want to help humanity and those who want to harm us. “Microwaves are used in microbiological warfare, atmospheric warfare, environmental warfare,” said Trower. “It seems that when you have half the world’s scientists engaged by the military, who have nothing else to do but to dream up ‘how can I harm someone else’ it’s not surprising that we have all of these things now. And to finish off, I’m not boasting when I say this, I have probably met around 40 royals, leaders of governments, leaders of peoples, other important people around the world and they started to tell me as I was going around. I was picking up a familiar theme.”

A true English academic in a much-photographed green tweed sports jacket and matching everything else in green, Trower is not given to the playfulness of British whimsy or wishful thinking, however he does admit that he had a crystal ball. “And I always wished I was the one who was clever enough to think this up but I wasn’t. It was a king who had an Oxbridge (Oxford-Cambridge) law degree and we were having lunch in his garden. He leaned forward and he said, ‘I can tell you one thing, Barrie,’ he said, ‘I am losing the viability of my country.’ And then the pieces started to fall in. He said, ‘Since the mobile industry moved in I lost a vast number of my insects which means I have to start importing fruits or we get scurvy. We grow vitamin C plants. I’m losing my cattle which means I’ll have to start importing other cattle. I’m losing my trees and all my other plants. My people are becoming sick and I have a paper that shows it could be as much as another 40 percent on your health bill. My people are becoming sick which means I’ll have to start importing medicines.’ He said, ‘Now if you think – let’s assume you have 10 million cell phone users in my country and the daily bill one euro a day, I’m losing the best part of 10 million euros a day going out. Admittedly tax comes off and they run shops and things but the majority of the money goes out.’ And he said, ‘Any child who knows how a money box works can tell you that I as a country am going to go bankrupt. Sooner or later I’ve got to go bankrupt.

“‘He said, when it gets worse, he said, the very countries that bring the cell towers in and cause the damage are the very countries - namely the Americans and the Indonesians - He said they are the very countries, the first in, to offer aid, a very generous package. He said, but there is a price for aid., He said they want mining rights, they want mineral rights, they want land rights and they want immigration rights. It’s a trickle but it’s a non-stop trickle. ‘So I have all of this going out and all of this coming in and,’ he said, ‘I’m going to lose the viability of my country. I might still be king but I will not be king of my country and my people and really that sums it up.’”

Trower's prediction (for Ireland and other countries) is not far removed from the experience the king outlined. "So, if you were to say to me," said Trower, "What's going to happen to Ireland? It's simple, you are going to see an epidemic of birth defects, with livestock and children that will put Thalidomide way into the shade. That is going to happen without a shadow of a doubt. You are also going to lose the viability of your country, that can't be helped as well - unless you do something."

There is a parallel to the king's story in Ireland where the cell phone industry with 5.5 million subscribers is worth €1.65 billion[15] according to the Central Statistics Office. In a country "bailed out" by the so-called Troika of financial interests and where the government pledged to save failed banks to the tune of €70 billion there is ample evidence of the king's saga being repeated. At present, Shared Access, a North American Company founded with backing from from financial powerhouses GoldmanSachs and JPMorgan, is attempting to buy the income stream from farmers who earn an income from having masts on their lands. For a once-off payment to the farmer, Shared Access will acquire all the income and the earnings will be lost to the Irish economy.

The issue is compounded by a relationship with the Irish Farmers Association which has agreed to a confidential arrangement. As a not-for-profit Non-Governmental Organization (N.G.O.) the organization is beyond the reach of government and any business arrangements a completely legal in site of the fact that individual farmers, fee-paying members of the group, are not allowed to ask questions

"What can you do?" asked Trower perhaps optimistically hanging onto an old fashioned concept of democracy. "One suggestion - you may have better suggestions - one suggestion is you get me back here to talk to your full Parliament for one hour. It sounds absurd but other than e-mails and you approaching people. If I could talk to them and I could make them realize the proof. If I could talk to your Parliament it may work. It may not but at least they know what is coming and their children and it is their country and it won't cost them a penny because I work for free. They can't say 'We can't afford it'. I'll even pay out of my own old age pension if that's what they want but it will cost them one hour of their time and that is all."

It all boils down to timing and money. In a time of austerity, money speaks louder than the health and well-being of the population. While Trower's advice may, in the long term be priceless, talk, they say, is cheap - even on a Tetra radio, a cell phone or a wireless network in a classroom.

While Trower was talking in Dublin...

While Trower was speaking in Dublin, a group of the world's top scientists[16] simultaneously came to a similar explanation and conclusion called the Potenza Piceno Resolution during a conference in Italy.

The resolution underscores Trower's warnings with scientists issuing the following conclusions:

- stricter safety standards for EMF needs to be adopted by governments and public health agencies because the existing ones are obsolete and they are not based on recent literature about biological effects.

- RF sources should be reduced as low as possible because at now it is not possible to establish a safe limit under which no biological effects can be observed.

- RF sources should be kept far from residential areas. For pulsed RF sources, such radars and Wi-Max antennas, the distance from the EMF source should be even greater because they cause more biologically effects than non pulsed signals.

- Wi-Fi should not be placed in schools and in public areas since they have characteristics of pulsed signals.

Five days after Trower gave his testimony to the audience in Dublin, the Federal Communications Commission in the United States waived objections to the use of Tetra in the United States.

Yet another young man, age 23, died in his bed of a heart attack in Ireland. The only country in the world that is monitoring the emergence of a "new" disease, Sudden Adult Death Syndrome (SADS).

It was less than a month after the Sepura company in the U.K. announced plans to deploy Tetra for the first time in North America in Washington State.

- John Weigel

Cites end of national sovereignty

Expert tells doctors of impending tragedy from EMF radiation as health of nations laid waste by technology

Barrie Trower lives in a world different to the rest of us. His world is every bit as dangerous as anything Tolkien could have dreamed up and with each passing day inches closer to engulf us. Very occasionally he surfaces to warn us but returns back to his world largely ignored.

While his words are reasoned and motivational - much like Tolkein's wizard, Gandalf - Trower is stoically centered. He sat alone for more than a hour waiting to address the annual general meeting of the Irish Doctors Environmental Association (IDEA) amid stacked chairs against the stark white walls between two tall Georgian windows with only a glass of water molecules to bring clarity before speaking to the group.

A lecturer in Advanced Physics at South Dartmoor College and living in a village in rural Devon - not unlike Tolkein's beloved Shires - Trower has travelled to 27 countries around the world explaining the unseen wonders of physics and the perilous ways mankind is commercially exploiting the invisible for profit and political power.

From the outset, Trower is courageous. Here is a truth-teller, not just an ordinary whistleblower, but a man who came out of retirement with a warning for all humanity. "I'll tell you very briefly where I'm coming from very before I start," began Trower, "In 1959 I studied my first paper on microwaves for my entry examination into the military. I studied all aspects of microwaves in the military - radar, health issues. Microwaves then were being used, as they are today, as stealth weapons. Stealth weapons specifically to cause severe neurological and physiological damage. There never, ever was any safe level of microwave radiation." Trower began his career with the British Royal Navy before his peacetime duties with the Secret Service. In addition to his experience he is uniquely

qualified to discuss microwaves due to education with a degree in physics, a second degree in research, as well as a teaching diploma in physiology.

Common sense tells us electricity is dangerous. Less generally known are the principles surrounding magnetism which, according to experts like Davis and Rawls in their book *Magnetism on Its Effects on the Living System*, can be equally dangerous. Combine the two principles, electricity and magnetism, into electro-magnetic frequencies (EMF) and there is a recipe for untold misery, pain, death and destruction. Electromagnetic frequencies (EMFs) are the signals used in modern communications systems, from the billions of cell phones and masts that service them to the pulsed signals of WiMAX and Tetra which are stronger still.

Although Trower came to the subject late, the Russians had been studying microwaves from as early as 1920, according to Czech writer Mojmir Babacek, founder of the International Movement Against Manipulation of Central Nervous System. Babacek told *El Spectador* that Russia was well advanced in the 20's investigating phenomena such as telepathy, telekinesis and clairvoyance, and that during the 60's and 70's there existed a real arms race between Russia and the U.S. in this area which supports Trower's explanation of debriefing victims for the British military - cold war spies - following their microwave radiation exposure. And as recently as April 2013, Russian President Vladimir Putin admitted that Russia plans to ramp up its arsenal with the development of "psychotronic" weapons.[1]

"Following my time in the military - we're into the cold war here - and those of you who remember the Cold War it was a very, very tense time for the world, I can specifically remember two occasions when we were within one second of total global nuclear war. A part of my job when I left the military because I had microwave knowledge, and they were being used as weapons, was to question captured spies or agents which I did for eleven years and in my defense and, might I please say, that the program, run by Sir William Melville, I never used pain, humiliation embarrassment, drugs, hypnosis, nothing. I treated the ladies and gentlemen as I would talk to you. It was nothing more than a conversation over a cup of coffee."

Melville is the real 'M', founding father of MI-5 and the inspiration for Ian Fleming's character in James Bond books and films.

Trower explained that during the Cold War, less than 20 years after the death of Nikola Tesla, the genius of electricity, and less than 15 years after the end of WWII, governments were already researching the effects of pulsed microwave signals in the 1960's. "I gathered the information," he said, "because different pulsed systems were being used to cause different neurological and physiological damage." As a former insider Trower is giving first hand fact-based evidence that microwave signals and radiation cause damage to living organisms and the built environment. Furthermore he is living testimony that governments have used that evidence to inflict pain and suffering on their opponents.

Trower claims that there is no defense against a microwave assault and that by alternating pleasure and pain frequencies broadcast from a van parked nearby "anyone can be broken in 30 hours." His statement is backed up by Drs. P.D. Whissell and M.A.

---

[1] Staff writers. *Russia working on electromagnetic radiation guns.* Herald Sun. Melbourne, Au. 4 April 2013. *http://www.heraldsun.com.au/technology/sci-tech/russia-working-on-electromagnetic-radiation-guns/story-fn5iztw3-1226317396841*

Persinger of Laurentian University, Ontario. who said in a 2007 paper, that "experiments showed a role of opiates in simple and pulsed EL-EMF response, but opiate-like effects induced by VHF-MF and microwave (MW) field also exist and have been characterized for more than a decade."[2]

Trower's testimony flies in the face of "Product Defense Consultant" Dr. William H. Bailey, advisor to the Irish government, power companies in Nevada and British Columbia as well as companies like Toyota that experience electromagnetic interference with their services or manufactured goods.

Shortly after embarking on a career in education, Trower explained that he was contacted by a police authority in the U.K. to review the literature and explain the implications of the proposed switch to a new communications system using Tetra technology - a microwave signal developed by the Motorola Corporation, a major U.S. military contractor based outside of Chicago, Illinois. "That resulted in me being commissioned to write the first safety report on the Tetra system for the emergency services which I condemned," said Trower. "Nine years later I was approached by another police union with the increased cancers and other neurological problems, saying would I update my report which I did."

Before launching into proof that low level microwave radiation causes disease and death, Trower said that he has never charged for his public engagements because once you accept money you can be told what to say and, secondly, even the poorest can afford to hear his message. The idealism of Trower's position is growing around the world against what is becoming increasingly the most powerful industry on the planet. While her husband has endorsed the electromagnetic Smart Meter, Michelle Obama, quietly contacted Trower for information through an agent in New York. After all, she has two daughters to protect. The hand that rocks the cradle may, yet again, rule ...

"Let's deal with the most important question first," he said as he stood behind a pile of documents neatly grouped and tied with string. "With low level microwaves, and lower level is actually more dangerous than a high level, with low level microwaves is there any proof? Let's deal with the proof argument first. More than you would probably imagine - there are 8,300 military papers proving microwaves cause severe neurological and physiological damage. There are seven high court cases now against the industry showing that they will cause this. There are 12 epidemiological studies. There are another 19 legal judgements around the world - by mayors, magistrates or people who have the ability to make a legal judgement. The industry themselves, this is what they say about the microwaves that children are walking around using."

Trower quoted a document prepared by the German Ecolog Institut on behalf of the T-Mobile holding company for Deutsche Telecom with its estimated 150 million customers world-wide. Reading from Section 7 of the document, Trower bridged direct quotes from the Ecolog study with his own links, "These are their actual words. 'It can be concluded that electromagnetic fields used in the mobile telecoms range do play a role in the development of cancer'... On the cellular level, a multitude of studies found these waves can induce the cancer initiation, cancer promotion agents to act in the body. 'DNA

---

synthesis and repair mechanisms' for continuous or pulsed fields can influence or directly damage the DNA.'"[3]

Trower referenced the ruling of an Italian court against the microwave industry. "I had to read this a few times just to believe it ... it was in the transcript of the judgement against the industry for cancer, and it actually states that if you use a cell phone five to six hours a day for 10 - 12 years you are more likely to develop ipsilateral cancer, that is from the direction of the source of the radiation, you are more likely to develop ipsilateral cancer than the survivors of the atomic bomb in Japan in 1945. There is no doubt microwaves are causing cancer, neurological and physiological damage. No doubt." said Trower.

If microwave radiation is causing so much damage, why is the public so unaware of the dangers? Before answering the question, Trower again lists the effects from still more sources - some top secret:

- TOP SECRET: From a U.S. conference, 1986. "Concerning low level microwaves, we can change behaviour of cells, tissue... Whole organisms have a six times higher fetal mortality rate, birth defects and induce malignant tumours in human cells."

- TOP SECRET: Course No. 11, 2001-07. "Students (scientists) will be familiar with current knowledge, ie. cancer, memory, brain function damage to the eye, skin, birth defects from low level microwave radiation."

- TOP SECRET: Naval Medical Research Institute: *Biological and Clinical Manifestations Attributed to Microwave Radiation (Low-Level)* which lists 2,000 medical references with the main paper, *Altered Menstrual and Fetal Development*.

- TOP SECRET: World Health Organization (W.H.O.), 1973. Biological Effects: Health and Excess Mortality from Artificial Irradiation of Radio Frequency, Microwave Radiation. The paper was the result of a symposium held in Warsaw and has been referred to by experts such as Dr. Magda Havas, Trent University, Canada, Henry Lai, of the University of Washington and by the Seletun Declaration signed by Prof. Olle Johansson, of the Karolinska Institute, among others.

"The damage caused by microwave radiation is irrefutable," says Trower, "There never is any doubt. There never was."

In reference to the Warsaw document, Trower held it high, telling the audience, "Again, top secret paper. This is a surprise This is actually from the World Health Organization and it says *Biological Effects: Health and Excess Mortality from Artificial Irradiation of Radio Frequency, Microwave Radiation.* They list pages upon pages of ill effects and when the W.H.O published this it was stamped Top Secret and hasn't seen the light of day since."

As it emerges from the shadows of secrecy, the document is becoming a cornerstone of the global reaction to microwave radiation, giving credence to the fact that dangers to human and animal health were established more than 40 years ago and that the evidence has been suppressed. In a sworn affidavit to the State of Oregon, Trower told the court

---

[3] http://www.hese-project.org/hese-uk/en/papers/ecolog2000.pdf. In context: " it can be concluded that electromagnetic fields with frequencies in the mobile telecommunications range do play a role in the development of cancer... Direct damage on DNA as well as influences on DNA synthesis and DNA repair mechanisms were demonstrated"

that health effects from microwave radiation had been noted as early as 1932 when it was called “radiowave sickness”.

A 2006 Freedom of Information request by Donald Friedman of Napa, California[4] supports Trower implicitly. The buried document revealed both the theory and practice behind inducing neurological events from subjects “hearing things” - the Frey Effect - to suffering epileptic seizures of varying severity.[5] The U.S. Army document, *Bioeffects of Selected Non Lethal Weapons*, which notes that human beings have been used as guinea pigs and the physical effects are a reality, states:

> Human subjects listened to very high levels of low-frequency noise and infrasound...Two minute duration as high as 140 to 155 dB produced a range of effects from mild discomfort to severe pressure sensations, nausea, gagging, and giddiness. Effects also included blurred vision and visual field distortions in some exposure exposure conditions...”

Naturally, by virtue of the fact that Friedman had to officially request the document and that it was originally labeled “Secret Noforn” until it was stamped unclassified clearly indicates that information is being suppressed and kept well away from public scrutiny. The label "SECRET NOFORN" means documents are designed to never be shown to non-US citizens.

According to Trower, the reason is simple. “The question is, ‘Why?’ Why has all of this damage which is known to be caused to children, why is it being suppressed? And the answer is here,” said Trower, holding before him yet another document.

“And I have said this was incredibly top secret. It is from the United States Defense Intelligence Agency. It’s dated 1971 and basically they list all of the illnesses which you can expect at this time from low level radiation including blood-brain barrier damage but it is the first three lines which I think are the most dangerous lines since the declaration of war and it’s certainly going to cause more casualties.... Those three lines of text from the U.S. Naval Centre are telling indeed: ‘If the governments of the more advanced nations of the West are strict in enforcement of stringent exposure standards, there could be unfavourable effects on industrial output and military effects.’[6]” The possibility / probability of costly law suits moved Swiss Re to refuse insurance to companies using microwave

---

[4] *Bioeffects of Selected NonlethalWeapons.* 1998. ”Application of electromagnetic pulses is also a conceptual nonlethal technology Uiat uses electromagnetic energy to induce neural synchrony and disruption of voluntary muscle control. The effectiveness of this concept has not been demonstrated. However, from past work in evaluating the potential for electromagnetic pulse generators to affect humans, it is estimated that sufficiently strong internal fields can be generated within the brain to trigger neurons. Estimates are that 50 to 100 kV/m free field of very sharp pulses (~ 1 nS) are required to produce a cell membranic potential of approximately 2 V; this would probably be sufficient to trigger neurons or make them more susceptible to firing. The electromagnetic pulse concept is one in which a very fast (nanosecond timeframe) high voltage (approximately 100 kV/m or greater) electromagnetic pulse is repeated at the alpha brain wave frequency (about 15 Hz), It is known that a similar frequency of pulsing light can trigger sensitive individuals (those with some degree of light-sensitivity epilepsy) into a seizure and it is thought that by using a method that could actually trigger nerve synapses directly with an electrical field, essentially 100% of individuals would be susceptible to seizure induction.” http://www.kat97305.byethost3.com/Bioeffects_of %20Selected_Non_Lethal_Weapons.html

[5] http://sigint.files.wordpress.com/2008/02/bioeffects_of_selected_non-lethal_weapons.pdf

technology. The risk-averse insurance sector bases it's assessment on risk, the concept explored by Australian Don Maish in his book, *The Procrustean Approach: setting exposure standards for telecommunications frequency electromagnetic radiation.* Maisch was savaged by the legal team representing FortisBC during hearings in British Columbia in March 2013 to consider deployment of the contentious Smart Meter. The contentious William Bailey, naturally enough, testified on behalf of the industry.

Blame for the paucity of public safety standards rests with the U.S. government, claims Trower. "The United States government are advising Western governments, namely us, to have such a relaxed safety level that the industry can never be taken to court," he said. "They also say that if we don't it will have a disastrous effect on industrial profit and, of course, line them up for law suits. Following this, if the American government says 'Jump', the English government says, 'How high?'"

Trower explained that the English government adopted a six-minute heating effect as the official standard and the rest of the world followed suit. There is, however, ample evidence of global financial interests bringing enormous pressure to bear. Names like Motorola. Westinghouse, JPMorgan and Rockefeller litter the resume of Nikola Tesla, the undisputed pioneering genius in the application of electricity and magnetism. Indeed, it was Tesla himself who alerted President Franklin Roosevelt of the theory behind creation of a death ray to end WWII and all wars while a friend petitioned Eleanor Roosevelt for financial help for the inventor who died penniless in January 1943.

Trower's assertion regarding the arbitrary adoption of the heating or so-called "Thermal Effect" caused by microwaves was expressed as early as 1981 by the World Health Organization. Titled *Environmental Health Criteria 16, Radiofrequency and Microwaves,* the report notes, "Thermal mechanisms seem wholly inadequate to account for the results of studies indicating that cerebral tissue, exposed to weak electromagnetic fields, responds only over a limited range of intensities and modulation frequencies of the RF carrier field. There appears to be evidence for both amplitude and modulation frequency windows, outside which effects are not observed."[7]

"And that is still the only standard today," said Trower, "six minutes of heating. In other words, providing you don't feel too warm, after six minutes of being near a transmitter or on the phone or whatever, it is deemed safe, that is it. That is the only safety level and today in the U.K. and the United States they'll have got away with that."

In Canada, Dr. Havas[8], of Trent University, Ontario, forced admission from health authorities that while they say they are using standards below the Thermal Effect, they are at wide variance with practice. In February 2013, Havas reported: "I just returned from a hearing in Montreal in front of the Superior Court of Quebec where Health Canada scientist, James McNamee, admitted that the Safety Code 6 guideline for microwave radiation (which includes radiation from most of the devices we are concerned about like mobile phones, cell phone antennas, Wi-Fi, wireless toys and baby monitors, smart meters etc.) is based ONLY on preventing a heating effect! Let me state that again. Health Canada admits that Safety Code 6 for frequencies between 100 kHz and 300 GHz are based ONLY on heating."

[8] http://www.magdahavas.com/health-canada-admits-safety-code-6-guideline-for-microwave-radiation-is-based-only-on-thermal-effects/

Trower is right again and Dr. Havas proved it.

Limits don't protect children

The problem with heating standards, if they can be called standards at all - except in a microwave oven - is the vulnerability of children. Tolerance is a more appropriate term. "Children are much more vulnerable than adults," says Trower, "for two reasons: one, they have a higher water content in the body which means they absorb around 10 times more radiation than adults and the other is that the mitochondrial DNA suffers 10 times more stress than other bodily DNA. If you look at the child, the child is taking a 20-fold increase in danger than adults. This is also before we get onto their size.They also absorb more radiation because they are nearer the size of the wavelength and they act as aerials."

In a court deposition presented in Portland, Oregon in 2011, Trower explained the phenomenon of children as aerials. "Children act like antennas and absorb more radiation than adults because they are smaller, and their very dimensions approximate the deployment's wavelength."[9]

As Trower explained it in Oregon, "A basic receiving antenna can be thought of as an apparatus that converts electromagnetic waves into electrical current. It turns out that the human body is also a very effective antenna over a broad frequency range. As an electrical conductor, when exposed to electromagnetic fields, it behaves as an antenna with a frequency resonance determined by various factors including height, posture, etc. Children are not merely small adults. They are physiologically and neurologically immature; their systems have not yet formed. Microwave radiation alters the blood-brain barrier so that toxins leak into the brain. This can cause neurologic and psychologic amongst many other problems more easily in children. A child's immune system, which fights off infection, takes 18 years to develop. Additionally, 122 layers of protein - myelin - insulate the electrically generated signals used by the nervous system to control muscles and organs. These layers of protein take 22 years to develop. MW radiation has been shown to affect protein synthesis. This could lead to muscular dystrophy-like symptoms in later life."

Trower's greatest concern about children is the fact that the blood-brain barrier in the human brain does not completely develop until the age of 18 months. "The blood brain barrier has been known to enlarge and let toxins in and out of the brain," he claims. "That takes 18 months before it is even made. Similarly the myelin sheet protein synthesis is known to be interfered with as well as the marrow within the bone which has a high water content"

Protect your daughters

"I want to talk at length about one particular problem which I believe is very, very important," said Trower, asking the audience to imagine themselves as young girls sitting at their school desks being irradiated by wi-fi, laptops and electronic tablet textbooks. "The problem with children and I think it is the most important question or topic now to deal with

---

[9] See example of humans acting as antennae: Cohn G, Morris D, Patel S, Tan D, Your Noise is My Command: Sensing Gestures Using the Body as an Antennae, http://research.microsoft.com/en-us/um/redmon d/groups/cue/publications/chi20 ll_rfgestures _cohn. pdf:

microwaves," he explained "With all of the research papers, the first thing that springs to mind (and I've already read them) is birth defects and we're looking, not just in humans, but right across the mammalian species, right across the planet. To explain this I need to keep it simple for myself. I would like you to imagine, please, that you are all five years old and you are all girls and you're sitting in a classroom and a wi-fi is plonked in front of you ...

"The wi-fi is transmitting as is the router on the wall. Now the wi-fi is transmitting generally through your ovaries and you have around 400,000 ovarian follicles - not fully developed - sitting there. They are being irradiated. Let's move the clock forward to the point where you are now 18. You have been through many years of having your ovaries irradiated. And let's say now you are 18 and you are pregnant and I have taught many pregnant students. In the first 100 days of your embryo the embryo is developing its own ovarian follicles. By 100 days, as you will probably know, they are virtually formed. " said Trower.

The ovarian follicles of the 18-year-old have been damaged and this damage is passed down to her daughter and her daughter. In short, the stage is being set for a catastrophe unseen before in human history.

"They have no defense mechanism at all against microwaves," said Trower. "There is no Protein 53 which are four protein structures. There is no nuclear core complex. Those are defense structures we have developed through evolution to protect us against electric storms when we were living in caves. They have nothing. So the ovarian follicles of the embryo and the mother may not even know she's pregnant at this stage - the ovarian follicles have no defense mechanism - and what we are looking at is when your child is born, which may or may not have genetic damage, it is that child's birth where the real problem is going to come out. And we are already seeing this with other mammalian species and if you're wondering how many people are going to be involved - there is only one paper I know of in the world written by a professor, oddly enough, by an advisor with the W.H.O. and he found when women were being deliberately microwaved the rate of stillbirth, miscarriage, genetically damaged children was 57.7 percent and this was at a level of radiation lower than a child would get in a classroom with 20 wi-fis (desktop units). We know a minimum of 57 percent. Now that's the good news."

The mitochondrial cells are where the cell takes in nutrients, breaks it down to create energy at the cellular level. Thus, if the mitochondrial cells are damaged, the cell can not function properly. Logically, when this occurs in the cells of ovarian follicles, eggs will not be healthy or even produced. At a personal level, infertility is unfortunate. At a social level, where a country needs healthy workers to prosper, damaged embryos can lead to widespread social problems. On a global scale, the consequences can be catastrophic. Trower is an academic who shies away from politics. He deals in theory.

Trower's assertions are, however, supported by sound science from researchers such as Prof. Olle Johansson at the Karolinska Institute in Stockholm who posits that after five generations, laboratory animals became infertile. As for DNA damage, Dr. Dimitris Panagopoulos at the University of Athens proved DNA damage to annoying creatures such as fruit flies. In a recent paper, Panagopoulos reported:

> ... external EMFs of varying/alternating nature, modulated and pulsed fields such as those associated with modern wireless telecommunications or produced by power lines, would not be expected to have beneficial action. Rather as demonstrated in the present chapter, these can be expected to be detrimental even at intensities thousands

> or even millions of times smaller than those of the current exposure limits. Ways of direct and indirect electromagnetic interaction between environmental fields and living systems are described in the present chapter.

"The bad news, as most of you will know," said Trower, "is that the mitochondrial DNA is irreparable. So what we're saying to your children is if we damage your mitochondrial DNA it is their children and their children and their children. As long as there is a female line you will have this genetic damage. So, by putting wi-fi in school classrooms, what you're actually doing is sentencing 57 percent of your children to some form of birth defect forever. This is where the joke stops. It isn't a decision we have the right to make."

Ireland's Minister for Education and Skills, Ruairi Quinn, T.D., disagrees. An architect and town planner, Quinn was quoted in February, 2013 by Breakingnews.ie, saying, "All of our (European Union) classrooms, right across the 27, soon to be 28 member states, have to embrace that technology because the rest of the world is doing so and we have to do so as well. It won't change education per se, but it will change the way in which we do education."

Mr. Quinn was proved wrong a month later when the French Assemblée Nationale voted to keep radiofrequency electromagnetic fields away from schools. As part of an amendment to the bill for the 'rebuilding the schools of the Republic', MPs voted to promote wired Ethernet connections in schools and not wi-fi, supporting the precautionary principle and protecting children's health.[10]

In addition to France, the Public Health Department of Salzburg has warned that wi-fi should not be put in schools or nurseries. The Austrian Medical Association is lobbying against the deployment of wi-fi in schools. In a letter to the parents of Salzburg, Dr. Gerd Oberfeld, who addressed the Irish Doctors Environmental Association two years ago, said, "Based on first empirical evidence from sensitive people, the signal seems to be 'very biologically active' The symptoms seen so far are the same seen in base station studies: headaches, concentration difficulty, restlessness, memory problems etc.The official advice of the Public Health Department of the Salzburg Region is not to use WLAN and DECT in School or Kindergardens." WLAN is an acronym for Wireless Local Area Network or the ubquitous wi-fi proposed for Irish schools and DECT stands for Digital European Cordless Telecommunications, the wireless phones found in homes and offices.

In Germany, too, the Bavarian Parliament has recommended that no schools in the province use wireless LAN (Local Area Network) networks. The Frankfurt City government said that it would not install wi-fi in its schools until it had been shown to be harmless.

From Russia, Prof. Yury Grigoriev, a member of the WHO International Advisory Committee on EMF and Health, said, "The short-term and long-term potential consequences for society from exposing children to microwave radiation from cellular communication devices must be immediately acknowledged globally, and responsibly addressed."[11]

---

[11] N. I. Khorseva, Yu. G. Grigoriev, N. V. Gorbunova. *Psychophysiological Indicators for Child Users of Mobile Communication. Message 1: Present State of the Problem.* Institution of the Russian Academy of Sciences, N. M. Emanuel Institute of Biochemical Physics, Russian Academy of Sciences, Moscow, 119334 Russia. 2011. http://electromagnetichealth.org/electromagnetic-health-blog/russian-res-children-emf/

In North America, David Morrison took court action to block wireless in schools in Oregor, he explained, “I brought a federal law suit against the school board of Portland OR. for installing wi-fi in the schools. The suit was based on 14th amendment rights to a safe environment for my daughter's education. My research led me to Barrie and he generously agreed to be a witness in our action. As a result we traveled to London to meet him for depositions and at another time spent three days interviewing him. The suit has been defined by the judge as a complaint against the FCC and not suitable for the courts. Of course it was an easy out for the judge. We are now preparing an action to reignite the case.”

Support for Trower and a growing numbers of experts is growing around the world.

Trower’s unmet challenge

It is at this point that Trower issues his first challenge - one that has never been taken up anywhere he has spoken, whether on television or at public meetings. “Now I have been right around the world lecturing and in every country in the last however many years,“ he said, “When I appear on television or radio I make a challenge and I say what I want. I want this country’s top scientists, government scientists, industry scientists, I don’t care how many there are...I want them to humiliate me live, on air, and would they please come and do it. I have one question, just one question. What is the safe level of microwave irradiation for the ovarian follicles of an embryo? Drug companies can tell you if they have produced a drug for a child but to date in all of the years in every country not one person will meet me live on television and tell me, not one And the reason is there isn’t one. I know there isn’t one because there can not be. There isn’t one. My reaction is, well, Why are we putting wi-fi in schools? Simple as that.”

Statistics

Trower relentlessly throws out statistics. When transmitters went up there were 200 cancer clusters in schools. The Council of Europe is recommending wired systems in schools. Eight other countries are negotiating or taking wi-fi out of schools.

“Unicef, a charity, the children’s charity that I think is beyond reproach,” noted Trower, “they did their own survey research for children and they found there was an 85 percent increase in central nervous system disorders, a 36 percent increase in epilepsy, 11 percent in psychiatric problems, 82 percent in blood / immune disorders in children and risk to the fetus,“ he said. “Recent news came in within the last few days, how big a part I played in this I don’t know, but I have been in touch with various people over there, but 60,000 pediatricians in the U.S. have petitioned Congress to take wi-fi out of schools. 60,000. That is not a small body of knowledge. If you add that to the 40,000 similar bodies who signed the Freiberger agreement - hospital consultants and people like yourselves - we have 100,000 of the most educated professionals in the world - probably the most educated professionals in the world - 100,000 saying, ‘Protect our children and get wi-fi out of schools’.”

“In China, parotid cancer from the cell phone - up 3,000 percent. Other countries are now listing huge increases in childhood brain tumours,” said Trower. “They are actually saying it is down to cell phones. Neurologically, and it is published here in the *Journal of Neurological Science*, on tens of thousands of children explaining why low level microwaves are causing all of the neurological problems they are in children. If you think of

some of the chemicals, just a few of them, whizzing around the brain, anandimide, encephalin, orexin, the balance between the frontal cortex and the amygdala, the frontal cortex and the ventral paradigm if you look at those and I'm going down from the morphine substitutes, the marijuannas, the severe hunger, the severe hopelessness and the severe anger just with those alone...

"The current used by that part of the brain to release those chemicals into the brain is around 2 milliamps. Under certain conditions, ordinary everyday conditions, that can be increased 17-fold by microwaves. 17-fold. It's not surprising when you have neurological papers saying it's causing this or it's causing this or this or this. We know it's going to because it's been used in stealth warfare to do this. So we know it but it can be increased 17-fold under normal, everyday household conditions." he said.

Trower displays photographs of a woman who carried her cell phone in her bra. He admitted that one woman suffering a breast tumour does not prove the cause of her tumour was where she placed her cell phone. "But," noted Trower, "I have on a disc in here, I have 45 peer reviewed research studies showing that the breast tissue is particularly sensitive to microwave radiation. Women suffer more than men because they have 13 circadian rhythms / frequencies in their bodies in which microwaves interact with that men don't have. They have much more complex hormones, again which are more susceptible to women so women do suffer more than men and obviously girls more more than boys."

It is relevant to note that University College in Dublin hosted a series of seminars supported by the Irish Cancer Society to address the issue of female breast cancer in October, 2012. The issue of microwave radiation was not included in the the group's focus, however, psychotherapy was. It is also relevant that the Irish Cancer Society is heavily supported by the microwave industry.

ICNIRP

In addition to the intentional suppression of evidence, there is the contentious issue posed by recognition of the Thermal Effect and standards issued by the International Commission on Non-Ionizing Radiation Protection (ICNIRP). It is a high-sounding title which wreaks of Orwellian *Newspeak*. "Some of the countries I have been to have asked where can we go from here? Can we actually fight the industry? The answer is, 'Yes'," said Trower. "Generally what I find when I talk to the people involved in the countries, generally they have been lied to. And if you have been lied to, you have obviously, through barristers and people, a recourse and one of the things that have been thrown in my face right around the world is what they call call the ICNIRP certificate...

ICNIRP was ostensibly established to set standards for public protection under the voluntary *Precautionary Principle*. "When we go to these countries they say, 'Ha' six minutes of heating, but that is not true and this is where the lie comes in. Generally the industry goes to a school or a body and say the levels are up here and we're down here and everything is okay. That is actually not true and I have fought two international cases on this. My first question when I have this thrown in my face is, 'Have you read it?' (ICNIRP guidelines)and to date, again around the world, I have never met a single person who's read the guidelines they are throwing in my face. Well, I have," said Trower.

Again citing official documentation, Trower chokes them with their own admissions. “Here, “ he said, “on page 545 it says, for example, some children, the elderly and chronically ill people might have a lower tolerance for the radiation than the rest of the population. They need separate guidelines and they go on to say, even under those guidelines, there will be other people which they call sensitive individuals who need, again, separate guidelines. In other words, the electro-sensitive. And it goes on... Page 546... this is the bit they don’t like, it says that decision-makers should read current scientific literature and set an exposure level at a tolerance lower than what is know to be causing illness and that is not the ICNIRP level which is up there. In other words you should set a safety level lower than what is known to be causing illness and they don’t do that.”

The international battle between the Thermal Effect advocates and those pressing for stricter guidelines and regulations has become heated in Canada where Health Canada proposed that Canadians are protected by vaunted and violated Safety Code 6 Guidelines. The debate exploded when it was learned that those guideline are also based on the Thermal Effect. Jerry Flynn, a former military man like Trower, offers parallel evidence. Flynn, too, is challenging the Canadian government and Dr. David Butler-Jones, chief Public Health Officer of Canada’s Public Health Agency.

Flynn, a retired Canadian Armed Forces captain, spent 22 of his 26-years-and-a-day years service in Electronic (EW) and Radio Warfare.. He spent two years as Executive Officer & Operations Officer at an ultra-sensitive radio station directly employing 200-plus specially-trained radio operators and technicians and another two years’ National Defense Headquarters, in the Directorate of Electronic Warfare, as the Staff Officer EW for Canada’s only Army EW Squadron. He has conducted Electronic Warfare at sea with the Royal Canadian Navy and on land with NATO army units.

Trower, Flynn and the former SAS member Victor Nixon who died last year, age 59, in Idaho, are just three military men to step forward and challenge government. Like Trower and Nixon - each working from separate perspectives and unknown to each other, they challenge authority. Flynn is challenging the health authorities in Canada. “I would like Dr. Butler-Jones to answer for me, please - in unambiguous language - how Health Canada can continue telling the public that they are protected by Safety Code 6 when Canada's own internationally respected and independent National Research Council (who are also based in Ottawa but report to Industry Canada), the Council of Europe (47 countries, 800 million people) and the Russian Federation all say Canada's Exposure Limits - being based solely on thermal effects of EMR/RFR - are amongst the highest, i.e., most dangerous in the world! I would appreciate an acknowledgement of receipt from Dr. Butler-Jones, please,” said Flynn.

For military men to step forward to defend themselves and their people against the actions of the governments they served is a remarkable act of courage.

Trower, Flynn and Nixon - all military men - raise the Roman poet, Juvenal’s question, “*Quis custodiet ipsos custodes*?” (“Who will guard the guards themselves?”). Indeed, who is protecting the military and the police who are using Tetra.

Why Bees Can't Survive

Nearly imperceptively, Trower is building a case. From his personal history to scientific evidence of experimentation on humans - forbidden by international agreement in the post-WWII Nuremberg Code, he moves to the complex - perhaps purposely so - issue of the disappearance of bees.

Obviously, it's not just people," explained Trower, "there are papers here we are looking at – birth problems and deformities researched by government veterinary clinics and we have something called the Glastonbury Festival in England. Twice I've been the guest speaker for the Glastonbury Festival and I spoke to university professors who are beekeepers and I cited 14 references as to why the bee can not survive in microwaves - or any other flying insects. We have birds are affected and it has appeared in *Nature* for the scientists here it's the cryptochrome mechanism in the brain. There have been further state government studies in cattle with birth defects – horses are particularly vulnerable to everything I've spoken of, whales, and there is a list here, cats, dogs, hamsters and they cite immune system birth problems, just about every animal there is on the planet is going to be affected which isn't surprising because, if you think about it, at the cellular level when you get down to the DNA and the four bases, we are really all the same. And if you're going to affect human cells you're going to affect tree cells, buttercup cells, even germ cells," he said.

"Unfortunately, the situation with the bees is a page out of the playbook that we deal with all the time with the mobile phone industry," said George Carlo[12], an epidemiologist and head of the Science and Public Policy Institute in Washington, D.C. "When the bee story first broke, it was based on a German study that showed information carrying radio waves disrupted the ability of bees to make it back to their hives. Most people in the public don't know the back story, so they do not see the manipulation coming or have the necessary bases for skepticism to see through it."

Carlo attributes the disappearance of bees (or CCD, Colony Collapse Disorder) to five factors: 1) timing, the speed at which the phenomenon has spread; 2) the absence of adequate scientific research to support chemical or biological causes; 3) The factthat microwaves interfere with intercellular communications; 4) the suggestion we are near a saturation point of these waves in the ambient environment with bees as the likely the harbinger or the proverbial 'canaries in the coal mine'; and 5) although there is at least one peer-reviewed study that supports it, the pattern is global which suggests a cause that is globally present.

"Taken together," said Carlo, "EMR is the only explanation that makes sense regarding the disappearing bees: the timing is correct -- the problem has occurred primarily within the past two years....when we have nearly tripled the background level of information carrying radio waves; the pattern is global so that suggests a cause that is globally present; there is at least one peer-reviewed study that supports it, and there is a mechanism documented that lends biological plausibility."

---

[12] Dr. George L. Carlo, Science and Public Policy Institute, 1101 Pennsylvania Ave. NW -- 7th Floor, Washington, D.C. 20004

"In our view, this is a serious 'red flag' of risk that should be heeded. This is yet another example of mobile phone industry orchestration aimed at distracting the public from data that can save lives," said Carlo.

In the winter of 2006-2007, CCD killed 32 percent of America's honeybees. The next winter, another 36 percent—more than a million hives—died. In 2009 Rowan Jacobson, editor of the Art of Eating reported from Vermont:

> "At first I was in denial," Olson recalled. "Then I just felt weak and had to lean against my truck. A year's hard work for naught!" Olson wound up losing all 50 hives that had overwintered in one particular bee yard. That's bad enough, but it pales next to some operations. Adee Honey Farms of South Dakota, the largest beekeeping business in the country, lost 28,000 of its 70,000 hives. That's about a billion bees gone missing. "It's off the charts," said Bret Adee. "It's not a sustainable thing, what's happening now."
>
> At first it looked as though the United States was the sole sufferer of CCD, but the rest of the world quickly reported losses also. "The situation for bees in Europe is no better than for bees in North America," says Bernard Vaissière, a pollination specialist with the French National Institute for Agricultural Research. A report issued last August by the European Food Safety Authority estimates that the UK lost about 30 percent of its honeybees in 2007, while Italy lost 40 to 50 percent. Whatever is taking down bees has gone global.[13]

And it isn't only bees that are disappearing. In the British Isles the ubiquitous Busy Lizzie or Impatiens beloved by millions of gardeners has disappeared from D.I.Y. shops and garden centers - ostensibly due to a fungal attack. Unofficial trials in unaffected areas are proving the plant does not want to germinate. A group of 9th grade school children found the same phenomenon in Denmark. Cress seeds placed next to a wi-fi router did not grow and some of those that did were mutated or died.[14]

"Now again," noted Trower, "very, very recently *Scientific American* published an article of the 27 greatest risks to the planet, I can link low level microwaves to 18 of them direct. 18 of the 27, 67 percent."

Sinister Course

Although Trower makes a concerted effort to avoid politics, he makes what is, perhaps, the most political statement of all – and it is of Biblical proportions. "Now, just to finish off," perhaps literally and figuratively, Trower says, "microwaves are taking a very, very sinister course at the moment. They are used in global weather warfare. A few years ago three papers were published showing that that the greatest contributor to carbon dioxide in the atmosphere now is the communications industry. They put more carbon dioxide into the atmosphere than any other industry even more than the aviation industry. 110 million tones, 29 million cars – that was a few years ago before all your iPods and iPods came along."

[14] http://mastsanity.org/health-52/research/324-experiments-with-cress-in-9th-grade-attracts-international-attention-denmark-16th-may-2013.html

Trower finds himself at the epicentre of conflict between the Global Warming crowd and the Deniers. “Now you may or may believe in global warming, I’m not going into that here,” he said, “but one thing cannot be disputed. When you have carbon dioxide in the atmosphere, and it mixes with rainwater, you have carbolic acid. And the carbolic acid comes down into the oceans. And again, *Scientific American* or *Nature*, have published that the acidity of the oceans has reached critical levels for the photosynthesisers in the ocean and they produce about 50 percent of the world’s oxygen. A lot of people don’t realize that.”

… for the punchline he adds, “We are really running the risk of losing our planet.”

Trower: The King and I

Were it not so serious, it would be laughable. Trower’s observation that if half of the world’s scientists are employed by the military, then the scientific world is nearly evenly divided between those who want to help humanity and those who want to harm us. “Microwaves are used in microbiological warfare, atmospheric warfare, environmental warfare,” said Trower. “It seems that when you have half the world’s scientists engaged by the military, who have nothing else to do but to dream up ‘how can I harm someone else’ it’s not surprising that we have all of these things now. And to finish off, I’m not boasting when I say this, I have probably met around 40 royals, leaders of governments, leaders of peoples, other important people around the world and they started to tell me as I was going around. I was picking up a familiar theme.”

A true English academic in a much-photographed green tweed sports jacket and matching everything else in green, Trower is not given to the playfulness of British whimsy or wishful thinking, however he does admit that he had a crystal ball. “And I always wished I was the one who was clever enough to think this up but I wasn’t. It was a king who had an Oxbridge (Oxford-Cambridge) law degree and we were having lunch in his garden. He leaned forward and he said, ‘I can tell you one thing, Barrie,’ he said, ‘I am losing the viability of my country.’ And then the pieces started to fall in. He said, ‘Since the mobile industry moved in I lost a vast number of my insects which means I have to start importing fruits or we get scurvy. We grow vitamin C plants. I’m losing my cattle which means I’ll have to start importing other cattle. I’m losing my trees and all my other plants. My people are becoming sick and I have a paper that shows it could be as much as another 40 percent on your health bill. My people are becoming sick which means I’ll have to start importing medicines.’ He said, ‘Now if you think – let’s assume you have 10 million cell phone users in my country and the daily bill one euro a day, I’m losing the best part of 10 million euros a day going out. Admittedly tax comes off and they run shops and things but the majority of the money goes out.’ And he said, ‘Any child who knows how a money box works can tell you that I as a country am going to go bankrupt. Sooner or later I’ve got to go bankrupt.

“‘He said, when it gets worse, he said, the very countries that bring the cell towers in and cause the damage are the very countries - namely the Americans and the Indonesians - He said they are the very countries, the first in, to offer aid, a very generous package. He said, but there is a price for aid., He said they want mining rights, they want mineral rights, they want land rights and they want immigration rights. It’s a trickle but it’s a non-stop trickle. ‘So I have all of this going out and all of this coming in and,’ he said, ‘I’m going to lose the viability of my country. I might still be king but I will not be king of my country and my people and really that sums it up.’”

Trower's prediction (for Ireland and other countries) is not far removed from the experience the king outlined. "So, if you were to say to me," said Trower, "What's going to happen to Ireland? It's simple, you are going to see an epidemic of birth defects, with livestock and children that will put Thalidomide way into the shade. That is going to happen without a shadow of a doubt. You are also going to lose the viability of your country, that can't be helped as well - unless you do something."

There is a parallel to the king's story in Ireland where the cell phone industry with 5.5 million subscribers is worth €1.65 billion[15] according to the Central Statistics Office. In a country "bailed out" by the so-called Troika of financial interests and where the government pledged to save failed banks to the tune of €70 billion there is ample evidence of the king's saga being repeated. At present, Shared Access, a North American Company founded with backing from from financial powerhouses GoldmanSachs and JPMorgan, is attempting to buy the income stream from farmers who earn an income from having masts on their lands. For a once-off payment to the farmer, Shared Access will acquire all the income and the earnings will be lost to the Irish economy.

The issue is compounded by a relationship with the Irish Farmers Association which has agreed to a confidential arrangement. As a not-for-profit Non-Governmental Organization (N.G.O.) the organization is beyond the reach of government and any business arrangements a completely legal in site of the fact that individual farmers, fee-paying members of the group, are not allowed to ask questions

"What can you do?" asked Trower perhaps optimistically hanging onto an old fashioned concept of democracy. "One suggestion - you may have better suggestions - one suggestion is you get me back here to talk to your full Parliament for one hour. It sounds absurd but other than e-mails and you approaching people. If I could talk to them and I could make them realize the proof. If I could talk to your Parliament it may work. It may not but at least they know what is coming and their children and it is their country and it won't cost them a penny because I work for free. They can't say 'We can't afford it'. I'll even pay out of my own old age pension if that's what they want but it will cost them one hour of their time and that is all."

It all boils down to timing and money. In a time of austerity, money speaks louder than the health and well-being of the population. While Trower's advice may, in the long term be priceless, talk, they say, is cheap - even on a Tetra radio, a cell phone or a wireless network in a classroom.

While Trower was talking in Dublin...

While Trower was speaking in Dublin, a group of the world's top scientists[16] simultaneously came to a similar explanation and conclusion called the Potenza Piceno Resolution during a conference in Italy.

The resolution underscores Trower's warnings with scientists issuing the following conclusions:

- stricter safety standards for EMF needs to be adopted by governments and public health agencies because the existing ones are obsolete and they are not based on recent literature about biological effects.

- RF sources should be reduced as low as possible because at now it is not possible to establish a safe limit under which no biological effects can be observed.

- RF sources should be kept far from residential areas. For pulsed RF sources, such radars and Wi-Max antennas, the distance from the EMF source should be even greater because they cause more biologically effects than non pulsed signals.

- Wi-Fi should not be placed in schools and in public areas since they have characteristics of pulsed signals.

Five days after Trower gave his testimony to the audience in Dublin, the Federal Communications Commission in the United States waived objections to the use of Tetra in the United States.

Yet another young man, age 23, died in his bed of a heart attack in Ireland. The only country in the world that is monitoring the emergence of a "new" disease, Sudden Adult Death Syndrome (SADS).

It was less than a month after the Sepura company in the U.K. announced plans to deploy Tetra for the first time in North America in Washington State.

The potential impact of radio frequencies and microwaves on wildlife

A number of studies have been carried out to investigate the impact of radio frequencies and microwaves on wildlife.

Radio frequency (RF) is a rate of oscillation in the range of about 3 kHz to 300 GHz, which corresponds to the frequency of radio waves, and the alternating currents which carry radio signals. Microwaves are electromagnetic waves with wavelengths ranging from as long as one metre to as short as one millimetre, or equivalently, with frequencies between 300 MHz (0.3 GHz) and 300 GHz. They are used for mobile telecommunication systems such as wireless internet and mobile telephone calls.

Wi-Fi antennas transmit and receive radio waves in order to allow wireless connections. The devices operate in certain frequency bands near 2.4 and 5 gigahertz (GHz). Mobile telecommunication systems transmit at a similar frequency and also use digitally pulsed information carrying signals. These characteristics are sufficiently close to consider in conjunction the potential impacts of mobile phones, their base stations and exposure from Wi-Fi masts.

Studies concerning bats

To date, results from studies[1] carried out investigating the aversive effect of electromagnetic radiation on foraging bats have been largely unclear. Bat activity was significantly reduced in habitats exposed to an EMF (electromagnetic field) strength of greater than 2 v/m when compared to matched sites registering EMF levels of zero. The reduction in bat activity was not significantly different at lower levels of EMF strength within 400m of the radar. This suggests that a signal with certain pulse characteristics can induce an aversive response in foraging bats. However, it was largely predicted that the reduction in bat activity within habitats exposed to electromagnetic radiation may be a result of thermal induction and an increased risk of hyperthermia rather than the direct impacts of radio and microwave frequencies.

The potential impact on bats

Microwave radiation**:**

Some studies have shown a negative effect on the reproductive output of insects and birds in the vicinity of mobile phone masts. If the reproductive output of insects within a certain area is impinged there is the possibility that this could have an effect on the localised insect population and consequently the presence of bats, but this is speculative.

[1] Nicholls B & Racey P (2009) - '*Bats Avoid Radar Installations: Could Electromagnetic Fields Deter Bats from Colliding with Wind Turbines?*' http://www.plosone.org/article/info%3Adoi%2F10.1371%2Fjournal.pone.0000297 & '*The Aversive Effect of Electromagnetic Radiation on Foraging Bats—A Possible Means of Discouraging Bats from Approaching Wind Turbines*' http://www.plosone.org/article/info:doi/10.1371/journal.pone.0006246

Mobile phone and Wi-Fi masts transmit an EMF of 0.5 – 2 v/m. It is therefore felt that the power output of these masts is too low to have a significant negative impact on bats. However, studies are still in their infancy and little is known on the impact of a mast in the direct vicinity of a roost.

High frequency noise

Ultra high frequency noise transmitted via Wi-Fi and mobile phone masts (2.4 and 5 gigahertz GHz) are considered too high for bats to hear. High frequency noises such as mosquito boxes (~17 kHz) can be heard by bats, but are generally considered to transmit at a sufficiently low frequency to avoid interfering with the echolocation calls for most UK bat species.

Nyctalus species such as noctules that echolocate at lower frequencies (~20 kHz) may hear these frequencies. In addition, many other species produce social calls below these frequencies (<20 kHz). However, bats exhibit an ability to tune out the calls of other bats. This suggests they may also be able to filter out these additional noises, unless the sound is extremely loud i.e. if it completely drowns out the bat calls, or if the structure of the signal is similar to those shown to elicit a response in bats (rapid broadband signal, gradually rising narrow bandwidth pulses).

Advice

As a precaution it is recommended that:

- the erection of masts should be carefully considered, locating the mast on a part of the building as far from known roosting locations and flight paths as possible
- advice should be sought to ensure that the obstruction of any access points, or damage of any roosts is avoided
- bat populations within the buildings should be surveyed on an annual basis to monitor any potential impacts

Common behaviors alterations after extremely low-frequency electromagnetic field exposure in rat animal model

Seyed Mohammad Mahdavi, Hedayat Sahraei, Mostafa Rezaei-Tavirani & Akram Najafi Abedi
Pages 222-227 | Received 02 Feb 2015, Accepted 10 May 2015, Published online: 16 Jul 2015

ABSTRACT

Naturally, the presence of electromagnetic waves in our living environment affects all components of organisms, particularly humans and animals, as the large part of their body consists of water. In the present study, we tried to investigate the relation between exposure to the extremely low-frequency electromagnetic field (ELF-EMF) and common behaviors such as body weight, food and water intake, anorexia (poor appetite), plasma glucose concentration, movement, rearing and sniffing in rats. For this purpose, rats were exposed to 40 Hz ELF-EMF once a day for 21 days, then at days 1, 3, 7, 14 and 21 after exposure, any changes in the above-mentioned items were assessed in the exposed rats and compared to the non-exposed group as control. Body weight of irradiated rats significantly increased only a week after exposure and decreased after that. No significant change was observed in food and water intake of irradiated rats compared to the control, and the anorexia parameter in the group exposed to ELF-EMF was significantly decreased at one and two weeks after irradiation. A week after exposure, the level of glucose was significantly increased but at other days these changes were not significant. Movements, rearing and sniffing of rats at day 1 after exposure were significantly decreased and other days these changes did not follow any particular pattern. However, the result of this study demonstrated that exposure to ELF-EMF can alter the normal condition of animals and may represent a harmful impact on behavior.

Mr. Donald Friedman
Confidential Legal Correspondence
1125 Third Street
Napa, California 94559-3015

Dear Mr. Friedman:

References:

a. Your Freedom of Information Act (FOIA) request dated May 25, 2006, to the Department of the Army, Freedom of Information/Privacy Act Division (DA FOIA/PA DIV), for all documents pertaining to the microwave auditory effect, microwave hearing effect, Frey effect, artificial telepathy, and/or any device/weapon which uses and/or causes such effect; and any covert or undisclosed use of hypnosis. On September 5, 2006, the DA FOIA/PA DIV referred a copy of your request to this office. Your request was received on September 11, 2006.

b. Our letter of September 13, 2006, informing you of the search for records at another element of our command and were unable to comply with the 20-day statutory time limit in processing your request.

As noted in our letter, the search has been completed with another element of this command and the record has been returned to this office for our review and direct response to you.

We have completed a mandatory declassification review in accordance with Executive Order (EO) 12958, as amended. As a result of this review, it has been determined that the Army information no longer warrants security classification protection and is releasable to you. A copy of the record is enclosed for your use.

Fees for processing your request are waived.

If you have any questions concerning this action, please feel free to contact this office at (301) 677-2308. Refer to case #614F-06.

Sincerely,

Susan J. Butterfield

Bioeffects of Selected Nonlethal Weapons(fn 1)

This addendum to the Nonlethal Technologies--Worldwide (NGIC-1147-101-98) study addresses in summary, some of the most often asked questions of nonlethal weapons technology, the physiological responses observed in clinical settings of the biophysical coupling and susceptibility of personnel to nonlethal effects weapons. These results identify and validate some aspects of maturing nonlethal technologies that may likely be encountered or used as nonlethal effectors in the future including:

- Laser and other light phenomena.
- Radiofrequency directed energy.
- Aural bioeffects.

The study of electromagnetic fields and their influence on biological systems is increasing rapidly. Much of this work is taking place because of health concerns. For example, increased concern has arisen regarding the effects of operator exposure to the electromagnetic fields associated with short-wave diathermy devices, high power microwave ovens, radar systems, magnetic resonance imaging units, etc. In addition, much concern has arisen about extremely low frequency (60 Hz power frequency) electric and magnetic fields that originate from high-voltage transmission lines, industrial equipment, and residential appliances. Both occupational and residential long-term exposure have been the focus of epidemiological studies. The studies have suggested possible adverse effects on human health (e.g., cancer, reproduction, etc.). Laboratory research is still being pursued to identify possible mechanisms of interaction. However, other than thermal heating for microwave frequencies, there is no yet agreed-upon mechanism of action. As a consequence, our knowledge base is developed entirely with phenomenological observations. Because of this fact, it is not possible to predict how nonthermal biological effects may differ from one exposure modality to another. It is especially difficult, because of the small data base for fast pulses, to predict biological effects that might be associated with high-power pulses of extremely short duration.

There is, however, a growing perception that microwave irradiation and exposure to low frequency fields can be involved in a wide range of biological interactions. Some investigators are even beginning to describe similarities between microwave irradiation and drugs regarding their effects on biological systems. For example, some suggest that power density and specific absorption rate of microwave irradiation may be thought of as analogous to the concentration of the injection solution and the dosage of drug

administration, respectively. Clearly, the effects of microwaves on brain tissue, chemistry, and functions are complex and selective. Observations of body weight and behavior revealed that rats, exposed under certain conditions to microwaves, eat and drink less, have smaller body weight as a result of nonspecific stress mediated through the central nervous system and have decreased motor activity. It has been found that exposure of the animals to one modality of radiofrequency electromagnetic energy substantially decreases aggressive behavior during exposure. However, the opposite effects of microwaves, in increasing the mobility and aggression of animals, has also been shown for a different exposure modality. Recent published data implicates microwaves as a factor related to a deficit in spatial memory function. A similar type of effect was observed with exposure to a "resonance tuned" extremely low frequency magnetic field. Thus, the data base is replete with phenomenological observations of biological systems "affected" by exposure to electromagnetic energy. (The fact that a biological system responds to an external influence does not automatically nor easily translate to the suggestion of adverse influence on health.) The objective of the present study was to identify information from this developing understanding of electomagnetic effects on animal systems that could be coupled with human biological susceptibilities. Situations where the intersection of these two domains coexist provide possibilities for use in nonlethal applications.

Incapacitating Effect: Microwave Heating

Body heating to mimic a fever is the nature of the RF incapacitation. The objective is to provide heating in a very controlled way so that the body receives nearly uniform heating and no organs are damaged. Core temperatures approximately 41° C are considered to be adequate. At such temperature a considerably changed demeanor will take place with the individual. Most people, under fever conditions, become much less aggressive; some people may become more irritable. The subjective sensations produced by this buildup of heat are far more unpleasant than those accompanying fever. In hyperthermia all the effector processes are strained to the utmost, whereas in fever they are not. It is also possible that microwave hyperthermia (even with only a 1° C increase in brain temperature) may disrupt working memory, thus resulting in disorientation.

Biological Target/Normal Functions/Disease State

The temperature of warm-blooded (homeothermic) animals like the human remains practically unchanged although the surrounding temperature may vary considerably. The normal human body temperature recorded from the mouth is usually given as 37° C, with the rectal temperature one degree higher. Variation between individuals is typically between 35.8° C and 37.8° C orally. Variations also occur in any one individual throughout the day--a difference of 1.0° C or even 2.0° C occurring between the maximum in the late afternoon or early evening, and the minimum between 3 and 5 o'clock in the morning. Strenuous muscular exercise causes a temporary rise in body temperature that is proportional to the severity of the exercise; the level may go as high as 40.0° C.

Extreme heat stress, such that the body's capacity for heat loss is exceeded, causes a pathological increase in the temperature of the body. The subjective sensations produced by this buildup of heat are far more unpleasant than those accompanying fever. In hyperthermia all the effector processes are strained to the utmost, whereas in fevers they are not. The limiting temperature for survival, however, is the same in both cases--a body temperature of 42° C. For brief periods, people have been known to survive temperatures as high as 43 ° C.

In prolonged hyperthermia, with temperatures over 40° C to 41° C, the brain suffers severe damage that usually leads to death. Periods of hyperthermia are accompanied by cerebral edema that damage neurons, and the victim exhibits disorientation, delirium, and convulsions. This syndrome is popularly referred to as sunstroke, or heatstroke, depending on the circumstances. When the hyperthermia is prolonged, brain damage interferes with the central thermoregulatory mechanisms. In particular, sweat secretion ceases, so that the condition is further exacerbated.

Mechanism to Produce the Desired Effects

This concept builds on about 40 years of experience with the heating effects of microwaves. Numerous studies have been performed on animals to identify characteristics of importance to the understanding of energy deposition in animals. As a result of the physics, the relationship between the size of the animal and the wavelength of the radiofrequency energy is most important. In fact, the human exposure guidelines to radiofrequency radiation are designed around knowledge of the differential absorption as a function of frequency and body size. The challenge is to minimize the time to effect while causing no permanent injury to any organ or the total body and to optimize the equipment function. The orientation of the incident energy with respect to the orientation of the animal is also important.

In a study of the effect of RF radiation on body temperature in the Rhesus monkey, a frequency (225 MHz) is purposely chosen that deposits energy deep within the body of the animal. A dose rate of 10 W/kg caused the body temperature to increase to 42° C in a short time (10-15 min). To avoid irreversible adverse effects, the exposure was terminated when a temperature of 42° C was reached. A lower dose rate of 5 W/kg caused the temperature to increase to 41.5° C in less than 2 hours. The reversible nature of this response was demonstrated by the rapid drop in body temperature when RF exposure was terminated before a critical temperature of 42° C was reached. It is estimated for rats that the absorbed threshold convulsive dose lies between 22 and 35 J/g for exposure durations from less than a second to 15 minutes. For 30-minute exposure, the absorbed threshold dose for decrease in endurance is near 20 J/g, the threshold for work stoppage approximately 9 J/g, and the threshold for work perturbation ranges from 5 to 7 J/g. All of the above measures, except convulsions, are types of nonlethal incapacition.

A rough estimate of the power required to heat a human for this technology is on the order of 10 W/kg given about 15 to 30 minutes of target activation. Actual power levels

depend on climatic factors, clothing, and other considerations that affect the heat loss from the individual concerned. A method for expressing dose rate in terms of body surface area (i.e., watts per square meter) rather than body mass (i.e., watts per kilogram) would permit a more reliable prediction of thermal effects across species. However, there are large uncertainties in the ability to extrapolate thermoregulatory effects in laboratory animals to those in human beings.

This technology is an adaptation of technology which has been around for many years. It is well known that microwaves can be used to heat objects. Not only is microwave technology used to cook foods, but it is also used as a directed source of heating in many industrial applications. It was even the subject of the "Pound Proposal" a few years ago in which the idea was to provide residential heating to people, not living space. Because of the apparently safe nature of body heating using microwave techniques, a variety of innovative uses of EM energy for human applications are being explored. The nonlethal application would embody a highly sophisticated microwave assembly that can be used to project microwaves in order to provide a controlled heating of persons. This controlled heating will raise the core temperature of the individuals to a predetermined level to mimic a high fever with the intent of gaining a psychological/capability edge on the enemy, while not inflicting deadly force. The concept of heating is straightforward; the challenge is to identify and produce the correct mix of frequencies and power levels needed to do the remote heating while not injuring specific organs in the individuals illuminated by the beam.

A variety of factors contribute to the attractiveness of this nonlethal technology. First, it is based on a well-known effect, heating. Every human is subject to the effects of heating; therefore, it would have a predictability rating of 100%. The time to onset can probably be engineered to between 15 and 30 minutes; however, timing is the subject of additional research to maximize heating while minimizing adverse effects of localized heating. The onset can be slow enough and/or of such frequency to be unrecognized by the person(s) being irradiated. Safety to innocents could be enhanced by the application and additional development of advanced sensor technologies. Incapacitation time could be extended to almost any desired period consistent with safety. (Given suitable R&D, temperature or other vital signs could be monitored remotely, and temperature could be maintained at a minimum effective point).

Time to Onset

The time to onset is a function of the power level being used. Carefully monitored uniform heating could probably take place in between 15 and 30 minutes. Time to onset could be reduced but with increased risk of adverse effects. Minimum time is dependent on the power level of the equipment and the efficiency of the aiming device.

Duration of Effect

Assuming that the heating is done carefully, reversal of elevated body temperature would begin as soon as the source of heat is removed.

Tunability

This concept is tunable in that any rate of heating, up to the maximum capacity of the source, may be obtained. Thus it is suitable for use in a gradual force or "rheostatic" approach. If the situation allows, and the source is sufficiently powerful, there is the possibility to use this technology in a lethal mode as well. Prolonged body temperature above 43° C is almost certain to result in permanent damage to the brain and death.

Distribution of Human Sensitivities to Desired Effects

No reason has been identified to suggest that anyone would be immune to this technology. Individuals with compromised thermoregulatory mechanisms would be susceptible with a lower incident energy density. This would include people with organic damage to the hypothalamus, the part of the brain that integrates the autonomic mechanisms which control heat loss as well as people with compromised somatic features of heat loss (e.g., respiration, water balance, etc.).

The technologies needed for the thermal technology concept are relatively well developed because of the known biophysical mechanism, the universal susceptibility of humans to the mechanism of heating, and because of a well developed technology base for the production of radiofrequency radiation. Because the human body is inhomogeneous, certain organs are, by virtue of their size and geometry, more easily coupled with one radiofrequency wavelength than another. Therefore, to avoid permanent damage to the suspect or to innocent bystanders, it may be necessary to vary the frequency to avoid localized heating and consequent damage to any organ. Additionally, it will be necessary to avoid the conditions thought to be associated with the induction of cataracts. Thus, while the technology of microwave heating in general is mature, adaptation as a nonlethal technology will require sophisticated biophysical calculations to identify the proper regimen of microwave frequencies and intensities; it will also be necessary to optimize existing hardware to meet the biophysical requirements.

Possible Influence on Subject(s)

If the technology functions approximately as envisioned, the targeted individual could be incapacitated within 15 to 30 minutes. Because this technology is focused on a relatively slow onset, it should only be used in situations where speed is not important. The very uncomfortable nature of a high body temperature may be useful in negotiations or possibly for controlling crowds. It would be equally useful on single persons or crowds. Evidence also indicates a disruption of working memory, thus disorientation may occur because of an inability to consolidate memory of the recent (minutes) past.

Technological Status of Generator/Aiming Device

Equipment needed to explore this concept in the laboratory is available today. Design and construction of the RF/microwave generator will depend on the constraints posed by the calculations, potential generation devices, and energy-directing structures. A variety of

options exist for both of these equipment needs. The use of advanced frequency and modulation-agile RF generation and amplification circuitry will be required to assess fully the frequency/power/time envelope of RF heating profiles required. Although much equipment is commercially available, it is likely that custom hardware and software will be necessary because available equipment has not been designed with the need for frequency/intensity variability, which will probably be needed for safety purposes. In addition, the design of antennas and other energy-directing structures will almost certainly involve unique configurations. Since this technology utilizes radiofrequency energy, it can be defeated by the use of shielding provided by conductive barriers like metal or metal screen.

Incapacitating Effect: Microwave Hearing

Microwave hearing is a phenomenon, described by human observers, as, the sensations of buzzing, ticking, hissing, or knocking sounds that originate within or immediately behind the head. There is no sound propagating through the air like normal sound. This technology in its crudest form could be used to distract individuals; if refined, it could also be used to communicate with hostages or hostage takers directly by Morse code or other message systems, possibly even by voice communication.

Biological Target/Normal Functions/Disease State

This technology makes use of a phenomenon first described in the literature over 30 years ago. Different types of sounds were heard depending on the particulars of the pulse characteristics. Various experiments were performed on humans and laboratory animals exploring the origin of this phenomenon. At this time, virtually all investigators who have studied the phenomenon now accept thermoelastic expansion of the brain, the pressure wave of which is received and processed by the cochlear microphonic system, to be the mechanism of acoustic perception of short pulses of RF energy. One study (in 1975) using human volunteers, identified the threshold energy of microwave-auditory responses in humans as a function of pulse width for 2450 MHz radiofrequency energy. It is also found that about 40 J/cm^2 incident energy density per pulse was required.

Mechanism to Produce the Desired Effects

After the phenomenon was discovered, several mechanisms were suggested to explain the hearing of pulsed RF fields. Thermoelastic expansion within the brain in response to RF pulses was first studied and demonstrated in inert materials and was proposed as the mechanism of hearing of pulsed RF fields. A pressure wave is generated in most solid and liquid materials by a pulse of RF energy--a pressure wave that is several orders of magnitude larger in amplitude than that resulting from radiation pressure or from electrostrictive forces. The characteristics of the field-induced cochlear microphonic in guinea pigs and cats, the relationship of pulse duration and threshold, physical measurements in water and in tissue-simulating materials, as well as numerous theoretical calculations--all point to thermoelastic expansion as the mechanism of the hearing phenomenon.

Scientists have determined the threshold energy level for human observers exposed to pulsed 2450-MHz fields (0.5-to 32 micron pulse widths). They found that, regardless of the peak of the power density and the pulse width, the per-pulse threshold for a normal subject is near 20 mJ/kg. The average elevation of brain temperature associated with a just-perceptible pulse was estimated to be about $5x10^{-6}$° C.

Time to Onset

The physical nature of this thermoelastic expansion dictates that the sounds are heard as the individual pulses are absorbed. Thus, the effect is immediate (within milliseconds). Humans have been exposed to RF energy that resulted in the production of sounds.

Duration of Effect

Microwave hearing lasts only as long as the exposure. There is no residual effect after cessation of RF energy.

Tunability

The phenomenon is tunable in that the characteristic sounds and intensities of those sounds depend on the characteristics of the RF energy as delivered. Because the frequency of the sound heard is dependent on the pulse characteristics of the RF energy, it seems possible that this technology could be developed to the point where words could be transmitted to be heard like the spoken word, except that it could only be heard within a person's head. In one experiment, communication of the words from one to ten using "speech modulated" microwave energy was successfully demonstrated. Microphones next to the person experiencing the voice could not pick up the sound. Additional development of this would open up a wide range of possibilities.

Distribution of Human Sensitivities to Desired Effects

Because the phenomenon acts directly on cochlear processes, the thermoelastic pressure waves produce sounds of varying frequency. Many of the tests run to evaluate the phenomenon produced sounds in the 5 kHz range and higher. Because humans are known to experience a wide range of hearing loss due to cochlear damage, it is possible that some people can hear RF induced sounds that others with high frequency hearing loss cannot. Thus, there is a likely range of sensitivity, primarily based on the type of pulse and the condition of the cochlea. Bilateral destruction of the cochlea has been demonstrated to abolish all RF-induced auditory stimuli.

Recovery/Safety

Humans have been subjected to this phenomenon for many years. The energy deposition required to produce this effect is so small that it is not considered hazardous experimentation when investigating responses at the just-perceptible levels.

Possible Influence on Subject(s)

Application of the microwave hearing technology could facilitate a private message transmission. It may be useful to provide a disruptive condition to a person not aware of the technology. Not only might it be disruptive to the sense of hearing, it could be psychologically devastating if one suddenly heard "voices within one's head."

Technological Status of Generator/Aiming Device

This technology requires no extrapolation to estimate its usefulness. Microwave energy can be applied at a distance, and the appropriate technology can be adapted from existing radar units. Aiming devices likewise are available but for special circumstances which require extreme specificity, there may be a need for additional development. Extreme directional specificity would be required to transmit a message to a single hostage surrounded by his captors. Signals can be transmitted long distances (hundreds of meters) using current technology. Longer distances and more sophisticated signal types will require more bulky equipment, but it seems possible to transmit some type of signals at closer ranges using man-portable equipment.

Range

The effective range could be hundreds of meters.

Incapacitating Effect: Disruption of Neural Control

The nature of the incapacitation is a rhythmic-activity synchronization of brain neurons that disrupts normal cortical control of the corticospinal and corticobulbar pathways; this disrupts normal functioning of the spinal motor neurons which control muscle contraction and body movements. Persons suffering from this condition lose voluntary control of their body. This synchronization may be accompanied by a sudden loss of consciousness and intense muscle spasms.

Biological Target/Normal Functions/Disease State

The normal function of the brain is to control all forms of behavior, voluntary control of body, and the homeostatic parameters of the organism. In normal conditions, all the brain structures, neuron populations, networks, and single units function with specific rhythmic activity depending on the incoming sensory information, information from mnemonic structures, and signals from visceral organs. Each single neuron provides specific processing of information it receives and forms a specific pattern of impulse firing as outgoing information. Synchronization of neuron activity is a natural mechanism of the brain function that uses such controlling processes as motivation, attention and memory (experience) in order to organize behavior. For example, motivational processes are considered as activating ascending signals that synchronize the neuron activity of specific brain structures and neuron networks; this activation/synchronization in turn activates specific forms of behavior such as sexual, aggressive, ingestive activities.

In normal functioning the degree of neuronal synchronization is highly controlled. From experiments that record the neuronal activity in different brain areas simultaneously in animals, it is known that correlation of spike activity between neurons (measured by the correlation level of synchronization) changes depending on the stage of behavior, motivation, attention, or activation of the memory processes. However, under some conditions, such as physical stress, heat shock, or strong emotional stress, the level of synchronization may become higher, involving nonspecific large populations of brain neurons and the synchronization may become uncontrollable.

Depending on at which frequency the synchronization rhythm occurs and how many neurons are involved, it may produce different physical effects; muscle weakness, involuntary muscle contractions, loss of consciousness, or intense (tonic) muscle spasms. The higher level of synchronization takes place in persons affected with epilepsy when they experience periodic seizures since they have a pathologic source (e.g., from injury to the brain) of rhythmic synchronization. Because the neurophysiological mechanisms of epileptiform synchronization are better documented, this incapacitating technology is described in terms of epileptogenesis.

The neurophysiological mechanisms active in epileptogenesis involve changes in membrane conductances and neurotransmitter alterations as they affect neuronal interaction. In the process of epileptogenesis, either some neurons are discharging too easily because of alterations in membrane conductances or there is a failure of inhibitory neurotransmission. The actual discharges have been recognized to result from a neuronal depolarization shift with electrical synchrony in cell populations related in part to changes in membrane conductances. The ionic basis and biochemical substrate of this activation have been areas of considerable study but still leave many questions unanswered. What are the basic cellular properties, present in normal cells and tissue, that could contribute to the generation of abnormal activity? What parts of the systems are low threshold and function as trigger elements?

One of the current hypotheses is involved with microcircuitry, particularly local synaptic interactions in neocortical and limbic system structures. In the hippocampus, the role of the trigger element has been long attributed to the CA3 pyramidal cells--a hypothesis based on the fact that spontaneous synchronous burst discharge can be established in CA3 neurons Some studies describe an intrinsically bursting cell type in the neocortex that plays a role similar to that of CA3 cells in the hippocampus and that of deep cells in the pyriform cortex. The intrinsic nature of these cells appears to be an important contributor to the establishment of synchronized bursting in these regions. Another apparent requirement in such a population is for a certain degree of synaptic interaction among neurons, such that discharge of even one cell enlists the activity of its neighbors. Given the presence of these bursting cells and the occurrence of excitatory interactions among them in normal tissue, it may actually be the morphologic substrate for epileptiform discharges.

Another hyptothesis has focused particularly on the role of N-methyl-D-aspartate (NMDA) receptors. Various factors regulate the efficacy of NMDA receptors: their

voltage-dependent blockade by magnesium and modulation by glycine and polyamines. For example, in the low magnesium model, spontaneous synchronous burst discharge in hippocampal pyramidal cell populations is sensitive to NMDA antagonists. That finding suggests that it is the opening of NMDA channels, by relieving the magnesium blockade, that facilitates epileptiform activity.

Significant attention in the literature is also being given to gamma-amino butyric acid (GABA) receptors for the potential role in control of excitability. Changes in GABA inhibitory efficacy can lead to important effects on the excitability of the system. GABAergic inhibitory post-synaptic potentials (IPSPs) have been shown to be quite labile in response to repetitive activation of cortical cell populations, as may occur during epileptiform discharge. Scientists have shown that even a small percentage change in GABA inhibition can have profound effects on neocortical epileptogenesis. These changes in GABAergic inhibition may be the key to an explanation of how repetitive discharge patterns give rise to ictal discharge. Further, there appears to be a significant increase in excitatory postsynaptic potential (EPSP) frequency prior to seizure initiation an observation that is consistent with loss of IPSP efficacy prior to ictal onset.

The above hypotheses describe different mechanisms of epileptogenesis, but it is quite possible that all of these mechanisms take place, and they reflect large variety of types of epileptic seizures. The common principle of the mechanisms proposed is the change of membrane properties (i.e., conductance, permeability etc.) of certain neurons which results in depolarization and burst discharging. Some factors (e.g., trauma) can affect these specific neurons and initiate synchrony for neurons that control internal communication and communication with various muscle systems not associated with vital functions (i.e., heart beating, breathing). High strength pulsed electric fields could also be such a factor.

Mechanism to Reproduce the Desired Effects

Application of electromagnetic pulses is also a conceptual nonlethal technology that uses electromagnetic energy to induce neural synchrony and disruption of voluntary muscle control. The effectiveness of this concept has not been demonstrated. However, from past work in evaluating the potential for electromagnetic pulse generators to affect humans, it is estimated that sufficiently strong internal fields can be generated within the brain to trigger neurons. Estimates are that 50 to 100 kV/m free field of very sharp pulses (~ 1 nS) are required to produce a cell membranic potential of approximately 2 V; this would probably be sufficient to trigger neurons or make them more susceptible to firing.

The electromagnetic pulse concept is one in which a very fast (nanosecond timeframe) high voltage (approximately 100 kV/m or greater) electromagnetic pulse is repeated at the alpha brain wave frequency (about 15 Hz). It is known that a similar frequency of pulsing light can trigger sensitive individuals (those with some degree of light-sensitivity epilepsy) into a seizure and it is thought that by using a method that could actually trigger nerve synapses directly with an electrical field, essentially 100% of individuals would be susceptible to seizure induction. The photic-induced seizure phenomenon was borne out

demonstrably on December 16, 1997 on Japanese television when hundreds of viewers of a popular cartoon show were treated, inadvertently, to photic seizure induction (figure 31). The photic-induced seizure is indirect in that the eye must receive and transmit the impulses which initially activate a portion of the brain associated with the optic nerve. From that point the excitability spreads to other portions of the brain. With the electromagnetic concept, excitation is directly on the brain, and all regions are excited concurrently. The onset of synchony and disruption of muscular control is anticipated to be nearly instantaneous. Recovery times are expected to be consistent with, or more rapid than, that which is observed in epileptic seizures.

Time to Onset

No experimental evidence is available for this concept. However, light-induced seizures latency onset in photosensitive epileptics varies from 0.1 to about 10 seconds. Because of the fact that the electrical impulses triggered by light must spread to other parts of the brain, photic-induced seizures are expected to have a generally slower onset than neural synchrony induced by high-strength pulsed electric fields.

Duration of Effect

For epileptic individuals, the typical duration of a petit mal event or a psychomotor event is 1 minute or 2, possibly longer, while the duration of a grand mal seizure is 1 to 5 minutes. In a non-epileptic individual who is induced by electromagnetic means, the durations of the different events are expected to be roughly the same as the epileptic individual's events after the external excitation is removed.

Tunability

There are many degrees of epileptic seizure in diseased persons, and it seems reasonable that electromagnetic stimulation of neural synchrony might be tunable with regard to type and degree of bodily influence, depending on the parameters associated with the chosen stimulus. Because there are no actual data to build on, these statements must be considered tentative. It is known that in the study of photic-induced seizures, parameters can be varied so that the individual under study does not actually undergo a grand mal seizure. This knowledge gives confidence that the proposed technology would be tunable.

Distribution of Human Sensitivities to Desired Effects

It is anticipated that 100% of the population would be susceptible. The mechanism is one that could act on many individual neuronal cells concurrently and hence does not depend on spreading regions of electrical activity as in the disease state.

Possible Influence on Subjects(s)

If the technology functions approximately as envisioned, the targeted individual could be incapacitated very quickly. Because there have been no reported studies using the

conditions specified, experimental work is required to characterize onset time. Different types of technologies could be employed to influence wide areas or single individuals. Because this technology is considered to be tunable, the influence on subjects could vary from mild disruption of concentration to muscle spasms and loss of consciousness. The subject(s) would have varying degrees of voluntary control depending on the chosen degree of incapacitation.

Technological Status of Generator/Aiming Device

An electric field strength of roughly 100 Kv/m over a time period of 1 nanosecond is approximately the condition thought to be necessary to produce the desired effect when provided to an overall repetition rate of 15 Hz. Such a field may be developed using a radar-like, high-peak-power, pulsed source or an electromagnetic pulse generator operated at 15 Hz. These technologies exist today sufficient to evaluate the disabling concept. Power requirements are not high because the duty factor is so low. Aiming devices are currently available, but a high degree of directionality at long distances will require development. It may be necessary to provide bursts of these nanosecond pulses in order to stimulate the desired effect. As the duty time increases so does the average power requirement for power source. Because there were no open literature reports from which to make inferences, there is some uncertainty about the power levels required.

Range

The effective range could be hundreds of meters.

Defeat Capabilities/Limitations

Shielding can be provided by conductive barriers like metal or metal screen. There are a number of drugs that are capable of inducing convulsive seizures and others, like phenobarbital, diphenyllhydantoin, trimethadione, 2-4 dinitrophenol, and acetazolamide, which are anticonvulsive. Anticonvulsive drugs are known to be helpful in reducing the effect of seizures in epileptic patients, but their ability to reduce the effect of the proposed technology is unknown (possibly no effect) but expected to be less than for photic-induced seizures.

Incapacitating Effect; Acoustic Energy

The nature of the incapacitation consists of severe pressure sensations, nystagmus (a spasmodic, involuntary motion of the eyes), and nausea caused by high intensities of 9140-155 dB). Nystagmus occurs when convection currents are produced (cupula movement) in the lateral ear canal. This cupula movement causes the eyes to move involuntarily; hence, the external world is interpreted as moving. The subject "sees" his surroundings turning round him and at the same time experiences a sensation of turning. Persons exposed to these levels of sound experience nausea.

Biological Target/Normal Functions/Disease State

The two lateral semicircular canals, one located in each inner ear, alert a person to the fact that his upright head is experiencing angular acceleration. Within the ampulla of the canal are several so called hair cells. The cilia of these cells protrude into the lumen of the ampulla where they are encased in a mass of jelly-like material (the cupula) which is attached to the opposite wall of the canal. As the head accelerates, the cilia are bent by an inertial force of the cupula and the viscous liquid in the canal lumen. The bending of the cilia excites hair cells which in turn excite afferent neurons; these then alert the brain that a change of position of the head has occurred. Similar events occur when the head stops moving. The result of a strong hair cell stimulus to the brain is a rapid eye movement, call nystagmus, a feeling of dizziness and disorientation, and a possibility of nausea and vomiting.

Normal hearing is in the range between the frequencies of 20,000 to 16,000 Hz with the optimal sensitivity for most people between the frequencies of 500 to 6000 Hz.

Mechanism to Produce the Desired Effects

Because the end organs for acoustic and vestibular perception are so closely related, intense acoustic stimulation can result in vestibular effects. The hypothesis is that the sound of normal intensity produces oscillations of the endolymph and perilymph, compensated for by oscillations of the round window. High intensity sound produces eddy currents, which are localized rotational fluid displacements. High intensity sound can also produce nonlinear displacement of the stapes, causing a volume displacement, the result of which can be a fluid void in the labyrinth. To fill the void, fluid may be displaced along the endolymphatic duct and/or block capillary pathways, which, in turn, could stimulate vestibular receptors. Stimulation of the vestibular receptors may lead to nausea and vomiting if the sound pressure level is high enough. Conclude that both eddy currents and volume displacement serve to stimulate vestibular receptors in humans, when exposed to high levels of noise.

One study found nystagmum in guinea pigs exposed to high levels of infrasound via stimulation of the vestibular receptors. However, the same lab was unable to produce nystagmus in human subjects at 5- and 10-second exposures to a pure tone at 135 dB, broadband engine noise, or a 100 Hz tone at 120 dB, pulsed three times/s or 2 minutes. The same research was unable to elicit nystagmus at levels up to 155 dB, and also equally unable to produce nystagmus using infrasound levels of 112-150 dB in guinea pigs, monkeys, and humans. However, research with audible components in the sound spectrum with guinea pigs and monkeys produced nystagmus. Other researchers report other vestibular effects in addition to nystagmus at the following thresholds: 125 dB from 200-500 Hz, 140 dB at 1000 Hz, and 155 dB at 200 Hz. Decrements in vestibular function occur consistently for broadband noise levels of 140 dB (with hearing protection).

Human subjects listened to very high levels of low-frequency noise and infrasound in the protected or unprotected modes. Two-minute duration as high as 140 to 155 dB produced a range of effects from mild discomfort to severe pressure sensations, nausea, gagging,

and giddiness. Effects also included blurred vision and visual field distortions in some exposure conditions. The nature and degree of all effects was dependent on both sound level and frequency with the most severe effects occurring in the audible frequency range (as opposed to infrasound), at levels above about 145 dB. The investigators found no temporary threshold shift (TTS) among their subjects, and the use of hearing protectors greatly alleviated the adverse effects.

Since the early days of jet-engine testing and maintenance, anecdotal evidence has appeared linking exposure to intense noise, with such complaints as dizziness, vertigo, nausea, and vomiting. As a result of siren noise at 140 dB, subjects consistently reported a feeling of being pushed sideways, usually away from the exposed ear, and one subject reported difficulty standing on one foot.

These effects were not as dramatic as from the jet-engine (broadband) noise at 140 dB. This research concludes that the threshold of labyrinthine dysfunction is about 135 to 140 dB and that these effects occur during, but not after, exposure.

Time to Onset

No times to onset of nausea or nystagmus were identified in the literature but is presumed to be relatively immediate based on effects to the labyrinth system occurring during, but not after, exposure to sound pressure levels of 135 to 140 dB.

Duration of Effect

The incapacitation lasts only as long as the incapacitating sound is present.

Tunability

Based on the data presented above, it is unclear whether the degree of nausea or nystagmus is tunable, but similar symptoms caused by other stimuli are variable in degree.

Distribution of Human Sensitivities to Desired Effects

It is most probable that all individuals will be susceptible to this stimulus with the exception of those with a disease or defect (i.e., deaf mutes) of some part or parts of the vestibular system. Data showed no consistent decrease in vestibulo-ocular reflects with increased age.

Recovery/Safety

Normal subjects are likely to recover immediately and experience no or unmeasurable changes in hearing unless well known frequency-intensity-time factors are exceeded. This is based on studies which found no temporary threshold shift in hearing of subjects tested at low frequency. Occupational safety personnel generally recognize that 115

dB(A) is to be avoided and that 70 dB(A) is assumed safe. Is believed that the noise energy with predominating frequencies above 500 Hz have a greater potential for hearing loss than noise energy at lower frequencies. Occupational standards for noise state that a person may be exposed continuously for 8 hours to 90 dB(A) or 15 minutes to 115 dB(A).

Possible Influence on Subject(s)

Induction of nystagmus and nausea will have variable effects on individuals. Effects may be sufficiently incapacitation to allow offensive advantage; the perception of sickness may make a subject susceptible to persuasion. It would be difficult to target single individuals at the present level of sound directing technology. This technology may be better suited for groups of people.

Technological Status of Generator/Aiming Device

Sound generating technology is well developed but not highly portable. Aiming devices are poorly developed.

Range

Under normal circumstances the sound pressure level decreases 6 dB(A) when the distance from the source is doubled. For example if the sound is 100 dB(A) at 100 ft, at 200 ft the sound would be 94 dB(A). At very high sound levels, certain conditions may lead to nonlinear effects in propagation and greatly increase range accuracy.

Defeat Capabilities/Limitations

Negative effects of audible sound are greatly decreased if hearing protection is worn. High frequency sound is more easily blocked than low frequency sound due to wavelength effects.

Laser-Induced Biological Effects

Their are three basic damage mechanisms associated with exposure to laser radiation: chemical, thermal, and mechanical or acoustic-mechanical.

The laser-induced, chemical alterations in irradiated tissue are referred to as photochemical damage. The likelihood of laser radiation in the blue-light portion of the electromagnetic spectrum (.380 to .550 microns) inducing photochemical reactions progressively decreases with increasing wavelength. Photochemical effects are not observed upon exposure to radiation with wavelengths exceeding .550 to .650 microns because the kinetic energy associated with these photons is insufficient to initiate a photochemical change.

On the other hand, the thermal effect is a primary mechanism for laser-induced injury. The extent of the injuries induced depends upon the wavelength and energy of the incident radiation, duration of exposure, and the nature of the exposed tissue and its absorption characteristics. Generally, this mechanism predominates in the visible and the near-infrared (.760 to 1.4 microns) portions of the electromagnetic spectrum and for almost all CW and pulsed exposures between 0.1 milliseconds and 1 to 5 seconds.

The third injury mechanism associated with exposure to laser radiation is the mechanical or acoustical-mechanical effect. The radiant energy is absorbed into the tissue and, as a result of rapid thermal expansion following a short (1 nanosecond to 0.1 millisecond) laser radiation pulse, a pressure wave is generated that may result in explosive tissue injury.

Generally, all three mechanisms operate concurrently in an irradiated animal. Thermal effects currently predominate for continuous wave (CW) lasers, while mechanical effects are of increased significance for pulsed-mode lasers. With even higher power, one must also consider nonlinear phenomena such as multiphoton absorption and electromagnetic field effects.

The organs most susceptible to external laser radiation are the skin and eyes. The severity of injury is affected by the nature of the target, the energy density delivered to the target, the frequency and power of the laser, atmospheric attenuation of the beam, and the use of filtering or amplifying optics by the target, etc.

The primary effect on the skin is thermal damage (burns). The severity varies from slight erythema or reddening to severe blistering or charring, depending on such factors as total energy deposition, skin pigmentation, and the tissue's ability to dissipate heat.

The eye is particularly susceptible to intense pulse of laser radiation because of its unique sensitivity to light. The focusing effect is similar to that of a magnifying lens, which focuses the energy on a particular spot. Since the cornea and lens of the eye amplify the intensity of the light incident upon the retina, the retina is extremely sensitive to visible and near-infrared light, and damage to the retina may result in temporary or permanent loss of visual acuity. Laser eye injuries vary according to incident power, spot size, beam angle, temporal mode (CW or pulsed), and pulse repetition frequency. Reported effects include corneal lesions, burns, cataracts, and retinal lesions.

Some high-power lasers can cause antipersonnel effects by the deposition of thermal energy. These lasers must operate at a wavelength that is readily absorbed by the skin or the cornea. These generally include the far- and mid-IR regions (10 to 12 microns and 3 to 5 microns) as well as the ultraviolet region (<0.4 microns). However, ultraviolet wavelengths generally do not propagate well in the atmosphere, so the primary threat wavelengths to be considered are between 3 and 12 microns. Although relatively modest amounts of far-IR laser power are required to produce superficial burns on the skin at short ranges, and efforts to design rheostatically lethal laser weapons are on going.

Nonlethal blinding laser weapons generally use collimated beams with very low beam divergence, and the energy contained in the beam diminishes relatively slowly over great distances. Imaging systems such as eyes and EO vision systems have focusing optics that bring the incident plane wave of light to focus at the sensor plane. This results in a high optical gain (greater than 100,000 for eyes), which makes the associated sensor vulnerable to relatively low fluences of laser energy.

The effects of lasers on eyes are threefold:

- Dazzling or induced glare.
- Flashblinding or loss of night adaptation.
- Permanent or semipermanent blinding.

The severity of laser eye injuries varies according to the incident power, spot size, beam angle, pupil diameter (ambient light conditions), temporal mode (CW or pulsed), and PRF of the laser. Reported effects include corneal burns, cataracts (a permanent cloudiness of the lens), and retinal burns and perforations. Low-energy laser weapons are capable of causing the latter.

Exposure to relatively low laser energies can produce temporary changes in the ability to see without producing permanent injury. Exposure to laser light can produce an effect called glare or dazzle, which is similar to the temporary loss of vision experience when viewing the headlights of an oncoming car. The visual effects last only as long as the light is present in the field of view (FOV). At slightly higher energy exposures, the same laser radiation can saturate or flashblind the photoreceptor cells, resulting in after images that fade with time after exposure. Only visible radiation will induce veiling glare or after images; near-IR radiation will not produce these effects even though the radiant energy reaches the photoreceptor cells. Flashblindness and dazzle, while not permanent injuries, can cause discomfort and temporary loss of vision. Some studies have shown that dazzle and flashblindness can seriously impact mission performance, especially in highly visual tasks such as piloting an aircraft or aiming.

Blinding is the permanent or semipermanent loss of visual acuity. The effect can last from several hours onward and generally is evidenced by a dark spot in the field of vision. This spot is called a scotoma. The impact of the scotoma on visual acuity will vary with the size and position of the injury. Human vision is greatly affected when the laser damage is to the central vision area of the retina called the fovea. Nonfoveal laser damage may be less severe or even go unnoticed because it affects only the peripheral vision. The most serious retinal injuries occur when the incident light is so intense that a perforation in the retina is formed, resulting in a hemorrhage into either the subretinal layer or, in the most severe cases, the vitreous humor of the eye. Less severe exposures result in lesions on the retina.

REPLY TO
ATTENTION OF:

DEC 13 2006

Freedom of Information/
Privacy Office

Mr. Donald Friedman
Confidential Legal Correspondence
1125 Third Street
Napa, California 94559-3015

Dear Mr. Friedman:

References:

a. Your Freedom of Information Act (FOIA) request dated May 25, 2006, to the Department of the Army, Freedom of Information/Privacy Act Division (DA FOIA/PA DIV), for all documents pertaining to the microwave auditory effect, microwave hearing effect, Frey effect, artificial telepathy, and/or any device/weapon which uses and/or causes such effect; and any covert or undisclosed use of hypnosis. On September 5, 2006, the DA FOIA/PA DIV referred a copy of your request to this office. Your request was received on September 11, 2006.

b. Our letter of September 13, 2006, informing you of the search for records at another element of our command and were unable to comply with the 20-day statutory time limit in processing your request.

As noted in our letter, the search has been completed with another element of this command and the record has been returned to this office for our review and direct response to you.

We have completed a mandatory declassification review in accordance with Executive Order (EO) 12958, as amended. As a result of this review, it has been determined that the Army information no longer warrants security classification protection and is releasable to you. A copy of the record is enclosed for your use.

Fees for processing your request are waived.

If you have any questions concerning this action, please feel free to contact this office at (301) 677-2308. Refer to case #614F-06.

Sincerely,

Susan J. Butterfield

Bioeffects of Selected Nonlethal Weapons(fn 1)

This addendum to the Nonlethal Technologies--Worldwide (NGIC-1147-101-98) study addresses in summary, some of the most often asked questions of nonlethal weapons technology, the physiological responses observed in clinical settings of the biophysical coupling and susceptibility of personnel to nonlethal effects weapons. These results identify and validate some aspects of maturing nonlethal technologies that may likely be encountered or used as nonlethal effectors in the future including:

- Laser and other light phenomena.
- Radiofrequency directed energy.
- Aural bioeffects.

The study of electromagnetic fields and their influence on biological systems is increasing rapidly. Much of this work is taking place because of health concerns. For example, increased concern has arisen regarding the effects of operator exposure to the electromagnetic fields associated with short-wave diathermy devices, high power microwave ovens, radar systems, magnetic resonance imaging units, etc. In addition, much concern has arisen about extremely low frequency (60 Hz power frequency) electric and magnetic fields that originate from high-voltage transmission lines, industrial equipment, and residential appliances. Both occupational and residential long-term exposure have been the focus of epidemiological studies. The studies have suggested possible adverse effects on human health (e.g., cancer, reproduction, etc.). Laboratory research is still being pursued to identify possible mechanisms of interaction. However, other than thermal heating for microwave frequencies, there is no yet agreed-upon mechanism of action. As a consequence, our knowledge base is developed entirely with phenomenological observations. Because of this fact, it is not possible to predict how nonthermal biological effects may differ from one exposure modality to another. It is especially difficult, because of the small data base for fast pulses, to predict biological effects that might be associated with high-power pulses of extremely short duration.

There is, however, a growing perception that microwave irradiation and exposure to low frequency fields can be involved in a wide range of biological interactions. Some investigators are even beginning to describe similarities between microwave irradiation and drugs regarding their effects on biological systems. For example, some suggest that power density and specific absorption rate of microwave irradiation may be thought of as analogous to the concentration of the injection solution and the dosage of drug

administration, respectively. Clearly, the effects of microwaves on brain tissue, chemistry, and functions are complex and selective. Observations of body weight and behavior revealed that rats, exposed under certain conditions to microwaves, eat and drink less, have smaller body weight as a result of nonspecific stress mediated through the central nervous system and have decreased motor activity. It has been found that exposure of the animals to one modality of radiofrequency electromagnetic energy substantially decreases aggressive behavior during exposure. However, the opposite effects of microwaves, in increasing the mobility and aggression of animals, has also been shown for a different exposure modality. Recent published data implicates microwaves as a factor related to a deficit in spatial memory function. A similar type of effect was observed with exposure to a "resonance tuned" extremely low frequency magnetic field. Thus, the data base is replete with phenomenological observations of biological systems "affected" by exposure to electromagnetic energy. (The fact that a biological system responds to an external influence does not automatically nor easily translate to the suggestion of adverse influence on health.) The objective of the present study was to identify information from this developing understanding of electomagnetic effects on animal systems that could be coupled with human biological susceptibilities. Situations where the intersection of these two domains coexist provide possibilities for use in nonlethal applications.

Incapacitating Effect: Microwave Heating

Body heating to mimic a fever is the nature of the RF incapacitation. The objective is to provide heating in a very controlled way so that the body receives nearly uniform heating and no organs are damaged. Core temperatures approximately 41° C are considered to be adequate. At such temperature a considerably changed demeanor will take place with the individual. Most people, under fever conditions, become much less aggressive; some people may become more irritable. The subjective sensations produced by this buildup of heat are far more unpleasant than those accompanying fever. In hyperthermia all the effector processes are strained to the utmost, whereas in fever they are not. It is also possible that microwave hyperthermia (even with only a 1° C increase in brain temperature) may disrupt working memory, thus resulting in disorientation.

Biological Target/Normal Functions/Disease State

The temperature of warm-blooded (homeothermic) animals like the human remains practically unchanged although the surrounding temperature may vary considerably. The normal human body temperature recorded from the mouth is usually given as 37° C, with the rectal temperature one degree higher. Variation between individuals is typically between 35.8° C and 37.8° C orally. Variations also occur in any one individual throughout the day--a difference of 1.0° C or even 2.0° C occurring between the maximum in the late afternoon or early evening, and the minimum between 3 and 5 o'clock in the morning. Strenuous muscular exercise causes a temporary rise in body temperature that is proportional to the severity of the exercise; the level may go as high as 40.0° C.

Extreme heat stress, such that the body's capacity for heat loss is exceeded, causes a pathological increase in the temperature of the body. The subjective sensations produced by this buildup of heat are far more unpleasant than those accompanying fever. In hyperthermia all the effector processes are strained to the utmost, whereas in fevers they are not. The limiting temperature for survival, however, is the same in both cases--a body temperature of 42° C. For brief periods, people have been known to survive temperatures as high as 43 ° C.

In prolonged hyperthermia, with temperatures over 40° C to 41° C, the brain suffers severe damage that usually leads to death. Periods of hyperthermia are accompanied by cerebral edema that damage neurons, and the victim exhibits disorientation, delirium, and convulsions. This syndrome is popularly referred to as sunstroke, or heatstroke, depending on the circumstances. When the hyperthermia is prolonged, brain damage interferes with the central thermoregulatory mechanisms. In particular, sweat secretion ceases, so that the condition is further exacerbated.

Mechanism to Produce the Desired Effects

This concept builds on about 40 years of experience with the heating effects of microwaves. Numerous studies have been performed on animals to identify characteristics of importance to the understanding of energy deposition in animals. As a result of the physics, the relationship between the size of the animal and the wavelength of the radiofrequency energy is most important. In fact, the human exposure guidelines to radiofrequency radiation are designed around knowledge of the differential absorption as a function of frequency and body size. The challenge is to minimize the time to effect while causing no permanent injury to any organ or the total body and to optimize the equipment function. The orientation of the incident energy with respect to the orientation of the animal is also important.

In a study of the effect of RF radiation on body temperature in the Rhesus monkey, a frequency (225 MHz) is purposely chosen that deposits energy deep within the body of the animal. A dose rate of 10 W/kg caused the body temperature to increase to 42° C in a short time (10-15 min). To avoid irreversible adverse effects, the exposure was terminated when a temperature of 42° C was reached. A lower dose rate of 5 W/kg caused the temperature to increase to 41.5° C in less than 2 hours. The reversible nature of this response was demonstrated by the rapid drop in body temperature when RF exposure was terminated before a critical temperature of 42° C was reached. It is estimated for rats that the absorbed threshold convulsive dose lies between 22 and 35 J/g for exposure durations from less than a second to 15 minutes. For 30-minute exposure, the absorbed threshold dose for decrease in endurance is near 20 J/g, the threshold for work stoppage approximately 9 J/g, and the threshold for work perturbation ranges from 5 to 7 J/g. All of the above measures, except convulsions, are types of nonlethal incapacition.

A rough estimate of the power required to heat a human for this technology is on the order of 10 W/kg given about 15 to 30 minutes of target activation. Actual power levels

depend on climatic factors, clothing, and other considerations that affect the heat loss from the individual concerned. A method for expressing dose rate in terms of body surface area (i.e., watts per square meter) rather than body mass (i.e., watts per kilogram) would permit a more reliable prediction of thermal effects across species. However, there are large uncertainties in the ability to extrapolate thermoregulatory effects in laboratory animals to those in human beings.

This technology is an adaptation of technology which has been around for many years. It is well known that microwaves can be used to heat objects. Not only is microwave technology used to cook foods, but it is also used as a directed source of heating in many industrial applications. It was even the subject of the "Pound Proposal" a few years ago in which the idea was to provide residential heating to people, not living space. Because of the apparently safe nature of body heating using microwave techniques, a variety of innovative uses of EM energy for human applications are being explored. The nonlethal application would embody a highly sophisticated microwave assembly that can be used to project microwaves in order to provide a controlled heating of persons. This controlled heating will raise the core temperature of the individuals to a predetermined level to mimic a high fever with the intent of gaining a psychological/capability edge on the enemy, while not inflicting deadly force. The concept of heating is straightforward; the challenge is to identify and produce the correct mix of frequencies and power levels needed to do the remote heating while not injuring specific organs in the individuals illuminated by the beam.

A variety of factors contribute to the attractiveness of this nonlethal technology. First, it is based on a well-known effect, heating. Every human is subject to the effects of heating; therefore, it would have a predictability rating of 100%. The time to onset can probably be engineered to between 15 and 30 minutes; however, timing is the subject of additional research to maximize heating while minimizing adverse effects of localized heating. The onset can be slow enough and/or of such frequency to be unrecognized by the person(s) being irradiated. Safety to innocents could be enhanced by the application and additional development of advanced sensor technologies. Incapacitation time could be extended to almost any desired period consistent with safety. (Given suitable R&D, temperature or other vital signs could be monitored remotely, and temperature could be maintained at a minimum effective point).

Time to Onset

The time to onset is a function of the power level being used. Carefully monitored uniform heating could probably take place in between 15 and 30 minutes. Time to onset could be reduced but with increased risk of adverse effects. Minimum time is dependent on the power level of the equipment and the efficiency of the aiming device.

Duration of Effect

Assuming that the heating is done carefully, reversal of elevated body temperature would begin as soon as the source of heat is removed.

Tunability

This concept is tunable in that any rate of heating, up to the maximum capacity of the source, may be obtained. Thus it is suitable for use in a gradual force or "rheostatic" approach. If the situation allows, and the source is sufficiently powerful, there is the possibility to use this technology in a lethal mode as well. Prolonged body temperature above 43° C is almost certain to result in permanent damage to the brain and death.

Distribution of Human Sensitivities to Desired Effects

No reason has been identified to suggest that anyone would be immune to this technology. Individuals with compromised thermoregulatory mechanisms would be susceptible with a lower incident energy density. This would include people with organic damage to the hypothalamus, the part of the brain that integrates the autonomic mechanisms which control heat loss as well as people with compromised somatic features of heat loss (e.g., respiration, water balance, etc.).

The technologies needed for the thermal technology concept are relatively well developed because of the known biophysical mechanism, the universal susceptibility of humans to the mechanism of heating, and because of a well developed technology base for the production of radiofrequency radiation. Because the human body is inhomogeneous, certain organs are, by virtue of their size and geometry, more easily coupled with one radiofrequency wavelength than another. Therefore, to avoid permanent damage to the suspect or to innocent bystanders, it may be necessary to vary the frequency to avoid localized heating and consequent damage to any organ. Additionally, it will be necessary to avoid the conditions thought to be associated with the induction of cataracts. Thus, while the technology of microwave heating in general is mature, adaptation as a nonlethal technology will require sophisticated biophysical calculations to identify the proper regimen of microwave frequencies and intensities; it will also be necessary to optimize existing hardware to meet the biophysical requirements.

Possible Influence on Subject(s)

If the technology functions approximately as envisioned, the targeted individual could be incapacitated within 15 to 30 minutes. Because this technology is focused on a relatively slow onset, it should only be used in situations where speed is not important. The very uncomfortable nature of a high body temperature may be useful in negotiations or possibly for controlling crowds. It would be equally useful on single persons or crowds. Evidence also indicates a disruption of working memory, thus disorientation may occur because of an inability to consolidate memory of the recent (minutes) past.

Technological Status of Generator/Aiming Device

Equipment needed to explore this concept in the laboratory is available today. Design and construction of the RF/microwave generator will depend on the constraints posed by the calculations, potential generation devices, and energy-directing structures. A variety of

options exist for both of these equipment needs. The use of advanced frequency and modulation-agile RF generation and amplification circuitry will be required to assess fully the frequency/power/time envelope of RF heating profiles required. Although much equipment is commercially available, it is likely that custom hardware and software will be necessary because available equipment has not been designed with the need for frequency/intensity variability, which will probably be needed for safety purposes. In addition, the design of antennas and other energy-directing structures will almost certainly involve unique configurations. Since this technology utilizes radiofrequency energy, it can be defeated by the use of shielding provided by conductive barriers like metal or metal screen.

Incapacitating Effect: Microwave Hearing

Microwave hearing is a phenomenon, described by human observers, as, the sensations of buzzing, ticking, hissing, or knocking sounds that originate within or immediately behind the head. There is no sound propagating through the air like normal sound. This technology in its crudest form could be used to distract individuals; if refined, it could also be used to communicate with hostages or hostage takers directly by Morse code or other message systems, possibly even by voice communication.

Biological Target/Normal Functions/Disease State

This technology makes use of a phenomenon first described in the literature over 30 years ago. Different types of sounds were heard depending on the particulars of the pulse characteristics. Various experiments were performed on humans and laboratory animals exploring the origin of this phenomenon. At this time, virtually all investigators who have studied the phenomenon now accept thermoelastic expansion of the brain, the pressure wave of which is received and processed by the cochlear microphonic system, to be the mechanism of acoustic perception of short pulses of RF energy. One study (in 1975) using human volunteers, identified the threshold energy of microwave-auditory responses in humans as a function of pulse width for 2450 MHz radiofrequency energy. It is also found that about 40 J/cm^2 incident energy density per pulse was required.

Mechanism to Produce the Desired Effects

After the phenomenon was discovered, several mechanisms were suggested to explain the hearing of pulsed RF fields. Thermoelastic expansion within the brain in response to RF pulses was first studied and demonstrated in inert materials and was proposed as the mechanism of hearing of pulsed RF fields. A pressure wave is generated in most solid and liquid materials by a pulse of RF energy--a pressure wave that is several orders of magnitude larger in amplitude than that resulting from radiation pressure or from electrostrictive forces. The characteristics of the field-induced cochlear microphonic in guinea pigs and cats, the relationship of pulse duration and threshold, physical measurements in water and in tissue-simulating materials, as well as numerous theoretical calculations--all point to thermoelastic expansion as the mechanism of the hearing phenomenon.

Scientists have determined the threshold energy level for human observers exposed to pulsed 2450-MHz fields (0.5-to 32 micron pulse widths). They found that, regardless of the peak of the power density and the pulse width, the per-pulse threshold for a normal subject is near 20 mJ/kg. The average elevation of brain temperature associated with a just-perceptible pulse was estimated to be about $5x10^{-6}$° C.

Time to Onset

The physical nature of this thermoelastic expansion dictates that the sounds are heard as the individual pulses are absorbed. Thus, the effect is immediate (within milliseconds). Humans have been exposed to RF energy that resulted in the production of sounds.

Duration of Effect

Microwave hearing lasts only as long as the exposure. There is no residual effect after cessation of RF energy.

Tunability

The phenomenon is tunable in that the characteristic sounds and intensities of those sounds depend on the characteristics of the RF energy as delivered. Because the frequency of the sound heard is dependent on the pulse characteristics of the RF energy, it seems possible that this technology could be developed to the point where words could be transmitted to be heard like the spoken word, except that it could only be heard within a person's head. In one experiment, communication of the words from one to ten using "speech modulated" microwave energy was successfully demonstrated. Microphones next to the person experiencing the voice could not pick up the sound. Additional development of this would open up a wide range of possibilities.

Distribution of Human Sensitivities to Desired Effects

Because the phenomenon acts directly on cochlear processes, the thermoelastic pressure waves produce sounds of varying frequency. Many of the tests run to evaluate the phenomenon produced sounds in the 5 kHz range and higher. Because humans are known to experience a wide range of hearing loss due to cochlear damage, it is possible that some people can hear RF induced sounds that others with high frequency hearing loss cannot. Thus, there is a likely range of sensitivity, primarily based on the type of pulse and the condition of the cochlea. Bilateral destruction of the cochlea has been demonstrated to abolish all RF-induced auditory stimuli.

Recovery/Safety

Humans have been subjected to this phenomenon for many years. The energy deposition required to produce this effect is so small that it is not considered hazardous experimentation when investigating responses at the just-perceptible levels.

Possible Influence on Subject(s)

Application of the microwave hearing technology could facilitate a private message transmission. It may be useful to provide a disruptive condition to a person not aware of the technology. Not only might it be disruptive to the sense of hearing, it could be psychologically devastating if one suddenly heard "voices within one's head."

Technological Status of Generator/Aiming Device

This technology requires no extrapolation to estimate its usefulness. Microwave energy can be applied at a distance, and the appropriate technology can be adapted from existing radar units. Aiming devices likewise are available but for special circumstances which require extreme specificity, there may be a need for additional development. Extreme directional specificity would be required to transmit a message to a single hostage surrounded by his captors. Signals can be transmitted long distances (hundreds of meters) using current technology. Longer distances and more sophisticated signal types will require more bulky equipment, but it seems possible to transmit some type of signals at closer ranges using man-portable equipment.

Range

The effective range could be hundreds of meters.

Incapacitating Effect: Disruption of Neural Control

The nature of the incapacitation is a rhythmic-activity synchronization of brain neurons that disrupts normal cortical control of the corticospinal and corticobulbar pathways; this disrupts normal functioning of the spinal motor neurons which control muscle contraction and body movements. Persons suffering from this condition lose voluntary control of their body. This synchronization may be accompanied by a sudden loss of consciousness and intense muscle spasms.

Biological Target/Normal Functions/Disease State

The normal function of the brain is to control all forms of behavior, voluntary control of body, and the homeostatic parameters of the organism. In normal conditions, all the brain structures, neuron populations, networks, and single units function with specific rhythmic activity depending on the incoming sensory information, information from mnemonic structures, and signals from visceral organs. Each single neuron provides specific processing of information it receives and forms a specific pattern of impulse firing as outgoing information. Synchronization of neuron activity is a natural mechanism of the brain function that uses such controlling processes as motivation, attention and memory (experience) in order to organize behavior. For example, motivational processes are considered as activating ascending signals that synchronize the neuron activity of specific brain structures and neuron networks; this activation/synchronization in turn activates specific forms of behavior such as sexual, aggressive, ingestive activities.

In normal functioning the degree of neuronal synchronization is highly controlled. From experiments that record the neuronal activity in different brain areas simultaneously in animals, it is known that correlation of spike activity between neurons (measured by the correlation level of synchronization) changes depending on the stage of behavior, motivation, attention, or activation of the memory processes. However, under some conditions, such as physical stress, heat shock, or strong emotional stress, the level of synchronization may become higher, involving nonspecific large populations of brain neurons and the synchronization may become uncontrollable.

Depending on at which frequency the synchronization rhythm occurs and how many neurons are involved, it may produce different physical effects; muscle weakness, involuntary muscle contractions, loss of consciousness, or intense (tonic) muscle spasms. The higher level of synchronization takes place in persons affected with epilepsy when they experience periodic seizures since they have a pathologic source (e.g., from injury to the brain) of rhythmic synchronization. Because the neurophysiological mechanisms of epileptiform synchronization are better documented, this incapacitating technology is described in terms of epileptogenesis.

The neurophysiological mechanisms active in epileptogenesis involve changes in membrane conductances and neurotransmitter alterations as they affect neuronal interaction. In the process of epileptogenesis, either some neurons are discharging too easily because of alterations in membrane conductances or there is a failure of inhibitory neurotransmission. The actual discharges have been recognized to result from a neuronal depolarization shift with electrical synchrony in cell populations related in part to changes in membrane conductances. The ionic basis and biochemical substrate of this activation have been areas of considerable study but still leave many questions unanswered. What are the basic cellular properties, present in normal cells and tissue, that could contribute to the generation of abnormal activity? What parts of the systems are low threshold and function as trigger elements?

One of the current hypotheses is involved with microcircuitry, particularly local synaptic interactions in neocortical and limbic system structures. In the hippocampus, the role of the trigger element has been long attributed to the CA3 pyramidal cells--a hypothesis based on the fact that spontaneous synchronous burst discharge can be established in CA3 neurons Some studies describe an intrinsically bursting cell type in the neocortex that plays a role similar to that of CA3 cells in the hippocampus and that of deep cells in the pyriform cortex. The intrinsic nature of these cells appears to be an important contributor to the establishment of synchronized bursting in these regions. Another apparent requirement in such a population is for a certain degree of synaptic interaction among neurons, such that discharge of even one cell enlists the activity of its neighbors. Given the presence of these bursting cells and the occurrence of excitatory interactions among them in normal tissue, it may actually be the morphologic substrate for epileptiform discharges.

Another hyptothesis has focused particularly on the role of N-methyl-D-aspartate (NMDA) receptors. Various factors regulate the efficacy of NMDA receptors: their

voltage-dependent blockade by magnesium and modulation by glycine and polyamines. For example, in the low magnesium model, spontaneous synchronous burst discharge in hippocampal pyramidal cell populations is sensitive to NMDA antagonists. That finding suggests that it is the opening of NMDA channels, by relieving the magnesium blockade, that facilitates epileptiform activity.

Significant attention in the literature is also being given to gamma-amino butyric acid (GABA) receptors for the potential role in control of excitability. Changes in GABA inhibitory efficacy can lead to important effects on the excitability of the system. GABAergic inhibitory post-synaptic potentials (IPSPs) have been shown to be quite labile in response to repetitive activation of cortical cell populations, as may occur during epileptiform discharge. Scientists have shown that even a small percentage change in GABA inhibition can have profound effects on neocortical epileptogenesis. These changes in GABAergic inhibition may be the key to an explanation of how repetitive discharge patterns give rise to ictal discharge. Further, there appears to be a significant increase in excitatory postsynaptic potential (EPSP) frequency prior to seizure initiation an observation that is consistent with loss of IPSP efficacy prior to ictal onset.

The above hypotheses describe different mechanisms of epileptogenesis, but it is quite possible that all of these mechanisms take place, and they reflect large variety of types of epileptic seizures. The common principle of the mechanisms proposed is the change of membrane properties (i.e., conductance, permeability etc.) of certain neurons which results in depolarization and burst discharging. Some factors (e.g., trauma) can affect these specific neurons and initiate synchrony for neurons that control internal communication and communication with various muscle systems not associated with vital functions (i.e., heart beating, breathing). High strength pulsed electric fields could also be such a factor.

Mechanism to Reproduce the Desired Effects

Application of electromagnetic pulses is also a conceptual nonlethal technology that uses electromagnetic energy to induce neural synchrony and disruption of voluntary muscle control. The effectiveness of this concept has not been demonstrated. However, from past work in evaluating the potential for electromagnetic pulse generators to affect humans, it is estimated that sufficiently strong internal fields can be generated within the brain to trigger neurons. Estimates are that 50 to 100 kV/m free field of very sharp pulses (~ 1 nS) are required to produce a cell membranic potential of approximately 2 V; this would probably be sufficient to trigger neurons or make them more susceptible to firing.

The electromagnetic pulse concept is one in which a very fast (nanosecond timeframe) high voltage (approximately 100 kV/m or greater) electromagnetic pulse is repeated at the alpha brain wave frequency (about 15 Hz). It is known that a similar frequency of pulsing light can trigger sensitive individuals (those with some degree of light-sensitivity epilepsy) into a seizure and it is thought that by using a method that could actually trigger nerve synapses directly with an electrical field, essentially 100% of individuals would be susceptible to seizure induction. The photic-induced seizure phenomenon was borne out

demonstrably on December 16, 1997 on Japanese television when hundreds of viewers of a popular cartoon show were treated, inadvertently, to photic seizure induction (figure 31). The photic-induced seizure is indirect in that the eye must receive and transmit the impulses which initially activate a portion of the brain associated with the optic nerve. From that point the excitability spreads to other portions of the brain. With the electromagnetic concept, excitation is directly on the brain, and all regions are excited concurrently. The onset of synchony and disruption of muscular control is anticipated to be nearly instantaneous. Recovery times are expected to be consistent with, or more rapid than, that which is observed in epileptic seizures.

Time to Onset

No experimental evidence is available for this concept. However, light-induced seizures latency onset in photosensitive epileptics varies from 0.1 to about 10 seconds. Because of the fact that the electrical impulses triggered by light must spread to other parts of the brain, photic-induced seizures are expected to have a generally slower onset than neural synchrony induced by high-strength pulsed electric fields.

Duration of Effect

For epileptic individuals, the typical duration of a petit mal event or a psychomotor event is 1 minute or 2, possibly longer, while the duration of a grand mal seizure is 1 to 5 minutes. In a non-epileptic individual who is induced by electromagnetic means, the durations of the different events are expected to be roughly the same as the epileptic individual's events after the external excitation is removed.

Tunability

There are many degrees of epileptic seizure in diseased persons, and it seems reasonable that electromagnetic stimulation of neural synchrony might be tunable with regard to type and degree of bodily influence, depending on the parameters associated with the chosen stimulus. Because there are no actual data to build on, these statements must be considered tentative. It is known that in the study of photic-induced seizures, parameters can be varied so that the individual under study does not actually undergo a grand mal seizure. This knowledge gives confidence that the proposed technology would be tunable.

Distribution of Human Sensitivities to Desired Effects

It is anticipated that 100% of the population would be susceptible. The mechanism is one that could act on many individual neuronal cells concurrently and hence does not depend on spreading regions of electrical activity as in the disease state.

Possible Influence on Subjects(s)

If the technology functions approximately as envisioned, the targeted individual could be incapacitated very quickly. Because there have been no reported studies using the

conditions specified, experimental work is required to characterize onset time. Different types of technologies could be employed to influence wide areas or single individuals. Because this technology is considered to be tunable, the influence on subjects could vary from mild disruption of concentration to muscle spasms and loss of consciousness. The subject(s) would have varying degrees of voluntary control depending on the chosen degree of incapacitation.

Technological Status of Generator/Aiming Device

An electric field strength of roughly 100 Kv/m over a time period of 1 nanosecond is approximately the condition thought to be necessary to produce the desired effect when provided to an overall repetition rate of 15 Hz. Such a field may be developed using a radar-like, high-peak-power, pulsed source or an electromagnetic pulse generator operated at 15 Hz. These technologies exist today sufficient to evaluate the disabling concept. Power requirements are not high because the duty factor is so low. Aiming devices are currently available, but a high degree of directionality at long distances will require development. It may be necessary to provide bursts of these nanosecond pulses in order to stimulate the desired effect. As the duty time increases so does the average power requirement for power source. Because there were no open literature reports from which to make inferences, there is some uncertainty about the power levels required.

Range

The effective range could be hundreds of meters.

Defeat Capabilities/Limitations

Shielding can be provided by conductive barriers like metal or metal screen. There are a number of drugs that are capable of inducing convulsive seizures and others, like phenobarbital, diphenyllhydantoin, trimethadione, 2-4 dinitrophenol, and acetazolamide, which are anticonvulsive. Anticonvulsive drugs are known to be helpful in reducing the effect of seizures in epileptic patients, but their ability to reduce the effect of the proposed technology is unknown (possibly no effect) but expected to be less than for photic-induced seizures.

Incapacitating Effect; Acoustic Energy

The nature of the incapacitation consists of severe pressure sensations, nystagmus (a spasmodic, involuntary motion of the eyes), and nausea caused by high intensities of 9140-155 dB). Nystagmus occurs when convection currents are produced (cupula movement) in the lateral ear canal. This cupula movement causes the eyes to move involuntarily; hence, the external world is interpreted as moving. The subject "sees" his surroundings turning round him and at the same time experiences a sensation of turning. Persons exposed to these levels of sound experience nausea.

Biological Target/Normal Functions/Disease State

The two lateral semicircular canals, one located in each inner ear, alert a person to the fact that his upright head is experiencing angular acceleration. Within the ampulla of the canal are several so called hair cells. The cilia of these cells protrude into the lumen of the ampulla where they are encased in a mass of jelly-like material (the cupula) which is attached to the opposite wall of the canal. As the head accelerates, the cilia are bent by an inertial force of the cupula and the viscous liquid in the canal lumen. The bending of the cilia excites hair cells which in turn excite afferent neurons; these then alert the brain that a change of position of the head has occurred. Similar events occur when the head stops moving. The result of a strong hair cell stimulus to the brain is a rapid eye movement, call nystagmus, a feeling of dizziness and disorientation, and a possibility of nausea and vomiting.

Normal hearing is in the range between the frequencies of 20,000 to 16,000 Hz with the optimal sensitivity for most people between the frequencies of 500 to 6000 Hz.

Mechanism to Produce the Desired Effects

Because the end organs for acoustic and vestibular perception are so closely related, intense acoustic stimulation can result in vestibular effects. The hypothesis is that the sound of normal intensity produces oscillations of the endolymph and perilymph, compensated for by oscillations of the round window. High intensity sound produces eddy currents, which are localized rotational fluid displacements. High intensity sound can also produce nonlinear displacement of the stapes, causing a volume displacement, the result of which can be a fluid void in the labyrinth. To fill the void, fluid may be displaced along the endolymphatic duct and/or block capillary pathways, which, in turn, could stimulate vestibular receptors. Stimulation of the vestibular receptors may lead to nausea and vomiting if the sound pressure level is high enough. Conclude that both eddy currents and volume displacement serve to stimulate vestibular receptors in humans, when exposed to high levels of noise.

One study found nystagmum in guinea pigs exposed to high levels of infrasound via stimulation of the vestibular receptors. However, the same lab was unable to produce nystagmus in human subjects at 5- and 10-second exposures to a pure tone at 135 dB, broadband engine noise, or a 100 Hz tone at 120 dB, pulsed three times/s or 2 minutes. The same research was unable to elicit nystagmus at levels up to 155 dB, and also equally unable to produce nystagmus using infrasound levels of 112-150 dB in guinea pigs, monkeys, and humans. However, research with audible components in the sound spectrum with guinea pigs and monkeys produced nystagmus. Other researchers report other vestibular effects in addition to nystagmus at the following thresholds: 125 dB from 200-500 Hz, 140 dB at 1000 Hz, and 155 dB at 200 Hz. Decrements in vestibular function occur consistently for broadband noise levels of 140 dB (with hearing protection).

Human subjects listened to very high levels of low-frequency noise and infrasound in the protected or unprotected modes. Two-minute duration as high as 140 to 155 dB produced a range of effects from mild discomfort to severe pressure sensations, nausea, gagging,

and giddiness. Effects also included blurred vision and visual field distortions in some exposure conditions. The nature and degree of all effects was dependent on both sound level and frequency with the most severe effects occurring in the audible frequency range (as opposed to infrasound), at levels above about 145 dB. The investigators found no temporary threshold shift (TTS) among their subjects, and the use of hearing protectors greatly alleviated the adverse effects.

Since the early days of jet-engine testing and maintenance, anecdotal evidence has appeared linking exposure to intense noise, with such complaints as dizziness, vertigo, nausea, and vomiting. As a result of siren noise at 140 dB, subjects consistently reported a feeling of being pushed sideways, usually away from the exposed ear, and one subject reported difficulty standing on one foot.

These effects were not as dramatic as from the jet-engine (broadband) noise at 140 dB. This research concludes that the threshold of labyrinthine dysfunction is about 135 to 140 dB and that these effects occur during, but not after, exposure.

Time to Onset

No times to onset of nausea or nystagmus were identified in the literature but is presumed to be relatively immediate based on effects to the labyrinth system occurring during, but not after, exposure to sound pressure levels of 135 to 140 dB.

Duration of Effect

The incapacitation lasts only as long as the incapacitating sound is present.

Tunability

Based on the data presented above, it is unclear whether the degree of nausea or nystagmus is tunable, but similar symptoms caused by other stimuli are variable in degree.

Distribution of Human Sensitivities to Desired Effects

It is most probable that all individuals will be susceptible to this stimulus with the exception of those with a disease or defect (i.e., deaf mutes) of some part or parts of the vestibular system. Data showed no consistent decrease in vestibulo-ocular reflects with increased age.

Recovery/Safety

Normal subjects are likely to recover immediately and experience no or unmeasurable changes in hearing unless well known frequency-intensity-time factors are exceeded. This is based on studies which found no temporary threshold shift in hearing of subjects tested at low frequency. Occupational safety personnel generally recognize that 115

dB(A) is to be avoided and that 70 dB(A) is assumed safe. Is believed that the noise energy with predominating frequencies above 500 Hz have a greater potential for hearing loss than noise energy at lower frequencies. Occupational standards for noise state that a person may be exposed continuously for 8 hours to 90 dB(A) or 15 minutes to 115 dB(A).

Possible Influence on Subject(s)

Induction of nystagmus and nausea will have variable effects on individuals. Effects may be sufficiently incapacitation to allow offensive advantage; the perception of sickness may make a subject susceptible to persuasion. It would be difficult to target single individuals at the present level of sound directing technology. This technology may be better suited for groups of people.

Technological Status of Generator/Aiming Device

Sound generating technology is well developed but not highly portable. Aiming devices are poorly developed.

Range

Under normal circumstances the sound pressure level decreases 6 dB(A) when the distance from the source is doubled. For example if the sound is 100 dB(A) at 100 ft, at 200 ft the sound would be 94 dB(A). At very high sound levels, certain conditions may lead to nonlinear effects in propagation and greatly increase range accuracy.

Defeat Capabilities/Limitations

Negative effects of audible sound are greatly decreased if hearing protection is worn. High frequency sound is more easily blocked than low frequency sound due to wavelength effects.

Laser-Induced Biological Effects

Their are three basic damage mechanisms associated with exposure to laser radiation: chemical, thermal, and mechanical or acoustic-mechanical.

The laser-induced, chemical alterations in irradiated tissue are referred to as photochemical damage. The likelihood of laser radiation in the blue-light portion of the electromagnetic spectrum (.380 to .550 microns) inducing photochemical reactions progressively decreases with increasing wavelength. Photochemical effects are not observed upon exposure to radiation with wavelengths exceeding .550 to .650 microns because the kinetic energy associated with these photons is insufficient to initiate a photochemical change.

On the other hand, the thermal effect is a primary mechanism for laser-induced injury. The extent of the injuries induced depends upon the wavelength and energy of the incident radiation, duration of exposure, and the nature of the exposed tissue and its absorption characteristics. Generally, this mechanism predominates in the visible and the near-infrared (.760 to 1.4 microns) portions of the electromagnetic spectrum and for almost all CW and pulsed exposures between 0.1 milliseconds and 1 to 5 seconds.

The third injury mechanism associated with exposure to laser radiation is the mechanical or acoustical-mechanical effect. The radiant energy is absorbed into the tissue and, as a result of rapid thermal expansion following a short (1 nanosecond to 0.1 millisecond) laser radiation pulse, a pressure wave is generated that may result in explosive tissue injury.

Generally, all three mechanisms operate concurrently in an irradiated animal. Thermal effects currently predominate for continuous wave (CW) lasers, while mechanical effects are of increased significance for pulsed-mode lasers. With even higher power, one must also consider nonlinear phenomena such as multiphoton absorption and electromagnetic field effects.

The organs most susceptible to external laser radiation are the skin and eyes. The severity of injury is affected by the nature of the target, the energy density delivered to the target, the frequency and power of the laser, atmospheric attenuation of the beam, and the use of filtering or amplifying optics by the target, etc.

The primary effect on the skin is thermal damage (burns). The severity varies from slight erythema or reddening to severe blistering or charring, depending on such factors as total energy deposition, skin pigmentation, and the tissue's ability to dissipate heat.

The eye is particularly susceptible to intense pulse of laser radiation because of its unique sensitivity to light. The focusing effect is similar to that of a magnifying lens, which focuses the energy on a particular spot. Since the cornea and lens of the eye amplify the intensity of the light incident upon the retina, the retina is extremely sensitive to visible and near-infrared light, and damage to the retina may result in temporary or permanent loss of visual acuity. Laser eye injuries vary according to incident power, spot size, beam angle, temporal mode (CW or pulsed), and pulse repetition frequency. Reported effects include corneal lesions, burns, cataracts, and retinal lesions.

Some high-power lasers can cause antipersonnel effects by the deposition of thermal energy. These lasers must operate at a wavelength that is readily absorbed by the skin or the cornea. These generally include the far- and mid-IR regions (10 to 12 microns and 3 to 5 microns) as well as the ultraviolet region (<0.4 microns). However, ultraviolet wavelengths generally do not propagate well in the atmosphere, so the primary threat wavelengths to be considered are between 3 and 12 microns. Although relatively modest amounts of far-IR laser power are required to produce superficial burns on the skin at short ranges, and efforts to design rheostatically lethal laser weapons are on going.

Nonlethal blinding laser weapons generally use collimated beams with very low beam divergence, and the energy contained in the beam diminishes relatively slowly over great distances. Imaging systems such as eyes and EO vision systems have focusing optics that bring the incident plane wave of light to focus at the sensor plane. This results in a high optical gain (greater than 100,000 for eyes), which makes the associated sensor vulnerable to relatively low fluences of laser energy.

The effects of lasers on eyes are threefold:

- Dazzling or induced glare.
- Flashblinding or loss of night adaptation.
- Permanent or semipermanent blinding.

The severity of laser eye injuries varies according to the incident power, spot size, beam angle, pupil diameter (ambient light conditions), temporal mode (CW or pulsed), and PRF of the laser. Reported effects include corneal burns, cataracts (a permanent cloudiness of the lens), and retinal burns and perforations. Low-energy laser weapons are capable of causing the latter.

Exposure to relatively low laser energies can produce temporary changes in the ability to see without producing permanent injury. Exposure to laser light can produce an effect called glare or dazzle, which is similar to the temporary loss of vision experience when viewing the headlights of an oncoming car. The visual effects last only as long as the light is present in the field of view (FOV). At slightly higher energy exposures, the same laser radiation can saturate or flashblind the photoreceptor cells, resulting in after images that fade with time after exposure. Only visible radiation will induce veiling glare or after images; near-IR radiation will not produce these effects even though the radiant energy reaches the photoreceptor cells. Flashblindness and dazzle, while not permanent injuries, can cause discomfort and temporary loss of vision. Some studies have shown that dazzle and flashblindness can seriously impact mission performance, especially in highly visual tasks such as piloting an aircraft or aiming.

Blinding is the permanent or semipermanent loss of visual acuity. The effect can last from several hours onward and generally is evidenced by a dark spot in the field of vision. This spot is called a scotoma. The impact of the scotoma on visual acuity will vary with the size and position of the injury. Human vision is greatly affected when the laser damage is to the central vision area of the retina called the fovea. Nonfoveal laser damage may be less severe or even go unnoticed because it affects only the peripheral vision. The most serious retinal injuries occur when the incident light is so intense that a perforation in the retina is formed, resulting in a hemorrhage into either the subretinal layer or, in the most severe cases, the vitreous humor of the eye. Less severe exposures result in lesions on the retina.

DEPARTMENT OF THE ARMY
UNITED STATES ARMY INTELLIGENCE AND SECURITY COMMAND
FREEDOM OF INFORMATION/PRIVACY OFFICE
FORT GEORGE G. MEADE, MARYLAND 20755-5995

REPLY TO
ATTENTION OF:

DEC 13 2006

Freedom of Information/
Privacy Office

Mr. Donald Friedman
Confidential Legal Correspondence
1125 Third Street
Napa, California 94559-3015

Dear Mr. Friedman:

References:

a. Your Freedom of Information Act (FOIA) request dated May 25, 2006, to the Department of the Army, Freedom of Information/Privacy Act Division (DA FOIA/PA DIV), for all documents pertaining to the microwave auditory effect, microwave hearing effect, Frey effect, artificial telepathy, and/or any device/weapon which uses and/or causes such effect; and any covert or undisclosed use of hypnosis. On September 5, 2006, the DA FOIA/PA DIV referred a copy of your request to this office. Your request was received on September 11, 2006.

b. Our letter of September 13, 2006, informing you of the search for records at another element of our command and were unable to comply with the 20-day statutory time limit in processing your request.

As noted in our letter, the search has been completed with another element of this command and the record has been returned to this office for our review and direct response to you.

We have completed a mandatory declassification review in accordance with Executive Order (EO) 12958, as amended. As a result of this review, it has been determined that the Army information no longer warrants security classification protection and is releasable to you. A copy of the record is enclosed for your use.

Fees for processing your request are waived.

If you have any questions concerning this action, please feel free to contact this office at (301) 677-2308. Refer to case #614F-06.

Sincerely,

Susan J. Butterfield

Bioeffects of Selected Nonlethal Weapons(fn 1)

This addendum to the Nonlethal Technologies--Worldwide (NGIC-1147-101-98) study addresses in summary, some of the most often asked questions of nonlethal weapons technology, the physiological responses observed in clinical settings of the biophysical coupling and susceptibility of personnel to nonlethal effects weapons. These results identify and validate some aspects of maturing nonlethal technologies that may likely be encountered or used as nonlethal effectors in the future including:

- Laser and other light phenomena.
- Radiofrequency directed energy.
- Aural bioeffects.

The study of electromagnetic fields and their influence on biological systems is increasing rapidly. Much of this work is taking place because of health concerns. For example, increased concern has arisen regarding the effects of operator exposure to the electromagnetic fields associated with short-wave diathermy devices, high power microwave ovens, radar systems, magnetic resonance imaging units, etc. In addition, much concern has arisen about extremely low frequency (60 Hz power frequency) electric and magnetic fields that originate from high-voltage transmission lines, industrial equipment, and residential appliances. Both occupational and residential long-term exposure have been the focus of epidemiological studies. The studies have suggested possible adverse effects on human health (e.g., cancer, reproduction, etc.). Laboratory research is still being pursued to identify possible mechanisms of interaction. However, other than thermal heating for microwave frequencies, there is no yet agreed-upon mechanism of action. As a consequence, our knowledge base is developed entirely with phenomenological observations. Because of this fact, it is not possible to predict how nonthermal biological effects may differ from one exposure modality to another. It is especially difficult, because of the small data base for fast pulses, to predict biological effects that might be associated with high-power pulses of extremely short duration.

There is, however, a growing perception that microwave irradiation and exposure to low frequency fields can be involved in a wide range of biological interactions. Some investigators are even beginning to describe similarities between microwave irradiation and drugs regarding their effects on biological systems. For example, some suggest that power density and specific absorption rate of microwave irradiation may be thought of as analogous to the concentration of the injection solution and the dosage of drug

administration, respectively. Clearly, the effects of microwaves on brain tissue, chemistry, and functions are complex and selective. Observations of body weight and behavior revealed that rats, exposed under certain conditions to microwaves, eat and drink less, have smaller body weight as a result of nonspecific stress mediated through the central nervous system and have decreased motor activity. It has been found that exposure of the animals to one modality of radiofrequency electromagnetic energy substantially decreases aggressive behavior during exposure. However, the opposite effects of microwaves, in increasing the mobility and aggression of animals, has also been shown for a different exposure modality. Recent published data implicates microwaves as a factor related to a deficit in spatial memory function. A similar type of effect was observed with exposure to a "resonance tuned" extremely low frequency magnetic field. Thus, the data base is replete with phenomenological observations of biological systems "affected" by exposure to electromagnetic energy. (The fact that a biological system responds to an external influence does not automatically nor easily translate to the suggestion of adverse influence on health.) The objective of the present study was to identify information from this developing understanding of electomagnetic effects on animal systems that could be coupled with human biological susceptibilities. Situations where the intersection of these two domains coexist provide possibilities for use in nonlethal applications.

Incapacitating Effect: Microwave Heating

Body heating to mimic a fever is the nature of the RF incapacitation. The objective is to provide heating in a very controlled way so that the body receives nearly uniform heating and no organs are damaged. Core temperatures approximately 41° C are considered to be adequate. At such temperature a considerably changed demeanor will take place with the individual. Most people, under fever conditions, become much less aggressive; some people may become more irritable. The subjective sensations produced by this buildup of heat are far more unpleasant than those accompanying fever. In hyperthermia all the effector processes are strained to the utmost, whereas in fever they are not. It is also possible that microwave hyperthermia (even with only a 1° C increase in brain temperature) may disrupt working memory, thus resulting in disorientation.

Biological Target/Normal Functions/Disease State

The temperature of warm-blooded (homeothermic) animals like the human remains practically unchanged although the surrounding temperature may vary considerably. The normal human body temperature recorded from the mouth is usually given as 37° C, with the rectal temperature one degree higher. Variation between individuals is typically between 35.8° C and 37.8° C orally. Variations also occur in any one individual throughout the day--a difference of 1.0° C or even 2.0° C occurring between the maximum in the late afternoon or early evening, and the minimum between 3 and 5 o'clock in the morning. Strenuous muscular exercise causes a temporary rise in body temperature that is proportional to the severity of the exercise; the level may go as high as 40.0° C.

Extreme heat stress, such that the body's capacity for heat loss is exceeded, causes a pathological increase in the temperature of the body. The subjective sensations produced by this buildup of heat are far more unpleasant than those accompanying fever. In hyperthermia all the effector processes are strained to the utmost, whereas in fevers they are not. The limiting temperature for survival, however, is the same in both cases--a body temperature of 42° C. For brief periods, people have been known to survive temperatures as high as 43 ° C.

In prolonged hyperthermia, with temperatures over 40° C to 41° C, the brain suffers severe damage that usually leads to death. Periods of hyperthermia are accompanied by cerebral edema that damage neurons, and the victim exhibits disorientation, delirium, and convulsions. This syndrome is popularly referred to as sunstroke, or heatstroke, depending on the circumstances. When the hyperthermia is prolonged, brain damage interferes with the central thermoregulatory mechanisms. In particular, sweat secretion ceases, so that the condition is further exacerbated.

Mechanism to Produce the Desired Effects

This concept builds on about 40 years of experience with the heating effects of microwaves. Numerous studies have been performed on animals to identify characteristics of importance to the understanding of energy deposition in animals. As a result of the physics, the relationship between the size of the animal and the wavelength of the radiofrequency energy is most important. In fact, the human exposure guidelines to radiofrequency radiation are designed around knowledge of the differential absorption as a function of frequency and body size. The challenge is to minimize the time to effect while causing no permanent injury to any organ or the total body and to optimize the equipment function. The orientation of the incident energy with respect to the orientation of the animal is also important.

In a study of the effect of RF radiation on body temperature in the Rhesus monkey, a frequency (225 MHz) is purposely chosen that deposits energy deep within the body of the animal. A dose rate of 10 W/kg caused the body temperature to increase to 42° C in a short time (10-15 min). To avoid irreversible adverse effects, the exposure was terminated when a temperature of 42° C was reached. A lower dose rate of 5 W/kg caused the temperature to increase to 41.5° C in less than 2 hours. The reversible nature of this response was demonstrated by the rapid drop in body temperature when RF exposure was terminated before a critical temperature of 42° C was reached. It is estimated for rats that the absorbed threshold convulsive dose lies between 22 and 35 J/g for exposure durations from less than a second to 15 minutes. For 30-minute exposure, the absorbed threshold dose for decrease in endurance is near 20 J/g, the threshold for work stoppage approximately 9 J/g, and the threshold for work perturbation ranges from 5 to 7 J/g. All of the above measures, except convulsions, are types of nonlethal incapacition.

A rough estimate of the power required to heat a human for this technology is on the order of 10 W/kg given about 15 to 30 minutes of target activation. Actual power levels

depend on climatic factors, clothing, and other considerations that affect the heat loss from the individual concerned. A method for expressing dose rate in terms of body surface area (i.e., watts per square meter) rather than body mass (i.e., watts per kilogram) would permit a more reliable prediction of thermal effects across species. However, there are large uncertainties in the ability to extrapolate thermoregulatory effects in laboratory animals to those in human beings.

This technology is an adaptation of technology which has been around for many years. It is well known that microwaves can be used to heat objects. Not only is microwave technology used to cook foods, but it is also used as a directed source of heating in many industrial applications. It was even the subject of the "Pound Proposal" a few years ago in which the idea was to provide residential heating to people, not living space. Because of the apparently safe nature of body heating using microwave techniques, a variety of innovative uses of EM energy for human applications are being explored. The nonlethal application would embody a highly sophisticated microwave assembly that can be used to project microwaves in order to provide a controlled heating of persons. This controlled heating will raise the core temperature of the individuals to a predetermined level to mimic a high fever with the intent of gaining a psychological/capability edge on the enemy, while not inflicting deadly force. The concept of heating is straightforward; the challenge is to identify and produce the correct mix of frequencies and power levels needed to do the remote heating while not injuring specific organs in the individuals illuminated by the beam.

A variety of factors contribute to the attractiveness of this nonlethal technology. First, it is based on a well-known effect, heating. Every human is subject to the effects of heating; therefore, it would have a predictability rating of 100%. The time to onset can probably be engineered to between 15 and 30 minutes; however, timing is the subject of additional research to maximize heating while minimizing adverse effects of localized heating. The onset can be slow enough and/or of such frequency to be unrecognized by the person(s) being irradiated. Safety to innocents could be enhanced by the application and additional development of advanced sensor technologies. Incapacitation time could be extended to almost any desired period consistent with safety. (Given suitable R&D, temperature or other vital signs could be monitored remotely, and temperature could be maintained at a minimum effective point).

Time to Onset

The time to onset is a function of the power level being used. Carefully monitored uniform heating could probably take place in between 15 and 30 minutes. Time to onset could be reduced but with increased risk of adverse effects. Minimum time is dependent on the power level of the equipment and the efficiency of the aiming device.

Duration of Effect

Assuming that the heating is done carefully, reversal of elevated body temperature would begin as soon as the source of heat is removed.

Tunability

This concept is tunable in that any rate of heating, up to the maximum capacity of the source, may be obtained. Thus it is suitable for use in a gradual force or "rheostatic" approach. If the situation allows, and the source is sufficiently powerful, there is the possibility to use this technology in a lethal mode as well. Prolonged body temperature above 43° C is almost certain to result in permanent damage to the brain and death.

Distribution of Human Sensitivities to Desired Effects

No reason has been identified to suggest that anyone would be immune to this technology. Individuals with compromised thermoregulatory mechanisms would be susceptible with a lower incident energy density. This would include people with organic damage to the hypothalamus, the part of the brain that integrates the autonomic mechanisms which control heat loss as well as people with compromised somatic features of heat loss (e.g., respiration, water balance, etc.).

The technologies needed for the thermal technology concept are relatively well developed because of the known biophysical mechanism, the universal susceptibility of humans to the mechanism of heating, and because of a well developed technology base for the production of radiofrequency radiation. Because the human body is inhomogeneous, certain organs are, by virtue of their size and geometry, more easily coupled with one radiofrequency wavelength than another. Therefore, to avoid permanent damage to the suspect or to innocent bystanders, it may be necessary to vary the frequency to avoid localized heating and consequent damage to any organ. Additionally, it will be necessary to avoid the conditions thought to be associated with the induction of cataracts. Thus, while the technology of microwave heating in general is mature, adaptation as a nonlethal technology will require sophisticated biophysical calculations to identify the proper regimen of microwave frequencies and intensities; it will also be necessary to optimize existing hardware to meet the biophysical requirements.

Possible Influence on Subject(s)

If the technology functions approximately as envisioned, the targeted individual could be incapacitated within 15 to 30 minutes. Because this technology is focused on a relatively slow onset, it should only be used in situations where speed is not important. The very uncomfortable nature of a high body temperature may be useful in negotiations or possibly for controlling crowds. It would be equally useful on single persons or crowds. Evidence also indicates a disruption of working memory, thus disorientation may occur because of an inability to consolidate memory of the recent (minutes) past.

Technological Status of Generator/Aiming Device

Equipment needed to explore this concept in the laboratory is available today. Design and construction of the RF/microwave generator will depend on the constraints posed by the calculations, potential generation devices, and energy-directing structures. A variety of

options exist for both of these equipment needs. The use of advanced frequency and modulation-agile RF generation and amplification circuitry will be required to assess fully the frequency/power/time envelope of RF heating profiles required. Although much equipment is commercially available, it is likely that custom hardware and software will be necessary because available equipment has not been designed with the need for frequency/intensity variability, which will probably be needed for safety purposes. In addition, the design of antennas and other energy-directing structures will almost certainly involve unique configurations. Since this technology utilizes radiofrequency energy, it can be defeated by the use of shielding provided by conductive barriers like metal or metal screen.

Incapacitating Effect: Microwave Hearing

Microwave hearing is a phenomenon, described by human observers, as, the sensations of buzzing, ticking, hissing, or knocking sounds that originate within or immediately behind the head. There is no sound propagating through the air like normal sound. This technology in its crudest form could be used to distract individuals; if refined, it could also be used to communicate with hostages or hostage takers directly by Morse code or other message systems, possibly even by voice communication.

Biological Target/Normal Functions/Disease State

This technology makes use of a phenomenon first described in the literature over 30 years ago. Different types of sounds were heard depending on the particulars of the pulse characteristics. Various experiments were performed on humans and laboratory animals exploring the origin of this phenomenon. At this time, virtually all investigators who have studied the phenomenon now accept thermoelastic expansion of the brain, the pressure wave of which is received and processed by the cochlear microphonic system, to be the mechanism of acoustic perception of short pulses of RF energy. One study (in 1975) using human volunteers, identified the threshold energy of microwave-auditory responses in humans as a function of pulse width for 2450 MHz radiofrequency energy. It is also found that about 40 J/cm^2 incident energy density per pulse was required.

Mechanism to Produce the Desired Effects

After the phenomenon was discovered, several mechanisms were suggested to explain the hearing of pulsed RF fields. Thermoelastic expansion within the brain in response to RF pulses was first studied and demonstrated in inert materials and was proposed as the mechanism of hearing of pulsed RF fields. A pressure wave is generated in most solid and liquid materials by a pulse of RF energy--a pressure wave that is several orders of magnitude larger in amplitude than that resulting from radiation pressure or from electrostrictive forces. The characteristics of the field-induced cochlear microphonic in guinea pigs and cats, the relationship of pulse duration and threshold, physical measurements in water and in tissue-simulating materials, as well as numerous theoretical calculations--all point to thermoelastic expansion as the mechanism of the hearing phenomenon.

Scientists have determined the threshold energy level for human observers exposed to pulsed 2450-MHz fields (0.5-to 32 micron pulse widths). They found that, regardless of the peak of the power density and the pulse width, the per-pulse threshold for a normal subject is near 20 mJ/kg. The average elevation of brain temperature associated with a just-perceptible pulse was estimated to be about $5x10^{-6}$° C.

Time to Onset

The physical nature of this thermoelastic expansion dictates that the sounds are heard as the individual pulses are absorbed. Thus, the effect is immediate (within milliseconds). Humans have been exposed to RF energy that resulted in the production of sounds.

Duration of Effect

Microwave hearing lasts only as long as the exposure. There is no residual effect after cessation of RF energy.

Tunability

The phenomenon is tunable in that the characteristic sounds and intensities of those sounds depend on the characteristics of the RF energy as delivered. Because the frequency of the sound heard is dependent on the pulse characteristics of the RF energy, it seems possible that this technology could be developed to the point where words could be transmitted to be heard like the spoken word, except that it could only be heard within a person's head. In one experiment, communication of the words from one to ten using "speech modulated" microwave energy was successfully demonstrated. Microphones next to the person experiencing the voice could not pick up the sound. Additional development of this would open up a wide range of possibilities.

Distribution of Human Sensitivities to Desired Effects

Because the phenomenon acts directly on cochlear processes, the thermoelastic pressure waves produce sounds of varying frequency. Many of the tests run to evaluate the phenomenon produced sounds in the 5 kHz range and higher. Because humans are known to experience a wide range of hearing loss due to cochlear damage, it is possible that some people can hear RF induced sounds that others with high frequency hearing loss cannot. Thus, there is a likely range of sensitivity, primarily based on the type of pulse and the condition of the cochlea. Bilateral destruction of the cochlea has been demonstrated to abolish all RF-induced auditory stimuli.

Recovery/Safety

Humans have been subjected to this phenomenon for many years. The energy deposition required to produce this effect is so small that it is not considered hazardous experimentation when investigating responses at the just-perceptible levels.

Possible Influence on Subject(s)

Application of the microwave hearing technology could facilitate a private message transmission. It may be useful to provide a disruptive condition to a person not aware of the technology. Not only might it be disruptive to the sense of hearing, it could be psychologically devastating if one suddenly heard "voices within one's head."

Technological Status of Generator/Aiming Device

This technology requires no extrapolation to estimate its usefulness. Microwave energy can be applied at a distance, and the appropriate technology can be adapted from existing radar units. Aiming devices likewise are available but for special circumstances which require extreme specificity, there may be a need for additional development. Extreme directional specificity would be required to transmit a message to a single hostage surrounded by his captors. Signals can be transmitted long distances (hundreds of meters) using current technology. Longer distances and more sophisticated signal types will require more bulky equipment, but it seems possible to transmit some type of signals at closer ranges using man-portable equipment.

Range

The effective range could be hundreds of meters.

Incapacitating Effect: Disruption of Neural Control

The nature of the incapacitation is a rhythmic-activity synchronization of brain neurons that disrupts normal cortical control of the corticospinal and corticobulbar pathways; this disrupts normal functioning of the spinal motor neurons which control muscle contraction and body movements. Persons suffering from this condition lose voluntary control of their body. This synchronization may be accompanied by a sudden loss of consciousness and intense muscle spasms.

Biological Target/Normal Functions/Disease State

The normal function of the brain is to control all forms of behavior, voluntary control of body, and the homeostatic parameters of the organism. In normal conditions, all the brain structures, neuron populations, networks, and single units function with specific rhythmic activity depending on the incoming sensory information, information from mnemonic structures, and signals from visceral organs. Each single neuron provides specific processing of information it receives and forms a specific pattern of impulse firing as outgoing information. Synchronization of neuron activity is a natural mechanism of the brain function that uses such controlling processes as motivation, attention and memory (experience) in order to organize behavior. For example, motivational processes are considered as activating ascending signals that synchronize the neuron activity of specific brain structures and neuron networks; this activation/synchronization in turn activates specific forms of behavior such as sexual, aggressive, ingestive activities.

In normal functioning the degree of neuronal synchronization is highly controlled. From experiments that record the neuronal activity in different brain areas simultaneously in animals, it is known that correlation of spike activity between neurons (measured by the correlation level of synchronization) changes depending on the stage of behavior, motivation, attention, or activation of the memory processes. However, under some conditions, such as physical stress, heat shock, or strong emotional stress, the level of synchronization may become higher, involving nonspecific large populations of brain neurons and the synchronization may become uncontrollable.

Depending on at which frequency the synchronization rhythm occurs and how many neurons are involved, it may produce different physical effects; muscle weakness, involuntary muscle contractions, loss of consciousness, or intense (tonic) muscle spasms. The higher level of synchronization takes place in persons affected with epilepsy when they experience periodic seizures since they have a pathologic source (e.g., from injury to the brain) of rhythmic synchronization. Because the neurophysiological mechanisms of epileptiform synchronization are better documented, this incapacitating technology is described in terms of epileptogenesis.

The neurophysiological mechanisms active in epileptogenesis involve changes in membrane conductances and neurotransmitter alterations as they affect neuronal interaction. In the process of epileptogenesis, either some neurons are discharging too easily because of alterations in membrane conductances or there is a failure of inhibitory neurotransmission. The actual discharges have been recognized to result from a neuronal depolarization shift with electrical synchrony in cell populations related in part to changes in membrane conductances. The ionic basis and biochemical substrate of this activation have been areas of considerable study but still leave many questions unanswered. What are the basic cellular properties, present in normal cells and tissue, that could contribute to the generation of abnormal activity? What parts of the systems are low threshold and function as trigger elements?

One of the current hypotheses is involved with microcircuitry, particularly local synaptic interactions in neocortical and limbic system structures. In the hippocampus, the role of the trigger element has been long attributed to the CA3 pyramidal cells--a hypothesis based on the fact that spontaneous synchronous burst discharge can be established in CA3 neurons Some studies describe an intrinsically bursting cell type in the neocortex that plays a role similar to that of CA3 cells in the hippocampus and that of deep cells in the pyriform cortex. The intrinsic nature of these cells appears to be an important contributor to the establishment of synchronized bursting in these regions. Another apparent requirement in such a population is for a certain degree of synaptic interaction among neurons, such that discharge of even one cell enlists the activity of its neighbors. Given the presence of these bursting cells and the occurrence of excitatory interactions among them in normal tissue, it may actually be the morphologic substrate for epileptiform discharges.

Another hyptothesis has focused particularly on the role of N-methyl-D-aspartate (NMDA) receptors. Various factors regulate the efficacy of NMDA receptors: their

voltage-dependent blockade by magnesium and modulation by glycine and polyamines. For example, in the low magnesium model, spontaneous synchronous burst discharge in hippocampal pyramidal cell populations is sensitive to NMDA antagonists. That finding suggests that it is the opening of NMDA channels, by relieving the magnesium blockade, that facilitates epileptiform activity.

Significant attention in the literature is also being given to gamma-amino butyric acid (GABA) receptors for the potential role in control of excitability. Changes in GABA inhibitory efficacy can lead to important effects on the excitability of the system. GABAergic inhibitory post-synaptic potentials (IPSPs) have been shown to be quite labile in response to repetitive activation of cortical cell populations, as may occur during epileptiform discharge. Scientists have shown that even a small percentage change in GABA inhibition can have profound effects on neocortical epileptogenesis. These changes in GABAergic inhibition may be the key to an explanation of how repetitive discharge patterns give rise to ictal discharge. Further, there appears to be a significant increase in excitatory postsynaptic potential (EPSP) frequency prior to seizure initiation an observation that is consistent with loss of IPSP efficacy prior to ictal onset.

The above hypotheses describe different mechanisms of epileptogenesis, but it is quite possible that all of these mechanisms take place, and they reflect large variety of types of epileptic seizures. The common principle of the mechanisms proposed is the change of membrane properties (i.e., conductance, permeability etc.) of certain neurons which results in depolarization and burst discharging. Some factors (e.g., trauma) can affect these specific neurons and initiate synchrony for neurons that control internal communication and communication with various muscle systems not associated with vital functions (i.e., heart beating, breathing). High strength pulsed electric fields could also be such a factor.

Mechanism to Reproduce the Desired Effects

Application of electromagnetic pulses is also a conceptual nonlethal technology that uses electromagnetic energy to induce neural synchrony and disruption of voluntary muscle control. The effectiveness of this concept has not been demonstrated. However, from past work in evaluating the potential for electromagnetic pulse generators to affect humans, it is estimated that sufficiently strong internal fields can be generated within the brain to trigger neurons. Estimates are that 50 to 100 kV/m free field of very sharp pulses (~ 1 nS) are required to produce a cell membranic potential of approximately 2 V; this would probably be sufficient to trigger neurons or make them more susceptible to firing.

The electromagnetic pulse concept is one in which a very fast (nanosecond timeframe) high voltage (approximately 100 kV/m or greater) electromagnetic pulse is repeated at the alpha brain wave frequency (about 15 Hz). It is known that a similar frequency of pulsing light can trigger sensitive individuals (those with some degree of light-sensitivity epilepsy) into a seizure and it is thought that by using a method that could actually trigger nerve synapses directly with an electrical field, essentially 100% of individuals would be susceptible to seizure induction. The photic-induced seizure phenomenon was borne out

demonstrably on December 16, 1997 on Japanese television when hundreds of viewers of a popular cartoon show were treated, inadvertently, to photic seizure induction (figure 31). The photic-induced seizure is indirect in that the eye must receive and transmit the impulses which initially activate a portion of the brain associated with the optic nerve. From that point the excitability spreads to other portions of the brain. With the electromagnetic concept, excitation is directly on the brain, and all regions are excited concurrently. The onset of synchony and disruption of muscular control is anticipated to be nearly instantaneous. Recovery times are expected to be consistent with, or more rapid than, that which is observed in epileptic seizures.

Time to Onset

No experimental evidence is available for this concept. However, light-induced seizures latency onset in photosensitive epileptics varies from 0.1 to about 10 seconds. Because of the fact that the electrical impulses triggered by light must spread to other parts of the brain, photic-induced seizures are expected to have a generally slower onset than neural synchrony induced by high-strength pulsed electric fields.

Duration of Effect

For epileptic individuals, the typical duration of a petit mal event or a psychomotor event is 1 minute or 2, possibly longer, while the duration of a grand mal seizure is 1 to 5 minutes. In a non-epileptic individual who is induced by electromagnetic means, the durations of the different events are expected to be roughly the same as the epileptic individual's events after the external excitation is removed.

Tunability

There are many degrees of epileptic seizure in diseased persons, and it seems reasonable that electromagnetic stimulation of neural synchrony might be tunable with regard to type and degree of bodily influence, depending on the parameters associated with the chosen stimulus. Because there are no actual data to build on, these statements must be considered tentative. It is known that in the study of photic-induced seizures, parameters can be varied so that the individual under study does not actually undergo a grand mal seizure. This knowledge gives confidence that the proposed technology would be tunable.

Distribution of Human Sensitivities to Desired Effects

It is anticipated that 100% of the population would be susceptible. The mechanism is one that could act on many individual neuronal cells concurrently and hence does not depend on spreading regions of electrical activity as in the disease state.

Possible Influence on Subjects(s)

If the technology functions approximately as envisioned, the targeted individual could be incapacitated very quickly. Because there have been no reported studies using the

conditions specified, experimental work is required to characterize onset time. Different types of technologies could be employed to influence wide areas or single individuals. Because this technology is considered to be tunable, the influence on subjects could vary from mild disruption of concentration to muscle spasms and loss of consciousness. The subject(s) would have varying degrees of voluntary control depending on the chosen degree of incapacitation.

Technological Status of Generator/Aiming Device

An electric field strength of roughly 100 Kv/m over a time period of 1 nanosecond is approximately the condition thought to be necessary to produce the desired effect when provided to an overall repetition rate of 15 Hz. Such a field may be developed using a radar-like, high-peak-power, pulsed source or an electromagnetic pulse generator operated at 15 Hz. These technologies exist today sufficient to evaluate the disabling concept. Power requirements are not high because the duty factor is so low. Aiming devices are currently available, but a high degree of directionality at long distances will require development. It may be necessary to provide bursts of these nanosecond pulses in order to stimulate the desired effect. As the duty time increases so does the average power requirement for power source. Because there were no open literature reports from which to make inferences, there is some uncertainty about the power levels required.

Range

The effective range could be hundreds of meters.

Defeat Capabilities/Limitations

Shielding can be provided by conductive barriers like metal or metal screen. There are a number of drugs that are capable of inducing convulsive seizures and others, like phenobarbital, diphenyllhydantoin, trimethadione, 2-4 dinitrophenol, and acetazolamide, which are anticonvulsive. Anticonvulsive drugs are known to be helpful in reducing the effect of seizures in epileptic patients, but their ability to reduce the effect of the proposed technology is unknown (possibly no effect) but expected to be less than for photic-induced seizures.

Incapacitating Effect; Acoustic Energy

The nature of the incapacitation consists of severe pressure sensations, nystagmus (a spasmodic, involuntary motion of the eyes), and nausea caused by high intensities of 9140-155 dB). Nystagmus occurs when convection currents are produced (cupula movement) in the lateral ear canal. This cupula movement causes the eyes to move involuntarily; hence, the external world is interpreted as moving. The subject "sees" his surroundings turning round him and at the same time experiences a sensation of turning. Persons exposed to these levels of sound experience nausea.

Biological Target/Normal Functions/Disease State

The two lateral semicircular canals, one located in each inner ear, alert a person to the fact that his upright head is experiencing angular acceleration. Within the ampulla of the canal are several so called hair cells. The cilia of these cells protrude into the lumen of the ampulla where they are encased in a mass of jelly-like material (the cupula) which is attached to the opposite wall of the canal. As the head accelerates, the cilia are bent by an inertial force of the cupula and the viscous liquid in the canal lumen. The bending of the cilia excites hair cells which in turn excite afferent neurons; these then alert the brain that a change of position of the head has occurred. Similar events occur when the head stops moving. The result of a strong hair cell stimulus to the brain is a rapid eye movement, call nystagmus, a feeling of dizziness and disorientation, and a possibility of nausea and vomiting.

Normal hearing is in the range between the frequencies of 20,000 to 16,000 Hz with the optimal sensitivity for most people between the frequencies of 500 to 6000 Hz.

Mechanism to Produce the Desired Effects

Because the end organs for acoustic and vestibular perception are so closely related, intense acoustic stimulation can result in vestibular effects. The hypothesis is that the sound of normal intensity produces oscillations of the endolymph and perilymph, compensated for by oscillations of the round window. High intensity sound produces eddy currents, which are localized rotational fluid displacements. High intensity sound can also produce nonlinear displacement of the stapes, causing a volume displacement, the result of which can be a fluid void in the labyrinth. To fill the void, fluid may be displaced along the endolymphatic duct and/or block capillary pathways, which, in turn, could stimulate vestibular receptors. Stimulation of the vestibular receptors may lead to nausea and vomiting if the sound pressure level is high enough. Conclude that both eddy currents and volume displacement serve to stimulate vestibular receptors in humans, when exposed to high levels of noise.

One study found nystagmum in guinea pigs exposed to high levels of infrasound via stimulation of the vestibular receptors. However, the same lab was unable to produce nystagmus in human subjects at 5- and 10-second exposures to a pure tone at 135 dB, broadband engine noise, or a 100 Hz tone at 120 dB, pulsed three times/s or 2 minutes. The same research was unable to elicit nystagmus at levels up to 155 dB, and also equally unable to produce nystagmus using infrasound levels of 112-150 dB in guinea pigs, monkeys, and humans. However, research with audible components in the sound spectrum with guinea pigs and monkeys produced nystagmus. Other researchers report other vestibular effects in addition to nystagmus at the following thresholds: 125 dB from 200-500 Hz, 140 dB at 1000 Hz, and 155 dB at 200 Hz. Decrements in vestibular function occur consistently for broadband noise levels of 140 dB (with hearing protection).

Human subjects listened to very high levels of low-frequency noise and infrasound in the protected or unprotected modes. Two-minute duration as high as 140 to 155 dB produced a range of effects from mild discomfort to severe pressure sensations, nausea, gagging,

and giddiness. Effects also included blurred vision and visual field distortions in some exposure conditions. The nature and degree of all effects was dependent on both sound level and frequency with the most severe effects occurring in the audible frequency range (as opposed to infrasound), at levels above about 145 dB. The investigators found no temporary threshold shift (TTS) among their subjects, and the use of hearing protectors greatly alleviated the adverse effects.

Since the early days of jet-engine testing and maintenance, anecdotal evidence has appeared linking exposure to intense noise, with such complaints as dizziness, vertigo, nausea, and vomiting. As a result of siren noise at 140 dB, subjects consistently reported a feeling of being pushed sideways, usually away from the exposed ear, and one subject reported difficulty standing on one foot.

These effects were not as dramatic as from the jet-engine (broadband) noise at 140 dB. This research concludes that the threshold of labyrinthine dysfunction is about 135 to 140 dB and that these effects occur during, but not after, exposure.

Time to Onset

No times to onset of nausea or nystagmus were identified in the literature but is presumed to be relatively immediate based on effects to the labyrinth system occurring during, but not after, exposure to sound pressure levels of 135 to 140 dB.

Duration of Effect

The incapacitation lasts only as long as the incapacitating sound is present.

Tunability

Based on the data presented above, it is unclear whether the degree of nausea or nystagmus is tunable, but similar symptoms caused by other stimuli are variable in degree.

Distribution of Human Sensitivities to Desired Effects

It is most probable that all individuals will be susceptible to this stimulus with the exception of those with a disease or defect (i.e., deaf mutes) of some part or parts of the vestibular system. Data showed no consistent decrease in vestibulo-ocular reflects with increased age.

Recovery/Safety

Normal subjects are likely to recover immediately and experience no or unmeasurable changes in hearing unless well known frequency-intensity-time factors are exceeded. This is based on studies which found no temporary threshold shift in hearing of subjects tested at low frequency. Occupational safety personnel generally recognize that 115

dB(A) is to be avoided and that 70 dB(A) is assumed safe. Is believed that the noise energy with predominating frequencies above 500 Hz have a greater potential for hearing loss than noise energy at lower frequencies. Occupational standards for noise state that a person may be exposed continuously for 8 hours to 90 dB(A) or 15 minutes to 115 dB(A).

Possible Influence on Subject(s)

Induction of nystagmus and nausea will have variable effects on individuals. Effects may be sufficiently incapacitation to allow offensive advantage; the perception of sickness may make a subject susceptible to persuasion. It would be difficult to target single individuals at the present level of sound directing technology. This technology may be better suited for groups of people.

Technological Status of Generator/Aiming Device

Sound generating technology is well developed but not highly portable. Aiming devices are poorly developed.

Range

Under normal circumstances the sound pressure level decreases 6 dB(A) when the distance from the source is doubled. For example if the sound is 100 dB(A) at 100 ft, at 200 ft the sound would be 94 dB(A). At very high sound levels, certain conditions may lead to nonlinear effects in propagation and greatly increase range accuracy.

Defeat Capabilities/Limitations

Negative effects of audible sound are greatly decreased if hearing protection is worn. High frequency sound is more easily blocked than low frequency sound due to wavelength effects.

Laser-Induced Biological Effects

Their are three basic damage mechanisms associated with exposure to laser radiation: chemical, thermal, and mechanical or acoustic-mechanical.

The laser-induced, chemical alterations in irradiated tissue are referred to as photochemical damage. The likelihood of laser radiation in the blue-light portion of the electromagnetic spectrum (.380 to .550 microns) inducing photochemical reactions progressively decreases with increasing wavelength. Photochemical effects are not observed upon exposure to radiation with wavelengths exceeding .550 to .650 microns because the kinetic energy associated with these photons is insufficient to initiate a photochemical change.

On the other hand, the thermal effect is a primary mechanism for laser-induced injury. The extent of the injuries induced depends upon the wavelength and energy of the incident radiation, duration of exposure, and the nature of the exposed tissue and its absorption characteristics. Generally, this mechanism predominates in the visible and the near-infrared (.760 to 1.4 microns) portions of the electromagnetic spectrum and for almost all CW and pulsed exposures between 0.1 milliseconds and 1 to 5 seconds.

The third injury mechanism associated with exposure to laser radiation is the mechanical or acoustical-mechanical effect. The radiant energy is absorbed into the tissue and, as a result of rapid thermal expansion following a short (1 nanosecond to 0.1 millisecond) laser radiation pulse, a pressure wave is generated that may result in explosive tissue injury.

Generally, all three mechanisms operate concurrently in an irradiated animal. Thermal effects currently predominate for continuous wave (CW) lasers, while mechanical effects are of increased significance for pulsed-mode lasers. With even higher power, one must also consider nonlinear phenomena such as multiphoton absorption and electromagnetic field effects.

The organs most susceptible to external laser radiation are the skin and eyes. The severity of injury is affected by the nature of the target, the energy density delivered to the target, the frequency and power of the laser, atmospheric attenuation of the beam, and the use of filtering or amplifying optics by the target, etc.

The primary effect on the skin is thermal damage (burns). The severity varies from slight erythema or reddening to severe blistering or charring, depending on such factors as total energy deposition, skin pigmentation, and the tissue's ability to dissipate heat.

The eye is particularly susceptible to intense pulse of laser radiation because of its unique sensitivity to light. The focusing effect is similar to that of a magnifying lens, which focuses the energy on a particular spot. Since the cornea and lens of the eye amplify the intensity of the light incident upon the retina, the retina is extremely sensitive to visible and near-infrared light, and damage to the retina may result in temporary or permanent loss of visual acuity. Laser eye injuries vary according to incident power, spot size, beam angle, temporal mode (CW or pulsed), and pulse repetition frequency. Reported effects include corneal lesions, burns, cataracts, and retinal lesions.

Some high-power lasers can cause antipersonnel effects by the deposition of thermal energy. These lasers must operate at a wavelength that is readily absorbed by the skin or the cornea. These generally include the far- and mid-IR regions (10 to 12 microns and 3 to 5 microns) as well as the ultraviolet region (<0.4 microns). However, ultraviolet wavelengths generally do not propagate well in the atmosphere, so the primary threat wavelengths to be considered are between 3 and 12 microns. Although relatively modest amounts of far-IR laser power are required to produce superficial burns on the skin at short ranges, and efforts to design rheostatically lethal laser weapons are on going.

Nonlethal blinding laser weapons generally use collimated beams with very low beam divergence, and the energy contained in the beam diminishes relatively slowly over great distances. Imaging systems such as eyes and EO vision systems have focusing optics that bring the incident plane wave of light to focus at the sensor plane. This results in a high optical gain (greater than 100,000 for eyes), which makes the associated sensor vulnerable to relatively low fluences of laser energy.

The effects of lasers on eyes are threefold:

- Dazzling or induced glare.
- Flashblinding or loss of night adaptation.
- Permanent or semipermanent blinding.

The severity of laser eye injuries varies according to the incident power, spot size, beam angle, pupil diameter (ambient light conditions), temporal mode (CW or pulsed), and PRF of the laser. Reported effects include corneal burns, cataracts (a permanent cloudiness of the lens), and retinal burns and perforations. Low-energy laser weapons are capable of causing the latter.

Exposure to relatively low laser energies can produce temporary changes in the ability to see without producing permanent injury. Exposure to laser light can produce an effect called glare or dazzle, which is similar to the temporary loss of vision experience when viewing the headlights of an oncoming car. The visual effects last only as long as the light is present in the field of view (FOV). At slightly higher energy exposures, the same laser radiation can saturate or flashblind the photoreceptor cells, resulting in after images that fade with time after exposure. Only visible radiation will induce veiling glare or after images; near-IR radiation will not produce these effects even though the radiant energy reaches the photoreceptor cells. Flashblindness and dazzle, while not permanent injuries, can cause discomfort and temporary loss of vision. Some studies have shown that dazzle and flashblindness can seriously impact mission performance, especially in highly visual tasks such as piloting an aircraft or aiming.

Blinding is the permanent or semipermanent loss of visual acuity. The effect can last from several hours onward and generally is evidenced by a dark spot in the field of vision. This spot is called a scotoma. The impact of the scotoma on visual acuity will vary with the size and position of the injury. Human vision is greatly affected when the laser damage is to the central vision area of the retina called the fovea. Nonfoveal laser damage may be less severe or even go unnoticed because it affects only the peripheral vision. The most serious retinal injuries occur when the incident light is so intense that a perforation in the retina is formed, resulting in a hemorrhage into either the subretinal layer or, in the most severe cases, the vitreous humor of the eye. Less severe exposures result in lesions on the retina.

SECTION I

Preface

Prepared for the BioInitiative Working Group
July 2007

PREFACE

The Organizing Committee thanks the participants of the BioInitiative Working Group for their integrity and intellectual courage in dealing with this controversial and important topic; and for devoting the time and energy to produce their chapters. The information and conclusions in each chapter are the responsibilities of the authors of that chapter.

The Group has produced what the authors hope will be a benchmark for good science and public health policy planning. It documents bioeffects, adverse health effects and public health conclusions about impacts of non-ionizing radiation (electromagnetic fields including extremely-low frequency ELF-EMF and radiofrequency/microwave or RF-EMF fields).

Societal decisions about this body of science have global implications. Good public health policy depends on acting soon enough, but not without cause, and with enough information to guide intelligent actions. To a great degree, it is the definition of the standard of evidence used to judge the scientific reports that shapes this debate. Disagreement about when the evidence is sufficient to take action has more to do with the outcome of various reviews and standard-setting proceedings than any other single factor. Whatever "standard of evidence" is selected to assess the strength of the science will deeply influence the outcome of decisions on public policy.

We are at a critical juncture in this world-wide debate. The answers lie not only in the various branches of science; but necessarily depend on the involvement of public health and policy professionals, the regulatory, legal and environmental protection sectors, and the public sector.

This has been a long-term collaboration of international scientists employing a multi-disciplinary approach to problem assessment and solving. Our work has necessarily relied on tools and approaches across the physical, biological and engineering sciences; and those of the environmental scientist and public health professional. Only when taken

together can we see the whole and begin to take steps that can prevent possible harm and protect future generations.

SECTION I

Preface

Prepared for the BioInitiative Working Group
December 2012

PREFACE

Today, the BioInitiative 2012 Report updates five years of science, public health, public policy and global response to the growing health issue of chronic exposure to electromagnetic fields and radiofrequency radiation in the daily life of billions of people around the world.

The BioInitiative 2012 Report has been prepared by 29 authors from ten countries*, ten holding medical degrees (MDs), 21 PhDs, and three MsC, MA or MPHs. Among the authors are three former presidents of the Bioelectromagnetics Society, and five full members of BEMS. One distinguished author is the Chair of the Russian National Committee on Non-Ionizing Radiation. Another is a Senior Advisor to the European Environmental Agency. As in 2007, each author is responsible for their own chapter.

The great strength of the BioInitiative Report (www.bioinitiative.org) is that it has been done independent of governments, existing bodies and industry professional societies that have clung to old standards. Precisely because of this, the BioInitiative Report presents a solid scientific and public health policy assessment that is evidence-based.

The BioInitiative Report was first posted in August 2007. It still has a significant international viewing audience. Each year, about 1,000,000 people still visit the site. In the five years since it's publication, the BioInitiative website has been accessed over 10.5 million times, or four times every minute. Every five minutes on the average, a person somewhere in the world has logged on. More than 5.2 million files and 1 million pages of information has been downloaded. That is equivalent to more than 93,000 full copies of the 650+ page report (288.5 million kbytes).

The global conversation on why public safety limits for electromagnetic and radiofrequency fields remain thousands of time higher than exposure levels that health studies consistently show to be associated with serious health impacts has intensified since 2007. Roughly, 1800 new studies have been published in the last five years reporting effects at exposure levels ten to hundreds or thousands of times lower than allowed under safety limits in most countries of the world. Yet, no government has instituted comprehensive reforms. Some actions have been taken that highlight partial solutions. The Global Actions chapter presents milestone events that characterize the international 'sea change' of opinion that has taken place, and reports on precautionary advice and actions from around the world.

The world's populations – from children to the general public to scientists and physicians – are increasingly faced with great pressures from advertising urging the incorporation of the latest wireless device into their everyday lives. This is occurring even while an elementary understanding the possible health consequences is beyond the ability of most people to grasp. The exposures are invisible, the testing meters are expensive and technically difficult to operate, the industry promotes new gadgets and generates massive advertising and lobbying campaigns that silence debate, and the reliable, non-wireless alternatives (like wired telephones and utility meters) are being discontinued against public will. There is little labeling, and little or no informed choice. In fact there is often not even the choice to stay with safer, wired solutions, as in the case of the 'smart grid' and smart wireless utility metering, an extreme example of a failed corporate-governmental partnership strategy, ostensibly for energy conservation.

A collision of the wireless technology rollout and the costs of choosing unwisely is beginning and will grow. The groundwork for this collision is being laid as a result of increased exposure, especially to radiofrequency fields, in education, in housing, in commerce, in communications and entertainment, in medical technologies and imaging, and in public and private transportation by air, bus, train and motor vehicles. Special concerns are the care of the fetus and newborn, the care for children with learning disabilities, and consideration of people under protections of the Americans With Disabilities Act, which includes people who have become sensitized and physiologically intolerant of chronic exposures. The 2012 Report now addresses these issues as well as presenting an update of issues previously discussed.

Table of Contents

I. SUMMARY FOR THE PUBLIC

A. Introduction

You cannot see it, taste it or smell it, but it is one of the most pervasive environmental exposures in industrialized countries today. Electromagnetic radiation (EMR) or electromagnetic fields (EMFs) are the terms that broadly describe exposures created by the vast array of wired and wireless technologies that have altered the landscape of our lives in countless beneficial ways. However, these technologies were designed to maximize energy efficiency and convenience; not with biological effects on people in mind. Based on new studies, there is growing evidence among scientists and the public about possible health risks associated with these technologies.

Human beings are bioelectrical systems. Our hearts and brains are regulated by internal bioelectrical signals. Environmental exposures to artificial EMFs can interact with fundamental biological processes in the human body. In some cases, this can cause discomfort and disease. Since World War II, the background level of EMF from electrical sources has risen exponentially, most recently by the soaring popularity of wireless technologies such as cell phones (two billion and counting in 2006), cordless phones, WI-FI and WI-MAX networks. Several decades of international scientific research confirm that EMFs are biologically active in animals and in humans, which could have major public health consequences.

In today's world, everyone is exposed to two types of EMFs: (1) extremely low frequency electromagnetic fields (ELF) from electrical and electronic appliances and power lines and (2) radiofrequency radiation (RF) from wireless devices such as cell phones and cordless phones, cellular antennas and towers, and broadcast transmission towers. In this report we will use the term EMFs when referring to all electromagnetic fields in general; and the terms ELF and RF when referring to the specific type of exposure. They are both types of non-ionizing radiation, which means that they do not have sufficient energy to break off electrons from their orbits around atoms and ionize (charge) the atoms, as do x-rays, CT scans, and other forms of ionizing radiation. A glossary and definitions are provided in Section 18 to assist you. Some handy definitions you will probably need when reading about ELF and RF in this summary section (the language for measuring it) are shown with the references for this section.

B. Purpose of the Report

This report has been written by 14 (fourteen) scientists, public health and public policy experts to document the scientific evidence on electromagnetic fields. Another dozen outside reviewers have looked at and refined the Report.

The purpose of this report is to assess scientific evidence on health impacts from electromagnetic radiation below current public exposure limits and evaluate what changes in these limits are warranted now to reduce possible public health risks in the future.

Not everything is known yet about this subject; but what is clear is that the existing public safety standards limiting these radiation levels in nearly every country of the world look to be thousands of times too lenient. Changes are needed.

New approaches are needed to educate decision-makers and the public about sources of exposure and to find alternatives that do not pose the same level of possible health risks, while there is still time to make changes.

A working group composed of scientists, researchers and public health policy professionals (The BioInitiative Working Group) has joined together to document the information that must be considered in the international debate about the adequacy (or inadequacy) of existing public exposure standards.

This Report is the product of an international research and public policy initiative to give an overview of what is known of biological effects that occur at low-intensity EMFs exposures (for both radiofrequency radiation RF and power-frequency ELF, and various forms of combined exposures that are now known to be bioactive). The Report examines the research and current standards and finds that these standards are far from adequate to protect public health.

Recognizing that other bodies in the United States, United Kingdom, Australia, many European Union and eastern European countries as well as the World Health Organization are actively debating this topic, the BioInitiative Working Group has conducted a independent science and public health policy review process. The report presents solid science on this issue, and makes recommendations to decision-makers and the public. Conclusions of the individual authors, and overall conclusions are given in Table 2-1 (BioInitiative Overall Summary Chart).

Eleven (11) chapters that document key scientific studies and reviews identifying low-intensity effects of electromagnetic fields have been written by members of the BioInitiative Working Group. Section 16 and 17 have been prepared by public health and policy experts. These sections discusses the standard of evidence which should be applied in public health planning, how the scientific information should be evaluated in the context of prudent public health policy, and identifies the basis for taking precautionary and preventative actions that are proportionate to the knowledge at hand. They also evaluate the evidence for ELF that leads to a recommendation for new public safety limits (not precautionary or preventative actions, as need is demonstrated).

Other scientific review bodies and agencies have reached different conclusions than we have by adopting standards of evidence so unreasonably high as to exclude any conclusions likely to lead to new public safety limits. Some groups are actually recommending a relaxation of the existing (and inadequate) standards. Why is this happening? One reason is that exposure limits for ELF and RF are developed by bodies of scientists and engineers that belong to professional societies who have traditionally developed recommendations; and then government agencies have adopted those recommendations. The standard-setting processes have little, if any, input from other stakeholders outside professional engineering and closely-related commercial interests. Often, the industry view of allowable risk and proof of harm is most influential, rather than what public health experts would determine is acceptable.

Main Reasons for Disagreement among Experts

1) Scientists and public health policy experts use very different definitions of the standard of evidence used to judge the science, so they come to different conclusions about what to do. Scientists do have a role, but it is not exclusive and other opinions matter.
2) We are all talking about essentially the same scientific studies, but use a different way of measuring when "enough is enough" or "proof exists".
3) Some experts keep saying that all studies have to be consistent (turn out the same way every time) before they are comfortable saying an effect exists.
4) Some experts think that it is enough to look only at short-term, acute effects.
5) Other experts say that it is imperative we have studies over longer time (showing the effects of chronic exposures) since that is what kind of world we live in.
6) Some experts say that everyone, including the very young, the elderly, pregnant women, and people with illnesses have to be considered – others say only the average person (or in the case of RF, a six-foot tall man) matter.
7) There is no unexposed population, making it harder to see increased risk of diseases.
8) The lack of consensus about a single biological mechanism of action.
9) The strength of human epidemiological studies reporting risks from ELF and RF exposures, but animal studies don't show a strong toxic effect.
10) Vested interests have a substantial influence on the health debate.

Public Policy Decisions

Safety limits for public exposure to EMFs need to be developed on the basis of interaction among not only scientists, but also public health experts, public policy makers and the general public.

"In principle, the assessment of the evidence should combine with judgment based on other societal values, for example, costs and benefits, acceptability of risks, cultural preferences, etc. and result in sound and effective decision-making. Decisions on these matters are eventually taken as a function of the views, values and interests of the stakeholders participating in the process, whose opinions are then weighed depending on several factors. Scientific evidence perhaps carries, or should carry, relatively heavy weight, but grants no exclusive status; decisions will be evidence-based but will also be based on other factors." (1)

The clear consensus of the BioInitiative Working Group members is that the existing public safety limits are inadequate for both ELF and RF.

These proposals reflect the evidence that a positive assertion of safety with respect to chronic exposure to low-intensity levels of ELF and RF cannot be made. As with many other standards for environmental exposures, these proposed limits may not be totally protective, but more stringent standards are not realistic at the present time. Even a small increased risk for cancer and neurodegenerative diseases translates into an enormous public health consequence. Regulatory action for ELF and preventative actions for RF are warranted at this time to reduce exposures and inform the public of the potential for increased risk; at what levels of chronic exposure these risks may be present; and what measures may be taken to reduce risks.

C. Problems with Existing Public Health Standards (Safety Limits)

Today's public exposure limits for telecommunications are based on the presumption that heating of tissue (for RF) or induced electric currents in the body (for ELF) are the only concerns when living organisms are exposed to RF. These exposures can create tissue heating that is well known to be harmful in even very short-term doses. As such, thermal limits do serve a purpose. For example, for people whose occupations require them to work around radar facilities or RF heat-sealers, or for people who install and service wireless antenna tower, thermally-based limits are necessary to prevent damage from heating (or, in the case of power-frequency ELF from induced current flow in tissues). In the past, scientists and engineers developed exposure standards for electromagnetic radiation based what we now believe are faulty assumptions that the right way to measure how much non-ionizing energy humans can tolerate (how much exposure) without harm is to measure only the heating of tissue (RF) or induced currents in the body (ELF).

In the last few decades, it has been established beyond any reasonable doubt that bioeffects and some adverse health effects occur at far lower levels of RF and ELF exposure where no heating (or induced currents) occurs at all; some effects are shown to occur at several hundred thousand times below the existing public safety limits where heating is an impossibility.

It appears it is the INFORMATION conveyed by electromagnetic radiation (rather than heat) that causes biological changes - some of these biological changes may lead to loss of wellbeing, disease and even death.

Effects occur at non-thermal or low-intensity exposure levels thousands of times below the levels that federal agencies say should keep the public safe. For many new devices operating with wireless technologies, the devices are exempt from any regulatory standards. The existing standards have been proven to be inadequate to control against harm from low-intensity, chronic exposures, based on any reasonable, independent assessment of the scientific literature. It means that an entirely new basis (a biological basis) for new exposure standards is needed. New standards need to take into account what we have learned about the effects of ELF and RF (all non-ionizing electromagnetic radiation and to design new limits based on biologically-

demonstrated effects that are important to proper biological function in living organisms. It is vital to do so because the explosion of new sources has created unprecedented levels of artificial electromagnetic fields that now cover all but remote areas of the habitable space on earth. Mid-course corrections are needed in the way we accept, test and deploy new technologies that expose us to ELF and RF in order to avert public health problems of a global nature.

Recent opinions by experts have documented deficiencies in current exposure standards. There is widespread discussion that thermal limits are outdated, and that biologically-based exposure standards are needed. Section 4 describes concerns expressed by WHO, 2007 in its ELF Health Criteria Monograph; the SCENIHR Report, 2006 prepared for the European Commission; the UK SAGE Report, 2007; the Health Protection Agency, United Kingdom in 2005; the NATO Advanced Research Workshop in 2005; the US Radiofrequency Interagency Working Group in 1999; the US Food and Drug Administration in 2000 and 2007; the World Health Organization in 2002; the International Agency for Cancer Research (IARC, 2001), the United Kingdom Parliament Independent Expert Group Report on Mobile Phones – Stewart Report, 2000) and others.

A pioneer researcher, the late Dr. Ross Adey, in his last publication in Bioelectromagnetic Medicine (P. Roche and M. Markov, eds. 2004) concluded:

> "*There are major unanswered questions about possible health risks that may arise from exposures to various man-made electromagnetic fields where these human exposures are intermittent, recurrent, and may extend over a significant portion of the lifetime of the individual."*
>
> *"Epidemiological studies have evaluated ELF and radiofrequency fields as possible risk factors for human health, with historical evidence relating rising risks of such factors as progressive rural electrification, and more recently, to methods of electrical power distribution and utilization in commercial buildings. Appropriate models describing these bioeffects are based in non-equilibrium thermodynamics, with nonlinear electrodynamics as an integral feature. Heating models, based in equilibrium thermodynamics, fail to explain an impressive new frontier of much greater significance. ..... Though incompletely understood, tissue free radical interactions with magnetic fields may extend to zero field levels." (2)*

There may be no lower limit at which exposures do not affect us. Until we know if there is a lower limit below which bioeffects and adverse health impacts do not occur, it is unwise from a public health perspective to continue "business-as-usual" deploying new technologies that increase ELF and RF exposures, particularly involuntary exposures.

II. SUMMARY OF THE SCIENCE

A. Evidence for Cancer

1. Childhood Leukemia

The evidence that power lines and other sources of ELF are consistently associated with higher rates of childhood leukemia has resulted in the International Agency for Cancer Research (an arm of the World Health Organization) to classify ELF as a Possible Human Carcinogen (in the Group 2B carcinogen list). Leukemia is the most common type of cancer in children.

There is little doubt that exposure to ELF causes childhood leukemia.

The exposure levels for increased risk are quite low – just above background or ambient levels and much lower than current exposure limits. The existing ICNIRP limit is 1000 mG (904 mG in the US) for ELF. Increased risk for childhood leukemia starts at levels almost one thousand times below the safety standard. Leukemia risks for young boys are reported in one study to double at only 1.4 mG and above (7) Most other studies combine older children with younger children (0 to 16 years) so that risk levels do not reach statistical significance until exposure levels reach 2 mG or 3 mG. Although some reviews have combined studies of childhood leukemia in ways that indicate the risk level starts at 4 mG and above; this does not reflect many of the studies reporting elevated risks at the lower exposure levels of 2 mG and 3 mG.

2. Other Childhood Cancers

Other childhood cancers have been studied, including brain tumors, but not enough work has been done to know if there are risks, how high these risks might be or what exposure levels might be associated with increased risks. The lack of certainty about other childhood cancers should not be taken to signal the "all clear"; rather it is a lack of study.

The World Health Organization ELF Health Criteria Monograph No 322 (2007) says that other childhood cancers "cannot be ruled out". (8)

There is some evidence that other childhood cancers may be related to ELF exposure but not enough studies have been done.

Several recent studies provide even stronger evidence that ELF is a risk factor for childhood leukemia and cancers later in life. In the first study (9), children who were recovering in high-ELF environments had poorer survival rates (a 450% increased risk of dying if the ELF fields were 3 mG and above). In the second study, children who were recovering in 2 mG and above ELF environments were 300% more likely to die than children exposed to 1 mG and below. In

this second study, children recovering in ELF environments between 1 and 2 mG also had poorer survival rates, where the increased risk of dying was 280%. (10) These two studies give powerful new information that ELF exposures in children can be harmful at levels above even 1 mG. The third study looked what risks for cancer a child would have later in life, if that child was raised in a home within 300 meters of a high-voltage electric power line. (11) For children who were raised for their first five years of life within 300 meters, they have a life-time risk that is 500% higher for developing some kinds of cancers.

Children who have leukemia and are in recovery have poorer survival rates if their ELF exposure at home (or where they are recovering) is between 1mG and 2 mG in one study; over 3 mG in another study.

Given the extensive study of childhood leukemia risks associated with ELF, and the relatively consistent findings that exposures in the 2 mG to 4 mG range are associated with increased risk to children, a 1 mG limit for habitable space is recommended for new construction. While it is difficult and expensive to retrofit existing habitable space to a 1 mG level, and is also recommended as a desirable target for existing residences and places where children and pregnant women may spend prolonged periods of time.

New ELF public exposure limits are warranted at this time, given the existing scientific evidence and need for public health policy intervention and prevention.

3. Brain Tumors and Acoustic Neuromas

Radiofrequency radiation from cell phone and cordless phone exposure has been linked in more than one dozen studies to increased risk for brain tumors and/or acoustic neuromas (a tumor in the brain on a nerve related to our hearing).

People who have used a cell phone for ten years or more have higher rates of malignant brain tumor and acoustic neuromas. It is worse if the cell phone has been used primarily on one side of the head.

For brain tumors, people who have used a cell phone for 10 years or longer have a 20% increase in risk (when the cell phone is used on both sides of the head). For people who have used a cell phone for 10 years or longer predominantly on one side of the head, there is a 200% increased risk of a brain tumor. This information relies on the combined results of many brain tumor/cell phone studies taken together (a meta-analysis of studies).

People who have used a cordless phone for ten years or more have higher rates of malignant brain tumor and acoustic neuromas. It is worse if the cordless phone has been used primarily on one side of the head.

The risk of brain tumor (high-grade malignant glioma) from cordless phone use is 220% higher (both sides of the head). The risk from use of a cordless phone is 470% higher when used mostly on only one side of the head.

For acoustic neuromas, there is a 30% increased risk with cell phone use at ten years and longer; and a 240% increased risk of acoustic neuroma when the cell phone is used mainly on one side of the head. These risks are based on the combined results of several studies (a meta-analysis of studies).

For use of cordless phones, the increased risk of acoustic neuroma is three-fold higher (310%) when the phone is mainly used on one side of the head.

The current standard for exposure to the emissions of cell phones and cordless phones is not safe considering studies reporting long-term brain tumor and acoustic neuroma risks.

Other indications that radiofrequency radiation can cause brain tumors comes from exposures to low-level RF other than from cell phone or cordless phone use. Studies of people who are exposed in their work (occupational exposure) show higher brain tumor rates as well. Kheifets (1995) reported a 10% to 20% increased risk of brain cancer for those employed in electrical occupations. This meta-analysis surveyed 29 published studies of brain cancer in relation to occupational EMFs exposure or work in electrical occupations. (6). The evidence for a link between other sources of RF exposure like working at a job with EMFs exposure is consistent with a moderately elevated risk of developing brain tumors.

4. *Other Adult Cancers*

There are multiple studies that show statistically significant relationships between occupational exposure and leukemia in adults (see Chapter 11), in spite of major limitations in the exposure assessment. A very recent study by Lowenthal et al. (2007) investigated leukemia in adults in relation to residence near to high-voltage power lines. While they found elevated risk in all adults living near to the high voltage power lines, they found an OR of 3.23 (95% CI = 1.26-8.29) for individuals who spent the first 15 years of life within 300 m of the power line. This study provides support for two important conclusions: adult leukemia is also associated with EMF exposure, and exposure during childhood increases risk of adult disease.

A significant excess risk for adult brain tumors in electrical workers and those adults with occupational EMF exposure was reported in a meta-analysis (review of many individual studies) by Kheifets et al., (1995). This is about the same size risk for lung cancer and secondhand smoke (US DHHS, 2006). A total of 29 studies with populations from 12 countries were included in this meta-analysis. The relative risk was reported as 1.16 (CI = 1.08 – 1.24) or a 16% increased risk

for all brain tumors. For gliomas, the risk estimate was reported to be 1.39 (1.07 – 1.82) or a 39% increased risk for those in electrical occupations. A second meta-analysis published by Kheifets et al., ((2001) added results of 9 new studies published after 1995. It reported a new pooled estimate (OR = 1.16, 1.08 – 1.01) that showed little change in the risk estimate overall from 1995.

The evidence for a relationship between exposure and breast cancer is relatively strong in men (Erren, 2001), and some (by no means all) studies show female breast cancer also to be elevated with increased exposure (see Chapter 12). Brain tumors and acoustic neuromas are more common in exposed persons (see Chapter 10). There is less published evidence on other cancers, but Charles et al. (2003) report that workers in the highest 10% category for EMF exposure were twice as likely to die of prostate cancer as those exposed at lower levels (OR 2.02, 95% CI = 1.34-3.04). Villeneuve et al. (2000) report statistically significant elevations of non-Hodgkin's lymphoma in electric utility workers in relation to EMF exposure, while Tynes et al. (2003) report elevated rates of malignant melanoma in persons living near to high voltage power lines. While these observations need replication, they suggest a relationship between exposure and cancer in adults beyond leukemia.

In total the scientific evidence for adult disease associated with EMF exposure is sufficiently strong for adult cancers that preventive steps are appropriate, even if not all reports have shown exactly the same positive relationship. This is especially true since many factors reduce our ability to see disease patterns that might be related to EMF exposure: there is no unexposed population for comparison, for example, and other difficulties in exposure assessment, The evidence for a relationship between EMF exposure and adult cancers and neurodegenerative diseases is sufficiently strong at present to merit preventive actions to reduce EMF exposure.

5. *Breast Cancer*

There is rather strong evidence from multiple areas of scientific investigation that ELF is related to breast cancer. Over the last two decades there have been numerous epidemiological studies (studies of human illness) on breast cancer in both men and women, although this relationship remains controversial among scientists. Many of these studies report that ELF exposures are related to increased risk of breast cancer (not all studies report such effects, but then, we do not expect 100% or even 50% consistency in results in science, and do not require it to take reasonable preventative action).

The evidence from studies on women in the workplace rather strongly suggests that ELF is a risk factor for breast cancer for women with long-term exposures of 10 mG and higher.

Breast cancer studies of people who work in relatively high ELF exposures (10 mG and above) show higher rates of this disease. Most studies of workers who are exposed to ELF have defined high exposure levels to be somewhere between 2 mG and 10 mG; however this kind of mixing of relatively low to relatively high ELF exposure just acts to dilute out real risk levels. Many of the occupational studies group exposures so that the highest group is exposed to 4 mG and above. What this means is that a) few people are exposed to much higher levels and b) illness patterns show up at relatively low ELF levels of 4 mG and above. This is another way of demonstrating

that existing ELF limits that are set at 933-1000 mG are irrelevant to the exposure levels reporting increased risks.

Laboratory studies that examine human breast cancer cells have shown that ELF exposure between 6 mG and 12 mG can interfere with protective effects of melatonin that fights the growth of these breast cancer cells. For a decade, there has been evidence that human breast cancer cells grow faster if exposed to ELF at low environmental levels. This is thought to be because ELF exposure can reduce melatonin levels in the body. The presence of melatonin in breast cancer cell cultures is known to reduce the growth of cancer cells. The absence of melatonin (because of ELF exposure or other reasons) is known to result in more cancer cell growth.

Laboratory studies of animals that have breast cancer tumors have been shown to have more tumors and larger tumors when exposed to ELF and a chemical tumor promoter at the same time. These studies taken together indicate that ELF is a likely risk factor for breast cancer, and that ELF levels of importance are no higher than many people are exposed to at home and at work. A reasonable suspicion of risk exists and is sufficient evidence on which to recommend new ELF limits; and to warrant preventative action.

Given the very high lifetime risks for developing breast cancer, and the critical importance of prevention; ELF exposures should be reduced for all people who are in high ELF environments for prolonged periods of time.

Reducing ELF exposure is particularly important for people who have breast cancer. The recovery environment should have low ELF levels given the evidence for poorer survival rates for childhood leukemia patients in ELF fields over 2 mG or 3 mG. Preventative action for those who may be at higher risk for breast cancer is also warranted (particularly for those taking tamoxifen as a way to reduce the risk of getting breast cancer, since in addition to reducing the effectiveness of melatonin, ELF exposure may also reduce the effectiveness of tamoxifen at these same low exposure levels). There is no excuse for ignoring the substantial body of evidence we already have that supports an association between breast cancer and ELF exposure; waiting for conclusive evidence is untenable given the enormous costs and societal and personal burdens caused by this disease.

Studies of human breast cancer cells and some animal studies show that ELF is likely to be a risk factor for breast cancer. There is supporting evidence for a link between breast cancer and exposure to ELF that comes from cell and animal studies, as well as studies of human breast cancers.

These are just some of the cancer issues to discuss. It may be reasonable now to make the assumption that all cancers, and other disease endpoints might be related to, or worsened by exposures to EMFs (both ELF and RF).

If one or more cancers are related, why would not all cancer risks be at issue? It can no longer be said that the current state of knowledge rules out or precludes risks to human health. The

enormous societal costs and impacts on human suffering by not dealing proactively with this issue require substantive public health policy actions; and actions of governmental agencies charged with the protection of public health to act on the basis of the evidence at hand.

B. Changes in the Nervous System and Brain Function

Exposure to electromagnetic fields has been studies in connection with Alzheimer's disease, motor neuron disease and Parkinson's disease. (4) These diseases all involve the death of specific neurons and may be classified as neurodegenerative diseases. There is evidence that high levels of amyloid beta are a risk factor for Alzheimer's disease, and exposure to ELF can increase this substance in the brain. There is considerable evidence that melatonin can protect the brain against damage leading to Alzheimer's disease, and also strong evidence that exposure to ELF can reduce melatonin levels. Thus it is hypothesized that one of the body's main protections against developing Alzheimer's disease (melatonin) is less available to the body when people are exposed to ELF. Prolonged exposure to ELF fields could alter calcium (Ca2+) levels in neurons and induce oxidative stress (4). It is also possible that prolonged exposure to ELF fields may stimulate neurons (particularly large motor neurons) into synchronous firing, leading to damage by the buildup of toxins.

Evidence for a relationship between exposure and the neurodegenerative diseases, Alzheimer's and amyotrophic lateral sclerosis (ALS), is strong and relatively consistent (see Chapter 12). While not every publication shows a statistically significant relationship between exposure and disease, ORs of 2.3 (95% CI = 1.0-5.1 in Qio et al., 2004), of 2.3 (95% CI = 1.6-3.3 in Feychting et al., 2003) and of 4.0 (95% CI = 1.4-11.7 in Hakansson et al., 2003) for Alzheimer's Disease, and of 3.1 (95% CI = 1.0-9.8 in Savitz et al., 1998) and 2.2 (95% CI = 1.0-4.7 in Hakansson et al., 2003) for ALS cannot be simply ignored.

Alzheimer's disease is a disease of the nervous system. There is strong evidence that long-term exposure to ELF is a risk factor for Alzheimer's disease.

Concern has also been raised that humans with epileptic disorders could be more susceptible to RF exposure. Low-level RF exposure may be a stressor based on similarities of neurological effects to other known stressors; low-level RF activates both endogenous opioids and other substances in the brain that function in a similar manner to psychoactive drug actions. Such effects in laboratory animals mimic the effects of drugs on the part of the brain that is involved in addiction.

Laboratory studies show that the nervous system of both humans and animals is sensitive to ELF and RF. Measurable changes in brain function and behavior occur at levels associated with new technologies including cell phone use. Exposing humans to cell phone radiation can change brainwave activity at levels as low as 0.1 watt per kilogram SAR (W/Kg)*** in comparison to the US allowable level of 1.6 W/Kg and the International Commission for Non-ionizing Radiation Protection (ICNIRP) allowable level of 2.0 W/Kg. It can affect memory and learning. It can affect normal brainwave activity. ELF and RF exposures at low levels are able to change behavior in animals.

There is little doubt that electromagnetic fields emitted by cell phones and cell phone use affect electrical activity of the brain.

Effects on brain function seem to depend in some cases on the mental load of the subject during exposure (the brain is less able to do two jobs well simultaneously when the same part of the brain is involved in both tasks). Some studies show that cell phone exposure speeds up the brain's activity level; but also that the efficiency and judgment of the brain are diminished at the same time. One study reported that teenage drivers had slowed responses when driving and exposed to cell phone radiation, comparable to response times of elderly people. Faster thinking does not necessarily mean better quality thinking.

Changes in the way in which the brain and nervous system react depend very much on the specific exposures. Most studies only look at short-term effects, so the long-term consequences of exposures are not known.

Factors that determine effects can depend on head shape and size, the location, size and shape of internal brain structures, thinness of the head and face, hydration of tissues, thickness of various tissues, dialectric constant of the tissues and so on. Age of the individual and state of health also appear to be important variables. Exposure conditions also greatly influence the outcome of studies, and can have opposite results depending on the conditions of exposure including frequency, waveform, orientation of exposure, duration of exposure, number of exposures, any pulse modulation of the signal, and when effects are measured (some responses to RF are delayed). There is large variability in the results of ELF and RF testing, which would be expected based on the large variability of factors that can influence test results. However, it is clearly demonstrated that under some conditions of exposure, the brain and nervous system functions of humans are altered. The consequence of long-term or prolonged exposures have not been thoroughly studied in either adults or in children.

The consequence of prolonged exposures to children, whose nervous systems continue to develop until late adolescence, is unknown at this time. This could have serious implications to adult health and functioning in society if years of exposure of the young to both ELF and RF result in diminished capacity for thinking, judgment, memory, learning, and control over behavior.

People who are chronically exposed to low-level wireless antenna emissions report symptoms such as problems in sleeping (insomnia), fatigue, headache, dizziness, grogginess, lack of concentration, memory problems, ringing in the ears (tinnitus), problems with balance and orientation, and difficulty in multi-tasking. In children, exposures to cell phone radiation have resulted in changes in brain oscillatory activity during some memory tasks. Although scientific studies as yet have not been able to confirm a cause-and-effect relationship; these complaints are

widespread and the cause of significant public concern in some countries where wireless technologies are fairly mature and widely distributed (Sweden, Denmark, France, Germany, Italy, Switzerland, Austria, Greece, Israel). For example, the roll-out of the new 3rd Generation wireless phones (and related community-wide antenna RF emissions in the Netherlands) caused almost immediate public complaints of illness.(5)

Conflicting results from those few studies that have been conducted may be based on the difficulty in providing non-exposed environments for testing to compare to environments that are intentionally exposed. People traveling to laboratories for testing are pre-exposed to a multitude of RF and ELF exposures, so they may already be symptomatic prior to actual testing. Also complicating this is good evidence that RF exposures testing behavioral changes show delayed results; effects are observed after termination of RF exposure. This suggests a persistent change in the nervous system that may be evident only after time has passed, so is not observed during a short testing period.

The effects of long-term exposure to wireless technologies including emissions from cell phones and other personal devices, and from whole-body exposure to RF transmissions from cell towers and antennas is simply not known yet with certainty. However, the body of evidence at hand suggests that bioeffects and health impacts can and do occur at exquisitely low exposure levels: levels that can be thousands of times below public safety limits.

The evidence reasonably points to the potential for serious public health consequences (and economic costs), which will be of global concern with the widespread public use of, and exposure to such emissions. Even a small increase in disease incidence or functional loss of cognition related to new wireless exposures would have a large public health, societal and economic consequences. Epidemiological studies can report harm to health only after decades of exposure, and where large effects can be seen across "average" populations; so these early warnings of possible harm should be taken seriously now by decision-makers.

C. Effects on Genes (DNA)

Cancer risk is related to DNA damage, which alters the genetic blueprint for growth and development. If DNA is damaged (the genes are damaged) there is a risk that these damaged cells will not die. Instead they will continue to reproduce themselves with damaged DNA, and this is one necessary pre-condition for cancer. Reduced DNA repair may also be an important part of this story. When the rate of damage to DNA exceeds the rate at which DNA can be repaired, there is the possibility of retaining mutations and initiating cancer. Studies on how ELF and RF may affect genes and DNA is important, because of the possible link to cancer.
Even ten years ago, most people believed that very weak ELF and RF fields could not possibly have any effect at all on DNA and how cells work (or are damaged and cannot do their work properly). The argument was that these weak fields are do not possess enough energy (are not physically strong enough) to cause damage. However, there are multiple ways we already know about where energy is not the key factor in causing damage. For example, exposure to toxic chemicals can cause damage. Changing the balance of delicate biological processes, including

hormone balances in the body, can damage or destroy cells, and cause illness. In fact, many chronic diseases are directly related to this kind of damage that does not require any heating at all. Interference with cell communication (how cells interact) may either cause cancer directly or promote existing cancers to grow faster.

Using modern gene-testing techniques will probably give very useful information in the future about how EMFs targets and affects molecules in the body. At the gene level, there is some evidence now that EMFs (both ELF and RF) can cause changes in how DNA works. Laboratory studies have been conducted to see whether (and how) weak EMFs fields can affect how genes and proteins function. Such changes have been seen in some, but not all studies.

Small changes in protein or gene expression might be able to alter cell physiology, and might be able to cause later effects on health and well-being. The study of genes, proteins and EMFs is still in its infancy, however, by having some confirmation at the gene level and protein level that weak EMFs exposures do register changes may be an important step in establishing what risks to health can occur.

What is remarkable about studies on DNA, genes and proteins and EMFs is that there should be no effect at all if it were true that EMFs is too weak to cause damage. Scientists who believe that the energy of EMFs is insignificant and unlikely to cause harm have a hard time explaining these changes, so are inclined to just ignore them. The trouble with this view is that the effects are occurring. Not being able to explain these effects is not a good reason to consider them imaginary or unimportant.

The European research program (REFLEX) documented many changes in normal biological functioning in tests on DNA (3). The significance of these results is that such effects are directly related to the question of whether human health risks might occur, when these changes in genes and DNA happen. This large research effort produced information on EMFs effects from more than a dozen different researchers. Some of the key findings included:

> *"Gene mutations, cell proliferation and apoptosis are caused by or result in altered gene and protein expression profiles. The convergence of these events is required for the development of all chronic diseases."* (3)
>
> *"Genotoxic effects and a modified expression of numerous genes and proteins after EMF exposure could be demonstrated with great certainty."* (3)
>
> *"RF-EMF produced genotoxic effects in fibroblasts, HL-60 cells, granulosa cells of rats and neural progenitor cells derived from mouse embryonic stem cells."* (Participants 2, 3 and 4). (3)
>
> *"Cells responded to RF exposure between SAR levels of 0.3 and 2 W/Kg with a significant increase in single- and double-strand DNA breaks and in micronuclei frequency."* (Participants 2, 3 and 4). (3)
>
> *"In HL-60 cells an increase in intracellular generation of free radicals accompanying RF-EMF exposure could clearly be demonstrated."* (Participant 2). (3)
>
> *"The induced DNA damage was not based on thermal effects and arouses consideration about the environmental safety limits for ELF-EMF exposure." (3)*

"The effects were clearly more pronounced in cells from older donors, which could point to an age-related decrease of DNA repair efficiency of ELF-EMF induced DNA strand breaks." (3)

Both ELF and RF exposures can be considered genotoxic (will damage DNA) under certain conditions of exposure, including exposure levels that are lower than existing safety limits.

D. Effects on Stress Proteins (Heat Shock Proteins)

In nearly every living organism, there is a special protection launched by cells when they are under attack from environmental toxins or adverse environmental conditions. This is called a stress response, and what are produced are stress proteins (also known as heat shock proteins). Plants, animals and bacteria all produce stress proteins to survive environmental stressors like high temperatures, lack of oxygen, heavy metal poisoning, and oxidative stress (a cause of premature aging). We can now add ELF and RF exposures to this list of environmental stressors that cause a physiological stress response.

Very low-level ELF and RF exposures can cause cells to produce stress proteins, meaning that the cell recognizes ELF and RF exposures as harmful. This is another important way in which scientists have documented that ELF and RF exposures can be harmful, and it happens at levels far below the existing public safety standards.

An additional concern is that if the stress goes on too long, the protective effect is diminished. There is a reduced response if the stress goes on too long, and the protective effect is reduced. This means the cell is less protected against damage, and it is why prolonged or chronic exposures may be quite harmful, even at very low intensities.

The biochemical pathway that is activated is the same for ELF and for RF exposures, and it is non-thermal (does not require heating or induced electrical currents, and thus the safety standards based on protection from heating are irrelevant and not protective). ELF exposure levels of only 5 to 10 mG have been shown to activate the stress response genes (Table 2, Section 6). The specific absorption rate or SAR is not the appropriate measure of biological threshold or dose, and should not be used as the basis for a safety standard, since SAR only regulates against thermal damage.

E. Effects on the Immune System

The immune system is another defense we have against invading organisms (viruses, bacteria, and other foreign molecules). It protects us against illness, infectious diseases, and tumor cells.

There are many different kinds of immune cells; each type of cell has a particular purpose, and is launched to defend the body against different kinds of exposures that the body determines might be harmful.

There is substantial evidence that ELF and RF can cause inflammatory reactions, allergy reactions and change normal immune function at levels allowed by current public safety standards.

The body's immune defense system senses danger from ELF and RF exposures, and targets an immune defense against these fields, much like the body's reaction in producing stress proteins. These are additional indicators that very low intensity ELF and RF exposures are a) recognized by cells and b) can cause reactions as if the exposure is harmful. Chronic exposure to factors that increase allergic and inflammatory responses on a continuing basis are likely to be harmful to health. Chronic inflammatory responses can lead to cellular, tissue and organ damage over time. Many chronic diseases are thought to be related to chronic problems with immune system function.

The release of inflammatory substances, such as histamine, are well-known to cause skin reactions, swelling, allergic hypersensitivity and other conditions that are normally associated with some kind of defense mechanism. The human immune system is part of a general defense barrier that protects against harmful exposures from the surrounding environment. When the immune system is aggravated by some kind of attack, there are many kinds of immune cells that can respond. Anything that triggers an immune response should be carefully evaluated, since chronic stimulation of the immune system may over time impair the system's ability to respond in the normal fashion.

Measurable physiological changes (mast cell increases in the skin, for example that are markers of allergic response and inflammatory cell response) are triggered by ELF and RF at very low intensities. Mast cells, when activated by ELF or RF, will break (degranulate) and release irritating chemicals that cause the symptoms of allergic skin reactions.

There is very clear evidence that exposures to ELF and RF at levels associated with cell phone use, computers, video display terminals, televisions, and other sources can cause these skin reactions. Changes in skin sensitivity have been measured by skin biopsy, and the findings are remarkable. Some of these reactions happen at levels equivalent to those of wireless technologies in daily life. Mast cells are also found in the brain and heart, perhaps targets of immune response by cells responding to ELF and RF exposures, and this might account for some of the other symptoms commonly reported (headache, sensitivity to light, heart arrhythmias and other cardiac symptoms). Chronic provocation by exposure to ELF and RF can lead to immune dysfunction, chronic allergic responses, inflammatory diseases and ill health if they occur on a continuing basis over time.

These clinical findings may account for reports of persons with electrical hypersensitivity, which is a condition where there is intolerance for any level of exposure to ELF and/or RF. Although there is not yet a substantial scientific assessment (under controlled conditions, if that is even possible); anecdotal reports from many countries show that estimates range from 3% to perhaps 5% of populations, and it is a growing problem. Electrical hypersensitivity, like multiple

chemical sensitivity, can be disabling and require the affected person to make drastic changes in work and living circumstances, and suffer large economic losses and loss of personal freedom. In Sweden, electrohypersensitivity (EHS) is officially recognized as fully functional impairment (i.e., it is not regarded as a disease – see Section 6, Appendix A).

F. Plausible Biological Mechanisms

Plausible biological mechanisms are already identified that can reasonably account for most biological effects reported for exposure to RF and ELF at low-intensity levels (oxidative stress and DNA damage from free radicals leading to genotoxicity; molecular mechanisms at very low energies are plausible links to disease, e.g., effect on electron transfer rates linked to oxidative damage, DNA activation linked to abnormal biosynthesis and mutation). It is also important to remember that traditional public health and epidemiological determinations do not require a proven mechanism before inferring a causal link between EMFs exposure and disease (12). Many times, proof of mechanism is not known before wise public health responses are implemented.

"Obviously, melatonin's ability to protect DNA from oxidative damage has implications for many types of cancer, including leukemia, considering that DNA damage due to free radicals is believed to be the initial oncostatic event in a majority of human cancers [Cerutti et al., 1994]. In addition to cancer, free radical damage to the central nervous system is a significant component of a variety of neurodegenerative diseases of the aged including Alzheimer's disease and Parkinsonism. In experimental animal models of both of these conditions, melatonin has proven highly effective in forestalling their onset, and reducing their severity [Reiter et al., 2001]." (13)

Oxidative stress through the action of free radical damage to DNA is a plausible biological mechanism for cancer and diseases that involve damage from ELF to the central nervous system.

G. Another Way of Looking at EMFs: Therapeutic Uses

Many people are surprised to learn that certain kinds of EMFs treatments actually can heal. These are medical treatments that use EMFs in specific ways to help in healing bone fractures, to heal wounds to the skin and underlying tissues, to reduce pain and swelling, and for other post-surgical needs. Some forms of EMFs exposure are used to treat depression.

EMFs have been shown to be effective in treating conditions of disease at energy levels far below current public exposure standards. This leads to the obvious question. How can scientists dispute the harmful effects of EMF exposures while at the same time using forms of EMF treatment that are proven to heal the body?

Medical conditions are successfully treated using EMFs at levels below current public safety standards, proving another way that the body recognizes and responds to low-intensity EMF signals. Otherwise, these medical treatments could not work. The FDA has approved EMFs medical treatment devices, so is clearly aware of this paradox.

Random exposures to EMFs, as opposed to EMFs exposures done with clinical oversight, could lead to harm just like the unsupervised use of pharmaceutical drugs. This evidence forms a strong warning that indiscriminate EMF exposure is probably a bad idea.

No one would recommend that drugs used in medical treatments and prevention of disease be randomly given to the public, especially to children. Yet, random and involuntary exposures to EMFs occur all the time in daily life.

The consequence of multiple sources of EMFs exposures in daily life, with no regard to cumulative exposures or to potentially harmful combinations of EMFs exposures means several things. First, it makes it very difficult to do clinical studies because it is almost impossible to find anyone who is not already exposed. Second, people with and without diseases have multiple and overlapping exposures – this will vary from person to person.

Just as ionizing radiation can be used to effectively diagnose disease and treat cancer, it is also a cause of cancer under different exposure conditions. Since EMFs are both a cause of disease, and also used for treatment of disease, it is vitally important that public exposure standards reflect our current understanding of the biological potency of EMF exposures, and develop both new public safety limits and measures to prevent future exposures.

III. EMF EXPOSURE AND PRUDENT PUBLIC HEALTH PLANNING

- **The scientific evidence is sufficient to warrant regulatory action for ELF; and it is substantial enough to warrant preventative actions for RF.**
- **The standard of evidence for judging the emerging scientific evidence necessary to take action should be proportionate to the impacts on health and well-being**
- **The exposures are widespread.**
- **Widely accepted standards for judging the science are used in this assessment.**

Public exposure to electromagnetic radiation (power-line frequencies, radiofrequency and microwave) is growing exponentially worldwide. There is a rapid increase in electrification in developing countries, even in rural areas. Most members of society now have and use cordless phones, cellular phones, and pagers. In addition, most populations are also exposed to antennas in communities designed to transmit wireless RF signals. Some developing countries have even given up running land lines because of expense and the easy access to cell phones. Long-term and cumulative exposure to such massively increased RF has no precedent in human history. Furthermore, the most pronounced change is for children, who now routinely spend hours each day on the cell phone. Everyone is exposed to a greater or lesser extent. No one can avoid exposure, since even if they live on a mountain-top without electricity there will likely be exposure to communication-frequency RF exposure. Vulnerable populations (pregnant women, very young children, elderly persons, the poor) are exposed to the same degree as the general population. Therefore it is imperative to consider ways in which to evaluate risk and reduce exposure. Good public health policy requires preventative action proportionate to the potential risk of harm and the public health consequence of taking no action.

IV. RECOMMENDED ACTIONS

A. Defining new exposure standards for ELF

This chapter concludes that new ELF limits are warranted based on a public health analysis of the overall existing scientific evidence. The public health view is that new ELF limits are needed now. They should reflect environmental levels of ELF that have been demonstrated to increase risk for childhood leukemia, and possibly other cancers and neurological diseases. ELF limits should be set below those exposure levels that have been linked in childhood leukemia studies to increased risk of disease, plus an additional safety factor. It is no longer acceptable to build new power lines and electrical facilities that place people in ELF environments that have been determined to be risky. These levels are in the 2 to 4 milligauss* (mG) range, not in the 10s of mG or 100s of mG. The existing ICNIRP limit is 1000 mG (904 mG in the US) for ELF is outdated and based on faulty assumptions. These limits are can no longer be said to be protective of public health and they should be replaced. A safety buffer or safety factor should also be applied to a new, biologically-based ELF limit, and the conventional approach is to add a safety factor lower than the risk level.

While new ELF limits are being developed and implemented, a reasonable approach would be a 1 mG planning limit for habitable space adjacent to all new or upgraded power lines and a 2 mG limit for all other new construction. It is also recommended for that a 1 mG limit be established for existing habitable space for children and/or women who are pregnant (because of the possible link between childhood leukemia and *in utero* exposure to ELF). This recommendation is based on the assumption that a higher burden of protection is required for children who cannot protect themselves, and who are at risk for childhood leukemia at rates that are traditionally high enough to trigger regulatory action. This situation in particular warrants extending the 1 mG limit to existing occupied space. "Establish" in this case probably means formal public advisories from relevant health agencies. While it is not realistic to reconstruct all existing electrical distribution
systems, in the short term; steps to reduce exposure from these existing systems need to be initiated, especially in places where children spend time, and should be encouraged. These limits should reflect the exposures that are commonly associated with increased risk of child hood leukemia (in the 2 to 5 mG range for all children, and over 1.4 mG for children age 6 and younger). Nearly all of the occupational studies for adult cancers and neurological diseases

report their highest exposure category is 4 mG and above, so that new ELF limits should target the exposure ranges of interest, and not necessarily higher ranges.

Avoiding chronic ELF exposure in schools, homes and the workplace above levels associated with increased risk of disease will also avoid most of the possible bioactive parameters of ELF discussed in the relevant literature.

B. Defining preventative actions for reduction in RF exposures

Given the scientific evidence at hand (Chapter 17), the rapid deployment of new wireless technologies that chronically expose people to pulsed RF at levels reported to cause bioeffects, which in turn, could reasonably be presumed to lead to serious health impacts, is of public health concern. Section 17 summarizes evidence that has resulted in a public health recommendation that preventative action is warranted to reduce or minimize RF exposures to the public. There is suggestive to strongly suggestive evidence that RF exposures may cause changes in cell membrane function, cell communication, cell metabolism, activation of proto-oncogenes and can trigger the production of stress proteins at exposure levels below current regulatory limits. Resulting effects can include DNA breaks and chromosome aberrations, cell death including death of brain neurons, increased free radical production, activation of the endogenous opioid system, cell stress and premature aging, changes in brain function including memory loss, retarded learning, slower motor function and other performance impairment in children, headaches and fatigue, sleep disorders, neurodegenerative conditions, reduction in melatonin secretion and cancers (Chapters 5, 6, 7, 8, 9, 10, and 12).

As early as 2000, some experts in bioelectromagnetics promoted a 0.1 μW/cm2 limit (which is 0.614 Volts per meter) for ambient outdoor exposure to pulsed RF, so generally in cities, the public would have adequate protection against involuntary exposure to pulsed radiofrequency (e.g., from cell towers, and other wireless technologies). The Salzburg Resolution of 2000 set a target of 0.1 μW/cm2 (or 0.614 V/m) for public exposure to pulsed radiofrequency. Since then, there are many credible anecdotal reports of unwellness and illness in the vicinity of wireless transmitters (wireless voice and data communication antennas) at lower levels. Effects include sleep disruption, impairment of memory and concentration, fatigue, headache, skin disorders,

visual symptoms (floaters), nausea, loss of appetite, tinnitus, and cardiac problems (racing heartbeat), There are some credible articles from researchers reporting that cell tower -level RF exposures (estimated to be between 0.01 and 0.5 μW/cm2) produce ill-effects in populations living up to several hundred meters from wireless antenna sites.

This information now argues for thresholds or guidelines that are substantially below current FCC and ICNIPR standards for whole body exposure. Uncertainty about how low such standards might have to go to be prudent from a public health standpoint should not prevent reasonable efforts to respond to the information at hand. No lower limit for bioeffects and adverse health effects from RF has been established, so the possible health risks of wireless WLAN and WI-FI systems, for example, will require further research and no assertion of safety at any level of wireless exposure (chronic exposure) can be made at this time. The lower limit for reported human health effects has dropped 100-fold below the safety standard (for mobile phones and PDAs); 1000- to 10,000-fold for other wireless (cell towers at distance; WI-FI and WLAN devices). The entire basis for safety standards is called into question, and it is not unreasonable to question the safety of RF at any level.

A cautionary target level for pulsed RF exposures for ambient wireless that could be applied to RF sources from cell tower antennas, WI-FI, WI-MAX and other similar sources is proposed. The recommended cautionary target level is 0.1 microwatts per centimeter squared (μW/cm2)** (or 0.614 Volts per meter or V/m)** for pulsed RF where these exposures affect the general public; this advisory is proportionate to the evidence and in accord with prudent public health policy. A precautionary limit of 0.1 μW/cm2 should be adopted for outdoor, cumulative RF exposure. This reflects the current RF science and prudent public health response that would reasonably be set for pulsed RF (ambient) exposures where people live, work and go to school. This level of RF is experienced as whole-body exposure, and can be a chronic exposure where there is wireless coverage present for voice and data transmission for cell phones, pagers and PDAs and other sources of radiofrequency radiation. An outdoor precautionary limit of 0.1 μW/cm2 would mean an even lower exposure level inside buildings, perhaps as low as 0.01 μW/cm2. Some studies and many anecdotal reports on ill health have been reported at lower levels than this; however, for the present time, it could prevent some of the most disproportionate burdens placed on the public nearest to such installations. Although this RF target level does not preclude further rollout of WI-FI technologies, we also recommend that wired alternatives to WI-FI be implemented, particularly in schools and libraries so that children are not subjected to

elevated RF levels until more is understood about possible health impacts. This recommendation should be seen as an interim precautionary limit that is intended to guide preventative actions; and more conservative limits may be needed in the future.

Broadcast facilities that chronically expose nearby residents to elevated RF levels from AM, FM and television antenna transmission are also of public health concern given the potential for very high RF exposures near these facilities (antenna farms). RF levels can be in the 10s to several 100's of μW/cm2 in residential areas within half a mile of some broadcast sites (for example, Lookout Mountain, Colorado and Awbrey Butte, Bend, Oregon). Such facilities that are located in, or expose residential populations and schools to elevated levels of RF will very likely need to be re-evaluated for safety.

For emissions from wireless devices (cell phones, personal digital assistant or PDA devices, etc) there is enough evidence for increased risk of brain tumors and acoustic neuromas now to warrant intervention with respect to their use. Redesign of cell phones and PDAs could prevent direct head and eye exposure, for example, by designing new units so that they work only with a wired headset or on speakerphone mode.

These effects can reasonably be presumed to result in adverse health effects and disease with chronic and uncontrolled exposures, and children may be particularly vulnerable. The young are also largely unable to remove themselves from such environments. Second-hand radiation, like second-hand smoke is an issue of public health concern based on the evidence at hand.

V. CONCLUSIONS

• We cannot afford 'business as usual" any longer. It is time that planning for new power lines and for new homes, schools and other habitable spaces around them is done with routine provision for low-ELF environments. The business-as-usual deployment of new wireless technologies is likely to be risky and harder to change if society does not make some educated decisions about limits soon. Research must continue to define what levels of RF related to new wireless technologies are acceptable; but more research should not prevent or delay substantive changes today that might save money, lives and societal disruption tomorrow.

• New regulatory limits for ELF are warranted. ELF limits should be set below those exposure levels that have been linked in childhood leukemia studies to increased risk of disease, plus an additional safety factor. It is no longer acceptable to build new power lines and electrical facilities that place people in ELF environments that have been determined to be risky (at levels generally at 2 mG and above).

• While new ELF limits are being developed and implemented, a reasonable approach would be a 1 mG planning limit for habitable space adjacent to all new or upgraded power lines and a 2 mG limit for all other new construction, It is also recommended for that a 1 mG limit be established for existing habitable space for children and/or women who are pregnant . This recommendation is based on the assumption that a higher burden of protection is required for children who cannot protect themselves, and who are at risk for childhood leukemia at rates that are traditionally high enough to trigger regulatory action. This situation in particular warrants extending the 1 mG limit to existing occupied space. "Establish" in this case probably means formal public advisories from relevant health agencies.

• While it is not realistic to reconstruct all existing electrical distributions systems, in the short term; steps to reduce exposure from these existing systems need to be initiated, especially in places where children spend time, and should be encouraged.

• A precautionary limit of 0.1 (μW/cm2 (which is also 0.614 Volts per meter) should be adopted for outdoor, cumulative RF exposure. This reflects the current RF science and prudent public health response that would reasonably be set for pulsed RF (ambient) exposures where people

live, work and go to school. This level of RF is experienced as whole-body exposure, and can be a chronic exposure where there is wireless coverage present for voice and data transmission for cell phones, pagers and PDAs and other sources of radiofrequency radiation. Some studies and many anecdotal reports on ill health have been reported at lower levels than this; however, for the present time, it could prevent some of the most disproportionate burdens placed on the public nearest to such installations. Although this RF target level does not preclude further rollout of WI-FI technologies, we also recommend that wired alternatives to WI-FI be implemented, particularly in schools and libraries so that children are not subjected to elevated RF levels until more is understood about possible health impacts. This recommendation should be seen as an interim precautionary limit that is intended to guide preventative actions; and more conservative limits may be needed in the future.

Some Quick Definitions for Units of Measurement of ELF and RF

***Milligauss (mG)**

A milligauss is a measure of ELF intensity and is abbreviated mG. This is used to describe electromagnetic fields from appliances, power lines, interior electrical wiring.

****Microwatts per centimeter squared (µW/cm2)**

Radiofrequency radiation in terms of power density is measured in microwatts per centimeter squared and abbreviated (µW/cm2). It is used when talking about emissions from wireless facilities, and when describing ambient RF in the environment. The amount of allowable RF near a cell tower is 1000 µW/cm2 for some cell phone frequencies, for example.

*****Specific Absorption Rate (SAR is measured in watts per kilogram or W/Kg)**

SAR stands for specific absorption rate. It is a calculation of how much RF energy is absorbed into the body, for example when a cell phone or cordless phone is pressed to the head. SAR is expressed in watts per kilogram of tissue (W/Kg). The amount of allowable energy into 1 gram of brain tissue from a cell phone is 1.6 W/Kg in the US. For whole body exposure, the exposure is 0.8 W/Kg averaged over 30 minutes for the general public. International standards in most countries are similar, but not exactly the same.

Table 1-1 BioInitiative Report Overall Conclusions

OVERALL SUMMARY OF CONCLUSIONS

- The existing ICNIRP and FCC limits for public and occupational exposure to ELF and RF are insufficiently protective of public health.

- Biologically-based public and occupational exposure standards for extra-low frequency and radiofrequency radiation are recommended to address bioeffects and potential adverse health effects of chronic exposure to ELF and RF. These effects are now widely reported to occur at exposure levels significantly below most current national and international limits.

- A biologically-based exposure limit is one that is protective against ELF and RF intensity and modulation factors which, with chronic exposure, can reasonably be presumed to result in significant impacts to health and well-being.

- Research is needed (but should not delay) regulatory action for ELF and substantive *preventative action* for RF proportionate to potential health and wellbeing risks from chronic exposure.

- A biologically-based exposure limit should reflect current scientific knowledge of bioeffects and health effects, and impose new limits based on preventative action as defined by the Precautionary Principle (EEA, 2001).

- Biologically-based exposure standards shall be protective against exposures levels of ELF and RF that affect or change normal biological functioning of organisms (humans). They shall not be based solely on energy absorption or thermal levels of energy input, or resulting tissue heating. They shall be protective against chronic exposure responses.

- The existing standards are based on thermal (heating) limits, and do not address non-thermal (or low-intensity) exposures which are widely reported to cause bioeffects, some likely leading to adverse health effects with chronic exposure.

- Biological effects may include both potential adverse health effects and loss of homeostasis and well-being.

- Biologically-based exposure standards are needed to prevent disruption of normal body processes. Effects are reported for DNS damage (genotoxicity that is directly linked to integrity of the human genome), cellular communication, cellular metabolism and repair, cancer surveillance within the body; and for protection against cancer and neurological diseases. Also reported are neurological effects including impairment of sleep and sleep architecture, cognitive function and memory; depression; cardiac effects; pathological leakage of the blood-brain barrier; and impairment of normal immune function, fertility and reproduction.

- Frequency, intensity, exposure duration, and the number of exposure episodes can affect the response, and these factors can interact with each other to produce different effects. In addition, in order to understand the biological consequences of EMF exposure, one must know whether the effect is cumulative, whether compensatory responses result, and when homeostasis will break down.

- Plausible biological mechanisms that can account for genotoxicity (DNA damage) are already well known (oxidative damage via free-radical actions) although it should also be said that there is not yet proof. *However, proof of mechanism is not required to set prudent public health policy, nor is it mandatory to set new guidelines or limits if adverse health effects occur at lower-than-existing IEEE and ICNIRP standards.*

Table 1-1 BioInitiative Report Overall Conclusions

OVERALL SUMMARY OF CONCLUSIONS (continued

• The SCENIHR report (2007) states that "for breast cancer and cardiovascular disease, recent research has indicated that an association with EMF is unlikely." The WHO ELF Health Criteria Monograph (2007) states "The evidence does not support an association between ELF exposure and cardiovascular disease" and "(T)he evidence for breast cancer was also considered to be effectively negative, while for other diseases it was judged to be inadequate." Neither conclusion is supported by any finding by IARC that would classify EMF as Class 4 (Not A Carcinogen), so it is premature for either group to dismiss the evidence for EMF as a potential risk factor for either breast cancer or for cardiovascular disease.

• The standard for taking action should be precautionary; action should not be deferred while waiting for final proof or causal evidence to be established that EMF is harmful to health and well-being.

• There is great public concern over increasing levels of involuntary exposure to radiofrequency and ELF-modulated radiofrequency exposures from new wireless technologies; there is widespread public resistance to radiofrequency and extra-low frequency radiation exposures which are allowable under current, thermally-based exposure standards.

• There is inadequate warning and notice to the public about possible risks from wireless technologies in the marketplace, which is resulting in adoption and use of technologies that may have adverse health consequences which are still unknown to the public. There is no "informed consent".

• No positive assertion of safety can be made by governments that continue to support and enforce exposure limits for RF and ELF based on ICNIRP or IEEE criteria (or the equivalent). Governments that are considering proposals to relax existing RF and ELF standards should reject these proposals given the weight of scientific evidence that is available; and the clear disconnect between existing public safety limits and their responsibility to provide safe and healthful living environments for all segments of affected populations.

Section 5 Genotoxicity Based on Proteomics

• EMF exposure can change gene and/or protein expression in certain types of cells, even at intensities lower than ICNIRP recommended values.

• The biological consequences of most of the changed genes/proteins are still unclear, and need to be further explored.

• The EMF research community should pay equal attention to the negative reports as to the positive ones. Not only the positive findings need to be replicated, all the negative ones are also needed to be validated.

• The IEEE and WHO data bases do not include the majority of ELF studies (only 6 of 14 in the WHO; 0 of 16 in IEEE); they do include the majority of the RF studies (14 of 16).

Table 1-1 BioInitiative Report Overall Conclusions

Section 6 Genotoxicity (DNA Damage from RF and ELF)

• Toxicity to the genome can lead to a change in cellular functions, cancer, and cell death. One can conclude that under certain conditions of exposure RF is genotoxic. Data available are mainly applicable only to cell phone radiation exposure. One study reports that RF at levels equivalent to the vicinity of base stations and RF- transmission towers is genotoxic and could cause DNA damage (Phillips et al., 1998).

• RF may be considered genotoxic (cause DNA damage). Of 28 total studies on radiofrequency radiation (RF) and DNA damage, 14 studies reported effects (50%) and 14 reported no significant effect (50%). Of 29 total studies on radiofrequency radiation and micronucleation, 16 studies reported effects (55%) and 13 reported no significant effect (45%). Of 21 total studies on chromosome and genome damage from radiofrequency radiation, 13 studies (62%) reported effects and 8 studies (38%) reported no significant effects.

• During cell phone use, a relatively constant mass of tissue in the brain is exposed to radiation at relatively high intensity (peak SAR of 4 - 8 W/kg). Several studies have reported DNA damage at lower than 4 W/kg.

• Since critical genetic mutations in one single cell are sufficient to lead to cancer and there are millions of cells in a gram of tissue, *it is* ***inconceivable*** that the base of the IEEE SAR standard was changed from averaged over 1 gram of tissue to 10 grams.

• Frequency, intensity, exposure duration, and the number of exposure episodes can affect the response, and these factors can interact with each other to produce different consequences. In order to understand the biological consequence of exposure, one must understand whether the effect is cumulative, whether compensatory responses result and when homeostasis will break down. The choice of cell type or organism studied can also influence the outcome.

• Extremely-low frequency (ELF) has also been shown to be genotoxic and cause DNA damage. Of 41 relevant studies of genotoxicity and ELF exposure, 27 studies (66%) report DNA damage and 14 studies (44%) report no significant effect.

Table 1-1 BioInitiative Report Overall Conclusions

Section 7: Stress Response

• Scientific research on stress proteins has shown that the public is not being protected from potential damage that can be caused by exposure to EMF, both power frequency (ELF) and radio frequency (RF).

• Cells react to an EMF as potentially harmful by producing stress proteins (heat shock proteins or hsp).

• Direct interaction of ELF and RF with DNA has been documented and both activate the synthesis of stress proteins.

• The biochemical pathway that is activated is the same pathway in both ELF and RF and it is non-thermal.

• Many biological systems are affected by EMFs (meaning both ELF and RF trigger stress proteins).

• Many frequencies are active. Field strength and exposure duration thresholds are very low.

• Molecular mechanisms at very low energies are plausible links to disease (e.g., effect on electron transfer rates linked to oxidative damage, DNA activation linked to abnormal biosynthesis and mutation). Cells react to an EMF as potentially harmful.

• Many lines of research now point to changes in DNA electron transfer as a plausible mechanism of action as a result of non-thermal ELF and RF.

• The same biological reaction (production of stress proteins) to an EMF can be activated in more than one division of the EM spectrum.

• Direct interaction of ELF and RF with DNA has been documented and both activate the synthesis of stress proteins.

• Thresholds triggering stress on biological systems occur at environment levels on the order of 0.5 to 1.0 μT for ELF.

• DNA damage (e.g., strand breaks), a cause of cancer, occurs at levels of ELF and RF that are below the safety limits. Also, there is no protection against cumulative effects stimulated by different parts of the EM spectrum.

• The scientific basis for EMF safety limits is flawed when the same biological mechanisms are activated in ELF and RF ranges at vastly different levels of the Specific Absorption Rate (SAR). Activation of DNA to synthesize stress proteins (the stress response) is stimulated in the ELF at a non-thermal SAR level that is over a billion times lower than the same process activated by RF at the thermal level.

• There is a need for a biological standard to replace the thermal standard and to also protect against cumulative effects across the EM spectrum.

• Based on studies of stress proteins, the specific absorption rate (SAR) is not the appropriate measure of biological threshold or dose, and should not be used as a basis for a safety standard since it regulates against thermal effects only.

Table 1-1 BioInitiative Report Overall Conclusions

Section 8 Effects on Immune Function

• Both human and animal studies report large immunological changes with exposure to environmental levels of electromagnetic fields (EMFs). Some of these exposure levels are equivalent to those of e.g. wireless technologies in daily life.

• Measurable physiological changes (mast cells increases, for example) that are bedrock indicators of allergic response and inflammatory conditions are stimulated by EMF exposures.

• Chronic exposure to such factors that increase allergic and inflammatory responses on a continuing basis may be harmful to health.

• It is possible that chronic provocation by exposure to EMF can lead to immune dysfunction, chronic allergic responses, inflammatory responses and ill health if they occur on a continuing basis over time. This is an important area for future research.

• Specific findings from studies on exposures to various types of modern equipment and/or EMFs report over-reaction of the immune system; morphological alterations of immune cells; profound increases in mast cells in the upper skin layers, increased degranulation of mast cells and larger size of mast cells in electrohypersensitive individuals; presence of biological markers for inflammation that are sensitive to EMF exposure at non-thermal levels; changes in lymphocyte viability; decreased count of NK cells; decreased count of T lymphocytes; negative effects on pregnancy (uteroplacental circulatory disturbances and placental dysfunction with possible risks to pregnancy); suppressed or impaired immune function; and inflammatory responses which can ultimately result in cellular, tissue and organ damage.

• Electrical hypersensitivity is reported by individuals in the United States, Sweden, Switzerland, Germany. Denmark and many other countries of the world. Estimates range from 3% to perhaps 10% of populations, and appears to be a growing condition of ill-health leading to lost work and productivity.

• The WHO and IEEE literature surveys do not include all of the relevant papers cited here, leading to the conclusion that evidence has been ignored in the current WHO ELF Health Criteria Monograph; and the proposed new IEEE C95.1 RF public exposure limits (April 2006).

• The current international public safety limits for EMFs do not appear to be sufficiently protective of public health at all, based on the studies of immune function. New, biologically-based public standards are warranted that take into account low-intensity effects on immune function and health that are reported in the scientific literature.

Table 1-1 BioInitiative Report Overall Conclusions

Section 9 Neurology and Behavioral Effects

• Effects on neurophysiological and cognitive functions are quite well established.

• Studies on EEG and brain evoked-potentials in humans exposed to cellular phone radiation predominantly showed positive effects (i.e., positive means the exposure has the ability to change brainwave activity even at exposure levels where no effect would be expected, based on traditional understanding and safety limits).

• There is little doubt that electromagnetic fields emitted by cell phones and cell phone use affect electrical activity in the brain.

• The behavioral consequences of these neuroelectrophysiological changes are not always predictable and research on electrophysiology also indicates that effects are dependent on the mental load of the subjects during exposure, e.g., on the complexity of the task that a subject is carrying out.

• Most of the studies carried out so far are short-term exposure experiments, whereas cell phone use causes long-term repeated exposure of the brain.

• In most of the behavioral experiments, effects were observed after the termination of RF exposure. In some experiments, tests were made days after exposure. This suggests a persistent change in the nervous system after exposure to RF.

• In many instances, neurological and behavioral effects were observed at a SAR less than 4 W/kg. This directly contradicts the basic assumption of the IEEE guideline criterion.

• Caution should be taken in concluding that a neurological effect resulted solely from the action of RF on the central nervous system because it is well known that the functions of the central nervous system can be affected by activity in the peripheral nervous system.

Table 1-1 BioInitiative Report Overall Conclusions

Section 10 Brain Tumors and Acoustic Neuromas

• Studies on brain tumors and use of mobile phones for ≥ 10 years gave a consistent pattern of an increased risk for acoustic neuroma and glioma.

• Cell phone use > 10 years give a consistent pattern of an increased risk for acoustic neuroma and glioma, most pronounced for high-grade glioma. The risk is highest for ipsilateral exposure.

Section 10 Brain Tumors and RF - Epidemiology

- Only a few studies of long-term exposure to low levels of RF fields and brain tumors exist, all of which have methodological shortcomings including lack of quantitative exposure assessment. Given the crude exposure categories and the likelihood of a bias towards the null hypothesis of no association, *the body of evidence is consistent with a moderately elevated risk.*

- Occupational studies indicate that long-term exposure at workplaces may be associated with an elevated brain tumor risk.

- Although the population attributable risk is low (likely below 4%), still more than 1,000 cases per year in the US can be attributed to RF exposure at workplaces alone. Due to the lack of conclusive studies of environmental RF exposure and brain tumors the potential of these exposures to increase the risk cannot be estimated.

- Overall, the evidence suggests that long-term exposure to levels generally below current guideline levels still carry the risk of increasing the incidence of brain tumors.

• Epidemiological studies as reviewed in the IEEE C95.1 revision (2006) are deficient to the extent that the entire analysis is professionally unsupportable. IEEEs dismissal of epidemiological studies that link RF exposure to cancer endpoints should be disregarded, as well as any IEEE conclusions drawn from this flawed analysis of epidemiological studies.

Table 1-1 BioInitiative Report Overall Conclusions

Brain Tumors and Acoustic Neuromas

Additional Data from Section 10

• Mobile phone use increases the risk of acoustic neuroma for persons using a mobile phone 10 years or longer by 30% (when used on both sides of head) to 240% (habitually used on one side of head). This information relies on a meta-analysis of several major studies. For acoustic neuroma studies by Lönn et al., (2004), Christensen et al., (2004) Schoemaker et al., (2005) and Hardell et al., (2006a) all giving results for at least 10 years latency period or more. Overall OR = 1.3, 95 % CI = 0.6-2.8 was obtained increasing to OR = 2.4, 95 % CI = 1.1-5.3 for ipsilateral mobile phone use (Lönn et al., 2004, Schoemaker et al., 2005, Hardell et al., 2006).

• There is observational support for the association between acoustic neuroma and the use of mobile phones since some studies report that the tumor is often located in an anatomical area with high exposure during calls with cellular or cordless phones (Hardell et al., 2003).

• Mobile phone use increases the risk of brain tumors (glioma) for persons using a mobile phone 10 years or longer by 20% (when used on both sides of head) to 200% (habitually used on one side of head). This information relies on a meta-analysis of several major studies. For glioma OR = 1.2, [95 % CI = 0.8-1.9] was calculated (Lönn et al., 2005, Christensen et al., 2005, Hepworth et al., 2006, Schüz et al., 2006, Hardell et al., 2006b, Lahkola et al., 2007). Ipsilateral use yielded OR = 2.0, [95 % CI = 1.2-3.4](Lönn et al., 2005, Hepworth et al., 2006, Hardell et al., 2006b, Lahkola et al., 2007).

• Cordless phone use is also associated with an increased risk for acoustic neuromas and brain tumors (both low-and high-grade gliomas (Hardell et al., 2006 a,b).

• The increased risk of acoustic neuroma from use of a cordless phone for ten years or more was reported to be 310% higher risk (when the cordless phone habitually used on the same-side of the head) in Hardell et al., 2006a.

• The increased risk of high-grade glioma from use of a cordless phone for ten years or more was reported to be 220% higher risk (when cordless used on both sides of head) to 470% higher risk (when cordless used habitually on same side of head) in Hardell et al., 2006b.

• The increased risk of low-grade glioma from use of a cordless phone for ten years or more was reported to be 60% higher risk (when cordless used on both sides of head) to 320% higher risk (when cordless used habitually on same side of head) in Hardell et al., 2006b.

• The current standard for exposure to microwaves during mobile phone use and for cordless phone use is not safe considering studies reporting long-term brain tumor risk.

Table 1-1 BioInitiative Report Overall Conclusions

Section 11 Leukemia

- The balance of evidence suggests that childhood leukemia is associated with exposure to power frequency EMFs either during early life or pregnancy.

- Considering only average ELF (MF flux densities) the population attributable risk is low to moderate. However there is a possibility that other exposure metrics are much more strongly related to childhood leukemia and may account for a substantial proportion of cases. The population attributable fraction ranges between 1-4% (Kheifets et al., 2007); 2-4% (Greenland & Kheifets 2006); and 3.3% (Greenland, 2001) assuming only exposures above 3 to 4 mG (0.3 – 0.4 μT) are relevant. However, if it is not average ELF (average MF flux density) that is the metric causally related to childhood leukemia the attributable fraction can be much higher. Up to 80% of childhood leukemia may be caused by exposure to ELF.

- Other childhood cancers except leukemia have not been studied in sufficient detail to allow conclusions about the existence and magnitude of the risk.

- IEEE guideline levels are designed to protect from short-term immediate effects, long-term effects, such as cancer are evoked by levels several orders of magnitudes below current guideline levels.

- Measures should be implemented to guarantee that exposure due to transmission and distribution lines is below an average of about 1 mG (0.1 μT) and precautionary measures are warranted that can reduce all aspects of exposure.

Table 1-1 BioInitiative Report Overall Conclusions

Section 12 Melatonin, Alzheimers Disease and Breast Cancer

- There is strong epidemiologic evidence that long-term exposure to ELF magnetic field (MF) is a risk factor for Alzheimers disease.

- There is now evidence that 1) high levels of peripheral amyloid beta are a risk factor for AD and 2) medium to high MF exposure can increase peripheral amyloid beta. High brain levels of amyloid beta are also a risk factor for AD and medium to high MF exposure to brain cells likely also increases these cells' production of amyloid beta.

- There is considerable *in vitro* and animal evidence that melatonin protects against Alzheimer's disease. Therefore it is certainly possible that low levels of melatonin production are associated with an increase in the risk of AD.

- There are insufficient studies to formulate an opinion as to whether radiofrequency MF exposure is a risk factor for AD.

- Some studies on EMF show reduced melatonin levels, There is sufficient evidence from *in vitro* and animal studies, from human biomarker studies, from occupational and light-at-night studies, and a single longitudinal study with appropriate collection of urine samples to conclude that high MF exposure may be a risk factor for breast cancer.

- There is rather strong evidence from case-control studies that longterm, high occupational exposure ($\geq$ 10 mG or 1.0 μT)) to ELF magnetic fields is a risk factor for breast cancer.

- Seamstresses are, in fact, one of the most highly MF exposed occupations, with exposure levels generally above 10 mG (1.0 μT) over a significant proportion of the workday. They have also been consistently found to be at higher risk of Alzheimer's disease and (female) breast cancer. This occupation deserves attention in future studies.

- There are no studies of RF magnetic fields on breast cancer that do not exclude ELF magnetic field, so that predictions of RF magnetic field alone on breast cancer cannot be assessed at this time.

Table 1-1 BioInitiative Report Overall Conclusions

Section 13 Melatonin – Cell and Animal Studies

• An association between power-frequency electromagnetic fields (ELF) and breast cancer is strongly supported in the scientific literature by a constellation of relevant scientific papers providing mutually-reinforcing evidence from cell and animal studies.

• ELF at environmental levels negatively affects the oncostatic effects of both melatonin and tamoxifen on human breast cancer cells at common environmental levels of ELF exposure at 6 to 12 mG (0.6 to 1.2 μT). Epidemiological studies over the last two decades have reported increased risk of male and female breast cancer with exposures to residential and occupational levels of ELF. Animal studies have reported increased mammary tumor size and incidence in association with ELF exposure.

• ELF limits for public exposure should be revised to reflect increased risk of breast cancer at environmental levels possibly as low as 2 mG or 3 mG (o.2 to 0.3 μT); certainly as low as 4 mG (0.4 μT).

Section 14 Effects of Modulation of Signal

• There is substantial scientific evidence that some modulated fields (pulsed or repeated signals) are bioactive, which increases the likelihood that they could have health impacts with chronic exposure even at very low exposure levels.

• Modulation signals may interfere with normal, non-linear biological processes.

• Modulation is a fundamental factor that should be taken into account in new public safety standards; at present it is not even a contributing factor.

• To properly evaluate the biological and health impacts of exposure to modulated RF (carrier waves), it is also essential to study the impact of the modulating signal (lower frequency fields or ELF-modulated RF).

.• Current standards have ignored modulation as a factor in human health impacts, and thus are inadequate in the protection of the public in terms of chronic exposure to some forms of ELF-modulated RF signals.

• The current IEEE and ICNIRP standards are not sufficiently protective of public health with respect to chronic exposure to modulated fields (particularly new technologies that are pulse-modulated and heavily used in cellular telephony).

Table 1-1 BioInitiative Report Overall Conclusions

Section 14 **Effects of Modulation of Signal** (continued)

• The collective papers on modulation appear to be omitted from consideration in the recent WHO and IEEE science reviews. This body of research has been ignored by current standard setting bodies that rely only on traditional energy-based (thermal) concepts.

• More research is needed to determine which modulation factors, and combinations are bioactive and deleterious at low intensities, and are likely to result in disease-related processes and/or health risks; however this should not delay preventative actions supporting public health and wellness.

• If signals need to be modulated in the development of new wireless technologies, for example, it makes sense to use what existing scientific information is available to avoid the most obviously deleterious exposure parameters and select others that may be less likely to interfere with normal biological processes in life.

• The current membership on Risk Assessment committees needs to be made more inclusive, by adding scientists experienced with the research reporting non-thermal biological effects.

• The current practice of segregating scientific investigations (and resulting public health limits) by artificial divisions of frequency needs to be changed because this approach dramatically dilutes the impact of the basic science results and eliminates consideration of modulation signals, thereby reducing and distorting the weight of evidence in any evaluation process.

Section 15 **Therapeutic Uses of EMF at Low-Intensity Levels**

• EMFs are both a cause of disease, and also used for treatment of disease (at levels far below existing public exposure standards).

• Electromagnetic fields are widely used in therapeutic medical applications.

• Proof of effectiveness has been demonstrated in numerous clinical applications of low-intensity ELF and RF.

• EMFs have been shown to be effective in treating conditions of disease at energy levels far below current public exposure standards.

• Indiscriminate EMF exposure is ill advised at even at common environmental levels.

• Multiple sources of EMF exposure in daily life, and cumulative exposures to potentially harmful combinations of EMF are ignored – we don’t even study it properly yet.

Table 1-1 BioInitiative Report Overall Conclusions

Section 16 The Precautionary Principle

• The Precautionary Principle has been developed to help justify public policy action on the protection of health where there are plausible, serious and irreversible hazards from current and future exposures and where there are many uncertainties and much scientific ignorance. EMF is characterized by such circumstances.

• The lessons from the histories of most well known hazards show that precautionary- based yet proportionate measures taken in response to robust early warnings can avoid the kinds of costs incurred by asbestos, smoking, PCBs ,X rays etc. Such lessons are relevant to the EMF issue.

• Policymakers need to be aware of the systematic biases within the environmental health science against finding a true hazard, in order to not compromise scientific integrity. However, this bias can lead to the health of people or environments being compromised.

• The Precautionary Principle introduces the use of different levels of proof (or strengths of evidence) to justify actions to reduce exposure, where the level of proof chosen depends upon the nature and distribution of the costs of being wrong in acting, or not acting; the benefits of the agent or substance in question; the availability of alternatives, etc. Waiting for high levels of scientific proof of causality, or for knowledge about mechanisms of action, can be very expensive in terms of compensation, health care, job losses, reductions in public trust of scientists etc.

• The level of proof chosen to justify action does not determine any particular policy measure, or type of action. This is dependent on factors such as the costs of different measures, equity, the origins of the risk, ie voluntary or imposed, etc.

• There is a need to involve stakeholders in helping to frame problems for risk assessments and to choose appropriate levels of proof and types of actions to reduce exposure.

Table 1-1 BioInitiative Report Overall Conclusions

Section 17: Key Scientific Evidence and Public Health Policy Recommendations

• We cannot afford 'business as usual" any longer. It is time that planning for new power lines and for new homes, schools and other habitable spaces around them is done with provision for low-ELF environments. The business-as-usual deployment of new wireless technologies is likely to be risky and harder to change if society does not make some educated decisions about limits soon. Research must continue to define what levels of RF related to new wireless technologies are acceptable; but more research should not prevent or delay substantive changes today that might save money, lives and societal disruption tomorrow.

• New regulatory limits for ELF are warranted. ELF limits should be set below those exposure levels that have been linked in childhood leukemia studies to increased risk of disease, plus an additional safety factor. It is no longer acceptable to build new power lines and electrical facilities that place people in ELF environments that have been determined to be risky (at levels generally at 2 mG (0.2 µT) and above).

• While new ELF limits are being developed and implemented, a reasonable approach would be a 1 mG (0.1 µT) planning limit for habitable space adjacent to all new or upgraded power lines and a 2 mG (0.2 µT) limit for all other new construction, It is also recommended for that a 1 mG (0,1 µT) limit be established for existing habitable space for children and/or women who are pregnant . This recommendation is based on the assumption that a higher burden of protection is required for children who cannot protect themselves, and who are at risk for childhood leukemia at rates that are traditionally high enough to trigger regulatory action. This situation in particular warrants extending the 1 mG (0.1 µT) limit to existing occupied space. "Establish" in this case probably means formal public advisories from relevant health agencies.

• While it is not realistic to reconstruct all existing electrical distributions systems, in the short term; steps to reduce exposure from these existing systems need to be initiated, especially in places where children spend time, and should be encouraged.

• A precautionary limit of 0.1 µW/cm2 (which is also 0.614 Volts per meter) should be adopted for outdoor, cumulative RF exposure. This reflects the current RF science and prudent public health response that would reasonably be set for pulsed RF (ambient) exposures where people live, work and go to school. This level of RF is experienced as whole-body exposure, and can be a chronic exposure where there is wireless coverage present for voice and data transmission for cell phones, pagers and PDAs and other sources of radiofrequency radiation. Some studies and many anecdotal reports on ill health have been reported at lower levels than this; however, for the present time, it could prevent some of the most disproportionate burdens placed on the public nearest to such installations. Although this RF target level does not preclude further rollout of WI-FI technologies, we also recommend that wired alternatives to WI-FI be implemented, particularly in schools and libraries so that children are not subjected to elevated RF levels until more is understood about possible health impacts. This recommendation should be seen as an interim precautionary limit that is intended to guide preventative actions; and more conservative limits may be needed in the future.

Table 1-1 BioInitiative Report Overall Conclusions

Section 17: Key Scientific Evidence and Public Health Policy Recommendations (continued)

• New public safety limits should be developed and implemented for ELF (50 Hz and 60 Hz electrical power frequencies). ELF limits should be set below those exposure levels that have been linked in childhood leukemia studies to increased risk of disease, plus an additional safety factor.

• Guidance should be provided to electric utilities on the need to reduce ELF exposures in siting and construction of new power lines and substations. Mitigation of existing sources of ELF over 1 mG (0.1 μT) should be encouraged, particularly where children and women who are pregnant, or who may be come pregnant spend significant portions of their time.

• Requests for measurement and monitoring of ELF and RF should be provided by utilities (for power line and household ELF) and by employers (for workplace ELF and RF) ,and those who request information should receive full results of such surveys on request.

• International health organizations and agencies should issue public health advisories for those exposed to levels of ELF and RF implicated with increased risks from cancer/neurodegenerative diseases and memory/learning/immune/stress responses. These advisories should address both residential and occupational exposures.

• Reliable, unbiased information should be developed and distributed through a clearinghouse that is available to the public. Scientific, public health and policy option information should be provided for independent review at an affordable cost to the public. Research articles and prudent avoidance strategies should be made available in many languages.

• Cell phones and other wireless devices should be redesigned to operate only on speaker-phone mode or text message mode.

• Restrictions should be placed on the sale and advertising of cell phones and other wireless devices to children age 0 to 18 years.

• All countries should continue to provide wired phone service; and should be strongly discouraged from phasing it out; including pay telephones in public places.

• Manufacturers of devices that operate with wireless features should be required to carry SAR level information and warning labels on the outside packaging (not hidden inside). Wireless devices that create elevated RF levels for the user should be required to warn the user of possible adverse effects on memory and learning, cognitive function, sleep disruption and insomnia, mood disorders, balance, headache, fatigue, ringing in the ears (tinnitus), immune function, and other adverse symptoms of use.

• Warning labels on cell phones and PDAs (personal digital assistant devices) and other wireless devices are needed to alert users to excessively high ELF emissions from the switching battery pack, and require labels to list mitigation measures to reduce exposure (do not wear on or near body in “ON-Receive” position; use only with earpiece or on speaker mode, etc).

• Disclosure should be provided to the public on the location and operating characteristics of all wireless antenna sites in a fashion easily accessible to the public so informed choices can be made about where to live, shop, work and go to school. Such information should mandatorily include cumulative RF/MW exposures based on calculations from FCC OET Bulletin 65 (or equivalent) at ground level and second story level in increments of 50 feet outward from the facility to a power density of 0.1 μW/cm2 or 0.614 V/m. Signage for the public should be a mandatory condition of approval for all sites, and should be kept current. Public agencies that approve and monitor wireless sites should require the applicant to identify locations of wireless facilities.

Table 1-1 BioInitiative Report Overall Conclusions

Section 17: Key Scientific Evidence and Public Health Policy Recommendations (continued)

• Mobile phone - free and WI-FI-free public areas should be established in areas where the public congregates and can have a reasonable expectation of safety; including airports, public shopping, hospitals, libraries, medical clinics, convalescent homes and assisted living facilities, theatres, restaurants, parks, etc.

• Health agencies and school districts should strongly discourage or prohibit cell towers on or near (within 1000’ of) school properties, should delay any new WLAN installations in school classrooms, pre-schools and day-care facilities; and should either remove or disable existing wireless facilities, or be required to offer classrooms with no RF exposure to those families who choose not to have their children involuntarily exposed.

SECTION 1

Summary for the Public (2014 Supplement)

Cindy Sage, MA
Sage Associates
Co-Editor, BioInitiative Report
Santa Barbara, CA USA

Prepared for the BioInitiative Working Group
March 2014

TABLE OF CONTENTS

I. SUMMARY FOR THE PUBLIC

A. Introduction

The BioInitiative Working Group concluded in 2007 that existing public safety limits were inadequate to protect public health, and agreed that new, biologically-based public safety limits were needed five years ago. The BioInitiative Report was prepared by more than a dozen world-recognized experts in science and public health policy; and outside reviewers also contributed valuable content and perspective.

From a public health standpoint, experts reasoned that it was not in the public interest to wait. In 2007, the evidence at hand coupled with the enormous populations placed at possible risk was argued as sufficient to warrant strong precautionary measures for RFR, and lowered safety limits for ELF-EMF. The ELF recommendations were biologically-based and reflected the ELF levels consistently associated with increased risk of childhood cancer, and further incorporated a safety factor that is proportionate to others used in similar circumstances. The public health cost of doing nothing was judged to be unacceptable in 2007.

What has changed in 2012? In twenty-four technical chapters, the contributing authors discuss the content and implications of about 1800 new studies. Overall, these new studies report abnormal gene transcription (Section 5); genotoxicity and single- and double-strand DNA damage (Section 6); stress proteins because of the fractal RF-antenna like nature of DNA (Section 7); chromatin condensation and loss of DNA repair capacity in human stem cells (Sections 6 and 15); reduction in free-radical scavengers, particularly melatonin (Sections 5, 9, 13, 14, 15, 16 and 17); neurotoxicity in humans and animals (Section 9); carcinogenicity in humans (Sections 11, 12, 13, 14, 15, 16 and 17); serious impacts on human and animal sperm morphology and function (Section 18); effects on the fetus, neonate and offspring (Section 18 and 19); effects on brain and cranial bone development in the offspring of animals that are exposed to cell phone radiation during pregnancy (Sections 5 and 18); and findings in autism spectrum disorders consistent with EMF/RFR exposure. This is only a snapshot of the evidence presented in the BioInitiative 2012 updated report.

There is reinforced scientific evidence of risk from chronic exposure to low-intensity electromagnetic fields and to wireless technologies (radiofrequency radiation including microwave radiation). The levels at which effects are reported to occur is lower by hundreds of times in comparison to 2007. The range of possible health effects that are adverse with chronic exposures has broadened. There has been a big increase in the number of studies looking at the effects of cell phones (on the belt, or in the pocket of men radiating only on standby mode) and from wireless laptops on impacts to sperm quality and motility; and sperm death (fertility and reproduction). In other new studies of the fetus, infant and young child, and child-in-school – there are a dozen or more new studies of importance. There is more evidence that such exposures damage DNA, interfere with DNA repair, evidence of toxicity to the human genome (genes), more worrisome effects on the nervous system (neurology) and more and better studies on the effects of mobile phone base stations (wireless antenna facilities or cell towers) that report lower RFR levels over time can result in adverse health impacts.

Importantly, some very large studies were completed on brain tumor risk from cell phone use. The 13-country World Health Organization Interphone Final study (2010) produced evidence (although highly debated

among fractious members of the research committee) that cell phone use at 10 years or longer, with approximately 1,640 hours of cumulative use of a cell and/or cordless phone approximately doubles glioma risk in adults. Gliomas are aggressive, malignant tumors where the average life-span following diagnosis is about 400 days. That brain tumors should be revealed in epidemiological studies at ONLY 10 or more years is significant; x-ray and other ionizing radiation exposures that can also cause brain tumors take nearly 15-20 years to appear making radiofrequency/microwave radiation from cell phones a very effective cancer-causing agent. Studies by Lennart Hardell and his research team at Orebro University in Sweden later showed that children who start using a mobile phone in early years have more than a 5-fold (more than a 500%) risk for developing a glioma by the time they are in the 20-29 year age group. This has significant ramifications for public health intervention.

In short order, in 2011 the World Health Organization International Agency on Cancer Research (IARC) classified radiofrequency radiation as a Group 2B Possible Human Carcinogen, joining the IARC classification of ELF-EMF that occurred in 2001. The evidence for carcinogenicity for RFR was primarily from cell phone/brain tumor studies but by IARC rules, applies to all RFR exposures (it applies to the exposure, not just to devices like cell phones or cordless phones that emit RFR).

B. Why We Care?

The stakes are very high. Exposure to electromagnetic fields (both extremely low-frequency ELF-EMF from power frequency sources like power lines and appliances; and radiofrequency radiation or RFR) has been linked to a variety of adverse health outcomes that may have significant public health consequences. The most serious health endpoints that have been reported to be associated with extremely low frequency (ELF) and/or radiofrequency radiation (RFR) include childhood and adult leukemia, childhood and adult brain tumors, and increased risk of the neurodegenerative diseases, Alzheimer's and amyotrophic lateral sclerosis (ALS). In addition, there are reports of increased risk of breast cancer in both men and women, genotoxic effects (DNA damage, chromatin condensation, micronucleation, impaired repair of DNA damage in human stem cells), pathological leakage of the blood–brain barrier, altered immune function including increased allergic and inflammatory responses, miscarriage and some cardiovascular effects. Insomnia (sleep disruption) is reported in studies of people living in very low-intensity RF environments with WI-FI and cell tower-level exposures. Short-term effects on cognition, memory and learning, behavior, reaction time, attention and concentration, and altered brainwave activity (altered EEG) are also reported in the scientific literature. Biophysical mechanisms that may account for such effects can be found in various articles and reviews (Sage, 2012).

Traditional scientific consensus and scientific method is but one contributor to deciding when to take public health action; rather, it is one of several voices that are important in determining when new actions are warranted to protect public health. Certainly it is important, but not the exclusive purview of scientists alone to determine for all of society when changes are in the public health interest and welfare of children.

C. Do We Know Enough to Take Action

Human beings are bioelectrical systems. Our hearts and brains are regulated by internal bioelectrical signals. Environmental exposures to artificial EMFs can interact with fundamental biological processes in the human body. In some cases, this may cause discomfort, or sleep disruption, or loss of well-being (impaired mental functioning and impaired metabolism) or sometimes, maybe it is a dread disease like cancer or Alzheimer's disease. It may be interfering with one's ability to become pregnant, or to carry a child to full term, or result in brain development changes that are bad for the child. It may be these exposures play a role in causing long-term impairments to normal growth and development of children, tipping the scales away from becoming productive adults. The use of common wireless devices like wireless laptops and mobile phones requires urgent action simply because the exposures are everywhere in daily life; we need to define whether and when these exposures can damage health, or the children of the future who will be born to parents now immersed in wireless exposures.

Since World War II, the background level of EMF from electrical sources has risen exponentially, most recently by the soaring popularity of wireless technologies such as cell phones (six billion in 2011-12, up from two billion in 2006), cordless phones, WI-FI ,WiMAX and LTE networks. Some countries are moving from telephone landlines (wired) to wireless phones exclusively, forcing wireless exposures on uninformed populations around the world. These wireless exposures at the same time are now classified by the world's highest authority on cancer assessment, the World Health Organization International Agency for Research on Cancer to be a possible risk to health. Several decades of international scientific research confirm that EMFs are biologically active in animals and in humans. Now, the balance has clearly shifted to one of 'presumption of possible adverse effects' from chronic exposure. It is difficult to conclude otherwise, when the bioeffects that are clearly now occurring lead to such conditions as pathological leakage of the blood-brain barrier (allowing toxins into the brain tissues); oxidative damage to DNA and the human genome, preventing normal DNA repair in human stem cells; interfering with healthy sperm production; producing poor quality sperm or low numbers of healthy sperm, altering fetal brain development that may be fundamentally tied to epidemic rates of autism and problems in school children with memory, attention, concentration, and behavior; and leading to sleep disruptions that undercut health and healing in numerous ways.

In today's world, everyone is exposed to two types of EMFs: (1) extremely low frequency electromagnetic fields (ELF) from electrical and electronic appliances and power lines and (2) radiofrequency radiation (RFR) from wireless devices such as cell phones and cordless phones, cellular antennas and towers, and broadcast transmission towers. In this report we will use the term EMFs when referring to all electromagnetic fields in general; and the terms ELF or RFR when referring to the specific type of exposure. They are both types of non-ionizing radiation, which means that they do not have sufficient energy to break off electrons from their orbits around atoms and ionize (charge) the atoms, as do x-rays, CT scans, and other forms of ionizing radiation. A glossary and definitions are provided in this report to assist you. Some handy definitions you will probably need when reading about ELF and RF in this summary section (the language for measuring it) are shown in Section 26 – Glossary.

II. SUMMARY OF THE SCIENCE

A. Evidence for Damage to Sperm and Reproduction

Several international laboratories have replicated studies showing adverse effects on sperm quality, motility and pathology in men who use and particularly those who wear a cell phone, PDA or pager on their belt or in a pocket (See Section 18 for references including Agarwal et al, 2008; Agarwal et al, 2009; Wdowiak et al, 2007; De Iuliis et al, 2009; Fejes et al, 2005; Aitken et al, 2005; Kumar, 2012). Other studies conclude that usage of cell phones, exposure to cell phone radiation, or storage of a mobile phone close to the testes of human males affect sperm counts, motility, viability and structure (Aitken et al, 2004; Agarwal et al, 2007; Erogul et al, 2006). Animal studies have demonstrated oxidative and DNA damage, pathological changes in the testes of animals, decreased sperm mobility and viability, and other measures of deleterious damage to the male germ line (Dasdag et al, 1999; Yan et al, 2007; Otitoloju et al, 2010; Salama et al, 2008; Behari et al, 2006; Kumar et al, 2012). There are fewer animal studies that have studied effects of cell phone radiation on female fertility parameters. Panagopoulous et al (2012) report decreased ovarian development and size of ovaries, and premature cell death of ovarian follicles and nurse cells in *Drosophila melanogaster*. Gul et al (2009) reported rats exposed to stand-by level RFR (phones on but not transmitting calls) had a decrease in the number of ovarian follicles in pups born to these exposed dams. Magras and Xenos (1997) reported irreversible infertility in mice after five (5) generations of exposure to RFR at cell phone tower exposure levels of less than one microwatt per centimeter squared (μW/cm2). See Section 18 for references.

HUMAN SPERM AND THEIR DNA ARE DAMAGED
Human sperm are damaged by cell phone radiation at very low intensities (0.00034 – 0.07 μW/cm2). There is a veritable flood of new studies reporting sperm damage in humans and animals, leading to substantial concerns for fertility, reproduction and health of the offspring (unrepaired de novo mutations in sperm). Exposure levels are similar to those resulting from wearing a cell phone on the belt, or in the pants pocket, or using a wireless laptop computer on the lap. Sperm lack the ability to repair DNA damage. (Behari and Rajamani, Section 18) young child are more vulnerable than older persons are to chemicals and ionizing radiation. The US Environmental Protection Agency (EPA) proposes a 10-fold risk adjustment for the first 2 years of life exposure to carcinogens, and a 3-fold adjustment for years 3 to 5. These adjustments do not deal with fetal risk, and the possibility of extending this protection to the fetus should be examined, because of fetus' rapid organ development.

The Presidential Cancer Panel (2010) found that children "are at special risk due to their smaller body mass and rapid physical development, both of which magnify their vulnerability to known carcinogens, including radiation." The American Academy of Pediatrics, in a letter to Congressman Dennis Kucinich dated 12 December 2012 states: "Children are disproportionately affected by environmental exposures, including cell phone radiation. The differences in bone density and the amount of fluid in a child's brain compared to an adult's brain could allow children to absorb greater quantities of RF energy deeper into their brains than adults. It is essential that any new standards for cell phones or other wireless devices be based on protecting the youngest and most vulnerable populations to ensure they are safeguarded through their lifetimes."

The issue around exposure of children to RFR is of critical importance. There is overwhelming evidence that children are more vulnerable than adults to many different exposures (Sly and Carpenter, 2012), including RFR, and that the diseases of greatest concern are cancer and effects on neurodevelopment. Yet parents place RFR-emitting baby monitors in cribs, provide very young children with wireless toys, and give cell phones to young children, usually without any knowledge of the potential dangers. A growing concern is the movement to make all student computer laboratories in schools wireless. A wired computer laboratory will not increase RFR exposure, and will provide safe access to the Internet (Section, Sage and Carpenter, BioInitiative 2012 Report).

C. Evidence for Fetal and Neonatal Effects

Effects on the developing fetus from in-utero exposure to cell phone radiation have been observed in both human and animal studies since 2006. Sources of fetal and neonatal exposures of concern include cell phone radiation (both paternal use of wireless devices worn on the body and maternal use of wireless phones during pregnancy). Sources include exposure to whole-body RFR from base stations and Wi-Fi, use of wireless laptops, use of incubators for newborns with excessively high ELF-EMF levels resulting in altered heart rate variability and reduced melatonin levels in newborns, fetal exposures to MRI of the pregnant mother, and greater susceptibility to leukemia and asthma in the child where there have been maternal exposures to ELF-EMF. Divan et al (2008) found that children born to mothers who used cell phones during pregnancy develop more behavioral problems by the time they have reached school age than children whose mothers did not use cell phones during pregnancy. Children whose mothers used cell phones during pregnancy had 25% more emotional problems, 35% more hyperactivity, 49% more conduct problems and 34% more peer problems (Divan et al, 2008). Aldad et al (2012) showed that cell phone radiation significantly altered fetal brain development and produced ADHD-like behavior in the offspring of pregnant mice. Exposed mice had a dose-dependent impaired glutamatergic synaptic transmission onto Layer V pyramidal neurons of the prefrontal cortex. The authors conclude the behavioral changes were the result of altered neuronal developmental programming in utero. Offspring mice were hyperactive and had impaired memory function and behavior problems, much like the human children in Divan et al (2008). See Sections 19 and 20 for references. Fragopoulou et al (2012) reports that brain astrocyte development followed by proteomic studies is adversely affected by DECT (cordless phone radiation) and mobile phone radiation.

> Fetal (in-utero) and early childhood exposures to cell phone radiation and wireless technologies in general may be a risk factor for hyperactivity, learning disorders and behavioral problems in school. Common sense measures to limit both ELF-EMF and RF EMF in these populations is needed, especially with respect to avoidable exposures like incubators that can be modified; and where education of the pregnant mother with respect to laptop computers, mobile phones and other sources of ELF-EMF and RF EMF are easily instituted.
>
> A precautionary approach may provide the frame for decision-making where remediation actions have to be realized to prevent high exposures of children and pregnant woman.
>
> (Bellieni and Pinto, 2012 – Section 19)

D. Evidence for Effects on Autism (Autism Spectrum Conditions)

Physicians and health care practitioners should raise the visibility of EMF/RFR as a plausible environmental factor in ASC clinical evaluations and treatment protocols. Reducing or removing EMF and wireless RFR stressors from the environment is a reasonable precautionary action given the overall weight of evidence for a link to ASCs.

Several thousand scientific studies over four decades point to serious biological effects and health harm from EMF and RFR. These studies report genotoxicity, single-and double-strand DNA damage, chromatin condensation, loss of DNA repair capacity in human stem cells, reduction in free-radical scavengers (particularly melatonin), abnormal gene transcription, neurotoxicity, carcinogenicity, damage to sperm morphology and function, effects on behavior, and effects on brain development in the fetus of human mothers that use cell phones during pregnancy. Cell phone exposure has been linked to altered fetal brain development and ADHD-like behavior in the offspring of pregnant mice.

Many disrupted physiological processes and impaired behaviors in people with ASCs closely resemble those related to biological and health effects of EMF/RFR exposure. Biomarkers and indicators of disease and their clinical symptoms have striking similarities. At the cellular and molecular level many studies of people with ASCs have identified oxidative stress and evidence of free-radical damage, as well as deficiencies of antioxidants such as glutathione. Elevated intracellular calcium in ASCs can be associated with genetic mutations but more often may be downstream of inflammation or chemical exposures. Lipid peroxidation of cell membranes, disruption of calcium metabolism, altered brain wave activity and consequent sleep, behavior and immune dysfunction, pathological leakage of critical barriers between gut and blood or blood and brain may also occur. Mitochondria may function poorly, and immune system disturbances of various kinds are common. Changes in brain and autonomic nervous system electrophysiology can be measured and seizures are far more common than in the population at large. Sleep disruption and high levels of stress are close to universal. All of these phenomena have also been documented to result from or be modulated by EMF/RFR exposure.

- • Children with existing neurological problems that include cognitive, learning, attention, memory, or behavioral problems should as much as possible be provided with wired (not wireless) learning, living and sleeping environments.
- • Special education classrooms should observe 'no wireless' conditions to reduce avoidable stressors that may impede social, academic and behavioral progress.
- • All children should reasonably be protected from the physiological stressor of significantly elevated EMF/RFR (wireless in classrooms, or home environments).
- • School districts that are now considering all-wireless learning environments should be strongly cautioned that wired environments are likely to provide better learning and teaching environments, and prevent possible adverse health consequences for both students and faculty in the long-term.
- • Monitoring of the impacts of wireless technology in learning and care environments should be performed with sophisticated measurement and data analysis techniques that are cognizant of the non-linear impacts of EMF/RFR and of data techniques most appropriate for discerning these impacts.
- • There is sufficient scientific evidence to warrant the selection of wired Internet, wired classrooms and wired learning devices, rather than making an expensive and potentially health-harming commitment to wireless devices that may have to be substituted out later.
- • Wired classrooms should reasonably be provided to all students who opt-out of wireless environments.

(Herbert and Sage, 2012 – Section 20)

The public needs to know that these risks exist, that transition to wireless should not be presumed safe, and that it is very much worth the effort to minimize exposures that still provide the benefits of technology in learning, but without the threat of health risk and development impairments to learning and behavior in the classroom.

Broader recommendations also apply, related to reducing the physiological vulnerability to exposures, reduce allostatic load and build physiological resiliency through high quality nutrition, reducing exposure to toxicants and infectious agents, and reducing stress, all of which can be implemented safely based upon presently available knowledge.

E. Evidence for Electrohypersensitivity

The contentious question of whether electrohypersensitivity exists as a medical condition and what kinds of testing might reveal biomarkers for diagnosis and treatment has been furthered by several new studies presented in Section 24 – Key Scientific Evidence and Public Health Policy Recommendations. What is evident is that a growing number of people world-wide have serious and debilitating symptoms that key to various types of EMF and RFR exposure. Of this there is little doubt. The continued massive rollout of wireless technologies, in particular the wireless 'smart' utility meter, has triggered thousands of complaints of ill-health and disabling symptoms when the installation of these meters is in close proximity to family home living spaces.

McCarty et al (2011) studied electrohypersensitivity in a patient (a female physician). The patient was unable to detect the presence or absence of EMF exposure, largely ruling out the possibility of bias. In multiple trials with the fields either on or not on, the subject experienced and reported temporal pain, feeling of unease, skipped heartbeats, muscle twitches and/or strong headache when the pulsed field (100 ms, duration at 10 Hz) was on, but no or mild symptoms when it was off. Symptoms from continuous fields were less severe than with pulsed fields. The differences between field on and sham exposure were significant at the $p < 0.05$ level. The authors conclude that electromagnetic hypersensitivity is a neurological syndrome, and statistically reliable somatic reactions can be provoked in this patient by exposure to 60-Hz electric fields at 300 volts per meter (V/m). Marino et al (2012) responded to comments on his study with McCarty saying:

> *"EMF hypersensitivity can occur as a bona fide environmentally inducible neurological syndrome. We followed an empirical approach and demonstrated a cause-and-effect relationship ($p < 0.05$) under conditions that permitted us to infer the existence of electromagnetic hypersensitivity (EHS), a novel neurological syndrome."*

The team of Sandstrom, Hansson Mild and Lyskov produced numerous papers between 1994 and 2003 involving people who are electrosensitive (See Section 24 - Lyskov et al, 1995; Lyskov et al, 1998; Sandstrom et al, 1994; Sandstrom et al, 1995;

Sandstrom et al, 1997; Sandstrom et al, 2003). Sandstrom et al (2003) presented evidence that heart rate variability is impaired in people with electrical hypersensitivity and showed disruption of the autonomic nervous system.

"EHS patients had a disturbed pattern of circadian rhythms of HRF and showed a relatively 'flat' representation of hourly-recorded spectral power of the HF component of HRV". This research team also found that "EHS patients have a dysbalance of the autonomic nervous system (ANS) regulation with a trend to hyper-sympathotonia, as measured by heart rate (HR) and electrodermal activity, and a hyperreactivity to different external physical factors, as measured by brain evoked potentials and sympathetic skin responses to visual and audio stimulation." (Lyskov et al, 2001 a,b; Sandstrom et al, 1997).

The reports referenced above provide evidence that persons who report being electrosensitive differ from others in having some abnormalities in the autonomic nervous system, reflected in measures such as heart rate variability.

F. Evidence for Effects from Cell Tower-Level RFR Exposures

Very low exposure RFR levels are associated with bioeffects and adverse health effects. At least five new cell tower studies are reporting bioeffects in the range of 0.001 to 0.05 μW/cm2 at lower levels than reported in 2007 (0.05 to 0.1 uW/cm2 was the range below which, in 2007, effects were not observed). Researchers report headaches, concentration difficulties and behavioral problems in children and adolescents; and sleep disturbances, headaches and concentration problems in adults. Public safety standards are 1,000 – 10,000 or more times higher than levels now commonly reported in mobile phone base station studies to cause bioeffects.

Since 2007, five new studies of base station level RFR at intensitites ranging from lessthan 0.001 uW/cm2 to 0.05 uW/cm2 report headaches, concentrationdifficulties and behavioral problems in children and adolescents; and sleep disturbances, headaches and concentration problems in adults.

G. Evidence for Effects on the Blood-brain Barrier (BBB)

The Lund University (Sweden) team of Leif Salford, Bertil Persson and Henrietta Nittby has done pioneering work on effects of very low level RFR on the human brain's protective lining – the barrier that protects the brain from large molecules and toxins that are in the blood.

THE BLOOD-BRAIN BARRIER IS AT RISK

The BBB is a protective barrier that prevents the flow of toxins into sensitive brain tissue. Increased permeability of the BBB caused by cell phone RFR may result in neuronal damage. Many research studies show that very low intensity exposures to RFR can affect the blood-brain barrier (BBB) (mostly animal studies). Summing up the research, it is more probable than unlikely that non-thermal EMF from cell phones and base stations do have effects upon biology. A single 2-hr exposure to cell phone radiation can result in increased leakage of the BBB, and 50 days after exposure, neuronal damage can be seen, and at the later time point also albumin leakage is demonstrated. The levels of RFR needed to affect the BBB have been shown to be as low as 0.001 W/kg, or less than holding a mobile phone at arm's length. The US FCC standard is 1.6 W/kg; the ICNIRP standard is 2 W/kg of energy (SAR) into brain tissue from cell/cordless phone use. Thus, BBB effects occur at about 1000 times lower RFR exposure levels than the US and ICNIRP limits allow.

(Salford et al, 2012 - Section 10)

H. Evidence for Effects on Brain Tumors

The Orebro University (Sweden) team led by Lennart Hardell, MD, an oncologist and medical researcher, has produced an extraordinary body of work on environmental toxins of several kinds, including the effects of radiofrequency/microwave radiation and cancer. Their 2012 work concludes:

> "Based on epidemiological studies there is a consistent pattern of increased risk for glioma and acoustic neuroma associated with use of mobile phones and cordless phones. The evidence comes mainly from two study centres, the Hardell group in Sweden and the Interphone Study Group. No consistent pattern of an increased risk is seen for meningioma. A systematic bias in the studies that explains the results would also have been the case for meningioma. The different risk pattern for tumor type strengthens the findings regarding glioma and acoustic neuroma. Meta-analyses of the Hardell group and Interphone studies show an increased risk for glioma and acoustic neuroma. Supportive evidence comes also from anatomical localisation of the tumor to the most exposed area of the brain, cumulative exposure in hours and latency time that all add to the biological relevance of an increased risk. In addition risk calculations based on estimated absorbed dose give strength to the findings. (Hardell et al, 2012 – Section 11)

> "There is reasonable basis to conclude that RF-EMFs are bioactive and have a potential to cause health impacts. There is a consistent pattern of increased risk for glioma and acoustic neuroma associated with use of wireless phones (mobile phones and cordless phones) mainly based on results from case-control studies from the Hardell group and Interphone Final Study results. Epidemiological evidence gives that RF-EMF should be classified as a human carcinogen. Based on our own research and review of other evidence the existing FCC/IEE and ICNIRP public safety limits and reference levels are not adequate to protect public health. New public health standards and limits are needed. (Hardell et al, 2012 – Section 11)

I. Evidence for Genotoxic Effects (Genotoxicity)

Genetic Damage (Genotoxicity Studies): There are at least several hundred published papers that report EMF (ELF/RFR) can affect cellular oxidative processes (oxidative damage). Increased free radical activity and changes in enzymes involved in cellular oxidative processes are the most consistent effects observed in cells and animals after EMF exposure. Aging may make an individual more susceptible to the detrimental effects of ELF EMF from oxidative damage, since anti-oxidants may decline with age. Clearly, the preponderance of genetic studies report DNA damage and failure to repair DNA damage.

> One hundred fourteen (114) new papers on genotoxic effects of RFR published between 2007 and early 2014 are profiled. Of these, 74 (65%) showed effects and 40 (35%) showed no effects. (Lai, 2014 – Section 6)
>
> Fifty nine (59) new ELF-EMF papers and two static magnetic field papers that report on genotoxic effects of ELF-EMF published between 2007 and early 2014 are profiled. Of these, 49 (83%) show effects and 10 (17%) show no effect. (Lai, 2014 – Section 6)

Factors that act directly or indirectly on the nervous system can cause morphological, chemical, or electrical changes in the nervous system that can lead to neurological effects. Both RF and ELF EMF affect neurological functions and behavior in animals and humans.

Two hundred eleven (211) new papers that report on neurological effects of RFR published between 2007 and early 2014 are profiled. Of these, 144 (68%) showed effects and 67 (32%) showed no effects.

One hundred five (105) new ELF-EMF papers (including two static field papers) that report on neurological effects of ELF-EMF published between 2007 and early 2014 are profiled. Of these, 95 (90%) show effects and 10 (10%) show no effect. (Lai, 2014 – Section 9)

K. Evidence for Cancer (Childhood Leukemia)

With overall 42 epidemiological studies published to datel power frequency ELF-EMF is among the most comprehensively studied environmental factors. Except ionizing radiation no other environmental factor has been as firmly established to increase the risk of childhood leukemia.

Sufficient evidence exists from epidemiological studies of an increased risk from exposure to EMF (power frequency ELF-EMF magnetic fields) and cannot be attributed to chance, bias or confounding. Therefore, according to the rules of IARC such exposures can be classified as a **Group 1 carcinogen (Known Carcinogen).**

There is no other risk factor identified so far for which such unlikely conditions have been put forward to postpone or deny the necessity to take steps towards exposure reduction. As one step in the direction of precaution, measures should be implemented to guarantee that exposure due to transmission and distribution lines is below an average of about 1 mG. This value is arbitrary at present and only supported by the fact that in many studies this level has been chosen as a reference. (Kundi, 2012 – Section 12)

L. Melatonin, Breast Cancer and Alzheimer's Disease

MELATONIN AND BREAST CANCER: Eleven (11) of the 13 published epidemiologic residential and occupational studies are considered to provide (positive) evidence that high ELF magnetic fields (MF) exposure can result in decreased melatonin production. The two negative studies had important deficiencies that may certainly have biased the results. There is sufficient evidence to conclude that long-term relatively high ELF MF exposure can result in a decrease in melatonin production. It has not been determined to what extent personal characteristics, e.g., medications, interact with ELF MF exposure in decreasing melatonin production.

There is sufficient evidence to conclude that long-term relatively high ELF MF exposure can result in a decrease in melatonin production, which may increase risk for breast cancer. It has not been determined to what extent personal characteristics, e.g., medications, interact with ELF MF exposure in decreasing melatonin production. New research indicates that ELF MF exposure, in vitro, can significantly decrease melatonin activity through effects on MT1, an important melatonin receptor. Five longitudinal studies have now been conducted of low melatonin production as a risk factor for breast cancer. There is increasingly strong longitudinal evidence that low melatonin production is a risk factor for at least post-menopausal breast cancer.

(Davanipour and Sobel, 2012 – Section 13)

ALZHEIMER'S DISEASE: There is now evidence that a) high levels of peripheral amyloid beta are a risk factor for AD, and b) medium to high ELF MF exposure can increase peripheral amyloid beta. High brain levels of amyloid beta are also a risk factor for AD and medium to high ELF MF exposure to brain cells likely also increases these cells' production of amyloid beta. There is considerable in vitro and animal evidence that melatonin protects against AD. Therefore it is certainly possible that low levels of melatonin production are associated with an increase in the risk of AD.

There is strong epidemiologic evidence that exposure to ELF MF is a risk factor for AD. There are now twelve (12) studies of ELF MF exposure and AD or dementia. Nine (9) of these studies are considered positive and three (3) are considered negative. The three negative studies have serious deficiencies in ELF MF exposure classification that results in subjects with rather low exposure being considered as having significant exposure. There are insufficient studies to formulate an opinion as to whether radiofrequency MF exposure is a risk or protective factor for AD.

There is now evidence that (i) high levels of peripheral amyloid beta are a risk factor for AD and (ii) medium to high ELF MF exposure can increase peripheral amyloid beta. High brain levels of amyloid beta are also a risk factor for AD and medium to high ELF MF exposure to brain cells likely also increases these cells' production of amyloid beta.

There is considerable in vitro and animal evidence that melatonin protects against AD. Therefore it is certainly possible that low levels of melatonin production are associated with an increase in the risk of AD.

(Davanipour and Sobel, 2012 – Section 13)

M. Stress, Stress Proteins and DNA as a Fractal Antenna

Any agent (EMF, ionizing radiation, chemicals, heavy metals, heat and other factors) that continuously generates stress proteins is not adaptive, and is harmful, if it is a constant provocation. The work of Martin Blank and Reba Goodman of Columbia University has established that stress proteins are produced by ELF-EMF and RFR at levels far below what current safety standards allow. Further, they think DNA is actually a very good fractal RF-antenna which is very sensitive to low doses of EMF, and may induce the cellular processes that result in chronic 'unrelenting' stress. That daily environmental levels of ELF-EMF and RFR can and do throw the human body into stress protein response mode (out of homeostasis) is a fundamental and continuous insult. Chronic exposures can then result in chronic ill-health**.**

> *"It appears that the DNA molecule is particularly vulnerable to damage by EMF because of the coiled-coil configuration of the compacted molecule in the nucleus. The unusual structure endows it with the self similarity of a fractal antenna and the resulting sensitivity to a wide range of frequencies. The greater reactivity of DNA with EMF, along with a vulnerability to damage,*

underscores the urgent need to revise EMF exposure standards in order to protect the public. Recent studies have also exploited the properties of stress proteins to devise therapies for limiting oxidative damage and reducing loss of muscle strength associated with aging." (Blank, 2012- Section 7)

- DNA acts as a 'fractal antenna' for EMF and RFR. The coiled-coil structure of DNA in the nucleus makes the molecule react like a fractal antenna to a wide range of frequencies.
- The structure makes DNA particularly vulnerable to EMF damage.
- The mechanism involves direct interaction of EMF with the DNA molecule (claims that there are no known mechanisms of interaction are patently false).
- Many EMF frequencies in the environment can and do cause DNA changes.
- The EMF-activated cellular stress response is an effective protective mechanism for cells exposed to a wide range of EMF frequencies.
- EMF stimulates stress proteins (indicating an assault on the cell).
- EMF efficiently harms cells at billions of times lower levels than conventional heating.
- Safety standards based on heating are irrelevant to protect against EMF-levels of exposure. There is an urgent need to revise EMF exposure standards. Research has shown thresholds are very low (safety standards must be reduced to limit biological responses). Biologically-based safety standards could be developed from the research on the stress response. (Blank, 2012 – Section 7).

N. Effects of Weak-Field Interactions on Non-Linear Biological Oscillators and Synchronized Neural Activity:

A unifying hypothesis for a plausible biological mechanism to account for very weak field EMF bioeffects other than cancer may lie with weak field interactions of pulsed RFR and ELF-modulated RFR as disrupters of synchronized neural activity. Electrical rhythms in our brains can be influenced by external signals. This is consistent with established weak field effects on coupled biological oscillators in living tissues. Biological systems of the heart, brain and gut are dependent on the cooperative actions of cells that function according to principles of non-linear, coupled biological oscillations for their synchrony, and are dependent on exquisitely timed cues from the environment at vanishingly small levels (Buzsaki, 2006; Strogatz, 2003). The key to synchronization is the joint actions of cells that co-operate electrically and link populations of biological oscillators that couple together in large arrays and synchronize spontaneously. Synchronous biological oscillations in cells (pacemaker cells) can be disrupted by artificial, exogenous environmental signals, resulting in desynchronization of neural activity that regulates critical functions (including metabolism) in the brain, gut and heart and circadian rhythms governing sleep and hormone cycles (Strogatz, 1987). The brain contains a population of oscillators with distributed natural frequencies, which pull one another into synchrony (the circadian pacemaker cells). Strogatz has addressed the unifying mathematics of biological cycles and external factors disrupt these cycles (Strogatz, 2001, 2003)

"Rhythms can be altered by a wide variety of agents and that these perturbations must seriously alter brain performance." (Busaki, 2006)

III. EMF EXPOSURE AND PRUDENT PUBLIC HEALTH PLANNING

Chronic exposure to low-intensity RFR and to ELF-modulated RFR at today's environmental levels in many cities will exceed thresholds for increased risk of many diseases and causes of death (Sage and Huttunen, 2012). RFR exposures in daily life alter homeostasis in human beings. These exposures can alter and damage genes, trigger epigenetic changes to gene expression and cause de novo mutations that prevent genetic recovery and healing mechanisms. These exposures may interfere with normal cardiac and brain function; alter circadian rhythms that regulate sleep, healing, and hormone balance; impair short-term memory, concentration, learning and behavior; provoke aberrant immune, allergic and inflammatory responses in tissues; alter brain metabolism; increase risks for reproductive failure (damage sperm and increase miscarriage risk); and cause cells to produce stress proteins. Exposures now common in home and school environments are likely to be physiologically addictive and the effects are particularly serious in the young (Sage and Huttunen, 2012).

RECOMMENDED ACTIONS

A. Defining Preventative Actions for Reduction in RFR Exposures

ELF-EMF and RFR are Classified as Possible Cancer-causing Agents – Why Are Governments Not Acting?

The World Health Organization International Agency for Research on Cancer has classified wireless radiofrequency as a Possible Human Carcinogen (May, 2011)*. The designation applies to low-intensity RFR in general, covering all RFR-emitting devices and exposure sources (cell and cordless phones, Wi-Fi, wireless laptops, wireless hotspots, electronic baby monitors, wireless classroom access points, wireless antenna facilities). The IARC Panel could have chosen to classify RFR as a Group 4 – Not A Carcinogen if the evidence was clear that RFR is not a cancer-causing agent. It could also have found a Group 3 designation was a good interim choice (Insufficient Evidence). IARC did neither.

New Safety Limits Must Be Established – Health Agencies Should Act Now

Existing public safety limits (FCC and ICNIRP public safety limits) do not sufficiently protect public health against chronic exposure from very low-intensity exposures. If no mid-course corrections are made to existing and outdated safety limits, such delay will magnify the public health impacts with even more applications of wireless-enabled technologies exposing even greater populations around the world in daily life.

Scientific Benchmarks for Harm Plus Safety Margins = New Safety Limits that are Valid

Health agencies and regulatory agencies that set public safety standards for ELF-EMF and RFR should act now to adopt new, biologically-relevant safety limits that key to the lowest scientific benchmarks for harm coming from the recent studies, plus a lower safety margin. Existing public safety limits are too high by several orders of magnitude, if prevention of bioeffects and resulting adverse health effects are to be minimized or

eliminated. Most safety standards are a thousand times or more too high to protect healthy populations, and even less effective in protecting sensitive subpopulations.

Sensitive Populations Must Be Protected

Safety standards for sensitive populations will more likely need to be set at lower levels than for healthy adult populations. Sensitive populations include the developing fetus, the infant, children, the elderly, those with pre-existing chronic diseases, and those with developed electrical sensitivity (EHS).

Protecting New Life – Infants and Children

Strong precautionary action and clear public health warnings are warranted immediately to help prevent a global epidemic of brain tumors resulting from the use of wireless devices (mobile phones and cordless phones). Commonsense measures to limit both ELF-EMF and RFR in the fetus and newborn infant (sensitive populations) are needed, especially with respect to avoidable exposures like baby monitors in the crib and baby isolettes (incubators) in hospitals that can be modified; and where education of the pregnant mother with respect to laptop computers, mobile phones and other sources of ELF-EMF and RFR are easily instituted.

Wireless laptops and other wireless devices should be strongly discouraged in schools for children of all ages.

Standard of Evidence for Judging the Science

The standard of evidence for judging the scientific evidence should be based on good public health principles rather than demanding scientific certainty before actions are taken.

Wireless Warnings for All

The continued rollout of wireless technologies and devices puts global public health at risk from unrestricted wireless commerce unless new, and far lower exposure limits and strong precautionary warnings for their use are implemented.

EMF and RFR are Preventable Toxic Exposures

We have the knowledge and means to save global populations from multi-generational adverse health consequences by reducing both ELF and RFR exposures. Proactive and immediate measures to reduce unnecessary EMF exposures will lower disease burden and rates of premature death.

B. Defining New 'Effect Level' for RFR

Section 24 concludes that RFR 'effect levels' for bioeffects and adverse health effects justify new and lower precautionary target levels for RFR exposure. New epidemiological and laboratory studies are finding effects on humans at lower exposure levels where studies are of longer duration (chronic exposure studies). Real-world experience is revealing worrisome evidence that sperm may be damaged by cell phones even on

stand-by mode; and people can be adversely affected by placing new wireless pulsed RFR transmitters (utility meters on the sides or interiors of homes), even when the time-weighted average for RFR is miniscule in both cases.

There is increasing reason to believe that the critical factor for biologic significance is the intermittent pulse of RF, not the time-averaged SAR. For example, Hansson Mild et al, (2012) concluded there could be no effect on sleep and testicular function from a GSM mobile phone because the "*exposure in stand-by mode can be considered negligible*". It may be that we, as a species, are more susceptible than we thought to intermittent, very low-intensity pulsed RFR signals that can interact with critical activities in living tissues. It is a mistake to conclude that the effect does not exist because we cannot explain HOW it is happening or it upsets our mental construct of how things should work.

This highlights the serious limitation of not taking the nature of the pulsed RFR signal (high intensity but intermittent, microsecond pulses of RFR) into account in the safety standards. This kind of signal is biologically active. Even if it is essentially mathematically invisible when the individual RFR pulses are time-averaged, it is apparently NOT invisible to the human body and its proper biological functioning.

For these reasons, and in light of parallel scientific work on non-linear biological oscillators including the accepted mathematics in this branch of science regarding coupled oscillators (Bezsaki, 2006; Strogatz, 2001, 2003), it is essential to think forward about the ramifications of shifting national energy strategies toward ubiquitous wireless systems. And, it is essential to re-think safety standards to take into account the exquisite sensitivity of biological systems and tissue interactions where the exposures are pulsed and cumulatively insignificant over time-scale averaging, but highly relevant to body processes and functioning. If it is true that weak-field effects have control elements over synchronous activity of neurons in the brain, and other pacemaker cells and tissues in the heart and gut that drive essential metabolic pathways as a result, then this will go far in explaining why living tissues are apparently so reactive to very small inputs of pulsed RFR, and lead to better understanding of what is required for new, biologically-based public exposure standards.

A reduction from the BioInitiative 2007 recommendation of 0.1 uW/cm2 (or one-tenth of a microwatt per square centimeter) for cumulative outdoor RFR down to something three orders of magnitude lower (in the low nanowatt per square centimeter range) is justified on a public health basis. We use the new scientific evidence documented in this Report to identify 'effect levels' and then apply one or more reduction factors to provide a safety margin. A cautionary target level for cumulative, outdoor pulsed RFR exposures for ambient wireless that could be applied to RFR sources from cell tower antennas, Wi-Fi, WiMAX and other similar sources is proposed. Research is needed to determine what is biologically damaging about intermittent pulses of RFR, and how to provide for protection in safety limits against it. With this knowledge it might be feasible to recommend a higher time-averaged number.

A scientific benchmark of 0.003 uW/cm2 or three nanowatts per centimeter squared for 'lowest observed effect level' for RFR is based on mobile phone base station-level studies. Applying a ten-fold reduction to compensate for the lack of long-term exposure (to provide a safety buffer for chronic exposure, if needed) or for children as a sensitive subpopulation (if studies are on adults, not children) yields a 300 to 600 picowatts per

square centimeter precautionary action level. This equates to a 0.3 nanowatts to 0.6 nanowatts per square centimeter as a reasonable, precautionary action level for chronic exposure to pulsed RFR. Even so, these levels may need to change in the future, as new and better studies are completed. This is what the authors said in 2007 (Carpenter and Sage, 2007, BioInitiative Report) and it remains true today in 2012.

We leave room for future studies that may lower or raise today's observed 'effects levels' and should be prepared to accept new information as a guide for new precautionary action.

BIOINITIATIVE 2012 - CONCLUSIONS Table 1-1

(Genetics and Neurological Effects Updated March 2014)

Overall, more than 1800 or so new studies report abnormal gene transcription (Section 5); genotoxicity and single-and double-strand DNA damage (Section 6); stress proteins because of the fractal RF-antenna like nature of DNA (Section 7); chromatin condensation and loss of DNA repair capacity in human stem cells (Sections 6 and 15); reduction in free-radical scavengers - particularly melatonin (Sections 5, 9, 13, 14, 15, 16 and 17); neurotoxicity in humans and animals (Section 9), carcinogenicity in humans (Sections 11, 12, 13, 14, 15, 16 and 17); serious impacts on human and animal sperm morphology and function (Section 18); effects on offspring behavior (Section 18, 19 and 20); and effects on brain and cranial bone development in the offspring of animals that are exposed to cell phone radiation during pregnancy (Sections 5 and 18). This is only a snapshot of the evidence presented in the BioInitiative 2012 updated report.

BIOEFFECTS ARE CLEARLY ESTABLISHED

Bioeffects are clearly established and occur at very low levels of exposure to electromagnetic fields and radiofrequency radiation. Bioeffects can occur in the first few minutes at levels associated with cell and cordless phone use. Bioeffects can also occur from just minutes of exposure to mobile phone masts (cell towers), WI-FI, and wireless utility 'smart' meters that produce whole-body exposure. Chronic base station level exposures can result in illness.

BIOEFFECTS WITH CHRONIC EXPOSURES CAN REASONABLY BE PRESUMED TO RESULT IN ADVERSE HEALTH EFFECTS

Many of these bioeffects can reasonably be presumed to result in adverse health effects if the exposures are prolonged or chronic. This is because they interfere with normal body processes (disrupt homeostasis), prevent the body from healing damaged DNA, produce immune system imbalances, metabolic disruption and lower resilience to disease across multiple pathways. Essential body processes can eventually be disabled by incessant external stresses (from system-wide electrophysiological interference) and lead to pervasive impairment of metabolic and reproductive functions.

LOW EXPOSURE LEVELS ARE ASSOCIATED WITH BIOEFFECTS AND ADVERSE HEALTH EFFECTS AT CELL TOWER RFR EXPOSURE LEVELS

At least five new cell tower studies are reporting bioeffects in the range of 0.003 to 0.05 μW/cm2 at lower levels than reported in 2007 (0.05 to 0.1 uW/cm2 was the range below which, in 2007, effects were not observed). Researchers report headaches, concentration difficulties and behavioral problems in children and adolescents; and sleep disturbances, headaches and concentration problems in adults. Public safety standards are 1,000 – 10,000 or more times higher than levels now commonly reported in mobile phone base station studies to cause bioeffects.

EVIDENCE FOR FERTILITY AND REPRODUCTION EFFECTS: HUMAN SPERM AND THEIR DNA ARE DAMAGED

Human sperm are damaged by cell phone radiation at very low intensities in the low microwatt and nanowatt/cm2 range (0.00034 – 0.07 uW/cm2). There is a veritable flood of new studies reporting sperm damage in humans and animals, leading to substantial concerns for fertility, reproduction and health of the offspring (unrepaired de novo mutations in sperm). Exposure levels are similar to those resulting from wearing a cell phone on the belt, or in the pants pocket, or using a wireless laptop computer on the lap. Sperm lack the ability to repair DNA damage.

Studies of human sperm show genetic (DNA) damage from cell phones on standby mode and wireless laptop use. Impaired sperm quality, motility and viability occur at exposures of 0.00034 uW/cm2 to 0.07 uW/cm2 with a resultant reduction in human male fertility. Sperm cannot repair DNA damage.

Several international laboratories have replicated studies showing adverse effects on sperm quality, motility and pathology in men who use and particularly those who wear a cell phone, PDA or pager on their belt or in a pocket (Agarwal et al, 2008; Agarwal et al, 2009; Wdowiak et al, 2007; De Iuliis et al, 2009; Fejes et al, 2005; Aitken et al, 2005; Kumar, 2012). Other studies conclude that usage of cell phones, exposure to cell phone radiation, or storage of a mobile phone close to the testes of human males affect sperm counts, motility, viability and structure (Aitken et al, 2004; Agarwal et al, 2007; Erogul et al., 2006). Animal studies have demonstrated oxidative and DNA damage, pathological changes in the testes of animals, decreased sperm mobility and viability, and other measures of deleterious damage to the male germ line (Dasdag et al, 1999; Yan et al, 2007; Otitoloju et al, 2010; Salama et al, 2008; Behari et al, 2006; Kumar et al, 2012). There are fewer animal studies that have studied effects of cell phone radiation on female fertility parameters. Panagopoulous et al. 2012 report decreased ovarian development and size of ovaries, and premature cell death of ovarian follicles and nurse cells in *Drosophila melanogaster*. Gul et al (2009) report rats exposed to stand-by level RFR (phones on but not transmitting calls) caused decrease in the number of ovarian follicles in pups born to these exposed dams. Magras and Xenos (1997) reported irreversible infertility in mice after five (5) generations of exposure to RFR at cell phone tower exposure levels of less than one microwatt per centimeter squared (μW/cm2).

EVIDENCE THAT CHILDREN ARE MORE VULNERABLE

There is good evidence to suggest that many toxic exposures to the fetus and very young child have especially detrimental consequences depending on when they occur during critical phases of growth and development (time windows of critical development), where such exposures may lay the seeds of health harm that develops even decades later. Existing FCC and ICNIRP public safety limits seem to be not sufficiently protective of public health, in particular for the young (embryo, fetus, neonate, very young child).

The Presidential Cancer Panel (2010) found that children '*are at special risk due to their smaller body mass and rapid physical development, both of which magnify their vulnerability to known carcinogens, including radiation.*'

The American Academy of Pediatrics, in a letter to Congressman Dennis Kucinich dated 12 December 2012 states "*Children are disproportionately affected by environmental exposures, including cell phone radiation. The differences in bone density and the amount of fluid in a child's brain compared to an adult's brain could allow children to absorb greater quantities of RF energy deeper into their brains than adults. It is essential that any new standards for cell phones or other wireless devices be based on protecting the youngest and most vulnerable populations to ensure thay are safeguarded through their lifetimes."*

FETAL AND NEONATAL EFFECTS OF EMF

Fetal (*in-utero*) and early childhood exposures to cell phone radiation and wireless technologies in general may be a risk factor for hyperactivity, learning disorders and behavioral problems in school.

Fetal Development Studies: Effects on the developing fetus from *in-utero* exposure to cell phone radiation have been observed in both human and animal studies since 2006. Divan et al (2008) found that children born of mothers who used cell phones during pregnancy develop more behavioral problems by the time they have reached school age than children whose mothers did not use cell phones during pregnancy. Children whose mothers used cell phones during pregnancy had 25% more emotional problems, 35% more hyperactivity, 49% more conduct problems and 34% more peer problems

(Divan et al., 2008).

Common sense measures to limit both ELF-EMF and RF EMF in these populations is needed, especially with respect to avoidable exposures like incubators that can be modified; and where education of the pregnant mother with respect to laptop computers, mobile phones and other sources of ELF-EMF and RF EMF are easily instituted.

Sources of fetal and neonatal exposures of concern include cell phone radiation (both paternal use of wireless devices worn on the body and maternal use of wireless phones during pregnancy). Exposure to whole-body RFR from base stations and WI-FI, use of wireless laptops, use of incubators for newborns with excessively high ELF-EMF levels resulting in altered heart rate variability and reduced melatonin levels in newborns, fetal exposures to MRI of the pregnant mother, and greater susceptibility to leukemia and asthma in the child where there have been maternal exposures to ELF-EMF.

A precautionary approach may provide the frame for decision-making where remediation actions have to be realized to prevent high exposures of children and pregnant woman.

(Bellieni and Pinto, 2012 – Section 19)

EMF/RFR AS A PLAUSIBLE BIOLGICAL MECHANISM FOR AUTISM (ASD)

- Children with existing neurological problems that include cognitive, learning, attention, memory, or behavioral problems should as much as possible be provided with wired (not wireless) learning, living and sleeping environments,
- Special education classrooms should observe 'no wireless' conditions to reduce avoidable stressors that may impede social, academic and behavioral progress.
- All children should reasonably be protected from the physiological stressor of significantly elevated EMF/RFR (wireless in classrooms, or home environments).
- School districts that are now considering all-wireless learning environments should be strongly cautioned that wired environments are likely to provide better learning and teaching environments, and prevent possible adverse health consequences for both students and faculty in the long-term.
- Monitoring of the impacts of wireless technology in learning and care environments should be performed with sophisticated measurement and data analysis techniques that are cognizant of the non-linear impacts of EMF/RFR and of data techniques most appropriate for discerning these impacts.
- There is sufficient scientific evidence to warrant the selection of wired internet, wired classrooms and wired learning devices, rather than making an expensive and potentially health-harming commitment to wireless devices that may have to be substituted out later, and
- Wired classrooms should reasonably be provided to all students who opt-out of wireless environments. (Herbert and Sage, 2012 – Section 20)

Many disrupted physiological processes and impaired behaviors in people with ASDs closely resemble those related to biological and health effects of EMF/RFR exposure. Biomarkers and indicators of disease and their clinical symptoms have striking similarities. Broadly speaking, these types of phenomena can fall into one or more of several classes: a) alteration of genes or gene expression, b) induction of change in brain or organismic development, c) alteration of phenomena modulating systemic and brain function on an ongoing basis throughout the life course (which can include systemic pathophysiology as well as brain-based changes), and d) evidence of functional alteration in domains such as behavior, social interaction and attention known to be challenged in ASD.

Several thousand scientific studies over four decades point to serious biological effects and health harm from EMF and RFR. These studies report genotoxicity, single-and double-strand DNA damage, chromatin condensation, loss of DNA repair capacity in human stem cells, reduction in free-radical scavengers (particularly melatonin), abnormal gene transcription, neurotoxicity, carcinogenicity, damage to sperm morphology and function, effects on behavior, and effects on brain development in the fetus of human mothers that use cell phones during pregnancy. Cell phone exposure has been linked to altered fetal brain development and ADHD-like behavior in the offspring of pregnant mice.

Reducing life-long health risks begins in the earliest stages of embryonic and fetal development, is accelerated for the infant and very young child compared to adults, and is not complete in young people (as far as brain and nervous system maturation) until the early 20's. Windows of critical development mean that risk factors once laid down in the cells, or in epigenetic changes in the genome may have grave and life-long consequences for health or illness for every individual.

All relevant environmental conditions, including EMF and RFR, which can degrade the human genome, and impair normal health and development of species including homo sapiens, should be given weight in defining and implementing prudent, precautionary actions to protect public health.

Allostatic load in autism and autistic decompensation - we may be at a tipping point that can be pushed back by removing unnecessary stressors like EMF/RFR and building resilience.

The consequence of ignoring clear evidence of large-scale health risks to global populations, when the risk factors are largely avoidable or preventable is too high a risk to take. With the epidemic of autism (ASD) putting the welfare of children, and their families in peril at a rate of one family in 88, the rate still increasing annually, we cannot afford to ignore this body of evidence. The public needs to know that these risks exist, that transition to wireless should not be presumed safe, and that it is very much worth the effort to minimize exposures that still provide the benefits of technology in learning, but without the threat of health risk and development impairments to learning and behavior in the classroom.

(Herbert and Sage, 2012 – Section 20)

THE BLOOD-BRAIN BARRIER IS AT RISK

The BBB is a protective barrier that prevents the flow of toxins into sensitive brain tissue. Increased permeability of the BBB caused by cell phone RFR may result in neuronal damage. Many research studies show that very low intensity exposures to RFR can affect the blood-brain barrier (BBB) (mostly animal studies). Summing up the research, it is more probable than unlikely that non-thermal EMF from cell phones and base stations do have effects upon biology. A single 2-hr exposure to cell phone radiation can result in increased leakage of the BBB, and 50 days after exposure, neuronal damage can be seen, and at the later time point also albumin leakage is demonstrated. *The levels of RFR needed to affect the BBB have been shown to be as low as 0.001 W/kg, or less than holding a mobile phone at arm's length. The US FCC standard is 1.6 W/kg; the ICNIRP standard is 2 W/kg of energy (SAR) into brain tissue from cell/cordless phone use. Thus, BBB effects occur at about 1000 times lower RFR exposure levels than the US and ICNIRP limits allow.* (Salford et al, 2012 - Section 10)

If the blood-brain barrier is vulnerable to serious and on-going damage from wireless exposures, then we should perhaps also be looking at the blood-ocular barrier (that protects the eyes), the blood-placenta barrier (that protects the developing fetus) and the blood-gut barrier (that protects proper digestion and nutrition), and the blood-testes barrier (that protects developing sperm) to see if they too can be damaged by RFR.

EPIDEMIOLOGICAL STUDIES CONSISTENTLY SHOW ELEVATIONS IN RISK OF BRAIN CANCERS

Brain Tumors: There is a consistent pattern of increased risk of glioma and acoustic neuroma associated with use of mobile phones and cordless phones.

"Based on epidemiological studies there is a consistent pattern of increased risk for glioma and acoustic neuroma associated with use of mobile phones and cordless phones. The evidence comes mainly from two study centres, the Hardell group in Sweden and the Interphone Study Group. No consistent pattern of an increased risk is seen for meningioma. A systematic bias in the studies that explains the results would also have been the case for meningioma. The different risk pattern for tumor type strengthens the findings regarding glioma and acoustic neuroma. Meta-analyses of the Hardell group and Interphone studies show an increased risk for glioma and acoustic neuroma. Supportive evidence comes also from anatomical localisation of the tumor to the most exposed area of the brain, cumulative exposure in hours and latency time that all add to the biological relevance of an increased risk. In addition risk calculations based on estimated absorbed dose give strength to the findings.

"There is reasonable basis to conclude that RF-EMFs are bioactive and have a potential to cause health impacts. There is a consistent pattern of increased risk for glioma and acoustic neuroma associated with use of wireless phones (mobile phones and cordless phones) mainly based on results from case-control studies from the Hardell group and Interphone Final Study results. Epidemiological evidence gives that RF-EMF should be classified as a human carcinogen.

Based on our own research and review of other evidence the existing FCC/IEE and ICNIRP public safety limits and reference levels are not adequate to protect public health. New public health standards and limits are needed.

(Hardell et al, 2012 –Section 11)

EVIDENCE FOR GENETIC EFFECTS (Updated March 2014)

One hundred fourteen (114) new papers on genotoxic effects of RFR published between 2007 and early 2014 are profiled. Of these, 74 (65%) showed effects and 40 (35%) showed no effects.

Fifty nine (59) new ELF-EMF papers and two static magnetic field papers that report on genotoxic effects of ELF-EMF between 2007 and early 2014 are profiled. Of these, 49 (83%) show effects and 10 (17%) show no effect. (Lai, 2014 – Section 6)

EVIDENCE FOR NEUROLOGICAL EFFECTS (Updated March 2014)

Two hundred eleven (211) new papers that report on neurological effects of RFR published between 2007 and early 2014 are profiled. Of these, 144 (68%) showed effects and 67 (32%) showed no effects.

One hundred five (105) new ELF-EMF papers (including two static field papers) that report on neurological-effects of ELF-EMF published between 2007 and early 2014 are profiled. Of these, 95 (90%) show effects and 10 (10%) show no effect. (Lai, 2014 – Section 9)

EVIDENCE FOR CHILDHOOD CANCERS (LEUKEMIA)

With overall 42 epidemiological studies published to date power frequency EMFs are among the most comprehensively studied environmental factors. Except ionizing radiation no other environmental factor has been as firmly established to increase the risk of childhood leukemia. Sufficient evidence from epidemiological studies of an increased risk from exposure to EMF (power frequency magnetic fields) that cannot be attributed to chance, bias or confounding. Therefore, according to the rules of IARC such exposures can be classified as a **Group 1 carcinogen (Known Carcinogen).**

There is no other risk factor identified so far for which such unlikely conditions have been put forward to postpone or deny the necessity to take steps towards exposure reduction. As one step in the direction of precaution, measures should be implemented to guarantee that exposure due to transmission and distribution lines is below an average of about 1 mG. This value is arbitrary at present and only supported by the fact that in many studies this level has been chosen as a reference.

Base-station level RFR at levels ranging from less than 0.001 uW/cm2 to 0.05 uW/cm2. In 5 new studies since 2007, researchers report headaches, concentration difficulties and behavioral problems in children and adolescents; and sleep disturbances, headaches and concentration problems in adults.

MELATONIN, BREAST CANCER AND ALZHEIMER'S DISEASE

MELATONIN AND BREAST CANCER

Conclusion: Eleven (11) of the 13 published epidemiologic residential and occupational studies are considered to provide (positive) evidence that high ELF MF exposure can result in decreased melatonin production. The two negative studies had important deficiencies that may certainly have biased the results. There is sufficient evidence to conclude that long-term relatively high ELF MF exposure can result in a decrease in melatonin production. It has not been determined to what extent personal characteristics, e.g., medications, interact with ELF MF exposure in decreasing melatonin production

Conclusion: New research indicates that ELF MF exposure, in vitro, can significantly decrease melatonin activity through effects on MT1, an important melatonin receptor.

(Davanipour and Sobel, 2012 – Section 13)

ALZHEIMER'S DISEASE

There is strong epidemiologic evidence that exposure to ELF MF is a risk factor for AD. There are now twelve (12) studies of ELF MF exposure and AD or dementia which . Nine (9) of these studies are considered positive and three (3) are considered negative. The three negative studies have serious deficiencies in ELF MF exposure classification that results in subjects with rather low exposure being considered as having significant exposure. There are insufficient studies to formulate an opinion as to whether radiofrequency MF exposure is a risk or protective factor for AD.

There is now evidence that (i) high levels of peripheral amyloid beta are a risk factor for AD and (ii) medium to high ELF MF exposure can increase peripheral amyloid beta. High brain levels of amyloid beta are also a risk factor for AD and medium to high ELF MF exposure to brain cells likely also increases these cells' production of amyloid beta.

There is considerable in vitro and animal evidence that melatonin protects against AD. Therefore it is certainly possible that low levels of melatonin production are associated with an increase in the risk of AD.

(Davanipour and Sobel, 2012 – Section 13)

STRESS PROTEINS AND DNA AS A FRACTAL ANTENNA FOR RFR

DNA acts as a 'fractal antenna' for EMF and RFR.

The coiled-coil structure of DNA in the nucleus makes the molecule react like a fractal antenna to a wide range of frequencies.

The structure makes DNA particularly vulnerable to EMF damage.

The mechanism involves direct interaction of EMF with the DNA molecule (claims that there are no known mechanisms of interaction are patently false)

Many EMF frequencies in the environment can and do cause DNA changes.

The EMF-activated cellular stress response is an effective protective mechanism for cells exposed to a wide range of EMF frequencies.

EMF stimulates stress proteins (indicating an assault on the cell).

EMF efficiently harms cells at a billion times lower levels than conventional heating. Blank, 2012 – Section 7)

Safety standards based on heating are irrelevant to protect against EMF-levels of exposure. There is an urgent need to revise EMF exposure standards. Research has shown thresholds are very low (safety standards must be reduced to limit biological responses). Biologically-based EMF safety standards could be developed from the research on the stress response. (Blank, 2012 – Section 7)

EVIDENCE FOR DISRUPTION OF THE MODULATING SIGNAL HUMAN STEM CELL DNA DOES NOT ADAPT OR REPAIR

Human stem cells do not adapt to chronic exposures to non-thermal microwave (cannot repair damaged DNA), and damage to DNA in genes in other cells generally do not repair as efficiently. (Belyaev, 2012 – Section 15)

Non-thermal effects of microwaves depend on variety of biological and physical parameters that should be taken into account in setting the safety standards. Emerging evidence suggests that the SAR concept, which has been widely adopted for safety standards, is not useful alone for the evaluation of health risks from non-thermal microwave of mobile communication. Other parameters of exposure, such as frequency, modulation, duration, and dose should be taken into account.

Lower intensities are not always less harmful; they may be more harmful.

Intensity windows exist, where bioeffects are much more powerful.

A linear, dose-response relationship test is probably invalid for testing of RFR and EMF (as is done in chemicals testing for toxicity).

Resonant frequencies may result in biological effects at very low intensities comparable to base station (cell tower) and other microwave sources used in mobile communications. These exposures can cause health risk. The current safety standards are insufficient to protect from non-thermal microwave effects.

The data about the effects of microwave at super-low intensities and significant role of duration of exposure in these effects along with the data showing that adverse effects of non-thermal microwave from GSM/UMTS mobile phones depend on carrier frequency and type of the microwave signal suggest that microwave from base-stations/masts, wireless routers, WI-FI and other wireless devices and exposures in common use today can also produce adverse effects at prolonged durations of exposure.

Most of the real signals that are in use in mobile communication have not been tested so far. Very little research has been done with real signals and for durations and intermittences of exposure that are relevant to chronic exposures from mobile communication. In some studies, so-called “mobile communication-like” signals were investigated that in fact were different from the real exposures in such important aspects as intensity, carrier frequency, modulation, polarization, duration and intermittence.

New standards should be developed based on knowledge of mechanisms of non-thermal effects. Importantly, because the signals of mobile communication are completely replaced by other signals faster then once per 10 years, duration comparable with latent period, epidemiologic studies cannot provide basement for cancer risk assessment from upcoming new signals.

In many cases, because of ELF modulation and additional ELF fields created by the microwave sources, for example by mobile phones, it is difficult to distinguish the effects of exposures to ELF and microwave. Therefore, these combined exposures and their possible cancer risks should be considered in combination.

As far as different types of microwave signals (carrier frequency, modulation, polarization, far and near field, intermittence, coherence, *etc.*) may produce different effects, cancer risks should ideally be estimated for each microwave signal separately.

The Precautionary Principle should be implemented while new standards are in progress.

It should be anticipated that some part of the human population, such as children, pregnant women and groups of hypersensitive persons could be especially sensitive to the non-thermal microwave exposures.
(Belyaev, 2012 – Section 15)

N. EFFECTS OF WEAK-FIELD INTERACTIONS ON NON-LINEAR BIOLOGICAL OSCILLATORS AND SYNCHRONIZED NEURAL ACTIVITY

A unifying hypothesis for a plausible biological mechanism to account for very weak field EMF bioeffects other than cancer may lie with weak field interactions of pulsed RFR and ELF-modulated RFR as disrupters of synchronized neural activity. Electrical rhythms in our brains can be influenced by external signals. This is consistent with established weak field effects on coupled biological oscillators in living tissues. Biological systems of the heart, brain and gut are dependent on the cooperative actions of cells that function according to principles of non-linear, coupled biological oscillations for their synchrony, and are dependent on exquisitely timed cues from the environment at vanishingly small levels (Buzsaki, 2006; Strogatz, 2003). The key to synchronization is the joint actions of cells that co-operate electrically - linking populations of biological oscillators that couple together in large arrays and synchronize spontaneously. Synchronous biological oscillations in cells (pacemaker cells) can be disrupted by artificial, exogenous environmental signals, resulting in desynchronization of neural activity that regulates critical functions (including metabolism) in the brain, gut and heart and circadian rhythms governing sleep and hormone cycles (Strogatz, 1987). The brain contains a population of oscillators with distributed natural frequencies, which pull one another into synchrony (the circadian pacemaker cells). Strogatz has addressed the unifying mathematics of biological cycles and external factors disrupt these cycles (Strogatz, 2001, 2003). *"Rhythms can be altered by a wide variety of agents and that these perturbations must seriously alter brain performance"* (Buzsaki, 2006).

"Organisms are biochemically dynamic. They are continuously subjected to time-varying conditions in the form of both extrinsic driving from the environment and intrinsic rhythms generated by specialized cellular clocks within the organism itself. Relevant examples of the latter are the cardiac pacemaker located at the sinoatrial node in mammalian hearts (1) and the circadian clock residing at the suprachiasmatic nuclei in mammalian brains (2). These rhythm generators are composed of thousands of clock cells that are intrinsically diverse but nevertheless manage to function in a coherent oscillatory state. This is the case, for instance, of the circadian oscillations exhibited by the suprachiasmatic nuclei, the period of which is known to be determined by the mean period of the individual neurons making up the circadian clock (3–7). The mechanisms by which this collective behavior arises remain to be understood." (Strogatz, 2001; Strogatz, 2003)

Synchronous biological oscillations in cells (pacemaker cells) can be disrupted by artificial, exogenous environmental signals, resulting in desynchronization of neural activity that regulates critical functions (including metabolism) in the brain, gut and heart and circadian rhythms governing sleep and hormone cycles. The brain contains a population of oscillators with distributed natural frequencies, which pull one another into synchrony (the circadian pacemaker cells). Strogatz has addressed the unifying mathematics of biological cycles and external factors disrupt these cycles.

EMF AND RFR MAKE CHEMICAL TOXINS MORE HARMFUL

EMF acts on the body like other environmental toxicants do (heavy metals, organic chemicals and pesticides). Both toxic chemicals and EMF may generate free radicals, produce stress proteins and cause indirect damage to DNA. Where there is combined exposure the damages may add or even synergistically interact, and result in worse damage to genes.
(Sage and Carpenter, 2012 – Section 24)

EMF IS SUCCESSFULLY USED IN HEALING AND DISEASE TREATMENTS

"The potential application of the up-regulation of the HSP70 gene by both ELF-EMF and nanosecond PEMF in clinical practice would include trauma, surgery, peripheral nerve damage, orthopedic fracture, and vascular graft support, among others. Regardless of pulse design, EMF technology has been shown to be effective in bone healing [5], wound repair [11] and neural regeneration [31,36,48,49,51,63,64,65,66]. In terms of clinical applica- tion, EMF-induction of elevated levels of hsp70 protein also confers protection against hypoxia [61] and aid myocardial function and survival [20,22]. Given these results, we are particularly interested in the translational significance of effect vs. efficacy which is not usually reported by designers or investigators of EMF devices. More precise description of EM pulse and sine wave parameters, including the specific EM output sector, will provide consistency and "scientific basis" in reporting findings."

"The degree of electromagnetic field-effects on biological systems is known to be dependent on a number of criteria in the waveform pattern of the exposure system used; these include frequency, duration, wave shape, and relative orientation of the fields [6,29,32,33,39,40]. In some cases pulsed fields have demonstrated increased efficacy over static designs [19,21] in both medical and experimental settings." (Madkan et al, 2009)

(Sage and Carpenter, 2012 – Section 24)

ELF-EMF AND RFR ARE CLASSIFIED AS POSSIBLE CANCER-CAUSING AGENTS – WHY ARE GOVERNMENTS NOT ACTING?

The World Health Organization International Agency for Research on Cancer has classified wireless radiofrequency as a Possible Human Carcinogen (May, 2011)*. The designation applies to low-intensity RFR in general, covering all RFR-emitting devices and exposure sources (cell and cordless phones, WI-FI, wireless laptops, wireless hotspots, electronic baby monitors, wireless classroom access points, wireless antenna facilities, etc). The IARC Panel could have chosen to classify RFR as a Group 4 – Not A Carcinogen if the evidence was clear that RFR is not a cancer-causing agent. It could also have found a Group 3 designation was a good interim choice (Insufficient Evidence). IARC did neither.

(Sage and Carpenter, 2012 – Section 24)

NEW SAFETY LIMITS MUST BE ESTABLISHED - HEALTH AGENCIES SHOULD ACT NOW

Existing public safety limits (FCC and ICNIRP public safety limits) do not sufficiently protect public health against chronic exposure from very low-intensity exposures. If no mid-course corrections are made to existing and outdated safety limits, such delay will magnify the public health impacts with even more applications of wireless-enabled technologies exposing even greater populations around the world in daily life. (Sage and Carpenter, 2012 – Section 24)

SCIENTIFIC BENCHMARKS FOR HARM PLUS SAFETY MARGIN = NEW SAFETY LIMITS THAT ARE VALID

Health agencies and regulatory agencies that set public safety standards for ELF-EMF and RFR should act now to adopt new, biologically-relevant safety limits that key to the lowest scientific benchmarks for harm coming from the recent studies, plus a lower safety margin. Existing public safety limits are too high by several orders of magnitude, if prevention of bioeffects and minimization or elimination of resulting adverse human health effects. Most safety standards are a thousand times or more too high to protect healthy populations, and even less effective in protecting sensitive subpopulations.

(Sage and Carpenter, 2012 – Section 24)

SENSITIVE POPULATIONS MUST BE PROTECTED

Safety standards for sensitive populations will more likely need to be set at lower levels than for healthy adult populations. Sensitive populations include the developing fetus, the infant, children, the elderly, those with pre-existing chronic diseases, and those with developed electrical sensitivity (EHS). (Sage and Carpenter, 2012 – Section 24)

PROTECTING NEW LIFE - INFANTS AND CHILDREN

Strong precautionary action and clear public health warnings are warranted immediately to help prevent a global epidemic of brain tumors resulting from the use of wireless devices (mobile phones and cordless phones). Common sense measures to limit both ELF-EMF and RFR in the fetus and newborn infant (sensitive populations) are needed, especially with respect to avoidable exposures like baby monitors in the crib and baby isolettes (incubators) in hospitals that can be modified; and where education of the pregnant mother with respect to laptop computers, mobile phones and other sources of ELF-EMF and RFR are easily instituted.

(Sage and Carpenter, 2012 – Section 24)

Wireless laptops and other wireless devices should be strongly discouraged in schools for children of all ages. (Sage and Carpenter, 2012 – Section 24)

STANDARD OF EVIDENCE FOR JUDGING THE SCIENCE

The standard of evidence for judging the scientific evidence should be based on good public health principles rather than demanding scientific certainty before actions are taken. (Sage and Carpenter, 2012 – Section 24)

WIRELESS WARNINGS FOR ALL

The continued rollout of wireless technologies and devices puts global public health at risk from unrestricted wireless commerce unless new, and far lower exposure limits and strong precautionary warnings for their use are implemented.
(Sage and Carpenter, 2012 – Section 24)

EMF AND RFR ARE PREVENTABLE TOXIC EXPOSURES

We have the knowledge and means to save global populations from multi-generational adverse health consequences by reducing both ELF and RFR exposures. Proactive and immediate measures to reduce unnecessary EMF exposures will lower disease burden and rates of premature death.
(Sage and Carpenter, 2012 – Section 24)

DEFINING A NEW 'EFFECT LEVEL' FOR RFR

On a precautionary public health basis, a reduction from the BioInitiative 2007 recommendation of 0.1 uW/cm2 (or one-tenth of a microwatt per square centimeter) for cumulative outdoor RFR down to something three orders of magnitude lower (in the low nanowatt per square centimeter range) is justified.

A scientific benchmark of 0.003 uW/cm2 or three nanowatts per centimeter squared for 'lowest observed effect level' for RFR is based on mobile phone base station-level studies. Applying a ten-fold reduction to compensate for the lack of long-term exposure (to provide a safety buffer for chronic exposure, if needed) or for children as a sensitive subpopulation yields a 300 to 600 picowatts per square centimeter precautionary action level. This equates to a 0.3 nanowatts to 0.6 nanowatts per square centimeter as a reasonable, precautionary action level for chronic exposure to pulsed RFR.

These levels may need to change in the future, as new and better studies are completed. We leave room for future studies that may lower or raise today's observed 'effects levels' and should be prepared to accept new information as a guide for new precautionary actions.

(Sage and Carpenter, 2012 – Section 24)

Reported Biological Effects from Radiofrequency Radiation at Low-Intensity Exposure

SECTION 2

Statement of the Problem

Cindy Sage, MA

Sage Associates, USA

Prepared for the BioInitiative Working Group

August 2007

STATEMENT OF THE PROBLEM

Background and Objectives

This Report is the product of an international research and public policy initiative to document what is known of biological effects that occur at low-intensity EMF exposures (for both radiofrequency radiation RF and power-frequency ELF, and various forms of combined exposures that are now known to be bioactive). The Report has been written to document the reasons why current public exposure standards for non-ionizing electromagnetic radiation are no longer good enough to protect public health.

A working group composed of scientists, researchers and public health policy professionals (The BioInitiative Working Group) has joined together to document the information that must be considered in the international debate about the adequacy (or inadequacy) of existing public exposure standards.

Recognizing that other bodies in the United States, United Kingdom, Australia, many European Union and eastern European countries as well as the World Health Organization are actively debating this topic, the BioInitiative Working Group has conducted a independent science and public health policy review process.

Objectives

1) To establish a working group

2) To evaluate literature reviews for IEEE (2006) and WHO (2007) initiatives on standards that have resulted in (or continue to recommend) no change in thermally-based public exposure limits.

3) To identify systematic screening-out techniques that consequently under-report, omit or overlook results of scientific studies reporting low-intensity bioeffects and/or potential health effects.

4) To document key scientific studies and reviews that identify low-intensity effects for which any new human exposure standards should provide safety limits.

5) To document key "chains of evidence" that must be taken into account in new human exposure standards (melatonin and free-radical production effects on DNA damage and/or repair; stress protein induction at low-intensity levels; etc.)

6) To write a rationale for a biologically-based human exposure standard,

7) To identify "next steps" in advancing biologically-based exposure standards that are protective of public health; that are derived in traditional public health approaches.

Eleven (11) chapters documenting key scientific studies and reviews that identify low-intensity effects of electromagnetic fields have been produced by the members of the BioInitiative Working Group; four additional chapters are provided that discuss public health considerations, how the scientific information should be evaluated in the context of prudent public health policy, and discussing the basis for taking precautionary and preventative actions that are proportionate to the knowledge at hand. Other scientific review bodies and agencies have reached different conclusions by adopting standards of evidence so unreasonably high as to exclude any finding of scientific concern, and thus justify retaining outdated thermal standards. The clear consensus of the BioInitiative Working Group members is that the existing public safety limits are inadequate. New approaches to development of public safety standards are needed based on biologically-based effects, rather than based solely on RF heating (or induced currents in the case of ELF). The Report concludes with recommended actions that are proportionate to the evidence and in accord with prudent public health policy.

The Report also presents information about what level of scientific evidence is sufficient to make changes now. It addresses the questions:

- What is "proof"? Do we need proof before we take any action? Is an unreasonably high and overly-restrictive definition of "proof" what is keeping some governments from facing the evidence that the need for new public exposure limits is demonstrated?
- What is sufficient evidence? How much evidence is needed? Do we have it yet?
- Do scientists and public health experts differ on when action is warranted? If so, how?
- What is the prudent course of action when the consequence of doing nothing is likely to have serious global consequences on public health, confidence in governments and social/economic resources?
- What are the costs of guessing wrong and under-reacting? Or, of over-reacting?
- Whose opinions should count in the process of deciding about health risks and harm?
- Is the global, governmental process addressing these questions transparent and responsive to public concerns? Or, is it a cosmetic process giving the illusion of transparency and democratic participation? Are some countries ostracized for views and actions that are more protective of public health? How can we equitably decide on the appropriate level of public protection within each country, when it is obvious that some countries would be best off spending their time and money on basic medical needs and infrastructure improvements to save lives, when others need to look at prevailing disease endpoints relevant to their populations, and wish to act accordingly?

- How has the effort for global harmonization of ELF and RF exposure standards thwarted the efforts of individual countries to read, reason and choose?
- How much control have special interests exerted over harmonization goals and safety standards? How much over scientific funding, research design, dissemination of research results and media control? Are the interests of the public being conserved?
- What actions are proportionate to the knowledge we now have? What is preventative action and how does it differ from precautionary action?

It describes what the existing exposure standards are, and how some international governmental bodies are standing by the old exposure standards despite evidence that change is needed.

A good way to compare what kind of actions should be taken now is to look at what has been done with other environmental toxicants. It is well-established that public health decision-makers should act before it is too late to prevent damage that can reasonably be expected now; especially where the harm may be serious and widespread. Some actions that can prevent future harm are identified. The basis for taking action now rather than later is explained. This report can serve as a basis for arguing the scientific and public health policy reasons that changes are needed. It documents information for decision-makers and the public who want to understand what is already known biological effects occuring at low-intensity exposures; and why it is reasonable to expect our governmental agencies to develop new, biologically-based exposure standards that protect the public.

Problems with Existing Public Health Standards (Safety Limits)

Today's public exposure limits are based on the presumption that heating is the only concern when living organisms are exposed to RF and ELF. These exposures can create tissue heating that is well known to be harmful in even very short-term doses. As such, thermal limits do serve a purpose. For example, for people whose occupations require them to work around electrical power lines or heat-sealers, or for people who install and service wireless antenna towers; thermally-based limits are necessary to prevent damage from heating (or, in the case of ELF - from induced currents in tissues). In the past, scientists and engineers developed exposure standards for electromagnetic radiation based what we now believe are faulty assumptions that the right way to measure how much non-ionizing energy humans can tolerate (how much exposure) without harm is to measure only the heating of tissue (for – induced currents in the body). In the last few decades, it has been established beyond any reasonable doubt that bioeffects and some adverse health effects occur at far lower levels of RF and exposure where no heating occurs at all; some effects are shown to occur at several hundred thousand times below the existing public safety limits

where heating is an impossibility. Effects occur at non-thermal or low-intensity exposure levels far below the levels that federal agencies say should keep the public safe. For many new devices operating with wireless technologies, the devices are exempt from any regulatory standards. The existing standards have been proven to be inadequate to control against harm from low-intensity, chronic exposures, based on any reasonable, independent assessment of the scientific literature. It means that an entirely new basis (a biological basis) for new exposure standards is needed. New standards need to take into account what we have learned about the effects of non-ionizing electromagnetic fields and to design new limits based on biologically-demonstrated effects that are important to proper biological function in living organisms. It is vital to do so because the explosion of new sources has created unprecedented levels of artificial electromagnetic fields that now cover all but remote areas of the habitable space on earth. Mid-course corrections are needed in the way we accept, test and deploy new technologies that expose us to ELF and RF in order to avert public health problems of a global nature.

At least three decades of scientific study and observation of effects on humans and animals shows that non-thermal exposure levels can result in biologically-relevant effects. There should be no effects occurring at all. Yet, clearly they do occur. This means the standards for protecting public health are based on the wrong premise - that only what heats tissue can result in harm. It does appear that it is the INFORMATION conveyed by electromagnetic radiation, rather than the heat, which causes biological changes, some of which may lead to unwellness, illness and even death, According to Adey (2004):

> *"There are major unanswered questions about possible health risks that may arise from human exposures to various man-made electromagnetic fields where these exposures are intermittent, recurrent, and may extend over a significant portion of the lifetime of an individual. Current equilibrium thermodynamic models fail to explain an impressive spectrum of observed bioeffects at non-thermal exposure levels."*

Recent opinions by experts have documented deficiencies in current exposure standards. There is widespread discussion that thermal limits are outdated, and that biologically-based exposure standards are needed. Section 4 describes concerns expressed by WHO, 2007 in its Health Criteria Monograph; the SCENIHR Report, 2006 prepared for the European Commission; the UK SAGE Report, 2007; the Health Protection Agency, United Kingdom in 2005; the NATO Advanced Research Workshop in 2005; the US Radiofrequency Interagency Working Group in 1999; the US Food and Drug Administration in 2000 and 2007; the World Health Organization in 2002; the World Health Organization International Agency for Cancer Research (IARC, 2001), the United Kingdom Parliament Independent Expert Group Report (Stewart Report, 2000) and others.

A pioneer researcher, the late Dr. Ross Adey, in his last publication in Bioelectromagnetic Medicine (P. Roche and M. Markov, eds. 2004) concluded:

> "*There are major unanswered questions about possible health risks that may arise from exposures to various man-made electromagnetic fields where these human exposures are intermittent, recurrent, and may extend over a significant portion of the lifetime of the individual."*[1]
>
> *"Epidemiological studies have evaluated and radiofrequency fields as possible risk factors for human health, with historical evidence relating rising risks of such factors as progressive rural electrification, and more recently, to methods of electrical power distribution and utilization in commercial buildings. Appropriate models describing these bioeffects are based in nonequilibrium thermodynamics, with nonlinear electrodynamics as an integral feature. Heating models, based in equilibrium thermodynamics, fail to explain an impressive new frontier of much greater significance. ..... Though incompletely understood, tissue free radical interactions with magnetic fields may extend to zero field levels. (Adey, 2004)*

The Existing Public Exposure Standards

Cindy Sage, MA

Sage Associates, USA

Prepared for the BioInitiative Working Group

August 2007

The US Federal Communications Commission (FCC) Exposure Standard Recommendations

In the United States, the Federal Communications Commission (FCC) enforces limits for both occupational exposures (in the workplace) and public exposures. The exposure limits are variable according to the frequency (in megahertz) and the duration of exposure time (6 minutes for occupational and 30 minutes for public exposures). Table 3.1 show exposure limits for occupational and uncontrolled public access to radiofrequency radiation such as is emitted from AM, FM, television and wireless sources through the air. As an example, 583 microwatts/cm2 (μW/cm2) is the public limit for the 875 MHz cell phone wireless frequency and 1000 μW/cm2 is the limit for PCS frequencies in the 1800 – 1950 MHz range averaged over 30 minutes. The limits in Table 3.1 would pertain to exposures in the vicinity of transmitting antennas (not devices like cell phones, for which exposure limits are shown in Table 3.2).

The FCC is required by the National Environmental Policy Act of 1969 to evaluate the effect of emissions from FCC-regulated transmitters on the quality of the human environment. At the present time there is no federally-mandated radio frequency (RF) exposure standard. However, several non-government organizations, such as the American National Standards Institute (ANSI), the Institute of Electrical and Electronics Engineers, Inc. (IEEE), and the National Council on Radiation Protection and Measurements (NCRP) have issued recommendations for human exposure to RF electromagnetic fields. The FCC has endorsed these recommendations, and enforces compliance. http://www.fcc.gov/oet/rfsafety/

Table 3.1 **FCC LIMITS FOR MAXIMUM PERMISSIBLE EXPOSURE (MPE)**

(A) Limits for Occupational/Controlled Exposure

Frequency Range (MHz)	Electric Field Strength (E) (V/m)	Magnetic Field Strength (H) (A/m)	Power Density (S) (mW/cm2)	Averaging Time $[E]^2$ $[H]^2$ or S (minutes)
0.3-3.0	614	1.63	(100)*	6
3.0-30	1842/f	4.89/f	$(900/f_2)$*	6
30-300	61.4	0.163	1.0	6
300-1500			f/300	6
1500-100,000			5	6

(B) FCC Limits for General Population/Uncontrolled Exposure

Frequency Range (MHz)	Electric Field Strength (E) (V/m)	Magnetic Field Strength (H) (A/m)	Power Density (S) (mW/cm2)	Averaging Time $[E]^2$ $[H]^2$ or S (minutes)
0.3-3.0	614	1.63	(100)*	30
3.0-30	824/f	2.19/f	$(180/f_2)$*	30
30-300	27.5	0.073	0.2	30
300-1500	--	--	f/1500	30
1500-100,000	--	--	1.0	30

f = frequency in MHz

*Plane-wave equivalent power density

NOTE 1: ***Occupational/controlled*** limits apply in situations in which persons are exposed as a consequence of their employment provided those persons are fully aware of the potential for exposure and can exercise control over their exposure. Limits for occupational/controlled exposure also apply in situations when an individual is transient through a location where occupational/controlled limits apply provided he or she is made aware of the potential for exposure.

NOTE 2: ***General population/uncontrolled*** exposures apply in situations in which the general public may be exposed, or in which persons that are exposed as a consequence of their employment may not be fully aware of the potential for exposure or can not exercise control over their exposure.

FCC Guidelines for Cell and PCS Phones (and other radiofrequency emitting devices)

Cell phones and portable transmitting devices that operate in the Cellular Radiotelephone Service, the Personal Communications Services (PCS), the Satellite Communications Services, the Maritime Services (ship earth stations only) and the Specialized Mobile Radio (SMR) Service are subject to routine environmental (not health) evaluation for RF exposure prior to equipment authorization or use by the FCC. Section 2.1093 of the FCC's Rules (47 CFR §2.1093) that apply to "portable" devices. For purposes of these requirements a portable device is defined as a transmitting device designed to be used so that the radiating structure(s) of the device is/are within 20 centimeters of the body of the user (OET, 1997).

Cell phones and some other wireless communication devices are regulated by the FCC according to their emissions, which depend on the amount of power absorbed into the body. The metric for measurement is specific absorption rate (SAR) and is expressed in watts per kilogram of tissue. The limit for absorption of radiofrequency radiation is limited to 1.6 W/kG within 1 gram of human tissue. This limit has been recommended for change (relaxation) by the IEEE in April of 2006. If adopted by the FCC, this amount of heat or 1.6 W/Kg would be measured over 10 times as much tissue (10 grams) so that far higher heating is possible from these devices over small amounts of tissue (would be far less strict that the current limit, if adopted). More cell phone and related PDA devices would then comply be able with the looser standard, and the public could potentially receive much higher radiofrequency radiation exposures, and it would be in compliance (legal).

"The SAR criteria to be used are specified below and apply for portable devices transmitting in the frequency range from 100 kHz to 6 GHz. The limits used for evaluation are based generally on criteria published by the Institute of Electrical and Electronics Engineers, Inc., (IEEE) for localized specific absorption rate ("SAR") in Section 4.2 of "IEEE Standard for Safety Levels with Respect to Human Exposure to Radio Frequency Electromagnetic Fields, 3 kHz to 300 GHz," ANSI/IEEE C95.1-1992.

These criteria for SAR evaluation are similar to those recommended by the National Council on Radiation Protection and Measurements (NCRP) in "Biological Effects and Exposure Criteria for Radiofrequency Electromagnetic Fields," NCRP Report No. 86, Section 17.4.5. Copyright NCRP, 1986, Bethesda, Maryland 20814."

(**1) FCC Limits for Occupational/Controlled exposure:** 0.4 W/kg as averaged over the whole-body and spatial peak SAR not exceeding 8 W/kg as averaged over any 1 gram of tissue (defined as a tissue volume in the shape of a cube). Exceptions are the hands, wrists, feet and ankles where the spatial peak SAR shall not exceed 20 W/kg, as averaged over any 10 grams of tissue (defined as a tissue volume in the shape of a cube). Occupational/Controlled limits apply when persons are exposed as a consequence of their

employment provided these persons are fully aware of and exercise control over their exposure. Awareness of exposure can be accomplished by use of warning labels or by specific training or education through appropriate means, such as an RF safety program in a work environment (OET, 1997).

(2) FCC Limits for General Population/Uncontrolled exposure: 0.08 W/kg as averaged over the whole-body and spatial peak SAR not exceeding 1.6 W/kg as averaged over any 1 gram of tissue (defined as a tissue volume in the shape of a cube). Exceptions are the hands, wrists, feet and ankles where the spatial peak SAR shall not exceed 4 W/kg, as averaged over any 10 grams of tissue (defined as a tissue volume in the shape of a cube). General Population/Uncontrolled limits apply when the general public may be exposed, or when persons that are exposed as a consequence of their employment may not be fully aware of the potential for exposure or do not exercise control over their exposure. Warning labels placed on consumer devices such as cellular telephones will not be sufficient reason to allow these devices to be evaluated subject to limits for occupational/controlled exposure (OET, 1997).

In the United States, two professional societies - the Institute of Electrical and Electronics Engineers, Inc. (IEEE) and the National Council for Radiation Protection and Measurements (NCRP) develop recommendations for safety standards. . The IEEE charter calls itself the world's leading professional association for the advancement of technology, as well as the instigator of public safety standards. The IEEE recommendations have historically been endorsed by the American National Standards Institute (ANSI) and finally considered by the FCC for implementation. The US Federal Communications Commission (FCC) may then take the recommendations and adopt them as mandatory exposure limits. Several standard-setting processes have occurred like this in the last few decades.

The most recent IEEE recommendations for 3 kHz to 300 GHz were developed in 2006 (IEEE, 2006). Rather than lower the existing limits for radiofrequency and microwave radiation exposure, they greatly increase the exposure limits. This is perplexing since it ignores or discounts a large body of scientific evidence clearly documenting biologically-relevant changes at levels LOWER (much lower) than the existing standards.

ICNIRP Guidelines (International Radiofrequency Guidelines)

In April 1998, the International Commission on Non-Ionizing Radiation Protection (ICNIRP) published guidelines for limiting exposure to time-varying electric, magnetic and electromagnetic fields in the frequency range up to 300 GHz.. These guidelines replaced previous advice issued in 1988 and 1990. The main objective of the ICNIRP Guidelines is to establish guidelines for limiting EMF exposure that will provide protection against known adverse health effects (ICNIRP, 1998). An adverse health effect is defined by ICNIRP as one which causes detectable impairment of the health of the exposed individual or of his or her offspring; a biological effect, on the other hand, may or may not result in an adverse health effect.

The guidelines presented in Table 3.2 apply to occupational and public exposure.

Table 3.2 ICNIRP Basic restrictions for time varying electric and magnetic fields for frequencies up to 10 GHz.

Exposure characteristics	Frequency range	Current density for head and trunk (mA m^{-2})(rms)	Whole-body average SAR (W kg^{-1})	Localized SAR (head and trunk) (W kg^{-1})	Localized SAR (limbs) (W kg^{-1})
Occupational exposure	up to 1 Hz	40	—	—	—
	1–4 Hz	40/*f*	—	—	—
	4 Hz–1 kHz	10	—	—	—
	1–100 kHz	*f*/100			
	100 kHz–10 MHz	*f*/100	0.4	10	20
	10 MHz–10 GHz		0.4	10	20
General public exposure	up to 1 Hz	8	—	—	—
	1–4 Hz	8/*f*	—	—	—
	4 Hz–1 kHz	2	—	—	—
	1–100 kHz	*f*/500			
	100 kHz–10 MHz	*f*/500	0.08	2	4
	10 MHz–10 GHz		0.08	2	4

Notes:

1. *f* is the frequency in hertz.
2. Because of electrical inhomogeneity of the body, current densities should be averaged over a cross-section of 1 cm^2 perpendicular to the current direction.
3. For frequencies up to 100 kHz, peak current density values can be obtained by multiplying the rms value by %2 (~1.414). For pulses of duration t_p the equivalent frequency to apply in the basic restrictions should be calculated as $f = 1/(2t_p)$. For frequencies up to 100 kHz and for pulsed magnetic fields, the maximum current density associated with the pulses can be calculated from the rise/fall times and the maximum rate of change of magnetic flux density. The induced current density can then be compared with the appropriate basic restriction.
4. All SAR values are to be averaged over any 6-minute period.
5. Localized SAR averaging mass is any 10 g of contiguous tissue; the maximum SAR so obtained should be the value used for the estimation of exposure.
6. For pulses of duration t_p the equivalent frequency to apply in the basic restrictions should be calculated as $f = 1/(2t_p)$. Additionally, for pulsed exposures, in the frequency range 0.3 to 10 GHz and for localized exposure of the head, in order to limit or avoid auditory effects caused by thermoelastic expansion, an additional basic restriction is recommended. This is that the SA should not exceed 10 mJ kg^{-1} for workers and 2 mJ kg^{-1} for the general public averaged over 10 g tissue.

In the frequency range from a few Hz to 1 kHz, for levels of induced current density above 100 mA m^{-2}, the thresholds for acute changes in central nervous system excitability and other acute effects such as reversal of the visually evoked potential are exceeded. In view of the safety considerations above, it was decided that, for frequencies in the range 4 Hz to 1 kHz, occupational exposure should be limited to fields that induce current densities less than 10 mA m^{-2}, i.e., to use a safety factor of 10. For the general public an additional factor of 5 is applied, giving a basic exposure restriction of 2 mA m^{-2}. Below 4 Hz and above 1 kHz, the basic restriction on induced current density increases progressively.

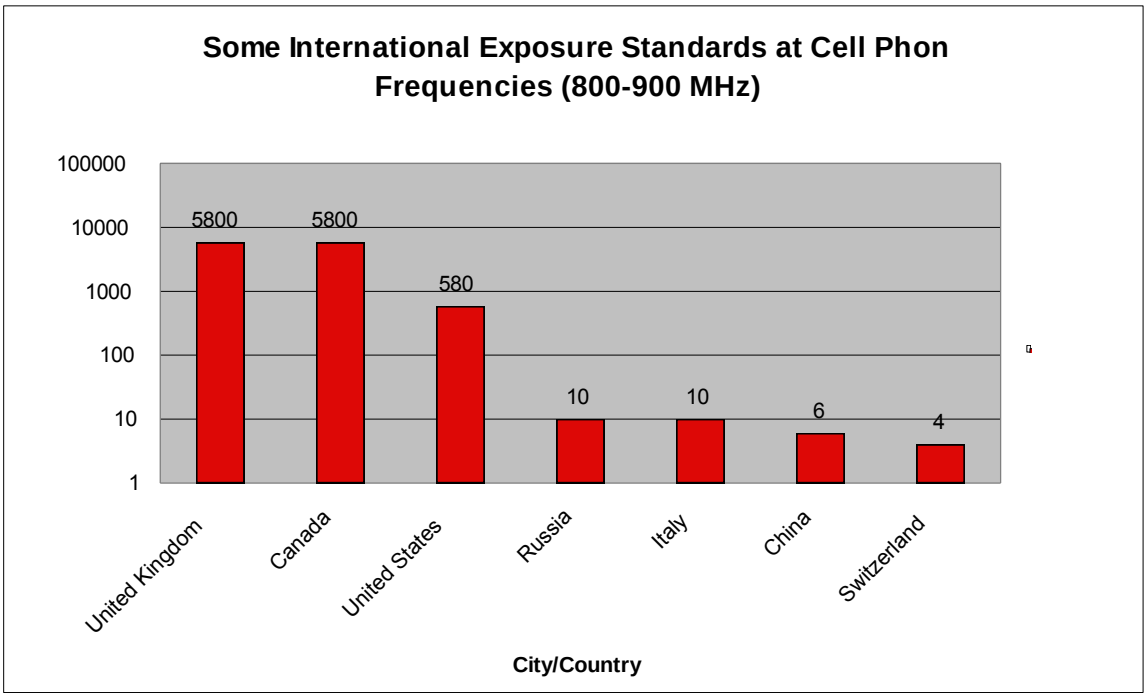
ICNRP maintains that guidelines for limiting exposure have been developed following a thorough review of all published scientific literature (ICNIRP, 1998).

"The criteria applied in the course of the review were designed to evaluate the credibility of the various reported findings (Repacholi and Stolwijk 1991; Repacholi and Cardis 1997); only established effects were used as the basis for the proposed exposure restrictions. Induction of cancer from long-term EMF exposure was not considered to be established, and so these guidelines are based on short-term, immediate health effects such as stimulation of peripheral nerves and muscles, shocks and burns caused by touching conducting objects, and elevated tissue temperatures resulting from absorption of energy during exposure to EMF. In the case of potential long-term effects of exposure, such as an increased risk of cancer, ICNIRP concluded that available data are insufficient to provide a basis for setting exposure restrictions, although epidemiological research has provided suggestive, but unconvincing, evidence of an association between possible carcinogenic effects and exposure at levels of 50/60 Hz magnetic flux densities substantially lower than those recommended in these guidelines. In-vitro effects of short-term exposure to ELF or ELF amplitude-modulated EMF are summarized. Transient cellular and tissue responses to EMF exposure have been observed, but with no clear exposure–response relationship. These studies are of limited value in the assessment of health effects because many of the responses have not been demonstrated in vivo. Thus, in-vitro studies alone were not deemed to provide data that could serve as a primary basis for assessing possible health effects of EMF. " (ICNIRP, 1998) http://www.icnirp.de

Guidelines and Limits (Other Countries)

On the other hand, some countries in the world have established new, low-intensity based exposure standards that respond to studies reporting effects that do not rely on heating. Consequently, new exposure guidelines are hundreds or thousands of times lower than those of IEEE and ICNIRP. Table 3.3 shows some of the countries that have lowered their limits, for example, in the cell phone frequency range of 800 MHz to 900 MHz. The levels range from 10 microwatts per centimeter squared in Italy and Russia to 4.2 microwatts per centimeter squared in Switzerland. In comparison, the United States and Canada limit such exposures to only 580 microwatts per centimeter squared (at 870 MHz) and then averaged over a time period (meaning that higher exposures are allowed for shorter times, but over a 30 minute period, the average must be 580 microwatts per centimeter squared or less at this frequency). The United Kingdom allows one hundred times this level, or 5800 microwatts per centimeter squared. Higher frequencies have higher safety limits, so that at 1000 MHz, for example, the limit is 1000 microwatts per centimeter squared (in the United States). Each individual frequency in the radiofrequency radiation range needs to be calculated. These are presented as reference points only. Emerging scientific evidence has encouraged some countries to respond by adopting planning targets, or interim action levels that are responsive to low-intensity or non-thermal radiofrequency radiation bioeffects and health impacts.

Table 3.3 Some International Exposure Standards at Cell Phone Frequencies



Professional bodies from technical societies like IEEE and ICNIRP continue to support "thermal-only" guidelines routinely defend doing so a) by omitting or ignoring study results reporting bioeffects and adverse impacts to health and wellbeing from a very large body of peer-reviewed, published science because it is not yet "proof" according to their definitions; b) by defining the proof of "adverse effects" at an impossibly high a bar (scientific proof or causal evidence) so as to freeze action; c) by requiring a conclusive demonstration of both "adverse effect" and risk before admitting low-intensity effects should be taken into account; e) by ignoring low-intensity studies that report bioeffects and health impacts due to modulation; f) by conducting scientific reviews with panels heavily burdened with industry experts and under-represented by public health experts and independent scientists with relevant low-intensity research experience; g) by limiting public participation in standard-setting deliberations; and other techniques that maintain the status quo.

Much of the criticism of the existing standard-setting bodies comes because their contributions are perceived as industry-friendly (more aligned with technology investment and dissemination of new technologies) rather than public health oriented. The view of the Chair of the latest IEEE standard-setting ICES Eleanor Adair is made clear by Osepchuk and Petersen (2003) who write in the abstract of their paper "*her goal and the goal of ICES is to establish rational standards that will make future beneficial applications of RF energy credible to humanity."* Authors Osepchuk and Petersen note that *"(I)t is important that safety standards be rational and avoid excessive safety margins."* The authors specifically dismiss the body of evidence for low-intensity effects with *"(A)lthough the literature reporting "athermal" bioeffects of exposure to*

microwave/RF energy (other than electrostimulation) is included in the review process, it has been found to be inconsistent and not useful for purposes of standard-setting."

This report addresses the substantial body of evidence reporting low-intensity effects from electromagnetic fields (both power-frequency fields in the ELF range, and radiofrequency/microwave fields at exposure levels that do not involve any heating. It also addresses the inconsistency in the literature quoted as the basis for retaining thermal-only exposure standards (see particularly the Genotoxics Section 6 where half of more of the published papers report negative effects and half positive effects).

SECTION 4

Evidence for Inadequacy of the Standards

Cindy Sage, MA

Sage Associates

Santa Barbara, CA USA

Prepared for the BioInitiative Working Group

September 2012

I. Introduction

Evidence for judging the adequacy (or inadequacy) of the existing ICNIRP and IEEE C95.1 radiofrequency radiation standards can be taken from many relevant sources. The ICNIRP standards are similar to the IEEE (except for the new C95.1 -2006) revisions by IEEE SC-4), and these discussions can be used to evaluate both sets of public exposure standards for adequacy (or inadequacy).

An important screen for assessment of how review bodies conduct their science reviews and resulting conclusions on the adequacy of ELF and RF exposure limits depends on embedded assumptions. The singularly most important embedded assumption is whether these bodies assume from the beginning that only conclusive scientific evidence (proof) will be sufficient to warrant change; or whether actions should be taken on the basis of a growing body of evidence which provides early but consequential warning of (but not yet proof) of possible risks.

As a result of current international research and scientific discussion on whether the prevailing RF and ELF standards are adequate for protection of public health, there are many recent developments prior to 2007 to provide valuable background on the uncertainty about whether current standards adequately protect the public. Since 2007, there are important new milestone publications that underscore the critical need to update public safety limits. These newer documents calling for review and updating are based on a deluge of new scientific studies reporting effects at non-thermal, low-intensity ELF and RF exposure levels. There is little doubt that bioeffects and adverse health effects are occurring at lower-than-safety limit levels, meaning the existing protections are inadequate.

II. United States Government Accountability Office

The US Government Accountability Office published a report in 2012 urging the US Federal Communications Commission to revisit the outdated safety standards for the exposures from wireless devices. (US GAO, 2012)

The rapid adoption of mobile phones has occurred amidst controversy over whether the technology poses a risk to human health as a result of long-term exposure to RF energy from mobile phone use. FCC and FDA share regulatory responsibilities for mobile phones. GAO was asked to examine several issues related to mobile phone health effects and regulation. Specifically, this report addresses:

> (1) what is known about the health effects of RF energy from mobile phones and what are current research activities,
> (2) how FCC set the RF energy exposure limit for mobile phones, and
> (3) federal agency and industry actions to inform the public about health issues related to mobile phones, among other things.

GAO reviewed scientific research; interviewed experts in fields such as public health and engineering, officials from federal agencies, and representatives of academic institutions, consumer groups, and the mobile phone industry; reviewed mobile phone testing and certification regulations and guidance; and reviewed relevant federal agency websites and mobile phone user manuals.

The Report noted that the FCC's RF energy exposure limit may not reflect the latest research. Redundant and overlapping jurisdiction over the setting of public safety limits is highlighted where the GAO Report notes:

> *"FCC told GAO that it relies on the guidance of federal health and safety agencies when determining the RF energy exposure limit, and to date, none of these agencies have advised FCC to change the limit. However, FCC has not formally asked these agencies for a reassessment. By not formally reassessing it's current limit, FCC cannot ensure it is using a limit that reflects the latest research on RF energy exposure. FCC has also not reassessed it's testing requirements to ensure that they identify the maximum RF energy exposure a user could experience. Some consumers may use mobile phones against the body, which FCC does not currently test, and could result in RF energy exposure higher than the FCC limit." (US GAO, 2012)*

The GAO Report recommends to the FCC that it formally reassess, and, if appropriate, change it's current RF energy exposure limit and mobile phone testing requirements related to likely usage configurations, particularly when phones are held against the body.

FCC noted that a draft document that is now under consideration by the FCC has the potential to address GAO's recommendations. (US GAO, 2012)

III. International Agency for Research on Cancer - World Health Organization Classifies Radiofrequency Radiation as 2B Possible Human Carcinogen

In 2011, a group of 30 researchers, scientists and medical doctors were invited to participate in an assessment of the scientific literature on radiofrequency radiation carcinogenicity in Lyon, France. Under the auspices of IARC, they conducted a comprehensive scientific assessment of RF studies and determined:

> *"In view of the limited evidence in humans and in experimental animals, the Working Group classified RF- EMF as "possibly carcinogenic to humans" (Group 2B). This evaluation was supported by a large majority of Working Group members." (Baan et al, 2011)*
>
> *"(T)he Working Group concluded that the (Interphone Final Report) findings could not be dismissed as reflecting bias alone, and that a causal interpretation between mobile phone RF-EMF exposure and glioma is possible. A similar conclusion was drawn from these two studies for acoustic neuroma, although the case numbers were substantially smaller than for glioma." (Baan et al, 2011)*

It is important to recognize that the IARC RF Working Group did not find the evidence insufficient to classify (Group 3) or not a carcinogen (Group 4). Both of these possible outcomes to the scientific assessment could have rendered a substantially weaker conclusion. Where there has been the necessity of a virtual scientific paradigm shift to accommodate ANY consideration of both ELF-EMF and RFR to the status where legitimate scientific attention is achieved is a notable achievement. There is a very high bar set to show that non-chemical carcinogens warrant IARC carcinogenicity evaluation - it greatly exceeds that necessary for chemicals and other toxins.

IV. World Health Organization *INTERPHONE* Study on Mobile Phone Cancer Risk

In 2010, the World Health Organization released the final results of it's investigation on

cell phones and cancer. (INTERPHONE Study Group, 2010) The ten-year long World Health Organization *INTERPHONE Study* confirms previous reports showing what many experts have warned – that regular use of a cell phone by adults can significantly increase the risk of glioma by 40% with 1640 hours or more of use (this is about one-half hour per day over ten years). Tumors were more likely to occur on the side of the head most used for calling. The risk increases to 96% for adults with ipsilateral cell phone use (when the cell phone is used predominantly on one side of the head). The study appears in the International Journal of Epidemiology. Thirteen teams from countries around the world combined their results. Only the glioma findings were released (final results on acoustic neuroma and parotid tumors are not yet published.

A comprehensive and technically reliable description of the *INTERPHONE* study findings is provided within the International Agency for Research on Cancer, 2011 RF Monograph as part of the publication in Lancet Oncology on IARC's classification of radiofrequency radiation as a 2B Possible Human Carcinogen. Results of the *INTERPHONE* Study were highly scrutinized by IARC, and influenced the classification of RF based on the cell phone-brain cancer findings of *INTERPHONE*.

From Baan et al, 2011:

> *"The INTERPHONE study, a multi-centre case-control study, is the largest investigation so far of mobile phone use and brain tumours, including glioma, acoustic neuroma, and meningioma.The pooled analysis included 2708 glioma cases and 2972controls(participation rates64% and 53%, respectively). Comparing those who ever used mobile phones with those who never did yielded an odds ratio (OR) of 0·81 (95% CI 0·70–0·94). In terms of cumulative call time, ORs were uniformly below or close to unity for all deciles of exposure except the highest decile (>1640 h of use), for which the OR for glioma was 1·40 (95% CI 1·03–1·89). There was suggestion of an increased risk for ipsilateral exposure(on the same side of the head as the tumour) and for tumours in the temporal lobe, where RF exposure is highest. Associations between glioma and cumulative specific energy absorbed at the tumour location were examined in a subset of 553 cases that had estimated RF doses.10 The OR for glioma increased with increasing RF dose for exposures 7 years or more before diagnosis, whereas there was no association with estimated dose for exposures less than 7 years before diagnosis.*
>
> *A Swedish research group did a pooled analysis of two very similar studies of associations between mobile and cordless phone use and glioma, acoustic neuroma, and meningioma.9 The analysis included 1148 glioma cases (ascertained 1997–2003) and 2438 controls,obtained through cancer and population registries,*

> *respectively. Self-administered mailed questionnaires were followed by telephone interviews to obtain information on the exposures and covariates of interest, including use of mobile and cordless phones (response rates 85% and 84%, respectively). Participants who had used a mobile phone for more than 1 year had an OR for glioma of 1.3 (95% CI 1·1–1·6). The OR increased with increasing time since first use and with total call time, reaching 3.2 (2·0–5·1) for more than 2000 h of use. Ipsilateral use of the mobile phone was associated with higher risk. Similar findings were reported for use of cordless phones.*
>
> *Although both the INTERPHONE study and the Swedish pooled analysis are susceptible to bias—due to recall error and selection for participation— the Working Group concluded that the findings could not be dismissed as reflecting bias alone, and that a causal interpretation between mobile phone RF-EMF exposure and glioma is possible. A similar conclusion was drawn from these two studies for acoustic neuroma, although the case numbers were substantially smaller than for glioma. Additionally, a study from Japan (11) found some evidence of an increased risk for acoustic neuroma associated with ipsilateral mobile phone use.*
>
> *(Baan et al, 2011)*

No that no increased risk was detected overall. But this is not unexpected. No exposures to carcinogens that cause solid tumors like brain cancer or lung cancers, for example from tobacco and asbestos have ever been shown to significantly increase cancer risk in people with such short duration of exposure. The latency period for brain cancer is 15-30 years.

The final INTERPHONE results support findings of several research groups who have published studies reporting that continuing use of a mobile phone increases risk of brain cancer. We would not expect to see substantially increased brain tumor risk for most cancer-causing agents except in the longer term (10 year and longer) as is the case here in the population of regular cell phone users. Further, the participants included in this study were 30-59 years old, excluding younger and older users. Use of cordless phones was neglected in the analysis. Radiofrequency radiation from some cordless phones can be as high as mobile phones in some countries, so excluding such use would underestimate the risk for brain tumors and other cancers.

For public health experts and members of the public who looked to IARC for further clarification of the scope of this 2B Possible Human Carcinogen designation, Dr. Baan replied to informal queries that:

"Although the key information came from mobile telephone use, the Working Group considered that the three types of exposure entail basically the same type of radiation, and decided to make an overall evaluation on RF-EMF, covering the whole radiofrequency region of the electromagnetic spectrum.

In support of this, information from studies with experimental animals showed that effects on cancer incidence and cancer latency were seen with exposures to different frequencies within the RF region.

So the classification 2B, possibly carcinogenic, holds for all types of radiation within the radiofrequency part of the electromagnetic spectrum, including the radiation emitted by base-station antennas, radio/ TV towers, radar, Wi-Fi, smart meters, etc." (Personal communication of Dr. Robert Baan to Connie Hudson, August 29, 2011)

V. President's Cancer Panel Report of 2010

The United States President's Cancer Panel Report (2010) includes important and unprecedented recognition of non-ionizing radiation as a possible carcinogen deserving of further research and possible public health action. The Report found "the true burden of environmentally induced cancers has been grossly underestimated" and strongly urged action to reduce peoples' widespread exposures to carcinogens. The 240-page report issued for 2008-2009 by a panel of experts that report to the US president indicate that environmental factors are underestimated in cancer prevention. The Report specifically addresses the link between cell phones and cancer. The Panel recommends that people reduce their cell phone exposure, even when absolute proof of harm is not yet available.

Research Recommended by Presidents Cancer Panel

- Resolve controversies regarding the safety or harm of low doses of various forms of radiation in adults and children. Identify circumstances under which low- dose radiation may have a hormetic effect.

- Develop radiation dose and risk estimates that better reflect the current and future U.S. population. Existing dose and risk estimates have been based on adult males; estimates should account for population diversity, including children. In addition, develop medical radiation risk estimates that are not based on acute doses received by atomic bomb survivors.

• Expand research on possible harmful effects of cell phone use, especially in children. Cell phone use still is relatively recent, and studies to date have had mixed findings; most involve users of older equipment. Findings from cohort studies now underway are anticipated, but longer-term studies of individuals using current equipment are needed.

• Conduct additional research on possible links between electromagnetic fields (EMF) and cancer; identify mechanism(s) of EMF carcinogenesis.

• Monitor changing patterns of radiation exposure.

• Raise the priority of and investment in research to develop non-toxic products anD processes.

• Develop, test, and evaluate prevention communication strategies and interventions, especially in high-risk occupations and populations.

(National Cancer Institute, 2010)

VI. World Health Organization Research Agenda for Radiofrequency Fields (2010)

In 2010, the WHO produced a research agenda to address growing scientific questions and public concern about health effects of radiofrequency radiation, particularly with the explosive rise in exposures from new telecommunications technologies. It replaced a 2006 research agenda developed by the International EMF Project.

"Telecommunication technologies based on radiofrequency (RF) transmission, such as radio and television, have been in widespread use for many decades. However, there are numerous new applications for the broadcast and reception of RF waves and the use of RF devices such as mobile phones is now ubiquitous.

The attendant increased public exposure to RF fields has made its effects on human health a topic of concern for scientists and the general public.
(emphasis added)

To respond to these concerns, an important research effort has been mounted over the past decade and many specific questions about potential health effects of RF fields have already been investigated by scientists around the world. Nonetheless, several areas still warrant further investigation and the rapid evolution of technology in this field is raising new questions." (WHO, 2010)

"This Research Agenda is developed ahead of the major hazard/health risk evalu-

ations that the IARC and WHO are due to carry out over the next two years. It focuses on identifying short- and long-term research needs that will enable more complete health risk assessments to be undertaken and communicated more effectively to the public." (WHO, 2010)

Recommendations of the WHO Research Agenda for Radiofrequency Fields are as follows. This section is necessarily extensive to document the advice of experts at WHO by 2010 in recognizing radiofrequency radiation has the potential to result in global health impacts; even if very slow to implement precautionary advice to the European Commission and member countries.

Priority: Epidemiology

High - Prospective cohort studies of children and adolescents with outcomes including behavioural and neurological disorders and cancer

Rationale: As yet, little research has been conducted in children and adolescents and it is still an open question whether children are more susceptible to Rf EMF since the brain continues to develop during childhood and adolescence. also, children are starting to use mobile phones at a younger age. given the existence of large-scale cohort studies of mothers and children with follow-up started during or before pregnancy, an Rf sources component could be added at a reasonably low cost. Billing records for mobile phones are not valid for children, therefore the prospective collection of exposure data is needed. for neuropsychological studies, one challenge is to distinguish the "training" of motor and neu- ropsychological skills caused by the use of a mobile phone from the effects of the Rf field. any future study should try to address this issue. in any case it should be of longitudinal design, thereby allowing the study of several outcomes and changes in technology and the use of mobile phones as well as other sources of Rf eMf exposure, such as wireless laptops.

High - Monitoring of brain tumour incidence trends through well-established population-based cancer registries, if possible combined with population exposure data

Rationale: If there is a substantial risk associated with mobile phone use, it should be observable in data sources of good quality. such time trend analyses can be performed quite quickly and inexpensively. By using modern statistical techniques for analysing popu- lation data it should be possible to link changes in exposure prevalence in the population to the incidence of brain tumours and, if high-quality surveillance data are available, the incidence of other diseases at the population level. given the shortcomings in the exposure assessment and participation of previous studies based on individual data, an ecological study would have benefits that may outweigh its limitations.

Other - case-control studies of neurological diseases provided that objective exposure data and confounder data are available and reasonable participation is achieved

Rationale: Neurological endpoints, such as alzheimer disease and Parkinson disease, may be as biologically plausible as brain cancer and an increased risk would have a major public health impact. This study could give an early warning sign that can be elaborated further in the prospective cohort studies. an analysis of time-trends in neurological disease could also serve as an early warning sign. However, a feasibility study would be necessary in order to determine whether a good quality case-control study could be carried out.

Priority: Human studies

High - further RF EMf provocation studies on children of different ages

Rationale: current research has focused primarily on adolescents; very little is known about possible effects in younger children. longitudinal testing at different ages, for example by studying children already participating in current cohort studies, is recommended. This would allow consideration of the influence of potentially confounding factors such as lifestyle.

High - Provocation studies to identify neurobiological mechanisms underlying possible effects of RF on brain function, including sleep and resting EEG

Rationale: These studies should include validation of these effects using a range of brain imaging methods. They should also include studies investigating possible thresholds and dose-response relationships at higher exposure levels such as those encountered during occupational exposure.

Priority: Animal studies

High - Effects of early-life and prenatal RF exposure on development and behaviour

Rationale: There is still a paucity of information concerning the effects of prenatal and early life exposure to RF EMf on subsequent development and behaviour. Such studies are regarded as important because of the widespread use of mobile phones by children and the increasing exposure to other RF sources such as wireless local area networks (Wlans) and the reported effects of RF EMf on the adult EEG. further study is required which should include partial (head only) exposure to mobile phones at relatively high specific absorption rate (SAR) levels.

High - effects of RF exposure on ageing and neurodegenerative diseases

Rationale: age-related diseases, especially neurodegenerative diseases of the brain such as alzheimer disease and Parkinson disease, are increasingly prevalent and are therefore an important public health issue. Mobile phone use typically involves repeated Rf eMf

exposure of the brain; a recent study has suggested that this type of exposure could affect alzheimer disease in a transgenic mouse model for this condition (arendash et al., 2010). There are a few ongoing studies of possible Rf eMf effects on neurodegenerative diseases but further studies are required to investigate this subject more fully.

Other research needs - Effects of RF exposure on reproductive organs

Rationale: The available data concerning possible effects of Rf eMf from mobile phones on male fertility are inconsistent and their quality and exposure assessments are weak. in vivo studies on fertility should consider effects on both males and females and investigate a range of relevant endpoints including Rf eMf effects on the development and function of the endocrine system.

Priority: Cellular studies

Other - Identify optimal sets of experimental tests to detect cellular response after exposure to new RF technologies and co-exposures of RF EMF with environmental agents

Rationale: a number of in vitro studies investigating the effects of exposure to mobile phone frequencies/signals, or co-exposures of RF EMf with chemical or physical agents, have been published in the last fifteen years. Results obtained have been inconsistent and contradictory, not least because of the use of a large variety of cell types and study approaches. a set of highly sensitive, well-harmonized cellular and molecular methods should be developed in order to screen the toxic potential of new types of RF signals used in new technologies and of co-exposures of RF EMf and environmental agents – especially those suspected to have toxic effects. This research must be multicentred in order to allow the widest possible acceptance and application of this screening tool.

Other - further studies on the influence of genetic background and cell type: possible effects of mobile phone type Rf exposure on a variety of cell types using newer, more sensitive methods less susceptible to artefact and/or bias

Rationale: More rigorous quantitative methods should be employed in the evaluation of positive results that suggest a specific cell type response, e.g. of embryonic cells (Czyz et al., 2004; Franzellitti et al., 2010), raising the possibility that RF impacts specific cell subpopulations or cell types. These studies should include a variety of cell types such as stem cells and cells with altered genetic backgrounds.

Priority: Mechanisms: none

Priority: Dosimetry

High - Assess characteristic RF EMF emissions, exposure scenarios and corresponding exposure levels for new and emerging RF technologies; also for changes in the use of established technologies

Rationale: The work should address the latest developments in areas such as mobile/cordless phones, wireless data networking, asset tracking and identification, wireless transfer of electrical power and body imaging/scanners. it should also consider the possible combined effect of exposure to multiple sources. This will allow exposures from new devices/scenarios to be compared with those that are more familiar and with exposure guidelines for risk communication purposes. This information will also be of value for exposure assessment in epidemiological studies and in the design of biological exposure systems.

High - quantify personal exposures from a range of RF sources and identify the determinants of exposure in the general population

Rationale: The quantification of personal exposure from a range of RF sources will provide valuable information for risk assessment and communication, and for the development of future epidemiological research. it is particularly useful for global exposure assessment in view of the upcoming WHO health risk assessment. The study will also provide baseline data for identification of any changes in the level of exposure and the dominant contributing factors over time. subgroup analyses should be carried out to identify any influence from demographic aspects of the user as well as the microenvironment in which the exposure occurs. exposure metrics should also be considered, especially in combining localized exposures from body-worn devices and whole-body exposures.

Other research needs - Monitoring of personal exposure of Rf workers

Rationale: The exposure patterns of both workers and the general public change continuously, mainly due to the development of new RF technologies. However, workers encounter industrial sources and exposure situations that lead to much higher energy deposition in the body. When epidemiological studies on RF workers are performed, it is imperative to monitor adequately their RF exposure. new instruments are needed to address the lack of adequate measurement tools for evaluating this type of exposure e.g. portable devices suitable for measuring different frequencies and waveforms. in addition, a study of the feasibility of monitoring the personal exposure of RF workers is required for future epidemiological studies. such studies would be facilitated by the production of a job exposure matrix (JeM) for RF workers – in which job designations can be characterized by their exposure. (WHO, 2010)

VII. National Academy of Sciences, National Research Council (2008)

The U.S. Food and Drug Administration (FDA) of the Department of Health and Human Services asked the National Academies to organize a workshop of national and international experts to identify research needs and gaps in knowledge of biological effects and adverse health outcomes of exposure to radiofrequency (RF) energy from wireless communications devices. To accomplish this task, the National Academies appointed a seven member committee to plan the workshop.1

Following the workshop, the committee was asked to issue a report based on the presentations and discussions at the workshop that identified research needs and current gaps in knowledge. The committee's task did not include the evaluation of health effects or the generation of recommendations relating to how the identified research needs should be met.

For the purposes of this report, the committee defines research needs as research that will increase our understanding of the potential adverse effects of RF energy on humans. Research gaps are defined as areas of research where the committee judges that scientific data that have potential value are presently lacking, but that closing of these gaps is either ongoing and results should be awaited before judgments are made on further research needs, or the gaps are not judged by the committee to be of as high a priority with respect to directly addressing health concerns at this time.

1. Committee on Identification of Research Needs Relating to Potential Biological or Adverse Health Effects of Wireless Communications Devices.

These needs and gaps are committee judgments derived from the workshop presentations and discussions, and the report does not necessarily reflect the views of the FDA, individual workshop speakers, or other workshop participants.

The committee judged that important research needs included, in order of appearance in the text, the following:

> • Characterization of exposure to juveniles, children, pregnant women, and fetuses from personal wireless devices and RF fields from base station antennas.
>
> • Characterization of radiated electromagnetic fields for typical multiple- element base station antennas and exposures to affected individuals.
>
> • Characterization of the dosimetry of evolving antenna configurations for cell phones and text messaging devices.
>
> • Prospective epidemiologic cohort studies of children and pregnant women.
>
> • Epidemiologic case-control studies and childhood cancers, including brain cancer.
>
> • Prospective epidemiologic cohort studies of adults in a general population and retrospective cohorts with medium to high occupational exposures.
>
> • Human laboratory studies that focus on possible adverse effects on electroencephalography2 activity and that include a sufficient number of subjects.
>
> • Investigation of the effect of RF electromagnetic fields on neural networks.
>
> • Evaluation of doses occurring on the microscopic level.
>
> • Additional experimental research focused on the identification of potential biophysical and biochemical/molecular mechanisms of RF action.
>
> (NAS-NRC, 2008)

VIII. World Health Organization Draft Framework for Electromagnetic Fields

The International EMF Project was established by WHO in 1996. Its mission was to *"pool resources and knowledge concerning the effects of exposure to EMF and make a concerted effort to identify gaps in knowledge, recommend focused research programmes that allow better health risk assessments to be made, conduct updated critical reviews of the scientific literature, and work towards an international consensus and solutions on the health concerns."* (WHO September 1996 Press Release - Welcome to the International EMF Project)

The stated role of the WHO Precautionary Framework on EMF Health Risk Research (Radiation and Environment Health) has termed its objectives as follows;

- to anticipate and respond to possible threats before introduction of an agent or technology
- to address public concerns that an uncertain health risk is minimized after introduction of an agent
- to develop and select options proportional to the degree of scientific certainty, the severity of harm, the size and nature of the affected population and the cost.

The role of WHO is advisory only to the countries of Europe but it is an important function and can significantly affect decision-making on public health issues. It provides analysis and recommendations on various topics of health and environment, for consideration by member countries of the EU. Given the EU Article 174 policy requires a precautionary approach to judging health and environmental risks, and given that the charter of WHO is to serve the needs of the EU, one would think it essential that the WHO EMF Program health criteria results should be guided by and tailored to compliance with Article 174. This needs to occur in the assessment of the scientific literature (e.g., not requiring studies to provide scientific proof or causal scientific evidence but paying attention to and acting on the evidence, and the trend of the evidence at hand) and in its environmental health criteria recommendations. If the WHO EMF Program instead chooses to use the definitions of adverse impact and risk based on reacting to nothing short of conclusive scientific evidence, it fails to comply with the over-arching EU principle of health.

The World Health Organization has issued a draft framework to address the adequacy of scientific information, and accepted definitions of bioeffects, adverse health effect and hazard (WHO EMF Program Framework for Developing EMF Standards, Draft, October 2003). These definitions are not subject to the whim of organizations preparing public exposure standard recommendations. The WHO definition states that:

> "(A)nnoyance or discomforts caused by EMF exposure may not be pathological per se, but, if substantiated, can affect the physical and mental well-being of a

person and the resultant effect may be considered as an adverse health effect. A health effect is thus defined as a biological effect that is detrimental to health or well-being. According to the WHO Constitution, health is a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity." **www.who.int/peh-emf**

IX. The European Union Treaties Article 174

The EU policy (Article 174-2) requires that the precautionary principle be the basis for environmental protection for the public, and that protecting public health and taking preventative action before certainty of harm is proven is the foundation of the Precautionary Principle. It is directly counter to the principles used by ICNIRP and IEEE in developing their recommendations for exposure standards. Both bodies require proof of adverse effect and risk before amending the exposure standards; this Treaty requires action to protect the public when a reasonable suspicion of risk exists (precautionary action).

Article 174 (2) [ex Article 130r]

1. Community policy on the environment shall contribute to pursuit of the following objectives:
—preserving, protecting and improving the quality of the environment;
—protecting human health;
—prudent and rational utilisation of natural resources;
—promoting measures at international level to deal with regional or worldwide environmental problems.

2. Community policy on the environment shall aim at a high level of protection taking into account the diversity of situations in the various regions of the Community. It shall be based on the precautionary principle and on the principles that preventive action should be taken, that environmental damage should as a priority be rectified at source and that the polluter should pay. In this context, harmonization measures answering environmental protection requirements shall include, where appropriate, as a safeguard clause allowing Member States to take provisional measures, for non-economic environmental reasons, subject to a Community inspection procedure.

3. In preparing its policy on the environment, the Community shall take account of:

—available scientific and technical data;
—environmental conditions in the various regions of the Community;

—the potential benefits and costs of action or lack of action;
—the economic and social development of the Community as a whole and the balanced development of its regions.

X. WHO ELF Environmental Health Criteria Monograph, June 2007

In 2007. the WHO EMF Program released its ELF Health Criteria Monograph and held a workshop in Geneva, Switzerland June 20-21st.

ELF Health Criteria Monograph

12.6 Conclusions

Acute biological effects have been established for exposure to ELF electric and magnetic fields in the frequency range up to 100 kHz that may have adverse consequences on health. Therefore, exposure limits are needed. International guidelines exist that have addressed this issue. Compliance with these guidelines provides adequate protection.

Consistent epidemiological evidence suggests that chronic low-intensity ELF magnetic field exposure is associated with an increased risk of childhood leukaemia. ***However, the evidence for a causal relationship is limited, therefore exposure limits based upon epidemiological evidence are not recommended, but some precautionary measures are warranted.*** (emphasis added).

The Monograph finds no reason to change the designation of EMF as a 2B (Possible) Human Carcinogen as defined by the International Agency for Cancer Research (IARC). In finding that ELF-EMF is classifiable as a possible carcinogen, it is inconsistent to conclude that no change in the exposure limits is warranted. If the Monograph confirms, as other review bodies have, that childhood leukemia occurs at least as low as the 3 mG to 4 mG exposure range, then ICNIRP limits of 1000 mG for 50 Hz and 60 Hz ELF exposures are clearly too high and pose a risk to the health of children.

The WHO Fact Sheet summarizes some of the Monograph findings but adds further recommendations.

"Potential long-term effects"

Much of the scientific research examining long-term risks from ELF magnetic field exposure has focused on childhood leukaemia. In 2002, IARC published a monograph classifying ELF magnetic fields as "possibly carcinogenic to humans. This classification was based on pooled analyses of epidemiological studies demonstrating a consistent

pattern of a two-fold increase in childhood leukaemia associated with average exposure to residential power-frequency magnetic field above 0.3 to 0.4 μT. ***The Task Group concluded that additional studies since then do not alter the status of this classification."*** *(emphasis added)*

"International exposure guidelines"

"Health effects related to short-term, high-level exposure have been established and form the basis of two international exposure limit guidelines (ICNIRP, 1998; IEEE, 2002). At present, these bodies consider the scientific evidence related to possible health effects from long-term, low-level exposure to ELF fields insufficient to justify lowering these quantitative exposure limits."

"Regarding long-term effects, given the weakness of the evidence for a link between exposure to ELF magnetic fields and childhood leukaemia, the benefits of exposure reduction on health are unclear. In view of this situation, the following recommendations are given:

> *1) Government and industry should monitor science and promote research programmes to further reduce the uncertainty of the scientific evidence on the health effects of ELF field exposure. Through the ELF risk assessment process, gaps in knowledge have been identified and these form the basis of a new research agenda.*
>
> *2) Member States are encouraged to establish effective and open communication programmes with all stakeholders to enable informed decision-making. These may include improving coordination and consultation among industry, local government, and citizens in the planning process for ELF EMF-emitting facilities.*
>
> *3) When constructing new facilities and designing new equipment, including appliances, low-cost ways of reducing exposures may be explored. Appropriate exposure reduction measures will vary from one country to another. However, policies based on the adoption of arbitrary low exposure limits are not warranted."*

The last bullet in the WHO ELF Fact Sheet does not come from the Monograph, nor is it consistent with conclusions of the Monograph. The Monograph does call for prudent avoidance measures, one of which could reasonably be to establish numeric planning targets or interim limits for new and upgraded transmission lines and appliances used by children, for example. Countries should not be dissuaded by WHO staff, who unlike the authors of the Monograph, go too far in defining appropriate boundaries for countries that may wish to implement prudent avoidance in ways that best suit their population needs, expectations and resources. www.who.int/peh-emf/project/en

XI. World Health Organization Report on Children's Health and Environment

Environmental Issue Report Number 29 from the World Health Organization (2002) cautions about the effects of radiofrequency radiation on children's health. As part of a publication on "Children's Health and Environment: A Review of Evidence" the World Health Organization (WHO) wrote:

> *"The possible adverse health effects in children associated with radiofrequency fields have not been fully investigated."*
>
> *"Because there are suggestions that RF exposure may be more hazardous for the fetus and child due to their greater susceptibility, prudent avoidance is one approach to keeping children's exposure as low as possible."*
>
> *"Further research is needed to clarify the potential risks of ELF-EMF and radiofrequency fields for children's health."*

XII. International Agency for Research on Cancer (IARC)

A 2001 report by the WHO International Agency for Research on Cancer (IARC) concluded that ELF-EMF power frequency fields are a Category 2B (Possible) Human Carcinogen. These are power-frequency electromagnetic fields (50-Hz and 60-Hz electric power frequency fields).

The World Health Organization (WHO) is conducting the International Electromagnetic Fields (EMF) Project to assess health and environmental effects of exposure to static and time varying electric and magnetic fields in the frequency range of 1 – 300 gigahertz (GHz). Project goals include the development of international guidelines on exposure limits. This work will address radio and television broadcast towers, wireless communications transmission and telecommunications facilities, and associated devices such as mobile phones, medical and industrial equipment, and radars. It is a multi-year program that began in 1996 and will end in 2005. www.who.int/peh-emf

XIII. SCENIHR Opinion (European Commission Study of EMF and Human Health)

An independent Scientific Committee on newly emerging risks commissioned by the European Union released an update of its 2001 opinion on electromagnetic fields and human health in 2007. "The Committed addressed questions related to potential risks associated with interaction of risk factors, synergistic effects, cumulative effects, anti-microbial resistance, new technologies such as nanotechnologies, medical devices, tissue engineeringm blood products, fertility reduction, cancer of endocrine organs, physical hazards such as noise and electromagnetic fields and methodologies for assessing new risks." SCENIHR, 2007

SCENIHR Conclusions on Extremely low frequency fields (ELF fields)

> The previous conclusion that ELF magnetic fields are possibly carcinogenic, chiefly based on childhood leukaemia results, is still valid. There is no generally accepted mechanism to explain how ELF magnetic field exposure may cause leukaemia.
>
> For breast cancer and cardiovascular disease, recent research has indicated that an association is unlikely. For neurodegenerative diseases and brain tumours, the link to ELF fields remains uncertain. A relation between ELF fields and symptoms (sometimes referred to as electromagnetic hypersensitivity) has not been demonstrated.

SCENIHR Conclusions on Radiofrequency Radiation fields (RF fields)

> Since the adoption of the 2001 opinion, extensive research has been conducted regarding possible health effects of exposure to low intensity RF fields. This research has investigated a variety of possible effects and has included epidemiologic, in vivo, and in vitro research. The overall epidemiologic evidence suggests that mobile phone use of less than 10 years does not pose any increased risk of brain tumour or acoustic neuroma. For longer use, data are sparse, since only some recent studies have reasonably large numbers of long-term users. Any conclusion therefore is uncertain and tentative. From the available data, however, it does appear that there is no increased risk for brain tumours in long-term users, with the exception of acoustic neuroma for which there is limited evidence of a weak association. Results of the so-called Interphone study will provide more insight, but it cannot be ruled out that some questions will remain open.

SCENIHR Conclusions on Sensitivity of Children

> Concerns about the potential vulnerability of children to RF fields have been

raised because of the potentially greater susceptibility of their developing nervous system; in addition, their brain tissue is more conductive than that of adults since it has a higher water content and ion concentration, RF penetration is greater relative to head size, and they have a greater absorption of RF energy in the tissues of the head at mobile telephone frequencies. Finally, they will have a longer lifetime exposure.

Few relevant epidemiological or laboratory studies have addressed the possible effects of RF field exposure on children. Owing to widespread use of mobile phones among children and adolescents and relatively high exposures to the brain, investigation of the potential effect of RF fields in the development of childhood brain tumour is warranted. The characteristics of mobile phone use among children, their potential biological vulnerability and longer lifetime exposure make extrapolation from adult studies problematic.

There is an ongoing debate on possible differences in RF absorption between children and adults during mobile phone usage, e.g. due to differences in anatomy (Wiart et al. 2005, Christ and Kuster, 2005). Several scientific questions like possible differences of the dielectric tissue parameters remain open. The anatomical development of the nervous system is finished around 2 years of age, when children do not yet use mobile phones although baby phones have recently been introduced. Functional development, however, continues up to adult age and could be disturbed by RF fields.

XIV. Health Protection Agency (Formerly the NRPB - United Kingdom)

The National Radiation Protection Board or NRPB (2004) concluded, based on a review of the scientific evidence, that the most coherent and plausible basis from which guidance could be developed on exposures to ELF concerned weak electric field interactions in the brain and CNS (NRPB, 2004). A cautious approach was used to indicate thresholds for possible adverse health effects.

> *"Health Effects - It was concluded from the review of scientific evidence (NRPB, 2004b) that the most coherent and plausible basis from which guidance could be developed on exposures to ELF EMFs concerned weak electric field interactions in the brain and CNS (NRPB, 2004). A cautious approach was used to indicate thresholds for possible adverse health effects."*

> *"The brain and nervous system operate using highly complex patterns of \electrical signals. Therefore, the basic restrictions are designed to limit the*

electric fields and current densities in these tissues so as to not adversely affect their normal functioning. The adverse effects that might occur cannot easily be characterized according to presenting signs or symptoms of disease or injury. They represent potential changes to mental processes such as attention and memory, as well as to regulatory functions with in the body. Thus, the basic restrictions should not be regarded as precisely determined values below which no adverse health effects can occur and above which clearly discernible effects will happen. The do, however, indicate an increasing likelihood of effects occurring as exposure increases above the basic restriction values."

*"From the results of the epidemiological investigations, there remain concerns about a possible increased risk of child leukaemia associated with exposure to magnetic fields above about 0.4 uT (*4 mG*). In this regard, it is important to consider the possible need for further precautionary measures."*

This recent statement by the UK Health Protection Agency clearly indicates that the current guidelines may not be protective of public health. Yet, the reference levels used in the United Kingdom remain at 5000 mG for 50 Hz power frequency fields for occupational exposure and 1000 mG for public exposure.

XV. US Government Radiofrequency Interagency Working Group Guidelines Statement

The United States Radiofrequency Interagency Working Group (RFIAWG) cited concerns about current federal standards for public exposure to radiofrequency radiation in 1999 (Lotz, 1999 for the Radiofrequency Interagency Working Group)

"*Studies continue to be published describing biological responses to nonthermal ELF-modulated RF radiation exposures that are not produced by CW (unmodulated) radiation. These studies have resulted in concern that 'exposure guidelines based on thermal effects, and using information and concepts (time-averaged dosimetry, uncertainty factors) that mask any differences between intensity-modulated RF radiation exposure and CW exposure, do not directly address public exposures, and therefore may not adequately protect the public."*

The United States government Federal Radiofrequency Interagency Working Group has reviewed the existing ANSI/IEEE RF thermal-based exposure standard upon which the FCC limit is based. This Working Group was made up of representatives from the US government's National Institute for Occupational Safety and Health (NIOSH), the

Federal Communications Commission (FCC), Occupational Health and Safety Administration (OSHA), the Environmental Protection Agency (US EPA), the National Telecommunication and Information Administration, and the US Food and Drug Administration (FDA).

On June 17, 1999, the RFIAWG issued a Guidelines Statement that concluded the present RF standard "may not adequately protect the public". The RFIAWG identified fourteen (14) issues that they believe are needed in the planned revisions of ANSI/IEEE RF exposure guidelines including **"**to provide a strong and credible rationale to support RF exposure guidelines". In particular, the RFIAWG criticized the existing standards as not taking into account chronic, as opposed to acute exposures, modulated or pulsed radiation (digital or pulsed RF is proposed at this site), time-averaged measurements that may erase the unique characteristics of an intensity-modulated RF radiation that may be responsible for reported biologic effects, and stated the need for a comprehensive review of long-term, low-level exposure studies, neurological-behavioral effects and micronucleus assay studies (showing genetic damage from low-level RF).

The existing federal standards may not be protective of public health in critical areas. The areas of improvement where changes are needed include: a) selection of an adverse effect level for chronic exposures not based on tissue heating and considering modulation effects; b) recognition of different safety criteria for acute and chronic exposures at non-thermal or low-intensity levels; c) recognition of deficiencies in using time-averaged measurements of RF that does not differentiate between intensity-modulated RF and continuous wave (CW) exposure, and *therefore may not adequately protect the public.*

As of 2007, requests to the RFIAWG on whether these issues have been satisfactorily resolved in the new 2006 IEEE recommendations for RF public safety limits have gone unanswered (BioInitiative Working Group, 2007).

XVI. United Kingdom - Parliament Independent Expert Group Report (Stewart Report)

The Parliament of the United Kingdom commissioned a scientific study group to evaluate the evidence for RF health and public safety concerns. In May of 2000, the United Kingdom Independent Expert Group on Mobile Phones issued a report underscoring concern that standards are not protective of public health related to both mobile phone use and exposure to wireless communication antennas.

Conclusions and recommendations from the Stewart Report (for Sir William Stewart) indicated that the Group has some reservation about continued wireless technology expansion without more consideration of planning, zoning and potential public health concerns. Further, the Report acknowledges significant public concern over community siting of mobile phone and other communication antennas in residential areas and near schools and hospitals.

> *"Children may be more vulnerable because of their developing nervous system, the greater absorption of energy in the tissue of the head and a longer lifetime of exposure."*
>
> *"The siting of base stations in residential areas can cause considerable concern and distress. These include schools, residential areas and hospitals."*
>
> *" There may be indirect health risks from living near base stations with a need for mobile phone operators to consult the public when installing base stations."*
>
> *"Monitoring should be expecially strict near schools, and that emissions of greatest intensity should not fall within school grounds."*
>
> *"The report recommends "a register of occupationally exposed workers be established and that cancer risks and mortality should be examined to determine whether there are any harmful effects."*
> *(*IEGMP, 2000)

XVII. Food and Drug Administration (US FDA)

The Food and Drug Administration announced on March 28, 2007 it is contracting with the National Academy of Science to conduct a symposium and issue a report on additional research needs related to possible health effects associated with exposure to radio frequency energy similar to those emitted by wireless communication devices. The National Academy of Sciences will organize an open meeting of national and international experts to discuss the research conducted to date, knowledge gaps, and additional research needed to fill those gaps. The workshop will consider the scientific literature and ongoing research from an international perspective in order to avoid duplication, and in recognition of the international nature of the scientific community and of the wireless industry.

Funding for the project will come from a Cooperative Research and Development Agreement (CRADA) between the Food and Drug Administration's Center for Devices and Radiological Health and the Cellular Telecommunications and Internet Association (CTIA). http://www.fda.gov/cellphones/index.html

XVIII. National Institutes for Health - National Toxicology Program

The National Toxicology Program (NTP) is a part of the National Institute for Environmental Health Sciences, National Institutes for Health. Public and agency comment has been solicited on whether to add radiofrequency radiation to its list of substances to be tested by NTP as carcinogens. In February 2000 the FDA made a recommendation to the NPT urging that RF be tested for carcinogenicity (www.fda.gov.us). The recommendation is based in part on written testimony stating:

> **"** *Animal experiments are crucial because meaningful data will not be available from epidemiological studies for many years due to the long latency period between exposure to a carcinogen and the diagnosis of a tumor.*
>
> *"There is currently insufficient scientific basis for concluding either that wireless communication technologies are safe or that they pose a risk to millions of users."*

> *"FCC radiofrequency radiation guidelines are based on protection from acute injury from thermal effects of RF exposure* and may not be protective *against any non-thermal effects of chronic exposures."*

In March of 2003, the National Toxicology Program issued a Fact Sheet regarding its toxicology and carcinogenicity testing of radiofrequency/microwave radiation. These studies will evaluate radiofrequency radiation in the cellular frequencies.

> "*The existing exposure guidelines are based on protection from acute injury from thermal effects of RF exposure. Current data are insufficient to draw definitive conclusions concerning the adequacy of these guidelines to be protective against any non-thermal effects of chronic exposures. "*

XIX. US Food and Drug Administration

In February of 2000, Russell D. Owen, Chief of the Radiation Biology Branch of the Center for Devices and Radiological Health, US Food and Drug Administration (FDA) commented that there is:

> *"currently insufficient scientific basis for concluding whether wireless communication technologies pose any health risk."*
>
> *"Little is known about the possible health effects of repeated or long-term exposures to low level RF of the sort emitted by such devices."*
>
> *"Some animal studies suggest the possibility for such low-level exposures to increase the risk of cancer…"*

Dr. Owen's comments are directed to users of cell phones, but the same questions are pertinent for long-term RF exposure to radiofrequency radiation for the larger broadcast transmissions of television, radio and wireless communications (Epidemiology Vol. 1, No. 2 March 2000 Commentary). The Food and Drug Administration signed an agreement (CRADA agreement) to provide funding for immediate research into RF health effects, to be funded by the Cellular Telephone Industry of America. The FDA no longer assures the safety of users. No completion date has been set.

XX. National Academy of Sciences - National Research Council

An Assessment of Non-Lethal Weapons Science and Technology by the Naval Studies Board, Division of Engineering and Physical Sciences (National Academies Press (2002) has produced a report that confirms the existence of non-thermal bioeffects from information transmitted by radiofrequency radiation at low intensities that cannot act by tissue heating (prepublication copy, page 2-13).

In this report, the section on Directed-Energy Non-Lethal Weapons it states that:

"The first radiofrequency non-lethal weapons, VMADS, is based on a biophysical susceptibility known empirically for decades. More in-depth health effects studies were launched only after the decision was made to develop that capability as a weapon. The heating action of RF signals is well understood and can be the basis for several additional directed-energy weapons. Leap-ahead non-lethal weapons technologies will probably be based on more subtle human/RF interactions in which the signal information within the RF exposure causes an effect other than simply heating: for example, stun, seizure, startle and decreased spontaneous activity. Recent developments in the technology are leading to ultrawideband, very high peak power and ultrashort signal capabilities, suggesting the the phase space to be explored for subtle, uyet potentially effective non-thermal biophysical susceptibilities is vast. Advances will require a dedicated effort to identify useful susceptibilities."

Page 2-13 of the prepublication report (emphasis added)

This admission by the Naval Studies Board confirms several critical issues with respect to non-thermal or low-intensity RF exposures. First, it confirms the existence of bioeffects from non-thermal exposure levels of RF. Second, it identifies that some of these non-thermal effects can be weaponized with bioeffects that are incontrovertibly adverse to health (stun, seizure, startle, decreased spontaneous activity). Third, it confirms that there has been knowledge for decades about the susceptibility of human beings to non-thermal levels of RF exposure. Fourth, it provides confirmation of the concept that radiofrequency interacts with humans based on the RF information content (signal information) rather than heating, so it can occur at subtle energy levels, not at high levels associated with tissue heating. Finally, the report indicates that a dedicated scientific research effort is needed to really understand and refine non-thermal RF as a weapon, but it is promising enough for continued federal funding.

XXI. The IEEE (United States)

IEEE ICES SCC-28 SC-4 Subcommittee (Radiofrequency/Microwave Radiation)

Members of the ICES SCC-28 SC-4 committee presented their views and justifications in a Supplement to the Bioelectromagnetics Journal (2003). It offers a window into the thinking that continues to support thermal-only risks, and on which the current United States IEEE recommendations have been made. The United States Federal Communications Commission (FCC) has historically based its federally-mandated public and occupational exposure standards on the recommendations of the IEEE.

Radiofrequency/Microwave Radiation

IEEE's original biological benchmark for setting human exposure standards (on which most contemporary human standards are based) is disruption of food-motivated learned behavior in subject animals. For RF, it was based on short, high intensity RF exposures that were sufficient to result in changes in animal behavior.

> *"The biological endpoint on which most contemporary standards are based is disruption of food- motivated learned behavior in subject animals. The threshold SAR for behavioral disruption has been found to reliably occur between 3 and 9 W/kg across a number of animal species and frequencies; a whole-body average SAR of 4 W/kg is considered the threshold below which adverse effects would not be expected. To ensure a margin of safety, the threshold SAR is reduced by a safety factor of 10 and 50 to yield basic restrictions of 0.4 W/kg and 0.08 W/kg for exposures in controlled (occupational) and uncontrolled (public) environments, respectively." (Osepchuk and Petersen, 2003).*

The development of public exposure standards for RF is thus based on acute, but not chronic exposures, fails to take into account intermittent exposures, fails to consider special impacts of pulsed RF and ELF-modulated RF, and fails to take into account bioeffects from long-term, low-intensity exposures that may lead to adverse health impacts over time.

XXII. BEMS Supplement 6 (Journal of the Bioelectromagnetics Society)

BEMS Supplement 6 was prepared in support of the IEEE SC-4 committee RF recommendations. In explaining and defending revised recommendations on RF limits contained within C.95.1, some key members took out space in Bioelectromagnetics (the Journal of the Bioelectromagnetic Society) to present papers ostensibly justifying a relaxation of the existing IEEE RF standards, rather than making the standards more conservative to reflect the emerging scientific evidence for both bioeffects and adverse health impacts.

Several clues are contained in the BEMS Supplement 6 to understand how the SC-4 IEEE C.95 revision working group and the ICES could arrive at a decision to not to recommend tighter limits on RF exposure. Not one but two definitions of "adverse effect" are described, one by Osepchuk/Petersen (2003) and another by the working group itself (D'Andrea et al, 2003). Both set a very high bar for demonstration of proof, and both are ignored in the final recommendations by the SC-4 Subcommittee.

Second, many of the findings presented in the papers by individual authors in the BEMS Supplement 6 do report that RF exposures are linked to bioeffects and to adverse effects; but these findings are evidently ignored or dismissed by the SC-4 Subcommittee, ICES and by the eventual adoption of these recommendations by the full IEEE membership (in 2006). Even with a very high bar of evidence set by the SC-4 Subcommittee (and two somewhat conflicting definitions of adverse effect against which all scientific papers were reviewed and analyzed); there is clear sign that the "deal was done' regardless of even some of the key Subcommittee member findings reporting such effects at exposure levels below the existing limits.* sidebar

The SC-4 Subcommittee has developed a new and highly limited definition on RF effects, adverse effects and hazards that is counter to the WHO Constitution Principle on Health. The definition as presented by D'Andrea et al (2003, page S138) is based on the SC-4 IEEE C.95 revision working group definition of adverse effect:

"An adverse effect is a biological effect characterized by a harmful change in health. For example, such changes can include organic disease, impaired mental function, behavioral disfunction, reduced longevity, and defective or deficient reproduction. Adverse effects do not include: biological effects without detrimental health effect, changes in subjective feelings of well-being that are a result of anxiety about RF effects or impacts of RF infrastructure that are not related to RF emissions, or indirect effects caused by electromagnetic interference with electronic devices. An adverse effects exposure level is the condition or set of conditions under which an electric, magnetic or electromagnetic field has an adverse effect."

Further, the working group extended its definition to include that of Michaelson and Lin (1987) which states:

"If an effect is of such an intense nature that it compromises the individual's ability to function properly or overcomes the recovery capability of the individual, then the 'effect' may be considered a hazard. In any discussion of the potential for 'biological effects' from exposure to electromagnetic energies we must first determine whether any 'effect' can be shown; and then determine whether such an observed 'effect' is hazardous."

The definition of adverse effect according to Osepchuk and Petersen (2003) reported in the same BEMS Supplement 6 is:

"An adverse biological response is considered any biochemical change, functional impairment, or pathological lesion that could impair performance and reduce the ability of an organism to respond to additional challenge. Adverse biological responses should be distinguished from biological responses in general, which could be adaptive or compensatory, harmful, or beneficial. "

In contrast, the World Health Organization draft framework has accepted definitions of bioeffect, adverse health effect and hazard (WHO EMF Program Framework for Developing EMF Standards, Draft, October 2003). These definitions are not subject to the whim of organizations preparing public exposure standard recommendations. The WHO definition states that:

"(A)nnoyance or discomforts caused by EMF exposure may not be pathological per se, but, if substantiated, can affect the physical and mental well-being of a person and the resultant effect may be considered as an adverse health effect. A health effect is thus defined as a biological effect that is detrimental to health or well-being. According to the WHO Constitution, health is a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity."

The SC-4 definitions require proof that RF has caused organic disease or other cited

effects that qualify. The burden of proof is ultimately shifted to the public, that bears the burden of unacknowledged health effects and diseases, where the only remedy is proof of illness over a large population of affected individuals, over a significant amount of time, and finally, delays until revisions of the standards can be implemented. The results of studies and reviews in the BEMS Supplement 6 already acknowledge the existence of bioeffects and adverse effects that occur at non-thermal exposure levels (below current FCC and ICNIRP standards that are supposedly protective of public health. However, they go on to ignore their own findings, and posit in advance that adverse effects seen today will, even with chronic exposure, not conclusively reveal disease or dysfunction tomorrow at exposure levels below the existing standards.

Sidebar: Quotes from BEMS Supplement 6

a) Studies and reviews where bioeffects likely to lead to adverse health effects with chronic exposure are reported;
b) adverse effects which are already documented;
c) studies where non-thermal RF effects are reported and unexplained;
d) effects are occurring below current exposure limits, and
e) conclusions by authors they cannot draw conclusions about hazards to human health

These quotes appear in articles presented by the IEEE SC-4 Subcommittee in BEMS Supplement 6. Despite these acknowledged gaps in information, lack of consistency in studies, abundant conflicting evidence documenting low level RF effects that can resulting serious adverse health impacts (DNA damage, cognitive impairment, neurological deficits, cancer, etc), and other clear instances of denial of ability to predict human health outcomes, the IEEE SC-4 Subcommittee has proposed recommendations to relax the existing limits.

XXIII. Proceedings of the NATO Advanced Research Workshop – Mechanisms of the Biological Effect on Extra High Power Pulses (EHPP) and UNESCO/WHO/IUPAB Seminar "Molecular and Cellular Mechanisms of Biological Effects of EMF" held March 2005, Yerevan, Armenia.

The proceedings conclude that "*the authors agreed with one main conclusion from these meeting(s): that in the future worldwide harmonization of standards have to be based on biological responses, rather than computed values*". The authors included 47 scientists, engineers, physicians and policy makers from 21 countries from Europe, North and South America, and Asia.

> *"The ICNIRP Guidelines for radiofrequency electromagnetic exposure are based only on thermal effects, and completely neglects the possibility of non-thermal effect."*
>
> *"The guidelines of the International Commission on Non-Ionizing Radiation Protection (ICNIRP) specify the quantative characteristics of EMF used to specify the basic restrictions are current density, specific absorption rate (SAR) and power density, i.e., the energetic characteristics of EMF. However, experimental data on energy-dependency of biological effects by EMF have shown that the SAR approach, very often, neither adequately describes or explains the real value of EMF-induced biological effects on cells and organisms, for at least two reasons: a) the non-linear character of EMF-induced bioeffects due to the existence of amplitude, frequency and 'exposure time-windows' and b) EMF-induced bioeffects significantly depend on physical and chemical composition of the surrounding medium."* (Preface pages XI – XIII).

TABLE OF CONTENTS

I. INTRODUCTION

Daily exposure to electromagnetic fields (EMF), including extremely low frequency magnetic fields (ELF MF) and radiofrequency (RF) EMF, in the environment has raised public concerns about whether they have harmful consequences on human health. Several epidemiological studies suggest that exposure to EMF might associate with an elevated risk of cancer and other diseases in humans (reviewed in [Feychting et al., 2005]). To explain and/or support epidemiological observations, many laboratory studies have been conducted, but the results were controversial and no clear conclusion could be drawn to assess EMF health risk.

It is reasoned that one of the priorities in EMF research is to elucidate the biological effects of EMF exposure and the underlining mechanisms of action. Gene and protein are key players in organisms, and it has been assumed that any biological impact of EMF must be mediated by alterations in gene and protein expression [Phillips et al., 1992; Wei et al., 1990]. For example, heat shock protein, c-myc, and c-jun have been identified as EMF responsive genes and/or proteins in certain biological systems. In order to reveal the global effects of EMF on gene and protein expression, transcriptomics and proteomics, as high-throughput screening techniques (HTSTs), were eventually employed in EMF research with an intention to screen potential EMF-responsive genes and/or proteins without any bias. In 2005, WHO organized a Workshop on Application of Proteomics and Transcriptomics in EMF Research in Helsinki, Finland to discuss the related problems and solutions in this field [Leszczynski 2006; Leszczynski and Meltz 2006]. Later the journal Proteomics published a special issue devoted to the application of proteomics and transcriptomics to EMF research. This review aims to summarize the current research progress and discuss the applicability of HTSTs in the field.

II. ELF MF

II A. TRANSCRIPTOMICS

Binninger and Ungvichian firstly measured purified mRNA levels of total RNA from MF- and sham-exposed yeast cells and reported that the levels of a significant proportion of mRNAs were altered in response to continuous exposure to 20 □T 60 Hz MF over a period of approximately 15 cell generations (24 h) [Binninger and Ungvichian 1997]. Unfortunately, no reproducible genes (polypetides) were identified in this study although the authors consistently found different proportions of transcripts whose abundances were altered in all four replication experiments.

Wu *et al*. have applied differential display reverse transcriptase–polymerase chain reaction (DD-RT-PCR) and Northern blotting to screen MF-responsive gene in Daudi cells. The cells were exposed to 0.8 mT of 50 Hz MF for 24 h. The authors screened out two candidate genes in Daudi cells and one was identified as a MF-responsive gene *ceramide glucosyltransferase*. They further found time-dependent changes in the transcription of *ceramide glucosyltransferase* induced by 0.8 mT MF [Wu et al., 2000]. With the help of DD-RT-PCR, Olivares-Banuelos *et al* reported that exposure to 0.7 mT 60 Hz MF for 7 days，4 h a day (2 h in the morning and 2 h in the afternoon), changed the global transcription profile of chromaffin cells. Eight RT-PCR products which correspond to six genes were identified, including *phosphoglucomutase*-1, *neurofibromatosis-2 interacting protein*, *microtubule associated protein*-2, *thiamine pyrophosphokinase*, and two hypothetical proteins (RNOR02022103 and ROR01044577). In addition, the authors found that presumed regulatory regions of these genes contained CTCT-clusters [Olivares-Banuelos et al., 2004], which has been identified as an electromagnetic field-responsive DNA element regulating gene expression [Goodman and Blank 2002].

Balcer-Kubiczek *et al*. have applied the two-gel cDNA library screening method (BIGEL) to screen MF-responsive genes, in which the gel arrays contained a total of

960 cDNAs selected at random from the cDNA library. The HL 60 cells were exposed to 2 mT of 60 Hz square wave MF for 24 h. Four candidate genes were shown responsive to the MF exposure, but could not be confirmed by following Northern analysis. Furthermore, the authors found that these four candidates and another four selected genes (*MYC*, *HSP70*, *RAN* and *SOD1*) did not react to either square wave or sine wave 60 Hz MF at 2 mT for 24 h [Balcer-Kubiczek et al., 2000]. However, the cellular responses to square wave and sine wave 60 Hz MF might be different. In order to systematically evaluate the effect of 60 Hz MF on gene expression in HL 60 cells, it is necessary for the authors to screen 60 Hz sine wave MF responsive candidate genes in HL 60 cells with BIGEL method as well, and then, perform validation with Northern blotting for these candidates.

Using cDNA arrays containing 588 cancer-related genes, Loberg *et al*. analyzed gene expression in normal (HME) and transformed (HBL-100) human mammary epithelial cells and human promyelocytic leukemia (HL60) cells after exposure to 60 Hz MF at intensity of 0.01 or 1.0 mT for 24 h. The authors reported that several genes were identified in MF-exposed cells whose expressions were increased by at least two folds or decreased by 50% or more, but no gene was found to be differentially expressed in each of three independent exposures for any cell type, and no relationship between exposure intensity and differential gene expression was found [Loberg et al., 2000].

In order to obtain a more global evaluation, genome-wide microarray screening methods were applied to identify genes responding to ELF MF in certain types of cells. By application of cDNA microarray, Nakasono *et al*. have investigated the effect of 50 Hz MF below 300 mT on gene expression in yeast. The authors reported that several genes were found differentially expressed in yeast cells with medium to low confidence level (CL) after exposure to 10, 150 and 300 mT for 24 h. Among these genes, seven showed a dose-response relationship in the normalized ratio data and three genes showed a reproducible change for all three intensities. They also proposed that these genes should be re-examined by methods with greater sensitivity or by quantitative

methods, such as real-time PCR. On the other hand, no high-confidence expression changes were observed for genes that are involved in heat-shock response, DNA repair, respiration, protein synthesis, or cell cycle. Thus, they concluded that 50 Hz MF up to 300 mT did not appear to affect gene expression linked to either defined cell processes stated above or unknown cell responses in investigated model eukaryotic cells [Nakasono et al., 2003]. Unfortunately, only single experiment for array analysis was performed in this study.

Recently, a similar study was conducted by Luceri *et al*. to investigate the global gene response to 50 Hz MF in human lymphocytes and yeast cells. These two types of cells were exposed to MF at intensity of 100 □T, 10 □T and 1 □T for 18 h. As a result, in lymphocytes, one gene was found down-regulated at 100 □T, one down-regulated gene and two up-regulated genes were screened out at 10 □T, and no gene was detected changed at 1 □T. As to the yeast cells, the results showed 2, 15 and 2 genes as differentially expressed (mainly down-regulated) after exposure to 100, 10 and 1 □T, respectively, in which SPS100 gene was consistently up-regulated after exposure to 50 Hz MF at all three intensities. But no genes were found differentially expressed when the authors analyzed the data by other statistical methods. Thus, the authors concluded that 50 Hz MF did not affect gene expression in these two types of cells and the variations of a few genes mentioned above could be due to experimental noise [Luceri et al., 2005]. However, it is necessary to examine the candidates, especially the SPS100 gene, to validate whether they were real “un-responsive” genes.

In Henderson’s report, human umbilical vein endothelial cells (HUVEC) were exposed to various patterns and intensities of 50 Hz MF, including continuous exposure at a two intensities (10 and 700 □T), intermittent exposure (60 min on/ 30 min off) at a single intensity (700 □T), and continuous exposure to a variable-intensity fields (10-30 □T). The transcriptional response of the cells was investigated using oligonucleotide microarrays containing up to 30, 000 unique features. Although different genes were

identified where their expressions appeared to be affected by exposure to MF in individual experiments, none of these genes were regulated in the same manner in subsequent repetition experiments [Henderson et al., 2006].

Antonini *et al* reported that intermittent exposure (5 min on/5 min off) to 50 Hz MF at flux densities of 2 mT for 16 h could change gene expression in human neuroblastoma cell line SH-SY5Y by application of whole-genome Human Unigene RZPD-2 cDNA array which contains about 75, 000 cDNA clones. Several genes were found down- or up-regulated at least five-fold after ELF MF exposure and the authors concluded that SH-SY5Y cells were sensitive to ELF MF [Antonini et al., 2006]. However, no reports indicated that these differentially expressed genes were confirmed by other methods.

Lupke *et al* investigated the effect of ELF MF on gene expression profiling in human umbilical cord blood-derived monocytes using the same Unigene RZPD-2. The results indicated that 0.1 mT 50 Hz MF exposure for 45 minutes altered the expressions of 986 genes involved in metabolism, cellular physiological processes, signal transduction, and immune response, among them, five genes were significantly regulated. Furthermore, the authors analyzed several genes by real-time RT-PCR and one ELF MF candidate responsive gene IL15RA was confirmed. However, this study only did single array analysis for pooling sample from 78 donors and two independent real-time RT-PCR analyses for samples from 5 and 6 different donors. The authors did not report the examinations of other candidates with real-time RT-PCR analysis [Lupke et al., 2006].

II B. PROTEOMICS

Nakasono *et al*. has investigated the effects of protein expression in model system such as *Escherichia coli* and *Saccharomyces cerevisiae* using two dimensional gels electrophoresis (2-DE) method. When the bacterial cells were exposed to each MF at 5-100 Hz under aerobic conditions (6.5 h) or at 50 Hz under anaerobic conditions (16 h) at the maximum intensity (7.8 to 14 mT), no reproducible changes were observed in the 2D gels. However, the stress-sensitive proteins did respond to most stress factors, including temperature change, chemical compounds, heavy metals, and nutrients. The authors concluded that the high-intensity ELF MF (14 mT at power frequency) did not act as a general stress factor [Nakasono and Saiki 2000]. When using *Saccharomyces cerevisiae* as a model system, Nakasono *et al*. reported that no reproducible changes in the 2D gels were observed in yeast cells after exposure to 50 Hz MF at the intensity up to 300 mT for 24 h [Nakasono et al., 2003]. In this study, only three sets of gels from three independent experiments were analyzed.

Li *et al*. have performed a proteomics approach to investigate the changes of protein expression profile induced by ELF MF in human breast cancer cell line MCF-7. With help of 2-DE and data analysis on nine gels for each group, 44 differentially expressed protein spots were screened in MCF-7 cells after exposure to 0.4 mT 50 Hz MF for 24 h. Three proteins were identified by LC-IT Tandem MS as RNA binding protein regulatory subunit, proteasome subunit beta type 7 precursor, and translationally controlled tumor protein, respectively [Li et al 2005]. Further investigations, such as Western blotting, are required to confirm these ELF responsive candidate proteins.

Using 2-D Fluorescence Difference Gel Electrophoresis (2-D DIGE) technology and MS in a blind study, Sinclair *et al* have investigated the effects of ELF MF on the proteomes of wild type *Schizosaccharomyces pombe* and a Sty1p deletion mutant which displays increased sensitivity to a variety of cellular stresses. The yeast cells were exposed to 50 Hz EMF at field strength of 1 mT for 60 min. While this study

identified a number of protein isoforms that displayed significant differential expressions across experimental conditions, there was no correlation between their patterns of expression and the ELF MF exposure regimen. The authors concluded that there were no significant effects of ELF MF on the yeast proteome at the sensitivity afforded by 2D-DIGE. They hypothesized that the proteins identified in the experiments must be sensitive to subtle changes in culture and/or handling conditions. Based on their experience, they suggested to the community that the interpretation of proteomic data in a biological context should be treated with caution [Sinclair et al., 2006].

II C. SUMMARY

Generally, recent studies on global gene and protein expression responding to ELF MF have been conducted in different biological systems by applications of HTSTs. Only a few studies reported to identify ELF MF responsive genes successfully. For example Wu *et al*. identified *ceramide glucosyltransferase* as a MF-responsive gene in Daudi cells [Wu et al., 2000] and Olivares-Banuelos *et al.* identified six ELF MF genes in chromaffin cells [Olivares-Banuelos et al., 2004] with the help of DD-RT-PCR and Northern blotting analysis; by combining cDNA array analysis with real-time RT-PCR confimation, Lupke *et al*. identified IL15RA as ELF MF responsive genes in human monocytes [Lupke et al., 2006]. Although many transcriptome and proteome analysis showed that ELF MF exposure could change gene and/or protein expression in certain cell types [Antonini et al., 2006; Binninger and Ungvichian 1997; Li et al., 2005], there are lack of confirmation to determine if they are real ELF MF responsive genes or proteins. Therefore, it is a priority to conduct confirmation experiments to demonstrate the author's findings.

As to those negative reports, few or no genes and proteins were found significantly changed according to their statistical analysis and screening standards. But these few

genes and proteins were neither reproducible [Henderson et al., 2006; Nakasono et al., 2003; Sinclair et al., 2006]nor confirmed by other methods [Balcer-Kubiczek et al., 2000], and the changes were not related to ELF MF exposure [Loberg et al., 2000; Luceri et al., 2005; Nakasono et al., 2003]. Therefore, these studies are also needed to be replicated or verified.

III. RF EMF

III A . TRANSCRIPTOMICS

In an initial study utilizing membrane-based cDNA microarray, Harvey and French studied the effects of 864.3 MHz (CW) on HMC-1 human monocytes. The exposure was carefully controlled and averaged at an SAR of 7 W/kg, almost double the exposure level of established adverse effects. Three 20 min exposures were performed at 4-h intervals daily for 7 days. cDNA microarray analyses revealed consistent alterations in steady-state mRNA levels of 3 of the 558 genes represented on the membranes including one proto-oncogene *c-kit* (increased), one apoptosis-associated gene *DAD-1* (decreased) and one potential tumor suppressor gene *NDPK* (decreased) [Harvey and French 1999]. However, there were considerable variabilities between the two experiments reported and the fold change of each differentially expressed gene was small (< 1.5 folds). Meanwhile, the authors did not use other methods to confirm the results.

Pacini *et al*. investigated the effect of gene expression in human skin fibroblasts by using cDNA arrays including 82 genes, and reported that exposure to GSM 902.4 MHz RF EMF at an average SAR of 0.6 W/kg for 1 h increased the expression of 14 genes which function in mitogenic signal transduction, cell growth and apoptosis controlling. The authors further demonstrated a significant increase in DNA synthesis and intracellular mitogenic second messenger formation which were matched the high expression of MAP kinase family genes [Pacini et al., 2002]. The authors suggested that the RF EMF exposure has significant biological effects on human skin fibroblasts.

However, only one experiment was performed in array analysis and no more experiment was made by the authors to confirm the array analysis result.

With help of cDNA microarray, Leszczynski *et al*. reported that exposure to GSM 900 MHz RF EMF at an average SAR of 2.4 W/kg for 1 h changed expression of 3600 genes, including down-regulated genes involved in forming the Fas/TNFa apoptotic pathway in human endothelial cell line EA.hy926 [Leszczynski et al., 2004]. The authors performed three separate experiments in array analysis, but no confirmation experiments were conducted to validate the array analysis result. Recently, Leszczynski group compared the global gene response of two human endothelial cells, EA.hy926 and its variant EA.hy926v1 to RF EMF and reported that the same genes were differently affected by the exposure to GSM 900 MHz RF EMF at an average SAR of 2.8 W/kg for 1 h in each of the cell lines [Nylund and Leszczynski 2006]. Similarly, no reports indicated that the differentially expressed genes in this study were confirmed by other methods.

Lee *et al*. used the serial analysis of gene expression (SAGE) method to measure the RF EMF effect on genome scale gene expression in HL 60 cells. The cells were exposed to 2.45 GHz RF EMF at an average SAR of 10 W/kg for 2 h and 6 h. The authors observed that 221 genes and 759 genes altered their expression after 2 h exposure and 6 h exposure respectively. Functional classification of the affected genes revealed that apoptosis-related genes were among the up-regulated ones and the cell cycle genes among the down-regulated ones, but no significant increase in the expression of heat shock genes were found [Lee et al., 2005]. However, the SAGE experiment was repeated only once and only one control with 2 h sham exposure was used. No confirmation experiment was reported to validate these differentially expressed genes.

Huang *et al*. investigated the effect of 1763 MHz RF EMF on gene expression in Jurkat cells by Applied Biosystems 1700 full genome expression microarray. The authors

found that 68 genes were differentially expressed in the cells after exposure to RF EMF at SAR of 10 W/kg for 1 h and harvested immediately or after 5 h [Huang et al., 2006]. The authors repeated sets of experiment five times to collect biological triplicates in every sample but the differentially expressed genes were not confirmed by other methods.

Whitehead *et al.* have performed *in vitro* experiments with C3H 10T(1/2) mouse cells to determine whether Frequency Division Multiple Access (FDMA) or Code Division Multiple Access (CDMA) modulated RF radiations can induce changes in gene expression using the Affymetrix U74Av2 GeneChip. The GenesChip data showed the number of probe sets with an expression change greater than 1.3-fold was less than or equal to the expected number of false positives in C3H 10T(1/2) mouse cells after 835.62 MHz FDMA or 847.74 MHz CDMA modulated RF EMF exposure at SAR of 5 W/kg for 24 h. The authors concluded that the 24 h exposures to FDMA or CDMA RF radiation at 5 W/kg had no statistically significant effect on gene expression [Whitehead et al., 2006a; Whitehead et al., 2006b]. However, the authors did not demonstrate that these differentially expressed genes were real "false positive" with other methods.

In Gurisik's report, human neuroblastoma cells (SK-N-SH) were exposed to GSM 900 MHz RF signal at SAR of 0.2 W/kg for 2 h and recovered without field for 2 h post-exposure. Gene expression were examined by Affymetrix Human Focus Gene Arrays including 8400 genes and followed by real-time RT-PCR of the genes of interest. Only six genes were found to be slightly down-regulated in response to RF exposure comparing with mock-exposed cells. Furthermore, these genes can not be confirmed by real-time RT-PCR analysis. Thus, the authors concluded that the RF EMF exposure applied in this study could not change gene expression in SK-N-SH cells [Gurisik et al., 2006]. However, the array analysis experiment was repeated only once and only one array for exposure or sham exposure group.

Qutob *et al* have assessed the ability of exposure to a 1.9 GHz pulse-modulated RF field to affect global gene expression in U87MG glioblastoma cells by application of Agilent Human 1A (v1) oligonucleotide 22K microarray slides. The U87MG cells were exposed to 1.9 GHz pulse-modulated (50 Hz, 1/3 duty cycle) RF field at an average SAR of 0.1, 1.0 and 10.0 W/kg for 4 hours, and incubated for an additional 6 hours. The authors found no evidence that exposure to RF fields under different exposure conditions can affect gene expression in cultured U87MG cells. In this paper, the authors performed five experiments, each containing a single replicate and some of genes were confirmed as real "un-effected genes" [Qutob et al., 2006].

Zeng *et al*. have investigated gene expression profile in MCF-7 after exposing to GSM 1800 MHz RF EMF using Affymetrix Genechip U133A. The result showed that no gene with 100% consistency change were found in MCF-7 cells after intermittent exposure (5 min on/ 10 min off) to RF EMF at an average SAR of 2.0 W/kg for 24 h while five genes with 100% consistency change were found in MCF-7 at same exposure conditions but at SAR of 3.5 W/kg. However, these five differentially transcribed genes could not be further confirmed by real-time RT-PCR assay. Thus, this study did not provide evidence that RF EMF exposure can produce distinct effects on gene expression in the MCF-7 cells [Zeng et al., 2006].

Remondini *et al*. have investigated the effect of RF EMF on gene expression profile in six different cell lines or primary cells, and found various types of cell reacted differently in RF EMF exposure). RF EMF exposure changed gene expression in 900 MHz-exposed EA.hy926 endothelial cells (22 up-regulations, ten down-regulations), 900 MHz-exposed U937 lymphoblastoma cells (32 up-regulations, two down-regulations), and 1800 MHz-exposed HL-60 leukemia cells (11 up-regulations, one down-regulation) while NB69 neuroblastoma cells, T-lymphocytes, and CHME5 microglial cells did not show significant changes in gene expression. The authors concluded that there were alterations in gene expression in some human cells types

exposed to RF-EMF but these chenges depended on the type of cells and RF-EMF signal [Remondini et al., 2006]. However, these RF responsive candidate genes in different types of cells were not confirmed yet.

Very recently, Zhao *et al*. have investigated the effects of RF EMF on gene expression of *in vitro* cultured rat neuron with Affymetrix Rat Neurobiology U34 array. Among 1200 candidate genes, 24 up-regulted genes and 10 down-regulated genes were identified after 24-h intermittent exposure (5 min on/ 10 min off) at an average SAR of 2.0 W/kg, which are associated with multiple cellular functions. The changes of most of genes were successfully validated by real-time RT-PCR, including genes involved in cytoskeleton, signal transduction pathway, metabolism [Zhao et al., 2007].

Belyaev et al. analyzed gene expression profile in RF exposed animals. Rats were exposed or sham exposed to GSM 915 MHz at whole body average SAR of 0.4 mW/g for 2 h and total RNA was extracted from cerebellum. Gene expression profiles were obtained by Affymetrix U34 GeneChips representing 8800 rat genes and analyzed with the Affymetrix Microarray Suite (MAS) 5.0 software. The results showed that 11 genes were up-regulated in a range of 1.34-2.74 folds and one gene was down-regulated 0.48-fold. The induced genes encode proteins with diverse functions including neurotransmitter regulation, blood-brain barrier (BBB), and melatonin production [Belyaev et al., 2006]. In this study, triplicate arrays were applied for three exposed samples or three sham exposed samples. But the differentially expressed genes were not confirmed by other methods.

III B . PROTEOMICS

Leszczynski *et al*. have provided perhaps some of the most relevant *in vitro* data by studying the effects of GSM 900 MHz RF EMF exposure [Leszczynski et al., 2002; Nylund and Leszczynski 2004; Nylund and Leszczynski 2006]. Firstly, the EA.hy926 cells were exposed to RF EMF at SAR of 2.0 W/kg over a one-hour period and the data

indicated the RF exposure changed protein expression at a proteome scale, and up-regulated the level of HSP 27 protein and induced its hyper-phosphorylation. The activation of p38 mitogen activated kinase (MAPK) was partially responsible for the phosphorylation of the HSP. They confirmed HSP27 protein expression, phosphorylation and cellular distribution by independent protein analytical techniques including western blotting and indirect immunofluorescence [Leszczynski et al., 2002]. Secondly, the group screened 38 proteins with statistically significantly altered expression in the same cell line after GSM 900 MHz exposure at SAR of 2.4 W/kg for 1 h. An isoform of vimentin was confirmed as a responsive protein by Western blotting and indirect immunofluorescence. The authors concluded that the cytoskeleton might be one of the mobile phone radiation-responding cytoplasmic structures [Nylund and Leszczynski 2004]. Furthermore, they compared *in vitro* response to GSM 900 MHz RF EMF in EA.hy926 with its variant EA.hy926v1 by examination of protein expression using 2-DE. The results showed protein expression profiles were altered in both examined cell lines after RF EMF exposure. However, the affected proteins were differently in each of the cell lines, 38 and 45 differentially expressed proteins were found in EA.hy926 and EA.hy926v1 respectively. Several differentially expressed proteins in EA.hy926 cells were confirmed by other methods, but no differentially expressed protein in EA.hy926v1 cells was confirmed. Base on the transcriptome and proteome analysis data, the authors concluded that the response might be genome- and proteome-dependent [Nylund and Leszczynski 2006]. One thing should be mentioned that all the 2-DE analyses in Leszczynski group reports were replicated ten times.

Zeng *et al*. systematically explored the effects of 1800 MHz RF EMF on protein expression in MCF-7 cells by 2-DE, and revealed that a few but different proteins were differentially expressed under continuous or intermittent RF EMF exposure at SAR of 3.5 W/kg for 24 h or less, implying that the observed effects might have occurred by chance. By combination with the transcriptomics analysis data, this study did not provide convincing evidence that RF EMF exposure could produce distinct effects on gene and protein expression in the MCF-7 cells. The authors supposed that the MCF-7

cells may be less sensitive to RF EMF exposure [Zeng et al., 2006]. However, in this study, only triplicate gels were performed in each exposure condition experiment.

III C . SUMMARY

The effects of RF EMF on global gene and protein expression have been investigated in different biological systems, and most of studies were focused on the mobile phone utilization frequency (800-2000 MHz) at relative low exposure density (average SAR near 2.0 W/kg). Some studies reported negative results of RF EMF exposure on gene expression. For example, Whitehead *et al*. did not find differentially expressed genes in RF exposed C3H 10T(1/2) mouse cells [Whitehead et al., 2006a; Whitehead et al., 2006b]. Remondini *et al*. reported that NB69 cells, T lymphocytes, and CHME5 cells did not show significant changes in gene expression after RF EMF exposure [Remondini et al., 2006]. In Gurisik *et al.* [Gurisik et al., 2006]and Zeng *et al.* [Zeng et al., 2006]study, although they screened out several RF EMF-responsive candidate genes, they could not confirm these genes by real-time RT-PCR method.

Meanwhile, several groups claimed that RF EMF exposure can change gene and protein expression profile in certain types of cells and identified certain EMF responsive genes and proteins. Only one report found RF EMF exposure changed gene expression profile in neurons and most of changed genes were confirmed by real-time RT-PCR [Zhao et al 2007]. As to proteome analysis, only two groups have analyzed protein expression by proteomic approaches, including 2-DE and Mass Spectrum. Zeng *et al*. systematically explored the effects of 1800 MHz RF EMF on protein expression in MCF-7 cells by 2-DE, and revealed that a few but different proteins were differentially expressed under different exposure conditions, implying that the observed effects might have occurred by chance [Zeng et al., 2006]. However, in this study, only triplicate gels were performed in each exposure condition experiment. In contrast, Leszczynski group identified two RF EMF responsive proteins in EA.hy926 cells, i.e. HSP27 [Leszczynski et al., 2002] and vimentin [Leszczynski et al., 2004] with help of 2-DE and MS analysis. This group further confirmed the expression and

cellular distribution of HSP27 and vimentin in RF exposed EA.hey926 cells by other methods including Western blotting and indirect immunofluorescence staining. Furthermore, they reported the changes of these RF EMF molecular targets had down-stream impact on cell physiology [Leszczynski et al., 2002; Leszczynski et al., 2004].

Generally, it seems that the response of a cell to RF EMF exposure depends on exposure condition, cell type, and/or the cell's genome- and proteome [[Remondini et al., 2006; Nylund and Leszczynski 2006].

IV. Overall Conclusion

Based on current available literature, it is justified to conclude that EMF exposure can change gene and/or protein expression in certain types of cells, even at intensities lower than ICNIRP recommended values. However, the biological consequences of most of the changed genes/proteins are still unclear, and need to be further explored. Thus, it is not the time point yet to assess the health impact of EMF based on the gene and protein expression data. The IEEE and WHO data bases do not include the majority of ELF studies; they do include the majority of the RF studies.

Currently, controversial data exist in the literature. The EMF research community should pay equal attention to the negative reports as to the positive ones. Not only the positive findings need to be replicated, all the negative ones are also needed to be validated.

It is noteworthy that low intensity EMF is a weak physical stimulus for a cell or organism, and high throughput screening techniques (HTSTs) would sacrifice its sensitivity to ensure its high throughput. It has been recognized there is methodological defects while analyzing weak effect with HTSTs, such as reproducibility and variability.

Thus, more experimental replications are needed to reduce the ratio of noise over signal. Meanwhile, confirmation study must be included to assure the validity of the data.

I. INTRODUCTION

Daily exposure levels for non-ionizing electromagnetic radiation (NI-EMR) have significantly increased in the last few decades for human populations, and for wildlife, plants, and other living creatures on earth. NI-EMR includes a wide range of frequencies, as low as extremely low frequencies (ELF) magnetic fields deriving from the power lines up to microwave radiofrequencies (MW-RF). Within this range are FM and TV broadcast stations, wireless technology devices (mobile phones and masts, cordless phones, Wi-Fi routers and units).

The exposure to any of these frequencies individually, or in combination, raises concern about potentially harmful effects and is the subject of intensive scientific studies around the world. Such studies include epidemiological, clinical, *in vivo* and*in vitro* studies. The pace of scientific study accelerated after 2010, when the World Health Organization following the ELF agenda of 2007 (WHO, 2007), announced the implementation of the International EMF Project's RF Research Agenda as a "*research topic for measurement surveys to characterize population exposures from all radio frequency (RF) sources with a particular emphasis on new wireless technologies*" (WHO, 2010). The IARC (International Agency for Research on Cancer) under the auspices of the WHO classified RFR as a Possible Human Carcinogen (Group 2B) on 2011 (Baan et al., 2011).

The studies published so far have utilized various model systems and approaches but not in a coordinated manner, although there have been international efforts (i.e., INTERPHONE Final Study; Cardis et al., 2011).

As reviewed by Vlaanderen et al. (2009), OMICS technologies are relatively new biomarker discovery tools that can be applied to study large sets of biological molecules. (The English-language neologism omics informally refers to a field of study in biology ending in -*omics*, such as genomics, proteomics or metabolomics). Their applications in EMF and RFR research have become feasible in recent years due to a spectacular increase in the sensitivity, resolution and throughput of OMICS-based assays (Vlaanderen et al., 2009).

.Although, the number of OMIC techniques is ever expanding, the five most developed OMICS technologies are genotyping, transcriptomics, epigenomics, proteomics and metabolomics.

A number of reports have dealt with possible changes on gene/protein expression, either at an individual gene/protein level or using the high throughput "omics" approaches (T & P -transcriptomics and proteomics respectively) (for reviews see Xu & Chen, 2007; Blankenburg et al., 2009; McNamee & Chauhan, 2009; Mevissen M., 2011; Leszczynski et al., 2012). These T & P approaches have gained ground in the investigation of the possible EMF effects the last decade (Blankenburg et al., 2009), since they can screen the whole genome or proteome and may contribute on the elucidation of EMF mechanisms of action.

Following the work of Xu and Chen who gathered all studies on EMF research using T & P high throughput approaches up to 2006 in the BioInitiative Report (Xu & Chen, 2007), this supplemental chapter on Transcriptomics and Proteomics updates newly published work since that initial review in 2007.

II. EXREMELY LOW FREQUENCY ELECTROMAGNETIC FIELDS (ELF-EMFS)

A. Transcriptomics

As explicitly described by M. Mevissen (2011), gene expression profiling is the identification and characterization of the mixture of mRNA that is present in a specific sample. Both the presence of specific forms of mRNA and the levels in which these forms occur are parameters that provide information on gene expression. A gene expression profile provides a quantitative overview of the mRNA transcripts that were present in a sample at the time of collection. Therefore, gene expression profiling can be used to determine which genes are differently expressed as a result of changes in environmental conditions. DNA Microarrays represent an innovative and comprehensive technology that allows researchers to assess the expression level of thousands of genes in a high-throughput fashion and has been exploited in EMF research studies.

Schwenzer et al. (2007) reported effects of static magnetic field on genome expression. Specifically, the researchers evaluated the influence of magnetic resonance imaging (MRI) on gene expression in embryonic human lung fibroblasts (Hel 299). The cells were exposed to the static magnetic field and to a turbo spin-echo sequence of an MR scanner at 3.0 Tesla. An MR group (exposed) and a control group

(sham-exposed) were set up using a special MR-compatible incubation system. The exposure time was two hours. Gene expression profiles were studied using a complementary deoxyribonucleic acid (cDNA) microarray containing 498 known genes involved in transcription, intracellular transport, structure/junction/adhesion or extracellular matrix, signalling, host defence, energetics, metabolism, cell shape, and death. No changes in gene expression were found in either group (exposed or sham-exposed cells) at the end of a two-hour exposure for any of the 498 tested protein genes. The results showed that MRI had no influence on protein–gene expression in eugenic human lung cells in this study.

The same year, Walther et al. (2007) analyzed the effects of BEMER type (combination of electromagnetic field and light therapy) electromagnetic field (BTEMF) on gene expression in human mesenchymal stem cells and chondrocytes. Primary mesenchymal stem cells from bone marrow and the chondrocyte cell line C28I2 were stimulated 5 times at 12-h intervals for 8 min each with BTEMF. RNA from treated and control cells was analyzed for gene expression using the affymetrix chip HG-U133A. A limited number of regulated gene products from both cell types, which control cell metabolism and cell matrix structure, was mainly affected. There was no increased expression though of cancer-related genes. RT-PCR analysis of selected transcripts partly confirmed array data. Results indicate that BTEMF in human mesenchymal stem cells and chondrocytes provide the first indications. A limitation of this study is the single array analysis which was performed. Therefore, as stated by the authors, the results should be regarded as a first hint on BTEMF effects on these cellular systems. Nevertheless, their findings indicate that matrix dynamics and cell metabolism/energy balance are processes that are affected by the electromagnetic field application.

In a follow-up study, using fibroblasts as in the study by Schwenzer et al. (2007), but exposing them to electric fields (EFs), Jennings et al. (2008) tried to elucidate the role of EFs during the course of normal wound healing. Fibroblasts at the wound edge are exposed to electric fields (EFs) ranging from 40 to 200 mV/mm and so various forms of EFs can influence fibroblast migration, proliferation, and protein synthesis and may contribute to fibroblast activation during wound repair. These authors compared gene expression in normal adult dermal fibroblasts exposed to a 100 mV/mm EF for 1 h to non-stimulated controls. Significantly increased expression of 162 transcripts and decreased expression of 302 transcripts was detected using

microarrays, with 126 transcripts above the level of 1.4-fold increase or decrease compared to the controls. Only 11 genes were significantly increased or decreased above the level of 2-fold, compared to controls. Many of these significantly regulated genes were associated with wound repair through the processes of matrix production, cellular signalling, and growth. Activity within specific cellular signalling pathways was noted, including TGF-b, G-proteins, and inhibition of apoptosis. In addition, RT-PCR analysis of the expression of KLF6, FN1, RGS2, and JMJD1C over continued stimulation and at different field strengths suggests that there are specific windows of field characteristics for maximum induction in the expression of these genes. EFs thus appeared to have an important role in controlling fibroblast activity in the process of wound healing. The authors highlight that 2-fold changes have traditionally and somewhat arbitrarily been designated as meaningful changes in gene expression, although there is little quantitative information connecting these values to changes in biological function. Therefore, multiple microarray experiments at different time points and field conditions may have revealed induction of different sets of genes under different experimental conditions. Follow-up studies should include proteomic analysis of altered protein production resulting from altered gene expression, alternative splicing in protein translation, and gene silencing studies to further delineate the mechanisms and locations of interaction between EFs and transcriptional regulators.

Kimura et al. (2008) using magnetic resonance imaging with high intensity static magnetic fields (SMFs) demonstrated in the nematode *Caenorhabditis elegans* that genes involved in motor activity, actin binding, cell adhesion, and cuticles were transiently and specifically induced following exposure to 3 or 5 T SMF in this metazoon experimental model . In addition, transient induction of hsp12 family genes was observed after SMF exposure. The small-heat shock protein gene hsp16 was also induced but to a much lesser extent, and the LacZ-stained population of hsp-16.1::lacZ transgenic worms did not significantly increase after exposure to SMFs with or without a second stressor, mild heat shock. Several genes encoding apoptotic cell-death activators and secreted surface proteins were upregulated after IR, but were not induced by SMFs. Real-time quantitative RT-PCR analyses for 12 of these genes confirmed these expression differences between worms exposed to SMFs and IR. In contrast to IR, exposure to high SMFs did not induce DNA double-strand breaks or germline cell apoptosis during meiosis. These results suggest that the response of *C.*

elegans to high SMFs is unique and capable of adjustment during long exposure, and that this treatment may be less hazardous than other therapeutic tools.

On 2010, Chung et al. conducted a study to investigate the possible effect of 60 Hz circularly polarized magnetic fields (MFs) as promoters of genetically initiated lymphoma in AKR mice. One hundred sixty female animals were divided into four different groups. They were exposed to four different intensities of circularly polarized MFs. Animals received exposure to 60 Hz circularly polarized MF at field strengths (rms-value) of 0 microT (sham control, T1, Group I), 5 microT (T2, Group II), 83.3 microT (T3, Group III), or 500 microT (T4, Group IV), for 21 h/day from the age of 4-6 weeks to the age of 44-46 weeks. There were no exposure-related changes in mean survival time, clinical signs, body weights, hematological values, micronucleus assay, gene expression arrays, analysis of apoptosis, and necropsy findings. Examination at the histopathological level, showed lymphoma in all the groups. The tumor incidence was 31/40(78%), 30/40(75%), 32/40(80%), and 31/40(78%) in sham control, 5, 83.3, and 500 microT groups, respectively. However, there were no differences in the tumor incidence between the sham control (T1) and circularly polarized MF exposure groups (T2-T4). In conclusion, there was no evidence that exposure to 60 Hz circularly polarized MF strengths up to 500 microT promoted lymphoma in AKR mice.

In a very recent attempt to support a causative relationship between environmental exposure to extremely low-frequency electromagnetic fields (EMFs) at power line frequencies and the associated increase in risk of childhood leukemia, Kirschenlohr et al. (2012) tried to determine if gene expression changes occur in white blood cells of volunteers exposed to an ELF-EMF. Each of 17 pairs of male volunteers age 20-30 was subjected either to a 50 Hz EMF exposure of 62.0 ± 7.1 μT (approximately 600 mG) for 2 h or to a sham exposure (0.21 ± 0.05 μT) at the same time (11:00 a.m. to 13:00 p.m.). The alternative regime for each volunteer was repeated on the following day and the two-day sequence was repeated 6 days later, with the exception that a null exposure (0.085 ± 0.01 μT) replaced the sham exposure. Five blood samples (10 ml) were collected at 2 h intervals from 9:00 to 17:00 with five additional samples during the exposure and sham or null exposure periods on each study day. RNA samples were pooled for the same time on each study day for the group of 17 volunteers that were subjected to the ELF-EMF exposure/sham or null exposure sequence and were analyzed on Illumina microarrays. Time courses for 16 mammalian genes previously

reported to be responsive to ELF-EMF exposure, including immediate early genes, stress response, cell proliferation and apoptotic genes were examined in detail. No genes or gene sets showed consistent response profiles to repeated ELF-EMF exposures. A stress response was detected as a transient increase in plasma cortisol at the onset of either exposure or sham exposure on the first study day. The cortisol response diminished progressively on subsequent exposures or sham exposures, and was attributable to mild stress associated with the experimental protocol.

Commenting the above data, we note that the overall experimental design seems to lack real life conditions since a) the suspicion refers to childhood leukaemia and not to adults, b) exposure is not supposed to be just 2 hours a day but day long for children living in the vicinity of power lines, c) continuous daily exposure for years is the rationale behind the possibility of ELFs causing or increasing leukaemia.

B. Proteomics

Proteins are the key molecules that participate and regulate nearly all cellular functions. The number of each protein species in a given cell changes over time according to the metabolic and signalling demand and is subject to differential gene expression. Proteomics, is the science that explores by high throughput techniques the so called "protein expression profile" of proteins.

The reports on ELF and proteomics are practically absent in the last 5 years leaving only the old study by Seyyedi et al. (2007) in human fibroblast (using 3 Hz, sinusoidal continuous ELF electromagnetic fields, 3 h duration and 4 mT magnetic field intensity) and one more in 2011 by Sulpizio et al. The first study showed that some protein expressions were affected by radiation after comparing the 2-DE separated proteins from the exposed and sham (control) cells. The two proteins that their expression was reduced about 50% were determined as alpha 1 antitrypsin (A1AT) and Transthyretin (TTR) and has been concluded that application of ELF-EMF in therapeutic aspects may be accompanied by their side effects.

Along the "leukaemia ELF rationale" and in addition a possible ELF link with cancer, cardiovascular, and neurological disorders, Sulpizio et al. (2011) exposed human SH-SY5Y neuroblastoma cells to a 50 Hz, 1 mT (10 Gauss) sinusoidal ELF-MF at three duration schemes, 5 days (T5), 10 days (T10), and 15 days (T15). The effects of ELF-MF on proteome expression and biological behavior were investigated. Through comparative analysis between treated and control samples they identified

nine new proteins after a 15-day treatment. They suggested that the proteins were involved in a cellular defence mechanism and/or in cellular organization and proliferation such as peroxiredoxin isoenzymes (2, 3, and 6), 3-mercaptopyruvate sulfurtransferase, actin cytoplasmatic 2, t-complex protein subunit beta, ropporin-1A, and profilin-2 and spindlin-1. These authors concluded that ELF-MFs exposure altered the proliferative status and other important cell biology-related parameters, such as cell growth pattern, and cytoskeletal organization and that ELF radiation could trigger a shift toward a more invasive phenotype.

III. RADIOFREQUENCY ELECTROMAGNETIC FIELDS (RF-EMFS)

A relatively small number of publications have dealt after 2007 with the effects of RF-EMF on the proteome and transcriptome of cells and even less number with the effects on animals.

A. Transcriptomics

Chauhan et al. (2007a) assessed non-thermal RF-field exposure effects on a variety of biological processes (including apoptosis, cell cycle progression, viability and cytokine production) in a series of human-derived cell lines (TK6, HL60 and Mono-Mac-6). Exponentially growing cells were exposed to intermittent (5 min on, 10 min off) 1.9 GHz pulse-modulated RF fields for 6 h at mean specific absorption rates (SARs) of 0, 1 and 10 W/kg. Concurrent negative (incubator) and positive (heat shock for 1 h at 43 degrees C) controls were included in each experiment. Immediately after the 6-h exposure period and 18 h after exposure, cell pellets were collected and analyzed for cell viability, the incidence of apoptosis, and alterations in cell cycle kinetics. The cell culture supernatants were assessed for the presence of a series of human inflammatory cytokines (TNFA, IL1B, IL6, IL8, IL10, IL12) using a cytometric bead array assay. No detectable changes in cell viability, cell cycle kinetics, incidence of apoptosis, or cytokine expression were observed in any of RF-field-exposed groups in any of the cell lines tested, relative to the sham controls. However, the positive (heat-shock) control samples displayed a significant decrease in cell viability, increase in apoptosis, and alteration in cell cycle kinetics (G(2)/M block). Overall, the researchers found no evidence that non-thermal RF-field exposure could elicit any detectable biological effect in three human-derived cell lines.

Chauhan et al. (2007b) have examined the effect of RF field exposure on the possible expression of late onset genes in U87MG cells after a 24 h RF exposure period. In addition, a human monocyte-derived cell-line (Mono-Mac-6, MM6) was exposed to intermittent (5 min ON, 10 min OFF) RF fields for 6 h and then gene expression was assessed immediately after exposure and at 18 h post exposure. Both cell lines were exposed to 1.9 GHz pulse-modulated RF fields for 6 or 24 h at specific absorption rates (SARs) of 0.1-10.0 W/kg (very high SAR value). In support of their previous results, they found no evidence that nonthermal RF field exposure could alter gene expression in either cultured U87MG or MM6 cells, relative to non irradiated control groups. However, exposure of both cell-lines to heat-shock conditions (43 degrees C for 1 h) caused an alteration in the expression of a number of well-characterized heat-shock proteins.

The same year, Zhao et al. (2007) investigated whether expression of genes related to cell death pathways are dysregulated in primary cultured neurons and astrocytes by exposure to a working GSM cell phone rated at a frequency of 1900 MHz. Primary cultures were exposed for 2h. Microarray analysis and real-time RT-PCR were applied and showed up-regulation of caspase-2, caspase-6 and Asc gene expression in neurons and astrocytes. Up-regulation occurred in both "on" and "stand-by" modes in neurons, but only in "on" mode in astrocytes. Additionally, astrocytes showed up-regulation of the Bax gene. The effects were specific since up-regulation was not seen for other genes associated with apoptosis, such as caspase-9 in either neurons or astrocytes, or Bax in neurons. The results showed that even relatively short-term exposure to cell phone radiofrequency emissions can up-regulate elements of apoptotic pathways in cells derived from the brain, and that neurons appear to be more sensitive to this effect than astrocytes.

In an *in vitro* study focusing on the effects of low-level radiofrequency (RF) fields from mobile radio base stations employing the International Mobile Telecommunication 2000 (IMT-2000) cellular system, Hirose et al. (2007) tested the hypothesis that modulated RF fields act to induce phosphorylation and overexpression of heat shock protein hsp27. The study evaluated the responses of human cells to microwave exposure at a specific absorption rate (SAR) of 80 mW/kg, which corresponds to the limit of the average whole-body SAR for general public exposure defined as a basic restriction in the International Commission on Non-Ionizing Radiation Protection (ICNIRP) guidelines. Secondly, the study investigated whether

continuous wave (CW) and Wideband Code Division Multiple Access (W-CDMA) modulated signal RF fields at 2.1425 GHz can induce activation or gene expression of hsp27 and other heat shock proteins (hsps). Human glioblastoma A172 cells were exposed to W-CDMA radiation at SARs of 80 and 800 mW/kg for 2-48 h, and CW radiation at 80 mW/kg for 24 h. Human IMR-90 fibroblasts from fetal lungs were exposed to W-CDMA at 80 and 800 mW/kg for 2 or 28 h, and CW at 80 mW/kg for 28 h. Under the RF field exposure conditions described above, no significant differences in the expression levels of phosphorylated hsp27 at serine 82 (hsp27[pS82]) were observed between the test groups exposed to W-CDMA or CW signal and the sham-exposed negative controls, as evaluated immediately after the exposure periods by bead-based multiplex assays. Moreover, no noticeable differences in the gene expression of hsps were observed between the test groups and the negative controls by DNA Chip analysis.

Paparini et al. (2008) found no evidence of major transcriptional changes in the brain of mice exposed to 1800 MHz GSM signal for 1 h at a whole body SAR of 1.1 W/kg. Gene expression was studied in the whole brain, where the average SAR was 0.2 W/kg, by expression microarrays containing over 22,600 probe sets. Comparison of data from sham and exposed animals showed no significant difference in gene expression modulation. However, when less stringent constraints were adopted to analyze microarray results, 75 genes were found to be modulated following exposure. Forty-two probes showed fold changes ranging from 1.5 to 2.8, whereas 33 were down-regulated from 0.67- to 0.29-fold changes, but these differences in gene expression were not confirmed by real-time PCR. Under these specific limited conditions, no consistent indication of gene expression changes in whole mouse brain was found associated to GSM 1800 MHz exposure. *We could possibly explain the lack of gene expression changes in this, as well in other studies, by the very short exposure duration used of 1 h.*

Nittby et al. (2008) applied Microarray hybridizations on Affymetrix rat2302 chips of RNA extracts from cortex and hippocampus of GSM 1800 exposed rats for just 6 h within TEM cells. Using four exposed and four control animals they found that a large number of genes were altered at hippocampus and cortex. The vast majority were downregulated. Since the genes that were differentially expressed between the two groups were responsible to membrane integral and signal transduction, the authors concluded that the change of their expression might be the cause of their

previous observations of blood-brain-barrier leakage and albumin transport through brain capillaries.

Huang et al. (2008a) monitored cellular and molecular changes in Jurkat human T lymphoma cells after irradiating with 1763 MHz RF radiation in order to test the effect on RF radiation in immune cells. Jurkat T-cells were exposed to RF radiation to assess the effects on cell proliferation, cell cycle progression, DNA damage and gene expression. Cells were exposed to 1763 MHz RF radiation at 10 W/kg specific absorption rate (SAR) and compared to sham exposed cells. RF exposure did not produce significant changes in cell numbers, cell cycle distributions, or levels of DNA damage. In genome-wide analysis of gene expressions, there were no genes changed more than 2-fold upon RF-radiation while ten genes changed from 1.3 to approximately 1.8-fold. Among these ten genes, two cytokine receptor genes such as chemokine (C-X-C motif) receptor 3 (CXCR3) and interleukin 1 receptor, type II (IL1R2) were down-regulated upon RF radiation. These results indicate that the alterations in cell proliferation, cell cycle progression, DNA integrity or global gene expression were not detected upon 1763 MHz RF radiation under 10 W/kg SAR for 24 h to Jurkat T cells.

In a follow-up study Huang et al. (2008b) chose HEI-OC1 immortalized mouse auditory hair cells to characterize the cellular response to 1763 MHz RF exposure, because auditory cells can be exposed to mobile phone frequencies. Cells were exposed to 1763 MHz RF at a 20 W/kg specific absorption rate (SAR) in a code division multiple access (CDMA) exposure chamber for 24 and 48 h to check for changes in cell cycle, DNA damage, stress response, and gene expression. Neither cell cycle changes nor DNA damage were detected in RF-exposed cells. The expression of heat shock proteins (HSP) and the phosphorylation of mitogen-activated protein kinases (MAPK) did not change, either. The researchers tried to identify any alteration in gene expression using microarrays. Using the Applied Biosystems 1700 full genome expression mouse microarray, they found that 29 genes (0.09% of total genes examined) were changed by more than 1.5-fold on RF exposure. From these results, they could not find any evidence of the induction of cellular responses, including cell cycle distribution, DNA damage, stress response and gene expression, after 1763 MHz RF exposure at an SAR of 20 W/kg (very high value) in HEI-OC1 auditory hair cells.

Concerning plant cell experiments Engelmann et al. (2008) searched for physiological processes of plant cells sensitive to RF fields. They reported significant changes (but not more than 2.5-fold) in transcription of 10 genes in cell suspension cultures of *Arabidopsis thaliana*, which were exposed for 24 h to an RF field protocol representing typical microwave exposition in an urban environment. The changes in transcription of these genes were compared with published microarray datasets and revealed a weak similarity of the microwave to light treatment experiments. Considering the large changes described in published experiments, it is questionable if the small alterations caused by a 24 h continuous microwave exposure would have any impact on the growth and reproduction of whole plants.

Using very low SAR values (0.9–3 mWkg) Dawe et al. (2009) applied microarray technology in the nematode *C. elegans.* They compared five Affymetrix gene arrays of pooled triplicate RNA populations from sham-exposed L4/adult worms against five gene arrays of pooled RNA from microwave-exposed worms (taken from the same source population in each run). No genes showed consistent expression changes across all five comparisons, and all expression changes appeared modest after normalisation (< or =40% up- or down-regulated). The number of statistically significant differences in gene expression (846) was less than the false-positive rate expected by chance (1131). The authors concluded that the pattern of gene expression in L4/adult *C. elegans* is substantially unaffected by low-intensity microwave radiation and that the minor changes observed in this study could well be false positives. As a positive control, they compared RNA samples from N2 worms subjected to a mild heat-shock treatment (30 ^{o}C) against controls at 26 ^{o}C (two gene arrays per condition). As expected, heat-shock genes were strongly up-regulated at 30 ^{o}C, particularly an hsp-70 family member (C12C8.1) and hsp-16.2. Under these heat-shock conditions, they confirmed that an hsp-16.2::GFP transgene was strongly up-regulated, whereas two non-heat-inducible transgenes (daf-16::GFP; cyp-34A9::GFP) showed little change in expression. Preliminary work in our lab has indicated that this model organism is highly resistant to EMF sources including mobile phone, DECT and Wi-Fi radiation exposures, for reasons that are under investigation (Margaritis et al., unpublished).

RF exposure up to the limit of whole-body average SAR levels as specified in the ICNIRP guidelines is unlikely to elicit a general stress response in the tested cell lines

under these conditions as reported by Sekijima et al. (2010). These authors investigated the mechanisms by which radiofrequency (RF) fields exert their activity, and the changes in both cell proliferation and the gene expression profile in the human cell lines, A172 (glioblastoma), H4 (neuroglioma), and IMR-90 (fibroblasts from normal fetal lung) following exposure to 2.1425 GHz continuous wave (CW) and Wideband Code Division Multiple Access (W-CDMA) RF fields at three field levels. During the incubation phase, cells were exposed at specific absorption rates (SARs) of 80, 250, or 800 mW/kg with both CW and W-CDMA RF fields for up to 96 h. Heat shock treatment was used as the positive control. No significant differences in cell growth or viability were observed between any test group exposed to W-CDMA or CW radiation and the sham-exposed negative controls. Using the Affymetrix Human Genome Array, only a very small (< 1%) number of available genes (ca. 16,000 to 19,000) exhibited altered expression in each experiment. According to the authors the results confirm that low-level exposure to 2.1425 GHz CW and W-CDMA RF fields for up to 96 h did not act as an acute cytotoxicant in either cell proliferation or the gene expression profile. These results suggest that RF exposure up to the limit of whole-body average SAR levels as specified in the ICNIRP guidelines is unlikely to elicit a general stress response in the tested cell lines under these conditions.

In order to investigate whether exposure to high-frequency electromagnetic fields (EMF) could induce adverse health effects, Trivino et al. (2012) cultured acute T-lymphoblastoid leukemia cells (CCRF-CEM) in the presence of 900 MHz MW-EMF generated by a transverse electromagnetic (TEM) cell at short and long exposure times and the effect of high-frequency EMF on gene expression has been evaluated. Significant changes in gene expression levels of genes involved in DNA repair, cell cycle arrest, apoptosis, chromosomal organization, and angiogenesis were observed.The authors have identified functional pathways influenced by 900 MHz MW-EMF exposure.

It is worth mentioning, although beyond the frequencies used in cellular communication, that changes were detected using millimeter-waves in 56 genes at 6 h exposure and 58 genes at 24 h exposure in rats as shown by Millenbaugh et al. (2008). The animals were subjected to 35 GHz millimeter waves at a power density of 75 mW/cm^2, to sham exposure and to 42 degrees Centigrade environmental heat. Skin

samples were collected at 6 and 24 h after exposure for Affymetrix Gene Chip analysis. The skin was harvested from a separate group of rats at 3-6 h or 24-48 h after exposure for histopathology analysis. Microscopic findings observed in the dermis of rats exposed to 35 GHz millimeter waves included aggregation of neutrophils in vessels, degeneration of stromal cells, and breakdown of collagen. Changes were detected in 56 genes at 6 h and 58 genes at 24 h in the millimeter-wave-exposed rats. Genes associated with regulation of transcription, protein folding, oxidative stress, immune response, and tissue matrix turnover were affected at both times. At 24 h, more genes related to extracellular matrix structure and chemokine activity were altered. Up-regulation of Hspa1a, Timp1, S100a9, Ccl2 and Angptl4 at 24 h by 35 GHz millimeter-wave exposure was confirmed by real-time RT-PCR. These results obtained from histopathology, microarrays and RT-PCR indicated that prolonged exposure to 35 GHz millimeter waves causes thermally related stress and injury in skin while triggering repair processes involving inflammation and tissue matrix recovery.

B. Proteomics

In a series of publications by Leszczynski's research group, consistently using human endothelial cell lines EA.hy926 and EA.hy926v1, protein expression changes occurred after exposure to 900 MHz.

The potential proteome expression changes by RF on the same cell line EA.hy926 have been further investigated by the same group in a follow-up study (Nylund et al., 2009), where they reported that 1h exposure to GSM 1800 MHz mobile phone radiation (SAR 2.0 W/kg) can also alter this cell line's proteome expression. Sham samples were produced simultaneously in the same conditions but without the radiation exposure. Cells were harvested immediately after 1-hour exposure to the radiation, and proteins were extracted and separated using 2-dimensional electrophoresis (2DE). In total, 10 experimental replicates were generated from both exposed and sham samples. About 900 protein spots were detected in the 2DE-gels using PDQuest software and eight of them were found to be differentially expressed in exposed cells ($p<0.05$, t-test). Three out of these eight proteins were identified using Maldi-ToF mass spectrometry (MS). These proteins were: spermidine synthase (SRM), 78 kDa glucose-regulated protein (55 kDa fragment) (GRP78) and proteasome subunit alpha type 1 (PSA1). Due to the lack of the availability of

commercial antibodies the researchers were able to further examine expression of only GRP78. Using SDSPAGE and western blot method they were not able to confirm the result obtained for GRP78 using 2DE. Additionally, no effects were reported this time for 1800GSM exposure on the expression of vimentin and Hsp27 - proteins that were affected by the 900 MHz GSM exposure in their earlier studies. The authors highlight that the observed discrepancy between the expression changes of GRP78 detected with 1DE and 2DE confirms the importance of validation of the results obtained with 2DE using other methods, e.g. western blot.

Using a higher definition technique, the 2D-DIGE, Leszczynski's group investigated whether GSM1800 radiation can alter the proteome of primary human umbilical vein endothelial cells and primary human brain microvascular endothelial cells (Nylund et al., 2010). The cells were exposed for 1 hour to 1800 MHz GSM mobile phone radiation at an average specific absorption rate of 2.0 W/kg. Following that, cells were harvested immediately and the protein expression patterns of the sham-exposed and radiation-exposed cells were examined using two dimensional difference gel electrophoresis based proteomics (2DE-DIGE). Numerous differences were observed between the proteomes of human umbilical vein endothelial cells and human brain microvascular endothelial cells (both sham-exposed). These differences are most likely representing physiological differences between endothelia in different vascular beds. However, the exposure of both types of primary endothelial cells to mobile phone radiation did not cause any statistically significant changes in protein expression. So, radiation did not provoke any proteome expression changes to these kinds of cells immediately at the end of the exposure and when the false discovery rate correction was applied to analysis. This observation agrees with earlier the earlier study of this group showing that the 1800 MHz GSM radiation exposure had only very limited effect on the proteome of human endothelial cell line EA.hy926, as compared with the effect of 900 MHz GSM radiation.

Another "omics" group exposing human lens epithelial cells detected heat-shock protein (HSP) 70 and heterogeneous nuclear ribonucleoprotein K (hnRNP K) to be upregulated following exposure to GSM 1800 MHz for 2 h (Li et al., 2007). In three separate experiments, HLECs were exposed and sham-exposed (six dishes each) to 1800-MHz GSM-like radiation for 2 h. The specific absorption rates were 1.0, 2.0, or 3.5 W/kg. Immediately after radiation, the proteome was extracted from the HLECs. Immobilized pH gradient two-dimensional polyacrylamide gel electrophoresis (2-DE;

silver staining) and PDQuest 2-DE analysis software were used to separate and analyze the proteome of exposed and sham-exposed HLECs. Four differentially expressed protein spots were selected and identified by using electrospray ionization tandem mass spectrometry (ESI-MS-MS). When the protein profiles of exposed cells were compared with those of sham-exposed cells, four proteins were detected as upregulated. After analysis by ESI-MS-MS and through a database search, heat-shock protein (HSP) 70 and heterogeneous nuclear ribonucleoprotein K (hnRNP K) were determined to be upregulated in the exposed cells.

Since the above *in vitro* effects cannot be easily translated into humans, in 2008, Leszczynski's group performed a pilot study on volunteers (Karinen et al., 2008) and showed that mobile phone radiation might alter protein expression in human skin cells. Small area of forearm's skin in 10 female volunteers was exposed to RF-EMF (specific absorption rate SAR = 1.3 W/kg) and punch biopsies were collected from exposed and non-exposed areas of skin. Proteins extracted from biopsies were separated using 2-DE and protein expression changes were analyzed using PDQuest software. Analysis has identified 8 proteins that were statistically significantly affected (Anova and Wilcoxon tests). Two of the proteins were present in all 10 volunteers. This suggests that protein expression in human skin might be affected by the exposure to RF-EMF. The number of affected proteins was similar to the number of affected proteins observed in this group's earlier *in vitro* studies. This is the first study showing that molecular level changes might take place in human volunteers in response to exposure to RF-EMF, although the overall conclusions were criticized by Leszczynski et al. (2012).

However, such a limited and non systematic number of publications using "omics" approaches does not allow for any conclusions to be drawn concerning the impact of mobile phone emitted radiation upon cell proteome, physiology and function (Nylund et al., 2009), as also pointed out by Vanderstraeten & Verschaeve (2008).

Kim et al. (2010) have monitored changes in protein expression profiles in RF-exposed MCF7 human breast cancer cells using two-dimensional gel electrophoresis. MCF7 cells were exposed to 849 MHz RF radiation for 1 h per day for three consecutive days at specific absorption rates (SARs) of either 2 W/Kg or 10 W/kg. During exposure, the temperature in the exposure chamber was kept in an isothermal condition. Twenty-four hours after the final RF exposure, the protein lysates from MCF cells were prepared and two-dimensional electrophoretic analyses were

conducted. The protein expression profiles of the MCF cells were not significantly altered as the result of RF exposure. None of the protein spots on the two-dimensional electrophoretic gels showed reproducible changes in three independent experiments. To determine effect of RF radiation on protein expression profiles more clearly, three spots showing altered expression without reproducibility were identified using electrospray ionization tandem mass spectrometry analysis and their expressions were examined with RT-PCR and Western blot assays. There was no alteration in their mRNA and protein levels. The authors concluded that it seems unlikely that RF exposure modulates the protein expression profile.

Since oxidative stress is gaining more and more ground as being the initial mechanism of action of EMFs, the review by Gaestel M. (2010) describes the (up to 2010) developments in analysing the influence of RF-EMFs on biological systems by monitoring the cellular stress response as well as overall gene expression. Recent data on the initiation and modulation of the classical cellular stress response by RF-EMFs, comprising expression of heat shock proteins and stimulation of stress-activated protein kinases, are summarised and evaluated. Since isothermic RF-EMF exposure is assumed rather than proven there are clear limitations in using the stress response to describe non-thermal effects of RF-EMFs. In particular, according to the authors further experiments are needed to characterise better the threshold of the thermal heat shock response and the homogeneity of the cellular response in the whole sample for each biological system used. Before then, it is proposed that the absence of the classical stress response can define isothermal experimental conditions and qualifies other biological effects of RF-EMFs detected under these conditions to be of non-thermal origin. To minimise the probability that by making this assumption valuable insights into the nature of biological effects of RF-EMFs could be lost, proteotoxic non-thermal RF-EMF effects should also be monitored by measuring activities of labile intracellular enzymes and/or levels of their metabolites before the threshold for the heat shock response is reached. In addition, non-thermal induction of the stress response via promoter elements distinct from the heat shock element (HSE) should be analysed using HSE-mutated heat shock promoter reporter constructs. Screening for non-thermal RF-EMF effects in the absence of a classical stress response should be performed by transcriptomics and proteomics. It is postulated that due to their high-throughput characteristics, these methods inherently generate false positive results and

require statistical evaluation based on quantitative expression analysis from a sufficient number of independent experiments with identical parameters. In future approaches, positive results must be confirmed by independent quantitative methods and should also be evaluated *in vivo* to prove possible non-thermal effects of RF-EMFs on living beings. If successful, this strategy should contribute to identification of new underlying molecular mechanisms of interaction between RF-EMFs and living beings distinct from absorption of thermal energy.

In the review by Leszczynski et al., (2012) the authors have analyzed all available data up through the end of 2010 and have raised a number of concerns regarding the handling of proteomics technology, such as the different proteome analysis methods used, the low number of replicates, the posttreatment sampling (one or very few time points), the large number of protein analyzed, the huge differences in the dynamic range of protein concentrations in cells or plasma, the variety of posttranslational modifications, the lack of validation of the results with a second method, as well as the various SAR/exposure conditions/duration/frequency dependencies in order to properly evaluate the EMF impact. The authors agree along with Gerner et al. (2010) that protein expression per se may be a reliable way to explain EMF effects. We might add that in terms of protein synthesis dynamics, the quantity of any protein species at a given time point (as detected by proteomics) should take into account the protein stability and turnover (as pointed out by Eden et al., 2011) as well as mRNA stability and maturation/translational-posttranslational control. In a hypothetical scenario that EMFs affect gene activation /deactivation (see Blank & Goodman, 2008), the end effect may not be seen by proteomics, since no net quantity change is taking place immediately but (possibly) a few hours following exposure and (also hypothetically) normal levels come back a few days or weeks later due homeostatic mechanisms.

Our own contribution to the field of RF-EMF induced protein expression changes was performed in mice exposed to mobile phone and wireless DECT base radiation under real-time exposure conditions and analyzing thereafter the proteome of three critical brain regions; hippocampus, cerebellum and frontal lobe (Fragopoulou et al. 2012). Three equally divided groups of Balb/c mice (6 animals/group) were used; the first group was exposed to a typical mobile phone, at a SAR level range of 0.17-0.37 W/kg for 3 h daily for 8 months, the second group was exposed to a wireless DECT

base (Digital Enhanced Cordless Telecommunications Telephone) at a SAR level range of 0.012-0.028 W/kg for 8 h/day for 8 months and the third group comprised the sham-exposed animals. Comparative proteomics analysis revealed that long-term irradiation from both EMF sources significantly altered ($p < 0.05$) the expression of 143 proteins in total (as low as 0.003 fold downregulation up to 114 fold overexpression). Several neural function related proteins (i.e., Glial Fibrillary Acidic Protein (GFAP), Alpha-synuclein, Glia Maturation Factor beta (GMF), and apolipoprotein E (apoE)), heat shock proteins, and cytoskeletal proteins (i.e., Neurofilaments and tropomodulin) are included in this list as well as proteins of the brain metabolism (i.e., Aspartate aminotransferase, Glutamate dehydrogenase) to nearly all brain regions studied. Western blot analysis on selected proteins confirmed the proteomics data. The observed protein expression changes may be related to brain plasticity alterations, indicative of oxidative stress in the nervous system or involved in apoptosis and might potentially explain human health hazards reported so far, such as headaches, sleep disturbance, fatigue, memory deficits, and long-term induction of brain tumors under similar exposure conditions.

As mentioned earlier, beyond the mobile phone frequencies, 35 GHz radiation had effects on gene expression. Similarly, Sypniewska et al. (2010) using proteomics reported that this frequency can also alter the proteome of NR8383 rat macrophages. Two-dimensional polyacrylamide gel electrophoresis, image analysis, and Western blotting were used to analyze approximately 600 protein spots in the cell lysates for changes in protein abundance and levels of 3-nitrotyrosine, a marker of macrophage stimulation. Proteins of interest were identified using peptide mass fingerprinting. Compared to plasma from sham-exposed rats, plasma from environmental heat- or millimeter wave-exposed rats increased the expression of 11 proteins, and levels of 3-nitrotyrosine in seven proteins, in the NR8383 cells. These altered proteins are associated with inflammation, oxidative stress, and energy metabolism. Findings of this study indicate both environmental heat and 35 GHz millimeter wave exposure elicit the release of macrophage-activating mediators into the plasma of rats.

Interestingly, there is a wealth of information regarding proteome and/or transcriptomics studies following exposure to ionizing radiation. In the perspective of similar mechanisms of action between NIR and IR, it is worth mentioning just one study using very low dose ionizing radiation by Pluder et al., 2011. In this study low-

dose radiation induced rapid and time-dependent changes in the cytoplasmic proteome of the human endothelial cell line EA.hy926 (used by Dariusz Leszczynski and his group in their EMF studies). The proteomes were investigated at 4 and 24 h after irradiation at two different dose rates (Co-60 gamma ray total dose 200 mGy; 20 mGy/min and 190 mGy/min) using 2D-DIGE technology. The researchers identified 15 significantly differentially expressed proteins, of which 10 were upregulated and 5 down-regulated, with more than ± 1.5-fold difference compared with unexposed cells. Pathways influenced by the low-dose exposures included the Ran and RhoA pathways, fatty acid metabolism and stress response which are reminiscent of EMF impact studies.

Concerning proteomics techniques, a recent review by Damm et al., (2012) re-evaluates the putative advantages of microwave-assisted tryptic digests compared to conventionally heated protocols performed at the same temperature. An initial investigation of enzyme stability in a temperature range of 37-80°C demonstrated that trypsin activity declines sharply at temperatures above 60°C, regardless if microwave dielectric heating or conventional heating is employed. Tryptic digests of three proteins of different size (bovine serum albumin, cytochrome c and β-casein) were thus performed at 37°C and 50°C using both microwave and conventional heating applying accurate internal fiber-optic probe reaction temperature measurements. The impact of the heating method on protein degradation and peptide fragment generation was analyzed by SDS-PAGE and MALDI-TOF-MS. Time-dependent tryptic digestion of the three proteins and subsequent analysis of the corresponding cleavage products by MALDI-TOF provided virtually identical results for both microwave and conventional heating. In addition, the impact of electromagnetic field strength on the tertiary structure of trypsin and BSA was evaluated by molecular mechanics calculations. These simulations revealed that the applied field in a typical laboratory microwave reactor is 3-4 orders of magnitude too low to induce conformational changes in proteins or enzymes.

IV. SUMMARY

The papers analyzed in this review have dealt with a very difficult research problem, which is EMF effects as measured by the highthroughput techniques of transcriptomics and proteomics. It is a very difficult task because the technical

complexity of the approaches is added to the enormous variations of the exposure details (duration, frequency, pulses, repetition, intensity, peak values, e.t.c). In total there were 29 original articles from 2007. Eight (8) of them were in the ELF frequencies, where the three of them indicate an effect in gene expression, the other three indicate no effect in gene expression and two studies show an effect in protein expression. Regarding radiofrequency studies (RF-EMF) a total of 21 papers were published in this area since 2007. Thirteen (13) dealt with transcriptomics [eight (8) effect- five (5) no effect] and eight (8) in proteomics [six (6) show effect and two (2) show no effect]. So, in total, 66% of the studies reveal an effect of EMF on transcriptome and proteome expression (Table 1).

Table 1

EMF Transcriptomics and Proteomics studies 2007-2012

(E=effect, NE= no effect)

The classification of the studies to the category "Effect – No effect" is based on the general conclusions of each article, although different conditions are used in exposure setup, biological system, duration, approaches. It is also considered as an effect even if a single gene or protein is affected by exposure to EMF.

	Exposed biological model	**Exposure set-up**	**SAR or/and power density or intensity of magnetic field**	**Duration of exposure / Time of sampling**	**Method of analysis**	**Category "Effect-No effect"**	**Comments**	**Reference/ Journal**
ELF –EMF Transcriptomics	**Primary human mesenchymal stem cells from the bone marrow and chondrocytes (cell line C28I2)**	BTEMF (combination of electromagnetic field and light therapy) Coil system	35 μT	Stimulated 5 times at 12-h intervals for 8 min each	Affymetrix GeneChip System, HG-U133A /RT-PCR partially confirmed the data	**E**	A limited number of regulated gene products from both cell types, which control cell metabolism and cell matrix structure,	Walther et al. V. CONCLUSIONS

It is clear that the effects of EMFs are very difficult to predict in the cells, and that SAR values do not provide any information about the molecular mechanisms likely to take place during exposure. Unlike drugs, EMFs are absorbed in a variety of different, diverse and non-linear ways depending on the "microenvironment" receiving the radiation, the orientation of the molecular targets and their shape, the metabolic state at the moment of exposure, the energy absorbance at the microscale of the cell and the modulation of the waves. On this basis, it is rather difficult to replicate experiments under different conditions and cell systems, which may explain the discrepancy of the results among research groups.

As far as changes in gene expression are concerned, they are observed within specific time duration with and without recovery time. As mentioned in some studies i.e., the same endothelial cell line responded to 1800 MHz intermittent exposure, but not to continuous exposure. Exposure time, exposure pattern and type of biological system (organism, tissue, cell) and experimental techniques may also play a key role in the end effect (Mevissen M., 2011).

In addition, we point out that all "averaging approaches" like proteomics and transcriptomics provide a mean value of changes in a specific protein/gene from all cell types of the tissue examined. The same is true for western blotting, RT-PCR and the entire battery of biochemical/molecular biological techniques. Of course, newly developed high sensitivity proteomics and transcriptomics might be able to analyse small quantities from individual cell types, since cell protein/gene expression changes would be the approach of choice in future experiments utilizing sophisticated state of the art microscopical techniques. Under these conditions, we will be able to understand why one cell type responds to EMF whereas another cell type is not responding, thus leading to a net "no effect" in case the second cell type is outnumbered.

Therefore the issue of examining by proteomics various time points during (or after) exposure is of utmost importance in order to unravel the mechanism(s) of EMF action. Approaches including 2D-autoradiography might be in addition very useful in this direction since the actual protein synthetic profile will be revealed (Gerner et al., 2010). As stated by these authors their findings of an association between metabolic activity and the observed cellular reaction to low intensity RF-EMF may reconcile conflicting results of previous studies. They further postulated that the observed

increased protein synthesis reflects an increased rate of protein turnover stemming from protein folding problems caused by the interference of radiofrequency electromagnetic fields with hydrogen bonds. These observations of course do not directly imply a health risk.

Needless to mention that a combination of all available high throughput techniques in the same system under identical exposure conditions will provide better data, especially if different laboratories replicate the results.

Taking into account that many studies using normal exposure conditions have revealed protein and gene expression changes, health hazards are possible.

It is clear that the existing guidelines are inadequate as pointed out by other studies as well (Fragopoulou et al., 2010). The transcriptomics and proteomics data reviewed here report that 66% of the papers published after 2007 show an effect. This is a clear indication of expression changes of proteins and genes at intensity levels commonly used by the wireless devices. Prudent avoidance of excessive usage of these devices is thus recommended.

Concerning the question of which model system is more suitable for such experiments in order to translate the effects into human EMF hazards, we might agree with Leszczynski's point that human volunteer skin is more suitable, but the major target of interest regarding EMF impacts is the brain which consists of an enormous complexity of nerve cell interactions far away from constituents of skin. Therefore, we argue that the system of choice for omics approaches should be rats or mice (preferably the second due to the possibility of handling transgenic material) as evolutionary very close to humans without neglecting the important work that has been (or will be) done using other biological systems, especially cell cultures.

TABLE OF CONTENTS

I. Introduction

Toxicity to the genome can lead to a change in cellular functions, cancer, and cell death. A large number of studies have been carried out to investigate the effects of electromagnetic field (EMF) exposure on DNA and chromosomal structures. The single-cell gel electrophoresis (comet assay) has been widely used to determine DNA damages: single and double strand breaks and cross-links. Studies have also been carried out to investigate chromosomal conformation and micronucleus formation in cells after exposure to EMF.

II. Radiofrequency radiation (RFR) and DNA damage (*28 total studies – 14 reported effects (50%) and 14 reported no significant effect (50%))*

II A. DNA studies that reported effects*:*

The following is a summary of the research data reported in the literature.

Aitken et al. [2005] exposed mice to 900-MHz RFR at a specific absorption rate (SAR) of 0.09 W/kg for 7 days at 12 h per day. DNA damage in caudal epididymal spermatozoa was assessed by quantitative PCR (QPCR) as well as alkaline and pulsed-field gel electrophoresis postexposure. Gel electrophoresis revealed no significant change in single- or double-DNA strand breakage in spermatozoa. However, QPCR revealed statistically significant damage to both the mitochondrial genome ($p < 0.05$) and the nuclear β-globin locus ($p < 0.01$).

Diem et al [2005] exposed human fibroblasts and rat granulosa cells to mobile phone signal (1800 MHz; SAR 1.2 or 2 W/kg; different modulations; during 4, 16 and 24 h; intermittent 5 min on/10min off or continuous). RFR exposure induced DNA single- and double-strand breaks as measured by the comet assay. Effects occurred after 16 h exposure in both cell types and after different mobile-phone modulations. The intermittent exposure showed a stronger effect in the than continuous exposure.

Gandhi and Anita [2005] reported increases in DNA strand breaks and micronucleation in lymphocytes obtained from cell phone users.

Garaj-Vrhovac et al [1990] reported changes in DNA synthesis and structure in Chinese hamster cells after various durations of exposure to 7.7 GHz field at 30 mW/cm^2.

Lai and Singh [1995; 1996; 1997a; 2005] and Lai et al. [1997] reported increases in single and double strand DNA breaks in brain cells of rats exposed for 2 hrs to 2450-MHz field at 0.6-1.2 W/kg.

Lixia et al. [2006] reported an increase in DNA damage in human lens epithelial cells at 0 and 30 min after 2 hrs of exposure to 1.8 GHz field at 3 W/kg.

Markova et al. [2005] reported that GSM signals affected chromatin conformation and gama-H2AX foci that colocalized in distinct foci with DNA double strand breaks in human lymphocytes.

Narasimhan and Huh [1991] reported changes in lambdaphage DNA suggesting single strand breaks and strand separation.

Nikolova et al. [2005] reported a low and transient increase in DNA double strand break in mouse embryonic stem cells after acute exposure to 1.7- GHz field.

Paulraj and Behari [2006] reported an increased in single strand breaks in brain cells of rats after 35 days of exposure to 2.45 and 16.5 GHz fields at 1 and 2.01 W/kg.

Phillips et al. [1998] found increase and decrease in DNA strand breaks in cells exposure to various forms of cell phone radiation.

Sun et al. [2006] reported an increase in DNA single strand breaks in human lens epithelial cells after 2 hrs of exposure to 1.8 GHz field at 3 and 4 W/kg. The DNA damages caused by 4 W/kg field were irreversible.

Zhang et al. [2002] reported that 2450-MHz field at 5 mW/cm^2 did not induce DNA and chromosome damage in human blood cells after 2 hrs of exposure, but could increase DNA damage effect induced by mitomycin-C.

Zhang et al. [2006] reported that 1800-MHz field at 3.0 W/kg induced DNA damage in Chinese hamster lung cells after 24 hrs of exposure.

II B. DNA studies that reported no significant effect*:*

Chang et al. [2005] using the Ames assay found no significant change in mutation frequency in bacteria exposed for 48 hrs at 4W/kg to an 835-MHz CDMA signal.

Hook et al. [2004] showed that 24-hr exposure of Molt-4 cells to CDMA, FDMA, iDEN or TDMA modulated RF radiation did not significantly alter the level of DNA damage.

Lagroye et al. [2004a] reported no significant change in DNA strand breaks in brain cells of rats exposed for 2 hrs to 2450-MHz field at 1.2 W/kg.

Lagroye et al. [2004b] found no significant increases in DNA-DNA and DNA-protein cross-link in C3H10T(1/2) cells after a 2-hr exposure to CW 2450 MHz field at 1.9 W/kg.

Li et al. [2001] reported no significant change in DNA strand breaks in murine C3H10T(1/2) fibroblasts after 2 hrs of exposure to 847.74 and 835.02 MHz fields at 3-5 W/kg.

Maes et al. [1993, 1996, 1997, 2000, 2001, 2006] published a series of papers on in vitro genotoxic effects of radiofrequency radiation and interaction with chemicals. Their mostly found no significant effect.

Malyapa et al. [1997a,b, 1998] reported no significant change in DNA strand-breaks in cells exposed to 2450-Hz and various forms of cell phone radiation. Both in vitro and in vivo experiments were carried out.

McNamee et al. [2002a,b, 2003] found no significant increase in DNA breaks and micronucleus formation in human leukocytes exposed for 2 hrs to 1.9 GHz field at SAR up to 10 W/kg.

Sakuma et al. [2006] exposed human glioblastoma A172 cells and normal human IMR-90 fibroblasts from fetal lungs to mobile communication radiation for 2 and 24 hrs. No significant change in DNA strand breaks were observed up to 800 mW/kg.

Stronati et al. [2006] showed that 24 hrs of exposure to 935-MHz GSM basic signal at 1 or 2 W/Kg did not cause DNA strand breaks in human blood cells.

Tice et al. [2002] measured DNA single strand breaks in human leukocytes using the comet assay after exposure to various forms of cell phone signals. Cells were exposed at 37±1°C, for 3 or 24 h at average specific absorption rates (SARs) of 1.0-10.0 W/kg. Exposure for either 3 or 24 h did not induce a significant increase in DNA damage in leukocytes.

Vershaeve et al. [2006] long-term exposure (2 hrs/day, 5 days/week for 2 years) of rats to 900 MHz GSM signal at 0.3 and 0.9 W/kg did not significantly affect levels of DNA strand breaks in cells.

Vijayalaximi et al [2000] reported no significant increase in single strand breaks in human lymphocytes after 2 hrs of exposure to 2450-MHz field at 2 W/kg.

Zeni et al. [2005] reported that a 2-hr exposure to 900-MHz GSM signal at 0.3 and 1 W/kg did not significantly affect levels of DNA strand breaks in human leukocytes.

III. Micronucleus studies (29 Total studies: 16 reported effects (55%) and 13 reported no significant effect (45%))

III A. Micronucleus studies that reported effects:

Balode [1996] obtained blood samples from female Latvian Brown cows from a farm close to and in front of the Skrunda Radar and from cows in a control area. Micronuclei in peripheral erythrocytes were significantly higher in the exposed cows.

Busljeta et al. [2004] exposed male rats to 2.45 GHz RFR fields for 2 hours daily, 7 days a week, at 5-10 mW/cm^2 for up to 30 days. Erythrocyte count, haemoglobin and haematocrit were increased in peripheral blood on irradiation days 8 and 15. Anuclear cells and erythropoietic precursor cells were significantly decreased in the bone marrow on day 15, but micronucleated cells were increased.

D'Ambrosio et al. [2002] exposed human peripheral blood to 1.748 GHz continuous wave (CW) or phase-modulated wave (GMSK) for 15 min at a maximum specific absorption rate of ~5 W/kg. No changes were found in cell proliferation kinetics after exposure to either CW or GMSK fields. Micronucleus frequency result was not affected by CW exposure but a statistically significant increase in micronucleus was found following GMSK exposure.

Ferreira et al. [2006] found that rat offspring exposed to radiation from a cellular phone during their embryogenesis showed a significant increase in micronucleus frequency.

Fucic et al. [1992] reported increase in frequencies of micronuclei in the lymphocytes of humans exposed to microwaves.

Gandhi and Singh [2005] analyzed short term peripheral lymphocyte cultures for chromosomal aberrations and the buccal mucosal cells for micronuclei. They reported an increase in the number of micronucleated buccal cells and cytological abnormalities in cultured lymphocytes.

Garaj-Vrhovac et al [1992] exposed human whole-blood samples to continuous-wave 7.7 GHz radiation at power density of 0.5, 10 and 30 mW/cm^2 for 10, 30 and 60 min. In all experimental conditions, the frequencies of all types of chromosomal aberrations

(dicentric and ring chromosomes) and micronucleus were significantly higher than in the control samples.

Garaj-Vrhovac et al. [1999] investigated peripheral blood lymphocytes of 12 subjects occupationally exposed to microwave radiation. Results showed an increase in frequency of micronuclei as well as disturbances in the distribution of cells over the first, second and third mitotic division in exposed subjects compared to controls.

Haider et al. [1994] exposed plant cuttings bearing young flower buds for 30 h on both sides of a slewable curtain antenna (300/500 kW, 40-170 V/m) and 15 m (90 V/m) and 30 m (70 V/m) distant from a vertical cage antenna (100 kW) as well as at the neighbors living near the broadcasting station (200 m, 1-3 V/m). Laboratory controls were maintained for comparison. Higher micronucleus frequencies than in laboratory controls were found for all exposure sites in the immediate vicinity of the antennae,

Tice et al. [2002] measured micronucleus frequency in human leukocytes using the comet assay after exposure to various forms of cell phone signals. Cells were exposed at 37±1°C, for 3 or 24 h at average specific absorption rates (SARs) of 1.0-10.0 W/kg. Exposure for 3 h did not induce a significant increase in micronucleated lymphocytes. However, exposure to each of the signals for 24 h at an average SAR of 5.0 or 10.0 W/kg resulted in a significant and reproducible increase in the frequency of micronucleated lymphocytes. The magnitude of the response (approximately four fold) was independent of the technology, the presence or absence of voice modulation, and the frequency.

Trosic et al. [2001] investigated the effect of a 2450-MHz microwave irradiation on alveolar macrophage kinetics and formation of multinucleated giant cells after whole body irradiation of rats at 5-15 mW/cm^2. A group of experimental animals was divided in four subgroups that received 2, 8, 13 and 22 irradiation treatments of two hours each. The animals were killed on experimental days 1, 8, 16, and 30. Multinucleated cells were significantly increased in treated animals. The increase in number of nuclei per cell was time- and dose-dependent. Macrophages with two nucleoli were more common in animals treated twice or eight times. Polynucleation was frequently observed after 13 or 22 treatments.

Trosic et al. [2002] exposed adult male Wistar for 2 h a day, 7 days a week for up to 30 days to continuous 2450-MHz microwaves at a power density of 5-10mW/cm^2. Frequency of micronuclei in polychromatic erythrocytes showed a significant increase in the exposed animals after 2, 8 and 15 days of exposure compared to sham-exposed control.

Trosic et al. [2004] investigated micronucleus frequency in bone marrow red cells of rats exposed to a 2450-MHz continuous–wave microwaves for 2 h daily, 7 days a week, at a power density of 5-10 mW/cm^2 (whole body SAR 1.25 +/- 0.36 (SE) W/kg). The frequency of micronucleated polychromatic erythrocytes was significantly increased on experimental day 15.

Trosic et al. [2006] exposed rats 2 h/day, 7 days/week to 2450-MHz microwaves at a whole-body SAR of 1.25 +/- 0.36W/kg. Control animals were included in the study. Bone marrow micronucleus frequency was increased on experimental day 15, and polychromatic erythrocytes micronucleus frequency in the peripheral blood was increased on day 8.

Zotti-Martelli et al. [2000] exposed human peripheral blood lymphocytes in G(0) phase to electromagnetic fields at different frequencies (2.45 and 7.7 GHz) and power

densities (10, 20 and 30 mW/cm^2) for 15, 30 or 60min. The results showed for both radiation frequencies an induction of micronuclei as compared to control cultures at a power density of 30mW/cm^2 and after an exposure of 30 and 60 min.

Zotti-Martelli et al. [2005] exposed whole blood samples from nine different healthy donors for 60, 120 and 180 min to continuous-wave 1800-MHz microwaves at power densities of 5, 10 and 20 mW/cm^2. A statistically significant increase of micronucleus in lymphocytes was observed dependent on exposure time and power density. A considerable decrease in spontaneous and induced MN frequencies was measured in a second experiment.

III B. Micronucleus studies that reported no significant effects:

Bisht et al. [2002] exposed C3H 10T½ cells to 847.74 MHz CDMA (3.2 or 4.8 W/kg) or 835.62 MHz FDMA (3.2 or 5.1 W/kg) RFR for 3, 8, 16 or 24 h. No exposure condition was found to result in a significant increase relative to sham-exposed cells either in the percentage of binucleated cells with micronuclei or in the number of micronuclei per 100 binucleated cells.

Juutilainen et al. [2007] found no significant change in micronucleus frequency in erythrocytes of mice after long-term exposure to various mobile phone frequencies.

Koyama et al. [2004] exposed Chinese hamster ovary (CHO)-K1 cells to 2450-MHz microwaves for 2 h at average specific absorption rates (SARs) of 5, 10, 20, 50, 100, and 200 W/kg. Micronucleus frequency in cells exposed at SARs of 100 and 200 W/kg were significantly higher when compared with sham-exposed controls. They speculated that the effect observed was a thermal effect.

Port et al. [2003] reported that exposure of HL-60 cells to EMFs 25 times higher than the ICNIRP reference levels for occupational exposure did not induce any significant changes in apoptosis, micronucleation, abnormal morphologies and gene expression.

Scarfi et al [2006] exposed human peripheral blood lymphocytes to 900 MHz GSM signal at specific absorption rates of 0, 1, 5 and 10 W/kg peak values. No significant change in micronucleus frequency was observed.

Vijayalaximi et al. [1997a] exposed human blood to continuous-wave 2450- MHz microwaves, either continuously for a period of 90 min or intermittently for a total exposure period of 90 min (30 min on and 30 min off, repeated three times). The mean power density at the position of the cells was 5.0 mW/cm^2 and mean specific absorption rate was 12.46 W/kg. There were no significant differences between RFR-exposed and sham-exposed lymphocytes with respect to; (a) mitotic indices; (b) incidence of cells showing chromosome damage; (c) exchange aberrations; (d) acentric fragments; (e) binucleate lymphocytes, and (f) micronuclei.

Vijayalaximi et al. [1997b] exposed C3H/HeJ mice for 20 h/day, 7 days/week, over 18 months to continuous-wave 2450 MHz microwaves at a whole-body average specific absorption rate of 1.0 W/kg. At the end of the 18 months, peripheral blood and bone marrow smears were examined for the extent of genotoxicity as indicated by the presence of micronuclei in polychromatic erythrocytes. The results indicate that the incidence of micronuclei/1,000 polychromatic erythrocytes was not significantly different between groups exposed to RF radiation and sham-exposed groups.

Vijayalaximi et al. [1999] exposed CF-1 male mice to ultra-wideband electromagnetic radiation (UWBR) for 15 min at an estimated whole-body average specific absorption rate of 37 mW/kg. Peripheral blood and bone marrow smears were examined to determine the extent of genotoxicity, as assessed by the presence of micronuclei (MN) in polychromatic erythrocytes (PCE). There was no evidence for excess genotoxicity in peripheral blood or bone marrow cells of mice exposed to UWBR.

Vijayalaximi et al. [2001a] reported that there was no evidence for the induction of micronuclei in peripheral blood and bone marrow cells of rats exposed for 24h to 2450-MHz continuous-wave microwaves at a whole body average SAR of 12 W/kg.

Vijayalaximi et al. [2001b] reported that there is no evidence for the induction of chromosomal aberrations and micronuclei in human blood lymphocytes exposed in vitro for 24 h to 835.62 MHz RF radiation at SARs of 4.4 or 5.0 W/kg.

Vijayalaximi et al. [2001c] reported no evidence for induction of chromosome aberrations and micronuclei in human blood lymphocytes exposed in vitro for 24 h to 847.74 MHz RF radiation (CDMA) at SARs of 4.9 or 5.5 W/kg.

Vijayalaximi et al. [2003] exposed timed-pregnant Fischer 344 rats (from nineteenth day of gestation) and their nursing offspring (until weaning) to a far-field 1.6 GHz Iridium wireless communication signal for 2 h/day, 7 days/week at power density of 0.43 mW/cm^2 and whole-body average specific absorption rate of 0.036 to 0.077 W/kg (0.10 to 0.22 W/kg in the brain). This was followed by chronic, head-only exposures of male and female offspring to a near-field 1.6 GHz signal for 2 h/day, 5 days/week, over 2 years. Near-field exposures were conducted at an SAR of 0.16 or 1.6 W/kg in the brain. At the end of 2 years, all rats were necropsied. Bone marrow smears were examined for the extent of genotoxicity, assessed from the presence of micronuclei in polychromatic erythrocytes. There was no evidence for excess genotoxicity in rats that were chronically exposed to 1.6 GHz microwaves compared to sham-exposed and cage controls.

Zeni et al. [2003] investigated the induction of micronucleus in human peripheral blood lymphocytes after exposure to electromagnetic fields at various duration of exposure, specific absorption rate (SAR), and signal [continuous-wave (CW) or GSM (Global System of Mobile Communication)-modulated signal]. No statistically significant difference was detected in any case.

IV. Chromosome and genome effects (21 studies total: 13 reported effects (62%) and 8 reported no significant effect (38%))

IV A. Chromosome and genome studies that reported effects:

Belyaev et al. [I992] studied the effect of low intensity microwaves on the conformational state of the genome of X-irradiated E. coli cells by the method of viscosity anomalous time dependencies. A power density of 1 $microW/cm^2$ is sufficient to suppress radiation-induced repair of the genome conformational state.

Belyaev et al. [1996] studied the effect of millimeter waves on the genome conformational state of E. coli AB1157 by the method of anomalous viscosity time dependencies in the frequency range of 51.64-51.85 GHz. Results indicate an electron-conformational interactions.

Belyaev et al. [2005] investigated response of lymphocytes from healthy subjects and from persons reporting hypersensitivity to microwaves from GSM mobile phone (915 MHz, specific absorption rate 37 mW/kg), and power frequency magnetic field (50 Hz, 15 microT peak value). Changes in chromatin conformation were measured with the method of anomalous viscosity time dependencies (AVTD). Exposure at room temperature to either 915 MHz or 50 Hz resulted in significant condensation of chromatin, shown as AVTD changes, which was similar to the effect of heat shock at 41 degrees C. No significant differences in responses between normal and hypersensitive subjects were detected.

Belyaev et al. [2006] investigated whether exposure of rat brain to microwaves of global system for mobile communication (GSM) induces DNA breaks, changes in chromatin conformation and in gene expression at a specific absorption rate (SAR) of 0.4 mW/g for 2 h. Data showed that GSM MWs at 915 MHz did not induce DNA double stranded breaks detectable by pulsed-field gel electrophoresis or changes in chromatin conformation, but affected expression of genes in rat brain cells.

Gadhia et al. [2003] reported a significant increase in dicentric chromosomes in blood cells among mobile users who were smoker–alcoholic as compared to nonsmoker–nonalcoholic; the same held true for controls of both types.

Garaj-Vrhovac et al. [1990] exposed V79 Chinese hamster cells to continuous-wave 7.7 GHz RFR at power density of 30 mW/cm^2 for 15, 30, and 60 min. Results suggest that the radiation causes changes in the synthesis as well as in the structure of DNA molecules.

Garaj-Vrhovac et al. [1991] exposed V79 Chinese hamster fibroblast cells to continuous wave 7.7 GHz radiation at power density of 0.5 mW/cm^2 for 15, 30 and 60 min. There was a significantly higher frequency of specific chromosome aberrations such as dicentric and ring chromosomes in irradiated cells.

Mashevich et al. [2003] found that human peripheral blood lymphocytes exposed to continuous 830-MHz electromagnetic fields (1.6-8.8 W/kg for 72 hr) showed a SAR-dependent chromosome aneuploidy, a major "somatic mutation" leading to genomic instability and thereby to cancer. The aneuploidy was accompanied by an abnormal mode of replication of the chromosome 17 region engaged in segregation (repetitive DNA arrays associated with the centromere), suggesting that epigenetic alterations are involved in the SAR dependent genetic toxicity. The effects were non-thermal.

Ono et al. (2004) exposed pregnant mice intermittently at a whole-body averaged specific absorption rate of 0.71 W/kg (10 seconds on, 50 seconds off which is 4.3 W/kg during the 10 seconds exposure) for 16 hours a day, from the embryonic age of 0 to 15 days. At 10 weeks of age, mutation frequencies at the lacZ gene in spleen, liver, brain, and testis were examined. Quality of mutation assessed by sequencing the nucleotides of mutant DNAs revealed no appreciable difference between exposed and non-exposed samples.

Sarimov et al. [2004] reported that exposure to microwaves of 895-915 MHz at 5.4 mW/kg resulted in statistically significant changes in condensation of chromatin in human lymphocytes. Effects are similar to stress response, differ at various frequencies, and vary among donors.

Sarkar et al. [1994] exposed mice to 2450-MHz microwaves at a power density of 1 mW/cm^2 for 2 h/day over a period of 120, 150 and 200 days. Rearrangement of DNA segments were observed in testis and brain of exposed animals.

Semin et al. [1995] exposed DNA samples at 18^oC at 10 different microwave frequencies (4- to 8 GHz, 25 ms pulses, 0.4 to 0.7 mW/cm^2 peak power, 1- to 6-Hz repetition rate, no heating). Irradiation at 3 or 4 Hz and 0.6 mW/cm^2 peak power clearly increased the accumulated damage to the DNA secondary structure ($P< .00001$). However, changing the pulse repetition rate to 1, 5, 6 Hz, as well as changing the peak power to 0.4 or 0.7 mW/cm^2 did not induce significant effect. Thus, the effect occurred only within narrow 'windows' of the peak intensities and modulation frequencies.

Sykes et al. [2001] exposed mice daily for 30 min to plane-wave fields of 900 MHz with a pulse repetition frequency of 217 Hz and a pulse width of 0.6 ms for 1, 5 or 25 days. Three days after the last exposure, spleen sections were screened for DNA inversion events. There was no significant difference between the control and treated groups in the 1- and 5-day exposure groups, but there was a significant reduction in inversions below the spontaneous frequency in the 25-day exposure group. This observation suggests that exposure to RF radiation can lead to a perturbation in recombination frequency which may have implications for recombination repair of DNA.

IV. B. Chromosome and genome studies that reported no significant effects:

Antonopoulos et al. [1997] found no significant change in cell cycle progression and the frequencies of sister-chromatid exchanges in human lymphocytes exposed to electromagnetic fields of 380, 900 and 1800 MHz.

Ciaravino et al. [1991] reported that RFR did not affect changes in cell progression caused by adriamycin, and the RFR did not change the number of sister chromatid exchanges that were induced by the adriamycin.

Garson et al. [1991] analyzed lymphocytes from Telecom Australia radio-linemen who had all worked with RFR in the range 400 kHz-20 GHz with exposures at or below the Australian occupational limits. There was no significant increase in chromosomal damage in circulating lymphocytes.

Gos et al. [2000] exposed actively growing and resting cells of the yeast Saccharomyces cerevisiae to 900-MHz Global System for Mobile Communication (GSM) pulsed modulation format signals at specific absorption rates (SAR) of 0.13 and 1.3 W/kg. They reported no significant effect of the fields on forward mutation rates on the frequency of petite formation, on rates of intrachromosomal deletion formation, or on rates of intragenic recombination in the absence or presence of the genotoxic agent methyl methansulfonate.

Kerbacher et al (1990) reported that exposure to pulsed 2450-MHz microwaves for 2 h at an SAR of 33.8 W/kg did not significantly cause chromosome aberrations in CHO cells. The radiation also did not interact with Mitomycin C and Adriamycin.

Komatsubara et al. [2005] reported that exposure to 2.45-GHz microwaves for 2 h with up to 100 W/kg SAR CW and an average 100 W/kg PW (a maximum SAR of 900 W/kg) did not induce chromosomal aberrations in mouse m5S cells.

Meltz et al. [1990] reported no significant mutagenic effect of exposure to 2.45-GHz RFR (40 W/kg) alone and interaction with proflavin, a DNA-intercalating drug, in L5178Y mouse leukemic cells.

Roti-Roti et al. [2001] reported no significant effect of exposure to radiofrequency radiation in the cellular phone communication range (835.62 MHz frequency division multiple access, FDMA; 847.74 MHz code division multiple access, CDMA) on neoplastic transformation frequency using the in vitro C3H 10T(1/2) cell transformation assay system.

Takahashi et al. [2002] exposed mice to 1.5 GHz EMF in the head region at 2.0, 0.67, and 0 W/kg specific absorption rate for 90 min/day, 5 days/week, for 4 weeks. No mutagenic effect in mouse brain cells was detected.

V. Conclusions

From this literature survey, since only 50% of the studies reported effects, it is apparent that there is no consistent pattern that radiofrequency radiation exposure could induce genetic damages/changes in cells and organisms. However, one can conclude that under certain conditions of exposure, radiofrequency radiation is genotoxic. Data available are mainly applicable only to cell phone radiation exposure. Other than the study by Phillips et al [1998], there is no indication that RFR at levels that one can experience in the vicinity of base stations and RF-transmission towers could cause DNA damage.

During cell phone use, a relatively constant mass of tissue in the brain is exposed to the radiation at relatively high intensity (peak SAR of 4 - 8 W/kg). Several studies reported DNA damage at lower than 4 W/kg. This questions the wisdom of the IEEE Committee in using 4 W/kg as the threshold of effect for exposure-standard setting. Furthermore, since critical genetic mutations in one single cell are sufficient to lead to cancer and there are millions of cells in a gram of tissue, it is inconceivable that the base of SAR standard was changed from averaged over 1 gm of tissue to 10 gm. (The limit of localized tissue exposure has been changed from 1.6 W/kg averaged over 1 gm of tissue to 2 W/kg over 10 gm of tissue. Since distribution of radiofrequency energy is non-homogenous inside tissue, this change allows a higher peak level of exposure.) What actually needed is a better refinement of SAR calculation to identify ‘peak values’ of SAR inside the brain,

Aside from influences that are not directly related to experimentation [Huss et al., 2007], many factors could influence the outcome of an experiment in bioelectromagnetics research.

Any effect of EMF has to depend on the energy absorbed by a biological entity and on how the energy is delivered in space and time. Frequency, intensity, exposure duration, and the number of exposure episodes can affect the response, and these factors can interact with each other to produce different effects. In addition, in order to understand the biological consequence of EMF exposure, one must know whether the effect is cumulative, whether compensatory responses result, and when homeostasis will break down. The contributions of these physical factors are discussed in a talk presented in

Vienna, Austria in 1998. The paper is posted in many websites (e.g., http://www.wave-guide.org/library/lai.html).

Thus, differences in outcomes of the research on genotoxic effects of RFR could be explained by the many different exposure conditions used in the studies. An example is the study of Phillips et al. [1998] showing that different cell phone signals could cause different effects on DNA (i.e., an increase in strand breaks with exposure to one type of signal and a decrease with another). This is further complicated by the fact that some of the studies listed above used very poor exposure procedures with very limited documentation of exposure parameters, e.g., using a cell phone to expose cells and even animals. Data from these experiments are questionable.

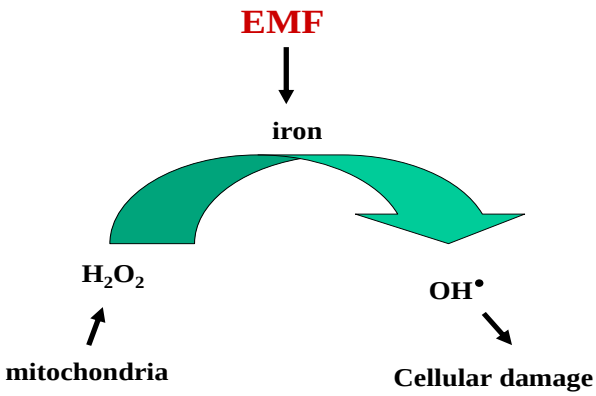
Another source of influence on an experimental outcome is the cell or organism studied. Many different biological systems were used in the genotoxicity studies. Different cell types [Hoyto et al., 2007] and organisms [Anderson et al., 2000; DiCarlo and Litovitz, 1999] may respond differently to EMF.

A few words have to be said on the 'comet assay', since it was used in most of the EMF studies to determine DNA damage. Different versions of the assay have been developed. These versions have different detection sensitivities and can be used to measure different aspects of DNA strand breaks. A comparison of data from experiments using different versions of the assay may be misleading. Another concern is that most of the 'comet assay' studies were carried out by experimenters who had no prior experience on the assay. My experience with the 'comet assay' is that it is a very sensitive assay and requires great care in performing. Thus, different detection sensitivities could result from different experimenters, even following the same procedures. One way to solve this experimental variation problem is for each researcher or laboratory to report their sensitivity of the 'comet assay', e.g., threshold of detecting strand breaks in human lymphocytes exposed to x-rays. This information is generally not available from the EMF-genotoxicity studies. However, in one incidence, an incredibly high sensitivity was even reported [Malyapa et al., 1998], suggesting the inexperience of the researchers on the assay.

A drawback in the interpretation and understanding of experimental data from bioelectromagnetic research is that there is no general acceptable mechanism on how EMF affects biological systems. The mechanism by which RFR causes genetic effect is unknown. Since the energy level is not sufficient to cause direct breakage of chemical bonds within molecules, the effects are probably indirect and secondary to other induced-chemical changes in the cell.

One possibility is via free radical formation inside cells. Free radicals kill cells by damaging macromolecules, such as DNA, protein and membrane. Several reports have indicated that electromagnetic fields (EMF) enhance free radical activity in cells [e.g., Lai and Singh, 1997a, b; 2004; Oral et al., 2006; Simko, 2007], particularly via the Fenton reaction [Lai and Singh, 2004]. The Fenton reaction is a catalytic process of iron

to convert hydrogen peroxides, a product of oxidative respiration in the mitochondria, into hydroxyl free radical, which is a very potent and toxic free radical.



THE FENTON REACTION

What is interesting that extremely-low frequency EMF has also been shown to cause DNA damage (see the list of papers on ELF EMF and DNA at the end of this chapter). Free radicals have also been implicated in this effect of ELF EMF. This further supports the view that EMF affects DNA via an indirect secondary process, since the energy content of ELF EMF is much lower than that of RFR.

Effects via the Fenton reaction predict how a cell would respond to EMF:

1. Cells that are metabolic active would be more susceptible to the effect because more hydrogen peroxide is generated by the mitochondria to fuel the reaction.

2. Cells that have high level of intracellular free iron would be more vulnerable. Cancer cells and cells undergoing abnormal proliferation have high concentration of free iron because they uptake more iron and have less efficient iron storage regulation. Thus, these cells could be selectively damaged by EMF, and EMF could potentially be used for the treatment of cancer and hyperplasia diseases. The effect could be further enhanced if one could shift anaerobic glycolysis of cancer cells to oxidative glycolysis. There is quite a large database of information on the effects of EMF (mostly in the ELF range) on cancer cells and tumors. The data tend to indicate that EMF could retard tumor growth and kill cancer cells.

3. Since the brain is exposed to rather high levels of EMF during cell phone use, the consequences of EMF-induced genetic damage in brain cells are of particular importance. Brain cells have high level of iron. Special molecular pumps are present on nerve cell nucleus membrane to pump iron into the nucleus. Iron atoms have been found to intercalate within DNA molecules. In addition, nerve cells have a low capability for DNA repair and DNA breaks could accumulate. Another concern is the presence of superparamagnetic iron-particles (magnetites) in body tissues,

particularly in the brain. These particles could enhance free radical activity in cells and cellular-damaging effects of EMF. These factors make nerve cells more vulnerable to EMF. Thus, the effect of EMF on DNA could conceivably be more significant on nerve cells than on other cell types of the body. Since nerve cells do not divide and are not likely to become cancerous, more likely consequences of DNA damage in nerve cells are changes in functions and cell death, which could either lead to or accelerate the development of neurodegenerative diseases. Double strand breaks, if not properly repaired, are known to lead to cell death. Cumulative DNA damage in nerve cells of the brain has been associated with neurodegenerative diseases, such as Alzheimer's, Huntington's, and Parkinson's diseases. However, another type of brain cells, the glial cells, can become cancerous, resulting from DNA damage. The question is whether the damaged cells would develop into tumors before they are killed by EMF due to over accumulation of genetic damages. The outcome depends on the interplay of these different physical and biological factors: an increase, decrease, or no significant change in cancer risk could result.

4. On the other hand, cells with high antioxidant potentials would be less susceptible to EMF. These include the amount of antioxidants and anti-oxidative enzymes in the cells. Furthermore, the effect of free radicals could depend on the nutritional status of an individual, e.g., availability of dietary antioxidants, consumption of alcohol, and amount of food consumption. Various life conditions, such as psychological stress and strenuous physical exercise, have been shown to increase oxidative stress and enhance the effect of free radicals in the body. Thus, one can also speculate that some individuals may be more susceptible to the effects of EMF exposure.

More research has to be carried out to prove the involvement of the free radicals in the biological effects of EMF. However, the Fenton reaction obviously can only explain some the genetic effects observed. For example, RF- and ELF EMF-induced DNA damages have been reported in normal lymphocytes, which contain a very low concentration of intracellular free iron.

APPENDIX 6-A
Abstracts on Effects of Extremely Low Frequency (ELF) EMF on DNA

27 (E)- effect reported; 14 (NE)- no significant effect reported

Ahuja YR, **Vijayashree B**, **Saran R**, **Jayashri EL**, **Manoranjani JK**, **Bhargava SC**. **In vitro effects of low-level, low-frequency electromagnetic fields on DNA damage in human leucocytes by comet assay.** Indian J Biochem Biophys. 36(5):318-322, 1999. (E)

The sources for the effects of electromagnetic fields (EMFs) have been traced to time-varying as well as steady electric and magnetic fields, both at low and high to ultra high frequencies. Of these, the effects of low-frequency (50/60 HZ) magnetic fields, directly related to time-varying currents, are of particular interest as exposure to some fields may be commonly experienced. In the present study, investigations have been carried out at low-level (mT) and low-frequency (50 Hz) electromagnetic fields in healthy human volunteers. Their peripheral blood samples were exposed to 5 doses of electromagnetic fields (2,3,5,7 and 10mT at 50 Hz) and analysed by comet assay. The results were compared to those obtained from unexposed samples from the same subjects. 50 cells per treatment per individual were scored for comet-tail length which is an estimate of DNA damage. Data from observations among males were pooled for each flux density for analysis. At each flux density, with one exception, there was a significant increase in the DNA damage from the control value. When compared with a similar study on females carried out by us earlier, the DNA damage level was significantly higher in the females as compared to the males for each flux density.

Cantoni O, **Sestili P**, **Fiorani M**, **Dacha M**. **Effect of 50 Hz sinusoidal electric and/or magnetic fields on the rate of repair of DNA single strand breaks in cultured mammalian cells exposed to three different carcinogens: methylmethane sulphonate, chromate and 254 nm U.V. radiation.** Biochem Mol Biol Int. 38(3):527-533, 1996. (NE)

Treatment of cultured mammalian cells with three different carcinogens, namely methylmethane sulphonate (MMS), chromate and 254 U.V. radiation, produces DNA single strand breaks (SSB) in cultured mammalian cells. The rate of removal of these lesions is not affected by exposure to 50 Hz electric (0.2 - 20 kV/m), magnetic (0.0002-0.2 mT), or combined electric and magnetic fields. These results indicate that, under the experimental conditions utilized in this study, 50 Hz electric, magnetic and electromagnetic fields (over a wide range of intensities) do not affect the machinery involved in the repair of DNA SSBs generated by different carcinogens in three different cultured mammalian cell lines, making it unlikely that field exposure enhances the ability of these carcinogens to induce transformation via inhibition of DNA repair.

Chahal R, **Craig DQ**, **Pinney RJ**. **Investigation of potential genotoxic effects of low frequency electromagnetic fields on Escherichia coli.** J Pharm Pharmacol. 45(1):30-33, 1993. (NE)

Exposure of growing cells of Escherichia coli strain AB1157 to a frequency of 1 Hz with field strengths of 1 or 3 kV m-1 did not affect spontaneous or ultraviolet light (UV)-induced mutation frequencies to rifampicin resistance. Neither did growth in the presence of charge alter the sensitivities of strains AB1157, TK702 umuC or TK501 umuC uvrB to UV. Similarly, although the resistance of strains TK702 umuC and TK501 umuC uvrB to UV was increased by the presence of plasmid pKM101, which carries DNA repair genes, pregrowth of plasmid-containing strains in electric fields did not increase UV resistance. Finally, growth in a low frequency field in the presence of sub-inhibitory concentrations of mitomycin C did not affect mitomycin C-induced mutation frequencies. It is concluded that low frequency electromagnetic fields do not increase spontaneous mutation, induce DNA repair or increase the mutagenic effects of UV or mitomycin C.

Chow K, **Tung WL** **Magnetic field exposure enhances DNA repair through the induction of DnaK/J synthesis.** FEBS Lett. 478(1-2):133-136, 2000. (E)

In contrast to the common impression that exposure to a magnetic field of low frequency causes mutations to organisms, we have demonstrated that a magnetic field can actually enhance the efficiency of DNA repair. Using Escherichia coli strain XL-1 Blue as the host and plasmid pUC8 that had been mutagenized by hydroxylamine as the vector for assessment, we found that bacterial transformants that had been exposed to a magnetic field of 50 Hz gave lower percentages of white colonies as compared to transformants that had not been exposed to the magnetic field. This result was indicative that the efficiency of DNA repair had been improved. The improvement was found to be mediated by the induced overproduction of heat shock proteins DnaK/J (Hsp70/40).

Delimaris J, **Tsilimigaki S**, **Messini-Nicolaki N**, **Ziros E**, **Piperakis SM** Effects of pulsed electric fields on DNA of human lymphocytes. Cell Biol Toxicol. 22(6):409-415, 2006. (E)

The effects of pulsed electric fields of low frequency (50 Hz) on DNA of human lymphocytes were investigated. The influence of additional external factors, such as hydrogen peroxide (H_2O_2) and gamma-irradiation, as well as the repair efficiency in these lymphocytes, was also evaluated. The comet assay, a very sensitive and rapid method for detecting DNA damage at the single cells level was the method used. A significant amount of damage was observed after exposure to the electric fields, compared to the controls. After 2 h incubation at 37 degrees C, a proportion of damage was repaired. H_2O_2 and gamma-irradiation increased the damage to lymphocytes exposed to pulsed electric fields according to the dose used, while the amount of the repair was proportional to the damage.

Fairbairn DW, **O'Neill KL** **The effect of electromagnetic field exposure on the formation of DNA single strand breaks in human cells.** Cell Mol Biol (Noisy-le-grand). 40(4):561-567, 1994. (NE)

Electromagnetic fields (EMF) have been reported to be associated with human cancers in a number of epidemiological studies. Agents that are associated with cancer affect DNA in an adverse manner. This is a report of a DNA damage study in human cells exposed to EMFs. Single strand breaks in DNA are proposed to be necessary events in both mutagenesis and carcinogenesis. The single cell gel assay is a sensitive and accurate technique that was used in this study for single strand break detection. The EMF exposure system used here appeared to have no direct effect on DNA damage induction in a series of experiments. Moreover, EMF did not have a significant effect in potentiating DNA damage in cells treated with oxidative stresses.

Fiorani M, **Cantoni O**, **Sestili P**, **Conti R**, **Nicolini P**, **Vetrano F**, **Dacha M**. **Electric and/or magnetic field effects on DNA structure and function in cultured human cells.** Mutat Res. 282(1):25-29, 1992. (NE)

Exposure of cultured K562 cells to 50 Hz electric (0.2-20 kV/m), magnetic (0.002-2 G), or combined electric and magnetic fields for up to 24 h did not result in the production of detectable DNA lesions, as assayed by the filter elution technique. The rate of cell growth was also unaffected as well as the intracellular ATP and NAD+ levels. These results indicate that, under the experimental conditions utilized in this study, 50 Hz electric, magnetic and electromagnetic fields are not geno- and cyto-toxic in cultured mammalian cells.

Frazier ME, **Reese JA**, **Morris JE**, **Jostes RF**, **Miller DL** **Exposure of mammalian cells to 60-Hz magnetic or electric fields: analysis of DNA repair of induced, single-strand breaks.** Bioelectromagnetics. 11(3):229-234, 1990. (NE)

DNA damage was induced in isolated human peripheral lymphocytes by exposure at 5 Gy to 60Co radiation. Cells were permitted to repair the DNA damage while exposed to 60-Hz fields or while sham-exposed. Exposed cells were subjected to magnetic (B) or electric (E) fields, alone or in combination, throughout their allotted repair time. Repair was stopped at specific times, and the cells were immediately lysed and then analyzed for the presence of DNA single-strand breaks (SSB) by the alkaline-elution technique. Fifty to 75 percent of the induced SSB were repaired 20 min after exposure, and most of the remaining damage was repaired after 180 min. Cells were exposed to a 60-Hz ac B field of 1 mT; an E field of 1 or 20 V/m; or combined E and B fields of 0.2 V/m and 0.05 mT, 6 V/m and 0.6 mT, or 20 V/m and 1 mT. None of the exposures was observed to affect significantly the repair of DNA SSB.

Hong R, **Zhang Y**, **Liu Y**, **Weng EQ**. [Effects of extremely low frequency electromagnetic fields on DNA of testicular cells and sperm chromatin structure in mice] Zhonghua Lao Dong Wei Sheng Zhi Ye Bing Za Zhi. 23(6):414-417, 2005. (E)

[Article in Chinese]

OBJECTIVE: To study the effects of 50 Hz electromagnetic fields (EMFs) on DNA of testicular cells and sperm chromatin structure in mice. METHODS: Mice were exposed to 50 Hz, 0.2 mT or 6.4 mT electromagnetic fields for 4 weeks. DNA strand breakage in testicular cells was detected by single-cell gel electrophoresis assay. Sperm chromatin structure was analyzed by sperm chromatin structure assay with flow cytometry. RESULTS: After 50 Hz, 0.2 mT or 6.4 mT EMFs exposure, the percentage of cells with DNA migration in total testicular cells increased from the control level of 25.64% to 37.83% and 39.38% respectively. The relative length of comet tail and the percentage of DNA in comet tail respectively increased from the control levels of 13.06% +/- 12.38% and 1.52% +/- 3.25% to 17.86% +/- 14.60% and 2.32% +/- 4.26% after 0.2 mT exposure and to 17.88% +/- 13.71% and 2.35% +/- 3.87% after 6.4 mT exposure ($P < 0.05$). Exposure to EMFs had not induced significant changes in S.D.alphaT and XalphaT, but COMPalphaT (cells outside the main population of alpha t), the percentage of sperms with abnormal chromatin structure, increased in the two exposed groups. CONCLUSION: 50 Hz EMFs may have the potential to induce DNA strand breakage in testicular cells and sperm chromatin condensation in mice.

Ivancsits S, **Pilger A**, **Diem E**, **Jahn O**, **Rudiger HW**.**Cell type-specific genotoxic effects of intermittent extremely low-frequency electromagnetic fields.** Mutat Res. 583(2):184-188, 2005. (E)

The issue of adverse health effects of extremely low-frequency electromagnetic fields (ELF-EMFs) is highly controversial. Contradictory results regarding the genotoxic potential of ELF-EMF have been reported in the literature. To test whether this controversy might reflect differences between the cellular targets examined we exposed cultured cells derived from different tissues to an intermittent ELF-EMF (50 Hz sinusoidal, 1 mT) for 1-24h. The alkaline and neutral comet assays were used to assess ELF-EMF-induced DNA strand breaks. We could identify three responder (human fibroblasts, human melanocytes, rat granulosa cells) and three non-responder cell types (human lymphocytes, human monocytes, human skeletal muscle cells), which points to the significance of the cell system used when investigating genotoxic effects of ELF-EMF.

Ivancsits S, **Diem E**, **Jahn O**, **Rudiger HW**. **Age-related effects on induction of DNA strand breaks by intermittent exposure to electromagnetic fields.** Mech Ageing Dev. 124(7):847-850, 2003. (E)

Several studies indicating a decline of DNA repair efficiency with age raise the question, if senescence per se leads to a higher susceptibility to DNA damage upon environmental exposures. Cultured fibroblasts of six healthy donors of different age exposed to intermittent ELF-EMF (50 Hz sinus, 1 mT) for 1-24 h exhibited different basal DNA strand break levels correlating with age. The cells revealed a maximum response at 15-19 h of exposure. This response was clearly more pronounced in cells from older donors,

which could point to an age-related decrease of DNA repair efficiency of ELF-EMF induced DNA strand breaks.

Ivancsits S, **Diem E**, **Pilger A**, **Rudiger HW**, **Jahn O**. **Induction of DNA strand breaks by intermittent exposure to extremely-low-frequency electromagnetic fields in human diploid fibroblasts.** Mutat Res. 519(1-2):1-13, 2002. (E)

Results of epidemiological research show low association of electromagnetic field (EMF) with increased risk of cancerous diseases and missing dose-effect relations. An important component in assessing potential cancer risk is knowledge concerning any genotoxic effects of extremely-low-frequency-EMF (ELF-EMF).Human diploid fibroblasts were exposed to continuous or intermittent ELF-EMF (50Hz, sinusoidal, 24h, 1000microT). For evaluation of genotoxic effects in form of DNA single- (SSB) and double-strand breaks (DSB), the alkaline and the neutral comet assay were used.In contrast to continuous ELF-EMF exposure, the application of intermittent fields reproducibly resulted in a significant increase of DNA strand break levels, mainly DSBs, as compared to non-exposed controls. The conditions of intermittence showed an impact on the induction of DNA strand breaks, producing the highest levels at 5min field-on/10min field-off. We also found individual differences in response to ELF-EMF as well as an evident exposure-response relationship between magnetic flux density and DNA migration in the comet assay.Our data strongly indicate a genotoxic potential of intermittent EMF. This points to the need of further studies in vivo and consideration about environmental threshold values for ELF exposure.

Ivancsits S, **Diem E**, **Pilger A**, **Rudiger HW**, **Jahn O**. **Induction of DNA strand breaks by intermittent exposure to extremely-low-frequency electromagnetic fields in human diploid fibroblasts.** Mutat Res. 519(1-2):1-13, 2002. (E)

Results of epidemiological research show low association of electromagnetic field (EMF) with increased risk of cancerous diseases and missing dose-effect relations. An important component in assessing potential cancer risk is knowledge concerning any genotoxic effects of extremely-low-frequency-EMF (ELF-EMF).Human diploid fibroblasts were exposed to continuous or intermittent ELF-EMF (50Hz, sinusoidal, 24h, 1000microT). For evaluation of genotoxic effects in form of DNA single- (SSB) and double-strand breaks (DSB), the alkaline and the neutral comet assay were used.In contrast to continuous ELF-EMF exposure, the application of intermittent fields reproducibly resulted in a significant increase of DNA strand break levels, mainly DSBs, as compared to non-exposed controls. Our data strongly indicate a genotoxic potential of intermittent EMF. This points to the need of further studies in vivo and consideration about environmental threshold values for ELF exposure.

Jajte J, **Zmyslony M**, **Palus J**, **Dziubaltowska E**, **Rajkowska E**. **Protective effect of melatonin against in vitro iron ions and 7 mT 50 Hz magnetic field-induced DNA damage in rat lymphocytes.** Mutat Res. 483(1-2):57-64, 2001. (E)

We have previously shown that simultaneous exposure of rat lymphocytes to iron ions and 50Hz magnetic field (MF) caused an increase in the number of cells with DNA strand breaks. Although the mechanism of MF-induced DNA damage is not known, we suppose that it involves free radicals. In the present study, to confirm our hypothesis, we have examined the effect of melatonin, an established free radicals scavenger, on DNA damage in rat peripheral blood lymphocytes exposed in vitro to iron ions and 50Hz MF. The alkaline comet assay was chosen for the assessment of DNA damage. During pre-incubation, part of the cell samples were supplemented with melatonin (0.5 or 1.0mM). The experiments were performed on the cell samples incubated for 3h in Helmholtz coils at 7mT 50Hz MF. During MF exposure, some samples were treated with ferrous chloride (FeCl2, 10microg/ml), while the rest served as controls. A significant increase in the number of cells with DNA damage was found only after simultaneous exposure of lymphocytes to FeCl2 and 7mT 50Hz MF, compared to the control samples or those incubated with FeCl2 alone. However, when the cells were treated with melatonin and then exposed to iron ions and 50Hz MF, the number of damaged cells was significantly reduced, and the effect depended on the concentration of melatonin. The reduction reached about 50% at 0.5mM and about 100% at 1.0mM. Our results indicate that melatonin provides protection against DNA damage in rat lymphocytes exposed in vitro to iron ions and 50Hz MF (7mT). Therefore, it can be suggested that free radicals may be involved in 50Hz magnetic field and iron ions-induced DNA damage in rat blood lymphocytes. The future experimental studies, in vitro and in vivo, should provide an answer to the question concerning the role of melatonin in the free radical processes in the power frequency magnetic field.

Kindzelskii AL, **Petty HR**. **Extremely low frequency pulsed DC electric fields promote neutrophil extension, metabolic resonance and DNA damage when phase-matched with metabolic oscillators.** Biochim Biophys Acta. 1495(1):90-111, 2000. (E)

Application of extremely low frequency pulsed DC electric fields that are frequency- and phase-matched with endogenous metabolic oscillations leads to greatly exaggerated neutrophil extension and metabolic resonance wherein oscillatory NAD(P)H amplitudes are increased. In the presence of a resonant field, migrating cell length grows from 10 to approximately 40 microm, as does the overall length of microfilament assemblies. In contrast, cells stop locomotion and become spherical when exposed to phase-mismatched fields. Although cellular effects were not found to be dependent on electrode type and buffer, they were sensitive to temporal constraints (phase and pulse length) and cell surface charge. We suggest an electromechanical coupling hypothesis wherein applied electric fields and cytoskeletal polymerization forces act together to overcome the surface/cortical tension of neutrophils, thus promoting net cytoskeletal assembly and heightened metabolic amplitudes. Metabolic resonance enhances reactive oxygen metabolic production by neutrophils. Furthermore, cellular DNA damage was observed

after prolonged metabolic resonance using both single cell gel electrophoresis ('comet' assay) and 3'-OH DNA labeling using terminal deoxynucleotidyl transferase. These results provide insights into transmembrane signal processing and cell interactions with weak electric fields.

Lai H, **Singh NP**. **Acute exposure to a 60 Hz magnetic field increases DNA strand breaks in rat brain cells.** Bioelectromagnetics. 18(2):156-165, 1997. (E)

Acute (2 h) exposure of rats to a 60 Hz magnetic field (flux densities 0.1, 0.25, and 0.5 mT) caused a dose-dependent increase in DNA strand breaks in brain cells of the animals (assayed by a microgel electrophoresis method at 4 h postexposure). An increase in single-strand DNA breaks was observed after exposure to magnetic fields of 0.1, 0.25, and 0.5 mT, whereas an increase in double-strand DNA breaks was observed at 0.25 and 0.5 mT. Because DNA strand breaks may affect cellular functions, lead to carcinogenesis and cell death, and be related to onset of neurodegenerative diseases, our data may have important implications for the possible health effects of exposure to 60 Hz magnetic fields.

Lai H, **Singh NP**. **Magnetic-field-induced DNA strand breaks in brain cells of the rat.** Environ Health Perspect. 112(6):687-694, 2004. (E)

In previous research, we found that rats acutely (2 hr) exposed to a 60-Hz sinusoidal magnetic field at intensities of 0.1-0.5 millitesla (mT) showed increases in DNA single- and double-strand breaks in their brain cells. Further research showed that these effects could be blocked by pretreating the rats with the free radical scavengers melatonin and N-tert-butyl-alpha-phenylnitrone, suggesting the involvement of free radicals. In the present study, effects of magnetic field exposure on brain cell DNA in the rat were further investigated. Exposure to a 60-Hz magnetic field at 0.01 mT for 24 hr caused a significant increase in DNA single- and double-strand breaks. Prolonging the exposure to 48 hr caused a larger increase. This indicates that the effect is cumulative. In addition, treatment with Trolox (a vitamin E analog) or 7-nitroindazole (a nitric oxide synthase inhibitor) blocked magnetic-field-induced DNA strand breaks. These data further support a role of free radicals on the effects of magnetic fields. Treatment with the iron chelator deferiprone also blocked the effects of magnetic fields on brain cell DNA, suggesting the involvement of iron. Acute magnetic field exposure increased apoptosis and necrosis of brain cells in the rat. We hypothesize that exposure to a 60-Hz magnetic field initiates an iron-mediated process (e.g., the Fenton reaction) that increases free radical formation in brain cells, leading to DNA strand breaks and cell death. This hypothesis could have an important implication for the possible health effects associated with exposure to extremely low-frequency magnetic fields in the public and occupational environments.

Lai H, **Singh NP**. **Melatonin and N-tert-butyl-alpha-phenylnitrone block 60-Hz magnetic field-induced DNA single and double strand breaks in rat brain cells.** J Pineal Res. 22(3):152-162, 1997. (E)

In previous research, we have found an increase in DNA single- and double-strand breaks in brain cells of rats after acute exposure (two hours) to a sinusoidal 60-Hz magnetic

field. The present experiment was carried out to investigate whether treatment with melatonin and the spin-trap compound N-tert-butyl-alpha-phenylnitrone (PBN) could block the effect of magnetic fields on brain cell DNA. Rats were injected with melatonin (1 mg/kg, sc) or PBN (100 mg/kg, ip) immediately before and after two hours of exposure to a 60-Hz magnetic field at an intensity of 0.5 mT. We found that both drug treatments blocked the magnetic field-induced DNA single- and double-strand breaks in brain cells, as assayed by a microgel electrophoresis method. Since melatonin and PBN are efficient free radical scavengers, these data suggest that free radicals may play a role in magnetic field-induced DNA damage.

Li SH, **Chow KC**. **Magnetic field exposure induces DNA degradation.** Biochem Biophys Res Commun. 280(5):1385-1388, 2001. (E)

In our earlier experiments, we discovered that magnetic field exposure could bring both stabilizing and destabilizing effects to the DNA of Escherichia coli, depending on our parameters of assessment, and both of these effects were associated with the induced synthesis of the heat shock proteins Hsp70/Hsp40 (DnaK/DnaJ). These contradicting results prompted us to explore in this study the effect of magnetic field exposure on the DNA stability in vivo when the heat shock response of the cell was suppressed. By using plasmid pUC18 in E. coli as the indicator, we found that without the protection of the heat shock response, magnetic field exposure indeed induced DNA degradation and this deleterious effect could be diminished by the presence of an antioxidant, Trolox C. In our in vitro test, we also showed that the magnetic field could potentiate the activity of oxidant radicals.

Lopucki M, **Schmerold I**, **Dadak A**, **Wiktor H**, **Niedermuller H**, **Kankofer M**. **Low dose magnetic fields do not cause oxidative DNA damage in human placental cotyledons in vitro.** Virchows Arch. 446(6):634-639, 2005. (NE)

The biological impact of low dose magnetic fields generated by electric appliances present in the human environment is still uncertain. In this study, human placentas served as a model tissue for the evaluation of the potential effect of oscillating low intensity magnetic fields on the concentration of 8-hydroxy-2'-deoxyguanosine (8-OH-dG) in cellular DNA. Cotyledons were dissected from placentas obtained immediately after physiological labours and exposed to magnetic fields (groups MF A, 2 mT, 50 Hz and MF B, 5 mT, 50 Hz) or sham exposed (group C) during an in vitro perfusion of 3 h. Cellular DNA was isolated, hydrolyzed and analyzed by HPLC. Native nucleosides were monitored at 254 nm and 8-OH-dG by electrochemical detection. Results were expressed as mumol 8-OH-dG/mol deoxyguanosine (dG). The concentrations of 8-OH-dG in group C, MF A and MF B were 28.45+/-15.27 micromol/mol dG, 62.80+/-31.91 mumol/mol dG, and 27.49+/-14.23 micromol/mol dG, respectively, demonstrating no significant difference between the groups. The results suggest that placental tissues possess a capacity to protect DNA against oxidative alterations by magnetic field of intensities previously shown to produce radical mediated DNA damage in rat brain cells in vivo and imbalances in electrolyte release of cotyledons under in vitro conditions.

Lourencini da Silva R, **Albano F**, **Lopes dos Santos LR**, **Tavares AD Jr**, **Felzenszwalb I**. **The effect of electromagnetic field exposure on the formation of DNA lesions.** Redox Rep. 5(5):299-301, 2000. (E)

In an attempt to determine whether electromagnetic field (EMF) exposure might lead to DNA damage, we exposed SnCl2-treated pBR322 plasmids to EMF and analysed the resulting conformational changes using agarose gel electrophoresis. An EMF-dependent potentiation of DNA scission (i.e. the appearance of relaxed plasmids) was observed. In confirmation of this, plasmids pre-exposed to EMF also were less capable of transforming Escherichia coli. The results indicate that EMF, in the presence of a transition metal, is capable of causing DNA damage. These observations support the idea that EMF, probably through secondary generation of reactive oxygen species, can be clastogenic and provide a possible explanation for the observed correlation between EMF exposure and the frequency of certain types of cancers in humans.

Extremely low-frequency electromagnetic fields do not affect DNA damage and gene expression profiles of yeast and human lymphocytes. Radiat Res. 164(3):277-285, 2005. (NE)

We studied the effects of extremely low-frequency (50 Hz) electromagnetic fields (EMFs) on peripheral human blood lymphocytes and DBY747 Saccharomyces cerevisiae. Graded exposure to 50 Hz magnetic flux density was obtained with a Helmholtz coil system set at 1, 10 or 100 microT for 18 h. The effects of EMFs on DNA damage were studied with the single-cell gel electrophoresis assay (comet assay) in lymphocytes. Gene expression profiles of EMF-exposed human and yeast cells were evaluated with DNA microarrays containing 13,971 and 6,212 oligonucleotides, respectively. After exposure to the EMF, we did not observe an increase in the amount of strand breaks or oxidated DNA bases relative to controls or a variation in gene expression profiles. The results suggest that extremely low-frequency EMFs do not induce DNA damage or affect gene expression in these two different eukaryotic cell systems.

McNamee JP, **Bellier PV**, **McLean JR**, **Marro L**, **Gajda GB**, **Thansandote A**. **DNA damage and apoptosis in the immature mouse cerebellum after acute exposure to a 1 mT, 60 Hz magnetic field.** Mutat Res. 513(1-2):121-133, 2002. (NE)

Several recent studies have reported that whole-body exposure of rodents to power frequency magnetic fields (MFs) can result in DNA single- and double-strand breaks in the brains of these animals. The current study was undertaken to investigate whether an acute 2h exposure of a 1 mT, 60 Hz MF could elicit DNA damage, and subsequently apoptosis, in the brains of immature (10-day-old) mice. DNA damage was quantitated at 0, 2, 4, and 24h after exposure using the alkaline comet assay. Apoptosis was quantitated in the external granule cell layer (EGCL) of the immature mouse cerebellum at 0 and 24h after exposure to MF by the TdT-mediated dUTP nick-end labeling (TUNEL) assay. Four

parameters (tail ratio, tail moment, comet length and tail length) were used to assess DNA damage for each comet. While increased DNA damage was detected by tail ratio at 2h after MF exposure, no supporting evidence of increased DNA damage was detected by the other parameters. In addition, no similar differences were observed using these parameters at any of the other post-exposure times. No increase in apoptosis was observed in the EGCL of MF-exposed mice, when compared to sham mice. Taken together, these results do not support the hypothesis that acute MF exposure causes DNA damage in the cerebellums of immature mice.

McNamee JP, **Bellier PV**, **Chauhan V**, **Gajda GB**, **Lemay E**, **Thansandote A**. Evaluating DNA damage in rodent brain after acute 60 Hz magnetic-field exposure. Radiat Res. 164(6):791-797, 2005. (NE)

In recent years, numerous studies have reported a weak association between 60 Hz magnetic-field exposure and the incidence of certain cancers. To date, no mechanism to explain these findings has been identified. The objective of the current study was to investigate whether acute magnetic-field exposure could elicit DNA damage within brain cells from both whole brain and cerebellar homogenates from adult rats, adult mice and immature mice. Rodents were exposed to a 60 Hz magnetic field (0, 0.1, 1 or 2 mT) for 2 h. Then, at 0, 2 and 4 h after exposure, animals were killed humanely, their brains were rapidly removed and homogenized, and cells were cast into agarose gels for processing by the alkaline comet assay. Four parameters (tail ratio, tail moment, comet length and tail length) were used to assess DNA damage for each comet. For each species, a significant increase in DNA damage was detected by each of the four parameters in the positive control (2 Gy X rays) relative to the concurrent nonirradiated negative and sham controls. However, none of the four parameters detected a significant increase in DNA damage in brain cell homogenates from any magnetic-field exposure (0- 2 mT) at any time after exposure. The dose-response and time-course data from the multiple animal groups tested in this study provide no evidence of magnetic-field-induced DNA damage.

Miyakoshi J, **Yoshida M**, **Shibuya K**, **Hiraoka M**. **Exposure to strong magnetic fields at power frequency potentiates X-ray-induced DNA strand breaks.** J Radiat Res (Tokyo). 41(3):293-302, 2000. (E)

We examined the effect of an extremely low-frequency magnetic field (ELFMF) at 5, 50 and 400 mT on DNA strand breaks in human glioma MO54 cells. A DNA damage analysis was performed using the method of alkaline comet assay. The cells were exposed to X-rays alone (5 Gy), ELFMF alone, or X-rays followed by ELFMF at 4 degrees C or on ice. No significant difference in the tail moment was observed between control and ELFMF exposures up to 400 mT. X-ray irradiation increased DNA strand breaks. When cells were exposed to X-rays followed by ELFMF at 50 and 400 mT, the tail moment increased significantly compared with that for X-rays alone. When the exposure of cells was performed at 37 degrees C, no significant change was observed between X-rays alone and X-rays plus 400 mT. We previously observed that exposure to

400 mT ELFMF for 2 h increased X-ray-induced mutations (Miyakoshi et al, Mutat. Res., 349: 109-114, 1996). Additionally, an increase in the mutation by exposure to the ELFMF was observed in cells during DNA-synthesizing phase (Miyakoshi et al., Int. J. Radiat. Biol., 71: 75-79, 1997). From these results, it appears that exposure to the high density ELFMF at more than 50 mT may potentiate X-ray-induced DNA strand breaks.

Moretti M, **Villarini M**, **Simonucci S**, **Fatigoni C**, **Scassellati-Sforzolini G**, **Monarca S**, **Pasquini R**, **Angelucci M**, **Strappini M** **Effects of co-exposure to extremely low frequency (ELF) magnetic fields and benzene or benzene metabolites determined in vitro by the alkaline comet assay.** Toxicol Lett. 157(2):119-128, 2005. (E)

In the present study, we investigated in vitro the possible genotoxic and/or co-genotoxic activity of 50 Hz (power frequency) magnetic fields (MF) by using the alkaline single-cell microgel-electrophoresis (comet) assay. Sets of experiments were performed to evaluate the possible interaction between 50 Hz MF and the known leukemogen benzene. Three benzene hydroxylated metabolites were also evaluated: 1,2-benzenediol (1,2-BD, catechol), 1,4-benzenediol (1,4-BD, hydroquinone), and 1,2,4-benzenetriol (1,2,4-BT). MF (1 mT) were generated by a system consisting of a pair of parallel coils in a Helmholtz configuration. To evaluate the genotoxic potential of 50 Hz MF, Jurkat cell cultures were exposed to 1 mT MF or sham-exposed for 1h. To evaluate the co-genotoxic activity of MF, the xenobiotics (benzene, catechol, hydroquinone, and 1,2,4-benzenetriol) were added to Jurkat cells subcultures at the beginning of the exposure time. In cell cultures co-exposed to 1 mT (50 Hz) MF, benzene and catechol did not show any genotoxic activity. However, co-exposure of cell cultures to 1 mT MF and hydroquinone led to the appearance of a clear genotoxic effect. Moreover, co-exposure of cell cultures to 1 mT MF and 1,2,4-benzenetriol led to a marked increase in the genotoxicity of the ultimate metabolite of benzene. The possibility that 50 Hz (power frequency) MF might interfere with the genotoxic activity of xenobiotics has important implications, since human populations are likely to be exposed to a variety of genotoxic agents concomitantly with exposure to this type of physical agent.

Nikolova T, **Czyz J**, **Rolletschek A**, **Blyszczuk P**, **Fuchs J**, **Jovtchev G**, **Schuderer J**, **Kuster N**, **Wobus AM**. **Electromagnetic fields affect transcript levels of apoptosis-related genes in embryonic stem cell-derived neural progenitor cells.** ASEB J. 19(12):1686-1688, 2005. (E)

Mouse embryonic stem (ES) cells were used as an experimental model to study the effects of electromagnetic fields (EMF). ES-derived nestin-positive neural progenitor cells were exposed to extremely low frequency EMF simulating power line magnetic fields at 50 Hz (ELF-EMF) and to radiofrequency EMF simulating the Global System for Mobile Communication (GSM) signals at 1.71 GHz (RF-EMF). Following EMF exposure, cells were analyzed for transcript levels of cell cycle regulatory, apoptosis-related, and neural-specific genes and proteins; changes in proliferation; apoptosis; and cytogenetic effects. Quantitative RT-PCR analysis revealed that ELF-EMF exposure to ES-derived neural cells significantly affected transcript levels of the apoptosis-related bcl-2, bax, and cell cycle regulatory "growth arrest DNA damage inducible" GADD45

genes, whereas mRNA levels of neural-specific genes were not affected. RF-EMF exposure of neural progenitor cells resulted in down-regulation of neural-specific Nurr1 and in up-regulation of bax and GADD45 mRNA levels. Short-term RF-EMF exposure for 6 h, but not for 48 h, resulted in a low and transient increase of DNA double-strand breaks. No effects of ELF- and RF-EMF on mitochondrial function, nuclear apoptosis, cell proliferation, and chromosomal alterations were observed. We may conclude that EMF exposure of ES-derived neural progenitor cells transiently affects the transcript level of genes related to apoptosis and cell cycle control. However, these responses are not associated with detectable changes of cell physiology, suggesting compensatory mechanisms at the translational and posttranslational level.

Reese JA, **Jostes RF**, **Frazier ME**. **Exposure of mammalian cells to 60-Hz magnetic or electric fields: analysis for DNA single-strand breaks.** Bioelectromagnetics. 9(3):237-247, 1998. (NE)

Chinese hamster ovary (CHO) cells were exposed for 1 h to 60-Hz magnetic fields (0.1 or 2 mT), electric fields (1 or 38 V/m), or to combined magnetic and electric fields (2 mT and 38 V/m, respectively). Following exposure, the cells were lysed, and the DNA was analyzed for the presence of single-strand breaks (SSB), using the alkaline elution technique. No significant differences in numbers of DNA SSB were detected between exposed and sham-exposed cells. A positive control exposed to X-irradiation sustained SSB with a dose-related frequency. Cells exposed to nitrogen mustard (a known cross-linking agent) and X-irradiation demonstrated that the assay could detect cross-linked DNA under our conditions of electric and magnetic field exposures.

Robison JG, **Pendleton AR**, **Monson KO**, **Murray BK**, **O'Neill KL**. **Decreased DNA repair rates and protection from heat induced apoptosis mediated by electromagnetic field exposure.** Bioelectromagnetics. 23(2):106-112, 2002. (E)

In this study, we demonstrate that electromagnetic field (EMF) exposure results in protection from heat induced apoptosis in human cancer cell lines in a time dependent manner. Apoptosis protection was determined by growing HL-60, HL-60R, and Raji cell lines in a 0.15 mT 60 Hz sinusoidal EMF for time periods between 4 and 24 h. After induction of apoptosis, cells were analyzed by the neutral comet assay to determine the percentage of apoptotic cells. To discover the duration of this protection, cells were grown in the EMF for 24 h and then removed for 24 to 48 h before heat shock and neutral comet assays were performed. Our results demonstrate that EMF exposure offers significant protection from apoptosis ($P<.0001$ for HL-60 and HL-60R, $P<.005$ for Raji) after 12 h of exposure and that protection can last up to 48 h after removal from the EMF. In this study we further demonstrate the effect of the EMF on DNA repair rates. DNA repair data were gathered by exposing the same cell lines to the EMF for 24 h before damaging the exposed cells and non-exposed cells with H2O2. Cells were allowed to repair for time periods between 0 and 15 min before analysis using the alkaline comet assay. Results showed that EMF exposure significantly decreased DNA repair rates in HL-60 and HL-60R cell lines ($P<.001$ and $P<.01$ respectively), but not in the Raji cell line. Importantly, our apoptosis results show that a minimal time exposure to an EMF is

needed before observed effects. This may explain previous studies showing no change in apoptosis susceptibility and repair rates when treatments and EMF exposure were administered concurrently. More research is necessary, however, before data from this in vitro study can be applied to in vivo systems.

Scarfi MR, **Sannino A**, **Perrotta A**, **Sarti M**, **Mesirca P**, **Bersani F**. **Evaluation of genotoxic effects in human fibroblasts after intermittent exposure to 50 Hz electromagnetic fields: a confirmatory study.** Radiat Res. 164(3):270-276, 2005. (NE)

The aim of this investigation was to confirm the main results reported in recent studies on the induction of genotoxic effects in human fibroblasts exposed to 50 Hz intermittent (5 min field on/10 min field off) sinusoidal electromagnetic fields. For this purpose, the induction of DNA single-strand breaks was evaluated by applying the alkaline single-cell gel electrophoresis (SCGE)/comet assay. To extend the study and validate the results, in the same experimental conditions, the potential genotoxicity was also tested by exposing the cells to a 50 Hz powerline signal (50 Hz frequency plus its harmonics). The cytokinesis-block micronucleus assay was applied after 24 h intermittent exposure to both sinusoidal and powerline signals to obtain information on cell cycle kinetics. The experiments were carried out on human diploid fibroblasts (ES-1). For each experimental run, exposed and sham-exposed samples were set up; positive controls were also provided by treating cells with hydrogen peroxide or mitomycin C for the comet or micronucleus assay, respectively. No statistically significant difference was detected in exposed compared to sham-exposed samples in any of the experimental conditions tested ($P > 0.05$). In contrast, the positive controls showed a statistically significant increase in DNA damage in all cases, as expected. Accordingly, our findings do not confirm the results reported previously for either comet induction or an increase in micronucleus frequency.

Schmitz C, **Keller E**, **Freuding T**, **Silny J**, **Korr H**. **50-Hz magnetic field exposure influences DNA repair and mitochondrial DNA synthesis of distinct cell types in brain and kidney of adult mice.** Acta Neuropathol (Berl). 107(3):257-264, 2004. (E)

Despite several recent investigations, the impact of whole-body magnetic field exposure on cell-type-specific alterations due to DNA damage and DNA repair remains unclear. In this pilot study adult mice were exposed to 50-Hz magnetic field (mean value 1.5 mT) for 8 weeks or left unexposed. Five minutes after ending exposure, the mice received [(3)H]thymidine and were killed 2 h later. Autoradiographs were prepared from paraffin sections of brains and kidneys for measuring unscheduled DNA synthesis and mitochondrial DNA synthesis, or in situ nick translation with DNA polymerase-I and [(3)H]dTTP. A significant ($P<0.05$) increase in both unscheduled DNA synthesis and in situ nick translation was only found for epithelial cells of the choroid plexus. Thus, these two independent methods indicate that nuclear DNA damage is produced by long-lasting and strong magnetic field exposure. The fact that only plexus epithelial cells were affected might point to possible effects of magnetic fields on iron transport across the blood-cerebrospinal fluid barrier, but the mechanisms are currently not understood. Mitochondrial DNA synthesis was exclusively increased in renal epithelial cells of distal

convoluted tubules and collecting ducts, i.e., cells with a very high content of mitochondria, possibly indicating increased metabolic activity of these cells.

Singh N, **Lai H**. **60 Hz magnetic field exposure induces DNA crosslinks in rat brain cells.** Mutat Res. 400(1-2):313-320, 1998. (E)

In previous research, we found an increase in DNA strand breaks in brain cells of rats acutely exposed to a 60 Hz magnetic field (for 2 h at an intensity of 0.5 mT). DNA strand breaks were measured with a microgel electrophoresis assay using the length of DNA migration as an index. In the present experiment, we found that most of the magnetic field-induced increase in DNA migration was observed only after proteinase-K treatment, suggesting that the field caused DNA-protein crosslinks. In addition, when brain cells from control rats were exposed to X-rays, an increase in DNA migration was observed, the extent of which was independent of proteinase-K treatment. However, the X-ray-induced increase in DNA migration was retarded in cells from animals exposed to magnetic fields even after proteinase-K treatment, suggesting that DNA-DNA crosslinks were also induced by the magnetic field. The effects of magnetic fields were also compared with those of a known DNA crosslink-inducing agent mitomycin C. The pattern of effects is similar between the two agents. These data suggest that both DNA-protein and DNA-DNA crosslinks are formed in brain cells of rats after acute exposure to a 60 Hz magnetic field.

Stronati L, **Testa A**, **Villani P**, **Marino C**, **Lovisolo GA**, **Conti D**, **Russo F**, **Fresegna AM**, **Cordelli E** **Absence of genotoxicity in human blood cells exposed to 50 Hz magnetic fields as assessed by comet assay, chromosome aberration, micronucleus, and sister chromatid exchange analyses.** Bioelectromagnetics. 25(1):41-48, 2004. (NE)

In the past, epidemiological studies indicated a possible correlation between the exposure to ELF fields and cancer. Public concern over possible hazards associated with exposure to extremely low frequency magnetic fields (ELFMFs) stimulated an increased scientific research effort. More recent research and laboratory studies, however, have not been able to definitively confirm the correlation suggested by epidemiological studies. The aim of this study was to evaluate the effects of 50 Hz magnetic fields in human blood cells exposed in vitro, using several methodological approaches for the detection of genotoxicity. Whole blood samples obtained from five donors were exposed for 2 h to 50 Hz, 1 mT uniform magnetic field generated by a Helmholtz coil system. Comet assay, sister chromatid exchanges (SCE), chromosome aberrations (CA), and micronucleus (MN) tests were used to assess DNA damage, one hallmark of malignant cell transformation. The effects of a combined exposure with X-rays were also evaluated. Results obtained do not show any significant difference between ELFMFs exposed and unexposed samples. Moreover, no synergistic effect with ionizing radiation has been observed. A slight but significant decrease of cell proliferation was evident in ELFMFs treated samples and samples subjected to the combined exposure.

Svedenstal BM, **Johanson KJ**, **Mild KH**. **DNA damage induced in brain cells of CBA mice exposed to magnetic fields.** In Vivo. 13(6):551-552, 1999. (E)

DNA migration, using single cell gel electrophoresis (comet assay), was studied on brain cells of CBA mice exposed continuously to 50 Hz, 0.5 mT magnetic fields (MF) for 2 hrs, 5 days or 14 days. No differences were observed in the groups MF-exposed for 2 hrs and 5 days compared with controls. However, in the group exposed to MF for 14 days, a significantly extended cell DNA migration was observed ($0.02 < p < 0.05$). These changes together with results from previous studies indicate that magnetic fields may have genotoxic effects in brain cells.

Testa A, **Cordelli E**, **Stronati L**, **Marino C**, **Lovisolo GA**, **Fresegna AM**, **Conti D**, **Villani P**. **Evaluation of genotoxic effect of low level 50 Hz magnetic fields on human blood cells using different cytogenetic assays.** Bioelectromagnetics. 25(8):613-619, 2004. (NE)

The question whether extremely low frequency magnetic fields (ELFMFs) may contribute to mutagenesis or carcinogenesis is of current interest. In order to evaluate the possible genotoxic effects of ELFMFs, human blood cells from four donors were exposed in vitro for 48 h to 50 Hz, 1 mT uniform magnetic field generated by a Helmholtz coil system. Comet assay (SCGE), sister chromatid exchanges (SCE), chromosome aberrations (CAs), and micronucleus (MN) test were used to assess the DNA damage. ELF pretreated cells were also irradiated with 1 Gy of X-ray to investigate the possible combined effect of ELFMFs and ionizing radiation. Furthermore, nuclear division index (NDI) and proliferation index (PRI) were evaluated. Results do not evidence any DNA damage induced by ELFMF exposure or any effect on cell proliferation. Data obtained from the combined exposure to ELFMFs and ionizing radiation do not suggest any synergistic or antagonistic effect.

Villarini M, **Moretti M**, **Scassellati-Sforzolini G**, **Boccioli B**, **Pasquini R**. Effects of co-exposure to extremely low frequency (50 Hz) magnetic fields and xenobiotics determined in vitro by the alkaline comet assay. Sci Total Environ. 361(1-3):208-219, 2006. (E)

In the present study, we used human peripheral blood leukocytes from 4 different donors, to investigate in vitro the possible genotoxic and/or co-genotoxic activity of extremely low frequency magnetic fields (ELF-MF) at 3 mT intensity. Two model mutagens were used to study the possible interaction between ELF-MF and xenobiotics: N-methyl-N'-nitro-N-nitrosoguanidine (MNNG) and 4-nitroquinoline N-oxide (4NQO). Primary DNA damage was evaluated by the alkaline single-cell microgel-electrophoresis ("comet") assay. Control cells (leukocytes not exposed to ELF-MF, nor treated with genotoxins) from the different blood donors showed a comparable level of basal DNA damage, whereas the contribution of individual susceptibility toward ELF-MF and the tested genotoxic compounds led to differences in the extent of DNA damage observed following exposure to the genotoxins, both in the presence and in the absence of an applied ELF-MF. A 3 mT ELF-MF alone was unable to cause direct primary DNA damage. In leukocytes exposed to ELF-MF and genotoxins, the extent of MNNG-induced DNA damage increased with exposure duration compared to sham-exposed cells. The

opposite was observed in cells treated with 4NQO. In this case the extent of 4NQO-induced DNA damage was somewhat reduced in leukocytes exposed to ELF-MF compared to sham-exposed cells. Moreover, in cells exposed to ELF-MF an increased concentration of GSH was always observed, compared to sham-exposed cells. Since following GSH conjugation the genotoxic pattern of MNNG and 4NQO is quite different, an influence of ELF-MF on the activity of the enzyme involved in the synthesis of GSH leading to different activation/deactivation of the model mutagens used was hypothesized to explain the different trends observed in MNNG and 4NQO genotoxic activity in the presence of an applied ELF-MF. The possibility that ELF-MF might interfere with the genotoxic activity of xenobiotics has important implications, since human populations are likely to be exposed to a variety of genotoxic agents concomitantly with exposure to this type of physical agent.

Williams PA, **Ingebretsen RJ**, **Dawson RJ**. 14.6 mT ELF magnetic field exposure yields no DNA breaks in model system Salmonella, but provides evidence of heat stress protection. Bioelectromagnetics. 27(6):445-450, 2006. (NE)

In this study, we demonstrate that common extremely low frequency magnetic field (MF) exposure does not cause DNA breaks in this Salmonella test system. The data does, however, provide evidence that MF exposure induces protection from heat stress. Bacterial cultures were exposed to MF (14.6 mT 60 Hz field, cycled 5 min on, 10 min off for 4 h) and a temperature-matched control. Double- and single-stranded DNA breaks were assayed using a recombination event counter. After MF or control exposure they were grown on indicator plates from which recombination events can be quantified and the frequency of DNA strand breaks deduced. The effect of MF was also monitored using a recombination-deficient mutant (recA). The results showed no significant increase in recombination events and strand breaks due to MF. Evidence of heat stress protection was determined using a cell viability assay that compared the survival rates of MF exposed and control cells after the administration of a 10 min 53 degrees C heat stress. The control cells exhibited nine times more cell mortality than the MF exposed cells. This Salmonella system provides many mutants and genetic tools for further investigation of this phenomenon.

Winker R, **Ivancsits S**, **Pilger A**, **Adlkofer F**, **Rudiger HW**. **Chromosomal damage in human diploid fibroblasts by intermittent exposure to extremely low-frequency electromagnetic fields.** Mutat Res. 585(1-2):43-49, 2005. (E)

Environmental exposure to extremely low-frequency electromagnetic fields (ELF-EMFs) has been implicated in the development of cancer in humans. An important basis for assessing a potential cancer risk due to ELF-EMF exposure is knowledge of biological effects on human cells at the chromosomal level. Therefore, we investigated in the present study the effect of intermittent ELF electromagnetic fields (50 Hz, sinusoidal, 5'field-on/10'field-off, 2-24 h, 1 mT) on the induction of micronuclei (MN) and chromosomal aberrations in cultured human fibroblasts. ELF-EMF radiation resulted in a time-dependent increase of micronuclei, which became significant after 10 h of intermittent exposure at a flux density of 1 mT. After approximately 15 h a constant level

of micronuclei of about three times the basal level was reached. In addition, chromosomal aberrations were increased up to 10-fold above basal levels. Our data strongly indicate a clastogenic potential of intermittent low-frequency electromagnetic fields, which may lead to considerable chromosomal damage in dividing cells.

Wolf FI, **Torsello A**, **Tedesco B**, **Fasanella S**, **Boninsegna A**, **D'Ascenzo M**, **Grassi C**, **Azzena GB**, **Cittadini A**. **50-Hz extremely low frequency electromagnetic fields enhance cell proliferation and DNA damage: possible involvement of a redox mechanism.** Biochim Biophys Acta. 1743(1-2):120-129, 2005. (E)

HL-60 leukemia cells, Rat-1 fibroblasts and WI-38 diploid fibroblasts were exposed for 24-72 h to 0.5-1.0-mT 50-Hz extremely low frequency electromagnetic field (ELF-EMF). This treatment induced a dose-dependent increase in the proliferation rate of all cell types, namely about 30% increase of cell proliferation after 72-h exposure to 1.0 mT. This was accompanied by increased percentage of cells in the S-phase after 12- and 48-h exposure. The ability of ELF-EMF to induce DNA damage was also investigated by measuring DNA strand breaks. A dose-dependent increase in DNA damage was observed in all cell lines, with two peaks occurring at 24 and 72 h. A similar pattern of DNA damage was observed by measuring formation of 8-OHdG adducts. The effects of ELF-EMF on cell proliferation and DNA damage were prevented by pretreatment of cells with an antioxidant like alpha-tocopherol, suggesting that redox reactions were involved. Accordingly, Rat-1 fibroblasts that had been exposed to ELF-EMF for 3 or 24 h exhibited a significant increase in dichlorofluorescein-detectable reactive oxygen species, which was blunted by alpha-tocopherol pretreatment. Cells exposed to ELF-EMF and examined as early as 6 h after treatment initiation also exhibited modifications of NF kappa B-related proteins (p65-p50 and I kappa B alpha), which were suggestive of increased formation of p65-p50 or p65-p65 active forms, a process usually attributed to redox reactions. These results suggest that ELF-EMF influence proliferation and DNA damage in both normal and tumor cells through the action of free radical species. This information may be of value for appraising the pathophysiologic consequences of an exposure to ELF-EMF.

Yaguchi H, **Yoshida M**, **Ejima Y**, **Miyakoshi J**. **Effect of high-density extremely low frequency magnetic field on sister chromatid exchanges in mouse m5S cells.** Mutat Res. 440(2):189-194, 1999. (E)

The induction of sister chromatid exchanges (SCEs) was evaluated in the cultured mouse m5S cells after exposure to extremely low frequency magnetic field (ELFMF; 5, 50 and 400 mT). Exposure to 5 mT and 50 mT ELFMF led to a very small increase in the frequency of SCEs, but no significant difference was observed between exposed and unexposed control cells. The cells exposed to 400 mT ELFMF exhibited a significant elevation of the SCE frequencies. There was no significant difference between data from treatments with mitomycin-C (MMC) alone and from combined treatments of MMC plus ELFMF (400 mT) at any MMC concentrations from 4 to 40 nM. These results suggest that exposure to highest-density ELFMF of 400 mT may induce DNA damage, resulting

in an elevation of the SCE frequencies. We suppose that there may be a threshold for the elevation of the SCE frequencies, that is at least over the magnetic density of 50 mT.

Yokus B, **Cakir DU**, **Akdag MZ**, **Sert C**, **Mete N**. **Oxidative DNA damage in rats exposed to extremely low frequency electro magnetic fields.** Free Radic Res. 39(3):317-323, 2005. (E)

Extremely low frequency (ELF) electromagnetic field (EMF) is thought to prolong the life of free radicals and can act as a promoter or co-promoter of cancer. 8-hydroxy-2'-deoxyguanosine (8OHdG) is one of the predominant forms of radical-induced lesions to DNA and is a potential tool to asses the cancer risk. We examined the effects of extremely low frequency electro magnetic field (ELF-EMF) (50 Hz, 0.97 mT) on 8OHdG levels in DNA and thiobarbituric acid reactive substances (TBARS) in plasma. To examine the possible time-dependent changes resulting from magnetic field, 8OHdG and TBARS were quantitated at 50 and 100 days. Our results showed that the exposure to ELF-EMF induced oxidative DNA damage and lipid peroxidation (LPO). The 8OHdG levels of exposed group (4.39+/-0.88 and 5.29+/-1.16 8OHdG/dG.10(5), respectively) were significantly higher than sham group at 50 and 100 days (3.02+/-0.63 and 3.46+/-0.38 8OHdG/dG.10(5)) ($p<0.001$, $p<0.001$). The higher TBARS levels were also detected in the exposure group both on 50 and 100 days ($p<0.001$, $p<0.001$). In addition, the extent of DNA damage and LPO would depend on the exposure time ($p<0.05$ and $p<0.05$). Our data may have important implications for the long-term exposure to ELF-EMF which may cause oxidative DNA damage.

Zmyslony M, **Palus J**, **Jajte J**, **Dziubaltowska E**, **Rajkowska E**. **DNA damage in rat lymphocytes treated in vitro with iron cations and exposed to 7 mT magnetic fields (static or 50 Hz).** Mutat Res. 453(1):89-96, 2000. (E)

The present study was undertaken to verify a hypothesis that exposure of the cells to static or 50 Hz magnetic fields (MF) and simultaneous treatment with a known oxidant, ferrous chloride, may affect the oxidative deterioration of DNA molecules.The comet assay was chosen for the assessment of DNA damage. The experiments were performed on isolated rat lymphocytes incubated for 3h in Helmholtz coils at 7 mT static or 50 Hz MF. During MF exposure, part of the cell samples were incubated with 0.01 microM H(2)O(2) and another one with 10 microg/ml FeCl(2,) the rest serving as controls.Lymphocyte exposure to MF at 7 mT did not increase the number of cells with DNA damage in the comet assay. Incubation of lymphocytes with 10 microg/ml FeCl(2) did not produce a detectable damage of DNA either. However, when the FeCl(2)-incubated lymphocytes were simultaneously exposed to 7 mT MF, the number of damaged cells was significantly increased and reached about 20% for static MF and 15% for power frequency MF. In the control samples about 97% of the cells did not have any DNA damage.It is not possible at present to offer a reasonable explanation for the findings of this investigation - the high increase in the number of lymphocytes showing symptoms of DNA damage in the comet assay, following simultaneous exposure to the

combination of two non-cytotoxic factors -10 microg/ml FeCl(2) and 7 mT MF. In view of the obtained results we can only hypothesise that under the influence of simultaneous exposure to FeCl(2) and static or 50 Hz MF, the number of reactive oxygen species generated by iron cations may increase substantially. Further studies will be necessary to confirm this hypothesis and define the biological significance of the observed effect.

Zmyslony M, **Palus J**, **Dziubaltowska E**, **Politanski P**, **Mamrot P**, **Rajkowska E**, **Kamedula M**. **Effects of in vitro exposure to power frequency magnetic fields on UV-induced DNA damage of rat lymphocytes.** Bioelectromagnetics. 25(7):560-562, 2004. (E)

The mechanisms of biological effects of 50/60 Hz (power frequency) magnetic fields (MF) are still poorly understood. There are a number of studies indicating that MF affect biochemical processes in which free radicals are involved, such as the biological objects' response to ultraviolet radiation (UVA). Therefore, the present study was aimed to assess the effect of 50 Hz MFs on the oxidative deterioration of DNA in rat lymphocytes irradiated in vitro by UVA. UVA radiation (150 J/m2) was applied for 5 min for all groups and 50 Hz MF (40 microT rms) exposure was applied for some of the groups for 5 or 60 min. The level of DNA damage was assessed using the alkaline comet assay, the fluorescence microscope, and image analysis. It has been found that the 1 h exposure to MF caused an evident increase in all parameters consistent with damaged DNA. This suggest that MF affects the radical pairs generated during the oxidative or enzymatic processes of DNA repair.

SECTION 6

Genetic Effects of Non-Ionizing Electromagnetic Fields

2014 Supplement

Prof. Henry Lai, PhD (Ret.)
Department of Bioengineering
University of Washington
Seattle, WA USA

Prepared for the BioInitiative Working Group
March 2014

I. INTRODUCTION

The following is an update of information and abstracts on research papers published since 2006/2007 on the genetic effects of nonionizing electromagnetic fields (EMF) in the radiofrequency (RF) and extremely-low frequency (ELF) ranges. Two static magnetic field papers (Jouni et al. 2012; Wang et al., 2009) are also included. Where additional information is relevant, some earlier papers, or papers not specifically related to genetic effects, are also included with citations contained within the discussion below. A list of abstracts, with summary sentences underlined for reader convenience, can be found at the end of this paper.

Analysis of these recent publications shows that there are more papers reporting effects than no effect.

In summary, the new radiofrequency studies report that 65% of genetic studies show effects and 35% do not show effects. **[Effects = 74 (65%) No Effects = 40 (35%)]**

In summary, the new ELF-EMF studies report that 82% of genetic studies show effects and 18% do not show effects **[Effects= 49 (83%) No Effects= 10 (17%)]**

Appendix A has references and abstracts for the RFR literature. Appendix B has references and abstracts for the ELF-EMF literature.

II. GENOTOXIC EFFECTS OF RADIOFREQUENCY RADIATION (RFR) AND OF EXTREMELY LOW FREQUENCY ELECTROMAGNETIC FIELDS (ELF-EMF) (2007-2014)

The following is an update of information and abstracts on research papers published since 2006/2007 on the genetic effects of nonionizing electromagnetic fields (EMF) in the radiofrequency (RF) and extremely-low frequency (ELF) ranges. Two static magnetic field papers (Jouni et al. 2012; Wang et al., 2009) are also included. Where additional information is relevant, some earlier papers, or papers not specifically related to genetic effects, are also included with citations contained within the discussion below. A list of abstracts, with summary sentences underlined for reader convenience, can be found at the end of this paper.

Analysis of these recent publications shows that there are more papers reporting effects than no effect. With E representing a biological effect, and NE representing no biological effects, the recent literature finds RFR-genetic effects at: E=74 publications (65%); NE=40 publications (35%); and ELF-genetic effects at: E=49 (83%); NE=10 (17%).

Discussion

1. The effects of both RF and ELF fields are very similar. This is surprising because the energies carried by these EMFs are billions of folds different. An explanation for similar genetic effects has been provided by a recent paper by Blank and Goodman (Blank M, Goodman R. DNA is a fractal antenna in electromagnetic fields. Int. J. Radiat. Biol. 87(4):409-415, 2011) in which they stated that '…the wide frequency range of interaction with EMF is the functional characteristic of a fractal antenna, and DNA appears to possess the two structural characteristics of fractal antennas, electronic conduction and self symmetry.' However, similarities in effects between ELF and RF fields have also been reported in studies of other physiological processes, e.g., neurochemical and behavioral effects (Cf. Lai, H., Carino, M.A., Horita, A. and Guy, A.W. Opioid receptor subtypes that mediate a microwave-induced decrease in central cholinergic activity in the rat. Bioelectromagnetics 13:237-246, 1992; Lai, H. and Carino, M.A. Intracerebroventricular injections of mu and delta-opiate receptor antagonists block 60-Hz magnetic field-induced decreases in cholinergic activity in the frontal cortex and hippocampus of the rat. Bioelectromagnetics 19:433-437, 1998; Lai, H., Carino, M.A. and Ushijima, I. Acute exposure to a 60 Hz magnetic field affects rats' performance in the water maze. Bioelectromagnetics 19:117-122, 1998; Wang, B.M. and Lai, H. Acute exposure to pulsed 2450-MHz microwaves affects water maze learning in the rat. Bioelectromagnetics 21:52-56, 2000.) Thus, there is a basic interaction mechanism of biological tissues with electromagnetic fields that is independent of frequency.
Many studies have implicated the involvement of free radical processes in the genetic effects of EMF: ELF-EMF (Butdak et al., 2012; Jouni et al., 2012; Luukkonen et al., 2014; Tiwari et al.,2014); RFR (Agarwal et al., 2009; Atasoy et al., 2012; Burlaka et al., 2013; Campisi et al., 2010; De Iuliis et al., 2009; Esmekaya et al., 2011; Ferreira et al., 2006; Gajski and Garaj-Vrhovac, 2009; Garaj-Vrhovac et al., 2011; Guler et al., 2010, 2012; Kesari and Behari, 2009; Kesari et al., 2010; Khalil et al., 2012; Kumar et al., 2010; Liu et al., 2013a,b; Luukkonan et al., 2009; Tomruk et al., 2010; Tkalec et al., 2013; Wu et al., 2008; Xu et al., 2010; Yao et al., 2003). Increase in free radical activity and changes in enzymes involved in cellular oxidative processes are the most consistent effects observed in cells and animals after EMF exposure. However, they are reports indicating that EMF could induce genetic effects without the involvement of free radicals (ELF- Alcaraz et al., 2013; RFR- Ferreira et al., 2006; Furtado-Filho et al., 2013) and increase in free radical after EMF exposure did not lead to genetic effects (Frahm et al., 2006). There are at least a couple of hundred published papers on the effects of EMF exposure on cellular oxidative processes. Many biological effects of EMF can be explained by intracellular changes in oxidative status, including the genetic effects reported in this review.

2. An important observation of the studies is that EMF can interact with other entities and synergistically cause genetic effects. These entities include: ELF-EMF- cisplastin (Buldak et al., 2012; El-Bialy et al., 2013), bleomycin (Cho et al., 2007), gadolinium (Cho et al., 2014); hydrogen peroxide and methyl methane sulfonate (Koyama et al., 2008), menadione (Luukkonan et al., 2011, 2014; Markkanen et al., 2008), ionizing radiation (Mairs et al., 2007; Journi et al., 2012 Yoon et al., 2014); RFR- chemical

mutagens (Baohong et al., 2005), clastogens (Kim et al., 2008), x-rays (Manti et al., 2008), ultraviolet ray (Baohong et al., 2007), aphidicolin (Tiwari et al., 2008), picrotoxin (López-Martín et al., 2009), doxorubicin (Zhijian et al., 2010), and incoherent electromagnetic noise (Wu et al., 2008; Yao et al., 2008). Most of the compounds that interact with EMF are mutagens. This is important because in real life situations, a person is usually exposed to many different environmental factors simultaneously. Synergism of these factors with EMF should be considered more seriously.

3. Several long term/repeated exposure papers are included in this update: ELF-EMF (Borhani et al., 2011; Cuccurazzu et al., 2010; Erdal et al., 2007; Fedrowitz and Loscher, 2012; Mariucci et al., 2010; Panagopoulous et al., 2013; Udroiu et al., 2006), and RFR (Asasoy et al., 2012; Atli Serkeroglu et al., 2013; Burlaka et al., 2013; Chavdoula et al., 2010; Deshmukh et al., 2013; Ferreira et al., 2006; Garaj-Vrhovac et al., 2011; Guler et al., 2010, 2012; Kesari and Behari, 2009; Kesari et al., 2010; Lakshmi et al., 2010; Paulraj and Behari, 2006; Tomruk et al., 2010; Yan et al., 2008). These data are important in the understanding of the biological effects of EMF exposure in real life situation, since human environmental EMF exposure is both chronic and intermittent. Within these long-term exposure studies, there are several that investigated the effect of EMF exposure on developing animals (ELF-EMF: Borhani et al., 2011; Cuccurazzu et al., 2010; Panagopoulous et al., 2013; Udroiu et al., 2006, RFR: Burlaka et al., 2013; Ferreira et al., 2006; Guler et al., 2010, 2012; Serkeroglu et al., 2013; Tomruk et al., 2010; Zalata et al., In press). Data of effects of EMF exposure on growth and development of young animals are urgently needed. There are several studies indicating that RFR may affect reproduction, particularly with effects on sperm physiology and DNA (Agarwal et al., 2009; Atasoy et al., 2012; Avendano et al., 2012; Chavdoula et al., 2010; de Iuliis et al., 2009; Liu et al., 2013b; Panagopoulous et al., 2007). Similar effects of ELF-EMF on sperm have also been reported, e.g., Hong R, Zhang Y, Liu Y, Weng EQ. Effects of extremely low frequency electromagnetic fields on DNA of testicular cells and sperm chromatin structure in mice. Zhonghua Lao Dong Wei Sheng Zhi Ye Bing Za Zhi. 23(6):414-417, 2005; Iorio R, Scrimaglio R, Rantucci E, Delle Monache S, Di Gaetano A, Finetti N, Francavilla F, Santucci R, Tettamanti E, Colonna R. A preliminary study of oscillating electromagnetic field effects on human spermatozoon motility. Bioelectromagnetics. 28(1):72-75, 2007; Iorio R, Delle Monache S, Bennato F, Di Bartolomeo C, Scrimaglio R, Cinque B, Colonna RC. Involvement of mitochondrial activity in mediating ELF-EMF stimulatory effect on human sperm motility. Bioelectromagnetics. 32(1):15-27, 2011.

4. Another area that needs more research is the biological effects of low-intensity exposure. This is particularly true for ELF-EMF, since intensities of ELF-EMF in the environment are in microtesla (μT) levels. There are many studies on biological effects of low-intensity RFR (see Table 1 in Levitt, B.B. and Lai, H. Biological effects from exposure to electromagnetic radiation emitted by cell tower base stations and other antenna arrays. Environ. Rev. 18:369-395, 2010.) However, most cell and animal studies in ELF-EMF used fields in the millitesla (mT) level. Exceptions are the study of Sarimov et al. (2011) listed below in the reference section and the study of de Bruyn and de Jager (2010) (de Bruyn L and de Jager L. Effect of long-term exposure to a randomly varied 50

Hz power frequency magnetic field on the fertility of the mouse. Electromag. Biol. Med. 29(1-2):52-61, 2010).

5. Two other important findings of these recent studies are that the effects of EMF are shown to be waveform specific and cell-type specific. Regarding waveform specificity, Campisi et al. (2010) reported increases in free radical activity and DNA fragmentation in brain cells after acute exposure to a 50-Hz amplitude-modulated 900-MHz RFR, whereas a continuous-wave 9000-MHz field produced no effect. Franzellitti et al. (2010) showed increased DNA strand breaks in trophoblasts after exposure to a 217-Hz modulated 1.8 GHz-RFR, but a continuous-wave field of the same carrier frequency was without effect. Tkalec et al (2013) reported that AM-modulated (1 KHz sinusoidal) 900-MHz RFR is more potent than non-modulated field in causing DNA damage in coelomocytes of exposed earthworms. Luukkonen et al. (2009) reported a continuous-wave 872-MHz RFR increased chemically-induced DNA strand breaks and free radicals in human neuroblastoma cells, whereas a GSM-modulated 872-MHz field had no significant effect. Zhang et al. (2008) found that gene expression in rat neurons is more sensitive to intermittent than continuous exposure to a 1.8 GHz-RFR. López-Martín et al. (2009) found that GSM and unmodulated RFR caused different effects on c-Fos gene expression in the rat brain. Regarding cell-type specificity, Nylund and Leszczynski (2006) and Remondini et al. (2006) reported different patterns of gene expression in different types of cells after exposure to RFR. Zhao et al. (2007) found than neurons are more sensitive to a 1.9 GHz cell phone radiation than astrocytes. Schwarz et al. (2008) reported DNA strand breaks and micronucleus formation in human fibroblasts, but not in lymphocytes, after exposure to a 1950-MHz UMTS field. Furthermore, Xu et al (2013) found DNA damages in some cell types and not in others after exposure to 1800-MHz RFR. Valbonesi et at. (2014) reported that HSP70 expression and MAPK signaling pathways in PC12 cells were affected by GSM-217 Hz signal and not by CW or GSM-talk signals. In ELF-EM research, Giorgi et al. (2011) found that DNA transposition in E. coli was *decreased* after exposure to a sinusoidal magnetic field and *increased* after exposure to a pulsed magnetic field. Kim et al. (2012) described DNA strand breaks in human fibroblasts after exposure to ELF magnetic field. They found that the pattern of changes depended on the eddy current and Lorentz force in the field. Nahab et al. (2007) reported that a square-continuous ELF magnetic field was more effective than sinusoidal-continuous or pulsed field in inducing sister chromatid exchange in human lymphocytes. These findings underscore the complicity of interaction of EMF with biological tissues and may partially explain why effects were observed in some studies and not others. It is essential to understand why and how certain wave-characteristics of an EMF are more effective than other characteristics in causing biological effects, and why certain types of cells are more susceptible to the effect of EMF? That there are different biological effects elicited by different EMF wave characteristics is critical proof for the existence of nonthermal effects.

6. Many biological/health effects have been reported in cells and animals after exposure to EMFs in both the ELF and RF ranges. (Sixty-five percent of the RFR papers and 82% of the ELF-EMF papers in the publication list below reported effects.) It is highly dishonest for a scientist to summarily deny the existence of biological effects of EMF. A

biological effect of EMF can be detrimental to health, but can also be turned into a beneficial means for the treatment of human diseases. Denying any effects hampers the development of electromagnetic treatments for diseases. Examples of possible clinical uses of EMF are: Alzheimer's disease (Arendash GW, Sanchez-Ramos J, Mori T, Mamcarz M, Lin X, Runfeldt M, Wang L, Zhang G, Sava V, Tan J, Cao C. Electromagnetic field treatment protects against and reverses cognitive impairment in Alzheimer's disease mice. J Alzheimers Dis. 19(1):191-210, 2010); Parkinson's disease (Wang Z, Che PL, Du J, Ha B, Yarema KJ. Static magnetic field exposure reproduces cellular effects of the Parkinson's disease drug candidate ZM241385. PLoS One. 5(11):e13883, 2010); bone regeneration (Lee HM, Kwon UH, Kim H, Kim HJ, Kim B, Park JO, Moon ES, Moon SH. Pulsed eltromagnetic field stimulates cellular proliferation in human intervertebral disc cells. Yonsei Med. J. 51(6):954-959, 2010); cancer treatment (Costa FP, de Oliveira AC, Meirelles R, Machado MC, Zanesco T, Surjan R, Chammas MC, de Souza Rocha M, Morgan D, Cantor A, Zimmerman J, Brezovich I, Kuster N, Barbault A, Pasche B. Treatment of advanced hepatocellular carcinoma with very low levels of amplitude-modulated electromagnetic fields. Br. J. Cancer. 105(5):640-648, 2011), and tissue regeneration (Gaetani R, Ledda M, Barile L, Chimenti I, De Carlo F, Forte E, Ionta V, Giuliani L, D'Emilia E, Frati G, Miraldi F, Pozzi D, Messina E, Grimaldi S, Giacomello A, Lisi A. Differentiation of human adult cardiac stem cells exposed to extremely low-frequency electromagnetic fields. Cardiovasc. Res. 82(3):411-420, 2009).

7. It must be pointed out that, consistent with previous research, not very much of the cellular and animal genetic research data directly indicate that EMF (both RF and ELF EMF) is a carcinogen. However, the data show that EMF can possibly alter genetic functions and thus it is advisable that one should limit one's exposure to EMF.

APPENDIX A - ABSTRACTS ON GENETIC EFFECTS OF RADIOFREQUENCY AND CELL PHONE RADIATION (2007-2014)

Below is a key to abbreviations used throughout the following list of abstracts for recent papers published since 2006 and serve as my comments to help the reader quickly identify the significance of each work. The summary sentences by each author are underlined. The list is divided into RF effects papers, and ELF effects papers.

(E- effect observed; NE- no effect observed) (LE- long term exposure; GT- genotoxic effect, e.g., DNA damage, micronucleus formation, chromosome alterations; GE- gene expression; HU- human study; OX- oxidative effects, i.e., involvement of free radicals and oxidative enzymes; IA- interaction with other factors to cause genetic effects; DE- effects on developing animals; RP- reproduction, e.g., sperm damage; EH- compared with electro-hypersensitive subjects; WS- waveform specific effect, e.g., modulation and frequency; CS- cell type specific effect).

(E) Agarwal A, Desai NR, Makker K, Varghese A, Mouradi R, Sabanegh E, Sharma R. Effects of radiofrequency electromagnetic waves (RF-EMW) from cellular phones on human ejaculated semen: an in vitro pilot study. Fertil Steril 92 1318-1325, 2009. (GT, RP, OX)

OBJECTIVE: To evaluate effects of cellular phone radiofrequency electromagnetic waves (RF-EMW) during talk mode on unprocessed (neat) ejaculated human semen. DESIGN: Prospective pilot study. SETTING: Center for reproductive medicine laboratory in tertiary hospital setting. SAMPLES: Neat semen samples from normal healthy donors (n = 23) and infertile patients (n = 9). INTERVENTION(S): After liquefaction, neat semen samples were divided into two aliquots. One aliquot (experimental) from each patient was exposed to cellular phone radiation (in talk mode) for 1 h, and the second aliquot (unexposed) served as the control sample under identical conditions. MAIN OUTCOME MEASURE(S): Evaluation of sperm parameters (motility, viability), reactive oxygen species (ROS), total antioxidant capacity (TAC) of semen, ROS-TAC score, and sperm DNA damage. RESULT(S): Samples exposed to RF-EMW showed a significant decrease in sperm motility and viability, increase in ROS level, and decrease in ROS-TAC score. Levels of TAC and DNA damage showed no significant differences from the unexposed group. CONCLUSION(S): Radiofrequency electromagnetic waves emitted from cell phones may lead to oxidative stress in human semen. We speculate that keeping the cell phone in a trouser pocket in talk mode may negatively affect spermatozoa and impair male fertility.

(E) Atasoy HI, Gunal MY, Atasoy P, Elgun S, Bugdayci G. Immunohistopathologic demonstration of deleterious effects on growing rat testes of radiofrequency waves emitted from conventional Wi-Fi devices.J Pediatr Urol. 2012 Mar 30. [Epub ahead of print] (GT, OX, LE, RP)

OBJECTIVE: To investigate effects on rat testes of radiofrequency radiation emitted from indoor Wi-Fi Internet access devices using 802.11.g wireless standards. METHODS: Ten Wistar albino male rats were divided into experimental and control groups, with five rats per group. Standard wireless gateways communicating at 2.437 GHz were used as radiofrequency wave sources. The experimental group was exposed to radiofrequency energy for 24 h a day for 20 weeks. The rats were sacrificed at the end of the study. Intracardiac blood was sampled for serum 8-hydroxy-2'-deoxyguanosine levels. Testes were removed and examined histologically and immunohistochemically. Testis tissues were analyzed for malondialdehyde levels and prooxidant-antioxidant enzyme activities. RESULTS: We observed significant increases in serum 8-hydroxy-2'-deoxyguanosine levels and 8-hydroxyguanosine staining in the testes of the experimental group indicating DNA damage due to exposure ($p < 0.05$). We also found decreased levels of catalase and glutathione peroxidase activity in the experimental group, which may have been due to radiofrequency effects on enzyme activity ($p < 0.05$). CONCLUSIONS: These findings raise questions about the safety of radiofrequency exposure from Wi-Fi Internet access devices for growing organisms of reproductive age, with a potential effect on both fertility and the integrity of germ cells.

(E) Atlı Şekeroğlu Z, Akar A, Sekeroğlu V. Evaluation of the cytogenotoxic damage in immature and mature rats exposed to 900 MHz radio frequency electromagnetic fields. Int J Radiat Biol. 89(11):985-992, 2013. [Epub ahead of print] (GT, DE, LE)

Abstract Purpose: One of the most important issues regarding radio frequency electromagnetic fields (RF-EMF) is their effect on genetic material. Therefore, we investigated the cytogenotoxic effects of 900 MHz radio frequency electromagnetic fields (RF-EMF) and the effect of a recovery period after exposure to RF-EMF on bone marrow cells of immature and mature rats. Materials and methods: The immature and mature rats in treatment groups were exposed to RF-EMF for 2 h/day for 45 days. Average electrical field values for immature and mature rats were 28.1±4.8 V/m and 20.0±3.2 V/m, respectively. Whole-body specific absorption rate (SAR) values for immature and mature rats were in the range of 0.38-0.78 W/kg, and 0.31-0.52 W/kg during the 45 days, respectively. Two recovery groups were kept for 15 days after RF-EMF exposure. Results: Significant differences were observed in chromosome aberrations (CA), micronucleus (MN) frequency, mitotic index (MI) and ratio of polychromatic erythrocytes (PCE) in all treatment and recovery groups. The cytogenotoxic damage in immature rats was statistically higher than the mature rats. The recovery period did not reduce the damage to the same extent as the corresponding control groups. Conclusions: The exposure of RF-EMF leads to cytotoxic and genotoxic damage in immature and mature rats. More sensitive studies are required to elucidate the possible carcinogenic risk of EMF exposure in humans, especially children.

(E) Avendaño C, Mata A, Sanchez Sarmiento CA, Doncel GF. Use of laptop computers connected to internet through Wi-Fi decreases human sperm motility and increases sperm DNA fragmentation. FertilSteril 97:39-45, 2012. (GT, RP)

OBJECTIVE: To evaluate the effects of laptop computers connected to local area networks wirelessly (Wi-Fi) on human spermatozoa. DESIGN: Prospective in vitro study. SETTING: Center for reproductive medicine. PATIENT(S): Semen samples from 29 healthy donors. INTERVENTION(S): Motile sperm were selected by swim up. Each sperm suspension was divided into two aliquots. One sperm aliquot (experimental) from each patient was exposed to an

internet-connected laptop by Wi-Fi for 4 hours, whereas the second aliquot (unexposed) was used as control, incubated under identical conditions without being exposed to the laptop. MAIN OUTCOME MEASURE(S): Evaluation of sperm motility, viability, and DNA fragmentation. RESULT(S): Donor sperm samples, mostly normozoospermic, exposed ex vivo during 4 hours to a wireless internet-connected laptop showed a significant decrease in progressive sperm motility and an increase in sperm DNA fragmentation. Levels of dead sperm showed no significant differences between the two groups. CONCLUSION(S): To our knowledge, this is the first study to evaluate the direct impact of laptop use on human spermatozoa. Ex vivo exposure of human spermatozoa to a wireless internet-connected laptop decreased motility and induced DNA fragmentation by a nonthermal effect. We speculate that keeping a laptop connected wirelessly to the internet on the lap near the testes may result in decreased male fertility. Further in vitro and in vivo studies are needed to prove this contention.

(E) Baohong Wang, Jiliang H, Lifen J, Deqiang L, Wei Z, Jianlin L, Hongping D. Studying the synergistic damage effects induced by 1.8 GHz radiofrequency field radiation (RFR) with four chemical mutagens on human lymphocyte DNA using comet assay in vitro. Mutat Res 578:149-57, 2005. (GT, IA)

The aim of this investigation was to study the synergistic DNA damage effects in human lymphocytes induced by 1.8GHz radiofrequency field radiation (RFR, SAR of 3W/kg) with four chemical mutagens, i.e. mitomycin C (MMC, DNA crosslinker), bleomycin (BLM, radiomimetic agent), methyl methanesulfonate (MMS, alkylating agent), and 4-nitroquinoline-1-oxide (4NQO, UV-mimetic agent). The DNA damage of lymphocytes exposed to RFR and/or with chemical mutagens was detected at two incubation time (0 or 21h) after treatment with comet assay in vitro. Three combinative exposure ways were used. Cells were exposed to RFR and chemical mutagens for 2 and 3h, respectively. Tail length (TL) and tail moment (TM) were utilized as DNA damage indexes. The results showed no difference of DNA damage indexes between RFR group and control group at 0 and 21h incubation after exposure ($P>0.05$). There were significant difference of DNA damage indexes between MMC group and RFR+MMC co-exposure group at 0 and 21h incubation after treatment ($P<0.01$). Also the significant difference of DNA damage indexes between 4NQO group and RFR+4NQO co-exposure group at 0 and 21h incubation after treatment was observed ($P<0.05$ or $P<0.01$). The DNA damage in RFR+BLM co-exposure groups and RFR+MMS co-exposure groups was not significantly increased, as compared with corresponding BLM and MMS groups ($P>0.05$). The experimental results indicated 1.8GHz RFR (SAR, 3W/kg) for 2h did not induce the human lymphocyte DNA damage effects in vitro, but could enhance the human lymphocyte DNA damage effects induced by MMC and 4NQO. The synergistic DNA damage effects of 1.8GHz RFR with BLM or MMS were not obvious.

(E) Baohong W, Lifen J, Lanjuan L, Jianlin L, Deqiang L, Wei Z, Jiliang H.Evaluating the combinative effects on human lymphocyte DNA damage induced by ultraviolet ray C plus 1.8GHz microwaves using comet assay in vitro. Toxicology. 232(3):311-316, 2007. (GT, IA)

The objective of this study was to observe whether 1.8GHz microwaves (MW) (SAR, 3 W/kg) exposure can influence human lymphocyte DNA damage induced by ultraviolet ray C (UVC). The lymphocytes, which were from three young healthy donors, were exposed to 254 nm UVC at the doses of 0.25, 0.5, 0.75, 1.0, 1.5 and 2.0 J m(-2), respectively. The lymphocytes were irradiated by 1.8GHz MW (SAR, 3 W/kg) for 0, 1.5 and 4 h. The combinative exposure of UVC

plus MW was conducted. The treated cells were incubated for 0, 1.5 and 4 h. Finally, comet assay was used to measure DNA damage of above treated lymphocytes. The results indicated that the difference of DNA damage induced between MW group and control group was not significant (P>0.05). The MTLs induced by UVC were 1.71+/-0.09, 2.02+/-0.08, 2.27+/-0.17, 2.27+/-0.06, 2.25+/-0.12, 2.24+/-0.11 microm, respectively, which were significantly higher than that (0.96+/-0.05 microm) of control (P<0.01). MTLs of some sub-groups in combinative exposure groups at 1.5-h incubation were significantly lower that those of corresponding UVC sub-groups (P<0.01 or P<0.05). However, MTLs of some sub-groups in combinative exposure groups at 4-h incubation were significantly higher that those of corresponding UVC sub-groups (P<0.01 or P<0.05). In this experiment it was found that 1.8GHz (SAR, 3 W/kg) MW exposure for 1.5 and 4 h did not enhance significantly human lymphocyte DNA damage, but could reduce and increase DNA damage of human lymphocytes induced by UVC at 1.5-h and 4-h incubation, respectively.

(E) Belyaev IY, Hillert L, Protopopova M, Tamm C, Malmgren LO, Persson BR, Selivanova G, Harms-Ringdahl M. 915 MHz microwaves and 50 Hz magnetic field affect chromatin conformation and 53BP1 foci in human lymphocytes from hypersensitive and healthy persons. Bioelectromagnetics 26:173-184, 2005. (GT, EH)

We used exposure to microwaves from a global system for mobile communication (GSM) mobile phone (915 MHz, specific absorption rate (SAR) 37 mW/kg) and power frequency magnetic field (50 Hz, 15 muT peak value) to investigate the response of lymphocytes from healthy subjects and from persons reporting hypersensitivity to electromagnetic field (EMF). The hypersensitive and healthy donors were matched by gender and age and the data were analyzed blind to treatment condition. The changes in chromatin conformation were measured with the method of anomalous viscosity time dependencies (AVTD). 53BP1 protein, which has been shown to colocalize in foci with DNA double strand breaks (DSBs), was analyzed by immunostaining in situ. Exposure at room temperature to either 915 MHz or 50 Hz resulted in significant condensation of chromatin, shown as AVTD changes, which was similar to the effect of heat shock at 41 degrees C. No significant differences in responses between normal and hypersensitive subjects were detected. Neither 915 MHz nor 50 Hz exposure induced 53BP1 foci. On the contrary, a distinct decrease in background level of 53BP1 signaling was observed upon these exposures as well as after heat shock treatments. This decrease correlated with the AVTD data and may indicate decrease in accessibility of 53BP1 to antibodies because of stress-induced chromatin condensation. Apoptosis was determined by morphological changes and by apoptotic fragmentation of DNA as analyzed by pulsed-field gel electrophoresis (PFGE). No apoptosis was induced by exposure to 50 Hz and 915 MHz microwaves. In conclusion, 50 Hz magnetic field and 915 MHz microwaves under specified conditions of exposure induced comparable responses in lymphocytes from healthy and hypersensitive donors that were similar but not identical to stress response induced by heat shock.

(E) Belyaev IY, Koch CB, Terenius O, Roxstrom-Lindquist K, Malmgren LO, H Sommer W, Salford LG, Persson BR. Exposure of rat brain to 915 MHz GSM microwaves induces changes in gene expression but not double stranded DNA breaks or effects on chromatin conformation. Bioelectromagnetics 27:295-306, 2006. (GE)

We investigated whether exposure of rat brain to microwaves (MWs) of global system for mobile communication (GSM) induces DNA breaks, changes in chromatin conformation and in gene expression. An exposure installation was used based on a test mobile phone employing a GSM signal at 915 MHz, all standard modulations included, output power level in pulses 2 W, specific absorption rate (SAR) 0.4 mW/g. Rats were exposed or sham exposed to MWs during 2 h. After exposure, cell suspensions were prepared from brain samples, as well as from spleen and thymus. For analysis of gene expression patterns, total RNA was extracted from cerebellum. Changes in chromatin conformation, which are indicative of stress response and genotoxic effects, were measured by the method of anomalous viscosity time dependencies (AVTD). DNA double strand breaks (DSBs) were analyzed by pulsed-field gel electrophoresis (PFGE). Effects of MW exposure were observed on neither conformation of chromatin nor DNA DSBs. Gene expression profiles were obtained by Affymetrix U34 GeneChips representing 8800 rat genes and analyzed with the Affymetrix Microarray Suite (MAS) 5.0 software. In cerebellum from all exposed animals, 11 genes were upregulated in a range of 1.34-2.74 fold and one gene was downregulated 0.48-fold ($P < .0025$). The induced genes encode proteins with diverse functions including neurotransmitter regulation, blood-brain barrier (BBB), and melatonin production. The data shows that GSM MWs at 915 MHz did not induce PFGE-detectable DNA double stranded breaks or changes in chromatin conformation, but affected expression of genes in rat brain cells

(E) Belyaev IY, Markovà E, Hillert L, Malmgren LO, Persson BR. Microwaves from UMTS/GSM mobile phones induce long-lasting inhibition of 53BP1/gamma-H2AX DNA repair foci in human lymphocytes. Bioelectromagnetics 30:129-41, 2009. (GT, EH)

We have recently described frequency-dependent effects of mobile phone microwaves (MWs) of global system for mobile communication (GSM) on human lymphocytes from persons reporting hypersensitivity to electromagnetic fields and healthy persons. Contrary to GSM, universal global telecommunications system (UMTS) mobile phones emit wide-band MW signals. Hypothetically, UMTS MWs may result in higher biological effects compared to GSM signal because of eventual "effective" frequencies within the wideband. Here, we report for the first time that UMTS MWs affect chromatin and inhibit formation of DNA double-strand breaks co-localizing 53BP1/gamma-H2AX DNA repair foci in human lymphocytes from hypersensitive and healthy persons and confirm that effects of GSM MWs depend on carrier frequency. Remarkably, the effects of MWs on 53BP1/gamma-H2AX foci persisted up to 72 h following exposure of cells, even longer than the stress response following heat shock. The data are in line with the hypothesis that the type of signal, UMTS MWs, may have higher biological efficiency and possibly larger health risk effects compared to GSM radiation emissions. No significant differences in effects between groups of healthy and hypersensitive subjects were observed, except for the effects of UMTS MWs and GSM-915 MHz MWs on the formation of the DNA repair foci, which were different for hypersensitive ($P < 0.02$[53BP1]//0.01[gamma-H2AX]) but not for control subjects ($P > 0.05$). The non-parametric statistics used here did not indicate specificity of the differences revealed between the effects of GSM and UMTS MWs on cells from hypersensitive subjects and more data are needed to study the nature of these differences.

(NE) Bourthoumieu S, Joubert V, Marin B, Collin A, Leveque P, Terro F, Yardin C. Cytogenetic studies in human cells exposed in vitro to GSM-900 MHz radiofrequency radiation using R-banded karyotyping. Radiat Res 174:712-718, 2010. (GT)

It is important to determine the possible effects of exposure to radiofrequency (RF) radiation on the genetic material of cells since damage to the DNA of somatic cells may be linked to cancer development or cell death and damage to germ cells may lead to genetic damage in next and subsequent generations. The objective of this study was to investigate whether exposure to radiofrequency radiation similar to that emitted by mobile phones of second-generation standard Global System for Mobile Communication (GSM) induces genotoxic effects in cultured human cells. The cytogenetic effects of GSM-900 MHz (GSM-900) RF radiation were investigated using R-banded karyotyping after in vitro exposure of human cells (amniotic cells) for 24 h. The average specific absorption rate (SAR) was 0.25 W/kg. The exposures were carried out in wire-patch cells (WPCs) under strictly controlled conditions of temperature. The genotoxic effect was assessed immediately or 24 h after exposure using four different samples. One hundred metaphase cells were analyzed per assay. Positive controls were provided by using bleomycin. We found no direct cytogenetic effects of GSM-900 either 0 h or 24 h after exposure. To the best of our knowledge, our work is the first to study genotoxicity using complete R-banded karyotyping, which allows visualizing all the chromosomal rearrangements, either numerical or structural.

(NE) Bourthoumieu S, Terro F, Leveque P, Collin A, Joubert V, Yardin C. Aneuploidy studies in human cells exposed in vitro to GSM-900 MHz radiofrequency radiation using FISH. Int J Radiat Biol 87:400-408, 2011. (GT)

PURPOSE: Since previous research found an increase in the rate of aneuploidies in human lymphocytes exposed to radiofrequencies, it seems important to perform further studies. The objective of this study was then to investigate whether the exposure to RF (radiofrequency) radiation similar to that emitted by mobile phones of a second generation standard, i.e., Global System for Mobile communication (GSM) may induce aneuploidy in cultured human cells. MATERIALS AND METHODS: The potential induction of genomic instability by GSM-900 MHz radiofrequency (GSM-900) was investigated after in vitro exposure of human amniotic cells for 24 h to average-specific absorption rates (SAR) of 0.25, 1, 2 and 4 W/kg in the temperature range of 36.3-39.7°C. The exposures were carried out in a wire-patch cell (WPC). The rate of aneuploidy of chromosomes 11 and 17 was determined by interphase FISH (Fluorescence In Situ Hybridisation) immediately after independent exposure of three different donors for 24 h. At least 100 interphase cells were analysed per assay. RESULTS: No significant change in the rate of aneuploidy of chromosomes 11 and 17 was found following exposure to GSM-900 for 24 h at average SAR up to 4 W/kg. CONCLUSION: Our study did not show any in vitro aneuploidogenic effect of GSM using FISH and is not in agreement with the results of previous research.

(NE) Bourthoumieu S, Magnaudeix A, Terro F, Leveque P, Collin A, Yardin C. Study of p53 expression and post-transcriptional modifications after GSM-900 radiofrequency exposure of human amniotic cells. Bioelectromagnetics. 2012 Jul 5. doi: 10.1002/bem.21744. [Epub ahead of print] (GE)

The potential effects of radiofrequency (RF) exposure on the genetic material of cells are very important to determine since genome instability of somatic cells may be linked to cancer development. In response to genetic damage, the p53 protein is activated and can induce cell cycle arrest allowing more time for DNA repair or elimination of damaged cells through

apoptosis. The objective of this study was to investigate whether the exposure to RF electromagnetic fields, similar to those emitted by mobile phones of the second generation standard, Global System for Mobile Communications (GSM), may induce expression of the p53 protein and its activation by post-translational modifications in cultured human cells. The potential induction of p53 expression and activation by GSM-900 was investigated after in vitro exposure of human amniotic cells for 24 h to average specific absorption rates (SARs) of 0.25, 1, 2, and 4 W/kg in the temperature range of 36.3-39.7 °C. The exposures were carried out using a wire-patch cell (WPC) under strictly controlled conditions of temperature. Expression and activation of p53 by phosphorylation at serine 15 and 37 were studied using Western blot assay immediately after three independent exposures of cell cultures provided from three different donors. Bleomycin-exposed cells were used as a positive control. According to our results, no significant changes in the expression and activation of the p53 protein by phosphorylation at serine 15 and 37 were found following exposure to GSM-900 for 24 h at average SARs up to 4 W/kg in human embryonic cells.

(E) Burlaka A, Tsybulin O, Sidorik E, Lukin S, Polishuk V, Tsehmistrenko S, Yakymenko I. Overproduction of free radical species in embryonal cells exposed to low intensity radiofrequency radiation. Exp Oncol. 35(3):219-225, 2013. (GT, LE, DE, OX)

Aim: Long-term exposure of humans to low intensity radiofrequency electromagnetic radiation (RF-EMR) leads to a statistically significant increase in tumor incidence. Mechanisms of such the effects are unclear, but features of oxidative stress in living cells under RF-EMR exposure were previously reported. Our study aims to assess a production of initial free radical species, which lead to oxidative stress in the cell. Materials and Methods: Embryos of Japanese quails were exposed in ovo to extremely low intensity RF-EMR of GSM 900 MHz (0.25 μW/cm2) during 158-360 h discontinuously (48 c - ON, 12 c - OFF) before and in the initial stages of development. The levels of superoxide ($O_2^{\cdot -}$), nitrogen oxide ($NO^{\cdot}$), thiobarbituric acid reactive substances (TBARS), 8-oxo-2'-deoxyguanosine (8-oxo-dG) and antioxidant enzymes' activities were assessed in cells/tissues of 38-h, 5- and 10-day RF-EMR exposed and unexposed embryos. Results: The exposure resulted in a significant persistent overproduction of superoxide and nitrogen oxide in embryo cells during all period of analyses. As a result, significantly increased levels of TBARS and 8-oxo-dG followed by significantly decreased levels of superoxide dismutase and catalase activities were developed in the exposed embryo cells. Conclusion: Exposure of developing quail embryos to extremely low intensity RF-EMR of GSM 900 MHz during at least one hundred and fifty-eight hours leads to a significant overproduction of free radicals/reactive oxygen species and oxidative damage of DNA in embryo cells. These oxidative changes may lead to pathologies up to oncogenic transformation of cells.

(E) Buttiglione M, Roca L, Montemurno E, Vitiello F, Capozzi V, Cibelli G. Radiofrequency radiation (900 MHz) induces Egr-1 gene expression and affects cell-cycle control in human neuroblastoma cells. J Cell Physiol. 213(3):759-767, 2007. (GE)

Many environmental signals, including ionizing radiation and UV rays, induce activation of Egr-1 gene, thus affecting cell growth and apoptosis. The paucity and the controversial knowledge about the effect of electromagnetic fields (EMF) exposure of nerve cells prompted us to investigate the bioeffects of radiofrequency (RF) radiation on SH-SY5Y neuroblastoma cells. The effect of a modulated RF field of 900 MHz, generated by a wire patch cell (WPC) antenna

exposure system on Egr-1 gene expression, was studied as a function of time. Short-term exposures induced a transient increase in Egr-1 mRNA level paralleled with activation of the MAPK subtypes ERK1/2 and SAPK/JNK. The effects of RF radiations on cell growth rate and apoptosis were also studied. Exposure to RF radiation had an anti-proliferative activity in SH-SY5Y cells with a significant effect observed at 24 h. RF radiation impaired cell cycle progression, reaching a significant G2-M arrest. In addition, the appearance of the sub-G1 peak, a hallmark of apoptosis, was highlighted after a 24-h exposure, together with a significant decrease in mRNA levels of Bcl-2 and survivin genes, both interfering with signaling between G2-M arrest and apoptosis. Our results provide evidence that exposure to a 900 MHz-modulated RF radiation affect both Egr-1 gene expression and cell regulatory functions, involving apoptosis inhibitors like Bcl-2 and survivin, thus providing important insights into a potentially broad mechanism for controlling in vitro cell viability.

(E) Cam ST, Seyhan N. Single-strand DNA breaks in human hair root cells exposed to mobile phone radiation. Int J Radiat Biol 88(5):420-424, 2012 (GT, HU)

Purpose: To analyze the short term effects of radiofrequency radiation (RFR) exposure on genomic deoxyribonucleic acid (DNA) of human hair root cells. Subjects and methods: Hair samples were collected from 8 healthy human subjects immediately before and after using a 900-MHz GSM (Global System for Mobile Communications) mobile phone for 15 and 30 minutes. Single-strand DNA breaks of hair root cells from the samples were determined using the 'comet assay'. Results: The data showed that talking on a mobile phone for 15 or 30 minutes significantly increased ($p < .05$) single-strand DNA breaks in cells of hair roots close to the phone. Comparing the 15-min and 30-min data using the paired t-test also showed that significantly more damages resulted after 30 minutes than after 15 minutes of phone use. Conclusions: A short-term exposure (15 and 30 minutes) to RFR (900-MHz) from a mobile phone caused a significant increase in DNA single-strand breaks in human hair root cells located around the ear which is used for the phone calls.

(E) Campisi A, Gulino M, Acquaviva R, Bellia P, Raciti G, Grasso R, Musumeci F, Vanella A, Triglia A. Reactive oxygen species levels and DNA fragmentation on astrocytes in primary culture after acute exposure to low intensity microwave electromagnetic field. Neurosci Lett 473:52-55. 2010. (GT, OX, WS)

The exposure of primary rat neocortical astroglial cell cultures to acute electromagnetic fields (EMF) in the microwave range was studied. Differentiated astroglial cell cultures at 14 days in vitro were exposed for 5, 10, or 20 min to either 900 MHz continuous waves or 900 MHz waves modulated in amplitude at 50 Hz using a sinusoidal waveform and 100% modulation index. The strength of the electric field (rms value) at the sample position was 10V/m. No change in cellular viability evaluated by MTT test and lactate dehydrogenase release was observed. A significant increase in ROS levels and DNA fragmentation was found only after exposure of the astrocytes to modulated EMF for 20 min. No evident effects were detected when shorter time intervals or continuous waves were used. The irradiation conditions allowed the exclusion of any possible thermal effect. Our data demonstrate, for the first time, that even acute exposure to low intensity EMF induces ROS production and DNA fragmentation in astrocytes in primary cultures, which also represent the principal target of modulated EMF. Our findings also suggest the hypothesis that the effects could be due to hyperstimulation of the glutamate receptors, which play a crucial

role in acute and chronic brain damage. Furthermore, the results show the importance of the amplitude modulation in the interaction between EMF and neocortical astrocytes.

(E) 1 **Cervellati F, Valacchi G, Lunghi L, Fabbri E,** Valbonesi **P, Marci R, Biondi C, Vesce F. 17-β-estradiol counteracts the effects of high frequency electromagnetic fields on trophoblastic connexins and integrins. Oxid Med Cell Longev. 2013;2013:280850. doi: 10.1155/2013/280850. (GE)**

We investigated the effect of high-frequency electromagnetic fields (HF-EMFs) and 17-β-estradiol on connexins (Cxs), integrins (Ints), and estrogen receptor (ER) expression, as well as on ultrastructure of trophoblast-derived HTR-8/SVneo cells. HF-EMF, 17-β-estradiol, and their combination induced an increase of Cx40 and Cx43 mRNA expression. HF-EMF decreased Int alpha1 and β 1 mRNA levels but enhanced Int alpha5 mRNA expression. All the Ints mRNA expressions were increased by 17-β-estradiol and exposure to both stimuli. ER-β mRNA was reduced by HF-EMF but augmented by 17-β-estradiol alone or with HF-EMF. ER-β immunofluorescence showed a cytoplasmic localization in sham and HF-EMF exposed cells which became nuclear after treatment with hormone or both stimuli. Electron microscopy evidenced a loss of cellular contact in exposed cells which appeared counteracted by 17-β-estradiol. We demonstrate that 17-β-estradiol modulates Cxs and Ints as well as ER-β expression induced by HF-EMF, suggesting an influence of both stimuli on trophoblast differentiation and migration.

(NE) Chang SK, Choi JS, Gil HW, Yang JO, Lee EY, Jeon YS, Lee ZW, Lee M, Hong MY, Ho Son T, Hong SY. Genotoxicity evaluation of electromagnetic fields generated by 835-MHz mobile phone frequency band. Eur J Cancer Prev 14:175-179, 2005. (GT, IA) (Some interaction effects with chemicals are reported in this paper.)

It is still unclear whether the exposure to electromagnetic fields (EMFs) generated by mobile phone radiation is directly linked to cancer. We examined the biological effects of an EMF at 835 MHz, the most widely used communication frequency band in Korean CDMA mobile phone networks, on bacterial reverse mutation (Ames assay) and DNA stability (in vitro DNA degradation). In the Ames assay, tester strains alone or combined with positive mutagen were applied in an artificial mobile phone frequency EMF generator with continuous waveform at a specific absorption rate (SAR) of 4 W/kg for 48 h. In the presence of the 835-MHz EMF radiation, incubation with positive mutagen 4-nitroquinoline-1-oxide and cumene hydroxide further increased the mutation rate in Escherichia coli WP2 and TA102, respectively, while the contrary results in Salmonella typhimurium TA98 and TA1535 treated with 4-nitroquinoline-1-oxide and sodium azide, respectively, were shown as antimutagenic. However, these mutagenic or co-mutagenic effects of 835-MHz radiation were not significantly repeated in other relevant strains with same mutation type. In the DNA degradation test, the exposure to 835-MHz EMF did not change the rate of degradation observed using plasmid pBluescriptSK(+) as an indicator. Thus, we suggest that 835-MHz EMF under the conditions of our study neither affected the reverse mutation frequency nor accelerated DNA degradation in vitro.

(NE) Chauhan V, Mariampillai A, Bellier PV, Qutob SS, Gajda GB, Lemay E, Thansandote A, McNamee JP. Gene expression analysis of a human lymphoblastoma cell

line exposed in vitro to an intermittent 1.9 GHz pulse-modulated radiofrequency field. Radiat Res. 165(4):424-429, 2006. (GE)

This study was designed to determine whether radiofrequency (RF) fields of the type used for wireless communications could elicit a cellular stress response. As general indicators of a cellular stress response, we monitored changes in proto-oncogene and heat-shock protein expression. Exponentially growing human lymphoblastoma cells (TK6) were exposed to 1.9 GHz pulse-modulated RF fields at average specific absorption rates (SARs) of 1 and 10 W/kg. Perturbations in the expression levels of the proto-oncogenes FOS, JUN and MYC after exposure to sham and RF fields were assessed by real-time RT-PCR. In addition, the transcript levels of the cellular stress proteins HSP27 and inducible HSP70 were also monitored. We demonstrated that transcript levels of these genes in RF-field-exposed cells showed no significant difference in relation to the sham treatment group. However, concurrent positive (heat-shock) control samples displayed a significant elevation in the expression of HSP27, HSP70, FOS and JUN. Conversely, the levels of MYC mRNA were found to decline in the positive (heat-shock) control. In conclusion, our study found no evidence that the 1.9 GHz RF-field exposure caused a general stress response in TK6 cells under our experimental conditions.

(NE) Chauhan V, Mariampillai A, Gajda GB, Thansandote A, McNamee JP. Analysis of proto-oncogene and heat-shock protein gene expression in human derived cell-lines exposed in vitro to an intermittent 1.9 GHz pulse-modulated radiofrequency field. Int J Radiat Biol. 82(5):347-354, 2006. (GE)

Purpose: Several studies have reported that radiofrequency (RF) fields, as emitted by mobile phones, may cause changes in gene expression in cultured human cell-lines. The current study was undertaken to evaluate this possibility in two human-derived immune cell-lines.Materials and methods: HL-60 and Mono-Mac-6 (MM6) cells were individually exposed to intermittent (5 min on, 10 min off) 1.9 GHz pulse-modulated RF fields at a average specific absorption rate (SAR) of 1 and 10 W/kg at 37 +/- 0.5 degrees C for 6 h. Concurrent negative and positive (heat-shock for 1 h at 43 degrees C) controls were conducted with each experiment. Immediately following RF field exposure (T = 6 h) and 18 h post-exposure (T = 24 h), cell pellets were collected from each of the culture dishes and analyzed for transcript levels of proto-oncogenes (c-jun, c-myc and c-fos) and the stress-related genes (heat shock proteins (HSP) HSP27 and HSP70B) by quantitative reverse transcriptase polymerase chain reaction (RT-PCR).Results: No significant effects were observed in mRNA expression of HSP27, HSP70, c-jun, c-myc or c-fos between the sham and RF-exposed groups, in either of the two cell-lines. However, the positive (heat-shock) control group displayed a significant elevation in the expression of HSP27, HSP70, c-fos and c-jun in both cell-lines at T = 6 and 24 h, relative to the sham and negative control groups.Conclusion: This study found no evidence that exposure of cells to non-thermalizing levels of 1.9 GHz pulse-modulated RF fields can cause any detectable change in stress-related gene expression.

(NE) Chauhan V, Qutob SS, Lui S, Mariampillai A, Bellier PV, Yauk CL, Douglas GR, Williams A, McNamee JP. Analysis of gene expression in two human-derived cell lines exposed in vitro to a 1.9 GHz pulse-modulated radiofrequency field. Proteomics. 7(21):3896-3905, 2007. (GE)

There is considerable controversy surrounding the biological effects of radiofrequency (RF) fields, as emitted by mobile phones. Previous work from our laboratory has shown no effect related to the exposure of 1.9 GHz pulse-modulated RF fields on the expression of 22,000 genes in a human glioblastoma-derived cell-line (U87MG) at 6 h following a 4 h RF field exposure period. As a follow-up to this study, we have now examined the effect of RF field exposure on the possible expression of late onset genes in U87MG cells after a 24 h RF exposure period. In addition, a human monocyte-derived cell-line (Mono-Mac-6, MM6) was exposed to intermittent (5 min ON, 10 min OFF) RF fields for 6 h and then gene expression was assessed immediately after exposure and at 18 h postexposure. Both cell lines were exposed to 1.9 GHz pulse-modulated RF fields for 6 or 24 h at specific absorption rates (SARs) of 0.1-10.0 W/kg. In support of our previous results, we found no evidence that nonthermal RF field exposure could alter gene expression in either cultured U87MG or MM6 cells, relative to nonirradiated control groups. However, exposure of both cell-lines to heat-shock conditions (43 degrees C for 1 h) caused an alteration in the expression of a number of well-characterized heat-shock proteins.

(E) Chavdoula ED, Panagopoulos DJ, Margaritis LH. Comparison of biological effects between continuous and intermittent exposure to GSM-900-MHz mobile phone radiation: detection of apoptotic cell-death features. Mutat Res 700:51-61, 2010. (RP, LE, GT)

In the present study we used a 6-min daily exposure of dipteran flies, Drosophila melanogaster, to GSM-900 MHz (Global System for Mobile Telecommunications) mobile phone electromagnetic radiation (EMR), to compare the effects between the continuous and four different intermittent exposures of 6min total duration, and also to test whether intermittent exposure provides any cumulative effects on the insect's reproductive capacity as well as on the induction of apoptotic cell death. According to our previous experiments, a 6-min continuous exposure per day for five days to GSM-900 MHz and DCS-1800 MHz (Digital Cellular System) mobile phone radiation, brought about a large decrease in the insect's reproductive capacity, as defined by the number of F pupae. This decrease was found to be non thermal and correlated with an increased percentage of induced fragmented DNA in the egg chambers' cells at early- and mid-oogenesis. In the present experiments we show that intermittent exposure also decreases the reproductive capacity and alters the actin cytoskeleton network of the egg chambers, another known aspect of cell death that was not investigated in previous experiments, and that the effect is also due to DNA fragmentation. Intermittent exposures with 10-min intervals between exposure sessions proved to be almost equally effective as continuous exposure of the same total duration, whereas longer intervals between the exposures seemed to allow the organism the time required to recover and partly overcome the above-mentioned effects of the GSM exposure.

(E) Chen G, Lu D, Chiang H, Leszczynski D, Xu Z. Using model organism Saccharomyces cerevisiae to evaluate the effects of ELF-MF and RF-EMF exposure on global gene expression. Bioelectromagnetics. 33(7):550-560, 2012 . (GE)

The potential health hazard of exposure to electromagnetic fields (EMF) continues to cause public concern. However, the possibility of biological and health effects of exposure to EMF remains controversial and their biophysical mechanisms are unknown. In the present study, we used Saccharomyces cerevisiae to identify genes responding to extremely low frequency magnetic fields (ELF-MF) and to radiofrequency EMF (RF-EMF) exposures. The yeast cells were exposed for 6 h to either 0.4 mT 50 Hz ELF-MF or 1800 MHz RF-EMF at a specific

absorption rate of 4.7 W/kg. Gene expression was analyzed by microarray screening and confirmed using real-time reverse transcription-polymerase chain reaction (RT-PCR). We were unable to confirm microarray-detected changes in three of the ELF-MF responsive candidate genes using RT-PCR ($P > 0.05$). On the other hand, out of the 40 potential RF-EMF responsive genes, only the expressions of structural maintenance of chromosomes 3 (SMC3) and aquaporin 2 (AQY2 (m)) were confirmed, while three other genes, that is, halotolerance protein 9 (HAL9), yet another kinase 1 (YAK1) and one function-unknown gene (open reading frame: YJL171C), showed opposite changes in expression compared to the microarray data ($P < 0.05$). In conclusion, the results of this study suggest that the yeast cells did not alter gene expression in response to 50 Hz ELF-MF and that the response to RF-EMF is limited to only a very small number of genes. The possible biological consequences of the gene expression changes induced by RF-EMF await further investigation. 1

(E) De Iuliis GN, Newey RJ, King BV, Aitken RJ. Mobile phone radiation induces reactive oxygen species production and DNA damage in human spermatozoa in vitro. PLoS One 4:e6446, 2009. (GT, OX, RP)

BACKGROUND: In recent times there has been some controversy over the impact of electromagnetic radiation on human health. The significance of mobile phone radiation on male reproduction is a key element of this debate since several studies have suggested a relationship between mobile phone use and semen quality. The potential mechanisms involved have not been established, however, human spermatozoa are known to be particularly vulnerable to oxidative stress by virtue of the abundant availability of substrates for free radical attack and the lack of cytoplasmic space to accommodate antioxidant enzymes. Moreover, the induction of oxidative stress in these cells not only perturbs their capacity for fertilization but also contributes to sperm DNA damage. The latter has, in turn, been linked with poor fertility, an increased incidence of miscarriage and morbidity in the offspring, including childhood cancer. In light of these associations, we have analyzed the influence of RF-EMR on the cell biology of human spermatozoa in vitro. PRINCIPAL FINDINGS: Purified human spermatozoa were exposed to radio-frequency electromagnetic radiation (RF-EMR) tuned to 1.8 GHz and covering a range of specific absorption rates (SAR) from 0.4 W/kg to 27.5 W/kg. In step with increasing SAR, motility and vitality were significantly reduced after RF-EMR exposure, while the mitochondrial generation of reactive oxygen species and DNA fragmentation were significantly elevated ($P<0.001$). Furthermore, we also observed highly significant relationships between SAR, the oxidative DNA damage bio-marker, 8-OH-dG, and DNA fragmentation after RF-EMR exposure. CONCLUSIONS: RF-EMR in both the power density and frequency range of mobile phones enhances mitochondrial reactive oxygen species generation by human spermatozoa, decreasing the motility and vitality of these cells while stimulating DNA base adduct formation and, ultimately DNA fragmentation. These findings have clear implications for the safety of extensive mobile phone use by males of reproductive age, potentially affecting both their fertility and the health and wellbeing of their offspring.

(E) Del Vecchio G, Giuliani A, Fernandez M, Mesirca P, Bersani F, Pinto R, Ardoino L, Lovisolo GA, Giardino L, Calzà L. Continuous exposure to 900MHz GSM-modulated EMF alters morphological maturation of neural cells. Neurosci Lett. 455(3):173-177, 2009. (GE, DE)

The effects of radiofrequency electromagnetic field (RF-EMF) exposure on neuronal phenotype maturation have been studied in two different in vitro models: murine SN56 cholinergic cell line and rat primary cortical neurons. The samples were exposed at a dose of 1W/kg at 900 MHz GSM modulated. The phenotype analysis was carried out at 48 and 72 h (24 and 48 h of SN56 cell line differentiation) or at 24, 72, 120 h (2, 4 and 6 days in vitro for cortical neurons) of exposure, on live and immunolabeled neurons, and included the morphological study of neurite emission, outgrowth and branching. Moreover, cortical neurons were studied to detect alterations in the expression pattern of cytoskeleton regulating factors, e.g. beta-thymosin, and of early genes, e.g. c-Fos and c-Jun through real-time PCR on mRNA extracted after 24h exposure to EMF. We found that RF-EMF exposure reduced the number of neurites generated by both cell systems, and this alteration correlates to increased expression of beta-thymosin mRNA.

(E) Deshmukh PS, Megha K, Banerjee BD, Ahmed RS, Chandna S, Abegaonkar MP, Tripathi AK. Detection of Low Level Microwave Radiation Induced Deoxyribonucleic Acid Damage Vis-à-vis Genotoxicity in Brain of Fischer Rats. Toxicol Int. 20(1):19-24, 2013. (GT, LE)

BACKGROUND: Non-ionizing radiofrequency radiation has been increasingly used in industry, commerce, medicine and especially in mobile phone technology and has become a matter of serious concern in present time. OBJECTIVE: The present study was designed to investigate the possible deoxyribonucleic acid (DNA) damaging effects of low-level microwave radiation in brain of Fischer rats. MATERIALS AND METHODS: Experiments were performed on male Fischer rats exposed to microwave radiation for 30 days at three different frequencies: 900, 1800 and 2450 MHz. Animals were divided into 4 groups: Group I (Sham exposed): Animals not exposed to microwave radiation but kept under same conditions as that of other groups, Group II: Animals exposed to microwave radiation at frequency 900 MHz at specific absorption rate (SAR) 5.953 × 10(-4) W/kg, Group III: Animals exposed to 1800 MHz at SAR 5.835 × 10(-4) W/kg and Group IV: Animals exposed to 2450 MHz at SAR 6.672 × 10(-4) W/kg. At the end of the exposure period animals were sacrificed immediately and DNA damage in brain tissue was assessed using alkaline comet assay. RESULTS: In the present study, we demonstrated DNA damaging effects of low level microwave radiation in brain. CONCLUSION: We concluded that low SAR microwave radiation exposure at these frequencies may induce DNA strand breaks in brain tissue.

(E) Engelmann JC, Deeken R, Müller T, Nimtz G, Roelfsema MR, Hedrich R. Is gene activity in plant cells affected by UMTS-irradiation? A whole genome approach. Adv Appl Bioinform Chem. 1:71-83, 2008. (GE)

Mobile phone technology makes use of radio frequency (RF) electromagnetic fields transmitted through a dense network of base stations in Europe. Possible harmful effects of RF fields on humans and animals are discussed, but their effect on plants has received little attention. In search for physiological processes of plant cells sensitive to RF fields, cell suspension cultures of Arabidopsis thaliana were exposed for 24 h to a RF field protocol representing typical microwave exposition in an urban environment. mRNA of exposed cultures and controls was used to hybridize Affymetrix-ATH1 whole genome microarrays. Differential expression analysis revealed significant changes in transcription of 10 genes, but they did not exceed a fold change

of 2.5. Besides that 3 of them are dark-inducible, their functions do not point to any known responses of plants to environmental stimuli. The changes in transcription of these genes were compared with published microarray datasets and revealed a weak similarity of the microwave to light treatment experiments. Considering the large changes described in published experiments, it is questionable if the small alterations caused by a 24 h continuous microwave exposure would have any impact on the growth and reproduction of whole plants.

(E) Esmekaya MA, Aytekin E, Ozgur E, Güler G, Ergun MA, Omeroğlu S, Seyhan N. Mutagenic and morphologic impacts of 1.8GHz radiofrequency radiation on human peripheral blood lymphocytes (hPBLs) and possible protective role of pre-treatment with Ginkgo biloba (EGb 761). Sci Total Environ. 410-411:59-64, 2011. (GT, OX)

The mutagenic and morphologic effects of 1.8GHz Global System for Mobile Communications (GSM) modulated RF (radiofrequency) radiation alone and in combination with Ginkgo biloba (EGb 761) pre-treatment in human peripheral blood lymphocytes (hPBLs) were investigated in this study using Sister Chromatid Exchange (SCE) and electron microscopy. Cell viability was assessed with 3-(4, 5-dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide (MTT) reduction assay. The lymphocyte cultures were exposed to GSM modulated RF radiation at 1.8GHz for 6, 8, 24 and 48h with and without EGb 761. We observed morphological changes in pulse-modulated RF radiated lymphocytes. Longer exposure periods led to destruction of organelle and nucleus structures. Chromatin change and the loss of mitochondrial crista occurred in cells exposed to RF for 8h and 24h and were more pronounced in cells exposed for 48h. Cytoplasmic lysis and destruction of membrane integrity of cells and nuclei were also seen in 48h RF exposed cells. There was a significant increase ($p<0.05$) in SCE frequency in RF exposed lymphocytes compared to sham controls. EGb 761 pre-treatment significantly decreased SCE from RF radiation. RF radiation also inhibited cell viability in a time dependent manner. The inhibitory effects of RF radiation on the growth of lymphoctes were marked in longer exposure periods. EGb 761 pre-treatment significantly increased cell viability in RF+EGb 761 treated groups at 8 and 24h when compared to RF exposed groups alone. The results of our study showed that RF radiation affects cell morphology, increases SCE and inhibits cell proliferation. However, EGb 761 has a protective role against RF induced mutagenity. We concluded that RF radiation induces chromosomal damage in hPBLs but this damage may be reduced by EGb 761 pre-treatment.

(NE) Falzone N, Huyser C, Franken DR, Leszczynski D. Mobile phone radiation does not induce pro-apoptosis effects in human spermatozoa. Radiat Res 174:169-176, 2010. (GT, OX)

Abstract Recent reports suggest that mobile phone radiation may diminish male fertility. However, the effects of this radiation on human spermatozoa are largely unknown. The present study examined effects of the radiation on induction of apoptosis-related properties in human spermatozoa. Ejaculated, density-purified, highly motile human spermatozoa were exposed to mobile phone radiation at specific absorption rates (SARs) of 2.0 and 5.7 W/kg. At various times after exposure, flow cytometry was used to examine caspase 3 activity, externalization of phosphatidylserine (PS), induction of DNA strand breaks, and generation of reactive oxygen species. Mobile phone radiation had no statistically significant effect on any of the parameters

studied. This suggests that the impairment of fertility reported in some studies was not caused by the induction of apoptosis in spermatozoa.

(E) Ferreira AR, Knakievicz T, de Bittencourt Pasquali MA, Gelain DP, Dal-Pizzol F, Fernandez CE, de Almeida de Salles AA, Ferreira HB, Moreira JC. Ultra high frequency-electromagnetic field irradiation during pregnancy leads to an increase in erythrocytes micronuclei incidence in rat offspring. Life Sci 80: 43-50, 2006. (GT, OX, LE, DE)

Mobile telephones and their base stations are an important ultra high frequency-electromagnetic field (UHF-EMF) source and their utilization is increasing all over the world. Epidemiological studies suggested that low energy UHF-EMF emitted from a cellular telephone may cause biological effects, such as DNA damage and changes on oxidative metabolism. An in vivo mammalian cytogenetic test, the micronucleus (MN) assay, was used to investigate the occurrence of chromosomal damage in erythrocytes from rat offspring exposed to a non-thermal UHF-EMF from a cellular phone during their embryogenesis; the irradiated group showed a significant increase in MN occurrence. In order to investigate if UHF-EMF could also alter oxidative parameters in the peripheral blood and in the liver - an important hematopoietic tissue in rat embryos and newborns - we also measured the activity of antioxidant enzymes, quantified total sulfhydryl content, protein carbonyl groups, thiobarbituric acid-reactive species and total non-enzymatic antioxidant defense. No significant differences were found in any oxidative parameter of offspring blood and liver. The average number of pups in each litter has also not been significantly altered. Our results suggest that, under our experimental conditions, UHF-EMF is able to induce a genotoxic response in hematopoietic tissue during the embryogenesis through an unknown mechanism.

(NE) Finnie JW, Cai Z, Blumbergs PC, Manavis J, Kuchel TR. Expression of the immediate early gene, c-fos, in fetal brain after whole of gestation exposure of pregnant mice to global system for mobile communication microwaves. Pathology. 38(4):333-335, 2006. (GE, DE)

AIMS: To study immediate early gene, c-fos, expression as a marker of neural stress after whole of gestation exposure of the fetal mouse brain to mobile telephone-type radiofrequency fields. METHODS: Using a purpose-designed exposure system at 900 MHz, pregnant mice were given a single, far-field, whole body exposure at a specific absorption rate of 4 W/kg for 60 min/day from day 1 to day 19 of gestation. Pregnant control mice were sham-exposed or freely mobile in a cage without further restraint. Immediately prior to parturition on gestational day 19, fetal heads were collected, fixed in 4% paraformaldehyde and paraffin embedded. Any stress response in the brain was detected by c-fos immunohistochemistry in the cerebral cortex, basal ganglia, thalamus, hippocampus, midbrain, cerebellum and medulla. RESULTS: c-fos expression was of limited, but consistent, neuroanatomical distribution and there was no difference in immunoreactivity between exposed and control brains. CONCLUSION: In this animal model, no stress response was detected in the fetal brain using c-fos immunohistochemistry after whole of gestation exposure to mobile telephony.

(E) Franzellitti S, Valbonesi P, Ciancaglini N, Biondi C, Contin A, Bersani F, Fabbri E. Transient DNA damage induced by high-frequency electromagnetic fields (GSM 1.8 GHz)

in the human trophoblast HTR-8/SVneo cell line evaluated with the alkaline comet assay. Mutat Res 683(1-2):35-42, 2010. (GT, WS)

One of the most controversial issue regarding high-frequency electromagnetic fields (HF-EMF) is their putative capacity to affect DNA integrity. This is of particular concern due to the increasing use of HF-EMF in communication technologies, including mobile phones. Although epidemiological studies report no detrimental effects on human health, the possible disturbance generated by HF-EMF on cell physiology remains controversial. In addition, the question remains as to whether cells are able to compensate their potential effects. We have previously reported that a 1-h exposure to amplitude-modulated 1.8 GHz sinusoidal waves (GSM-217 Hz, SAR=2 W/kg) largely used in mobile telephony did not cause increased levels of primary DNA damage in human trophoblast HTR-8/SVneo cells. Nevertheless, further investigations on trophoblast cell responses after exposure to GSM signals of different types and durations were considered of interest. In the present work, HTR-8/SVneo cells were exposed for 4, 16 or 24h to 1.8 GHz continuous wave (CW) and different GSM signals, namely GSM-217 Hz and GSM-Talk (intermittent exposure: 5 min field on, 10 min field off). The alkaline comet assay was used to evaluate primary DNA damages and/or strand breaks due to uncompleted repair processes in HF-EMF exposed samples. The amplitude-modulated signals GSM-217 Hz and GSM-Talk induced a significant increase in comet parameters in trophoblast cells after 16 and 24h of exposure, while the un-modulated CW was ineffective. However, alterations were rapidly recovered and the DNA integrity of HF-EMF exposed cells was similar to that of sham-exposed cells within 2h of recovery in the absence irradiation. Our data suggest that HF-EMF with a carrier frequency and modulation scheme typical of the GSM signal may affect the DNA integrity.

(E) Furtado-Filho OV, Borba JB, Dallegrave A, Pizzolato TM, Henriques JA, Moreira JC, Saffi J. Effect of 950 MHz UHF electromagnetic radiation on biomarkers of oxidative damage, metabolism of UFA and antioxidants in the livers of young rats of different ages. Int J Radiat Biol. 2013 Jul 25. [Epub ahead of print] (LE, GT, OX)

Purpose: To assess the effect of 950 MHz ultra-high-frequency electromagnetic radiation (UHF EMR) on biomarkers of oxidative damage, as well as to verify the concentration of unsaturated fatty acids (UFA) and the expression of the catalase in the livers of rats of different ages. Materials and methods: Twelve rats were equally divided into two groups as controls (CR) and exposed (ER), for each age (0, 6, 15 and 30 days). Radiation exposure lasted half an hour per day for up to 51 days (21 days of gestation and 6, 15 or 30 days of life outside the womb). The specific absorption rate (SAR) ranged from 1.3-1.0 W/kg. The damage to lipids, proteins and DNA was verified by thiobarbituric acid reactive substances (TBARS), protein carbonyls and comets, respectively. UFA were determined by gas chromatography with a flame ionization detector. The expression of catalase was by Western blotting. Results: The neonates had low levels of TBARS and concentrations of UFA after exposure. There was no age difference in the accumulation of protein carbonyls for any age. The DNA damage of ER 15 or 30 days was different. The exposed neonates exhibited lower expression of catalase. Conclusions: 950 MHz UHF EMR does not cause oxidative stress (OS), and it is not genotoxic to the livers of neonates or those of 6 and 15 day old rats, but it changes the concentrations of polyunsaturated fatty acid (PUFA) in neonates. For rats of 30 days, no OS, but it is genotoxic to the livers of ER to total body irradiation.

(E) Gajski G, Garaj-Vrhovac V. Radioprotective effects of honeybee venom (Apismellifera) against 915-MHz microwave radiation-induced DNA damage in wistar rat lymphocytes: in vitro study. Int J Toxicol 28:88-98, 2009. (GT, OX)

The aim of this study is to investigate the radioprotective effect of bee venom against DNA damage induced by 915-MHz microwave radiation (specific absorption rate of 0.6 W/kg) in Wistar rats. Whole blood lymphocytes of Wistar rats are treated with 1 microg/mL bee venom 4 hours prior to and immediately before irradiation. Standard and formamidopyrimidine-DNA glycosylase (Fpg)-modified comet assays are used to assess basal and oxidative DNA damage produced by reactive oxygen species. Bee venom shows a decrease in DNA damage compared with irradiated samples. Parameters of Fpg-modified comet assay are statistically different from controls, making this assay more sensitive and suggesting that oxidative stress is a possible mechanism of DNA damage induction. Bee venom is demonstrated to have a radioprotective effect against basal and oxidative DNA damage. Furthermore, bee venom is not genotoxic and does not produce oxidative damage in the low concentrations used in this study.

(E) Gandhi G, Anita, Genetic damage in mobile phone users: some preliminary findings. Ind J Hum Genet 11:99-104, 2005. (GT, HU)

BACKGROUND: The impact of microwave (MW)/radio frequency radiation (RFR) on important biological parameters is probably more than a simply thermal one. Exposure to radio frequency (RF) signals generated by the use of cellular telephones have increased dramatically and reported to affect physiological, neurological, cognitive and behavioural changes and to induce, initiate and promote carcinogenesis. Genotoxicity of RFR has also been reported in various test systems after in vitro and/or in vivo exposure but none in mobile phone users. AIMS: In the present study, DNA and chromosomal damage investigations were carried out on the peripheral blood lymphocytes of individuals using mobile phones, being exposed to MW frequency ranging from 800 to 2000 MHz. METHODS: DNA damage was assessed using the single cell gel electrophoresis assay and aneugenic and clastogenic damage by the in vivo capillary blood micronucleus test (MNT) in a total of 24 mobile phone users. RESULTS: Mean comet tail length (26.76 ± 0.054 mm; 39.75% of cells damaged) in mobile phone users was highly significant from that in the control group. The in vivo capillary blood MNT also revealed highly significant (0.25) frequency of micronucleated (MNd) cells. CONCLUSIONS: These results highlight a correlation between mobile phone use (exposure to RFR) and genetic damage and require interim public health actions in the wake of widespread use of mobile telephony.

(E) Gandhi G, Singh P. Cytogenetic damage in mobile phone users: preliminary data. Int J Hum Genet 5:259-265, 2005. (GT, HU)

Mobile telephones, sometimes called cellular (cell) phones or handies, are now an integral part of modern life. The mobile phone handsets are low-powered radiofrequency transmitters, emitting maximum powers in the range of 0.2 to 0.6 watts. Scientific concenrns have increased sufficiently over the possible hazard to health from using cell phones. The reported adverse health effects include physiological, behavioural and cognitive changes as well as tumour formation and genetic damage. However findings are controversial and no consensus exists. Genotoxicity has been observed either in lower organisms or in vitro studies. The aim of the present study hence was to detect any cytogenertic damage in mobile phone users by analysing short term peripheral lymphocyte cultures for chromosomal aberrations and the buccal mucosal

cells for micronuclei (aneugenicity and clastogenicity). The results revealed increased number of micronucleated buccal cells and cytological abnormalities in cultured lymphocytes indicating the genotoxic response from mobile phone use.

(E) Garaj-Vrhovac V, Gajski G, Pažanin S, Sarolić A, Domijan AM, Flajs D, Peraica M. Assessment of cytogenetic damage and oxidative stress in personnel occupationally exposed to the pulsed microwave radiation of marine radar equipment. Int J Hyg Environ Health. 4(1):59-65, 2011. (GT, HU, OX)

Due to increased usage of microwave radiation, there are concerns of its adverse effect in today's society. Keeping this in view, study was aimed at workers occupationally exposed to pulsed microwave radiation, originating from marine radars. Electromagnetic field strength was measured at assigned marine radar frequencies (3 GHz, 5.5 GHz and 9.4 GHz) and corresponding specific absorption rate values were determined. Parameters of the comet assay and micronucleus test were studied both in the exposed workers and in corresponding unexposed subjects. Differences between mean tail intensity (0.67 vs. 1.22) and moment (0.08 vs. 0.16) as comet assay parameters and micronucleus test parameters (micronuclei, nucleoplasmic bridges and nuclear buds) were statistically significant between the two examined groups, suggesting that cytogenetic alterations occurred after microwave exposure. Concentrations of glutathione and malondialdehyde were measured spectrophotometrically and using high performance liquid chromatography. The glutathione concentration in exposed group was significantly lower than in controls (1.24 vs. 0.53) whereas the concentration of malondialdehyde was significantly higher (1.74 vs. 3.17), indicating oxidative stress. Results suggests that pulsed microwaves from working environment can be the cause of genetic and cell alterations and that oxidative stress can be one of the possible mechanisms of DNA and cell damage.

(E) Guler G, Tomruk A, Ozgur E, Seyhan N.The effect of radiofrequency radiation on DNA and lipid damage in non-pregnant and pregnant rabbits and their newborns. Gen Physiol Biophys 29:59-66, 2010. (GT, OX, LE, DE)

The concerns of people on possible adverse health effects of radiofrequency radiation (RFR) generated from mobile phones as well as their supporting transmitters (base stations) have increased markedly. RFR effect on oversensitive people, such as pregnant women and their developing fetuses, and older people is another source of concern that should be considered. In this study, oxidative DNA damage and lipid peroxidation levels in the brain tissue of pregnant and non-pregnant New Zealand White rabbits and their newborns exposed to RFR were investigated. Thirteen-month-old rabbits were studied in four groups as non-pregnant-control, non-pregnant-RFR exposed, pregnant-control and pregnant-RFR exposed. They were exposed to RFR (1800 MHz GSM; 14 V/m as reference level) for 15 min/day during 7 days. Malondialdehyde (MDA) and 8-hydroxy-2'-deoxyguanosine (8-OHdG) levels were analyzed. MDA and 8-OHdG levels of non-pregnant and pregnant-RFR exposed animals significantly increased with respect to controls ($p < 0.001$, Mann-Whitney test). No difference was found in the newborns ($p > 0.05$, Mann-Whitney). There exist very few experimental studies on the effects of RFR during pregnancy. It would be beneficial to increase the number of these studies in order to establish international standards for the protection of pregnant women from RFR.

(E) Güler G, Tomruk A, Ozgur E, Sahin D, Sepici A, Altan N, Seyhan N. The effect of radiofrequency radiation on DNA and lipid damage in female and male infant rabbits. Int J Radiat Biol. 88(4):367-373, 2012. (LE, GT, OX, DE)

PURPOSE: We aimed to design a prolonged radiofrequency (RF) radiation exposure and investigate in an animal model, possible bio-effects of RF radiation on the ongoing developmental stages of children from conception to childhood. **MATERIALS AND METHODS:** A total of 72 New Zealand female and male white rabbits aged one month were used. Females were exposed to RF radiation for 15 min/day during 7 days, whereas males were exposed to the same level of radiation for 15 min/day during 14 days. Thirty-six female and 36 male infant rabbits were randomly divided into four groups: Group I [Intrauterine (IU) exposure (-); Extrauterine (EU) exposure (-)]: Sham exposure which means rabbits were exposed to 1800 MHz Global System for Mobile Telecommunication (GSM)-like RF signals neither in the IU nor in the EU periods. Group II [IU exposure (-); EU exposure (+)]: Infant rabbits were exposed to 1800 MHz GSM-like RF signals when they reached one month of age. Group III [IU exposure (+); EU exposure (-)]: Infant rabbits were exposed to 1800 MHz GSM-like RF signals in the IU period (between 15th and 22nd days of the gestational period). Group IV [IU exposure (+); EU exposure (+)]: Infant rabbits were exposed to 1800 MHz GSM-like RF signals both in the IU period (between 15th and 22nd days of the gestational period) and in the EU period when they reached one month of age. Biochemical analysis for lipid peroxidation and DNA damage were carried out in the livers of all rabbits. **RESULTS:** Lipid peroxidation levels in the liver tissues of female and male infant rabbits increased under RF radiation exposure. Liver 8-hydroxy-2'-deoxyguanosine (8-OHdG) levels of female rabbits exposed to RF radiation were also found to increase when compared with the levels of non-exposed infants. However, there were no changes in liver 8-OHdG levels of male rabbits under RF exposure. **CONCLUSION:** Consequently, it can be concluded that GSM-like RF radiation may induce biochemical changes by increasing free radical attacks to structural biomolecules in the rabbit as an experimental animal model.

(NE) Gurbuz N, Sirav B, Yuvaci HU, Turhan N, Coskun ZK, Seyhan N. Is there any possible genotoxic effect in exfoliated bladder cells of rat under the exposure of 1800 MHz GSM-like modulated radio frequency radiation (RFR)? Electromagn Biol Med. 29(3):98-104, 2010. (LE, GT)

People are exposed to many carcinogenic and mutagenic chemicals in their everyday lives. These include antineoplastic drugs, Polycyclic aromatic hydrocarbons (PAH)s, aromatic amines, nitrosamines, metals, and electromagnetic radiation. Based on the state of knowledge acquired during the last 50 years of research on possible biological effects of electromagnetic fields (EMF), the majority of the scientific community is convinced that exposure to EMF below the existing security limits does not cause a risk to the health of the general public. However, this position is questioned by others, who are of the opinion that the available research data are contradictory or inconsistent and, therefore, unreliable. In this study, we aimed to investigate if there is any effect of 1800 MHz GSM modulated radio frequency radiation (RFR) on the number of micronucleus in exfoliated bladder cells of rat which will be informative about the genotoxic damage. Exposure period was 20 min/day, 5 days/week during a month. Six female Wistar rats were used for two groups: Group I (n=6): controls; Group II (n=6): 1.8 GHz exposed animals.

1800 MHz RFR did not showed a significant MN frequencies in rat bladder cells when compared with the control group (p>0.05). 1800 MHz RFR-exposed animals did not produce any genotoxic effect when compared with the control group (p>0.05). Kinetic studies are important for any biomarker, especially those in which tissue differentiation and maturation processes will heavily influence the time between induction of damage and collection of damaged cells for micronucleus analysis.

(NE) Gurbuz N, Sirav B, Colbay M, Yetkin I, Seyhan N. No genotoxic effect in exfoliated bladder cells of rat under the exposure of 1800 and 2100-MHz radio frequency radiation. Electromagn Biol Med. 2013 Nov 27. [Epub ahead of print] (GT, LE)

Abstract In this study, we aimed to investigate the effects of 1800 and 2100 MHz Radio Frequency (RF) radiation on the number of micronucleus (MN) in exfoliated bladder cells of rat which shows the genotoxic damage. Exposure period was 30 min/day, 6 days/week for a month and two months exposure periods. Thirty male wistar albino rats were used for five groups: Group I (n = 6): 1800 MHz RF exposed animals for one month, Group II (n = 6): 2100 MHz RF exposed animals for one month, Group III (n = 6): 2100 MHz RF exposed for two months, Group IV (n = 6): control group for one month, Group V (n = 6): control group for two months. Rats of the control groups were housed in their home cages during the entire experimental period without subjecting to any experimental manipulation. 1800 and 2100 MHz RF exposures did not result in any significant MN frequencies in rat bladder cells with respect to the control groups (p > 0.05). There was no statistically significant difference between 2100 MHz RF exposed groups, either. Further studies are needed to demonstrate if there is any genotoxic effect, micronucleus formation in other tissues of rats.

(NE) Hansteen IL, Lågeide L, Clausen KO, Haugan V, Svendsen M, Eriksen JG, Skiaker R, Hauger E, Vistnes AI, Kure EH. Cytogenetic effects of 18.0 and 16.5 GHz microwave radiation on human lymphocytes in vitro. Anticancer Res 29:2885-2892, 2009. (GT, IA, WS)

BACKGROUND: There are few cell studies on the direct genotoxic effects of microwave radiation. In this study, cytogenetic effects of microwave radiation alone or in combination with mitomycin C (MMC) were investigated. MATERIALS AND METHODS: Lymphocytes from two smoking and four non-smoking donors were exposed for 53 hours in vitro to 1.0 W/m continuous-wave radiation at 18.0 GHz or 10 W/m pulsed-wave at 16.5 GHz, alone or in combination with MMC. DNA synthesis and repair were inhibited in vitro in some cultures. RESULTS: No synergistic effect was observed in cells exposed to combinations of microwave radiation and in vitro exposure to MMC, or to cells pre-exposed in vivo to tobacco smoke. For the 16.5 GHz pulsed exposure, a non-significant trend consisting of an increase in aberration frequencies with microwave radiation was shown for the DNA synthesis and repair inhibited cultures both with and without MMC. CONCLUSION: Neither 18.0 GHz continuous-wave nor 16.5 GHz pulsed-wave exposure to human lymphocytes in vitro induced statistically significant increases in chromosomal aberration frequencies. 16.5 GHz pulsed-wave exposure requires further documentation before a true negative conclusion can be drawn.

(NE) Hansteen IL, Clausen KO, Haugan V, Svendsen M, Svendsen MV, Eriksen JG, Skiaker R, Hauger E, Lågeide L, Vistnes AI, Kure EH. Cytogenetic effects of exposure to

2.3 GHz radiofrequency radiation on human lymphocytes in vitro. Anticancer Res 29:4323-4330, 2009. (GT, IA)

BACKGROUND: No previous in vitro studies have tested radio frequency radiation for at least one full cell cycle in culture. The aim was to test if exposure used in mobile phones and wireless network technologies would induce DNA damage in cultured human lymphocytes with and without a known clastogen. MATERIALS AND METHODS: Lymphocytes from six donors were exposed to 2.3 GHz, 10 W/m continuous waves, or 2.3 GHz, 10 W/m pulsed waves (200 Hz pulse frequency, 50% duty cycle). Mitomycin C was added to half of the cultures. DNA synthesis and repair were inhibited in one experiment. RESULTS: No statistically significant differences were observed between control and exposed cultures. A weak trend for more chromosomal damage with the interaction of pulsed fields with mitomycin C compared to a constant field was observed. CONCLUSION: Exposure during the whole cell cycle in inhibited cultures did not resulted in significant differences in chromosomal aberrations as compared to controls.

(E) Hekmat A, Saboury AA, Moosavi-Movahedi AA. The toxic effects of mobile phone radiofrequency (940MHz) on the structure of calf thymus DNA. Ecotoxicol Environ Saf. 2012 Nov 16. pii: S0147-6513(12)00368-5. doi: 10.1016/j.ecoenv.2012.10.016. [Epub ahead of print] (GT)

Currently, the biological effects of nonionizing electromagnetic fields (EMFs) including radiofrequency (RF) radiation have been the subject of numerous experimental and theoretical studies. The aim of this study is to evaluate the possible biological effects of mobile phone RF (940MHz, 15V/m and SAR=40mW/kg) on the structure of calf thymus DNA (ct DNA) immediately after exposure and 2h after 45min exposure via diverse range of spectroscopic instruments. The UV-vis and circular dichroism (CD) experiments depict that mobile phone EMFs can remarkably cause disturbance on ct DNA structure. In addition, the DNA samples, immediately after exposure and 2h after 45min exposure, are relatively thermally unstable compared to the DNA solution, which was placed in a small shielded box (unexposed ct DNA). Furthermore, the exposed DNA samples (the DNA samples that were exposed to 940MHz EMF) have more fluorescence emission when compared with the unexposed DNA, which may have occurred attributable to expansion of the exposed DNA structure. The results of dynamic light scattering (DLS) and zeta potential experiments demonstrate that RF-EMFs lead to increment in the surface charge and size of DNA. The structure of DNA immediately after exposure is not significantly different from the DNA sample 2h after 45min exposure. In other words, the EMF-induced conformational changes are irreversible. Collectively, our results reveal that 940MHz can alter the structure of DNA. The displacement of electrons in DNA by EMFs may lead to conformational changes of DNA and DNA disaggregation. Results from this study could have an important implication on the health effects of RF-EMFs exposure. In addition, this finding could proffer a novel strategy for the development of next generation of mobile phone.

(NE) Hintzsche H, Stopper H. Micronucleus frequency in buccal mucosa cells of mobile phone users. Toxicol Lett. 193(1):124-130, 2010. (GT, HU)

Mobile phones are being used extensively throughout the world, with more than four billion accounts existing in 2009. This technology applies electromagnetic radiation in the microwave

range. Health effects of this radiation have been subject of debate for a long time, both within the scientific community and within the general public. This study investigated the effect of mobile phone use on genomic instability of the human oral cavity's mucosa cells. 131 Individuals donated buccal mucosa cells extracted by slightly scraping the oral cavity with a cotton swab. Every participant filled out a questionnaire about mobile phone use including duration of weekly use, overall period of exposure and headset usage. 13 Individuals did not use mobile phones at all, 85 reported using the mobile phone for three hours per week or less, and 33 reported use of more than three hours per week. Additionally, information on age, gender, body weight, smoking status, medication and nutrition was retrieved. For staining of the cells a procedure using alpha-tubulin-antibody and chromomycin A(3) was applied. Micronuclei and other markers were evaluated in 1000 cells per individual at the microscope. A second scorer counted another 1000 cells, resulting in 2000 analyzed cells per individual. Mobile phone use did not lead to a significantly increased frequency of micronuclei.

(NE) Hintzsche H, Jastrow C, Kleine-Ostmann T, Schrader T, Stopper H. 900 MHz radiation does not induce micronucleus formation in different cell types. Mutagenesis. 27(4):477-483, 2012 . (GT)

The exposure of the population to non-ionising electromagnetic radiation is still increasing, mainly due to mobile communication. Whether low-intensity electromagnetic fields can cause other effects apart from heating has been a subject of debate. One of the effects, which were proposed to be caused by mobile phone radiation, is the occurrence of mitotic disturbances. The aim of this study was to investigate possible consequences of these mitotic disturbances as manifest genomic damage, i.e. micronucleus induction. Cells were irradiated at a frequency of 900 MHz, which is located in one of the main frequency bands applied for mobile communication. Two cell types were used, HaCaT cells as human cells and A(L) cells (human-hamster hybrid cells), in which mitotic disturbances had been reported to occur. After different post-exposure incubation periods, cells were fixed and micronucleus frequencies were evaluated. Both cell types did not show any genomic damage after exposure. To adapt the protocol for the micronucleus test into the direction of the protocol for mitotic disturbances, the post-exposure incubation period was reduced and exposure time was extended to one cell cycle length. This did not result in any increase of the genomic damage. In conclusion, micronucleus induction was not observed as a consequence of exposure to non-ionising radiation, even though this agent was reported to cause mitotic disturbances under similar experimental conditions.

(NE) Hirose H, Sakuma N, Kaji N, Suhara T, Sekijima M, Nojima T, Miyakoshi J. Phosphorylation and gene expression of p53 are not affected in human cells exposed to 2.1425 GHz band CW or W-CDMA modulated radiation allocated to mobile radio base stations. Bioelectromagnetics 27:494-504, 2006. (GT)

A large-scale in vitro study focusing on low-level radiofrequency (RF) fields from mobile radio base stations employing the International Mobile Telecommunication 2000 (IMT-2000) cellular system was conducted to test the hypothesis that modulated RF fields induce apoptosis or other cellular stress response that activate p53 or the p53-signaling pathway. First, we evaluated the response of human cells to microwave exposure at a specific absorption rate (SAR) of 80 mW/kg, which corresponds to the limit of the average whole-body SAR for general public exposure defined as a basic restriction by the International Commission on Non-Ionizing

Radiation Protection (ICNIRP) guidelines. Second, we investigated whether continuous wave (CW) and wideband code division multiple access (W-CDMA) modulated signal RF fields at 2.1425 GHz induced apoptosis or any signs of stress. Human glioblastoma A172 cells were exposed to W-CDMA radiation at SARs of 80, 250, and 800 mW/kg, and CW radiation at 80 mW/kg for 24 or 48 h. Human IMR-90 fibroblasts from fetal lungs were exposed to both W-CDMA and CW radiation at a SAR of 80 mW/kg for 28 h. Under the RF field exposure conditions described above, no significant differences in the percentage of apoptotic cells were observed between the test groups exposed to RF signals and the sham-exposed negative controls, as evaluated by the Annexin V affinity assay. No significant differences in expression levels of phosphorylated p53 at serine 15 or total p53 were observed between the test groups and the negative controls by the bead-based multiplex assay. Moreover, microarray hybridization and real-time RT-PCR analysis showed no noticeable differences in gene expression of the subsequent downstream targets of p53 signaling involved in apoptosis between the test groups and the negative controls. Our results confirm that exposure to low-level RF signals up to 800 mW/kg does not induce p53-dependent apoptosis, DNA damage, or other stress response in human cells.

(NE) Hirose H, Sakuma N, Kaji N, Nakayama K, Inoue K, Sekijima M, Nojima T, Miyakoshi J. Mobile phone base station-emitted radiation does not induce phosphorylation of Hsp27. Bioelectromagnetics 28:99-108, 2007. (GE)

An in vitro study focusing on the effects of low-level radiofrequency (RF) fields from mobile radio base stations employing the International Mobile Telecommunication 2000 (IMT-2000) cellular system was conducted to test the hypothesis that modulated RF fields act to induce phosphorylation and overexpression of heat shock protein hsp27. First, we evaluated the responses of human cells to microwave exposure at a specific absorption rate (SAR) of 80 mW/kg, which corresponds to the limit of the average whole-body SAR for general public exposure defined as a basic restriction in the International Commission on Non-Ionizing Radiation Protection (ICNIRP) guidelines. Second, we investigated whether continuous wave (CW) and Wideband Code Division Multiple Access (W-CDMA) modulated signal RF fields at 2.1425 GHz induced activation or gene expression of hsp27 and other heat shock proteins (hsps). Human glioblastoma A172 cells were exposed to W-CDMA radiation at SARs of 80 and 800 mW/kg for 2-48 h, and CW radiation at 80 mW/kg for 24 h. Human IMR-90 fibroblasts from fetal lungs were exposed to W-CDMA at 80 and 800 mW/kg for 2 or 28 h, and CW at 80 mW/kg for 28 h. Under the RF field exposure conditions described above, no significant differences in the expression levels of phosphorylated hsp27 at serine 82 (hsp27[pS82]) were observed between the test groups exposed to W-CDMA or CW signal and the sham-exposed negative controls, as evaluated immediately after the exposure periods by bead-based multiplex assays. Moreover, no noticeable differences in the gene expression of hsps were observed between the test groups and the negative controls by DNA Chip analysis. Our results confirm that exposure to low-level RF field up to 800 mW/kg does not induce phosphorylation of hsp27 or expression of hsp gene family.

(NE) Huang TQ, Lee MS, Oh E, Zhang BT, Seo JS, Park WY. Molecular responses of Jurkat T-cells to 1763 MHz radiofrequency radiation.Int J RadiatBiol 84:734-741, 2008. (GT, GE)

PURPOSE: The biological effects of exposure to mobile phone emitted radiofrequency (RF) radiation are the subject of intense study, yet the hypothesis that RF exposure is a potential health hazard remains controversial. In this paper, we monitored cellular and molecular changes in Jurkat human T lymphoma cells after irradiating with 1763 MHz RF radiation to understand the effect on RF radiation in immune cells. MATERIALS AND METHODS: Jurkat T-cells were exposed to RF radiation to assess the effects on cell proliferation, cell cycle progression, DNA damage and gene expression. Jurkat cells were exposed to 1763 MHz RF radiation at 10 W/kg specific absorption rate (SAR) and compared to sham exposed cells. RESULTS: RF exposure did not produce significant changes in cell numbers, cell cycle distributions, or levels of DNA damage. In genome-wide analysis of gene expressions, there were no genes changed more than two-fold upon RF-radiation while ten genes change to 1.3 approximately 1.8-fold. Among ten genes, two cytokine receptor genes such as chemokine (C-X-C motif) receptor 3 (CXCR3) and interleukin 1 receptor, type II (IL1R2) were down-regulated upon RF radiation, but they were not directly related to cell proliferation or DNA damage responses. CONCLUSION: These results indicate that the alterations in cell proliferation, cell cycle progression, DNA integrity or global gene expression was not detected upon 1763 MHz RF radiation under 10 W/kg SAR for 24 h to Jurkat T cells.

(NE) Huang TQ, Lee MS, Oh EH, Kalinec F, Zhang BT, Seo JS, Park WY. Characterization of biological effect of 1763 MHz radiofrequency exposure on auditory hair cells.Int J Radiat Biol 84:909-915, 2008. (GT, GE)

Purpose: Radiofrequency (RF) exposure at the frequency of mobile phones has been reported not to induce cellular damage in in vitro and in vivo models. We chose HEI-OC1 immortalized mouse auditory hair cells to characterize the cellular response to 1763 MHz RF exposure, because auditory cells could be exposed to mobile phone frequencies. Materials and methods: Cells were exposed to 1763 MHz RF at a 20 W/kg specific absorption rate (SAR) in a code division multiple access (CDMA) exposure chamber for 24 and 48 h to check for changes in cell cycle, DNA damage, stress response, and gene expression. Results: Neither of cell cycle changes nor DNA damage was detected in RF-exposed cells. The expression of heat shock proteins (HSP) and the phosphorylation of mitogen-activated protein kinases (MAPK) did not change, either. We tried to identify any alteration in gene expression using microarrays. Using the Applied Biosystems 1700 full genome expression mouse microarray, we found that only 29 genes (0.09% of total genes examined) were changed by more than 1.5-fold on RF exposure. Conclusion: From these results, we could not find any evidence of the induction of cellular responses, including cell cycle distribution, DNA damage, stress response and gene expression, after 1763 MHz RF exposure at an SAR of 20 W/kg in HEI-OC1 auditory hair cells.

(E) Jiang B, Nie J, Zhou Z, Zhang J, Tong J, Cao Y. Adaptive response in mice exposed to 900 MHz radiofrequency fields: primary DNA damage. PLoS One. 7(2):e32040, 2012. (LE, GT, IA)

The phenomenon of adaptive response (AR) in animal and human cells exposed to ionizing radiation is well documented in scientific literature. We have examined whether such AR could be induced in mice exposed to non-ionizing radiofrequency fields (RF) used for wireless communications. Mice were pre-exposed to 900 MHz RF at 120 μW/cm(2) power density for 4 hours/day for 1, 3, 5, 7 and 14 days and then subjected to an acute dose of 3 Gy γ-radiation. The

primary DNA damage in the form of alkali labile base damage and single strand breaks in the DNA of peripheral blood leukocytes was determined using the alkaline comet assay. The results indicated that the extent of damage in mice which were pre-exposed to RF for 1 day and then subjected to γ-radiation was similar and not significantly different from those exposed to γ-radiation alone. However, mice which were pre-exposed to RF for 3, 5, 7 and 14 days showed progressively decreased damage and was significantly different from those exposed to γ-radiation alone. Thus, the data indicated that RF pre-exposure is capable of inducing AR and suggested that the pre-exposure for more than 4 hours for 1 day is necessary to elicit such AR.

(NE) Juutilainen J, Heikkinen P, Soikkeli H, Mäki-Paakkanen J. Micronucleus frequency in erythrocytes of mice after long-term exposure to radiofrequency radiation. Int J Radiat Biol. 83(4):213-220, 2007. (LE, GT)

PURPOSE: The aim of the study was to investigate genotoxicity of long-term exposure to radiofrequency (RF) electromagnetic fields by measuring micronuclei in erythrocytes. The blood samples were collected in two animal studies evaluating possible cocarcinogenic effects of RF fields. METHODS: In study A, female CBA/S mice were exposed for 78 weeks (1.5 h/d, 5 d/week) to either a continuous 902.5 MHz signal similar to that emitted by analog NMT (Nordic Mobile Telephone) phones at a whole-body specific absorption rate (SAR) of 1.5 W/kg, or to a pulsed 902.4 MHz signal similar to that of digital GSM (Global System for Mobile Communications) phones at 0.35 W/kg. A third group was sham-exposed, and a fourth group served as cage controls. All but the cage control animals were exposed to 4 Gy of x-rays during three first weeks of the experiment. In study B, female transgenic mice (line K2) and their nontransgenic littermates were exposed for 52 weeks (1.5 h/d, 5 d/week). Two digital mobile phone signals, GSM and DAMPS (Digital Advanced Mobile Phone System), were used at 0.5 W/kg. All but the cage-control animals were exposed 3 times per week to an ultraviolet radiation dose of 1.2 MED (minimum erythema dose). RESULTS AND CONCLUSIONS: The results did not show any effects of RF fields on micronucleus frequency in polychromatic or normochromatic erythrocytes. The results were consistent in two mouse strains (and in a transgenic variant of the second strain), after 52 or 78 weeks of exposure, at three SAR levels relevant to human exposure from mobile phones, and for three different mobile signals.

(E) Karaca E, Durmaz B, Altug H, Yildiz T, Guducu C, Irgi M, Koksal MG, Ozkinay F, Gunduz C, Cogulu O. The genotoxic effect of radiofrequency waves on mouse brain. J Neurooncol 106:53-58, 2012. (GT, GE)

Erratum: J Neurooncol 2012 May;107:665.

Concerns about the health effects of radiofrequency (RF) waves have been raised because of the gradual increase in usage of cell phones, and there are scientific questions and debates about the safety of those instruments in daily life. The aim of this study is to evaluate the genotoxic effects of RF waves in an experimental brain cell culture model. Brain cell cultures of the mice were exposed to 10.715 GHz with specific absorbtion rate (SAR) 0.725 W/kG signals for 6 h in 3 days at 25°C to check for the changes in the micronucleus (MNi) assay and in the expression of 11 proapoptotic and antiapoptotic genes. It was found that MNi rate increased 11-fold and STAT3 expression decreased 7-fold in the cell cultures which were exposed to RF. Cell phones which spread RF may damage DNA and change gene expression in brain cells.

(E) Kesari KK, Behari J. Fifty-gigahertz Microwave exposure effect of radiations on rat brain. Appl Biochem Biotechnol 158:126-139, 2009. (GT, OX, LE)

The object of this study is to investigate the effects of 50-GHz microwave radiation on the brain of Wistar rats. Male rats of the Wistar strain were used in the study. Animals of 60-day age were divided into two groups-group 1, sham-exposed, and group 2, experimental (microwave-exposed). The rats were housed in a temperature-controlled room (25 degrees C) with constant humidity (40-50%) and received food and water ad libitum. During exposure, rats were placed in Plexiglas cages with drilled ventilation holes and kept in an anechoic chamber. The animals were exposed for 2 h a day for 45 days continuously at a power level of 0.86 muW/cm with nominal specific absorption rate 8.0 x 10(-4) w/kg. After the exposure period, the rats were killed and homogenized, and protein kinase C (PKC), DNA double-strand break, and antioxidant enzyme activity [superoxides dismutase (SOD), catalase, and glutathione peroxidase (GPx)] were estimated in the whole brain. Result shows that the chronic exposure to these radiations causes DNA double-strand break (head and tail length, intensity and tail migration) and a significant decrease in GPx and SOD activity ($p = <0.05$) in brain cells, whereas catalase activity shows significant increase in the exposed group of brain samples as compared with control ($p = <0.001$). In addition to these, PKC decreased significantly in whole brain and hippocampus ($p < 0.05$). All data are expressed as mean +/- standard deviation. We conclude that these radiations can have a significant effect on the whole brain.

(E) Kesari KK, Behari J, Kumar S. Mutagenic response of 2.45 GHz radiation exposure on rat brain. Int J Radiat Biol 86:334-343, 2010. (GT, OX, LE)

Purpose: To investigate the effect of 2.45 GHz microwave radiation on rat brain of male wistar strain. Material and methods: Male rats of wistar strain (35 days old with 130 +/- 10 g body weight) were selected for this study. Animals were divided into two groups: Sham exposed and experimental. Animals were exposed for 2 h a day for 35 days to 2.45 GHz frequency at 0.34 mW/cm power density. The whole body specific absorption rate (SAR) was estimated to be 0.11 W/Kg. Exposure took place in a ventilated Plexiglas cage and kept in anechoic chamber in a far field configuration from the horn antenna. After the completion of exposure period, rats were sacrificed and the whole brain tissue was dissected and used for study of double strand DNA (Deoxyribonucleic acid) breaks by micro gel electrophoresis and the statistical analysis was carried out using comet assay (IV-2 version software). Thereafter, antioxidant enzymes and histone kinase estimation was also performed. Results: A significant increase was observed in comet head ($P < 0.002$), tail length ($P < 0.0002$) and in tail movement ($P < 0.0001$) in exposed brain cells. An analysis of antioxidant enzymes glutathione peroxidase ($P < 0.005$), and superoxide dismutase ($P < 0.006$) showed a decrease while an increase in catalase ($P < 0.006$) was observed. A significant decrease ($P < 0.023$) in histone kinase was also recorded in the exposed group as compared to the control (sham-exposed) ones. One-way analysis of variance (ANOVA) method was adopted for statistical analysis. Conclusion: The study concludes that the chronic exposure to these radiations may cause significant damage to brain, which may be an indication of possible tumour promotion (Behari and Paulraj 2007).

(E) Khalil AM, Gagaa M, Alshamali A. 8-Oxo-7, 8-dihydro-2'-deoxyguanosine as a biomarker of DNA damage by mobile phone radiation. Hum ExpToxicol 31(7):734-740, 2012. (GT, OX)

We examined the effect of exposure to mobile phone 1800 MHz radio frequency radiation (RFR) upon the urinary excretion of 8-oxo-7, 8-dihydro-2'-deoxyguanosine (8-oxodG), one major form of oxidative DNA damage, in adult male Sprague-Dawley rats. Twenty-four rats were used in three independent experiments (RFR exposed and control, 12 rats, each). The animals were exposed to RFR for 2 h from Global System for Mobile Communications (GSM) signal generator with whole-body-specific absorption rate of 1.0 W/kg. Urine samples were collected from the rat while housed in a metabolic cage during the exposure period over a 4-h period at 0.5, 1.0, 2.0 and 4.0 h from the beginning of exposure. In the control group, the signal generator was left in the turn-off position. The creatinine-standardized concentrations of 8-oxodG were measured. With the exception of the urine collected in the last half an hour of exposure, significant elevations were noticed in the levels of 8-oxodG in urine samples from rats exposed to RFR when compared to control animals. Significant differences were seen overall across time points of urine collection with a maximum at 1 h after exposure, suggesting repair of the DNA lesions leading to 8-oxodG formation.

(E) Kim JY, Hong SY, Lee YM, Yu SA, Koh WS, Hong JR, Son T, Chang SK, Lee M.In vitro assessment of clastogenicity of mobile-phone radiation (835 MHz) using the alkaline comet assay and chromosomal aberration test. Environ Toxicol 23:319-327, 2008. (GT, IA)

Recently we demonstrated that 835-MHz radiofrequency radiation electromagnetic fields (RF-EMF) neither affected the reverse mutation frequency nor accelerated DNA degradation in vitro. Here, two kinds of cytogenetic endpoints were further investigated on mammalian cells exposed to 835-MHz RF-EMF (the most widely used communication frequency band in Korean CDMA mobile phone networks) alone and in combination with model clastogens: in vitro alkaline comet assay and in vitro chromosome aberration (CA) test. No direct cytogenetic effect of 835-MHz RF-EMF was found in the in vitro CA test. The combined exposure of the cells to RF-EMF in the presence of ethylmethanesulfonate (EMS) revealed a weak and insignificant cytogenetic effect when compared to cells exposed to EMS alone in CA test. Also, the comet assay results to evaluate the ability of RF-EMF alone to damage DNA were nearly negative, although showing a small increase in tail moment. However, the applied RF-EMF had potentiation effect in comet assay when administered in combination with model clastogens (cyclophosphamide or 4-nitroquinoline 1-oxide). Thus, our results imply that we cannot confidently exclude any possibility of an increased risk of genetic damage, with important implications for the possible health effects of exposure to 835-MHz electromagnetic fields.

(E) Kumar S, Kesari KK, Behari J. Evaluation of genotoxic effects in male Wistar rats following microwave exposure. Indian J Exp Biol 48:586-592, 2010. (GT, OX)

Wistar rats (70 days old) were exposed for 2 h a day for 45 days continuously at 10 GHz [power density 0.214 mW/cm2, specific absorption rate (SAR) 0.014 W/kg] and 50 GHz (power density 0.86 microW/cm2, SAR 8.0 x10(-4) W/kg). Micronuclei (MN), reactive oxygen species (ROS), and antioxidant enzymes activity were estimated in the blood cells and serum. These radiations induce micronuclei formation and significant increase in ROS production. Significant changes in the level of serum glutathione peroxidase, superoxide dismutase and catalase were observed in exposed group as compared with control group. It is concluded that microwave exposure can be affective at genetic level. This may be an indication of tumor promotion, which comes through the overproduction of reactive oxygen species.

(E) Lakshmi NK, Tiwari R, Bhargava SC, Ahuja YR. Investigations on DNA damage and frequency of micronuclei in occupational exposure to electromagnetic fields (EMFs) emitted from video display terminals (VDTs). Gen MolBiol 33, 154-158, 2010. (GT, HU, LE)

The potential effect of electromagnetic fields (EMFs) emitted from video display terminals (VDTs) to elicit biological response is a major concern for the public. The software professionals are subjected to cumulative EMFs in their occupational environments. This study was undertaken to evaluate DNA damage and incidences of micronuclei in such professionals. To the best of our knowledge, the present study is the first attempt to carry out cytogenetic investigations on assessing bioeffects in personal computer users. The study subjects (n = 138) included software professionals using VDTs for more than 2 years with age, gender, socioeconomic status matched controls (n = 151). DNA damage and frequency of micronuclei were evaluated using alkaline comet assay and cytochalasin blocked micronucleus assay respectively. Overall DNA damage and incidence of micronuclei showed no significant differences between the exposed and control subjects. With exposure characteristics, such as total duration (years) and frequency of use (minutes/day) sub-groups were assessed for such parameters. Although cumulative frequency of use showed no significant changes in the DNA integrity of the classified sub-groups, the long-term users (> 10 years) showed higher induction of DNA damage and increased frequency of micronuclei and micro nucleated cells.

(E) Liu C, Duan W, Xu S, Chen C, He M, Zhang L, Yu Z, Zhou Z. Exposure to 1800 MHz radiofrequency electromagnetic radiation induces oxidative DNA base damage in a mouse spermatocyte-derived cell line. Toxicol Lett 218(1): 2-9, 2013a. (GT, OX, RP)

Whether exposure to radiofrequency electromagnetic radiation (RF-EMR) emitted from mobile phones can induce DNA damage in male germ cells remains unclear. In this study, we conducted a 24 h intermittent exposure (5 min on and 10 min off) of a mouse spermatocyte-derived GC-2 cell line to 1800 MHz Global System for Mobile Communication (GSM) signals in GSM-Talk mode at specific absorption rates (SAR) of 1 W/kg, 2 W/kg or 4 W/kg. Subsequently, through the use of formamidopyrimidine DNA glycosylase (FPG) in a modified comet assay, we determined that the extent of DNA migration was significantly increased at a SAR of 4 W/kg. Flow cytometry analysis demonstrated that levels of the DNA adduct 8-oxoguanine (8-oxoG) were also increased at a SAR of 4 W/kg. These increases were concomitant with similar increases in the generation of reactive oxygen species (ROS); these phenomena were mitigated by co-treatment with the antioxidant α-tocopherol. However, no detectable DNA strand breakage was observed by the alkaline comet assay. Taking together, these findings may imply the novel possibility that RF-EMR with insufficient energy for the direct induction of DNA strand breaks may produce genotoxicity through oxidative DNA base damage in male germ cells.

(E) Liu C, Gao P, Xu SC, Wang Y, Chen CH, He MD, Yu ZP, Zhang L, Zhou Z. Mobile phone radiation induces mode-dependent DNA damage in a mouse spermatocyte-derived cell line: a protective role of melatonin. Int J Radiat Biol. 2013b Aug 19. [Epub ahead of print] (GT, OX, RP)

Purpose: To evaluate whether exposure to mobile phone radiation (MPR) can induce DNA damage in male germ cells. Materials and methods: A mouse spermatocyte-derived GC-2 cell line was exposed to a commercial mobile phone handset once every 20 minutes in standby,

listen, dialed or dialing modes for 24 h. DNA damage was determined using an alkaline comet assay. Results: The levels of DNA damage were significantly increased following exposure to MPR in the listen, dialed and dialing modes. Moreover, there were significantly higher increases in the dialed and dialing modes than in the listen mode. Interestingly, these results were consistent with the radiation intensities of these modes. However, the DNA damage effects of MPR in the dialing mode were efficiently attenuated by melatonin pretreatment. Conclusions: These results regarding mode-dependent DNA damage have important implications for the safety of inappropriate mobile phone use by males of reproductive age and also suggest a simple preventive measure, keeping our body from mobile phones as far away as possible, not only during conversations but during "dialed" and "dialing" operation modes as well. Since the "dialed" mode is actually part of the standby mode, mobile phones should be kept at a safe distance from our body even during standby operation. Furthermore, the protective role of melatonin suggests that it may be a promising pharmacological candidate for preventing mobile phone use-related reproductive impairments.

(E) Lixia S, Yao K, Kaijun W, Deqiang L, Huajun H, Xiangwei G, Baohong W, Wei Z, Jianling L, Wei W. Effects of 1.8GHz radiofrequency field on DNA damage and expression of heat shock protein 70 in human lens epithelial cells. Mutat Res 602(1-2):135-42, 2006. (GT, GE)

To investigate the DNA damage, expression of heat shock protein 70 (Hsp70) and cell proliferation of human lens epithelial cells (hLEC) after exposure to the 1.8GHz radiofrequency field (RF) of a global system for mobile communications (GSM). An Xc-1800 RF exposure system was used to employ a GSM signal at 1.8GHz (217Hz amplitude-modulated) with the output power in the specific absorption rate (SAR) of 1, 2 and 3W/kg. After 2h exposure to RF, the DNA damage of hLEC was accessed by comet assay at five different incubation times: 0, 30, 60, 120 and 240min, respectively. Western blot and RT-PCR were used to determine the expression of Hsp70 in hLECs after RF exposure. The proliferation rate of cells was evaluated by bromodeoxyuridine incorporation on days 0, 1 and 4 after exposure. The results show that the difference of DNA-breaks between the exposed and sham-exposed (control) groups induced by 1 and 2W/kg irradiation were not significant at any incubation time point ($P>0.05$). The DNA damage caused by 3W/kg irradiation was significantly increased at the times of 0 and 30min after exposure ($P<0.05$), a phenomenon that could not be seen at the time points of 60, 120 or 240min ($P>0.05$). Detectable mRNA as well as protein expression of Hsp70 was found in all groups. Exposure at SARs of 2 and 3W/kg for 2h exhibited significantly increased Hsp70 protein expression ($P<0.05$), while no change in Hsp70 mRNA expression could be found in any of the groups ($P>0.05$). No difference of the cell proliferation rate between the sham-exposed and exposed cells was found at any exposure dose tested ($P>0.05$). The results indicate that exposure to non-thermal dosages of RF for wireless communications can induce no or repairable DNA damage and the increased Hsp70 protein expression in hLECs occurred without change in the cell proliferation rate. The non-thermal stress response of Hsp70 protein increase to RF exposure might be involved in protecting hLEC from DNA damage and maintaining the cellular capacity for proliferation.

(E) López-Martín E, Bregains J, Relova-Quinteiro JL, Cadarso-Suárez C, Jorge-Barreiro FJ, Ares-Pena FJ. The action of pulse-modulated GSM radiation increases regional changes in brain activity and c-Fos expression in cortical and subcortical areas in a rat

model of picrotoxin-induced seizure proneness. J Neurosci Res. 87(6):1484-1499, 2009. (AS, GE, WS, IA)

The action of the pulse-modulated GSM radiofrequency of mobile phones has been suggested as a physical phenomenon that might have biological effects on the mammalian central nervous system. In the present study, GSM-exposed picrotoxin-pretreated rats showed differences in clinical and EEG signs, and in c-Fos expression in the brain, with respect to picrotoxin-treated rats exposed to an equivalent dose of unmodulated radiation. Neither radiation treatment caused tissue heating, so thermal effects can be ruled out. The most marked effects of GSM radiation on c-Fos expression in picrotoxin-treated rats were observed in limbic structures, olfactory cortex areas and subcortical areas, the dentate gyrus, and the central lateral nucleus of the thalamic intralaminar nucleus group. Nonpicrotoxin-treated animals exposed to unmodulated radiation showed the highest levels of neuronal c-Fos expression in cortical areas. These results suggest a specific effect of the pulse modulation of GSM radiation on brain activity of a picrotoxin-induced seizure-proneness rat model and indicate that this mobile-phone-type radiation might induce regional changes in previous preexcitability conditions of neuronal activation.

(E) Luukkonen J, Hakulinen P, Mäki-Paakkanen J, Juutilainen J, Naarala J. Enhancement of chemically induced reactive oxygen species production and DNA damage in human SH-SY5Y neuroblastoma cells by 872MHz radiofrequency radiation. Mutat Res 662:54-58, 2009. (GT, OX, WS)

The objective of the study was to investigate effects of 872 MHz radiofrequency (RF) radiation on intracellular reactive oxygen species (ROS) production and DNA damage at a relatively high SAR value (5W/kg). The experiments also involved combined exposure to RF radiation and menadione, a chemical inducing intracellular ROS production and DNA damage. The production of ROS was measured using the fluorescent probe dichlorofluorescein and DNA damage was evaluated by the Comet assay. Human SH-SY5Y neuroblastoma cells were exposed to RF radiation for 1h with or without menadione. Control cultures were sham exposed. Both continuous waves (CW) and a pulsed signal similar to that used in global system for mobile communications (GSM) mobile phones were used. Exposure to the CW RF radiation increased DNA breakage ($p<0.01$) in comparison to the cells exposed only to menadione. Comparison of the same groups also showed that ROS level was higher in cells exposed to CW RF radiation at 30 and 60 min after the end of exposure ($p<0.05$ and $p<0.01$, respectively). No effects of the GSM signal were seen on either ROS production or DNA damage. The results of the present study suggest that 872MHz CW RF radiation at 5W/kg might enhance chemically induced ROS production and thus cause secondary DNA damage. However, there is no known mechanism that would explain such effects from CW RF radiation but not from GSM modulated RF radiation at identical SAR.

(NE) Luukkonen J, Juutilainen J, Naarala J. Combined effects of 872 MHz radiofrequency radiation and ferrous chloride on reactive oxygen species production and DNA damage in human SH-SY5Y neuroblastoma cells. Bioelectromagnetics 31:417-424, 2010. (GT, OX)

The aim of the present study was to investigate possible cooperative effects of radiofrequency (RF) radiation and ferrous chloride (FeCl) on reactive oxygen species (ROS) production and

DNA damage. In order to test intracellular ROS production as a possible underlying mechanism of DNA damage, we applied the fluorescent probe DCFH-DA. Integrity of DNA was quantified by alkaline comet assay. The exposures to 872 MHz RF radiation were conducted at a specific absorption rate (SAR) of 5 W/kg using continuous waves (CW) or a modulated signal similar to that used in Global System for Mobile Communications (GSM) phones. Four groups were included: Sham exposure (control), RF radiation, Chemical treatment, Chemical treatment, and RF radiation. In the ROS production experiments, human neuroblastoma (SH-SY5Y) cells were exposed to RF radiation and 10 microg/ml FeCl for 1 h. In the comet assay experiments, the exposure time was 3 h and an additional chemical (0.015% diethyl maleate) was used to make DNA damage level observable. The chemical treatments resulted in statistically significant responses, but no effects from either CW or modulated RF radiation were observed on ROS production, DNA damage or cell viability.

(NE) Maes A, Van Gorp U, Verschaeve L. Cytogenetic investigation of subjects professionally exposed to radiofrequency radiation. Mutagenesis 21:139-42, 2006. (GT, IA)

Nowadays, virtually everybody is exposed to radiofrequency radiation (RFR) from mobile phone base station antennas or other sources. At least according to some scientists, this exposure can have detrimental health effects. We investigated cytogenetic effects in peripheral blood lymphocytes from subjects who were professionally exposed to mobile phone electromagnetic fields in an attempt to demonstrate possible RFR-induced genetic effects. These subjects can be considered well suited for this purpose as their RFR exposure is 'normal' though rather high, and definitely higher than that of the 'general population'. The alkaline comet assay, sister chromatid exchange (SCE) and chromosome aberration tests revealed no evidence of RFR-induced genetic effects. Blood cells were also exposed to the well known chemical mutagen mitomycin C in order to investigate possible combined effects of RFR and the chemical. No cooperative action was found between the electromagnetic field exposure and the mutagen using either the comet assay or SCE test.

(E) Manti L, Braselmann H, Calabrese ML, Massa R, Pugliese M, Scampoli P, Sicignano G, Grossi G. Effects of modulated microwave radiation at cellular telephone frequency (1.95 GHz) on X-ray-induced chromosome aberrations in human lymphocytes in vitro. Radiat Res 169:575-583, 2008. (GT, IA)

The case for a DNA-damaging action produced by radiofrequency (RF) signals remains controversial despite extensive research. With the advent of the Universal Mobile Telecommunication System (UMTS) the number of RF-radiation-exposed individuals is likely to escalate. Since the epigenetic effects of RF radiation are poorly understood and since the potential modifications of repair efficiency after exposure to known cytotoxic agents such as ionizing radiation have been investigated infrequently thus far, we studied the influence of UMTS exposure on the yield of chromosome aberrations induced by X rays. Human peripheral blood lymphocytes were exposed in vitro to a UMTS signal (frequency carrier of 1.95 GHz) for 24 h at 0.5 and 2.0 W/kg specific absorption rate (SAR) using a previously characterized waveguide system. The frequency of chromosome aberrations was measured on metaphase spreads from cells given 4 Gy of X rays immediately before RF radiation or sham exposures by fluorescence in situ hybridization. Unirradiated controls were RF-radiation- or sham-exposed. No significant variations due to the UMTS exposure were found in the fraction of aberrant cells. However, the frequency of exchanges per cell was affected by the SAR, showing a small but

statistically significant increase of 0.11 exchange per cell compared to 0 W/kg SAR. We conclude that, although the 1.95 GHz signal (UMTS modulated) does not exacerbate the yield of aberrant cells caused by ionizing radiation, the overall burden of X-ray-induced chromosomal damage per cell in first-mitosis lymphocytes may be enhanced at 2.0 W/kg SAR. Hence the SAR may either influence the repair of X-ray-induced DNA breaks or alter the cell death pathways of the damage response.

(E) Mazor R, Korenstein-Ilan A, Barbul A, Eshet Y, Shahadi A, Jerby E, Korenstein R. Increased levels of numerical chromosome aberrations after in vitro exposure of human peripheral blood lymphocytes to radiofrequency electromagnetic fields for 72 hours. Radiat Res. 169(1):28-37, 2008. (GT)

We investigated the effects of 72 h in vitro exposure of 10 human lymphocyte samples to radiofrequency electromagnetic fields (800 MHz, continuous wave) on genomic instability. The lymphyocytes were exposed in a specially designed waveguide resonator at specific absorption rates (SARs) of 2.9 and 4.1 W/kg in a temperature range of 36-37 degrees C. The induced aneuploidy of chromosomes 1, 10, 11 and 17 was determined by interphase FISH using semi-automated image analysis. We observed increased levels of aneuploidy depending on the chromosome studied as well as on the level of exposure. In chromosomes 1 and 10, there was increased aneuploidy at the higher SAR, while for chromosomes 11 and 17, the increases were observed only for the lower SAR. Multisomy (chromosomal gains) appeared to be the primary contributor to the increased aneuploidy. The effect of temperature on the level of aneuploidy was examined over the range of 33.5-40 degrees C for 72 h with no statistically significant difference in the level of aneuploidy compared to 37 degrees C. These findings suggest the possible existence of an athermal effect of RF radiation that causes increased levels of aneuploidy. These results contribute to the assessment of potential health risks after continuous chronic exposure to RF radiation at SARs close to the current levels set by ICNIRP guidelines.

(E) Nikolova T, Czyz J, Rolletschek A, Blyszczuk P, Fuchs J, Jovtchev G, Schuderer J, Kuster N, Wobus AM. Electromagnetic fields affect transcript levels of apoptosis-related genes in embryonic stem cell-derived neural progenitor cells. ASEB J 19(12):1686-1688, 2005. (GT, GE)

Mouse embryonic stem (ES) cells were used as an experimental model to study the effects of electromagnetic fields (EMF). ES-derived nestin-positive neural progenitor cells were exposed to extremely low frequency EMF simulating power line magnetic fields at 50 Hz (ELF-EMF) and to radiofrequency EMF simulating the Global System for Mobile Communication (GSM) signals at 1.71 GHz (RF-EMF). Following EMF exposure, cells were analyzed for transcript levels of cell cycle regulatory, apoptosis-related, and neural-specific genes and proteins; changes in proliferation; apoptosis; and cytogenetic effects. Quantitative RT-PCR analysis revealed that ELF-EMF exposure to ES-derived neural cells significantly affected transcript levels of the apoptosis-related bcl-2, bax, and cell cycle regulatory "growth arrest DNA damage inducible" GADD45 genes, whereas mRNA levels of neural-specific genes were not affected. RF-EMF exposure of neural progenitor cells resulted in down-regulation of neural-specific Nurr1 and in up-regulation of bax and GADD45 mRNA levels. Short-term RF-EMF exposure for 6 h, but not for 48 h, resulted in a low and transient increase of DNA double-strand breaks. No effects of ELF- and RF-EMF on mitochondrial function, nuclear apoptosis, cell proliferation, and

chromosomal alterations were observed. We may conclude that EMF exposure of ES-derived neural progenitor cells transiently affects the transcript level of genes related to apoptosis and cell cycle control. However, these responses are not associated with detectable changes of cell physiology, suggesting compensatory mechanisms at the translational and posttranslational level.

(E) Nittby H, Widegren B, Krogh M, Grafström G, Berlin H, Rehn G, Eberhardt JL, Malmgren L, Persson BRR, Salford L. Exposure to radiation from global system for mobile communications at 1,800 MHz significantly changes gene expression in rat hippocampus and cortex. Environmentalist 28(4), 458-465, 2008. (GE)

We have earlier shown that radio frequency electromagnetic fields can cause significant leakage of albumin through the blood–brain barrier of exposed rats as compared to non-exposed rats, and also significant neuronal damage in rat brains several weeks after a 2 h exposure to a mobile phone, at 915 MHz with a global system for mobile communications (GSM) frequency modulation, at whole-body specific absorption rate values (SAR) of 200, 20, 2, and 0.2 mW/kg. We have now studied whether 6 h of exposure to the radiation from a GSM mobile test phone at 1,800 MHz (at a whole-body SAR-value of 13 mW/kg, corresponding to a brain SAR-value of 30 mW/kg) has an effect upon the gene expression pattern in rat brain cortex and hippocampus—areas where we have observed albumin leakage from capillaries into neurons and neuronal damage. Microarray analysis of 31,099 rat genes, including splicing variants, was performed in cortex and hippocampus of 8 Fischer 344 rats, 4 animals exposed to global system for mobile communications electromagnetic fields for 6 h in an anechoic chamber, one rat at a time, and 4 controls kept as long in the same anechoic chamber without exposure, also in this case one rat at a time. Gene ontology analysis (using the gene ontology categories biological processes, molecular functions, and cell components) of the differentially expressed genes of the exposed animals versus the control group revealed the following highly significant altered gene categories in both cortex and hippocampus: extracellular region, signal transducer activity, intrinsic to membrane, and integral to membrane. The fact that most of these categories are connected with membrane functions may have a relation to our earlier observation of albumin transport through brain capillaries.

(E) Nylund R, Leszczynski D. Mobile phone radiation causes changes in gene and protein expression in human endothelial cell lines and the response seems to be genome- and proteome-dependent. Proteomics 6:4769-4780, 2006. (GE, CS)

We have examined in vitro cell response to mobile phone radiation (900 MHz GSM signal) using two variants of human endothelial cell line: EA.hy926 and EA.hy926v1. Gene expression changes were examined in three experiments using cDNA Expression Arrays and protein expression changes were examined in ten experiments using 2-DE and PDQuest software. Obtained results show that gene and protein expression were altered, in both examined cell lines, in response to one hour mobile phone radiation exposure at an average specific absorption rate of 2.8 W/kg. However, the same genes and proteins were differently affected by the exposure in each of the cell lines. This suggests that the cell response to mobile phone radiation might be genome- and proteome-dependent. Therefore, it is likely that different types of cells and from different species might respond differently to mobile phone radiation or might have different sensitivity to this weak stimulus. Our findings might also explain, at least in part, the origin of discrepancies in replication studies between different laboratories.

(E) Panagopoulos DJ, Chavdoula ED, Nezis IP, Margaritis LH. Cell death induced by GSM 900-MHz and DCS 1800-MHz mobile telephony radiation. Mutat Res 626:69-78, 2007. (GT, RP)

In the present study, the TUNEL (Terminal deoxynucleotidetransferasedUTP Nick End Labeling) assay - a well known technique widely used for detecting fragmented DNA in various types of cells - was used to detect cell death (DNA fragmentation) in a biological model, the early and mid stages of oogenesis of the insect Drosophila melanogaster. The flies were exposed in vivo to either GSM 900-MHz (Global System for Mobile telecommunications) or DCS 1800-MHz (Digital Cellular System) radiation from a common digital mobile phone, for few minutes per day during the first 6 days of their adult life. The exposure conditions were similar to those to which a mobile phone user is exposed, and were determined according to previous studies of ours [D.J Panagopoulos, A. Karabarbounis, L.H. Margaritis, Effect of GSM 900-MHz mobile phone radiation on the reproductive capacity of D. melanogaster, Electromagn. Biol Med 23 (2004) 29-43; D.J Panagopoulos, N. Messini, A. Karabarbounis, A.L. Philippetis, L.H. Margaritis, Radio frequency electromagnetic radiation within "safety levels" alters the physiological function of insects, in: P. Kostarakis, P. Stavroulakis (Eds.), Proceedings of the Millennium International Workshop on Biological Effects of Electromagnetic Fields, Heraklion, Crete, Greece, October 17-20, 2000, pp. 169-175, ISBN: 960-86733-0-5; D.J Panagopoulos, L.H. Margaritis, Effects of electromagnetic fields on the reproductive capacity of D. melanogaster, in: P. Stavroulakis (Ed.), Biological Effects of Electromagnetic Fields, Springer, 2003, pp. 545-578], which had shown a large decrease in the oviposition of the same insect caused by GSM radiation. Our present results suggest that the decrease in oviposition previously reported, is due to degeneration of large numbers of egg chambers after DNA fragmentation of their constituent cells, induced by both types of mobile telephony radiation. Induced cell death is recorded for the first time, in all types of cells constituting an egg chamber (follicle cells, nurse cells and the oocyte) and in all stages of the early and mid-oogenesis, from germarium to stage 10, during which programmed cell death does not physiologically occur. Germarium and stages 7-8 were found to be the most sensitive developmental stages also in response to electromagnetic stress induced by the GSM and DCS fields and, moreover, germarium was found to be even more sensitive than stages 7-8.

(NE) Paparini A, Rossi P, Gianfranceschi G, Brugaletta V, Falsaperla R, De Luca P, Romano Spica V. No evidence of major transcriptional changes in the brain of mice exposed to 1800 MHz GSM signal. Bioelectromagnetics. 29(4):312-323, 2008. (GE)

To analyze possible effects of microwaves on gene expression, mice were exposed to global system for mobile communication (GSM) 1800 MHz signal for 1 h at a whole body SAR of 1.1 W/kg. Gene expression was studied in the whole brain, where the average SAR was 0.2 W/kg, by expression microarrays containing over 22,600 probe sets. Comparison of data from sham and exposed animals showed no significant difference in gene expression modulation. However, when less stringent constraints were adopted to analyze microarray results, 75 genes were found to be modulated following exposure. Forty-two probes showed fold changes ranging from 1.5 to 2.8, whereas 33 were down-regulated from 0.67- to 0.29-fold changes, but these differences in gene expression were not confirmed by real-time PCR. Under these specific limited conditions, no consistent indication of gene expression modulation in whole mouse brain was found associated to GSM 1800 MHz exposure.

(E) Paulraj R, Behari J. Single strand DNA breaks in rat brain cells exposed to microwave radiation. Mutat Res 596:76-80, 2006. (GT, LE)

This investigation concerns with the effect of low intensity microwave (2.45 and 16.5GHz, SAR 1.0 and 2.01W/kg, respectively) radiation on developing rat brain. Wistar rats (35 days old, male, six rats in each group) were selected for this study. These animals were exposed for 35 days at the above mentioned frequencies separately in two different exposure systems. After the exposure period, the rats were sacrificed and the whole brain tissue was dissected and used for study of single strand DNA breaks by micro gel electrophoresis (comet assay). Single strand DNA breaks were measured as tail length of comet. Fifty cells from each slide and two slides per animal were observed. One-way ANOVA method was adopted for statistical analysis. This study shows that the chronic exposure to these radiations cause statistically significant ($p<0.001$) increase in DNA single strand breaks in brain cells of rat.

(E) Pesnya DS, Romanovsky AV. Comparison of cytotoxic and genotoxic effects of plutonium-239 alpha particles and mobile phone GSM 900 radiation in the Allium cepa test. Mutat Res. 2012 Oct 8. pii: S1383-5718(12)00291-4. doi: 10.1016/j.mrgentox.2012.08.010. [Epub ahead of print] (GT)

The goal of this study was to compare the cytotoxic and genotoxic effects of plutonium-239 alpha particles and GSM 900 modulated mobile phone radiation in the Allium cepa test. Three groups of bulbs were exposed to mobile phone radiation during 0 (sham), 3 and 9hours. A positive control group was treated during 20 min with plutonium-239 alpha-radiation. Mitotic abnormalities, chromosome aberrations, micronuclei and mitotic index were analyzed. Exposure to alpha-radiation from plutonium-239 and exposure to modulated radiation from mobile phone during 3 and 9h significantly increased the mitotic index. GSM 900 mobile phone radiation as well as alpha-radiation from plutonium-239 induced both clastogenic and aneugenic effects. However, the aneugenic activity of mobile phone radiation was more pronounced. After 9 hours of exposure to mobile phone radiation, polyploid cells, three-groups metaphases, amitoses and some unspecified abnormalities were detected, which were not registered in the other experimental groups. Importantly, GSM 900 mobile phone radiation increased the mitotic index, the frequency of mitotic and chromosome abnormalities, and the micronucleus frequency in a time-dependent manner. Due to its sensitivity, the Allium cepa test can be recommended as a useful cytogenetic assay to assess cytotoxic and genotoxic effects of radiofrequency electromagnetic fields.

(NE) Qutob SS, Chauhan V, Bellier PV, Yauk CL, Douglas GR, Berndt L, Williams A, Gajda GB, Lemay E, Thansandote A, McNamee JP. Microarray gene expression profiling of a human glioblastoma cell line exposed in vitro to a 1.9 GHz pulse-modulated radiofrequency field. Radiat Res 165:636-644, 2006. (GE)

The widespread use of mobile phones has led to public concerns about the health effects associated with exposure to radiofrequency (RF) fields. The paramount concern of most persons relates to the potential of these fields to cause cancer. Unlike ionizing radiation, RF fields used for mobile telecommunications (800-1900 MHz) do not possess sufficient energy to directly damage DNA. Most rodent bioassay and in vitro genotoxicity/mutation studies have reported that RF fields at non-thermal levels have no direct mutagenic, genotoxic or carcinogenic effects.

However, some evidence has suggested that RF fields may cause detectable postexposure changes in gene expression. Therefore, the purpose of this study was to assess the ability of exposure to a 1.9 GHz pulse-modulated RF field for 4 h at specific absorption rates (SARs) of 0.1, 1.0 and 10.0 W/kg to affect global gene expression in U87MG glioblastoma cells. We found no evidence that non-thermal RF fields can affect gene expression in cultured U87MG cells relative to the nonirradiated control groups, whereas exposure to heat shock at 43 degrees C for 1 h up-regulated a number of typical stress-responsive genes in the positive control group. Future studies will assess the effect of RF fields on other cell lines and on gene expression in the mouse brain after in vivo exposure.

(E) Remondini D, Nylund R, Reivinen J, Poulletier de Gannes F, Veyret B, Lagroye I, Haro E, Trillo MA, Capri M, Franceschi C, Schlatterer K, Gminski R, Fitzner R, Tauber R, Schuderer J, Kuster N, Leszczynski D, Bersani F, Maercker C. Gene expression changes in human cells after exposure to mobile phone microwaves. Proteomics 6:4745-4754, 2006. (GE, CS)

Possible biological effects of mobile phone microwaves were investigated in vitro. In this study, which was part of the 5FP EU project REFLEX (Risk Evaluation of Potential Environmental Hazards From Low-Energy Electromagnetic Field Exposure Using Sensitive in vitro Methods), six human cell types, immortalized cell lines and primary cells, were exposed to 900 and 1800 MHz. RNA was isolated from exposed and sham-exposed cells and labeled for transcriptome analysis on whole-genome cDNA arrays. The results were evaluated statistically using bioinformatics techniques and examined for biological relevance with the help of different databases. NB69 neuroblastoma cells, T lymphocytes, and CHME5 microglial cells did not show significant changes in gene expression. In EA.hy926 endothelial cells, U937 lymphoblastoma cells, and HL-60 leukemia cells we found between 12 and 34 up- or down-regulated genes. Analysis of the affected gene families does not point towards a stress response. However, following microwave exposure, some but not all human cells might react with an increase in expression of genes encoding ribosomal proteins and therefore up-regulating the cellular metabolism.

(NE) Ros-Llor I, Sanchez-Siles M, Camacho-Alonso F, Lopez-Jornet P. Effect of mobile phones on micronucleus frequency in human exfoliated oral mucosal cells. Oral Dis. 18:786-792, 2012. (GT)

Objective: In the last two decades, the use of mobile phones has increased enormously all over the world. The controversy regarding whether radiofrequency (RF) fields exert effects upon biological systems is a concern for the general population. An evaluation is made of DNA damage and cytokinetic defects, proliferative potential, and cell death because of RF radiation emitted by mobile phones in healthy young users. Study design: This cohort study was carried out in 50 Caucasian mobile phone users. We collected two cell samples from each subject (a total of 100 cell samples), corresponding to the right and left cheek mucosa, respectively. Case histories and personal information were assessed, including age, gender, body height and weight, history of cancer, smoking and alcohol consumption, exposure to chemical carcinogens or radiation, and dietary habits. Sampling comprised cell collection from both cheeks with a cytobrush, centrifugation, slide preparation, fixation, and staining, followed by fluorescent microscopic analysis. A total of 2000 exfoliated cells were screened for nuclear abnormalities,

especially micronucleus. Results: No statistically significant changes were recorded in relation to age, gender, body mass index, or smoking status. A comparison of the results vs the control area according to the side of the face on which the mobile phone was placed, and in relation to the duration of exposure (years) to mobile phone radiation in the total 100 samples, yielded no significant differences. Conclusions: No genotoxic effects because of RF exposure were observed in relation to any of the study parameters.

(NE) Sakuma N, Komatsubara Y, Takeda H, Hirose H, Sekijima M, Nojima T, Miyakoshi J. DNA strand breaks are not induced in human cells exposed to 2.1425 GHz band CW and W-CDMA modulated radiofrequency fields allocated to mobile radio base stations. Bioelectromagnetics 27:51-57, 2006. (CT)

We conducted a large-scale in vitro study focused on the effects of low level radiofrequency (RF) fields from mobile radio base stations employing the International Mobile Telecommunication 2000 (IMT-2000) cellular system in order to test the hypothesis that modulated RF fields may act as a DNA damaging agent. First, we evaluated the responses of human cells to microwave exposure at a specific absorption rate (SAR) of 80 mW/kg, which corresponds to the limit of the average whole body SAR for general public exposure defined as a basic restriction in the International Commission on Non-Ionizing Radiation Protection (ICNIRP) guidelines. Second, we investigated whether continuous wave (CW) and Wideband Code Division Multiple Access (W-CDMA) modulated signal RF fields at 2.1425 GHz induced different levels of DNA damage. Human glioblastoma A172 cells and normal human IMR-90 fibroblasts from fetal lungs were exposed to mobile communication frequency radiation to investigate whether such exposure produced DNA strand breaks in cell culture. A172 cells were exposed to W-CDMA radiation at SARs of 80, 250, and 800 mW/kg and CW radiation at 80 mW/kg for 2 and 24 h, while IMR-90 cells were exposed to both W-CDMA and CW radiations at a SAR of 80 mW/kg for the same time periods. Under the same RF field exposure conditions, no significant differences in the DNA strand breaks were observed between the test groups exposed to W-CDMA or CW radiation and the sham exposed negative controls, as evaluated immediately after the exposure periods by alkaline comet assays. Our results confirm that low level exposures do not act as a genotoxicant up to a SAR of 800 mW/kg.

(NE) Sakurai T, Kiyokawa T, Narita E, Suzuki Y, Taki M, Miyakoshi J. Analysis of gene expression in a human-derived glial cell line exposed to 2.45 GHz continuous radiofrequency electromagnetic fields. J Radiat Res. 52(2):185-192, 2011. (GE)

The increasing use of mobile phones has aroused public concern regarding the potential health risks of radiofrequency (RF) fields. We investigated the effects of exposure to RF fields (2.45 GHz, continuous wave) at specific absorption rate (SAR) of 1, 5, and 10 W/kg for 1, 4, and 24 h on gene expression in a normal human glial cell line, SVGp12, using DNA microarray. Microarray analysis revealed 23 assigned gene spots and 5 non-assigned gene spots as prospective altered gene spots. Twenty-two genes out of the 23 assigned gene spots were further analyzed by reverse transcription-polymerase chain reaction to validate the results of microarray, and no significant alterations in gene expression were observed. Under the experimental conditions used in this study, we found no evidence that exposure to RF fields affected gene expression in SVGp12 cells.

(NE) Sannino A, Di Costanzo G, Brescia F, Sarti M, Zeni O, Juutilainen J, Scarfì MR. Human fibroblasts and 900 MHz radiofrequency radiation: evaluation of DNA damage after exposure and co-exposure to 3-Chloro-4-(dichloromethyl)-5-Hydroxy-2(5h)-furanone (MX). Radiat Res 171:743-751, 2009. (NT, IA)

Abstract Sannino, A., Di Costanzo, G., Brescia, F., Sarti, M., Zeni, O., Juutilainen, J and Scarfì, M. R. Human Fibroblasts and 900 MHz Radiofrequency Radiation: Evaluation of DNA Damage after Exposure and Co-exposure to 3-Chloro-4-(dichloromethyl)-5-Hydroxy-2(5h)-furanone (MX). Radiat Res 171, 743-751 (2009). The aim of this study was to investigate DNA damage in human dermal fibroblasts from a healthy subject and from a subject affected by Turner's syndrome that were exposed for 24 h to radiofrequency (RF) radiation at 900 MHz. The RF-radiation exposure was carried out alone or in combination with 3-chloro-4-(dichloromethyl)-5-hydroxy-2(5H)-furanone (MX), a well-known environmental mutagen and carcinogen produced during the chlorination of drinking water. Turner's syndrome fibroblasts were also exposed for a shorter time (1 h). A signal similar to that emitted by Global System for Mobile Communications (GSM) mobile phones was used at a specific absorption rate of 1 W/kg under strictly controlled conditions of temperature and dosimetry. To evaluate DNA damage after RF-radiation exposure alone, the alkaline comet assay and the cytokinesis-block micronucleus assay were used. In the combined-exposure experiments, MX was given at a concentration of 25 microM for 1 h immediately after the RF-radiation exposure, and the effects were evaluated by the alkaline comet assay. The results revealed no genotoxic and cytotoxic effects from RF radiation alone in either cell line. As expected, MX treatment induced an increase in DNA migration in the comet assay, but no enhancement of the MX-induced DNA damage was observed in the cells exposed to RF radiation.

(E) Schwarz C, Kratochvil E, Pilger A, Kuster N, Adlkofer F, Rüdiger HW. Radiofrequency electromagnetic fields (UMTS, 1,950 MHz) induce genotoxic effects in vitro in human fibroblasts but not in lymphocytes. Int Arch Occup Environ Health 81:755-767, 2008. (GT, CS)

OBJECTIVE: Universal Mobile Telecommunication System (UMTS) was recently introduced as the third generation mobile communication standard in Europe. This was done without any information on biological effects and genotoxic properties of these particular high-frequency electromagnetic fields. This is discomforting, because genotoxic effects of the second generation standard Global System for Mobile Communication have been reported after exposure of human cells in vitro. METHODS: Human cultured fibroblasts of three different donors and three different short-term human lymphocyte cultures were exposed to 1,950 MHz UMTS below the specific absorption rate (SAR) safety limit of 2 W/kg. The alkaline comet assay and the micronucleus assay were used to ascertain dose and time-dependent genotoxic effects. Five hundred cells per slide were visually evaluated in the comet assay and comet tail factor (CTF) was calculated. In the micronucleus assay 1,000 binucleated cells were evaluated per assay. The origin of the micronuclei was determined by fluorescence labeled anticentromere antibodies. All evaluations were performed under blinded conditions. RESULTS: UMTS exposure increased the CTF and induced centromere-negative micronuclei (MN) in human cultured fibroblasts in a dose and time-dependent way. Incubation for 24 h at a SAR of 0.05 W/kg generated a statistically significant rise in both CTF and MN (P = 0.02). At a SAR of 0.1 W/kg the CTF was significantly

increased after 8 h of incubation (P = 0.02), the number of MN after 12 h (P = 0.02). No UMTS effect was obtained with lymphocytes, either unstimulated or stimulated with Phytohemagglutinin. CONCLUSION: UMTS exposure may cause genetic alterations in some but not in all human cells in vitro.

(E) Sekeroğlu V, Akar A, Sekeroğlu ZA. Cytotoxic and genotoxic effects of high-frequency electromagnetic fields (GSM 1800 MHz) on immature and mature rats. Ecotoxicol Environ Saf. 80:140-144, 2012. (LE, GT, DE)

We investigated the cytogenotoxic effects of high frequency electromagnetic fields (HF-EMF) for 45 day and the effect of a recovery period of 15 day after exposure to EMF on bone marrow cells of immature and mature rats. The animals in treatment groups were exposed to 1800 MHz EMF at SAR of 0.37 W/kg and 0.49 W/kg for 2h/day for 45 day. Two recovery groups were kept for a recovery period of 15 day without EMF after exposure to HF-EMF. Two control groups for both immature and mature rats were also included. Significant differences were also observed in chromosome aberrations (CA), micronucleus (MN) frequency, mitotic index (MI) and ratio of polychromatic erythrocytes (PCEs) in all treatment groups. The cytogenotoxic damage was more remarkable in immature rats and, the recovery period did not improve this damage in immature rats. Because much higher and irreversible cytogenotoxic damage was observed in immature rats than in mature rats, further studies are needed to understand effects of EMF on DNA damage and DNA repair, and to determine safe limits for environment and human, especially for children.

(NE) Sekijima M, Takeda H, Yasunaga K, Sakuma N, Hirose H, Nojima T, Miyakoshi J. 2-GHz band CW and W-CDMA modulated radiofrequency fields have no significant effect on cell proliferation and gene expression profile in human cells. J Radiat Res. 51(3):277-284, 2010. (GE)

We investigated the mechanisms by which radiofrequency (RF) fields exert their activity, and the changes in both cell proliferation and the gene expression profile in the human cell lines, A172 (glioblastoma), H4 (neuroglioma), and IMR-90 (fibroblasts from normal fetal lung) following exposure to 2.1425 GHz continuous wave (CW) and Wideband Code Division Multiple Access (W-CDMA) RF fields at three field levels. During the incubation phase, cells were exposed at the specific absorption rates (SARs) of 80, 250, or 800 mW/kg with both CW and W-CDMA RF fields for up to 96 h. Heat shock treatment was used as the positive control. No significant differences in cell growth or viability were observed between any test group exposed to W-CDMA or CW radiation and the sham-exposed negative controls. Using the Affymetrix Human Genome Array, only a very small (< 1%) number of available genes (ca. 16,000 to 19,000) exhibited altered expression in each experiment. The results confirm that low-level exposure to 2.1425 GHz CW and W-CDMA RF fields for up to 96 h did not act as an acute cytotoxicant in either cell proliferation or the gene expression profile. These results suggest that RF exposure up to the limit of whole-body average SAR levels as specified in the ICNIRP guidelines is unlikely to elicit a general stress response in the tested cell lines under these conditions.

(E) Souza LD, Cerqueira ED, Meireles JR. Assessment of nuclear abnormalities in exfoliated cells from the oral epithelium of mobile phone users. Electromagn Biol Med. 2013 May 28. [Epub ahead of print] (GE, HU)

Abstract Transmission and reception of mobile telephony signals take place through electromagnetic wave radiation, or electromagnetic radiofrequency fields, between the mobile terminal and the radio base station. Based on reports in the literature on adverse effects from exposure to this type of radiation, the objective of this study was to evaluate the genotoxic and cytotoxic potential of such exposure, by means of the micronucleus test on exfoliated cells from the oral epithelium. The sample included 45 individuals distributed in 3 groups according to the amount of time in hours per week (t) spent using mobile phones: group I, $t > 5$ h; group II, $t > 1$ h and ≤ 5 h; and group III, $t \leq 1$ h. Cells from the oral mucosa were analyzed to assess the numbers of micronuclei, broken egg structures and degenerative nuclear abnormalities indicative of apoptosis (condensed chromatin, karyorrhexis and pyknosis) or necrosis (karyolysis in addition to these changes). The occurrences of micronuclei and degenerative nuclear abnormalities did not differ between the groups, but the number of broken egg (structures that may be associated with gene amplification) was significantly greater in the individuals in group I ($p < 0.05$).

(NE) Speit G, Schütz P, Hoffmann H. Genotoxic effects of exposure to radiofrequency electromagnetic fields (RF-EMF) in cultured mammalian cells are not independently reproducible. Mutat Res. 626(1-2):42-47, 2007. (GT)

Conflicting results have been published regarding the induction of genotoxic effects by exposure to radiofrequency electromagnetic fields (RF-EMF). Using the comet assay, the micronucleus test and the chromosome aberration test with human fibroblasts (ES1 cells), the EU-funded "REFLEX" project (Risk Evaluation of Potential Environmental Hazards From Low Energy Electromagnetic Field Exposure Using Sensitive in vitro Methods) reported clearly positive effects for various exposure conditions. Because of the ongoing discussion on the biological significance of the effects observed, it was the aim of the present study to independently repeat the results using the same cells, the same equipment and the same exposure conditions. We therefore exposed ES1 cells to RF-EMF (1800 MHz; SAR 2 W/kg, continuous wave with intermittent exposure) for different time periods and then performed the alkaline (pH>13) comet assay and the micronucleus test (MNT). For both tests, clearly negative results were obtained in independently repeated experiments. We also performed these experiments with V79 cells, a sensitive Chinese hamster cell line that is frequently used in genotoxicity testing, and also did not measure any genotoxic effect in the comet assay and the MNT. Appropriate measures of quality control were considered to exclude variations in the test performance, failure of the RF-EMF exposure or an evaluation bias. The reasons for the difference between the results reported by the REFLEX project and our experiments remain unclear.

(NE) Stronati L, Testa A, Moquet J, Edwards A, Cordelli E, Villani P, Marino C, Fresegna AM, Appolloni M, Lloyd D. 935 MHz cellular phone radiation. An in vitro study of genotoxicity in human lymphocytes. Int J Radiat Biol 82:339-346, 2006. (GT, IA)

Purpose: The possibility of genotoxicity of radiofrequency radiation (RFR) applied alone or in combination with x-rays was investigated in vitro using several assays on human lymphocytes. The chosen specific absorption rate (SAR) values are near the upper limit of actual energy absorption in localized tissue when persons use some cellular telephones. The purpose of the combined exposures was to examine whether RFR might act epigenetically by reducing the fidelity of repair of DNA damage caused by a well-characterized and established mutagen.Methods: Blood specimens from 14 donors were exposed continuously for 24 h to a

Global System for Mobile Communications (GSM) basic 935 MHz signal. The signal was applied at two SAR; 1 and 2 W/Kg, alone or combined with a 1-min exposure to 1.0 Gy of 250 kVp x-rays given immediately before or after the RFR. The assays employed were the alkaline comet technique to detect DNA strand breakage, metaphase analyses to detect unstable chromosomal aberrations and sister chromatid exchanges, micronuclei in cytokinesis-blocked binucleate lymphocytes and the nuclear division index to detect alterations in the speed of in vitro cell cycling.Results: By comparison with appropriate sham-exposed and control samples, no effect of RFR alone could be found for any of the assay endpoints. In addition RFR did not modify any measured effects of the x-radiation. Conclusions: This study has used several standard in vitro tests for chromosomal and DNA damage in Go human lymphocytes exposed in vitro to a combination of x-rays and RFR. It has comprehensively examined whether a 24-h continuous exposure to a 935 MHz GSM basic signal delivering SAR of 1 or 2 W/Kg is genotoxic per se or whether, it can influence the genotoxicity of the well-established clastogenic agent; x-radiation. Within the experimental parameters of the study in all instances no effect from the RFR signal was observed.

(E) Sun LX, Yao K, He JL, Lu DQ, Wang KJ, Li HW.[Effect of acute exposure to microwave from mobile phone on DNA damage and repair of cultured human lens epithelial cells in vitro.] Zhonghua Lao Dong Wei Sheng Zhi Ye Bing ZaZhi. 24:465-467, 2006. [Article in Chinese] (GT)

OBJECTIVE: To investigate the DNA damage of human lens epithelial cells (LECs) caused by acute exposure to low-power 217 Hz modulated 1.8 GHz microwave radiation and DNA repair. METHODS: Cultured LECs were exposed to 217 Hz modulated 1.8 GHz microwave radiation at SAR (specific absorption rate) of 0, 1, 2, 3 and 4 W/kg for 2 hours in an sXc-1800 incubator and irradiate system. The DNA single strand breaks were detected with comet assay in sham-irradiated cells and irradiated cells incubated for varying periods: 0, 30, 60, 120 and 240 min after irradiation. Images of comets were digitized and analyzed using an Imagine-pro plus software, and the indexes used in this study were tail length (TL) and tail moment (TM). RESULTS: The difference in DNA-breaks between the exposure and sham exposure groups induced by 1 and 2 W/kg irradiation was not significant at every detect time ($P > 0.05$). As for the dosage of 3 and 4 W/kg there was difference in both groups immediately after irradiation ($P < 0.01$). At the time of 30 min after irradiation the difference went on at both group ($P < 0.01$). However, the difference disappeared after one hour's incubation in 3 W/kg group ($P > 0.05$), and existed in 4 W/kg group. CONCLUSION: No or repairable DNA damage was observed after 2 hour irradiation of 1.8 GHz microwave on LECs when SAR </= 3 W/kg. The DNA damages caused by 4 W/kg irradiation were irreversible.

(E) Tiwari R, Lakshmi NK, Surender V, Rajesh AD, Bhargava SC, Ahuja YR. Combinative exposure effect of radio frequency signals from CDMA mobile phones and aphidicolin on DNA integrity. Electromagn Biol Med 27:418-425, 2008. (GT, IA)

The aim of present study is to assess DNA integrity on the effect of exposure to a radio frequency (RF) signal from Code Division Multiple Access (CDMA) mobile phones. Whole blood samples from six healthy male individuals were exposed for RF signals from a CDMA mobile phone for 1 h. Alkaline comet assay was performed to assess the DNA damage. The combinative exposure effect of the RF signals and APC at two concentrations on DNA integrity was studied. DNA repair efficiency of the samples was also studied after 2 h of exposure. The

RF signals and APC (0.2 microg/ml) alone or in synergism did not have any significant DNA damage as compared to sham exposed. However, univariate analysis showed that DNA damage was significantly different among combinative exposure of RF signals and APC at 0.2 microg/ml ($p < 0.05$) and at 2 microg/ml ($p < 0.02$). APC at 2 microg/ml concentration also showed significant damage levels ($p < 0.05$) when compared to sham exposed. DNA repair efficiency also varied in a significant way in combinative exposure sets ($p < 0.05$). From these results, it appears that the repair inhibitor APC enhances DNA breaks at 2 microg/ml concentration and that the damage is possibly repairable. Thus, it can be inferred that the in vitro exposure to RF signals induces reversible DNA damage in synergism with APC.

(E) Tkalec M, Stambuk A, Srut M, Malarić K, Klobučar GI. Oxidative and genotoxic effects of 900MHz electromagnetic fields in the earthworm Eisenia fetida. Ecotoxicol Environ Saf. 90:7-12, 2013. (GT, OX, WS)

Accumulating evidence suggests that exposure to radiofrequency electromagnetic field (RF-EMF) can have various biological effects. In this study the oxidative and genotoxic effects were investigated in earthworms Eisenia fetida exposed in vivo to RF-EMF at the mobile phone frequency (900MHz). Earthworms were exposed to the homogeneous RF-EMF at field levels of 10, 23, 41 and 120Vm(-1) for a period of 2h using a Gigahertz Transversal Electromagnetic (GTEM) cell. At the field level of 23Vm(-1) the effect of longer exposure (4h) and field modulation (80% AM 1kHz sinusoidal) was investigated as well. All exposure treatments induced significant genotoxic effect in earthworms coelomocytes detected by the Comet assay, demonstrating DNA damaging capacity of 900MHz electromagnetic radiation. Field modulation additionally increased the genotoxic effect. Moreover, our results indicated the induction of antioxidant stress response in terms of enhanced catalase and glutathione reductase activity as a result of the RF-EMF exposure, and demonstrated the generation of lipid and protein oxidative damage. Antioxidant responses and the potential of RF-EMF to induce damage to lipids, proteins and DNA differed depending on the field level applied, modulation of the field and duration of E. fetida exposure to 900MHz electromagnetic radiation. Nature of detected DNA lesions and oxidative stress as the mechanism of action for the induction of DNA damage are discussed.

(E) Tomruk A, Guler G, Dincel AS. The influence of 1800 MHz GSM-like signals on hepatic oxidative DNA and lipid damage in nonpregnant, pregnant, and newly born rabbits. Cell Biochem Biophys 56:39-47, 2010. (GT, OX, DE, LE)

The aim of our study is to evaluate the possible biological effects of whole-body 1800 MHz GSM-like radiofrequency (RF) radiation exposure on liver oxidative DNA damage and lipid peroxidation levels in nonpregnant, pregnant New Zealand White rabbits, and in their newly borns. Eighteen nonpregnant and pregnant rabbits were used and randomly divided into four groups which were composed of nine rabbits: (i) Group I (nonpregnant control), (ii) Group II (nonpregnant-RF exposed), (iii) Group III (pregnant control), (iv) Group IV (pregnant-RF exposed). Newborns of the pregnant rabbits were also divided into two groups: (v) Group V (newborns of Group III) and (vi) Group VI (newborns of Group III). 1800 MHz GSM-like RF radiation whole-body exposure (15 min/day for a week) was applied to Group II and Group IV. No significant differences were found in liver 8 OHdG/10 dG levels of exposure groups (Group II and Group IV) compared to controls (Group I and Group III). However, in Group II and Group IV malondialdehyde (MDA) and ferrous oxidation in xylenol orange (FOX) levels were

increased compared to Group I (P < 0.05, Mann-Whitney). No significant differences were found in liver tissue of 8 OHdG/10 dG and MDA levels between Group VI and Group V (P > 0.05, Mann-Whitney) while liver FOX levels were found significantly increased in Group VI with respect to Group V (P < 0.05, Mann-Whitney). Consequently, the whole-body 1800 MHz GSM-like RF radiation exposure may lead to oxidative destruction as being indicators of subsequent reactions that occur to form oxygen toxicity in tissues.

(E) Trivino Pardo JC, Grimaldi S, Taranta M, Naldi I, Cinti C. Microwave electromagnetic field regulates gene expression in T-lymphoblastoid leukemia CCRF-CEM cell line exposed to 900 MHz. Electromagn Biol Med. 31(1):1-18, 2012. (GE)

Electric, magnetic, and electromagnetic fields are ubiquitous in our society, and concerns have been expressed regarding possible adverse effects of these exposures. Research on Extremely Low-Frequency (ELF) magnetic fields has been performed for more than two decades, and the methodology and quality of studies have improved over time. Studies have consistently shown increased risk for childhood leukemia associated with ELF magnetic fields. There are still inadequate data for other outcomes. More recently, focus has shifted toward Radio Frequencies (RF) exposures from mobile telephony. There are no persuasive data suggesting a health risk, but this research field is still immature with regard to the quantity and quality of available data. This technology is constantly changing and there is a need for continued research on this issue. To investigate whether exposure to high-frequency electromagnetic fields (EMF) could induce adverse health effects, we cultured acute T-lymphoblastoid leukemia cells (CCRF-CEM) in the presence of 900 MHz MW-EMF generated by a transverse electromagnetic (TEM) cell at short and long exposure times. We evaluated the effect of high-frequency EMF on gene expression and we identified functional pathways influenced by 900 MHz MW-EMF exposure.

(E) Trosić I, Pavicić I, Milković-Kraus S, Mladinić M, Zeljezić D. Effect of electromagnetic radiofrequency radiation on the rats' brain, liver and kidney cells measured by comet assay. Coll Antropol 35:1259-1264, 2011. (GT)

The goal of study was to evaluate DNA damage in rat's renal, liver and brain cells after in vivo exposure to radiofrequency/microwave (Rf/Mw) radiation of cellular phone frequencies range. To determine DNA damage, a single cell gel electrophoresis/comet assay was used. Wistar rats (male, 12 week old, approximate body weight 350 g) (N = 9) were exposed to the carrier frequency of 915 MHz with Global System Mobile signal modulation (GSM), power density of 2.4 W/m2, whole body average specific absorption rate SAR of 0.6 W/kg. The animals were irradiated for one hour/day, seven days/week during two weeks period. The exposure set-up was Gigahertz Transversal Electromagnetic Mode Cell (GTEM--cell). Sham irradiated controls (N = 9) were apart of the study. The body temperature was measured before and after exposure. There were no differences in temperature in between control and treated animals. Comet assay parameters such as the tail length and tail intensity were evaluated. In comparison with tail length in controls (13.5 +/- 0.7 microm), the tail was slightly elongated in brain cells of irradiated animals (14.0 +/- 0.3 microm). The tail length obtained for liver (14.5 +/- 0.3 microm) and kidney (13.9 +/- 0.5 microm) homogenates notably differs in comparison with matched sham controls (13.6 +/- 0.3 microm) and (12.9 +/- 0.9 microm). Differences in tail intensity between control and exposed animals were not significant. The results of this study suggest that, under the experimental conditions applied, repeated 915 MHz irradiation could be a cause of DNA breaks

in renal and liver cells, but not affect the cell genome at the higher extent compared to the basal damage.

(NE) Valbonesi P, Franzellitti S, Piano A, Contin A, Biondi C, Fabbri E. Evaluation of HSP70 Expression and DNA damage in cells of a human trophoblast cell line exposed to 1.8 GHz amplitude-modulated radiofrequency fields. Radiat Res 169:270-279, 2008. (GT, GE)

The aim of this study was to determine whether high-frequency electromagnetic fields (EMFs) could induce cellular effects. The human trophoblast cell line HTR-8/SVneo was used as a model to evaluate the expression of proteins (HSP70 and HSC70) and genes (HSP70A, B, C and HSC70) of the HSP70 family and the primary DNA damage response after nonthermal exposure to pulse-modulated 1817 MHz sinusoidal waves (GSM-217 Hz; 1 h; SAR of 2 W/kg). HSP70 expression was significantly enhanced by heat, which was applied as the prototypical stimulus. The HSP70A, B and C transcripts were differentially expressed under basal conditions, and they were all significantly induced above basal levels by thermal stress. Conversely, HSC70 protein and gene expression was not influenced by heat. Exposing HTR-8/SVneo cells to high-frequency EMFs did not change either HSP70 or HSC70 protein or gene expression. A significant increase in DNA strand breaks was caused by exposure to HO, which was used as a positive stimulus; however, no effect was observed after exposure of cells to high-frequency EMFs. Overall, no evidence was found that a 1-h exposure to GSM-217 Hz induced a HSP70-mediated stress response or primary DNA damage in HTR-8/SVneo cells. Nevertheless, further investigations on trophoblast cell responses after exposure to GSM signals of different types and durations are needed.

(E) Valbonesi P, Franzellitti S, Bersani F, Contin A, Fabbri E. Effects of the exposure to intermittent 1.8 GHz radio frequency electromagnetic fields on HSP70 expression and MAPK signaling pathways in PC12 cells. Int J Radiat Biol. 2014 Feb 11. [Epub ahead of print] (GE, WS)

Purpose: We previously reported effects on heat shock protein 70 (HSP70) mRNA expression, a cytoprotective protein induced under stressful condition, in human trophoblast cells exposed to amplitude-modulated Global System for Mobile Communication (GSM) signals. In the present work the same experimental conditions were applied to the rat PC12 cells, in order to assess the stress responses mediated by HSP70 and by the Mitogen Activated Protein Kinases (MAPK) in neuronal-like cells, an interesting model to study possible effects of mobile phone frequencies exposure. Materials and methods: HSP70 gene expression level was evaluated by reverse transcriptase polymerase chain reaction, HSP70 protein expression and MAPK phosphorylation were assessed by Western blotting. PC12 cells were exposed for 4, 16 or 24 h to 1.8 GHz continuous wave signal (CW, carrier frequency without modulation) or to two different GSM modulation schemes, GSM-217Hz and GSM-Talk (which generates temporal changes between two different GSM signals, active during talking or listening phases respectively, thus simulating a typical conversation). Specific adsorption rate (SAR) was 2 W/kg. Results: After PC12 cells exposure to the GSM-217Hz signal for 16 or 24 h, HSP70 transcription significantly increased, whereas no effect was observed in cells exposed to the CW or GSM-Talk signals. HSP70 protein expression and three different MAPK signaling pathways were not affected by the exposure to any of the three different 1.8 GHz signals. Conclusion: The positive effect on HSP70 mRNA expression, observed only in cells exposed to the GSM-217Hz signal, is a repeatable response

previously reported in human trophoblast cells and now confirmed in PC12 cells. Further investigations towards a possible role of 1.8 GHz signal modulation are therefore advisable.

(NE) Verschaeve L, Heikkinen P, Verheyen G, Van Gorp U, Boonen F, Vander Plaetse F, Maes A, Kumlin T, Maki-Paakkanen J, Puranen L, Juutilainen J. Investigation of co-genotoxic effects of radiofrequency electromagnetic fields in vivo. Radiat Res 165:598-607, 2006. (GT, LE, IA)

We investigated the possible combined genotoxic effects of radiofrequency (RF) electromagnetic fields (900 MHz, amplitude modulated at 217 Hz, mobile phone signal) with the drinking water mutagen and carcinogen 3-chloro-4-(dichloromethyl)-5-hydroxy-2(5H)-furanone (MX). Female rats were exposed to RF fields for a period of 2 years for 2 h per day, 5 days per week at average whole-body specific absorption rates of 0.3 or 0.9 W/kg. MX was given in the drinking water at a concentration of 19 mug/ml. Blood samples were taken at 3, 6 and 24 months of exposure and brain and liver samples were taken at the end of the study (24 months). DNA damage was assessed in all samples using the alkaline comet assay, and micronuclei were determined in erythrocytes. We did not find significant genotoxic activity of MX in blood and liver cells. However, MX induced DNA damage in rat brain. Co-exposures to MX and RF radiation did not significantly increase the response of blood, liver and brain cells compared to MX exposure only. In conclusion, this 2-year animal study involving long-term exposures to RF radiation and MX did not provide any evidence for enhanced genotoxicity in rats exposed to RF radiation.

(NE) Vijayalaxmi. Cytogenetic studies in human blood lymphocytes exposed in vitro to 2.45 GHz or 8.2 GHz radiofrequency radiation. Radiat Res 166, 532–538, 2006. (GT)

Peripheral blood samples collected from healthy human volunteers were exposed in vitro to 2.45 GHz or 8.2 GHz pulsed-wave radiofrequency (RF) radiation. The net forward power, average power density, mean specific absorption rate, and the temperature maintained during the 2-h exposure of the cells to 2.45 GHz or 8.2 GHz were, respectively, 21 W or 60 W, 5 mW/cm2 or 10 mW/cm2, 2.13 W/kg or 20.71 W/kg, and 36.9 ± 0.1°C or 37.5 ± 0.2°C. Aliquots of the same blood samples that were either sham-exposed or exposed in vitro to an acute dose of 1.5 Gy γ radiation were used as unexposed and positive controls, respectively. Cultured lymphocytes were examined to determine the extent of cytogenetic damage assessed from the incidence of chromosomal aberrations and micronuclei. Under the conditions used to perform the experiments, the levels of damage in RF-radiation-exposed and sham-exposed lymphocytes were not significantly different. Also, there were no significant differences in the response of unstimulated lymphocytes and lymphocytes stimulated with phytohemagglutinin when exposed to 8.2 GHz RF radiation. In contrast, the positive control cells that had been subjected to γ irradiation exhibited significantly more damage than RF-radiation- and sham-exposed lymphocytes.

(NE) Waldmann P, Bohnenberger S, Greinert R, Hermann-Then B, Heselich A, Klug SJ, Koenig J, Kuhr K, Kuster N, Merker M, Murbach M, Pollet D, Schadenboeck W, Scheidemann-Wesp U, Schwab B, Volkmer B, Weyer V, Blettner M. Influence of GSM Signals on Human Peripheral Lymphocytes: Study of Genotoxicity. Radiat Res. 2013 Jan 14. [Epub ahead of print] (GT)

Exposure to radiofrequency (RF) electromagnetic fields (EMF) is continuously increasing worldwide. Yet, conflicting results of a possible genotoxic effect of RF EMF continue to be discussed. In the present study, a possible genotoxic effect of RF EMF (GSM, 1,800 MHz) in human lymphocytes was investigated by a collaboration of six independent institutes (institutes a, b, c, d, e, h). Peripheral blood of 20 healthy, nonsmoking volunteers of two age groups (10 volunteers 16-20 years old and 10 volunteers 50-65 years old) was taken, stimulated and intermittently exposed to three specific absorption rates (SARs) of RF EMF (0.2 W/kg, 2 W/kg, 10 W/kg) and sham for 28 h (institute a). The exposures were performed in a setup with strictly controlled conditions of temperature and dose, and randomly and automatically determined waveguide SARs, which were designed and periodically maintained by ITIS (institute h). Four genotoxicity tests with different end points were conducted (institute a): chromosome aberration test (five types of structural aberrations), micronucleus test, sister chromatid exchange test and the alkaline comet assay (Olive tail moment and % DNA). To demonstrate the validity of the study, positive controls were implemented. The genotoxicity end points were evaluated independently by three laboratories blind to SAR information (institute c = laboratory 1; institute d = laboratory 2; institute e = laboratory 3). Statistical analysis was carried out by institute b. Methods of primary statistical analysis and rules to adjust for multiple testing were specified in a statistical analysis plan based on a data review before unblinding. A linear trend test based on a linear mixed model was used for outcomes of comet assay and exact permutation test for linear trend for all other outcomes. It was ascertained that only outcomes with a significant SAR trend found by at least two of three analyzing laboratories indicated a substantiated suspicion of an exposure effect. On the basis of these specifications, none of the nine end points tested for SAR trend showed a significant and reproducible exposure effect. Highly significant differences between sham exposures and positive controls were detected by each analyzing laboratory, thus validating the study. In conclusion, the results show no evidence of a genotoxic effect induced by RF EMF (GSM, 1,800 MHz).

(E) Wu W, Yao K, Wang KJ, Lu DQ, He JL, Xu LH, Sun WJ. [Blocking 1800 MHz mobile phone radiation-induced reactive oxygen species production and DNA damage in lens epithelial cells by noise magnetic fields.]Zhejiang Da XueXueBao Yi Xue Ban 37:34-38, 2008. [Article in Chinese] (GT, IA, OX)

OBJECTIVE: To investigate whether the exposure to the electromagnetic noise can block reactive oxygen species (ROS) production and DNA damage of lens epithelial cells induced by 1800 MHz mobile phone radiation. METHODS: The DCFH-DA method and comet assay were used respectively to detect the intracellular ROS and DNA damage of cultured human lens epithelial cells induced by 4 W/kg 1800 MHz mobile phone radiation or/and 2microT electromagnetic noise for 24 h intermittently. RESULT: 1800 MHz mobile phone radiation at 4 W/kg for 24 h increased intracellular ROS and DNA damage significantly ($P<0.05$). However, the ROS level and DNA damage of mobile phone radiation plus noise group were not significant enhanced ($P>0.05$) as compared to sham exposure group. Conclusion: Electromagnetic noise can block intracellular ROS production and DNA damage of human lens epithelial cells induced by 1800 MHz mobile phone radiation.

(E) Xu S, Zhong M, Zhang L, Zhou Z, Zhang W, Wang Y, Wang X, Li M, Chen Y, Chen C, He M, Zhang G, Yu Z. Exposure to 1800 MHz radiofrequency radiation induces

oxidative damage to mitochondrial DNA in primary cultured neurons. Brain Res 1311:189-196. 2010. (GT, OX)

Increasing evidence indicates that oxidative stress may be involved in the adverse effects of radiofrequency (RF) radiation on the brain. Because mitochondrial DNA (mtDNA) defects are closely associated with various nervous system diseases and mtDNA is highly susceptible to oxidative stress, the purpose of this study was to determine whether radiofrequency radiation can cause oxidative damage to mtDNA. In this study, we exposed primary cultured cortical neurons to pulsed RF electromagnetic fields at a frequency of 1800 MHz modulated by 217 Hz at an average special absorption rate (SAR) of 2 W/kg. At 24h after exposure, we found that RF radiation induced a significant increase in the levels of 8-hydroxyguanine (8-OHdG), a common biomarker of DNA oxidative damage, in the mitochondria of neurons. Consistent with this finding, the copy number of mtDNA and the levels of mitochondrial RNA (mtRNA) transcripts showed an obvious reduction after RF exposure. Each of these mtDNA disturbances could be reversed by pretreatment with melatonin, which is known to be an efficient in the brain. Together, these results suggested that 1800 MHz RF radiation could cause oxidative damage to mtDNA in primary cultured neurons. Oxidative damage to mtDNA may account for the neurotoxicity of RF radiation in the brain.

(E) Xu S, Chen G, Chen C, Sun C, Zhang D, Murbach M, Kuster N, Zeng Q, Xu Z. Cell Type-Dependent Induction of DNA Damage by 1800 MHz Radiofrequency Electromagnetic Fields Does Not Result in Significant Cellular Dysfunctions. PLoS One. 8(1):e54906, 2013. (GT, CS)

BACKGROUND: Although IARC clarifies radiofrequency electromagnetic fields (RF-EMF) as possible human carcinogen, the debate on its health impact continues due to the inconsistent results. Genotoxic effect has been considered as a golden standard to determine if an environmental factor is a carcinogen, but the currently available data for RF-EMF remain controversial. As an environmental stimulus, the effect of RF-EMF on cellular DNA may be subtle. Therefore, more sensitive method and systematic research strategy are warranted to evaluate its genotoxicity. **OBJECTIVES:** To determine whether RF-EMF does induce DNA damage and if the effect is cell-type dependent by adopting a more sensitive method γH2AX foci formation; and to investigate the biological consequences if RF-EMF does increase γH2AX foci formation. **METHODS:** Six different types of cells were intermittently exposed to GSM 1800 MHz RF-EMF at a specific absorption rate of 3.0 W/kg for 1 h or 24 h, then subjected to immunostaining with anti-γH2AX antibody. The biological consequences in γH2AX-elevated cell type were further explored with comet and TUNEL assays, flow cytometry, and cell growth assay. **RESULTS:** Exposure to RF-EMF for 24 h significantly induced γH2AX foci formation in Chinese hamster lung cells and Human skin fibroblasts (HSFs), but not the other cells. However, RF-EMF-elevated γH2AX foci formation in HSF cells did not result in detectable DNA fragmentation, sustainable cell cycle arrest, cell proliferation or viability change. RF-EMF exposure slightly but not significantly increased the cellular ROS level. **CONCLUSIONS:** RF-EMF induces DNA damage in a cell type-dependent manner, but the elevated γH2AX foci formation in HSF cells does not result in significant cellular dysfunctions.

(NE) Yadav AS, Sharma MK. Increased frequency of micronucleated exfoliated cells among humans exposed in vivo to mobile telephone radiations. Mutat Res.650(2):175-180, 2008. (LE, GT, HU)

The health concerns have been raised following the enormous increase in the use of wireless mobile telephones throughout the world. This investigation had been taken, with the motive to find out whether mobile phone radiations cause any in vivo effects on the frequency of micronucleated exfoliated cells in the exposed subjects. A total of 109 subjects including 85 regular mobile phone users (exposed) and 24 non-users (controls) had participated in this study. Exfoliated cells were obtained by swabbing the buccal-mucosa from exposed as well as sex-age-matched controls. One thousand exfoliated cells were screened from each individual for nuclear anomalies including micronuclei (MN), karyolysis (KL), karyorrhexis (KH), broken egg (BE) and binucleated (BN) cells. The average daily duration of exposure to mobile phone radiations is 61.26 min with an overall average duration of exposure in term of years is 2.35 years in exposed subjects along with the 9.84+/-0.745 micronucleated cells (MNCs) and 10.72+/-0.889 total micronuclei (TMN) as compared to zero duration of exposure along with average 3.75+/-0.774 MNC and 4.00+/-0.808 TMN in controls. The means are significantly different in case of MNC and TMN at 0.01% level of significance. The mean of KL in controls is 13.17+/-2.750 and in exposed subjects is 13.06+/-1.793. The value of means of KH in exposed subjects (1.84+/-0.432) is slightly higher than in controls (1.42+/-0.737). Mean frequency of broken egg is found to be more in exposed subjects (0.65+/-0.276) as compared to controls (0.50+/-0.217). Frequency of presence of more than one nucleus in a cell (binucleated) is also higher in exposed (2.72+/-0.374) in comparison to controls (0.67+/-0.231). Although there is a slight increase in mean frequency of KH, BE and BN in exposed subjects but the difference is not found statistically significant. Correlation between 0-1, 1-2, 2-3 and 3-4 years of exposure and the frequency of MNC and TMN has been calculated and found to be positively correlated.

(E) Yan JG, Agresti M, Zhang LL, Yan Y, Matloub HS. Upregulation of specific mRNA levels in rat brain after cell phone exposure. Electromagn Biol Med. 27(2):147-154, 2008. (LE, GE)

Adult Sprague-Dawley rats were exposed to regular cell phones for 6 h per day for 126 days (18 weeks). RT-PCR was used to investigate the changes in levels of mRNA synthesis of several injury-associated proteins. Calcium ATPase, Neural Cell Adhesion Molecule, Neural Growth Factor, and Vascular Endothelial Growth Factor were evaluated. The results showed statistically significant mRNA up-regulation of these proteins in the brains of rats exposed to cell phone radiation. These results indicate that relative chronic exposure to cell phone microwave radiation may result in cumulative injuries that could eventually lead to clinically significant neurological damage.

(E) Yao K, Wu W, Wang K, Ni S, Ye P, Yu Y, Ye J, Sun L. Electromagnetic noise inhibits radiofrequency radiation-induced DNA damage and reactive oxygen species increase in human lens epithelial cells. Mol Vis 14:964-969, 2008. (GT, IA, OX)

PURPOSE: The goal of this study was to investigate whether superposing of electromagnetic noise could block or attenuate DNA damage and intracellular reactive oxygen species (ROS) increase of cultured human lens epithelial cells (HLECs) induced by acute exposure to 1.8 GHz

radiofrequency field (RF) of the Global System for Mobile Communications (GSM). METHODS: An sXc-1800 RF exposure system was used to produce a GSM signal at 1.8 GHz (217 Hz amplitude-modulated) with the specific absorption rate (SAR) of 1, 2, 3, and 4 W/kg. After 2 h of intermittent exposure, the ROS level was assessed by the fluorescent probe, 2',7'-dichlorodihydrofluorescein diacetate (DCFH-DA). DNA damage to HLECs was examined by alkaline comet assay and the phosphorylated form of histone variant H2AX (gammaH2AX) foci formation assay. RESULTS: After exposure to 1.8 GHz RF for 2 h, HLECs exhibited significant intracellular ROS increase in the 2, 3, and 4 W/kg groups. RF radiation at the SAR of 3 W/kg and 4 W/kg could induce significant DNA damage, examined by alkaline comet assay, which was used to detect mainly single strand breaks (SSBs), while no statistical difference in double strand breaks (DSBs), evaluated by gammaH2AX foci, was found between RF exposure (SAR: 3 and 4 W/kg) and sham exposure groups. When RF was superposed with 2 muT electromagnetic noise could block RF-induced ROS increase and DNA damage. CONCLUSIONS: DNA damage induced by 1.8 GHz radiofrequency field for 2 h, which was mainly SSBs, may be associated with the increased ROS production. Electromagnetic noise could block RF-induced ROS formation and DNA damage.

(NE) Yildirim MS, Yildirim A, Zamani AG, Okudan N. Effect of mobile phone station on micronucleus frequency and chromosomal aberrations in human blood cells. Genet Couns. 21(2):243-251, 2010. (HU, LE, GT)

The use of mobile telephones has rapidly increased worldwide as well as the number of mobile phone base stations that lead to rise low level radiofrequency emissions which may in turn have possible harm for human health. The national radiation protection board has published the known effects of radio waves exposure on humans living close to mobile phone base stations. However, several studies have claimed that the base station has detrimental effects on different tissues. In this study, we aimed to evaluate the effects of mobile phone base stations on the micronucleus (MN) frequency and chromosomal aberrations on blood in people who were living around mobile phone base stations and healthy controls. Frequency of MN and chromosomal aberrations in study and control groups was 8.96 +/- 3.51 and 6.97 +/- 1.52 (p: 0.16); 0.36 +/- 0.31 and 0.75 +/- 0.61 (p: 0.07), respectively. Our results show that there was not a significant difference of MN frequency and chromosomal aberrations between the two study groups. The results claim that cellular phones and their base stations do not produce important carcinogenic changes.

(E) Zalata, A., A. Z. El-Samanoudy, D. Shaalan, Y. El-Baiomy, and T. Mostafa. In vitro effect of cell phone radiation on motility, DNA fragmentation and clusterin gene expression of sperm. Int J Fertil Steril, In Press. Published online ahead of print. (GT, GE, RP)

Background: Use of cellular phones that emits radiofrequency electromagnetic field (RF-EMF) has been increased exponentially and became a part of everyday life. This study aimed to investigate the effects of RF-EMF radiation emitted from cellular phones on sperm motility variables, sperm DNA fragmentation and clusterin (CLU) gene expression. Materials and Methods: 124 semen samples were grouped into; normozoospermia (N, n=26), asthenozoospermia (A, n=32), asthenoteratozoospermia (AT, n=31) and oligoasthenoteratozoospermia (OAT, n=35). Semen samples were divided into two aliquots; samples not exposed to cell phone and samples exposed to cell phone radiation (850 MHz, maximum power < 1 watt; SAR 1.46 W/kg at 10 cm distance) for 1 hr. Before and immediately

after exposure both aliquots were subjected to assessment of sperm motility, acrosin activity, sperm DNA fragmentation and CLU gene expression. Statistical differences were analyzed using paired t-student test for comparisons where P< 0.05 was set as significant. Results: There was significant decrease in sperm motility, sperm linear velocity, sperm linearity index, sperm acrosin activity and significant increase in sperm DNA fragmentation percent, CLU gene expression and CLU protein levels in the exposed semen samples to RF-EMF compared with non- exposed samples in OAT > AT > A > N groups (P<0.05).
Conclusions: Cell phone emissions have a negative impact on exposed sperm motility indices, sperm acrosin activity, sperm DNA fragmentation and CLU gene expression especially in OAT cases.

(NE) Zeni O, Schiavoni A, Perrotta A, Forigo D, Deplano M, Scarfi MR. Evaluation of genotoxic effects in human leukocytes after in vitro exposure to 1950 MHz UMTS radiofrequency field. Bioelectromagnetics 29:177-184, 2008. (GT)

In the present study the third generation wireless technology of the Universal Mobile Telecommunication System (UMTS) signal was investigated for the induction of genotoxic effects in human leukocytes. Peripheral blood from six healthy donors was used and, for each donor, intermittent exposures (6 min RF on, 2 h RF off) at the frequency of 1950 MHz were conducted at a specific absorption rate of 2.2 W/kg. The exposures were performed in a transverse electro magnetic (TEM) cell hosted in an incubator under strictly controlled conditions of temperature and dosimetry. Following long duration intermittent RF exposures (from 24 to 68 h) in different stages of the cell cycle, micronucleus formation was evaluated by applying the cytokinesis block micronucleus assay, which also provides information on cell division kinetics. Primary DNA damage (strand breaks/alkali labile sites) was also investigated following 24 h of intermittent RF exposures, by applying the alkaline single cell gel electrophoresis (SCG)/comet assay. Positive controls were included by treating cell cultures with Mitomycin-C and methylmethanesulfonate for micronucleus and comet assays, respectively. The results obtained indicate that intermittent exposures of human lymphocytes in different stages of cell cycle do not induce either an increase in micronucleated cells, or change in cell cycle kinetics; moreover, 24 h intermittent exposures also fail to affect DNA structure of human leukocytes soon after the exposures, likely indicating that repairable DNA damage was not induced.

(E) Zhang DY, Xu ZP, Chiang H, Lu DQ, Zeng QL. [Effects of GSM 1800 MHz radiofrequency electromagnetic fields on DNA damage in Chinese hamster lung cells.] Zhonghua Yu Fang Yi XueZaZhi 40:149-152, 2006. [Article in Chinese] (GT)

OBJECTIVE: To study the effects of GSM 1800 MHz radiofrequency electromagnetic fields (RF EMF) on DNA damage in Chinese hamster lung (CHL) cells. METHODS: The cells were intermittently exposed or sham-exposed to GSM 1800 MHz RF EMF (5 minutes on/10 minutes off) at a special absorption rate (SAR) of 3.0 W/kg for 1 hour or 24 hours. Meanwhile, cells exposed to 2-acetaminofluorene, a DNA damage agent, at a final concentration of 20 mg/L for 2 hours were used as positive control. After exposure, cells were fixed by using 4% paraformaldehyde and processed for phosphorylated form of H2AX (gammaH2AX) immunofluorescence measurement. The primary antibody used for immunofluorescence was mouse monoclonal antibody against gammaH2AX and the secondary antibody was fluorescein

isothiocyanate (FITC)-conjugated goat anti-mouse IgG. Nuclei were counterstained with 4, 6-diamidino-2-phenylindole (DAPI). The gammaH2AX foci and nuclei were visualized with an Olympus AX70 fluorescent microscope. Image Pro-Plus software was used to count the gammaH2AX foci in each cell. For each exposure condition, at least 50 cells were selected to detect gammaH2AX foci. Cells were classified as positive when more than five foci were detected. The percentage of gammaH2AX foci positive cells was adopted as the index of DNA damage. RESULTS: The percentage of gammaH2AX foci positive cell of 1800 MHz RF EMF exposure for 24 hours (37.9 +/- 8.6)% or 2-acetylaminofluorene exposure (50.9 +/- 9.4)% was significantly higher compared with the sham-exposure (28.0 +/- 8.4)%. However, there was no significant difference between the sham-exposure and RF EMF exposure for 1 hour (31.8 +/- 8.7)%. CONCLUSION: 1800 MHz RF EMF (SAR, 3.0 W/kg) for 24 hours might induce DNA damage in CHL cells.

(E) Zhang SZ, Yao GD, Lu DQ, Chiang H, Xu ZP. [Effect of 1.8 GHz radiofrequency electromagnetic fields on gene expression of rat neurons]. Zhonghua Lao Dong Wei Sheng Zhi Ye Bing Za Zhi. 26(8):449-452, 2008. [Article in Chinese] (GE, WS)

OBJECTIVE: To investigate the changes of gene expression in rat neuron induced by 1.8 GHz radiofrequency electromagnetic fields (RF EMF) to screen for RF EMF-responsive genes and the effect of different exposure times and modes on the gene expression in neuron. METHODS: Total RNA was extracted immediately and purified from the primary culture of neurons after intermittent exposed or sham-exposed to a frequency of 1.8 GHz RF EMF for 24 hours at an average special absorption rate (SAR) of 2 W/kg. Affymetrix Rat Neurobiology U34 array was applied to investigate the changes of gene expression in rat neuron. Differentially expressed genes (Egr-1, Mbp and Plp) were further confirmed by semi-quantitative revere transcription polymerase chain reaction (RT PCR). The expression levels of Egr-1, Mbp and Plp were observed at different exposure times (6, 24 h) and modes (intermittent and continuous exposure). RESULTS: Among 1200 candidate genes, 24 up-regulated and 10 down-regulated genes were found by using Affymetrix microarray suite software 5.0 which are associated with multiple cellular functions (cytoskeleton, signal transduction pathway, metabolism, etc.) after functional classification. Under 24 h and 6 h intermittent exposure, Egr-1 and Plp in experiment groups showed statistic significance ($P < 0.05$) compared with the control groups, while expression of Mbp did not change significantly ($P > 0.05$). After 24 h continuous exposure, Egr-1 and Mbp in experiment groups showed statistic significance ($P < 0.05$) compared with the control group, while expression of Plp did not change significantly ($P > 0.05$). Under the same exposure mode 6 h, expression of all the 3 genes did not change significantly. Different times (6, 24 h) and modes (intermittent and continuous exposure) of exposure exerted remarkable different influences on the expression of Egr-1, Mbp, Plp genes ($P < 0.01$). CONCLUSION: The changes of many genes transcription were involved in the effect of 1.8 GHz RF EMF on rat neurons; Down-regulation of Egr-1 and up-regulation of Mbp, Plp indicated the negative effects of RF EMF on neurons; The effect of RF intermittent exposure on gene expression was more obvious than that of continuous exposure; The effect of 24 h RF exposure (both intermittent and continuous) on gene expression was more obvious than that of 6 h (both intermittent and continuous).

(E) Zhao R, Zhang S, Xu Z, Ju L, Lu D, Yao G. Studying gene expression profile of rat neuron exposed to 1800MHz radiofrequency electromagnetic fields with cDNA microassay. Toxicology 235:167-175, 2007. (GE)

A widespread use of mobile phone (MP) evokes a growing concern for their possible adverse effects on human, especially the brain. Gene expression is a unique way of characterizing how cells and organism adapt to changes in the external environment, so the aim of this investigation was to determine whether 1800 MHz radiofrequency electromagnetic fields (RF EMF) can influence the gene expression of neuron. Affymetrix Rat Neurobiology U34 array was applied to investigate the changes of gene expression in rat neuron after exposed to the pulsed RF EMF at a frequency of 1800 MHz modulated by 217 Hz which is commonly used in MP. Among 1200 candidate genes, 24 up-regulated genes and 10 down-regulated genes were identified after 24-h intermittent exposure at an average special absorption rate (SAR) of 2 W/kg, which are associated with multiple cellular functions (cytoskeleton, signal transduction pathway, metabolism, etc.) after functional classification. The results were further confirmed by quantitative real-time polymerase chain reaction (RT PCR). The present results indicated that the gene expression of rat neuron could be altered by exposure to RF EMF under our experimental conditions.

(E) Zhao TY, Zou SP, Knapp PE. Exposure to cell phone radiation up-regulates apoptosis genes in primary cultures of neurons and astrocytes. Neurosci Lett. 412(1):34-38, 2007. (GE, CS)

The health effects of cell phone radiation exposure are a growing public concern. This study investigated whether expression of genes related to cell death pathways are dysregulated in primary cultured neurons and astrocytes by exposure to a working Global System for Mobile Communication (GSM) cell phone rated at a frequency of 1900MHz. Primary cultures were exposed to cell phone emissions for 2h. We used array analysis and real-time RT-PCR to show up-regulation of caspase-2, caspase-6 and Asc (apoptosis associated speck-like protein containing a card) gene expression in neurons and astrocytes. Up-regulation occurred in both "on" and "stand-by" modes in neurons, but only in "on" mode in astrocytes. Additionally, astrocytes showed up-regulation of the Bax gene. The effects are specific since up-regulation was not seen for other genes associated with apoptosis, such as caspase-9 in either neurons or astrocytes, or Bax in neurons. The results show that even relatively short-term exposure to cell phone radiofrequency emissions can up-regulate elements of apoptotic pathways in cells derived from the brain, and that neurons appear to be more sensitive to this effect than astrocytes.

(E) Zhijian C, Xiaoxue L, Yezhen L, Shijie C, Lifen J, Jianlin L, Deqiang L, Jiliang H. Impact of 1.8-GHz radiofrequency radiation (RFR) on DNA damage and repair induced by doxorubicin in human B-cell lymphoblastoid cells. Mutat Res. 695(1-2):16-21, 2010. (GT, IA)

In the present in vitro study, a comet assay was used to determine whether 1.8-GHz radiofrequency radiation (RFR, SAR of 2W/kg) can influence DNA repair in human B-cell lymphoblastoid cells exposed to doxorubicin (DOX) at the doses of 0microg/ml, 0.05microg/ml, 0.075microg/ml, 0.10microg/ml, 0.15microg/ml and 0.20microg/ml. The combinative exposures to RFR with DOX were divided into five categories. DNA damage was detected at 0h, 6h, 12h, 18h and 24h after exposure to DOX via the comet assay, and the percent of DNA in the tail (% tail DNA) served as the indicator of DNA damage. The results demonstrated that (1) RFR could not directly induce DNA damage of human B-cell lymphoblastoid cells; (2) DOX could significantly induce DNA damage of human B-cell lymphoblastoid cells with the dose-effect

relationship, and there were special repair characteristics of DNA damage induced by DOX; (3) E-E-E type (exposure to RFR for 2h, then simultaneous exposure to RFR and DOX, and exposure to RFR for 6h, 12h, 18h and 24h after exposure to DOX) combinative exposure could obviously influence DNA repair at 6h and 12h after exposure to DOX for four DOX doses (0.075microg/ml, 0.10microg/ml, 0.15microg/ml and 0.20microg/ml) in human B-cell lymphoblastoid cells.

(NE) Zhijian C, Xiaoxue L, Yezhen L, Deqiang L, Shijie C, Lifen J, Jianlin L, Jiliang H. Influence of 1.8-GHz (GSM) radiofrequency radiation (RFR) on DNA damage and repair induced by X-rays in human leukocytes in vitro. Mutat Res. 677(1-2):100-104, 2009. (GT, IA)

In the present study, the in vitro comet assay was used to determine whether 1.8-GHz radiofrequency radiation (RFR) can influence DNA repair in human leukocytes exposed to X-rays. The specific energy absorption rate (SAR) of 2 W/kg (the current European safety limit) was applied. The leukocytes from four young healthy donors were intermittently exposed to RFR for 24 h (fields on for 5 min, fields off for 10 min), and then irradiated with X-rays at doses of 0.25, 0.5, 1.0 and 2.0 Gy. DNA damage to human leukocytes was detected using the comet assay at 0, 15, 45, 90, 150 and 240 min after exposure to X-rays. Using the comet assay, the percent of DNA in the tail (% tail DNA) served as the indicator of DNA damage; the DNA repair percentage (DRP) served as the indicator of the DNA repair speed. The results demonstrated that (1) the DNA repair speeds of human leukocytes after X-ray exposure exhibited individual differences among the four donors; (2) the intermittent exposures of 1.8-GHz RFR at the SAR of 2 W/kg for 24 h did not directly induce DNA damage or exhibit synergistic effects with X-rays on human leukocytes.

(NE) Ziemann C, Brockmeyer H, Reddy SB, Vijayalaxmi, Prihoda TJ, Kuster N, Tillmann T, Dasenbrock C. Absence of genotoxic potential of 902 MHz (GSM) and 1747 MHz (DCS) wireless communication signals: In vivo two-year bioassay in B6C3F1 mice. Int J Radiat Biol. 85(5):454-464, 2009. (GT, LE)

PURPOSE: The aim of the present investigation was to determine the incidence of micronuclei in peripheral blood erythrocytes of B6C3F1 mice that had been chronically exposed to radiofrequencies (RF) used for mobile communication. MATERIALS AND METHODS: 'Ferris wheels' were used to expose tube-restrained male and female mice to simulated environmental RF signals of the Global System for Mobile Communications (GSM, 902 MHz) or Digital Cellular System (DCS, 1747 MHz). RF signals were applied to the mice for 2 hours/day on 5 days/week for two years, at maximal whole-body-averaged specific absorption rates of 0.4, 1.3, and 4.0 W/kg body weight. Concurrent sham-exposed mice, cage controls, and positive controls injected with mitomycin C were included in this investigation. At necropsy, peripheral blood smears were prepared, and coded slides were stained using May-Grunwald-Giemsa or acridine orange. The incidence of micronuclei was recorded for each mouse in 2000 polychromatic and 2000 normochromatic erythrocytes. RESULTS: There were no significant differences in the frequency of micronuclei between RF-exposed, sham-exposed, and cage control mice, irrespective of the staining/counting method used. Micronuclei were, however, significantly increased in polychromatic erythrocytes of the positive control mice.

CONCLUSIONS: In conclusion, the data did not indicate RF-induced genotoxicity in mice after two years of exposure.

APPENDIX B - ABSTRACTS ON GENETIC EFFECTS OF EXTREMELY-LOW FREQUENCY ELECTROMAGNETIC FIELDS (2007-2014)

Below is a key to abbreviations used throughout the following list of abstracts for recent papers published since 2006 and serve as my comments to help the reader quickly identify the significance of each work. The summary sentences by each author are underlined. The list is divided into RF effects papers, and ELF effects papers.

(E- effect observed; NE- no effect observed) (LE- long term exposure; GT- genotoxic effect, e.g., DNA damage, micronucleus formation, chromosome alterations; GE- gene expression; HU- human study; OX- oxidative effects, i.e., involvement of free radicals and oxidative enzymes; IA- interaction with other factors to cause genetic effects; DE- effects on developing animals; RP- reproduction, e.g., sperm damage; EH- compared with electro-hypersensitive subjects; WS- waveform specific effect, e.g., modulation and frequency; CS- cell type specific effect).

(NE) Albert GC, McNamee JP, Marro L, Bellier PV, Prato FS, Thomas AW. Assessment of genetic damage in peripheral blood of human volunteers exposed (whole-body) to a 200 muT, 60 Hz magnetic field. Int J Radiat Biol. 85(2):144-152, 2009. (GT, IA)

AIM: To investigate the extent of damage in nucleated cells in peripheral blood of healthy human volunteers exposed to a whole-body 60 Hz, 200 microT magnetic field. **MATERIALS AND METHODS:** In this study, 10 male and 10 female healthy human volunteers received a 4 h whole-body exposure to a 200 microT, 60 Hz magnetic field. In addition, five males and five females were treated in a similar fashion, but were exposed to sham conditions. For each subject, a blood sample was obtained prior to the exposure period and aliquots were used as negative- (pre-exposure) and positive- [1.5 Gray (Gy) (60)Cobalt ((60)Co) gamma-irradiation] controls. At the end of the 4 h exposure period, a second blood sample was obtained. The extent of DNA damage was assessed in peripheral human blood leukocytes from all samples using the alkaline comet assay. To detect possible clastogenic effects, the incidence of micronuclei was assessed in phytohemagglutinin (PHA)-stimulated lymphocytes using the cytokinesis-block micronucleus assay. **RESULTS:** There was no evidence of either increased DNA damage, as indicated by the alkaline comet assay, or increased incidence of micronuclei (MN) in the magnetic field exposed group. However, an in vitro exposure of 1.5 Gy gamma-irradiation caused a significant increase in both DNA damage and MN induction. **CONCLUSIONS:** This study found no evidence that an acute, whole-body exposure to a 200 microT, 60 Hz magnetic field for 4 hours could cause DNA damage in human blood.

(E) Alcaraz M, Olmos E, Alcaraz-Saura M, Achel DG, Castillo J. Effect of long-term 50 Hz magnetic field exposure on the micronucleated polychromatic erythrocytes of mice. Electromagn Biol Med. 2013 Jun 19. [Epub ahead of print] (GT)

Abstract In recent years extremely low-frequency magnetic fields (ELF-EMF) have become widely used in human activities, leading to an increased chance of exposure to ELF-EMF. There are few reports on in vivo mammalian genotoxic effects using micronucleus (MN) assays, which generally have been used as a short-term screening system. We analyzed the possible genotoxic effect induced by long-term exposure (7, 14, 21, 28 d) of a 50 Hz ELM-MF to mice by measuring the increase in frequency of micronucleated polychromatic erythrocyte in their bone marrow (MNPCEs) and we compared it with that induced by 50 cGy of X-rays. Subsequently, we tried to reduce this chromosomal damage by administering four antioxidants substances with radioprotective capacities: dimethyl sulfoxide (DMSO), 6-n-propyl-2-thiouracil (PTU), grape-procyanidins (P) and citrus flavonoids extract (CE). The increase in micronucleated cells was higher in both physical treatments (Control < ELF-EMF ($p < 0.01$) <X-rays ($p > 0.001$)); however, the antioxidant substances only showed a genoprotective capacity against the damage induced by ionizing radiation (Ci > PTU = DMSO ($p < 0.001$) >P = CE ($p < 0.001$). The 50 Hz ELM-MF increased MNPCEs in mouse bone marrow, expressing a genotoxic capacity. Administration of antioxidant substances with radioprotective capacities known to act through the elimination of free radicals did not diminish the genotoxic effect induced by ELM-MF.

(E) Balamuralikrishnan B, Balachandar V, Kumar SS, Stalin N, Varsha P, Devi SM, Arun M, Manikantan P, Venkatesan C, Sasikala K, Dharwadkar SN. Evaluation of Chromosomal Alteration in Electrical Workers Occupationally Exposed to Low Frequency of Electro Magnetic Field (EMFs) in Coimbatore Population, India. Asian Pac J Cancer Prev. 13(6):2961-2966, 2012. (HU, LE, GT)

Extremely low frequency electromagnetic fields (EMFs) have been classified as possibly carcinogenic to humans by the International Agency for Research on Cancer. An increased number of chromosomal alterations in peripheral lymphocytes are correlated with elevated incidence of cancer. The aim of the present study was to assess occupationally induced chromosomal damage in EMF workers exposed to low levels of radiation. We used conventional metaphase chromosome aberration (CA) analysis and the micronucleus (MN) assay as biological indicators of nonionizing radiation exposure. In the present study totally 70 subjects were selected including 50 exposed and 20 controls. Informed written consent was obtained from all participants and the study was performed in accordance with the Declaration of Helsinki and the approval of the local ethical committee. A higher degree of CA and MN was observed in exposed subjects compared to controls, the frequency of CA being significantly enhanced with long years of exposure ($P<0.05$). Moreover increase in CA and MN with age was noted in both exposed subjects and controls, but was significantly greater in the former. The results of this study demonstrated that a significant induction of cytogenetic damage in peripheral lymphocytes of workers occupationally exposed to EMFs in electric transformer and distribution stations. In conclusion, our findings suggest that EMFs possess genotoxic capability, as measured by CA and MN assays; CA analysis appeared more sensitive than other cytogenetic end-points. It can be concluded that chronic occupational exposure to EMFs may lead to an increased risk of genetic damage among electrical workers.

(E) Belyaev IY, Hillert L, Protopopova M, Tamm C, Malmgren LO, Persson BR, Selivanova G, Harms-Ringdahl M. 915 MHz microwaves and 50 Hz magnetic field affect chromatin conformation and 53BP1 foci in human lymphocytes from hypersensitive and healthy persons. Bioelectromagnetics 26:173-184, 2005. (GT, EH)

We used exposure to microwaves from a global system for mobile communication (GSM) mobile phone (915 MHz, specific absorption rate (SAR) 37 mW/kg) and power frequency magnetic field (50 Hz, 15 muT peak value) to investigate the response of lymphocytes from healthy subjects and from persons reporting hypersensitivity to electromagnetic field (EMF). The hypersensitive and healthy donors were matched by gender and age and the data were analyzed blind to treatment condition. The changes in chromatin conformation were measured with the method of anomalous viscosity time dependencies (AVTD). 53BP1 protein, which has been shown to colocalize in foci with DNA double strand breaks (DSBs), was analyzed by immunostaining in situ. Exposure at room temperature to either 915 MHz or 50 Hz resulted in significant condensation of chromatin, shown as AVTD changes, which was similar to the effect of heat shock at 41 degrees C. No significant differences in responses between normal and hypersensitive subjects were detected. Neither 915 MHz nor 50 Hz exposure induced 53BP1 foci. On the contrary, a distinct decrease in background level of 53BP1 signaling was observed upon these exposures as well as after heat shock treatments. This decrease correlated with the AVTD data and may indicate decrease in accessibility of 53BP1 to antibodies because of stress-induced chromatin condensation. Apoptosis was determined by morphological changes and by apoptotic fragmentation of DNA as analyzed by pulsed-field gel electrophoresis (PFGE). No apoptosis was induced by exposure to 50 Hz and 915 MHz microwaves. In conclusion, 50 Hz magnetic field and 915 MHz microwaves under specified conditions of exposure induced comparable responses in lymphocytes from healthy and hypersensitive donors that were similar but not identical to stress response induced by heat shock.

(E) Borhani N, Rajaei F, Salehi Z, Javadi A. Analysis of DNA fragmentation in mouse embryos exposed to an extremely low-frequency electromagnetic field. Electromagn Biol Med. 30(4):246-252, 2011. (GT, DE, LE)

Effects of extremely low-frequency electromagnetic fields (ELF-EMFs) on DNA damage in biological systems are still a matter of dispute. The aim of the present study was to investigate the possible effect of electromagnetic field exposure on DNA fragmentation in cells (blastomers) of mouse blastocysts. Eighty female NMRI mice were randomly divided into 2 groups of 40 animals each. The control group was left unexposed whereas the animals in the EMF-group were exposed to a 50-Hz EMF at 0.5 mT 4 h per day, 6 days a week for a duration of 2 weeks. After the 8(th) day of exposure, the female mice in both groups were superovulated (with injections of pregnant mare serum gonadotropin and human chorionic gonadotropin) and then mated overnight. At approximately 4 days after mating (102 h after the human chorionic gonadotropin treatment), blastocysts were obtained by flushing the uterus horns. The mean numbers of pregnant mice, blastocysts after flushing, blastomers within the blastocysts, and the DNA fragmentation index following staining in both groups were compared using statistical methods (SPSS, the Chi-square test, the Student's t-test and the Mann-Whitney U-test, $P < 0.05$). The results showed that the mean number of blastocysts after flushing was significantly decreased in the EMF-group compared to that of the control group ($P < 0.03$). The DNA fragmentation index was significantly increased in the EMF-group compared to control (10.53% vs. 7.14%; P <

0.001). However, there was no significant difference in the mean numbers of blastomers and numbers of pregnant mice between the EMF-exposed and control group. Our findings indicate that the EMF exposure in preimplantation stage could have detrimental effects on female mouse fertility and embryo development by decreasing the number of blastocysts and increasing the blastocysts DNA fragmentation.

(E) Bułdak RJ, Polaniak R, Bułdak L, Zwirska-Korczala K, Skonieczna M, Monsiol A, Kukla M, Duława-Bułdak A, Birkner E. Short-term exposure to 50 Hz ELF-EMF alters the cisplatin-induced oxidative response in AT478 murine squamous cell carcinoma cells. Bioelectromagnetics. 2012 Apr 25. doi: 10.1002/bem.21732. [Epub ahead of print] (GT, IA, OX)

The aim of this study was to assess the influence of cisplatin and an extremely low frequency electromagnetic field (ELF-EMF) on antioxidant enzyme activity and the lipid peroxidation ratio, as well as the level of DNA damage and reactive oxygen species (ROS) production in AT478 carcinoma cells. Cells were cultured for 24 and 72 h in culture medium with cisplatin. Additionally, the cells were irradiated with 50 Hz/1 mT ELF-EMF for 16 min using a solenoid as a source of the ELF-EMF. The amount of ROS, superoxide dismutase (SOD) isoenzyme activity, glutathione peroxidase (GSH-Px) activity, DNA damage, and malondialdehyde (MDA) levels were assessed. Cells that were exposed to cisplatin exhibited a significant increase in ROS and antioxidant enzyme activity. The addition of ELF-EMF exposure to cisplatin treatment resulted in decreased ROS levels and antioxidant enzyme activity. A significant reduction in MDA concentrations was observed in all of the study groups, with the greatest decrease associated with treatment by both cisplatin and ELF-EMF. Cisplatin induced the most severe DNA damage; however, when cells were also irradiated with ELF-EMF, less DNA damage occurred. Exposure to ELF-EMF alone resulted in an increase in DNA damage compared to control cells. ELF-EMF lessened the effects of oxidative stress and DNA damage that were induced by cisplatin; however, ELF-EMF alone was a mild oxidative stressor and DNA damage inducer. We speculate that ELF-EMF exerts differential effects depending on the exogenous conditions. This information may be of value for appraising the pathophysiologic consequences of exposure to ELF-EMF.

(E) Calabrò E, Condello S, Magazù S, Ientile, R. Static and 50 Hz electromagnetic fields effects on human neuronal-like cells vibration bands in the mid-infrared region. J Electromagnetic Analysis and Applications 3(2) 69-78, 2011. (GT)

Human neuronal-like cells were exposed to static and 50 Hz electromagnetic fields at the intensities of 2 mT and 1 mT, respectively. The effects of exposure were investigated in the mid-infrared region by means of Fourier self deconvolution spectroscopic analysis. After exposure of 3 hours to static and 50 Hz electromagnetic fields, the vibration bands of CH2 methilene group increased significantly after both exposures, suggesting a relative increase of lipid related to conformational changes in the cell membrane due to electromagnetic fields. In addition, PO2- stretching phosphate bands decreased after both exposures, suggesting that alteration in DNA/RNA can be occurred. In particular, exposure of 3 hours to 50 Hz electromagnetic fields produced significant increases in β-sheet contents in amide I, and around the 1740 cm^{-1} band assigned to non-hydrogen-bonded ester carbonyl stretching mode, that can be

related to unfolding processes of proteins structure and cells death. Further exposure up to 18 hours to static magnetic field produced an increase in β-sheet contents as to α-helix components of amide I region, as well.

(E) Celikler S, Aydemir N, Vatan O, Kurtuldu S, Bilaloglu R. A biomonitoring study of genotoxic risk to workers of transformers and distribution line stations. Int J Environ Health Res. 19(6):421-430, 2009. (GT, HU)

A cytogenetic monitoring study was carried out on a group of workers from transformer and distribution line stations in the Bursa province of Turkey, to investigate the genotoxic risk of occupational exposure to extremely low frequency electric (ELF) and magnetic fields (EMF). Cytogenetic analysis, namely chromosomal aberrations (CAs) and micronucleus (MN) tests were performed on a strictly selected group of 55 workers and compared to 17 controls. CA and MN frequencies in electrical workers appeared significantly higher than in controls ($p < 0.001$, 0.05, respectively). The frequency of CA in exposed groups were significantly enhanced with the years of exposure ($p < 0.01$). The effect of smoking on the level of CA and MN was not significant in the control and exposure groups. The results of this study demonstrated that a significant induction of cytogenetic damage in peripheral lymphocytes of workers engaged to occupational exposure to ELMF in electric transformer and distribution stations.

(E) Chen GD, Lu DQ, Jiang H, Xu ZP.[Effects of 50 Hz magnetic fields on gene expression in MCF-7 cells]. Zhejiang Da Xue Xue Bao Yi Xue Ban. 37(1):15-22, 2008. [Article in Chinese] **(GT, GE)**

OBJECTIVE: To investigate whether 50 Hz magnetic fields (MF) can change the gene expression profile in MCF-7 cells and to screen MF responsive genes. **METHODS:** In vitro cultured MCF-7 cells were continuously exposed or sham-exposed to 0.4 mT of 50 Hz MF for 24 hours. Affymetrix Human Genome Genechips (U133A) were applied to analyze gene expression profiles in MF exposed and sham-exposed MCF-7 cells and the data were processed with Genechip data analysis software MAS 5.0 and DMT 3.0. Real-time RT-PCR assay was employed to examine the differentially expressed genes. **RESULT:** Thirty differentially expressed genes were screened with 100 % consistency change calls in the MF exposed MCF-7 cells. Six independent real-time RT-PCR analyses showed that SCNN1A, METTL3 and GPR137B were slightly but statistically significantly changed in MCF-7 cells after exposure to 50 Hz MF ($P<0.05$), while other analyzed genes exhibited slight up-and down-fluctuations in expressions and no increase or decrease in each gene expression reached statistical significance ($P>0.05$). **CONCLUSION:** The present study identified three 50 Hz MF responsive genes in MCF-7 cells and the biological consequences of expression changes in these MF responsive genes need to be further investigated.0.4 mT 50 Hz MF exposure for longer duration might induce DNA double-strand breaks in human lens epithelial cells in vitro.

(NE) Chen G, Lu D, Chiang H, Leszczynski D, Xu Z. Using model organism Saccharomyces cerevisiae to evaluate the effects of ELF-MF and RF-EMF exposure on global gene expression. Bioelectromagnetics. 33(7):550-560, 2012. (GE)

The potential health hazard of exposure to electromagnetic fields (EMF) continues to cause public concern. However, the possibility of biological and health effects of exposure to EMF remains controversial and their biophysical mechanisms are unknown. In the present study, we used Saccharomyces cerevisiae to identify genes responding to extremely low frequency magnetic fields (ELF-MF) and to radiofrequency EMF (RF-EMF) exposures. The yeast cells were exposed for 6 h to either 0.4 mT 50 Hz ELF-MF or 1800 MHz RF-EMF at a specific absorption rate of 4.7 W/kg. Gene expression was analyzed by microarray screening and confirmed using real-time reverse transcription-polymerase chain reaction (RT-PCR). We were unable to confirm microarray-detected changes in three of the ELF-MF responsive candidate genes using RT-PCR ($P > 0.05$). On the other hand, out of the 40 potential RF-EMF responsive genes, only the expressions of structural maintenance of chromosomes 3 (SMC3) and aquaporin 2 (AQY2 (m)) were confirmed, while three other genes, that is, halotolerance protein 9 (HAL9), yet another kinase 1 (YAK1) and one function-unknown gene (open reading frame: YJL171C), showed opposite changes in expression compared to the microarray data ($P < 0.05$). In conclusion, the results of this study suggest that the yeast cells did not alter gene expression in response to 50 Hz ELF-MF and that the response to RF-EMF is limited to only a very small number of genes. The possible biological consequences of the gene expression changes induced by RF-EMF await further investigation.

(E) Cho S, Lee Y, Lee S, Choi YJ, Chung HW. Enhanced cytotoxic and genotoxic effects of gadolinium following ELF-EMF irradiation in human lymphocytes. Drug Chem Toxicol. 2014 Jan 30. [Epub ahead of print] (GT, IA)

Gadolinium (Gd) and its chelated derivatives are widely utilized for various industrial and medical purposes, particularly as a contrast agent for magnetic resonance imaging (MRI). There are many studies of Gd nephrotoxicity and neurotoxicity, whereas research on cyto- and genotoxicity in normal human lymphocytes is scarce. It is important to investigate the effect of extremely low-frequency electromagnetic fields (ELF-EMF) on Gd toxicity, as patients are co-exposed to Gd and ELF-EMF generated by MRI scanners. We investigated the cytotoxicity and genotoixcity of Gd and the possible enhancing effect of ELF-EMF on Gd toxicity in cultured human lymphocytes by performing a micronuclei (MN) assay, trypan blue dye exclusion, single cell gel electrophoresis, and apoptosis analyses using flow cytometry. Isolated lymphocytes were exposed to 0.2-1.2 mM of Gd only or in combination with a 60-Hz ELF-EMF of 0.8-mT field strength. Exposing human lymphocytes to Gd resulted in a concentration- and time-dependent decrease in cell viability and an increase in MN frequency, single strand DNA breakage, apoptotic cell death, and ROS production. ELF-EMF (0.8 mT) exposure also increased cell death, MN frequency, olive tail moment, and apoptosis induced by Gd treatment alone. These results suggest that Gd induces DNA damage and apoptotic cell death in human lymphocytes and that ELF-EMF enhances the cytotoxicity and genotoxicity of Gd.

(E) Cho YH, Jeon HK, Chung HW. Effects of extremely low-frequency electromagnetic fields on delayed chromosomal instability induced by bleomycin in normal human fibroblast cells. J Toxicol Environ Health A. 70(15-16):1252-1258, 2007. (GT, IA)

This study was carried out to examine the interaction of extremely low-frequency electromagnetic fields (ELF-EMF) on delayed chromosomal instability by bleomycin (BLM) in

human fibroblast cells. A micronucleus-centromere assay using DNA probes for chromosomes 1 and 4 was performed and a 60-Hz ELF-EMF of 0.8 mT field strength was applied either alone or with BLM throughout the culture period. The frequencies of micronuclei (MN) and aneuploidy were analyzed at 28, 88, and 240 h after treatment with BLM. The coexposure of cells to BLM and ELF-EMF led to a significant increase in the frequencies of MN and aneuploidy compared to the cells treated with BLM alone. No difference was observed between field-exposed and sham-exposed control cells. The frequency of MN induced by BLM was increased at 28 h, and further analysis showed a persistent increase up to 240 h, but the new levels were not significantly different from the level at 28 h. BLM increased the frequencies of aneuploidy at 28, 88, and 240 h, and significantly higher frequency of aneuploidy was observed in the cells analyzed at 240 h compared to the cells examined at 28 h. No interaction of ELF-EMF on delayed chromosomal instability by BLM was observed. Our results suggest that ELF-EMF enhances the cytotoxicity of BLM. BLM might induce delayed chromosomal instability, but no effect of ELF-EMF was observed on the BLM-induced delayed chromosomal instability in fibroblast cells.

(E) Collard JF, Lazar C, Nowé A, Hinsenkamp M. Statistical validation of the acceleration of the differentiation at the expense of the proliferation in human epidermal cells exposed to extremely low frequency electric fields. Prog Biophys Mol Biol. 111(1):37-45, 2013. (GE)

An acceleration of differentiation at the expense of proliferation is observed in our previous publications and in the literature after exposure of various biological models to low frequency and low-amplitude electric and electromagnetic fields. This observation is related with a significant modification of genes expression. We observed and compared over time this modification. This study use microarray data obtained on epidermis cultures harvested from human abdominoplasty exposed to ELF electric fields. This protocol is repeated with samples collected on three different healthy patients. The sampling over time allows comparison of the effect of the stimulus at a given time with the evolution of control group. After 4 days, we observed a significant difference of the genes expression between control (D4C) and stimulated (D4S) ($p < 0.05$). On the control between day 4 and 7, we observed another group of genes with significant difference ($p < 0.05$) in their expression. We identify the common genes between these two groups and we select from them those expressing no difference between stimulate at 4 days (D4S) and control after 7 days (D7C). The same analysis was performed with D4S-D4C-D12C and D7S-D7C-D12C. The lists of genes which follow this pattern show acceleration in their expressions under stimulation appearing on control at a later time. In this list, genes such as DKK1, SPRR3, NDRG4, and CHEK1 are involved in cell proliferation or differentiation. Numerous other genes are also playing a function in mitosis, cell cycle or in the DNA replication transcription and translation. 1

Exposure to extremely low-frequency (50 Hz) electromagnetic fields enhances adult hippocampal neurogenesis in C57BL/6 mice. Exp Neurol. 226(1):173-182, 2010. (LE, GE, DE)

Throughout life, new neurons are continuously generated in the hippocampus, which is therefore a major site of structural plasticity in the adult brain. We recently demonstrated that extremely low-frequency electromagnetic fields (ELFEFs) promote the neuronal differentiation of neural stem cells in vitro by up-regulating Ca(v)1-channel activity. The aim of the present study was to determine whether 50-Hz/1 mT ELFEF stimulation also affects adult hippocampal neurogenesis in vivo, and if so, to identify the molecular mechanisms underlying this action and its functional impact on synaptic plasticity. ELFEF exposure (1 to 7 h/day for 7 days) significantly enhanced neurogenesis in the dentate gyrus (DG) of adult mice, as documented by increased numbers of cells double-labeled for 5-bromo-deoxyuridine (BrdU) and double cortin. Quantitative RT-PCR analysis of hippocampal extracts revealed significant ELFEF exposure-induced increases in the transcription of pro-neuronal genes (Mash1, NeuroD2, Hes1) and genes encoding Ca(v)1.2 channel α(1C) subunits. Increased expression of NeuroD1, NeuroD2 and Ca(v)1 channels was also documented by Western blot analysis. Immunofluorescence experiments showed that, 30 days after ELFEF stimulation, roughly half of the newly generated immature neurons had survived and become mature dentate granule cells (as shown by their immunoreactivity for both BrdU and NeuN) and were integrated into the granule cell layer of the DG. Electrophysiological experiments demonstrated that the new mature neurons influenced hippocampal synaptic plasticity, as reflected by increased long-term potentiation. Our findings show that ELFEF exposure can be an effective tool for increasing in vivo neurogenesis, and they could lead to the development of novel therapeutic approaches in regenerative medicine.

(E) Di Campli E, Di Bartolomeo S, Grande R, Di Giulio M, Cellini L. Effects of extremely low-frequency electromagnetic fields on Helicobacter pylori biofilm. Curr Microbiol. 60(6):412-418, 2010. (GE)

The aim of this work was to investigate the effects of exposure to extremely low-frequency electromagnetic fields (ELF-EMF) both on biofilm formation and on mature biofilm of Helicobacter pylori. Bacterial cultures and 2-day-old biofilm of H. pylori ATCC 43629 were exposed to ELF-EMF (50 Hz frequency-1 mT intensity) for 2 days to assess their effect on the cell adhesion and on the mature biofilm detachment, respectively. All the exposed cultures and the respective sham exposed controls were studied for: the cell viability status, the cell morphological analysis, the biofilm mass measurement, the genotypic profile, and the luxS and amiA gene expression. The ELF-EMF acted on the bacterial population during the biofilm formation displaying significant differences in cell viability, as well as, in morphotypes measured by the prevalence of spiral forms (58.41%) in respect to the controls (33.14%), whereas, on mature biofilm, no significant differences were found when compared to the controls. The measurement of biofilm cell mass was significantly reduced in exposed cultures in both examined experimental conditions. No changes in DNA patterns were recorded, whereas a modulation in amiA gene expression was detected. An exposure to ELF-EMF of H. pylori biofilm induces phenotypic changes on adhering bacteria and decreases the cell adhesion unbalancing the bacterial population therefore reducing the H. pylori capability to protect itself.

(E) Dominici L, Villarini M, Fatigoni C, Monarca S, Moretti M. Genotoxic hazard evaluation in welders occupationally exposed to extremely low-frequency magnetic fields (ELF-MF). Int J Hyg Environ Health. 215(1):68-75, 2011. (GT, HU)

Electric arc welding is known to involve considerable exposure to extremely low-frequency magnetic fields (ELF-MF). A cytogenetic monitoring study was carried out in a group of welders to investigate the genotoxic risk of occupational exposure to ELF-MF. This study assessed individual occupational exposure to ELF-MF using a personal magnetic-field dosimeter, and the cytogenetic effects were examined by comparing micronuclei (MN) and sister chromatid exchange (SCE) frequencies in the lymphocytes of the exposed workers with those of non-exposed control subjects (blood donors) matched for age and smoking habit. Cytogenetic analyses were carried out on 21 workers enrolled from two different welding companies in Central Italy and compared to 21 controls. Some differences between the groups were observed on analysis of SCE and MN, whereas replication indices in the exposed were found not to differ from the controls. In particular, the exposed group showed a significantly higher frequency of MN (group mean±SEM: 6.10±0.39) compared to the control group (4.45±0.30). Moreover, the increase in MN is associated with a proportional increase in ELF-MF exposure levels with a dose-response relationship. A significant decrease in SCE frequency was observed in exposed subjects (3.73±0.21) compared to controls (4.89±0.12). The hypothesis of a correlation between genotoxic assays and ELF-MF exposure value was partially supported, especially as regards MN assay. Since these results are derived from a small-scale pilot study, a larger scale study should be undertaken.

(E) Du XG, Xu SS, Chen Q, Lu DQ, Xu ZP, Zeng QL. [Effects of 50 Hz magnetic fields on DNA double-strand breaks in human lens epithelial cells]. Zhejiang Da Xue Xue Bao Yi Xue Ban. 37(1):9-14, 2008. [Article in Chinese] (GT)

OBJECTIVE: To investigate the effects of 50 Hz magnetic fields (MF) on DNA double-strand breaks in human lens epithelial cells (hLECs). **METHODS:** The cultured human lens epithelial cells were exposed to 0.4 mT 50 Hz MF for 2 h, 6 h, 12 h, 24 h and 48 h. Cells exposed to 4-nitroquinoline-1-oxide, a DNA damage agent, at a final concentration of 0.1 micromol/L for 1 h were used as positive controls.After exposure, cells were fixed with 4 % paraformaldehyde and for H2AX (gamma H2AX) immunofluorescence measurement. gamma H2AX foci were detected at least 200 cells for each sample. Cells were classified as positive when more than three foci per cell were observed. Mean values of foci per cell and percentage of foci positive cells were adopted as indexes of DNA double-strand breaks. **RESULT:** The mean value of foci per cell and the percentage of gamma H2AX foci positive cells in 50 Hz MF exposure group for 24 h were (2.93 +/-0.43) and (27.88 +/-2.59)%, respectively, which were significantly higher than those of sham-exposure group [(1.77 +/-0.37) and (19.38+/-2.70)%, P <0.05], and the mean value of foci per cell and the percentage of gamma H2AX foci positive cells in 50 Hz MF exposure group for 48 h were (3.14 +/-0.35) and (31.00 +/-3.44)%, which were significantly higher than those of sham-exposure group (P <0.01). However there was no significant difference between 50 Hz MF exposure groups for 2 h, 6 h, 12 h and sham-exposure group for above two indexes (P >0.05). **CONCLUSION:** 0.4 mT 50 Hz MF exposure for longer duration might induce DNA double-strand breaks in human lens epithelial cells in vitro.

(E) El-Bialy NS, Rageh MM. Extremely low-frequency magnetic field enhances the therapeutic efficacy of low-dose cisplatin in the treatment of Ehrlich carcinoma. Biomed Res Int. 2013;2013:189352. doi: 10.1155/2013/189352. Epub 2013 Jan 14. (GT, IA)

The present study examines the therapeutic efficacy of the administration of low-dose cisplatin (cis) followed by exposure to extremely low-frequency magnetic field (ELF-MF), with an average intensity of 10 mT, on Ehrlich carcinoma in vivo. The cytotoxic and genotoxic actions of this combination were studied using comet assay, mitotic index (MI), and the induction of micronucleus (MN). Moreover, the inhibition of tumor growth was also measured. Treatment with cisplatin and ELF-MF (group A) increased the number of damaged cells by 54% compared with 41% for mice treated with cisplatin alone (group B), 20% for mice treated by exposure to ELF-MF (group C), and 9% for the control group (group D). Also the mitotic index decreased significantly for all treated groups ($P < 0.001$). The decrement percent for the treated groups (A, B, and C) were 70%, 65%, and 22%, respectively, compared with the control group (D). Additionally, the rate of tumor growth at day 12 was suppressed significantly ($P < 0.001$) for groups A, B, and C with respect to group (D). These results suggest that ELF-MF enhanced the cytotoxic activity of cisplatin and potentiate the benefit of using a combination of low-dose cisplatin and ELF-MF in the treatment of Ehrlich carcinoma.

(E) Erdal N, Gürgül S, Celik A. Cytogenetic effects of extremely low frequency magnetic field on Wistar rat bone marrow. Mutat Res. 630(1-2):69-77, 2007. (GT, LE)

In this study, the genotoxic and cytotoxic potential of extremely low frequency magnetic fields (ELF-MF) was investigated in Wistar rat tibial bone marrow cells, using the chromosomal aberration (CA) and micronucleus (MN) test systems. In addition to these test systems, we also investigated the mitotic index (MI), and the ratio of polychromatic erythrocytes (PCEs) to normochromatic erythrocytes (NCEs). Wistar rats were exposed to acute (1 day for 4h) and long-term (4h/day for 45 days) to a horizontal 50Hz, 1mT uniform magnetic field generated by a Helmholtz coil system. Mitomycin C (MMC, 2mg/kg BW) was used as positive control. Results obtained by chromosome analysis do not show any statistically significant differences between the negative control and both acute and long-term ELF-MF exposed samples. When comparing the group mean CA of long-term exposure with the negative control and acute exposure, the group mean of the long-term exposed group was higher, but this was not statistically significant. However, the mean micronucleus frequency of the longer-term exposed group was considerably higher than the negative control and acutely exposed groups. This difference was statistically significant ($p<0.01$). The results of the MI in bone marrow showed that the averages of both A-MF and L-MF groups significantly decreased when compared to those in the negative control ($p<0.001$ and $p<0.01$, respectively). No significant differences were found between the group mean MI of A-MF exposure with L-MF. We found that the average of PCEs/NCEs ratios of A-MF exposed group was significantly lower than the negative control and L-MF exposed groups ($p<0.001$ and $p<0.01$, respectively). In addition, the group mean of the PCEs/NCEs ratios of L-MF was significantly lower than negative control ($p<0.01$). We also found that the MMC treated group showed higher the number of CA and the frequency of MN formation when compared to those in all other each groups (p-values of all each groups <0.01) and also MMC treated group showed lower MI and the PCEs/NCEs ratios when compared to those in all other each groups (p-values of all groups <0.01). These observations indicate the in vivo suspectibility of mammals to the genotoxicity potential of ELF-MF.

(E) Fedrowitz M, Löscher W. Gene expression in the mammary gland tissue of female Fischer 344 and Lewis rats after magnetic field exposure (50 Hz, 100 µT) for 2 weeks. Int J

Radiat Biol. 88(5):425-429, 2012. (GE, LE) See also: Fedrowitz M, Hass R, Löscher W. Effects of 50 Hz magnetic field exposure on the stress marker α-amylase in the rat mammary gland. Int J Radiat Biol. 88(7):556-564, 2012.

PURPOSE: The issue of whether exposure to environmental power-frequency magnetic fields (MF) has impact on breast cancer development still remains equivocal. Previously, we observedrat strain differences in the MF response of breast tissue, so that the genetic background plays a role in MF effects. The present experiment aimed to elucidate candidate genes involved in MF effects by comparison of MF-susceptible Fischer 344 (F344) rats and MF-insensitive Lewis rats. **MATERIALS AND METHODS:** Female F344 and Lewis rats were exposed to MF (50 Hz, 100 μT) for two weeks, and a whole genome microarray analysis in the mammary gland tissue was performed. **RESULTS:** A remarkably decreased α-amylase gene expression, decreases in carbonic anhydrase 6 and lactoperoxidase, both relevant for pH regulation, and an increased gene expression of cystatin E/M, a tumor suppressor, were observed in MF-exposed F344, but not in Lewis rats. **CONCLUSION:** The MF-exposed F344 breast tissue showed alterations in gene expression, which were absent in Lewis and may therefore be involved in the MF-susceptibility of F344. Notably α-amylase might serve as a promising target to study MF effects, because first experiments indicate that MF exposure alters the functionality of this enzyme in breast tissue.

(E) Focke F, Schuermann D, Kuster N, Schär P. DNA fragmentation in human fibroblasts under extremely low frequency electromagnetic field exposure. Mutat Res. 683(1-2):74-83, 2010. (GT)

Extremely low frequency electromagnetic fields (ELF-EMFs) were reported to affect DNA integrity in human cells with evidence based on the Comet assay. These findings were heavily debated for two main reasons; the lack of reproducibility, and the absence of a plausible scientific rationale for how EMFs could damage DNA. Starting out from a replication of the relevant experiments, we performed this study to clarify the existence and explore origin and nature of ELF-EMF induced DNA effects. Our data confirm that intermittent (but not continuous) exposure of human primary fibroblasts to a 50 Hz EMF at a flux density of 1 mT induces a slight but significant increase of DNA fragmentation in the Comet assay, and we provide first evidence for this to be caused by the magnetic rather than the electric field. Moreover, we show that EMF-induced responses in the Comet assay are dependent on cell proliferation, suggesting that processes of DNA replication rather than the DNA itself may be affected. Consistently, the Comet effects correlated with a reduction of actively replicating cells and a concomitant increase of apoptotic cells in exposed cultures, whereas a combined Fpg-Comet test failed to produce evidence for a notable contribution of oxidative DNA base damage. Hence, ELF-EMF induced effects in the Comet assay are reproducible under specific conditions and can be explained by minor disturbances in S-phase processes and occasional triggering of apoptosis rather than by the generation of DNA damage.

(E) Frisch P, Li GC, McLeod K, Laramee CB. Induction of heat shock gene expression in RAT1 primary fibroblast cells by ELF electric fields. Bioelectromagnetics. 34(5):405-413, 2013. (GE)

Recent studies have demonstrated that the Ku70 gene fragment can be placed in the anti-sense orientation under the control of a heat-inducible heat shock protein 70 (HSP70) promoter and activated through heat shock exposure. This results in attenuation of the Ku70 protein expression, inhibiting cellular repair processes, and sensitizing the transfected cells to exposures such as the ionizing radiation exposures used clinically. However, achieving the tissue temperatures necessary to thermally induce the HSP70 response presents significant limitations to the clinical application of this strategy. Previous findings suggest an alternative approach to inducing a heat shock response, specifically through the use of extremely low frequency (ELF) electrical field stimulation. To further pursue this approach, we investigated HSP70 responses in transfected rat primary fibroblast (RAT1) cells exposed to 10 Hz electric fields at intensities of 20-500 V/m. We confirmed that low frequency electric fields can induce HSP70 heat shock expression, with peak responses obtained at 8 h following a 2 h field exposure. However, the approximate threefold increase in expression is substantially lower than that obtained using thermal stimulation, raising questions of the clinical utility of the response.

(E) Giorgi G, Marcantonio P, Bersani F, Gavoçi E, Del Re B. Effect of extremely low frequency magnetic field exposure on DNA transposition in relation to frequency, wave shape and exposure time. Int J Radiat Biol. 87(6):601-608, 2011. (GT, WS)

PURPOSE: To examine the effect of extremely low frequency magnetic field (ELF-MF) exposure on transposon (Tn) mobility in relation to the exposure time, the frequency and the wave shape of the field applied. **MATERIALS AND METHODS:** Two Escherichia coli model systems were used: (1) Cells unable to express β-galactosidase (LacZ(-)), containing a mini-transposon Tn10 element able to give ability to express β-galactosidase (LacZ(+)) upon its transposition; therefore in these cells transposition activity can be evaluated by analysing LacZ(+) clones; (2) cells carrying Fertility plasmid (F(+)), and a Tn5 element located on the chromosome; therefore in these cells transposition activity can be estimated by a bacterial conjugation assay. Cells were exposed to sinusoidal (SiMF) or pulsed-square wave (PMF) magnetic fields of various frequencies (20, 50, 75 Hz) and for different exposure times (15 and 90 min). **RESULTS:** Both mini-Tn10 and Tn5 transposition decreased under SiMF and increased under PMF, as compared to sham exposure control. No significant difference was found between frequencies and between exposure times. **CONCLUSIONS:** ELF-MF exposure affects transposition activity and the effects critically depend on the wave shape of the field, but not on the frequency and the exposure time, at least in the range observed.

(E) Heredia-Rojas JA, Rodríguez de la Fuente AO, Alcocer González JM, Rodríguez-Flores LE, Rodríguez-Padilla C, Santoyo-Stephano MA, Castañeda-Garza E, Taméz-Guerra RS. Effect of 60 Hz magnetic fields on the activation of hsp70 promoter in cultured INER-37 and RMA E7 cells. In Vitro Cell Dev Biol Anim. 46(9):758-63, 2010. (GE)

It has been reported that 50-60 Hz magnetic fields (MF) with flux densities ranging from microtesla to millitesla are able to induce heat shock factor or heat shock proteins in various cells. In this study, we investigated the effect of 60 Hz sinusoidal MF at 8 and 80 μT on the expression of the luciferase gene contained in a plasmid labeled as electromagnetic field-plasmid (pEMF). This gene construct contains the specific sequences previously described for the

induction of hsp70 expression by MF, as well as the reporter for the luciferase gene. The pEMF vector was transfected into INER-37 and RMA E7 cell lines that were later exposed to either MF or thermal shock (TS). Cells that received the MF or TS treatments and their controls were processed according to the luciferase assay system for evaluate luciferase activity. An increased luciferase gene expression was observed in INER-37 cells exposed to MF and TS compared with controls ($p < 0.05$), but MF exposure had no effect on the RMA E7 cell line.

(NE) Huwiler SG, Beyer C, Fröhlich J, Hennecke H, Egli T, Schürmann D, Rehrauer H, Fischer HM. Genome-wide transcription analysis of Escherichia coli in response to extremely low-frequency magnetic fields. Bioelectromagnetics. 2012 Feb 13. doi: 10.1002/bem.21709. [Epub ahead of print] (GE)

The widespread use of electricity raises the question of whether or not 50 Hz (power line frequency in Europe) magnetic fields (MFs) affect organisms. We investigated the transcription of Escherichia coli K-12 MG1655 in response to extremely low-frequency (ELF) MFs. Fields generated by three signal types (sinusoidal continuous, sinusoidal intermittent, and power line intermittent; all at 50 Hz, 1 mT) were applied and gene expression was monitored at the transcript level using an Affymetrix whole-genome microarray. Bacterial cells were grown continuously in a chemostat (dilution rate D = 0.4 h(-1)) fed with glucose-limited minimal medium and exposed to 50 Hz MFs with a homogenous flux density of 1 mT. For all three types of MFs investigated, neither bacterial growth (determined using optical density) nor culturable counts were affected. Likewise, no statistically significant change (fold-change > 2, $P \leq 0.01$) in the expression of 4,358 genes and 714 intergenic regions represented on the gene chip was detected after MF exposure for 2.5 h (1.4 generations) or 15 h (8.7 generations). Moreover, short-term exposure (8 min) to the sinusoidal continuous and power line intermittent signal neither affected bacterial growth nor showed evidence for reliable changes in transcription. In conclusion, our experiments did not indicate that the different tested MFs (50 Hz, 1 mT) affected the transcription of E. coli.

(NE) Jin YB, Kang GY, Lee JS, Choi JI, Lee JW, Hong SC, Myung SH, Lee YS. Effects on micronuclei formation of 60-Hz electromagnetic field exposure with ionizing radiation, hydrogen peroxide, or c-Myc overexpression. Int J Radiat Biol. 88(4):374-380, 2012. (GT, IA)

PURPOSE: Epidemiological studies have demonstrated a possible correlation between exposure to extremely low-frequency magnetic fields (ELF-MF) and cancer. However, this correlation has yet to be definitively confirmed by epidemiological studies. The principal objective of this study was to assess the effects of 60 Hz magnetic fields in a normal cell line system, and particularly in combination with various external factors, via micronucleus (MN) assays. **MATERIALS AND METHODS:** Mouse embryonic fibroblast NIH3T3 cells and human lung fibroblast WI-38 cells were exposed for 4 h to a 60 Hz, 1 mT uniform magnetic field with or without ionizing radiation (IR, 2 Gy), H(2)O(2) (100 μM) and cellular myelocytomatosis oncogene (c-Myc) activation. **RESULTS:** The results obtained showed no significant differences between the cells exposed to ELF-MF alone and the unexposed cells. Moreover, no synergistic effects were observed when ELF-MF was combined with IR, H(2)O(2), and c-Myc

activation. **CONCLUSIONS:** Our results demonstrate that ELF-MF did not enhance MN frequency by IR, H(2)O(2) and c-Myc activation.

(NE) Jin YB, Choi SH, Lee JS, Kim JK, Lee JW, Hong SC, Myung SH, Lee YS. Absence of DNA damage after 60-Hz electromagnetic field exposure combined with ionizing radiation, hydrogen peroxide, or c-Myc overexpression. Radiat Environ Biophys. 2013 Dec 5. [Epub ahead of print] (GT, IA)

The principal objective of this study was to assess the DNA damage in a normal cell line system after exposure to 60 Hz of extremely low frequency magnetic field (ELF-MF) and particularly in combination with various external factors, via comet assays. NIH3T3 mouse fibroblast cells, WI-38 human lung fibroblast cells, L132 human lung epithelial cells, and MCF10A human mammary gland epithelial cells were exposed for 4 or 16 h to a 60-Hz, 1 mT uniform magnetic field in the presence or absence of ionizing radiation (IR, 1 Gy), H_2O_2 (50 μM), or c-Myc oncogenic activation. The results obtained showed no significant differences between the cells exposed to ELF-MF alone and the unexposed cells. Moreover, no synergistic or additive effects were observed after 4 or 16 h of pre-exposure to 1 mT ELF-MF or simultaneous exposure to ELF-MF combined with IR, H_2O_2, or c-Myc activation.

(E) Jouni FJ, Abdolmaleki P, Ghanati F. Oxidative stress in broad bean (Vicia faba L.) induced by static magnetic field under natural radioactivity. Mutat Res. 741(1-2):116-121, 2012. (LE, GT, OX, IA)

The investigation was performed to evaluate the influence of the static magnetic field on oxidative stress in Vicia faba cultivated in soil from high background natural radioactivity in Iran. Soil samples were collected from Ramsar, Iran where the annual radiation absorbed dose from background radiation is substantially higher than 20 mSv/year. The soil samples were then divided into 2 separate groups including high and low natural radioactivity. The plants were continuously exposed to static magnetic field of 15 mT for 8 days, each 8h/day. The results showed that in the plants cultivated in soils with high background natural radioactivity and low background natural radioactivity the activity of antioxidant enzymes as well as flavonoid content were lower than those of the control. Treatment of plants with static magnetic field showed similar results in terms of lowering of antioxidant defense system and increase of peroxidation of membrane lipids. Accumulation of ROS also resulted in chromosomal aberration and DNA damage. This phenomenon was more pronounced when a combination of natural radiation and treatment with static magnetic field was applied. The results suggest that exposure to static magnetic field causes accumulation of reactive oxygen species in V. faba and natural radioactivity of soil exaggerates oxidative stress.

(E) Kim J, Ha CS, Lee HJ, Song K. Repetitive exposure to a 60-Hz time-varying magnetic field induces DNA double-strand breaks and apoptosis in human cells. Biochem Biophys Res Commun. 400(4):739-744, 2010. (GT)

We investigated the effects of extremely low frequency time-varying magnetic fields (MFs) on human normal and cancer cells. Whereas a single exposure to a 60-Hz time-varying MF of 6 mT for 30min showed no effect, repetitive exposure decreased cell viability. This decrease was

accompanied by phosphorylation of γ-H2AX, a common DNA double-strand break (DSB) marker, and checkpoint kinase 2 (Chk2), which is critical to the DNA damage checkpoint pathway. In addition, repetitive exposure to a time-varying MF of 6 mT for 30 min every 24 h for 3 days led to p38 activation and induction of apoptosis in cancer and normal cells. Therefore, these results demonstrate that repetitive exposure to MF with extremely low frequency can induce DNA DSBs and apoptosis through p38 activation. These results also suggest the need for further evaluation of the effects of repetitive exposure to environmental time-varying MFs on human health.

(E) Kim J, Yoon Y, Yun S, Park GS, Lee HJ, Song K. Time-varying magnetic fields of 60 Hz at 7 mT induce DNA double-strand breaks and activate DNA damage checkpoints without apoptosis. Bioelectromagnetics. 33(5):383-393, 2012. (GT, WS)

The potential genotoxic effect of a time-varying magnetic field (MF) on human cells was investigated. Upon continuous exposure of human primary fibroblast and cervical cancer cells to a 60 Hz MF at 7 mT for 10-60 min, no significant change in cell viability was observed. However, deoxyribonucleic acid (DNA) double-strand breaks (DSBs) were detected, and the DNA damage checkpoint pathway was activated in these cells without programmed cell death (called apoptosis). The exposure of human cells to a 60 Hz MF did not induce intracellular reactive oxygen species (ROS) production, suggesting that the observed DNA DSBs are not directly caused by ROS. We also compared the position and time dependency of DNA DSBs with numerical simulation of MFs. The Lorentz force and eddy currents in these experiments were numerically calculated to investigate the influence of each factor on DNA DSBs. The DNA DSBs mainly occurred at the central region, where the MF was strongest, after a 30-min exposure. After 90 min, however, the amount of DNA DSBs increased rapidly in the outer regions, where the eddy current and Lorentz force were strong.

(NE) Kirschenlohr H, Ellis P, Hesketh R, Metcalfe J. Gene Expression Profiles in White Blood Cells of Volunteers Exposed to a 50 Hz Electromagnetic Field. Radiat Res. 178(3): 138-149, 2012. (GE, HU)

Consistent and independently replicated laboratory evidence to support a causative relationship between environmental exposure to extremely low-frequency electromagnetic fields (EMFs) at power line frequencies and the associated increase in risk of childhood leukemia has not been obtained. In particular, although gene expression responses have been reported in a wide variety of cells, none has emerged as robust, widely replicated effects. DNA microarrays facilitate comprehensive searches for changes in gene expression without a requirement to select candidate responsive genes. To determine if gene expression changes occur in white blood cells of volunteers exposed to an ELF-EMF, each of 17 pairs of male volunteers age 20-30 was subjected either to a 50 Hz EMF exposure of 62.0 ± 7.1 μT for 2 h or to a sham exposure (0.21 ± 0.05 μT) at the same time (11:00 a.m. to 13:00 p.m.). The alternative regime for each volunteer was repeated on the following day and the two-day sequence was repeated 6 days later, with the exception that a null exposure (0.085 ± 0.01 μT) replaced the sham exposure. Five blood samples (10 ml) were collected at 2 h intervals from 9:00 to 17:00 with five additional samples during the exposure and sham or null exposure periods on each study day. RNA samples were pooled for the same time on each study day for the group of 17 volunteers that were subjected to the

ELF-EMF exposure/sham or null exposure sequence and were analyzed on Illumina microarrays. Time courses for 16 mammalian genes previously reported to be responsive to ELF-EMF exposure, including immediate early genes, stress response, cell proliferation and apoptotic genes were examined in detail. No genes or gene sets showed consistent response profiles to repeated ELF-EMF exposures. A stress response was detected as a transient increase in plasma cortisol at the onset of either exposure or sham exposure on the first study day. The cortisol response diminished progressively on subsequent exposures or sham exposures, and was attributable to mild stress associated with the experimental protocol.

(E) Koyama S, Sakurai T, Nakahara T, Miyakoshi J. Extremely low frequency (ELF) magnetic fields enhance chemically induced formation of apurinic/apyrimidinic (AP) sites in A172 cells. Int J Radiat Biol. 84(1):53-59, 2008. (GT, IA)

PURPOSE: To detect the effects of extremely low frequency (ELF) magnetic fields, the number of apurinic/apyrimidinic (AP) sites in human glioma A172 cells was measured following exposure to ELF magnetic fields. **MATERIALS AND METHODS:** The cells were exposed to an ELF magnetic field alone, to genotoxic agents (methyl methane sulfonate (MMS) and hydrogen peroxide (H2O2)) alone, or to an ELF magnetic field with the genotoxic agents. After exposure, DNA was extracted, and the number of AP sites was measured. **RESULTS:** There was no difference in the number of AP sites between cells exposed to an ELF magnetic field and sham controls. With MMS or H2O2 alone, the number of AP sites increased with longer treatment times. Exposure to an ELF magnetic field in combination with the genotoxic agents increased AP-site levels compared with the genotoxic agents alone. **CONCLUSIONS:** Our results suggest that the number of AP sites induced by MMS or H2O2 is enhanced by exposure to ELF magnetic fields at 5 millitesla (mT). This may occur because such exposure can enhance the activity or lengthen the lifetime of radical pairs.

(E) Lee JW, Kim MS, Kim YJ, Choi YJ, Lee Y, Chung HW. Genotoxic effects of 3 T magnetic resonance imaging in cultured human lymphocytes. Bioelectromagnetics. 32(7):535-542, 2011. (GT)

The clinical and preclinical use of high-field intensity (HF, 3 T and above) magnetic resonance imaging (MRI) scanners have significantly increased in the past few years. However, potential health risks are implied in the MRI and especially HF MRI environment due to high-static magnetic fields, fast gradient magnetic fields, and strong radiofrequency electromagnetic fields. In this study, the genotoxic potential of 3 T clinical MRI scans in cultured human lymphocytes in vitro was investigated by analyzing chromosome aberrations (CA), micronuclei (MN), and single-cell gel electrophoresis. Human lymphocytes were exposed to electromagnetic fields generated during MRI scanning (clinical routine brain examination protocols: three-channel head coil) for 22, 45, 67, and 89 min. We observed a significant increase in the frequency of single-strand DNA breaks following exposure to a 3 T MRI. In addition, the frequency of both CAs and MN in exposed cells increased in a time-dependent manner. The frequencies of MN in lymphocytes exposed to complex electromagnetic fields for 0, 22, 45, 67, and 89 min were 9.67, 11.67, 14.67, 18.00, and 20.33 per 1000 cells, respectively. Similarly, the frequencies of CAs in lymphocytes exposed for 0, 45, 67, and 89 min were 1.33, 2.33, 3.67, and 4.67 per 200 cells,

respectively. These results suggest that exposure to 3 T MRI induces genotoxic effects in human lymphocytes.

(E) Leone L, Fusco S, Mastrodonato A, Piacentini R, Barbati SA, Zaffina S, Pani G, Podda MV, Grassi C. Epigenetic Modulation of Adult Hippocampal Neurogenesis by Extremely Low-Frequency Electromagnetic Fields. Mol Neurobiol. 2014 Feb 16. [Epub ahead of print] (GE)

Throughout life, adult neurogenesis generates new neurons in the dentate gyrus of hippocampus that have a critical role in memory formation. Strategies able to stimulate this endogenous process have raised considerable interest because of their potential use to treat neurological disorders entailing cognitive impairment. We previously reported that mice exposed to extremely low-frequency electromagnetic fields (ELFEFs) showed increased hippocampal neurogenesis. Here, we demonstrate that the ELFEF-dependent enhancement of hippocampal neurogenesis improves spatial learning and memory. To gain insights on the molecular mechanisms underlying ELFEFs' effects, we extended our studies to an in vitro model of neural stem cells (NSCs) isolated from the hippocampi of newborn mice. We found that ELFEFs enhanced proliferation and neuronal differentiation of hippocampal NSCs by regulation of epigenetic mechanisms leading to pro-neuronal gene expression. Upon ELFEF stimulation of NSCs, we observed a significant enhancement of expression of the pro-proliferative gene hairy enhancer of split 1 and the neuronal determination genes NeuroD1 and Neurogenin1. These events were preceded by increased acetylation of H3K9 and binding of the phosphorylated transcription factor cAMP response element-binding protein (CREB) on the regulatory sequence of these genes. Such ELFEF-dependent epigenetic modifications were prevented by the Ca_v1-channel blocker nifedipine, and were associated with increased occupancy of CREB-binding protein (CBP) to the same loci within the analyzed promoters. Our results unravel the molecular mechanisms underlying the ELFEFs' ability to improve endogenous neurogenesis, pointing to histone acetylation-related chromatin remodeling as a critical determinant. These findings could pave the way to the development of novel therapeutic approaches in regenerative medicine.

(E) Li SS, Zhang ZY, Yang CJ, Lian HY, Cai P. Gene expression and reproductive abilities of male Drosophila melanogaster subjected to ELF-EMF exposure. Mutat Res. 758(1-2):95-103, 2013. (GE, LE, RP)

Extremely low frequency electromagnetic field (ELF-EMF) exposure is attracting increased attention as a possible disease-inducing factor. The in vivo effects of short-term and long-term ELF-EMF exposure on male Drosophila melanogaster were studied using transcriptomic analysis for preliminary screening and QRT-PCR for further verification. Transcriptomic analysis indicated that 439 genes were up-regulated and 874 genes were down-regulated following short-term exposures and that 514 genes were up-regulated and 1206 genes were down-regulated following long-term exposures (expression >2- or <0.5-fold, respectively). In addition, there are 238 up-regulated genes and 598 down-regulated genes in the intersection of short-term and long-term exposure (expression >2- or <0.5-fold). The DEGs (differentially expressed genes) in D. melanogaster following short-term exposures were involved in metabolic processes, cytoskeletal organization, mitotic spindle organization, cell death, protein modification and proteolysis. Long-term exposure let to changes in expression of genes involved in metabolic

processes, response to stress, mitotic spindle organization, aging, cell death and cellular respiration. In the intersection of short-term and long-term exposure, a series of DEGs were related to apoptosis, aging, immunological stress and reproduction. To check the ELF-EMF effects on reproduction, some experiments on male reproduction ability were performed. Their results indicated that short-term ELF-EMF exposure may decrease the reproductive ability of males, but long-term exposures had no effect on reproductive ability. Down-regulation of ark gene in the exposed males suggests that the decrease in reproductive capacity may be induced by the effects of ELF-EMF exposure on spermatogenesis through the caspase pathway. QRT-PCR analysis confirmed that jra, ark and decay genes were down regulated in males exposed for 1 Generation (1G) and 72 h, which suggests that apoptosis may be inhibited in vivo. ELF-EMF exposure may have accelerated cell senescence, as suggested by the down-regulation of both cat and jra genes and the up-regulation of hsp22 gene. Up-regulation of totA and hsp22 genes during exposure suggests that exposed flies might induce an in vivo immune response to counter the adverse effects encountered during ELF-EMF exposure. Down-regulation of cat genes suggests that the partial oxidative protection system might be restrained, especially during short-term exposures. This study demonstrates the bioeffects of ELF-EMF exposure and provides evidence for understanding the in vivo mechanisms of ELF-EMF exposure on male D. melanogaster.

(E) Lupke M, Frahm J, Lantow M, Maercker C, Remondini D, Bersani F, Simkó M. Gene expression analysis of ELF-MF exposed human monocytes indicating the involvement of the alternative activation pathway. Biochim Biophys Acta. 1763(4):402-12, 2006. (GE)

This study focused on the cell activating capacity of extremely low frequency magnetic fields (ELF-MF) on human umbilical cord blood-derived monocytes. Our results confirm the previous findings of cell activating capacity of ELF-MF (1.0 mT) in human monocytes, which was detected as an increased ROS release. Furthermore, gene expression profiling (whole-genome cDNA array Human Unigene RZPD-2) was performed to achieve a comprehensive view of involved genes during the cell activation process after 45 min ELF-MF exposure. Our results indicate the alteration of 986 genes involved in metabolism, cellular physiological processes, signal transduction and immune response. Significant regulations could be analyzed for 5 genes (expression >2- or <0.5-fold): IL15RA (Interleukin 15 receptor, alpha chain), EPS15R (Epidermal growth factor receptor pathway substrate 15 - like 1), DNMT3A (Hypothetical protein MGC16121), DNMT3A (DNA (cytosine-5) methyltransferase 3 alpha), and one gene with no match to known genes, DKFZP586J1624. Real-time RT-PCR analysis of the kinetic of the expression of IL15RA, and IL10RA during 45 min ELF-MF exposure indicates the regulation of cell activation via the alternative pathway, whereas the delayed gene expression of FOS, IL2RA and the melatonin synthesizing enzyme HIOMT suggests the suppression of inflammatory processes. Accordingly, we suggest that ELF-MF activates human monocytes via the alternative pathway.

(E) Luukkonen J, Liimatainen A, Höytö A, Juutilainen J, Naarala J. Pre-exposure to 50 Hz magnetic fields modifies menadione-induced genotoxic effects in human SH-SY5Y neuroblastoma cells. PLoS One. 2011 Mar 23;6(3):e18021. (GT, IA)

BACKGROUND: Extremely low frequency (ELF) magnetic fields (MF) are generated by power lines and various electric appliances. They have been classified as possibly carcinogenic

by the International Agency for Research on Cancer, but a mechanistic explanation for carcinogenic effects is lacking. A previous study in our laboratory showed that pre-exposure to ELF MF altered cancer-relevant cellular responses (cell cycle arrest, apoptosis) to menadione-induced DNA damage, but it did not include endpoints measuring actual genetic damage. In the present study, we examined whether pre-exposure to ELF MF affects chemically induced DNA damage level, DNA repair rate, or micronucleus frequency in human SH-SY5Y neuroblastoma cells. **METHODOLOGY/PRINCIPAL FINDINGS:** Exposure to 50 Hz MF was conducted at 100 μT for 24 hours, followed by chemical exposure for 3 hours. The chemicals used for inducing DNA damage and subsequent micronucleus formation were menadione and methyl methanesulphonate (MMS). Pre-treatment with MF enhanced menadione-induced DNA damage, DNA repair rate, and micronucleus formation in human SH-SY5Y neuroblastoma cells. Although the results with MMS indicated similar effects, the differences were not statistically significant. No effects were observed after MF exposure alone. **CONCLUSIONS:** The results confirm our previous findings showing that pre-exposure to MFs as low as 100 μT alters cellular responses to menadione, and show that increased genotoxicity results from such interaction. The present findings also indicate that complementary data at several chronological points may be critical for understanding the MF effects on DNA damage, repair, and post-repair integrity of the genome.

(E) Luukkonen J, Liimatainen A, Juutilainen J, Naarala J. Induction of genomic instability, oxidative processes, and mitochondrial activity by 50Hz magnetic fields in human SH-SY5Y neuroblastoma cells. Mutat Res. 760:33-41, 2014. (GT, OX, IA)

Epidemiological studies have suggested that exposure to 50Hz magnetic fields (MF) increases the risk of childhood leukemia, but there is no mechanistic explanation for carcinogenic effects. In two previous studies we have observed that a 24-h pre-exposure to MF alters cellular responses to menadione-induced DNA damage. The aim of this study was to investigate the cellular changes that must occur already during the first 24h of exposure to MF, and to explore whether the MF-induced changes in DNA damage response can lead to genomic instability in the progeny of the exposed cells. In order to answer these questions, human SH-SY5Y neuroblastoma cells were exposed to a 50-Hz, 100-μT MF for 24h, followed by 3-h exposure to menadione. The main finding was that MF exposure was associated with increased level of micronuclei, used as an indicator of induced genomic instability, at 8 and 15d after the exposures. Other delayed effects in MF-exposed cells included increased mitochondrial activity at 8d, and increased reactive oxygen species (ROS) production and lipid peroxidation at 15d after the exposures. Oxidative processes (ROS production, reduced glutathione level, and mitochondrial superoxide level) were affected by MF immediately after the exposure. In conclusion, the present results suggest that MF exposure disturbs oxidative balance immediately after the exposure, which might explain our previous findings on MF altered cellular responses to menadione-induced DNA damage. Persistently elevated levels of micronuclei were found in the progeny of MF-exposed cells, indicating induction of genomic instability.

(E) Ma Q, Deng P, Zhu G, Liu C, Zhang L, Zhou Z, Luo X, Li M, Zhong M, Yu Z, Chen C, Zhang Y. Extremely low-frequency electromagnetic fields affect transcript levels of

neuronal differentiation-related genes in embryonic neural stem cells. PLoS One. 2014 Mar 3;9(3):e90041. doi: 10.1371/journal.pone.0090041. eCollection 2014. (GE)

Previous studies have reported that extremely low-frequency electromagnetic fields (ELF-EMF) can affect the processes of brain development, but the underlying mechanism is largely unknown. The proliferation and differentiation of embryonic neural stem cells (eNSCs) is essential for brain development during the gestation period. To date, there is no report about the effects of ELF-EMF on eNSCs. In this paper, we studied the effects of ELF-EMF on the proliferation and differentiation of eNSCs. Primary cultured eNSCs were treated with 50 Hz ELF-EMF; various magnetic intensities and exposure times were applied. Our data showed that there was no significant change in cell proliferation, which was evaluated by cell viability (CCK-8 assay), DNA synthesis (Edu incorporation), average diameter of neurospheres, cell cycle distribution (flow cytometry) and transcript levels of cell cycle related genes (P53, P21 and GADD45 detected by real-time PCR). When eNSCs were induced to differentiation, real-time PCR results showed a down-regulation of Sox2 and up-regulation of Math1, Math3, Ngn1 and Tuj1 mRNA levels after 50 Hz ELF-EMF exposure (2 mT for 3 days), but the percentages of neurons (Tuj1 positive cells) and astrocytes (GFAP positive cells) were not altered when detected by immunofluorescence assay. Although cell proliferation and the percentages of neurons and astrocytes differentiated from eNSCs were not affected by 50 Hz ELF-EMF, the expression of genes regulating neuronal differentiation was altered. In conclusion, our results support that 50 Hz ELF-EMF induce molecular changes during eNSCs differentiation, which might be compensated by post-transcriptional mechanisms to support cellular homeostasis.

(E) Mairs RJ, Hughes K, Fitzsimmons S, Prise KM, Livingstone A, Wilson L, Baig N, Clark AM, Timpson A, Patel G, Folkard M, Angerson WJ, Boyd M. Microsatellite analysis for determination of the mutagenicity of extremely low-frequency electromagnetic fields and ionising radiation in vitro. Mutat Res. 626(1-2):34-41, 2007. (GT, IA)

Extremely low-frequency electromagnetic fields (ELF-EMF) have been reported to induce lesions in DNA and to enhance the mutagenicity of ionising radiation. However, the significance of these findings is uncertain because the determination of the carcinogenic potential of EMFs has largely been based on investigations of large chromosomal aberrations. Using a more sensitive method of detecting DNA damage involving microsatellite sequences, we observed that exposure of UVW human glioma cells to ELF-EMF alone at a field strength of 1 mT (50 Hz) for 12 h gave rise to 0.011 mutations/locus/cell. This was equivalent to a 3.75-fold increase in mutation induction compared with unexposed controls. Furthermore, ELF-EMF increased the mutagenic capacity of 0.3 and 3 Gy gamma-irradiation by factors of 2.6 and 2.75, respectively. These results suggest not only that ELF-EMF is mutagenic as a single agent but also that it can potentiate the mutagenicity of ionising radiation. Treatment with 0.3 Gy induced more than 10 times more mutations per unit dose than irradiation with 3 Gy, indicating hypermutability at low dose.

Brain DNA damage and 70-kDa heat shock protein expression in CD1 mice exposed to extremely low frequency magnetic fields. Int J Radiat Biol. 86(8):701-710, 2010. (GT, LE)

PURPOSE: The question of whether exposure to extremely low frequency magnetic fields (ELF-MF), may contribute to cerebral cancer and neurodegeneration is of current interest. In this study we investigated whether exposure to ELF-MF (50 Hz-1 mT) harms cerebral DNA and induces expression of 70-kDa heat shock protein (hsp70). **MATERIALS AND METHODS:** CD1 mice were exposed to a MF (50 Hz-1 mT) for 1 or 7 days (15 h/day) and sacrificed either at the end of exposure or after 24 h. Unexposed and sham-exposed mice were used as controls. Mouse brains were dissected into cerebral cortex-striatum, hippocampus and cerebellum to evaluate primary DNA damage and hsp70 gene expression. Food intake, weight gain, and motor activity were also evaluated. **RESULTS:** An increase in primary DNA damage was detected in all cerebral areas of the exposed mice sacrificed at the end of exposure, as compared to controls. DNA damage, as can be evaluated by the comet assay, appeared to be repaired in mice sacrificed 24 h after a 7-day exposure. Neither a short (15 h) nor long (7 days) MF-exposure induced hsp70 expression, metabolic and behavioural changes. **CONCLUSIONS:** These results indicate that in vivo ELF-MF induce reversible brain DNA damage while they do not elicit the stress response.

(E) Markkanen A, Juutilainen J, Naarala J. Pre-exposure to 50 Hz magnetic fields modifies menadione-induced DNA damage response in murine L929 cells. Int J Radiat Biol. 84(9):742-751, 2008. (IA)

PURPOSE: Effects on DNA damage response were investigated in murine L929 cells exposed to 50 Hz magnetic fields (MF) with or without ultraviolet B (UVB, wavelength 280-320 nm) radiation or menadione (MQ). **MATERIALS AND METHODS:** Cells were exposed to MF at 100 or 300 microT combined with MQ (150 microM, 1 hour) or UVB radiation (160 J/m(2)) using various exposure schedules. The samples were stained with propidium iodide (PI) and analysed by flow cytometer for cell cycle stages. Apoptotic cells were defined as sub G(1) events. **RESULTS:** In cells first exposed to 100 microT MF for 24 h, the response to subsequent MQ treatment was significantly altered so that the proportion of sub G(1) cells was decreased and the proportion of cells in the G(2)/M phase was increased. When a 300 microT MF was used, also the proportion of cells in the G(1) phase was decreased. MF exposures after MQ treatment did not alter responses to MQ. No effects were found from MF exposure alone or from MF combined with UVB radiation. **CONCLUSIONS:** The results strengthen previous findings suggesting that pre-exposure to MF can alter cellular responses to other agents, and indicate that MF as low as 100 microT has measurable impacts on cancer-relevant cellular processes such as DNA-damage.

(NE) Mizuno K, Narita E, Yamada M, Shinohara N, Miyakoshi J. ELF magnetic fields do not affect cell survival and DNA damage induced by ultraviolet B. Bioelectromagnetics. 35(2):108-115, 2014. (GT, IA)

We investigated whether extremely low frequency (ELF) magnetic field exposure has modification effects on cell survival after ultraviolet B (UV-B) irradiation and on repair process of DNA damage induced by UV-B irradiation in WI38VA13 subcloned 2RA and XP2OS(SV) cells. The ELF magnetic field exposure was conducted using a Helmholtz coil-based system that was designed to generate a sinusoidal magnetic field at 5 mT and 60 Hz. Cell survival was assessed by WST assay after UV-B irradiation at 20-80 J/m(2) , ELF magnetic field exposure for

24 h, followed by incubation for 48 h. DNA damage was assessed by quantification of cyclobutane pyrimidine dimer formation and 6-4 photoproduct formation using ELISA after UV-B irradiation at 20-80 J/m(2) followed by ELF magnetic field exposure for 24 h. No significant changes were observed in cell survival between ELF magnetic field and sham exposures. Similarly, DNA damage induced by UV-B irradiation did not change significantly following ELF magnetic field exposure. Our results suggest that ELF magnetic field exposure at 5 mT does not have modification effect on cell survival after UV-B irradiation and on repair process of DNA damage induced by UV-B irradiation.

(E) Nikolova T, Czyz J, Rolletschek A, Blyszczuk P, Fuchs J, Jovtchev G, Schuderer J, Kuster N, Wobus AM. Electromagnetic fields affect transcript levels of apoptosis-related genes in embryonic stem cell-derived neural progenitor cells. ASEB J 19(12):1686-1688, 2005. (GT, GE)

Mouse embryonic stem (ES) cells were used as an experimental model to study the effects of electromagnetic fields (EMF). ES-derived nestin-positive neural progenitor cells were exposed to extremely low frequency EMF simulating power line magnetic fields at 50 Hz (ELF-EMF) and to radiofrequency EMF simulating the Global System for Mobile Communication (GSM) signals at 1.71 GHz (RF-EMF). Following EMF exposure, cells were analyzed for transcript levels of cell cycle regulatory, apoptosis-related, and neural-specific genes and proteins; changes in proliferation; apoptosis; and cytogenetic effects. Quantitative RT-PCR analysis revealed that ELF-EMF exposure to ES-derived neural cells significantly affected transcript levels of the apoptosis-related bcl-2, bax, and cell cycle regulatory "growth arrest DNA damage inducible" GADD45 genes, whereas mRNA levels of neural-specific genes were not affected. RF-EMF exposure of neural progenitor cells resulted in down-regulation of neural-specific Nurr1 and in up-regulation of bax and GADD45 mRNA levels. Short-term RF-EMF exposure for 6 h, but not for 48 h, resulted in a low and transient increase of DNA double-strand breaks. No effects of ELF- and RF-EMF on mitochondrial function, nuclear apoptosis, cell proliferation, and chromosomal alterations were observed. We may conclude that EMF exposure of ES-derived neural progenitor cells transiently affects the transcript level of genes related to apoptosis and cell cycle control. However, these responses are not associated with detectable changes of cell physiology, suggesting compensatory mechanisms at the translational and posttranslational level.

(NE) Okudan N, Celik I, Salbacak A, Cicekcibasi AE, Buyukmumcu M, Gökbel H. Effects of long-term 50 Hz magnetic field exposure on the micro nucleated polychromatic erythrocyte and blood lymphocyte frequency and argyrophilic nucleolar organizer regions in lymphocytes of mice. Neuro Endocrinol Lett. 31(2):208-214, 2010. (GT)

OBJECTIVES: We aimed to investigate the effects of weak extremely low frequency electromagnetic fields (ELF-EMFs) on the nucleus size, the silver staining nucleolar organizer regions (AgNORs), the frequency of micro nucleated peripheral blood lymphocytes (MPBLs) and the micro nucleated polychromatic erythrocytes (MPCEs).**METHODS:** One hundred and twenty Swiss albino mice were equally divided into 6 groups. The study groups were exposed to 1, 2, 3, 4 and 5 microT 50 Hz-EMFs for 40 days. Micronucleus number (MN) per PBL was determined. **RESULTS:** ELF-EMF exposure caused a nonlinear decline of nucleus area. A sharp drop occurred in AgNOR area of 1 microT group, and following it gained an insignificantly higher level than that of the control group. The field did not change mean AgNOR

numbers per nucleus of the groups. Relative AgNOR area had the highest level in 1 microT-exposure group, and the level was quite similar to that of the 5 microT-exposure group. The remaining groups had significantly lower values quite similar to that of the control level. The field exposure at any intensity did not affect significantly the frequency of either MPBLs or MPCEs. The number of MN per PBL in the 4 and 5 microT-exposure groups were significantly higher than those of the lower intensity exposure groups. The males in 4 microT-exposure group displayed the highest MN number per PBL, whereas values changed in a nonlinear manner. **CONCLUSIONS:** The results of the present study suggest that </=5 microT intensities of 50 Hz EMFs did not cause genotoxic effect on the mouse.

(E) Panagopoulos DJ, Karabarbounis A, Lioliousis C. ELF alternating magnetic field decreases reproduction by DNA damage induction. Cell Biochem Biophys. 67(2):703-16, 2013. (LE, GT, RP)

In the present experiments, the effect of 50-Hz alternating magnetic field on Drosophila melanogaster reproduction was studied. Newly eclosed insects were separated into identical groups of ten males and ten females and exposed to three different intensities of the ELF magnetic field (1, 11, and 21 G) continuously during the first 5 days of their adult lives. The reproductive capacity was assessed by the number of F1 pupae according to a well-defined protocol of ours. The magnetic field was found to decrease reproduction by up to 4.3%. The effect increased with increasing field intensities. The decline in reproductive capacity was found to be due to severe DNA damage (DNA fragmentation) and consequent cell death induction in the reproductive cells as determined by the TUNEL assay applied during early and mid-oogenesis (from germarium to stage 10) where physiological apoptosis does not occur. The increase in DNA damage was more significant than the corresponding decrease in reproductive capacity (up to ~7.5%). The TUNEL-positive signal denoting DNA fragmentation was observed exclusively at the two most sensitive developmental stages of oogenesis: the early and mid-oogenesis checkpoints (i.e. region 2a/2b of the germarium and stages 7-8 just before the onset of vitellogenesis)-in contrast to exposure to microwave radiation of earlier work of ours in which the DNA fragmentation was induced at all developmental stages of early and mid-oogenesis. Moreover, the TUNEL-positive signal was observed in all three types of egg chamber cells, mainly in the nurse and follicle cells and also in the oocyte, in agreement with the microwave exposure of our earlier works. According to previous reports, cell death induction in the oocyte was observed only in the case of microwave exposure and not after exposure to other stress factors as toxic chemicals or food deprivation. Now it is also observed for the first time after ELF magnetic field exposure. Finally, in contrast to microwave exposure of previous experiments of ours in which the germarium checkpoint was found to be more sensitive than stage 7-8, in the magnetic field exposure of the present experiments the mid-oogenesis checkpoint was found to be more sensitive than the germarium.

(E) Rageh MM, El-Gebaly RH, El-Bialy NS. Assessment of genotoxic and cytotoxic hazards in brain and bone marrow cells of newborn rats exposed to extremely low-frequency magnetic field. J Biomed Biotechnol. 2012;2012:716023. (LE, GT, DE, OX)

The present study aimed to evaluate the association between whole body exposure to extremely low frequency magnetic field (ELF-MF) and genotoxic , cytotoxic hazards in brain and bone

marrow cells of newborn rats. Newborn rats (10 days after delivery) were exposed continuously to 50 Hz, 0.5 mT for 30 days. The control group was treated as the exposed one with the sole difference that the rats were not exposed to magnetic field. Comet assay was used to quantify the level of DNA damage in isolated brain cells. Also bone marrow cells were flushed out to assess micronucleus induction and mitotic index. Spectrophotometric methods were used to measure the level of malondialdehyde (MDA) and the activity of glutathione (GSH) and superoxide dismutase (SOD). The results showed a significant increase in the mean tail moment indicating DNA damage in exposed group ($P < 0.01$, 0.001, 0.0001). Moreover ELF-MF exposure induced a significant ($P < 0.01$, 0.001) four folds increase in the induction of micronucleus and about three folds increase in mitotic index ($P < 0.0001$). Additionally newborn rats exposed to ELF-MF showed significant higher levels of MDA and SOD ($P < 0.05$). Meanwhile ELF-MF failed to alter the activity of GSH. In conclusion, the present study suggests an association between DNA damage and ELF-MF exposure in newborn rats.

(E) Reyes-Guerrero G, Guzmán C, García DE, Camacho-Arroyo I, Vázquez-García M. Extremely low-frequency electromagnetic fields differentially regulate estrogen receptor-alpha and -beta expression in the rat olfactory bulb. Neurosci Lett. 471(2):109-13, 2010. (GE)

Recently, the effects of extremely low-frequency electromagnetic fields (ELF EMF) on biological systems have been extensively investigated. In this report, the influence of ELF EMF on olfactory bulb (OB) estrogen receptor-alpha (ER alpha) mRNA and -beta (ER beta) mRNA expression was studied by RT-PCR in adult female and male rats. Results reveal for the first time that ELF EMF exerted a biphasic effect on female OB ER beta mRNA gene expression, which increased during diestrous and decreased during estrous. We did not observe any influence of ELF EMF on female OB ER alpha mRNA expression. Our data demonstrate a fluctuating pattern of ER-alpha and -beta mRNA expression in the female OB throughout the phases of the estrous cycle in non-ELF EMF-exposed animals. Thus the highest ER alpha expression was observed in diestrous and the lowest in proestrous. The pattern of ER beta mRNA was less variable, the lowest expression was observed in diestrous. ER-alpha mRNA and -beta mRNA expression level in the male OB did not exhibit any variation either in ELF EMF-exposed or non-ELF EMF-exposed animals. In summary, ELF EMF modulate ER beta gene expression in the OB of female adult rats but not in males.

(E) Ruiz-Gómez MJ, Sendra-Portero F, Martínez-Morillo M. Effect of 2.45 mT sinusoidal 50 Hz magnetic field on Saccharomyces cerevisiae strains deficient in DNA strand breaks repair. Int J Radiat Biol. 86(7):602-611, 2010. (GT)

PURPOSE: To investigate whether extremely-low frequency magnetic field (MF) exposure produce alterations in the growth, cell cycle, survival and DNA damage of wild type (wt) and mutant yeast strains. **MATERIALS AND METHODS:** wt and high affinity DNA binding factor 1 (hdf1), radiation sensitive 52 (rad52), rad52 hdf1 mutant Saccharomyces cerevisiae strains were exposed to 2.45 mT, sinusoidal 50 Hz MF for 96 h. MF was generated by a pair of Helmholtz coils. During this time the growth was monitored by measuring the optical density at 600 nm and cell cycle evolution were analysed by microscopic morphological analysis. Then, yeast survival was assayed by the drop test and DNA was extracted and electrophoresed.

RESULTS: A significant increase in the growth was observed for rad52 strain (P = 0.005, Analysis of Variance [ANOVA]) and close to significance for rad52 hdf1 strain (P = 0.069, ANOVA). In addition, the surviving fraction values obtained for MF-exposed samples were in all cases less than for the controls, being the P value obtained for the whole set of MF-treated strains close to significance (P = 0.066, Student's t-test). In contrast, the cell cycle evolution and the DNA pattern obtained for wt and the mutant strains were not altered after exposure to MF. **CONCLUSIONS:** The data presented in the current report show that the applied MF (2.45 mT, sinusoidal 50 Hz, 96 h) induces alterations in the growth and survival of S. cerevisiae strains deficient in DNA strand breaks repair. In contrast, the MF treatment does not induce alterations in the cell cycle and does not cause DNA damage.

(E) Sarimov R, Alipov ED, Belyaev IY. Fifty hertz magnetic fields individually affect chromatin conformation in human lymphocytes: dependence on amplitude, temperature, and initial chromatin state. Bioelectromagnetics. 32(7):570-579, 2011. (GT)

Effects of magnetic field (MF) at 50 Hz on chromatin conformation were studied by the method of anomalous viscosity time dependence (AVTD) in human lymphocytes from two healthy donors. MF within the peak amplitude range of 5-20 μT affected chromatin conformation. These MF effects differed significantly between studied donors, and depended on magnetic flux density and initial condensation of chromatin. While the initial state of chromatin was rather stable in one donor during one calendar year of measurements, the initial condensation varied significantly in cells from another donor. Both this variation and the MF effect depended on temperature during exposure. Despite these variations, the general rule was that MF condensed the relaxed chromatin and relaxed the condensed chromatin. Thus, in this study we show that individual effects of 50 Hz MF exposure at peak amplitudes within the range of 5-20 μT may be observed in human lymphocytes in dependence on the initial state of chromatin and temperature.

(E) Tiwari R, Lakshmi NK, Bhargava SC, Ahuja YR. Epinephrine, DNA integrity and oxidative stress in workers exposed to extremely low-frequency electromagnetic fields (ELF-EMFs) at 132 kV substations. Electromagn Biol Med. 2014 Jan 24. [Epub ahead of print] (LE, GT, HU, OX)

There is apprehension about widespread use of electrical and electromagnetic gadgets which are supposed to emit electromagnetic radiations. Reports are controversy. These electromagnetic fields (EMFs) have considerable effect on endocrine system of exposed subjects. This study was focused to assess the possible bioeffects of extremely low-frequency (ELF)-EMFs on epinephrine level, DNA damage and oxidative stress in subjects occupationally exposed to 132 kV high-voltage substations. The blood sample of 142 exposed subjects and 151 non-exposed individuals was analyzed. Plasma epinephrine was measured by enzyme-linked immunosorbent assay, DNA damage was studied by alkaline comet assay along with oxidative stress. Epinephrine levels of sub-groups showed mean concentration of 75.22 ± 1.46, 64.43 ± 8.26 and 48.47 ± 4.97 for high, medium and low exposed groups, respectively. DNA damage ranged between 1.69 μm and 9.91 μm. The oxidative stress levels showed significant increase. The individuals employed in the live-line procedures were found to be vulnerable for EM stress with altered epinephrine concentrations, DNA damage and increased oxidative stress.

(E) Udroiu I, Cristaldi M, Ieradi LA, Bedini A, Giuliani L, Tanzarella C. Clastogenicity and aneuploidy in newborn and adult mice exposed to 50 Hz magnetic fields. Int J Radiat Biol. 82(8):561-567, 2006. (GT, DE, LE)

PURPOSE: To detect possible clastogenic and aneugenic properties of a 50 Hz, 650 muT magnetic field. **MATERIALS AND METHODS:** The micronucleus test with CREST (Calcinosis, Raynaud's phenomenon, Esophageal dismotility, Sclerodactility, Telangectasia) antibody staining was performed on liver and peripheral blood sampled from newborn mice exposed to an ELF (Extremely Low Frequency) magnetic field during the whole intra-uterine life (21 days), and on bone marrow and peripheral blood sampled from adult mice exposed to the same magnetic field for the same period. **RESULTS:** Data obtained in newborn mice show a significant increase in micronuclei frequencies. In absolute terms, most of the induced micronuclei were CREST-negative (i.e., formed by a chromosome fragment). However, in relative terms, ELF exposure caused a two-fold increase in CREST-negative micronuclei and a four-fold increase in CREST-positive micronuclei (i.e., formed by a whole chromosome). No significant effect was recorded on exposed adults. **CONCLUSIONS:** These findings suggest the need for investigation of aneugenic properties of ELF magnetic fields in order to establish a possible relationship to carcinogenesis.

(NE) Verschaeve L, Anthonissen R, Grudniewska M, Wudarski J, Gevaert L, Maes A. Genotoxicity investigation of ELF-magnetic fields in Salmonella typhimurium with the sensitive SOS-based VITOTOX test. Bioelectromagnetics. 32(7):580-584, 2011. (GT, IA)

We performed a genotoxicity investigation of extremely low-frequency (ELF) magnetic fields (MFs, 50 Hz, 100 and 500 μT, 1 and 2 h exposure) alone and in combination with known chemical mutagens using the VITOTOX test. This test is a very sensitive reporter assay of Salmonella typhimurium bacteria based on the SOS response. Our study showed that ELF-MFs do not induce SOS-based mutagenicity in S. typhimurium bacteria and do not show any synergetic effect when combined with chemical mutagens.

(E) Villarini M, Ambrosini MV, Moretti M, Dominici L, Taha E, Piobbico D, Gambelunghe C, Mariucci G. Brain hsp70 expression and DNA damage in mice exposed to extremely low frequency magnetic fields: a dose-response study. Int J Radiat Biol. 89(7):562-570, 2013. (LE, GT)

Purpose: To determine whether a dose-response relationship exists among exposure to extremely low frequency magnetic fields (ELF-MF) at different densities and 70-kDa heat shock protein (hsp70) expression and DNA damage in mouse brain. Materials and Methods: Male CD1 mice were exposed to ELF-MF (50 Hz; 0.1, 0.2, 1 or 2 mT) for 7 days (15 hours/day) and sacrificed either at the end of exposure or after 24 h. Hsp70 expression was determined in cerebral cortex-striatum, hippocampus and cerebellum by real-time reverse-transcriptase polymerase chain reaction (RT-PCR) and western blot analysis. Primary DNA damage was evaluated in the same tissues by comet assay. Sham-exposed mice were used as controls. Results: No changes in both hsp70 mRNA and corresponding protein occurred following exposure to ELF-MF, except for a weak increase in the mRNA in hippocampus of exposed mice to 0.1 mT ELF-MF. Only mice exposed to 1 or 2 mT and sacrificed immediately after exposure presented DNA strand

breaks higher than controls in all the cerebral areas; such DNA breakage reverted to baseline in the mice sacrificed 24 h after exposure. Conclusions: These data show that high density ELF-MF only induce reversible brain DNA damage while they do not affect hsp70 expression.

(E) Wahab MA, Podd JV, Rapley BI, Rowland RE. Elevated sister chromatid exchange frequencies in dividing human peripheral blood lymphocytes exposed to 50 Hz magnetic fields. Bioelectromagnetics. 28(4):281-288, 2007. (GT, WS)

The in vitro cytomolecular technique, sister chromatid exchange (SCE), was applied to test the clastogenic potentiality of extremely low frequency (ELF) electromagnetic fields (EMFs) on human peripheral blood lymphocytes (HPBLs). SCE frequencies were scored in dividing peripheral blood lymphocytes (PBLs) from six healthy male blood donors in two rounds of experiments, R1 and R2, to determine reproducibility. Lymphocyte cultures in the eight experiments conducted in each round were exposed to 50 Hz sinusoidal (continuous or pulsed) or square (continuous or pulsed) MFs at field strengths of 1 microT or 1 mT for 72 h. A significant increase in the number of SCEs/cell in the grouped experimental conditions compared to the controls was observed in both rounds. The highest SCE frequency in R1 was 10.03 for a square continuous field, and 10.39 for a square continuous field was the second highest frequency in R2. DNA crosslinking at the replication fork is proposed as a model which could explain the mechanistic link between ELF EMF exposure and increased SCE frequency.

(E) Wang Z, Sarje A, Che PL, Yarema KJ. Moderate strength (0.23-0.28 T) static magnetic fields (SMF) modulate signaling and differentiation in human embryonic cells. BMC Genomics. 10:356, 2009. (GE)

BACKGROUND: Compelling evidence exists that magnetic fields modulate living systems. To date, however rigorous studies have focused on identifying the molecular-level biosensor (e.g., radical ion pairs or membranes) or on the behavior of whole animals leaving a gap in understanding how molecular effects are translated into tissue-wide and organism-level responses. This study begins to bridge this gulf by investigating static magnetic fields (SMF) through global mRNA profiling in human embryonic cells coupled with software analysis to identify the affected signaling pathways. **RESULTS:** Software analysis of gene expression in cells exposed to 0.23-0.28 T SMF showed that nine signaling networks responded to SMF; of these, detailed biochemical validation was performed for the network linked to the inflammatory cytokine IL-6. We found the short-term (<24 h) activation of IL-6 involved the coordinate up-regulation of toll-like receptor-4 (TLR4) with complementary changes to NEU3 and ST3GAL5 that reduced ganglioside GM3 in a manner that augmented the activation of TLR4 and IL-6. Loss of GM3 also provided a plausible mechanism for the attenuation of cellular responses to SMF that occurred over longer exposure periods. Finally, SMF-mediated responses were manifest at the cellular level as morphological changes and biochemical markers indicative of pre-oligodendrocyte differentiation. **CONCLUSION:** This study provides a framework describing how magnetic exposure is transduced from a plausible molecular biosensor (lipid membranes) to cell-level responses that include differentiation toward neural lineages. In addition, SMF provided a stimulus that uncovered new relationships - that exist even in the absence of magnetic fields - between gangliosides, the time-dependent regulation of IL-6 signaling by these glycosphingolipids, and the fate of embryonic cells.

(NE) Williams PA, Ingebretsen RJ, Dawson RJ. 14.6 mT ELF magnetic field exposure yields no DNA breaks in model system Salmonella, but provides evidence of heat stress protection. Bioelectromagnetics. 27(6):445-450, 2006. (GT)

In this study, we demonstrate that common extremely low frequency magnetic field (MF) exposure does not cause DNA breaks in this Salmonella test system. The data does, however, provide evidence that MF exposure induces protection from heat stress. Bacterial cultures were exposed to MF (14.6 mT 60 Hz field, cycled 5 min on, 10 min off for 4 h) and a temperature-matched control. Double- and single-stranded DNA breaks were assayed using a recombination event counter. After MF or control exposure they were grown on indicator plates from which recombination events can be quantified and the frequency of DNA strand breaks deduced. The effect of MF was also monitored using a recombination-deficient mutant (recA). The results showed no significant increase in recombination events and strand breaks due to MF. Evidence of heat stress protection was determined using a cell viability assay that compared the survival rates of MF exposed and control cells after the administration of a 10 min 53 degrees C heat stress. The control cells exhibited nine times more cell mortality than the MF exposed cells. This Salmonella system provides many mutants and genetic tools for further investigation of this phenomenon.

(E) Yokus B, Akdag MZ, Dasdag S, Cakir DU, Kizil M. Extremely low frequency magnetic fields cause oxidative DNA damage in rats. Int J Radiat Biol. 84(10):789-795, 2008. (GT)

PURPOSE: To detect the genotoxic effects of extremely low frequency (ELF) -magnetic fields (MF) on oxidative DNA base modifications [8-hydroxyguanine (8-OH-Gua), 2,6-diamino-4-hydroxy-5-formamidopyrimidine (FapyGua) and 4,6-diamino-5-formamidopyrimidine (FapyAde)] in rat leucocytes, measured following exposure to ELF-MF. **MATERIALS AND METHODS:** After exposure to ELF-MF (50 Hz, 100 and 500 microT, for 2 hours/day during 10 months), DNA was extracted, and measurement of DNA lesions was achieved by gas chromatography/mass spectrometry (GC/MS) and liquid chromatography/mass spectrometry (LC/MS). **RESULTS:** Levels of FapyAde, FapyGua and 8OHdG in DNA were increased by both 100 microT and 500 microT ELF-MF as compared to a cage-control and a sham group; however, statistical significance was observed only in the group exposed to 100 microT. **CONCLUSION:** This is the first study to report that ELF-MF exposure generates oxidatively induced DNA base modifications which are mutagenic in mammalian cells, such as FapyGua, FapyAde and 8-OH-Gua, in vivo. This may explain previous studies showing DNA damage and genomic instability. These findings support the hypothesis that chronic exposure to 50-Hz MF may be potentially genotoxic. However, the intensity of ELF-MF has an important influence on the extent of DNA damage.

(E) Yoon HE, Lee JS, Myung SH, Lee YS. Increased γ-H2AX by exposure to a 60-Hz magnetic fields combined with ionizing radiation, but not hydrogen peroxide, in non-tumorigenic human cell lines. Int J Radiat Biol. 2014 Jan 28. [Epub ahead of print] (GT, IA)

Purpose: Genotoxic effects have been considered the gold standard to determine if an environmental factor is a carcinogen, but the currently available data for extremely low

frequency time-varying magnetic fields (ELF-MFs) remain controversial. As an environmental stimulus, the effect of ELF-MF on cellular DNA may be subtle. Therefore, a more sensitive method and systematic research strategy are warranted to evaluate genotoxicity. Materials and methods: We investigated the effect of ELF-MFs in combination with ionizing radiation (IR) or H_2O_2 on the DNA damage response of expression of phosphorylated H2AX (γ-H2AX) and production of γ-H2AX foci in non-tumorigenic human cell systems consisting of human lung fibroblast WI38 cells and human lung epithelial L132 cells. Results: Exposure to a 60-Hz, 2 mT ELF-MFs for 6 h produced increased γ-H2AX expression, as well as γ-H2AX foci production, a common DNA double-strand break (DSB) marker. However, exposure to a 1 mT ELF-MFs did not have the same effect. Moreover, 2 mT ELF-MFs exposure potentiated the expression of γ-H2AX and γ-H2AX foci production when combined with IR, but not when combined with H_2O_2. Conclusions: ELF-MFs could affect the DNA damage response and, in combination with different stimuli, provide different effects on γ-H2AX.

A Scientific Perspective on Health Risk of Electromagnetic Fields: Research on the Stress Response

Table of Contents

I. Abstract

The stress response is a protective cellular mechanism that is characterized by stress protein synthesis. The stress response, by its very nature, shows that *cells react to EMFs as potentially harmful*. The stress response is an important protective mechanism that enables cells from animals, plants and bacteria to survive environmental stressors with the aid of heat shock proteins (hsp). It is stimulated by both non-thermal power (ELF), and non-thermal radiofrequency (RF) as well as thermal radio (RF) frequency EMFs, so the greatly differing energies are not critical in activating the DNA to synthesize proteins. Direct interaction of both ELF and RF EMFs with DNA is likely, since specific DNA sequences are sensitive to EMFs and retain their sensitivity when transferred to artificial molecular constructs. Basic science research is essential for determining the biological parameters needed to assess health risks of electromagnetic fields (EMFs) and the molecular mechanisms that explain them. However, the adversarial nature of the debate about risk has clouded the evaluation of the science. To clarify the results of research on EMF stimulation of the stress response, it is necessary to consider the scientific context as well as the research. There is ample evidence that ELF and RF fields activate DNA in cells and cause damage at exposure levels that are considered 'safe' (i.e., below current exposure limits that are based on tissue heating as measured in Specific Absorption Rate or SAR). Because non-thermal EMFs are biologically active and potentially harmful, new safety standards must be developed to protect against possible damage at non-thermal levels, and the standards must be defined in terms of a non-thermal biological dose. Fewer than one quarter of the relevant references listed in Table 1 appear in the IEEE list leading to the newly revised IEEE C95.1 recommendations (April, 2006).

II. Stress Proteins - Conclusions (Heat Shock Proteins)

Conclusion: Scientific research has shown that the public is not being protected from potential damage that can be caused by exposure to EMF, both power frequency (ELF) and radio frequency (RF).

Conclusion: DNA damage (e.g., strand breaks), a cause of cancer, occurs at levels of ELF and RF that are below the safety limits. Also, there is no protection against cumulative effects stimulated by different parts of the EM spectrum.

Conclusion: The scientific basis for EMF safety limits is flawed when the same biological mechanisms are activated in ELF and RF ranges at vastly different levels of the Specific Absorption Rate (SAR). Activation of DNA to synthesize stress proteins (the stress response), is stimulated in the ELF at a non-thermal SAR level that is over a billion times lower than the same process activated in the RF at the thermal level.

Conclusion: There is a need for a biological standard to replace the thermal standard and to also protect against cumulative effects across the EM spectrum.

III. ELF and RF activation of the stress response

Much detailed information about the stress response will be presented in the following sections and in the tables, but the most important finding to keep in mind is that *both ELF and RF fields activate the synthesis of stress proteins*. All cells do not respond to EMF, but activation of the same cellular mechanism by both thermal and non-thermal stimuli in a variety of cells shows that both ELF and RF are biologically active and that a biological 'dose' of EMF cannot be described in terms of SAR (Blank and Goodman, 2004a). SAR is irrelevant for non-thermal ELF responses, where energy thresholds are many orders of magnitude lower than in RF. A new definition of EMF dose is necessary for describing a safety limit, and SAR must be replaced by a measure of exposure that can be defined in biological terms.

The stress response, by its very nature, shows that *cells react to EMFs as potentially harmful*. The stress response is an important protective mechanism that enables cells from animals, plants and bacteria to survive environmental stressors, such as sharp increases in temperature (originally called 'heat shock'), hypoxia, and dissolved toxic heavy metals like Cd^{+2} and oxidative species that can damage proteins and DNA ('oxidative stress'). The stress response is evolutionarily conserved in essentially all eukaryotic and prokaryotic organisms, but not all stressors are effective in all cells, and different stress proteins are activated under different conditions. Stress proteins are a family of about 20 different proteins, ranging in size from a few kilodaltons to over 100kD. The 27kD and 70kD protein families are the most common and most frequently studied.

Kültz (2005) has called the stress response a '... defense reaction of cells to damage that environmental forces inflict on macromolecules.', based on evidence from gene analysis showing that the stress response is a reaction to molecular damage. The genes activated as a group along with stress genes, which Kültz calls the 'universally conserved proteome', are those associated with sensing and repairing damage to DNA and proteins. Stress proteins help damaged proteins refold to regain their conformations, and also act as "chaperones" for transporting cellular proteins to their destinations in cells. The molecular damage stimulated by non-thermal ELF fields occurs in the absence of an increase in temperature. ELF energy thresholds are estimated to be about 10^{-12} W/kg, over a billion times lower than the thermal stimuli that cause damage in the RF range (Blank and Goodman, 2004a).

The classic stress response to a sharp increase in temperature (i.e., 'heat shock') is associated with a biochemical pathway where transcription factors known as heat shock factors, HSFs, translocate from the cytoplasm to the nucleus, trimerize and bind to DNA at the heat shock elements (HSEs) in the promoters of the genes. The promoter is the DNA segment where protein synthesis is initiated and it is not part of the coding region.

The HSEs contain specific nucleotide sequences, nGAAn, that are the consensus sequences for thermal stimuli. The binding of HSFs to HSEs, etc is similar for heat shock in plant, animal and bacterial cells. ELF range EMFs have been shown to follow the same sequence of events in inducing stress response proteins in human cells, including breast (MCF7, HTB124), leukemia (HL60), epithelial cells, as well as E. coli and yeast cells.

Studies done with chick embryos and cells from *Drosophila* and *Sciara* salivary gland chromosomes have produced graphic evidence of the effects of EMF. In *Drosophila* and *Sciara* salivary gland chromosomes, EMF causes the formation of 'puff's, enlarged regions along the chromosome, at loci associated with activation of heat shock genes. This is followed by elevated concentrations of transcripts at the sites and eventually stress protein synthesis (Goodman and Blank, 1998). The changes in chromosome morphology are characteristic of the stress response to both EMF and elevated temperature. Chick embryos develop hearts that stop beating when the oxygen concentration is lowered, but that can be protected and kept beating if stress proteins have been induced by ELF fields (DiCarlo et al, 1998) and in the RF range (Shallom et al, 2002).

The cellular response pathways to EMF have been characterized in the ELF range (Goodman and Blank, 2002), and have been found to share some of the characteristics of heat shock stress, such as the movement of heat shock factor monomers from the cytoplasm to the nucleus. The biochemical mechanism that is activated, the MAPK signaling pathway, differs from the thermal pathway (Goodman and Blank, 2002), but is the same as the non-thermal pathway in the RF range (Leszczynski et al, 2002).

The HSP70 gene is activated within minutes in cells exposed to ELF fields (Lin et al, 1997), and is accompanied by the binding of HSFs to the specific nucleotide sites in the promoter of the gene. However, different segments of the DNA promoter function as HSEs. Research in the ELF range has shown that the promoter of the major stress protein, hsp70, has two domains that respond to two different physical stimuli, EMF and an increase in temperature (Lin et al, 1999). The stimulus-specific domains have different DNA sequences that cannot be interchanged. The ***DNA consensus sequences that respond to EMF are nCTCTn*** (Lin et al, 1997; 1999). These differ from the nGAAn consensus sequences for thermal stimuli. The existence of two different consensus sequences that respond to EMF and temperature increase, respectively, are molecular evidence of different pathways that respond to non-thermal and thermal stimuli.

In another series of experiments, a DNA sequence from the promoter of an EMF sensitive gene was included in a construct containing a reporter gene, either chloramphenicol amino transferase (CAT) or luciferase. In each case, the construct proved to be EMF sensitive and reacted when an ELF field was applied (Lin et al, 2001). The ability to transfer EMF sensitive DNA sequences that subsequently respond to an EMF is further evidence linking the cellular response to a DNA structure.

In heat shock, the stress response is activated when extracellular signals affect receptors in the plasma membrane. This probably does not happen with an EMF, which can easily penetrate throughout the cell and whose actions are therefore not limited to the

membrane. One can transfer the EMF response by transferring the DNA consensus sequences (Lin et al, 2001), so it is likely that the activation mechanism involves direct EMF interaction with the DNA consensus sequences. The cell based signal transduction pathways of the heat shock response are involved in regulation of the EMF stimulated process, probably through the feedback control mechanisms that respond to the stress proteins synthesized or the mRNA concentrations that code for them (Lin et al, 1998).

Repeated induction of the stress response in a cell has been shown to induce cytoprotection, a reduced response associated with restimulation (Blank and Goodman, 1998). This is analogous to thermotolerance, the reduced response to an increase in temperature after an initial heat shock response. Experiments with developing chick embryos show similar habituation to repeated stimulation in the ELF range (DiCarlo et al, 2002). There are different effects of continuous and intermittent EMF exposures that show feedback control features in the EMF stimulated stress response (Lin et al, 1997). This autoregulatory reaction is an indication that the thermotolerance mechanism is inherent in the response to a single stimulus as well.

It has now been shown in many laboratories that RF also stimulates the cellular stress response and cells start to synthesize stress proteins in many different kinds of cells (e.g., Kwee et al, 2001; Shallom et al, 2002; Leszczynski et al, 2002; Weisbrot et al, 2004). Cotgreave (2005) included many cells that did not synthesize stress proteins in response to RF stimulation in his summary of data. The listings in Table 1 contain additional positive and negative results. It is quite clear that certain cell lines do not respond to EMF by synthesizing stress proteins. The reasons are not known, but the changes in cells in tissue culture and in cancer cells may render some of them unable to respond to EMF. In addition to mutations in cell lines, pre-exposure to ambient ELF and RF fields in the laboratory can also affect an ability to respond. What we can say in summary at this stage is that:

- the stress response has been demonstrated in many cells and linked to changes in the DNA and chromosomes.

- there are similarities in stress protein synthesis stimulated in the non-thermal ELF and thermal RF frequency ranges.

- the biochemical mechanism that is activated is the same non-thermal pathway in both ELF and RF, and is not associated with the thermal response.

IV. DNA activation mechanisms: EMFs and electrons

We think of DNA as a very stable polymer that stores and transmits genetic information from generation to generation. However, DNA must also come apart relatively easily to enable the continuous protein synthesis that is needed to sustain living cells. Usually, this process is started when specialized proteins called transcription factors bind to DNA.

However, both ELF and RF fields also stimulate DNA to start protein synthesis. EMF stimulation of stress protein synthesis indicates activation of DNA, even by relatively weak non-thermal ELF. This raises the possibility that EMF can cause other changes in DNA that interfere with the copying and repair processes in DNA, and that can lead to mutations and cancer.

Protein synthesis starts when the two chains of DNA come apart to make an mRNA copy of the amino acid code for a particular protein. This occurs at the specific DNA segment where the transcription factor binds, and in forming a bond changes the electron distribution. Since recent research has shown electron conduction in DNA (Wan et al, 1999; 2000; Ratner, 1999; Porath et al, 2000; Giese and Spichty, 2000), it is possible that EMF affects electron distribution and movement in DNA, and helps it to come apart to initiate protein synthesis, not unlike the action of a transcription factor. Charge transport through DNA depends on the DNA sequence (Shao et al, 2005), and there are reasons to believe that EMFs would cause the DNA to come apart at the EMF consensus sequence, nCTCTn (Blank and Goodman, 2002).

The ability of relatively small perturbations to stimulate DNA to initiate biosynthesis is consistent with larger perturbations that lead to DNA strand breaks. Several experimental studies have reported both single and double strand breaks in DNA and other chromosome damage after exposure to ELF fields (Lai and Singh, 1997a; Ivancsits et al, 2005, Diem et al, 2005; Winker et al, 2005). Ivancsits et al (2005) found DNA damage in fibroblasts, melanocytes and rat granulosa cells, but not in lymphocytes, monocytes and skeletal muscle cells. Single and double strand breaks and other DNA damage after exposure to RF fields have also been reported (Phillips et al, 1998; Sarimov et al, 2004; Lai and Singh, 2005).

The Ivancsits, Diem and Winker studies cited above are part of the REFLEX Project, a collaboration of twelve laboratories in seven countries of the European Union (REFLEX, 2004). The group found that both ELF and RF exposures, below the current safety limits, modified the expression of many genes and proteins. They also reported DNA damage (e.g., strand breaks, micronuclei, chromosomal damage) due to ELF fields at exposures of 35μT. Similar genotoxic effects were produced in fibroblasts, granulosa cells and HL60 cells by RF fields at SARs between 0.3 and 2W/kg. The expression and phosphorylation of the stress protein hsp27 was one of the many proteins affected.

The REFLEX Project Report (2004) is available on the internet and well worth consulting as a source of much information about the effects on cells *in vitro* due to the ELF and RF exposures we encounter in our environment. The Report has an introduction by Ross Adey, one of the last things he wrote, telling us about the importance of establishing "...essential exposure metrics ... based on mechanisms of field interactions in tissues". One needs a biological metric in order to characterize EMF exposure.

The possibility that EMFs could cause greater damage to DNA in the RF range and at longer exposures was demonstrated by Phillips et al (1998) who reported more DNA breaks when cells were exposed at higher SARs. They suggested that the rate at which

DNA damage can be repaired (or eliminated by apoptosis) is limited, and when the rate of damage at the higher SARs exceeds the repair rate, there is the possibility of retaining mutations and initiating carcinogenesis. Chow and Tung (2000) reported that exposure to a 50Hz magnetic field enhances DNA repair through the induction of DnaK/J synthesis. The eternal struggle in cells and organisms between the forces tending to break things down (catabolism) and those tending to build up and repair (anabolism) probably accounts for much of the variability one finds in experiments with cells as well as with people.

The changes in DNA initiated by ELF fields cannot be explained by thermal effects. Electric and magnetic fields interact with charges and magnetic dipoles, and fundamental mechanisms must ultimately be based on these interactions. From the data in Table 2, it is clear that relatively little energy is needed for effects on electron transfer (Blank and Goodman, 2002; 2004b; Blank, 2005). The low energies needed to perturb DNA in the ELF range suggest that the mechanism involves electrons, e.g., probably in the H-bonds that hold the two chains of DNA together. Electrons have very high charge to mass ratio and are most likely to be affected even by weak electric and magnetic fields.

There are many indications that electrons are involved in EMF reactions with DNA. In experiments that stimulate the stress response, the estimated force of $\sim 10^{-21}$ newtons that activates DNA can move a free electron about the length of a H-bond (~.3nm) in 1ns. The calculated electron velocity is comparable to electron velocities measured in DNA (Wan et al, 1999; 2000), and is also expected if electrons move at the ~nanometer/picosecond flickering rate of protons in H-bonded networks (Fecko et al, 2003) that would be present at normally hydrated DNA sites. Electrons can tunnel nanometer distances in proteins (Gray and Winkler, 2003), and experiments have shown comparable electron movement in DNA (Wan et al, 1999; 2000). Electrons might be expected to move more readily from the CTCT bases in the consensus sequence, because of their low electron affinities. Finally, ELF fields have been shown to accelerate electron transfer in oxidation-reduction reactions (Blank and Soo, 1998; 2003).

The fact that the same non-thermal mechanism is activated in ELF and RF ranges emphasizes that it is not the total energy associated with the EMF that is critical, but rather the regular oscillations of the stimulating force. As already mentioned earlier, the energy associated with each wave (i.e., energy/cycle) is more or less independent of the frequency. If the same energy is needed to reach threshold in both ELF and RF, the many repetitions at the higher frequency cause the non-thermal threshold to be reached in a shorter time and the total energy absorbed over time to increase with frequency. Even in the ELF range, where SAR levels are very low, the stress response is activated by short exposures to fields of less than 1μT, while single and double strand breaks in DNA have been reported at longer exposures to higher field strengths ~0.1mT (Lai and Singh, 2005). The two mechanisms appear to be related in that breaks in DNA appear to result from free radical mechanisms that also involve electron transfer reactions (Lai and Singh, 1997b).

The reaction of EMFs with DNA differs from those listed in Table 2 in that they appear

to occur with equal ease at the widely differing frequencies in ELF and RF ranges. The frequency dependence of a reaction provides information about how time constants of charge transfer processes are affected by fields, and the frequency responses of the few EMF sensitive biological systems that have been studied suggest that fields are most effective at frequencies that are close to the natural rhythms of the processes affected (Blank and Soo, 2001a; Blank and Goodman, 2004b; Blank, 2005). Frequency optima for the enzymes, Na,K-ATPase and cytochrome oxidase, differ by an order of magnitude with maximums at about 60Hz and 800Hz, respectively (Blank and Soo, 2001a), in both cases close to the observed frequency maximum of the enzyme reaction. The rate constant of the BZ reaction is about 250Hz, the frequency of the rate limiting step in a multi-step process with at least 10 sub-reactions (Blank and Soo, 2003).

The electrons in DNA that are affected by EMFs are probably not engaged in electron transfer reactions. They respond to frequencies that range from ELF to RF and are more likely to be tied to the wide frequency range of fluctuations than to the frequency of a particular reaction. The displacement of electrons in DNA would charge small groups of base pairs and lead to disaggregation forces overcoming H-bonds, separating the two chains and enabling transcription. Studies have shown that biopolymers can be made to disaggregate when the molecular charge is increased (Blank, 1994; Blank and Soo, 1987). This explanation would also apply to the effect of applied electric fields that also activate DNA. Electric fields exert a force on electrons, and have been shown to stimulate protein synthesis in HL60 cells (Blank et al, 1992), E coli (Laubitz et al, 2006) and muscle *in vivo* (Blank, 1995). The genes for the hsp70 stress protein are more likely to be activated since they have been shown to be 'bookmarked' on the DNA chain, that is, more exposed to externally applied forces (Xing et al, 2005).

The outline of a plausible mechanism to account for EMF activation of DNA through interaction with electrons has relied on evidence from many lines of research. This mechanism may or may not hold up under further testing, but the experimental facts it is based on have been verified. It has been clearly demonstrated that exposure of cells to non-thermal power and thermal radio frequency EMFs, at levels deemed to be safe for human exposure, activate DNA production of stress proteins and could increase the number of DNA breaks. There is ample experimental evidence to support the possibility of DNA damage at non-thermal levels of exposure, and the need for greater protection.

V. The critical role of scientific research

The connection between the results of scientific research and assessing EMF risk does not appear to be working well. We all agree that EMFs are unsafe at the level where they cause electrocution, and that we must protect against that possibility. We also agree that if other risks are associated with EMFs, we must identify them and determine the exposure levels at which they occur. This task requires that we define a biological dose of EMF, and that we obtain information about cellular mechanisms activated at different doses. As we have seen, the currently accepted measure of EMF dose, the specific absorption rate (SAR), is definitely not a measure of the effective biological dose when

stress protein synthesis can be stimulated by SAR levels that differ by many orders of magnitude in the ELF and RF ranges (Blank and Goodman, 2004a). Yet, there is strong opposition to accepting the consequences of these experimental facts.

Regarding EMF mechanisms, we still have much to learn, but we know that the energy and field strength thresholds of many biological reactions are very low (Table 2). These findings indicate that safe exposure levels for the public should be substantially lowered, if only as a precautionary measure. Even when stated in vague terms, so as to require little more than lip service, a precautionary policy has not yet been recommended by the WHO. Thus, the two main problems of research on EMF risk, defining a biological dose and the desired level of exposure protection, remain to be solved.

Scientific research can contribute to defining a biological dose, but the desired level of exposure protection is a more complicated issue. Guidance for EMF policy on exposure protection has come primarily from epidemiology studies of health risks associated with power lines in the case of ELF, and cell phones in the case of RF. Basic research studies do not provide insight into the effects of long term exposures that are so important in determining risk, and they appear to have been used almost entirely to probe biochemical mechanisms that might underlie health risks identified in epidemiology studies. However, the research does overcome a basic weakness of epidemiology studies, an inability to determine a causal relation and to rule out effects of possible confounders. Epidemiology studies can correlate EMF exposure and health effects in human populations, and show quantitative dose-response relations, but it is only when coupled with basic research on molecular mechanisms that one can test and establish the scientific plausibility of effects of exposure. This scientific capability has become more important with recent advances in research on DNA, where mutations associated with initiation and promotion of cancer can be identified. EMF laboratory research has also played an indirect role in the practical aspects of risk by showing that:

- many biological systems are affected by EMFs,
- EMFs compete with intrinsic forces in a system, so effects can be variable,
- many frequencies are active,
- field strength and exposure duration thresholds are very low,
- molecular mechanisms at very low energies are plausible links to disease (e.g., effect on electron transfer rates linked to oxidative damage, DNA activation linked to abnormal biosynthesis and mutation).

Research on the stress response, a protective mechanism that involves activation of DNA and protein synthesis, was not included in previous scientific reviews prior to evaluating safety standards, and thus provides additional insights into EMF interactions (Blank and Goodman, 2004a). Activation of this protective mechanism by non-thermal as well as thermal EMF frequencies has demonstrated:

- the reality and importance of non-thermal effects of EMFs,

- that cells react to an EMF as potentially harmful,

- the same biological reaction to an EMF can be activated in more than one division of the EM spectrum,

- direct interaction of ELF and RF with DNA has been documented and both activate the synthesis of stress proteins,

- the biochemical pathway that is activated is the same pathway in both ELF and RF and it is non-thermal,

- thresholds triggering stress on biological systems occur at environment levels on the order of 0.5 to 1.0 μT for ELF,

- many lines of research now point to changes in DNA electron transfer as a plausible mechanism of action as a result of non-thermal ELF and RF.

Given these findings, the *specific absorption rate (SAR) is not the appropriate measure of biological threshold or dose*, and should not be used as a basis for a safety standard since it regulates against thermal effects only.

Cellular processes are unusually sensitive to non-thermal ELF frequency fields. The thresholds for a number of biological systems are shown in Table 2, and many are in the range of 0.5 to 1.0 μT, not very much higher than the usual environmental backgrounds of ~0.1μT. The low biological thresholds in the non-thermal ELF range undermine claims that an EMF must increase the temperature in order to cause changes in cells. They also show that many biochemical reactions can be affected by relatively low field strengths, similar to those in the environment. -Non-thermal ELF fields can also cause DNA damage, and therefore add to health and safety concerns.

In addition to very low thresholds, exposure durations do not have to be very long to be effective. Litovitz et al (1991, 1993), working with the enzyme ornithine decarboxylase, have shown a full response to an EMF when cells were exposed for only 10sec. This occurred with ELF sine waves or ELF modulated 915MHz sine waves. The exposure had to be continuous, since gaps in the sine wave resulted in a reduced response. Interference with the sine wave in the form of superimposed ELF noise also reduced the response (Mullins et al, 1998). The interfering effect of noise has been shown in the RF range by Lai and Singh (2005), who reported that noise interferes with the ability of an RF signal to cause breaks in DNA strands. The decreased effect when noise is added to a signal is yet another indication that EMF energy is not the critical factor in causing a response.

The finding that the stress response threshold can be stimulated in both ELF and RF frequency ranges appears to suggest that the threshold is independent of EMF energy. Energy increases with the frequency, so compared to an ELF energy of ~1a.u. (arbitrary unit of energy), the energy at RF is $\sim 10^{11}$a.u. Actually, it is the energy/cycle that is independent of frequency. A typical ELF cycle at 10^{2}Hz lasts 10^{-2}sec and a typical RF

cycle at 10^{11}Hz lasts 10^{-11}sec. Because the energy is spread over a different number of cycles each second in the two ranges, the same value of ~10^{-2} a.u./cycle applies to both ELF and RF ranges.
